- The index is altered to be **PADDED** or **NOT PADDED**.
- The index is a partitioning index on a table that uses index-controlled partitioning, and one or more limit key values is altered.
- The index is altered to **REGENERATE**.

**Restrictions on SQL data change statements in the same commit scope as ALTER INDEX:**
SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER INDEX statements that affect that index.

**Altering indexes for tables that are involved in a clone relationship:**
You cannot change any index for a table that is involved in a clone relationship (base table or clone table). If a change to an index is required, the clone table must be dropped before the index can be changed. After the index is changed, the clone table can be created again.

**Adding a varying length column to a key for a system with NOT PADDED as the default:**
If the system default is NOT PADDED (the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE is NO), no varying length columns are in the key, and the PADDED or NOT PADDED option is not explicitly specified when the index is created, the PADDED column of the SYSIBM.SYSINDEXES catalog table is populated with a blank value. If a varying length column is later added to the key, the value of the PADDED column in SYSIBM.SYSINDEXES is changed to 'Y' to indicate that the index is now a PADDED index.

**Running utilities:**
You cannot execute the ALTER INDEX statement while a DB2 utility has control of the index or its associated table space.

**Alternative syntax and synonyms:**
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when altering the partitions of a partitioned index:

- **PART** can be specified as a synonym for **PARTITION**. In addition, the **ALTER** keyword that precedes **PARTITION** is optional. In addition, if you alter more than one partition, specifying a comma between each **ALTER PARTITION** integer clause is optional.
VALUES can be specified as a synonym for ENDING AT. Although these keywords are supported as alternatives, they are not the preferred syntax.

**Examples**

*Example 1:* Alter the index DSN8B10.XEMP1. Indicate that DB2 is not to close the data sets that support the index when there are no current users of the index.
```
ALTER INDEX DSN8B10.XEMP1
CLOSE NO;
```

*Example 2:* Alter the index DSN8B10.XPROJ1. Use BP1 as the buffer pool that is to be associated with the index, indicate that full image or concurrent copies on the index are allowed, and change the maximum size of each data set to 8 megabytes.
```
ALTER INDEX DSN8B10.XPROJ1
BUFFERPOOL BP1
COPY YES
PIECESIZE 8M;
```

*Example 3:* Assume that index X1 contains at least one varying-length column and is a padded index. Alter the index to an index that is not padded.
```
ALTER INDEX X1
NOT PADDED;
```

The index is placed in restricted rebuild-pending status (RBDP) and cannot be accessed until it is rebuilt from the table.

*Example 4:* Alter partitioned index DSN8B10.DEPT1. For partition 3, leave one page of free space for every 13 pages and 13 percent of free space per page. For partition 5, leave one page for every 25 pages and 25 percent of free space. For all the other partitions, leave one page of free space for every 6 pages and 11 percent of free space. Ensure that index pages are cached to the group buffer pool for all partitions except partition 4. For partition 4, write pages only when there is inter-DB2 read-write interest on the partition.
```
ALTER INDEX DSN8B10.XDEPT1
BUFFERPOOL BP1
CLOSE YES
COPY YES
USING VCAT CATLGG
FREEPAGE 6
PCTFREE 11
GBPCACHE ALL
ALTER PARTITION 3
USING VCAT CATLGG
FREEPAGE 13
PCTFREE 13,
ALTER PARTITION 4
USING VCAT CATLGG
GBPCACHE CHANGED,
ALTER PARTITION 5
USING VCAT CATLGG
FREEPAGE 25
PCTFREE 25;
```
ALTER MASK

The ALTER MASK statement changes a column mask that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER MASK mask-name
   ENABLE
   DISABLE
   REGENERATE
```

Description

`mask-name`
Identifies the column mask to be altered. The name must identify a mask that exists at the current server.

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for the table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

A column mask with a regeneration error cannot be enabled. To clear the status of the column mask, the column mask must be dropped and re-created with a modified definition.

ENABLE is ignored if the column mask is already defined as enabled for column access control.

DISABLE

Specifies that the column mask is to be disabled for column access control. If column access control is not currently activated for the table, the column mask will remain ineffective when column access control is activated for the table. If column access control is currently activated for the table, the column mask...
becomes ineffective immediately and all packages and dynamic cached statements that reference the table are invalidated.

DISABLE is ignored if the column mask is already defined as disabled for column access control.

**REGENERATE**

Specifies that the column mask is to be regenerated. The column mask definition in the catalog is used, and existing dependencies and authorization, if any, are retained. The column mask definition is reevaluated as if the column mask was being created. The user-defined functions that are referenced in the column mask definition must be resolved to the same secure UDFs as that were resolved during the column mask creation.

**Notes**

**Applying DB2 maintenance:**

When DB2 maintenance is applied that affects how a column mask is generated, the column mask might need to be regenerated to ensure the column mask is still valid.

If the column mask is regenerated successfully, the status of the column mask is set to a blank in the catalog table. If the column mask is enabled and column access control is currently activated for the table, all packages and dynamic cached statements that reference the table are invalidated.

If the column mask cannot be regenerated successfully, an error is returned. The regeneration status of the column mask is an error. If the column mask is enabled and column access control is currently activated for the table, all packages and dynamic cached statements that reference the table are marked invalid. To clear the status of the column mask, the column mask must be dropped and re-created with a modified definition. Or the column mask can be disabled if not disabled yet. A disabled column mask becomes ineffective to a column access control enforced table.

When the table is referenced in a data manipulation statement, the statement returns an error if any enabled column mask has a regeneration error.

**Examples**

*Example 1:*

Enable column mask M1.

```
ALTER MASK M1 ENABLE;
```

*Example 2:*

Regenerate column mask M1.

```
ALTER MASK M1 REGENERATE;

COMMIT;
```
ALTER PERMISSION

The ALTER PERMISSION statement alters a row permission that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```plaintext
ALTER PERMISSION permission-name [ ENABLE | DISABLE | REGENERATE ]
```

Description

(permission-name)

Identifies the permission to be altered. The name must identify a row permission that exists at the current server. The name must not identify a default row permission that is created implicitly by DB2.

ENABLE

Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

A row permission with a regeneration error cannot be enabled. To clear the status of the row permission, the row permission must be dropped and re-created with a modified definition.

ENABLE is ignored if the row permission is already defined as enabled for row access control.

DISABLE

Specifies that the row permission is to be disabled for row access control. If row access control is not currently activated for the table, the row permission will remain ineffective when row access control is activated for the table. If row access control is currently activated for the table, the row permission
becomes ineffective immediately and all packages and dynamic cached
statements that reference the table are invalidated.

DISABLE is ignored if the row permission is already defined as disabled for
row access control.

REGENERATE
Specifies that the row permission is to be regenerated. The row permission
definition in the catalog is used, and existing authorizations and dependencies,
if any, are retained. The user-defined functions that are referenced in the row
permission definition must be resolved to the same secure UDFs as that were
resolved during the row permission creation.

Notes
Applying DB2 maintenance:
When DB2 maintenance is applied that affects how a row permission is
generated, the row permission might need to be regenerated to ensure the
row permission is still valid.

If the row permission is regenerated successfully, the status of the row
permission is set to a blank in the catalog table. If the row permission is
enabled and row access control is currently activated for the table, all
packages and dynamic cached statements that reference the table are
invalidated.

If the row permission cannot be regenerated successfully, an error is
returned. The regeneration status of the row permission is set to an error. If
the row permission is enabled and row access control is currently activated
for the table, all packages and dynamic cached statements that reference the table are
invalidated. To clear the status of the row permission, the row permission must be dropped and re-created with a modified
definition. Or the row permission can be disabled if not disabled yet. A
disabled row permission becomes ineffective to a row access control
enforced table.

When the table is referenced in a data manipulation statement, the
statement returns an error if any enabled row permission has an
regeneration error.

Examples
Example 1:
Enable permission P1.
ALTER PERMISSION P1 ENABLE;

Example 2:
Regenerate permission P1.
ALTER PERMISSION P1 REGENERATE;
ALTER PROCEDURE (external)

The ALTER PROCEDURE statement changes the description of an external stored procedure at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

When LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:
- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

If the environment in which the stored procedure is to run is being changed, the authorization ID must have authority to use the WLM environment. This authorization is obtained from an external security product, such as RACF.

Syntax

```
ALTER PROCEDURE procedure-name option-list
```
**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

```
DYNAMIC RESULT SETS integer EXTERNAL NAME external-program-name identifier

LANGUAGE ASSEMBLE PARAMETER STYLE SQL identifier

LANGUAGE C COBOL JAVA PLI REXX

PACKAGE PATH package-path

PACKAGE PATH NO PACKAGE PATH

MODIFIES SQL DATA NO DBINFO NO COLLID

READS SQL DATA DBINFO COLLID collection-id

WLM ENVIRONMENT name

WLM ENVIRONMENT (name, +) ASUTIME NO LIMIT STAY RESIDENT NO

PROGRAM TYPE SUB SECURITY DB2 RUN OPTIONS run-time-options

PROGRAM TYPE MAIN USER DEFINER

COMMIT ON RETURN NO INHERIT SPECIAL REGISTERS CALLED ON NULL INPUT

COMMIT ON RETURN YES DEFAULT SPECIAL REGISTERS

STOP AFTER SYSTEM DEFAULT FAILURES

STOP AFTER integer FAILURES

CONTINUE AFTER FAILURE

ALLOW DEBUG MODE

DISABLE DEBUG MODE

Notes:

1 If **LANGUAGE** is **JAVA**, **EXTERNAL NAME** must be specified with a valid external-java-routine-name.
### Notes:

1. The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.

2. The exclamation point (!) is supported for compatibility with other products in the DB2 family.

---

**Description**

`procedure-name`  
Identifies the stored procedure to be altered.

**DYNAMIC RESULT SETS** `integer`  
Specifies the maximum number of query result sets that the stored procedure can return. The value must be between 0 and 32767.

**EXTERNAL NAME** `external-program-name` or `identifier`  
Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement.

If `LANGUAGE` is `JAVA`, `external-program-name` must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid `external-java-routine-name`. If multiple `external-program-name` values are specified, the total length of all of the values must not be greater than 1305 bytes and each value must be separated by a space or a line break. Do not specify a JAR file for a Java procedure for which NO SQL is in effect.

An `external-java-routine-name` contains the following parts:
**jar-name**
Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the ALTER PROCEDURE statement is processed.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

**method-name**
Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

**package-id**
Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "*/myPacks/StoredProcs/*" for the classes.

**class-id**
Identifies the class identifier of the Java object.

**method-id**
Identifies the method identifier with the Java class to be invoked.

**method-signature**
Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER PROCEDURE statement.

For other values of **LANGUAGE**, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8
bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

**LANGUAGE**
Specifies the application programming language in which the stored procedure is written. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

**ASSEMBLE**
The stored procedure is written in Assembler.

**C**
The stored procedure is written in C or C++.

**COBOL**
The stored procedure is written in COBOL, including the OO-COBOL language extensions.

**JAVA**
The stored procedure is written in Java and is executed in the Java Virtual Machine. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid **external-java-routine-name** and **PARAMETER STYLE** must be specified with **JAVA**. The procedure must be a public static method of the specified Java class.

Do not specify **LANGUAGE JAVA** when **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is in effect.

**PLI**
The stored procedure is written in PL/I.

**REXX**
The stored procedure is written in REXX. Do not specify **LANGUAGE REXX** when **PARAMETER STYLE SQL** is specified.

**PARAMETER STYLE**
Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *DB2 Application Programming and SQL Guide*.

**SQL**
Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first *n* parameters that are specified on the CREATE PROCEDURE statement.
- *n* parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If **DBINFO** is specified, the **DBINFO** structure.

Do not specify **PARAMETER STYLE SQL** when **LANGUAGE REXX** is specified.
GENERAL
Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

GENERAL WITH NULLS
Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short integers. The indicator array enables the stored procedure to accept or return null parameter values.

JAVA
Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER STYLE JAVA can be specified only if LANGUAGE is JAVA. If the ALTER PROCEDURE statement results in changing LANGUAGE to JAVA, PARAMETER STYLE JAVA, and an EXTERNAL NAME clause might need to be specified to provide appropriate values. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

PARAMETER STYLE SQL cannot be used with LANGUAGE REXX.

DETERMINISTIC or NOT DETERMINISTIC
Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

DETERMINISTIC
The stored procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

NOT DETERMINISTIC
The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

DB2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

NO PACKAGE PATH or PACKAGE PATH package-path
Identifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

NO PACKAGE PATH
Specifies that the list of package collections for the procedure is the same as the list of package collections for the calling program. If the calling program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see DB2 Application Programming and SQL Guide.
PACKAGE PATH  
   package-path
   Specifies a list of package collections, in the same format as used in the
   CURRENT PACKAGE PATH special register.

   If the COLLID clause is specified with PACKAGE PATH, the COLLID
   clause is ignored when the routine is invoked.

   The package-path value that is associated with the procedure definition is
   checked when the procedure is invoked. If package-path contains
   SESSION_USER, USER, PATH, or PACKAGE PATH, an error is returned
   when the package-path value is checked.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL
   Specifies which SQL statements, if any, can be executed in the procedure or
   any routine that is called from this procedure. For the data access classification
   of each statement, see Table 167 on page 2096.

MODIFIES SQL DATA
   Specifies that the procedure can execute any SQL statement except
   statements that are not supported in procedures.

READS SQL DATA
   Specifies that procedure can execute statements with a data access
   indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The
   procedure cannot execute SQL statements that modify data.

CONTAINS SQL
   Specifies that the procedure can execute only SQL statements with an
   access indication of CONTAINS SQL. The procedure cannot execute
   statements that read or modify data.

NO SQL
   Specifies that the procedure can execute only SQL statements with a data
   access classification of NO SQL. Do not specify NO SQL for a Java
   procedure that uses a JAR file.

NO DBINFO or DBINFO
   Specifies whether additional status information is passed to the stored
   procedure when it is invoked.

   NO DBINFO
   Additional information is not passed.

   DBINFO
   An additional argument is passed when the stored procedure is invoked.
   The argument is a structure that contains information such as the
   application run time authorization ID, the schema name, the name of a
   table or column that the procedure might be inserting into or updating,
   and identification of the database server that invoked the procedure. For
   details about the argument and its structure, see DB2 Application
   Programming and SQL Guide.

   DBINFO can be specified only if PARAMETER STYLE SQL is specified.

NO COLLID or COLLID  
   collection-id
   Identifies the package collection that is to be used when the stored procedure
   is executed. This is the package collection into which the DBRM that is
   associated with the stored procedure is bound.

   NO COLLID
   Specifies that the package collection for the stored procedure is the same as
   the package collection of the calling program. If the invoking program does
not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in DB2 Application Programming and SQL Guide.

**COLLID collection-id**
Identifies the package collection that is to be used when the stored procedure is executed. It is the name of the package collection into which the DBRM associated with the stored procedure is bound.

For REXX stored procedures, collection-id can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

**WLM ENVIRONMENT**
Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The name of the WLM environment is an SQL identifier.

**name**
The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

**name, * **
When the stored procedure is called directly by an SQL application program, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**
Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column in the resource limit specification table.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on CPU service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**
There is no limit on the service units.

**LIMIT integer**
The limit on the service units is a positive integer in the range of 1 to 2,147,483,647. If the stored procedure uses more service units than the specified value, DB2 cancels the stored procedure.

**STAY RESIDENT**
Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends.

**NO** The load module is deleted from memory after the stored procedure ends. Use NO for non-reentrant stored procedures.
YES
The load module remains resident in memory after the stored procedure ends.

PROGRAM TYPE
Specifies whether the stored procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

SUB
The stored procedure runs as a subroutine.
Do not specify PROGRAM TYPE SUB for stored procedures with a LANGUAGE value of REXX.

MAIN
The stored procedure runs as a main routine.
Do not specify PROGRAM TYPE MAIN when LANGUAGE JAVA is specified.

SECURITY
Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

DB2
The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space.

USER
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

DEFINER
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

RUN OPTIONS \textit{run-time-options}
Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to DB2. You must specify \textit{run-time-options} as a character string that is no longer than 254 bytes. To replace any existing run time options with no options, specify an empty string with RUN OPTIONS. When you specify an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment run time options, see \textit{z/OS Language Environment Programming Reference}.
Do not specify RUN OPTIONS when LANGUAGE JAVA is specified.

COMMIT ON RETURN
Indicates whether DB2 is to commit the transaction immediately on return from the stored procedure.

\textbf{NO} DB2 does not issue a commit when the stored procedure returns.
YES
DB2 issues a commit when the stored procedure returns if the following statements are true:
- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Indicates that values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 40 on page 212.

DEFAULT SPECIAL REGISTERS
Indicates that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 40 on page 212.

CALLED ON NULL INPUT
Specifies that the procedure is to be called even if any or all of the argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values.

STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE
Specifies whether the routine is to be put in a stopped state after some number of failures.

STOP AFTER SYSTEM DEFAULT FAILURES
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation field DSNTIPX.

STOP AFTER nn FAILURES
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any failure.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE
Specifies whether the procedure can be run in debugging mode.

Do not specify this option unless the procedure is defined with LANGUAGE JAVA.

ALLOW DEBUG MODE
Specifies that the procedure can be run in debugging mode.

DISALLOW DEBUG MODE
Specifies that the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.
DISABLE DEBUG MODE

Specifies that the procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or
DISALLOW DEBUG MODE when the procedure has been created or
altered to use DISABLE DEBUG MODE. To change this option, you must
drop and re-create the procedure using the option that you want.

Notes

Invalidation of packages: When an external procedure is altered, all the packages
that refer to that procedure are marked invalid.

LANGUAGE C and the PARAMETER VARCHAR clause: The ALTER
PROCEDURE statement does not allow you to alter the value of the PARAMETER
VARCHAR or PARAMETER CCSID clauses that are associated with the
procedure definition. However, you can alter the LANGUAGE clause for the
procedure. If the PARAMETER VARCHAR clause is specified for the creation of a
LANGUAGE C procedure, the catalog information for that option is not affected
by subsequent ALTER PROCEDURE statements. The procedure might be changed
to a language other than C, in which case the PARAMETER VARCHAR setting is
ignored. If the procedure is later changed back to LANGUAGE C, the setting of
the PARAMETER VARCHAR option that was specified for the CREATE
PROCEDURE statement (which is still in the catalog) will be used.

Alternative syntax and synonyms: To provide compatibility with previous releases
of DB2 or other products in the DB2 family, DB2 supports the following keywords:
  • DYNAMIC RESULT SET, RESULT SET, and RESULT SETS as synonyms for
    DYNAMIC RESULT SETS
  • STANDARD CALL as a synonym for DB2SQL
  • SIMPLE CALL as a synonym for GENERAL
  • SIMPLE CALL WITH NULLS as a synonym for GENERAL WITH NULLS
  • VARIANT as a synonym for NOT DETERMINISTIC
  • NOT VARIANT as a synonym for DETERMINISTIC
  • NULL CALL as a synonym for CALLED ON NULL INPUT
  • PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

Example

Assume that stored procedure SYSPROC.MYPROC is currently defined to run in
WLM environment PARTSA and that you have appropriate authority on that WLM
environment and WLM environment PARTSEC. Change the definition of the stored
procedure so that it runs in PARTSEC.

ALTER PROCEDURE SYSPROC.MYPROC WLM ENVIRONMENT PARTSEC;
The ALTER PROCEDURE statement changes the description, at the current server, of an external SQL procedure.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include at least one of the following:
- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:
- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

The SQL authorization ID that is used to alter the procedure definition must have appropriate authority for the WLM environment in which the procedure is currently defined to run. This authorization is obtained from an external security product, such as RACF.

**Syntax**

```
ALTER PROCEDURE procedure-name option-list
```

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

<td>Specifies the classification of SQL statements that the procedure can execute. For the data access classification of each statement, see <a href="#">Table 167 on page 2096</a>. Statements that are not supported in any procedure will return an error.</td>
</tr>
</tbody>
</table>

**Description**

- `procedure-name` identifies the stored procedure to be altered.
- `DYNAMIC RESULT SETS integer` specifies the maximum number of query result sets that the procedure can return. The value must be between 0 and 32767.
- `EXTERNAL NAME external-program-name or identifier` specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.
- `NOT DETERMINISTIC or DETERMINISTIC` specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.
  - `NOT DETERMINISTIC` indicates that the procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.
  - `DETERMINISTIC` indicates that the procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.
- `MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL` specifies the classification of SQL statements that the procedure can execute. For the data access classification of each statement, see Table 167 on page 2096. Statements that are not supported in any procedure will return an error.
MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

READS SQL DATA
Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

CONTAINS SQL
Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

NO COLLID or COLLID collection-id
Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

NO COLLID
Indicates that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in DB2 Application Programming and SQL Guide.

COLLID collection-id
Specifies the package collection for the procedure.

WLM ENVIRONMENT name or (name,*)
Identifies the WLM (workload manager) environment in which the procedure is to run when the DB2 stored procedure address space is WLM-established. The name of the WLM environment is an SQL identifier.

name
Specifies the WLM environment in which the procedure must run. If another routine calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

(name,*)
When an SQL application program directly calls a procedure, name specifies the WLM environment in which the stored procedure runs. If another routine calls the procedure, the procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

ASUTIME
Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.
When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**
There is no limit on the number of CPU service units that the procedure can run.

**LIMIT** `integer`
The limit on the number of CPU service units is a positive `integer` in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**
Specifies whether the load module for the procedure is to remain resident in memory when the procedure ends.

**NO**
The load module is deleted from memory after the procedure ends.

**YES**
The load module remains resident in memory after the procedure ends.

**PROGRAM TYPE**
Specifies whether the procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

**SUB**
The procedure runs as a subroutine.

**MAIN**
The procedure runs as a main routine.

**SECURITY**
Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**
The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

**USER**
An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

**DEFINER**
An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

**RUN OPTIONS** `run-time-options`
Specifies the Language Environment run time options that are to be used for the procedure. You must specify `run-time-options` as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty
string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

**COMMIT ON RETURN**
Indicates whether DB2 commits the transaction immediately on return from the procedure.

**NO** DB2 does not issue a commit when the procedure returns.

**YES** DB2 issues a commit when the procedure returns if the following statements are true:
- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**
Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**
Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a procedure in Table 40 on page 212.

**DEFAULT SPECIAL REGISTERS**
Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 40 on page 212.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE**
Specifies if the routine is stopped after failures.

**STOP AFTER SYSTEM DEFAULT FAILURES**
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

**STOP AFTER nn FAILURES**
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURES**
Specifies that this routine should not be placed in a stopped state after any failure.

**Notes**

*Changing to a native SQL procedure:* You cannot change an external SQL procedure to a native SQL procedure. You can drop the procedure that you want to change using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.
Invalidation of packages: When an SQL procedure is altered, all packages that refer to that procedure are marked invalid.

Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 UDB family, DB2 supports the following keywords:
- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for DYNAMIC RESULT SETS.
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

Example

Modify the definition for an SQL procedure so that SQL changes are committed on return from the SQL procedure and the SQL procedure runs in the WLM environment named WLMSQLP:

```
ALTER PROCEDURE UPDATE_SALARY_1
  COMMIT ON RETURN YES
  WLM ENVIRONMENT WLMSQLP;
```
ALTER PROCEDURE (SQL - native)

The ALTER PROCEDURE statement changes the definition of an SQL procedure at the current server. The procedure options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER PROCEDURE statement.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 7, “SQL control statements for SQL routines,” on page 2029.

Invocation

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

If the authorization ID that is used to alter the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure when the procedure definition is reevaluated.

Additional privileges might be required in the following situations:

- If SQL-routine-body is specified, the privilege set must include the privileges that are required to execute the statements in SQL-routine-body.
- If a user-defined type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:
  - Ownership of the user-defined type
  - The USAGE privilege on the user-defined type
  - SYSADM authority
- If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:
  - Ownership of the table
  - The SELECT privilege on the table
  - SYSADM authority
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must include the authority to define programs that run in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.
- When defining a new version of a procedure (using the ADD VERSION clause) or when replacing an existing version (using the REPLACE VERSION clause), the privilege set must include the required authorization to add a new package
or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization IDs of the process. The specified routine name can include a schema name (a qualifier). However, if the schema name is not the same as one of these SQL authorization IDs, one of the following conditions must be met:
- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the ALTERIN privilege on the schema

**Syntax**

### routine-specification:

```
(1) option-list
```

**Notes:**
1. All versions of the procedure must have the same number of parameters.

### parameter-declaration:
**data-type:**

- **built-in-type**
  - **distinct-type-name**
  - **array-type-name**

**built-in-type:**
option-list: (The options can be specified in any order, but each option can be specified only one time.)
### SQL-control-statement

- ALTER DATABASE statement
- ALTER FUNCTION statement (external scalar, external table, sourced, SQL scalar, or SQL table)
- ALTER INDEX statement
- ALTER PROCEDURE statement (external, SQL - external, or SQL - native)
- ALTER SEQUENCE statement
- ALTER STOGROUP statement
- ALTER TABLE statement
- ALTER TABLESPACE statement
- ALTER TRUSTED CONTEXT statement
- ALTER VIEW statement
- COMMENT statement
- COMMIT statement
- CONNECT statement
- CREATE ALIAS statement
- CREATE DATABASE statement
- CREATE FUNCTION statement (external scalar, external table, or sourced)
- CREATE GLOBAL TEMPORARY TABLE statement
- CREATE INDEX statement
- CREATE PROCEDURE (external) statement
- CREATE ROLE statement
- CREATE SEQUENCE statement
- CREATE SYNONYM statement
- CREATE TABLE statement
- CREATE TABLESPACE statement
- CREATE TRUSTED CONTEXT statement
- CREATE TYPE statement
- CREATE VIEW statement
- DECLARE GLOBAL TEMPORARY TABLE statement
- DELETE statement
- DROP statement
- EXCHANGE statement
- EXECUTE IMMEDIATE statement
- GRANT statement
- INSERT statement
- LABEL statement
- LOCK TABLE statement
- MERGE statement
- REFRESH TABLE statement
- RELEASE statement
- RELEASE SAVEPOINT statement
- RENAME statement
- REVOKE statement
- ROLLBACK statement
- SAVEPOINT statement
- SELECT INTO statement
- SET CONNECTION statement
- SET special-register statement
- TRUNCATE statement
- UPDATE statement
- VALUES INTO statement

### Notes:

1. An ALTER FUNCTION (SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION or REPLACE clause is not allowed in an SQL-routine-body.

2. The COMMIT statement and the ROLLBACK statement (without the TO SAVEPOINT clause) must not be issued in a routine body if the routine is in the calling chain of an SQL routine, an external routine, or a trigger.

### Description

**procedure-name**

Identifies the procedure to alter. The procedure that is identified in **procedure-name** must exist at the current server.
**ACTIVE VERSION** or **ALL VERSIONS** or **VERSION** *routine-version-id*

Identifies the version of the procedure that is to be changed, replaced, or regenerated depending on whether the ALTER, REPLACE, or REGENERATE keyword is specified.

**ACTIVE VERSION**

Specifies that the currently active version of the procedure is to be changed, replaced, or regenerated.

**ALL VERSIONS**

Specifies that all of the versions of the procedure are to be changed. Only the following options can be changed when this option is specified:

- **AUTONOMOUS** or **COMMIT ON RETURN**

**VERSION** *routine-version-id*

Identifies the version of the procedure that is to be changed, replaced, or regenerated. *routine-version-id* is the version identifier that is assigned when the version is defined. *routine-version-id* must identify a version of the specified procedure that exists at the current server.

**ALTER**

Specifies that a version of the procedure is to be changed.

When you change a procedure to add or replace a version of the procedure, any option that is not explicitly specified will use the existing value from the version of the procedure that is being changed.

**REPLACE**

Specifies that a version of the procedure is to be replaced.

Binding the replaced version of the procedure might result in a new access path even if the routine body is not changed.

When you replace a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the procedure that is being replaced. This is not the case for versions of the procedure that specified **DISABLE DEBUG MODE**. If **DISABLE DEBUG MODE** is specified for a version of a procedure, it cannot be changed by the REPLACE clause.

**ADD VERSION** *routine-version-id*

Specifies that a new version of the procedure is to be created. *routine-version-id* is the version identifier for the new version of the procedure. *routine-version-id* must not identify a version of the specified procedure that already exists at the current server.

When a new version of a procedure is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.

When you add a new version of a procedure the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter names can differ from the other versions of the procedure. For options that are not explicitly specified, the system default values will be used.

**ACTIVATE VERSION** *routine-version-id*

Specifies the version of the procedure that is to be the currently active version
of the procedure. *routine-version-id* is the version identifier that is assigned
when the version of the procedure is defined. The version that is specified with
*routine-version-id* is the version that will be invoked by the CALL statement,
unless the value of the CURRENT ROUTINE VERSION special register
overrides the currently active version of the procedure when the procedure is
invoked. *routine-version-id* must identify a version of the procedure that already
exists at the current server.

**REGENERATE**

Regenerates a version of the procedure. When DB2 maintenance is applied that
changes how an SQL procedure is generated, the procedure might need to be
regenerated to process the maintenance changes.

REGENERATE automatically rebinds, at the local server, the package for the
SQL control statements for the procedure and rebinds the package for the SQL
statements that are included in the procedure body. If a remote bind is also
needed, the BIND PACKAGE COPY command must be explicitly done for all
of the remote servers.

REGENERATE is different from a REBIND PACKAGE command where the
SQL statements are rebound (i.e. to generate better access paths for those
statements), but the SQL control statements in the procedure definition remain
the same.

**DROP VERSION** *routine-version-id*

Drops the version of the procedure that is identified with *routine-version-id*.
*routine-version-id* is the version identifier that is assigned when the version is
defined. *routine-version-id* must identify a version of the procedure that already
exists at the current server and must not identify the currently active version of
the procedure. Only the identified version of the procedure is dropped.

When only a single version of the procedure exists at the current server, use
the DROP PROCEDURE statement to drop the procedure. A version of the
procedure for which the version identifier is the same as the contents of the
CURRENT ROUTINE VERSION special register can be dropped if that version
is not the currently active version of the procedure.

* (parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type and usage
of each parameter, and the name of each parameter for the version of the
procedure that is being defined or changed. The number of parameters and the
specified data type and usage of each parameter must match the data types in
the corresponding position of the parameter for all other versions of this
procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the
parameters must match the implicit or explicit usage of the parameters of other
versions of the same procedure.

IN Identifies the parameter as an input parameter to the procedure. The value
of the parameter on entry to the procedure is the value that is returned to
the calling SQL application, even if changes are made to the parameter
within the procedure.

IN is the default.

OUT Identifies the parameter as an output parameter that is returned by the
procedure. If the parameter is not set within the procedure, the null value
is returned.
INOUT
Identifies the parameter as both an input and output parameter for the
procedure. If the parameter is not set within the procedure, its input value
is returned.

parameter-name
Names the parameter for use as an SQL variable. The name cannot be the
same as the name of any other parameter-name for this version of the
procedure. The name of the parameter in this version of the procedure can
be different than the name of the corresponding parameter for other
versions of this procedure.

built-in-type
Specifies the data type of the parameter. See CREATE PROCEDURE (SQL
native) on page 1405 for more information on data type specifications.

distinct-type-name
The data type of the input parameter is a distinct type. Any length,
precision, scale, subtype, or encoding scheme attributes for the parameter
are those of the source type of the distinct type. The distinct type must not
be based on a LOB data type.

array-type-name
The data type of the input parameter is a user-defined array type.

If you specify array-type-name without a schema name, DB2 resolves the
array type by searching the schemas in the SQL path.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the procedure returns the same results each time it is called
with the same IN and INOUT arguments.

NOT DETERMINISTIC
The procedure might not return the same result each time it is called with
the same IN and INOUT arguments, even when the data that is referenced
in the database has not changed.

NOT DETERMINISTIC is the default.

DETERMINISTIC
The procedure always returns the same results each time it is called with
the same IN and INOUT arguments if the data that is referenced in the
database has not changed.

DB2 does not verify that the procedure code is consistent with the specification
of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL
Specifies the classification of SQL statements that the procedure can execute.

MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except
statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

READS SQL DATA
Specifies that procedure can execute statements with a data access
indication of READS SQL DATA or CONTAINS SQL. The procedure
cannot execute SQL statements that modify data.
CONTAINS SQL
Specifies that the procedure can execute only SQL statements with an
access indication of CONTAINS SQL. The procedure cannot execute
statements that read or modify data.

CALLED ON NULL INPUT
Specifies that the procedure will be called if any, or even if all parameter
values are null.

DYNAMIC RESULT SETS integer
Specifies the maximum number of query result sets that the procedure can
return. The default is DYNAMIC RESULT SETS 0, which indicates that there
are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE
Specifies whether the version of the procedure can be run in debugging mode.
The default for a new version of a procedure is determined using the value of
the CURRENT DEBUG MODE special register.

ALLOW DEBUG MODE
Specify that this version of the procedure can be run in debugging mode.
When this version of the procedure is invoked and debugging is
attempted, a WLM environment must be available.

DISALLOW DEBUG MODE
Specify that the version of the procedure cannot be run in debugging
mode.

You can use a subsequent ALTER PROCEDURE statement to change this
option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE
Specify that the version of the procedure can never be run in debugging
mode.

The version of the procedure cannot be changed to specify ALLOW
DEBUG MODE or DISALLOW DEBUG MODE after the version of the
procedure has been created, replaced, or altered to use DISABLE DEBUG
MODE. To change DEBUG MODE for a version of a procedure that
specifies DISABLE DEBUG MODE, you must drop and re-create the
version of the procedure using the option that you want.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT
FOR DEBUG MODE option is ignored.

PARAMETER CCSID
Indicates whether the encoding scheme for character or graphic string
parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is
the value that is specified in the CCSID clauses of the parameter list or in the
field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for
character or graphic string parameters. If individual CCSID clauses are
specified for individual parameters in addition to this PARAMETER CCSID
clause, the value that is specified in all of the CCSID clauses must be the same
value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined
as a character or graphic type string, the CCSID of the distinct type must be
the same as the value that is specified in this clause.
If the data type for a parameter is a user-defined array type that is defined with character or graphic string array elements, or a character string array index, the CCSID of these array attributes must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER schema-name**

Specifies the implicit qualifier that is used for unqualified names of tables, views, indexes, and aliases that are referenced in the procedure body. The default value is determined from the CURRENT SCHEMA special register.

**PACKAGE OWNER authorization-name**

Specifies the owner of the package that is associated with the version of the procedure. The SQL authorization ID of the process is the default value.

This authorization ID must have the privileges required to execute the SQL statements that are contained in the body of the routine and must contain the necessary bind privileges. The value of the PACKAGE OWNER option is subject to translation when sent to a remote system.

If the privilege set lacks SYSADM or SYSCtrl authority, *authorization-name* must be the same as one of the authorization IDs of the process. If the privilege set includes SYSADM or SYSCtrl authority, *authorization-name* can be any authorization ID that contains the necessary bind privileges.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

Specifies that there is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

**LIMIT integer**

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**COMMIT ON RETURN NO, COMMIT ON RETURN YES, or AUTONOMOUS**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**COMMIT ON RETURN NO**

DB2 does not issue a commit when the procedure returns. NO is the default.

**COMMIT ON RETURN YES,**

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.
The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**AUTONOMOUS**

DB2 executes the SQL procedure in a unit of work that is independent from the calling application. When this option is specified the procedure follows the rules of the COMMIT ON RETURN YES option before returning to the calling application. However, it does not commit changes in the calling application. When autonomous is specified:

- DYNAMIC RESULT SETS 0 must be in effect.
- Stored procedure parameters must not be defined as:
  - A LOB type
  - The XML data type
  - A distinct data type that is based on a LOB or XML value
  - An array type that is defined with array elements that are a LOB type

A value must not be assigned to a global variable when an autonomous procedure is executing.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 40 on page 212. INHERIT SPECIAL REGISTERS is the default.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 40 on page 212.

**WLM ENVIRONMENT FOR DEBUG MODE** name

Specifies the WLM (workload manager) application environment used by DB2 when debugging the procedure. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space that is specified at installation time.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

To change the environment that DB2 uses for debugging this procedure, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**DEFER PREPARE or NODEFER PREPARE**

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.
The default depends on the value that is specified for the REOPT option. If REOPT NONE is specified, the default is NODEFER PREPARE. Otherwise, the default is DEFER PREPARE.

**DEFER PREPARE**
- Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in *DB2 Command Reference* for considerations with distributed processing.

**NODEFER PREPARE**
- Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

**CURRENT DATA**
- Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors. For more information about updating the current row of a cursor, block fetch, and data currency, see *DB2 Application Programming and SQL Guide*.

**YES**
- Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquired page or row locks to ensure data currency. Block fetch is not allowed for distributed, ambiguous cursors.

**NO**
- Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA(NO) is not recommended if the procedure attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your procedure attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:
  - A cursor that is using block fetch
  - A cursor that is using query parallelism
  - A cursor that is positioned on a row that is modified by this or another application process

No is the default.

**DEGREE**
- Specifies whether to attempt to run a query using parallel processing to maximize performance.

**1**
- Specifies that parallel processing should not be used.

1 is the default.

**ANY**
- Specifies that parallel processing can be used.

**CONCURRENT ACCESS RESOLUTION**
- Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**
- Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.
**USE CURRENTLY COMMITTED**

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

**DYNAMICRULES** also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a native SQL procedure controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

**BIND**

Specifies that dynamic SQL statements are to be processed using bind behavior.

**DEFINEBIND**

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

**DEFINERUN**

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

**INVOKEBIND**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

**INVOKE_RUN**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.
See “Authorization IDs and dynamic SQL” on page 77 for information on the effects of these options.

**APPLICATION ENCODING SCHEME**

Specifies the default encoding scheme for SQL variables in static SQL statements in the procedure body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

**ASCII**

Specifies that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

**WITH EXPLAIN or WITHOUT EXPLAIN**

Specifies whether information will be provided about how SQL statements in the procedure will execute.

**WITHOUT EXPLAIN**

Specifies that information will not be provided about how SQL statements in the procedure will execute.

You can get EXPLAIN output for a statement that is embedded in a native SQL procedure that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the procedure body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the procedure body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

**WITH EXPLAIN**

Specifies that information will be provided about how SQL statements in the procedure will execute. Information is inserted into the table `owner.PLAN_TABLE`. `owner` is the authorization ID of the owner of the procedure package. Alternatively, the authorization ID of the owner of the procedure can have an alias as `owner.PLAN_TABLE` that points to the base table, `PLAN_TABLE`. `owner` must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. `PLAN_TABLE` must have a base table and can have multiple aliases with the same table name, `PLAN_TABLE`, but have different schema qualifiers; it cannot be a view or a synonym. It should exist before the version is added or replaced. In all inserts to `owner.PLAN_TABLE`, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN_STATEMNT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMNT_TABLE contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. DSN_FUNCTION_TABLE contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.
For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1706.

**WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. DB2 Command Reference shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this procedure option) as it affects run time.

**WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

**WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the procedure from the effects of other running applications. For information about isolation levels, see DB2 Performance Monitoring and Tuning Guide.

- **RR** Specifies repeatable read.
- **RS** Specifies read stability.
- **CS** Specifies cursor stability. CS is the default.
- **UR** Specifies uncommitted read.

**WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC**

Specifies whether DB2 keeps dynamic SQL statements after commit points.

**WITHOUT KEEP DYNAMIC**

Specifies that DB2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

**WITH KEEP DYNAMIC**

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps
only the SQL statement string past a commit point. If the application
executes an OPEN, EXECUTE, or DESCRIBE operation for that statement,
the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used
to execute procedures or packages that have this option in effect will
remain active. Active DDF server threads are subject to idle thread time
outs, as described in DB2 Installation Guide for installation panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT
ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually
exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT
ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client
application uses a cursor that is defined as WITH HOLD. The DB2
subsystem automatically closes a held cursor when there are no more rows
to retrieve, which eliminates an extra network message.

**OPTHINT** *string-constant*

Specifies whether query optimization hints are used for static SQL statements
that are contained within the body of the procedure.

*string-constant* is a character string of up to 128 bytes in length, which is used
by the DB2 subsystem when searching the PLAN_TABLE for rows to use as
input. The default value is an empty string, which indicates that the DB2
subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for you
system. See DB2 Installation Guide for information about enabling optimization
hints.

**SQL PATH**

Specifies the SQL path that the DB2 subsystem uses to resolve unqualified
user-defined types, functions, and procedure names (in CALL statements) in
the body of the procedure.

The maximum length of the SQL path is 2048 bytes. DB2 calculates the length
by taking each *schema-name* specified and removing any trailing blanks from it,
adding two delimiters around it, and adding one comma after each schema
name except for the last one. The length of the resulting string cannot exceed
2048 bytes.

*schema-name*

Specifies a schema. DB2 does not validate that the specified schema
actually exists when the ALTER statement is processed.

SYSPUBLIC must not be specified for the SQL path.

*schema-name-list*

Specifies a comma separated list of schema names. The same schema name
should not appear more than one time in the list of schema names. The
number of schema names that you can specify is limited by the maximum
length of the resulting SQL path.

SYSPUBLIC must not be specified for the SQL path.

**SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC",
"SYSIBMADM".

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (or USER) special register. At the
time the ALTER statement is processed, the actual length is included in the total length of the list of schema names that is specified for the PATH option. If you specify SESSION_USER (or USER) in a list of schema names, do not use delimiters around the SESSION_USER (or USER) keyword.

**RELEASE AT**
Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

**COMMIT**
Specifies that resources will be released at each commit point.
COMMIT is the default.

**DEALLOCATE**
Specifies that resources will be released only when the procedure terminates. DEALLOCATE has no effect on packages that run on a DB2 server through a DRDA connection with a client system. DEALLOCATE also has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and SQL data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:
- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package size because additional items become resident in the package. For more information about how the RELEASE clause affects locking and concurrency, see *DB2 Performance Monitoring and Tuning Guide*.

**QUERY ACCELERATION**
Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

**NONE**
Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

**ENABLE**
Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in DB2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application:
A failure occurs while running the static query on the accelerator.
The accelerator returns an error for the query.
The accelerator is not started and DB2 cannot route the static query to
the accelerator for execution.

**ENABLE WITH FAILBACK**
Results in the same behavior as ENABLE, except if one of the error
conditions occurs on the first OPEN of the accelerated static query when
the application is run. In this case, instead of failing the static query and
returning a negative SQL code to the application, DB2 performs a
temporary statement-level incremental bind of the query and runs the query
in DB2. The application does not see the acceleration failure. Failback to
DB2 is not possible after the application does a successful OPEN for the
query on the accelerator.

**ELIGIBLE**
Specifies that a static SQL query is bound for acceleration if the query
meets the basic acceleration criteria, regardless of the cost or heuristics
criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.

**ALL**
Specifies that all of the static SQL queries in the application are to be
bound for acceleration and routed to the accelerator when the application
runs. If DB2 determines that a static query cannot be bound to run on the
accelerator and the query references a user base table or view, the BIND or
REBIND PACKAGE operation fails with an error message for that query.
(A failure exception is made for declared global temporary tables (DGTTs)
and created global temporary tables (CGTTs) because these tables
cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.

This bind option does not apply to a fullselect or WITH common-table-expression
that is specified in a RETURN statement for the routine, or in a SET
host-variable-assignment that is used in the routine. The queries that are
specified in these cases cannot be accelerated.

**GET ACCEL_ARCHIVE**
Specifies whether a static SQL query that is bound for acceleration retrieves
archived data on the accelerator, instead of active data.

**NO** Specifies that no static SQL query is bound to retrieve archived data from
the accelerator. If the static query also is not bound for acceleration, the
query is bound to run in DB2.

If the static query is bound for acceleration because the
QUERYACCELERATION bind option was specified, the query is routed to
the accelerator when the application runs; however, the query does not
retrieve any archived data.

**YES** Specifies that if all of the following criteria are met, the query is bound for
acceleration and retrieves the archived data on the accelerator when the
application runs:
• The QUERYACCELERATION bind option is also specified.
• The static SQL query references an accelerated table that has partitioned
data archived on an accelerator.
• The static query satisfies the acceleration criteria that is specified by the
QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified
by the QUERYACCELERATION bind option, the BIND or REBIND
PACKAGE operation fails with an error message for that query.

This bind option does not apply to a fullselect or WITH common-table-expression
that is specified in a RETURN statement for the routine, or in a SET
host-variable-assignment that is used in the routine. The queries that are
specified in these cases cannot be accelerated.

REOPT
Specifies if DB2 will determine the access path at run time by using the values
of SQL variables or SQL parameters, parameter markers, and special registers.

NONE
Specifies that DB2 does not determine the access path at run time by using
the values of SQL variables or SQL parameters, parameter markers, and
special registers.

NONE is the default.

ALWAYS
Specifies that DB2 always determine the access path at run time each time
an SQL statement is run.

ONCE
Specifies that DB2 determine the access path for any dynamic SQL
statements only one time, at the first time the statement is opened. This
access path is used until the prepared statement is invalidated or removed
from the dynamic statement cache and needs to be prepared again.

VALIDATE RUN or VALIDATE BIND
Specifies whether to recheck, at run time, errors of the type "OBJECT not
FOUND" and NOT AUTHORIZED" that are found during bind or rebind. The
option has no effect if all objects and needed privileges exist.

VALIDATE RUN
Specifies that if needed objects or privileges do not exist when the ALTER
PROCEDURE statement is processed, warning messages are returned, but the
ALTER PROCEDURE statement succeeds. The DB2 subsystem rechecks
for the objects and privileges at run time for those SQL statements that
failed the checks during processing of the ALTER PROCEDURE statement.
The authorization checks the use of the authorization ID of the owner of
the procedure package.

VALIDATE RUN is the default.

VALIDATE BIND
Specifies that if needed objects or privileges do not exist at the time the
ALTER PROCEDURE statement is processed, an error is issued and the
ALTER PROCEDURE statement fails.

ROUNDING
Specifies the rounding mode for manipulation of DECFLOAT data.
DEC_ROUND_CEILING
    Specifies numbers are rounded towards positive infinity.

DEC_ROUND_DOWN
    Specifies numbers are rounded towards 0 (truncation).

DEC_ROUND_FLOOR
    Specifies numbers are rounded towards negative infinity.

DEC_ROUND_HALF_DOWN
    Specifies numbers are rounded to nearest; if equidistant, round down.

DEC_ROUND_HALF_EVEN
    Specifies numbers are rounded to nearest; if equidistant, round so that the
    final digit is even.

DEC_ROUND_HALF_UP
    Specifies numbers are rounded to nearest; if equidistant, round up.

DEC_ROUND_UP
    Specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL
    Specifies the date format for result values that are string representations of
    date or time values. See String representations of datetime values on page
    103 for more information.

    The default format is specified in the DATE FORMAT field of installation panel
    DSNTIP4 of the system where the procedure is defined. You cannot use the
    LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)
    Specifies the maximum precision that is to be used for decimal arithmetic
    operations. See Arithmetic with two decimal operands on page 247 for more
    information. The default format is specified in the DECIMAL ARITHMETIC
    field of installation panel DSNTIPF of the system where the procedure is
    defined. If the form pp.s is specified, s must be a number between 1 and 9. s
    represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED
    Specifies whether the FOR UPDATE clause is required for a DECLARE
    CURSOR statement if the cursor is to be used to perform positioned updates.

    FOR UPDATE CLAUSE REQUIRED
        Specifies that a FOR UPDATE clause must be specified as part of the
        cursor definition if the cursor will be used to make positioned updates.
        FOR UPDATE CLAUSE REQUIRED is the default.

    FOR UPDATE CLAUSE OPTIONAL
        Specifies that the FOR UPDATE clause does not need to be specified in
        order for a cursor to be used for positioned updates. The procedure body
        can include positioned UPDATE statements that update columns that the
        user is authorized to update.

        If the resulting DBRM for the procedure is very large, you might need
        extra storage when you specify FOR UPDATE CLAUSE OPTIONAL.

    The FOR UPDATE clause of the select-statement with no column list applies to
    static or dynamic SQL statements. You can specify the FOR UPDATE OF clause
    of the select-statement with a column list to restrict updates to only the
    columns that are named in the column list and to specify the acquisition of
    update locks.
TIME FORMAT ISO, EUR, USA, JIS, or LOCAL
Specifies the time format for result values that are string representations of
date or time values. See “String representations of datetime values” on page
103 for more information.

The default format is specified in the TIME FORMAT field of installation panel
DSNTIP4 of the system where the procedure is defined. You cannot use the
LOCAL option unless you have a date exit routine.

BUSINESS_TIME SENSITIVE
Determines whether references to application-period temporal tables in both
static and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL BUSINESS_TIME special register.

YES
References to application-period temporal tables are affected by the value
of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the
default value.

NO References to application-period temporal tables are not affected by the
value of the CURRENT TEMPORAL BUSINESS_TIME special register.

Related information:
“CURRENT TEMPORAL BUSINESS_TIME” on page 201

SYSTEM_TIME SENSITIVE
Determines whether references to system-period temporal tables in both static
and dynamic SQL statements are affected by the value of the CURRENT
TEMPORAL SYSTEM_TIME special register.

YES
References to system-period temporal tables are affected by the value of
the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the
default value.

NO References to system-period temporal tables are not affected by the value
of the CURRENT TEMPORAL SYSTEM_TIME special register.

Related information:
“CURRENT TEMPORAL SYSTEM_TIME” on page 203

ARCHIVE SENSITIVE
Determines whether references to archive-enabled tables in SQL statements are
affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

YES
References to archive-enabled tables are affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

NO References to archive-enabled tables are not affected by the value of the
SYSIBMADM.GET_ARCHIVE global variable.

Related information:
“Built-in global variables” on page 340

APPLCOMPAT compatibility-level
Specifies the package compatibility level behavior for static SQL. If this option
is not specified then the behavior is determined, in priority order, by the
compatibility-level of the last BIND or REBIND of the package or the
APPLCOMPAT system parameter. The following values of compatibility-level
can be specified:
The static SQL statements in the package have V10R1 compatibility behavior.

The static SQL statements in the package have V11R1 compatibility behavior.

Related information:

  APPL COMPAT LEVEL field (APPLCOMPAT subsystem parameter) (DB2 Installation and Migration)

SQL-routine-body

  Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 7, “SQL control statements for SQL routines,” on page 2029. If an SQL-procedure-statement is the only statement in the procedure body, the statement must not end with a semicolon.

Notes

Considerations for altering a version of a procedure: To alter a version of a procedure, the environment settings that are in effect when the ALTER PROCEDURE statement is issued must be the same as the environment settings that are in effect when the version of the procedure is first created using the CREATE PROCEDURE or ALTER PROCEDURE statements if one of the following options is specified:

• QUALIFIER
• PACKAGE OWNER
• WLM ENVIRONMENT FOR DEBUG MODE
• OPPTHINT
• SQL PATH
• DECIMAL (if the value includes a comma)

Changing to a native SQL procedure: You cannot change an external SQL procedure to a native SQL procedure. You can drop the external SQL procedure that you want to change by using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.

Identifier resolution: See Chapter 7, “SQL control statements for SQL routines,” on page 2029 for information on how names are resolved to columns, SQL variables, or SQL routines for native SQL procedures. Name resolution is unchanged for external SQL procedures.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the procedure name for parameters, and the label name for SQL variables.

Characteristics of the package that is generated for a version of a procedure: The package that is associated with a version of a procedure is named as follows:

• location is set to the value of the CURRENT SERVER special register
• collection-id (schema) for the package is the same as the schema qualifier of the procedure
• package-id is the same as the specific name of the procedure
• version-id is the same as the version identifier for the initial version of the procedure

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See Table 101 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:
• DBPROTOCOL(DRDA)
• FLAG(1)
• SQLERROR(NOPACKAGE)
• ENABLE(*)

Considerations for a procedure that is defined using a TABLE LIKE name AS LOCATOR clause: If a procedure is defined with a table parameter (the TABLE LIKE name AS LOCATOR clause was specified in the CREATE PROCEDURE statement to indicate that one of the input parameters is a transition table), the procedure cannot be changed with an ALTER PROCEDURE statement if the change requires that the parameter list be specified. For example, to add or replace a version of a native SQL procedure, the procedure must be dropped and re-created.

Considerations for SQL processor programs: SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see DB2 Application Programming and SQL Guide.

Correspondence of procedure options to BIND options: The following table lists options for CREATE PROCEDURE and ALTER PROCEDURE and the corresponding options for the bind commands. See DB2 Command Reference for more information about the effects of the options of the bind commands.

Invalidation of packages: When a version of an SQL procedure is altered to change any option that is specified for the active version, all the packages that refer to that procedure are marked invalid. Additionally, when certain attributes of a native SQL procedure are changed, the body of the procedure might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of Y in a row indicates that a rebind or regeneration occurs if the option is changed for a version of the procedure. A value of N in a row indicates that a rebind or regeneration does not occur.

Table 102. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed.

Table 102. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed. (continued)

<table>
<thead>
<tr>
<th>CREATE PROCEDURE or ALTER PROCEDURE option</th>
<th>Change requires rebind of invoking applications?</th>
<th>Change results in implicit rebind of the non-control statements of the body of the procedure?</th>
<th>Change results in implicit regeneration of the entire body of the procedure?</th>
</tr>
</thead>
</table>

**Note:**
1. The procedure package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE.
2. Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE.

*Considerations for SYSENVIRONMENTS catalog table:* An ALTER statement that specifies a new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the ALTER statement. Thus, a new SYSENVIRONMENTS row might be added even for an ALTER statement that fails.

*Stored procedures with a parameter that is defined as an array type:* A procedure that is defined with a parameter that is an array type can be invoked only from within an SQL PL context.

*Compatibilities:* For compatibility with previous versions of DB2, when any of the following options are implicitly or explicitly specified as part of option-list, a warning is issued, but the statement is executed. However, if REPLACE or ADD VERSION is specified with one of the following options, an error is issued, and the statement does not execute. For example, if ADD VERSION and STAY RESIDENT are specified, an error is issued.

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER \( nn \) FAILURES
- CONTINUE AFTER FAILURES

If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

For compatibility with the CREATE PROCEDURE statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for DYNAMIC RESULT SETS.
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
**Considerations for catalog comments for a routine definition:** When a function definition is replaced any existing comment in the catalog for the definition is removed, and when a function definition is regenerated any existing comment in the catalog for the definition is retained.

**Example**

**Example 1:** The following statement changes the existing procedure options for the active version of the UPDATE_SALARY_1 native SQL procedure. If you need to change a different version of the procedure, you would specify `VERSION routine-version-id` in place of `ACTIVE VERSION`. Note that the `ALTER` clause that precedes the version specification can be omitted.

```
ALTER PROCEDURE UPDATE_SALARY_1
   ALTER ACTIVE VERSION
   NOT DETERMINISTIC
   CALLED ON NULL INPUT
   ALLOW DEBUG MODE
   ASUTIME LIMIT 10
```

**Example 2:** To change the procedure body of any existing version of a procedure, you need to use the `REPLACE` clause. The following statement changes both the procedure body and the existing SQL data access option for version V2 of the UPDATE_SALARY_1 SQL procedure. Note that the list of parameters is specified even though no changes are made to the list. To replace an existing version of a procedure, you must specify the list of parameters, any options that are to have non-default values (even if those options are specified in the version of the procedure that you are replacing), and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
   REPLACE VERSION V2 (P1 INTEGER, P2 CHAR(5))
   MODIFIES SQL DATA
   UPDATE EMP SET SALARY = SALARY * RATE
   WHERE EMPNO = EMPLOYEE_NUMBER;
```

**Example 3:** To add a new version of an existing procedure, use the ADD VERSION clause. The following statement adds a new version of the UPDATE_SALARY_1 procedure to apply a larger salary increase. Note that the list of parameters is specified even though the new version of the procedure uses the same parameters as the existing version of the procedure. To add a new version of a procedure, you must specify the list of parameters, any options that will have non-default values, and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
   ADD VERSION V3 (P1 INTEGER, P2 CHAR(5))
   UPDATE EMP SET SALARY = SALARY * (RATE*10)
   WHERE EMPNO = EMPLOYEE_NUMBER;
```

**Example 4:** When the new version of the procedure has been defined, as in Example 3, you must use the `ALTER PROCEDURE` statement with the `ACTIVATE VERSION` clause if the new version of the procedure is to be the currently active version, as in the following example.

```
ALTER PROCEDURE UPDATE_SALARY_1
   ACTIVATE VERSION V3;
```

**Example 5:** To regenerate the currently active version of a procedure, use the following statement.

```
ALTER PROCEDURE UPDATE_SALARY_1
   REGENERATE ACTIVE VERSION;
```
ALTER SEQUENCE

The ALTER SEQUENCE statement changes the attributes of a sequence at the current server. Only future values of the sequence are affected by the ALTER SEQUENCE statement.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the sequence
- The ALTER privilege for the sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCtrl authority
- System DBADM

Installation SYSADM privilege is required to alter the SYSIBM.DSNSEQ_IMPLICITDB sequence (which specifies the maximum number of implicitly created databases).

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.
### Syntax

```
ALTER SEQUENCE sequence-name (1)
   RESTART
   WITH numeric-constant
   INCREMENT BY numeric-constant
   NO MINVALUE
   MINVALUE numeric-constant
   NO MAXVALUE
   MAXVALUE numeric-constant
   NO CYCLE
   CYCLE
   NO CACHE
   CACHE integer-constant
   NO ORDER
   ORDER
```

### Notes:
1. At least one option must be specified and the same clause must not be specified more than once. Separator commas can be specified between sequence attributes when a sequence is defined.

### Description

**sequence-name**

Identifies the sequence. The combination of sequence name and the implicit or explicit qualifier must identify an existing sequence at the current server. *sequence-name* must not identify a sequence that is generated by DB2 for an identity column or a DB2_GENERATED_DOCID_FOR_XML column.

**RESTART**

Restarts the sequence. If *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the CREATE SEQUENCE statement that originally created the sequence.

**WITH numeric-constant**

Specifies the value at which to restart the sequence. The value can be any positive or negative value that could be assigned to a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values in effect for all the options after the ALTER statement is issued.

After a sequence is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated by the sequence previously.

**INCREMENT BY numeric-constant**

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point.
If INCREMENT BY numeric-constant is positive, the sequence ascends. If INCREMENT BY numeric-constant is negative, the sequence descends. If INCREMENT BY numeric-constant is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

**NO MINVALUE or MINVALUE**
Specifications whether or not there is a minimum end point of the range of values for the sequence.

**NO MINVALUE**
Specifications that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the value for MINVALUE becomes one of the following:
- For an ascending sequence, the value is the original starting value.
- For a descending sequence, the value is the minimum of the data type that is associated with the sequence.

**MINVALUE numeric-constant**
Specifications the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

**NO MAXVALUE or MAXVALUE**
Specifications whether or not there is a maximum end point of the range of values for the sequence.

**NO MAXVALUE**
Specifications either explicitly or implicitly that the minimum end point of the range of values for the sequence has not be set. In such a case, the default value for MAXVALUE becomes one of the following:
- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence.
- For a descending sequence, the value is the original starting value.

If NO MAXVALUE is explicitly specified in the ALTER SEQUENCE statement, the value of the MAXVALUE column in the catalog table is reset to the maximum value of the data type associated with the sequence if the sequence is ascending or the value stored in the START column of the catalog table if the sequence is descending. Whether the sequence is ascending or descending depends on whether or not the INCREMENT BY option is reset. If it is, the new INCREMENT BY VALUE determines if the sequence is ascending or descending. If it is not explicitly reset, the value stored in the INCREMENT column of the catalog table determines if the sequence is ascending or descending.

**MAXVALUE numeric-constant**
Specifications the maximum value at which an ascending sequence either cycles or stops generating values or a descending sequence cycles to after
reaching the minimum value. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

**NO CYCLE or CYCLE**

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it.

**NO CYCLE**

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached.

**CYCLE**

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

**NO CACHE or CACHE**

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

**NO CACHE**

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O.

**CACHE integer-constant**

Specifies the maximum number of sequence values that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.
The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

**NO ORDER or ORDER**
Specifies whether the sequence numbers must be generated in order of request.

**NO ORDER**
Specifies that the sequence numbers do not need to be generated in order of request.

**ORDER**
Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1, 21, 2 if DB2A requested for next value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple DB2 members using the same sequence concurrently, specify the ORDER option.

**Notes**

**Altering a sequence:** The changes to the attributes of a sequence take effect after the ALTER SEQUENCE statement is committed. Only future sequence numbers are affected by the ALTER SEQUENCE statement. If the ALTER SEQUENCE request results in an error or is rolled back, nothing is changed; however, unused cache values might be lost.

- The data type of a sequence cannot be changed. Instead, drop and re-create the sequence specifying the desired data type for the new sequence.
- All cached values are lost when a sequence is altered.
- After restarting a sequence or changing it to cycle, it is possible that a generated value will duplicate a value previously generated for that sequence.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- NOCACHE (single key word) as a synonym for NO CACHE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOORDER (single key word) as a synonym for NO ORDER
Examples

Example 1: Reset a sequence to the START WITH value to generate the numbers from 1 up to the number of rows in the table:

    ALTER SEQUENCE org_seq
    RESTART;
**ALTER STOGROUP**

The ALTER STOGROUP statement changes the description of a storage group at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include one of the following:

- Ownership of the storage group
- SYSADM or SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

**Syntax**

```
ALTER STOGROUP stogroup-name
  ADD VOLUMES (volume-id)
  REMOVE VOLUMES (volume-id)
```

**Notes:**

1. The same clause must not be specified more than once.
2. The same `volume-id` must not be specified more than once in the same clause.

**Description**

`stogroup-name`

Identifies the storage group to be altered. The name must identify a storage group that exists at the current server.
ADD VOLUMES(volume-id,...) or ADD VOLUMES('*',...)

Adds volumes to the storage group. Each volume-id is the volume serial number of a storage volume to be added. It can have a maximum of six characters and is specified as an identifier or a string constant.

A volume-id must not be specified if any volume of the storage group is designated by an asterisk (*). An asterisk must not be specified if any volume of the storage group is designated by a volume-id.

You cannot add a volume that is already in the storage group unless you first remove it with REMOVE VOLUMES.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

REMOVE VOLUMES(volume-id,...) or REMOVE VOLUMES('*',...)

Removes volumes from the storage group. Each volume-id is the volume serial number of a storage volume to be removed. Each volume-id must identify a volume that is in the storage group.

The REMOVE VOLUMES clause is applied to the current list of volumes before the ADD VOLUMES clause is applied. Removing a volume from a storage group does not affect existing data, but a volume that has been removed is not used again when the storage group is used to allocate storage for table spaces or index spaces.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified.

DATACLAS dc-name
Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

MGMTCLAS mc-name
Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

STORCLAS sc-name
Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The
SMS storage administrator defines the storage class that can be used. STORCLAS must not be specified more than one time.

Notes

**Work file databases:** If the storage group altered contains data sets in a work file database, the database must be stopped and restarted for the effects of the ALTER to be recognized. To stop and restart a database, issue the following commands:

- STOP DATABASE(database-name)
- START DATABASE(database-name)

**Device types:** When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

**Number of volumes:** There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

If the VOLUMES clause is specified, the maximum number of volumes is 59.

**Verifying the existence of volumes and classes:** When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the existence of the volumes or classes or determine the types of devices that are identified or if SMS is active. Later, when the storage group allocates data sets, the list of volumes is passed in the specified order to Data Facilities (DFSMSdfp). See DB2 Administration Guide for more information about creating DB2 storage groups.

**SMS data set management:** You can have Storage Management Subsystem (SMS) manage the storage needed for the objects that the storage group supports. To do so, specify ADD VOLUMES(*) and REMOVE VOLUMES(current-vols) in the ALTER statement, where current-vols is the list of the volumes currently assigned to the storage group. SMS manages every data set created later for the storage group. SMS does not manage data sets created before the execution of the statement.

You can also specify ADD VOLUMES(volume-id) and REMOVE VOLUMES(*) to make the opposite change.

See DB2 Administration Guide for considerations for using SMS to manage data sets.

Examples

**Example 1:** Alter storage group DSN8G110. Add volumes DSNV04 and DSNV05.

```sql
ALTER STOGROUP DSN8G110
   ADD VOLUMES (DSNV04,DSNV05);
```

**Example 2:** Alter storage group DSN8G110. Remove volumes DSNV04 and DSNV05.

```sql
ALTER STOGROUP DSN8G110
   REMOVE VOLUMES (DSNV04,DSNV05);
```
The ALTER TABLE statement changes the description of a table at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include at least one of the following:
- The ALTER privilege on the table
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

To alter a system-period temporal table when one or more of the changes also result in changes to the associated history table, the privileges that are held by the authorization ID of the statement must also include at least one of the following:
- The ALTER privilege on the history table
- Ownership of the history table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

The privilege set must include SECADM authority if one of the following clauses is specified:
- ACTIVATE
- DEACTIVATE

Additional privileges might be required in the following situations:
- FOREIGN KEY, ADD PRIMARY KEY, ADD UNIQUE, DROP PRIMARY KEY, DROP FOREIGN KEY, or DROP CONSTRAINT is specified.
- The data type of a column that is added to the table is a distinct type.
- A fullselect is specified.
- A column is defined as a security label column.
- A column is defined as ROWID GENERATED BY DEFAULT.

See the description of the appropriate clauses for the details about these privileges.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.
Syntax

ALTER TABLE table-name

(1) (2) (3) COLUMN
ADD column-definition
ALTER COLUMN column-alteration
RENAME COLUMN source-column-name TO target-column-name
DROP column-name
ADD PERIOD period-definition
ADD unique-constraint
referential-constraint
check-constraint
DROP PRIMARY KEY
UNIQUE constraint-name
FOREIGN KEY
CHECK CONSTRAINT
ADD PARTITION BY partitioning-clause
ADD PARTITION partition-clause
ALTER PARTITION integer partition-clause
ROTATE PARTITION FIRST TO LAST rotate-partition-clause
ADD ORGANIZE BY HASH organization-clause
ALTER ORGANIZATION SET HASH SPACE integer
DROP ORGANIZATION
ADD VERSIONING USE HISTORY TABLE history-table-name extra-row-option
DROP VERSIONING
ADD materialized-query-definition
ALTER materialized-query-alteration
DROP materialized-query
DATA CAPTURE NONE CHANGES CARDINALITY
VOLATILE NOT VOLATILE
ADD clone-table-name
DROP clone
ADD RESTRICT ON DROP
DROP RESTRICT ON DROP
ACTIVATE ROW ACCESS CONTROL
DEACTIVATE ROW ACCESS CONTROL
ACTIVATE COLUMN ACCESS CONTROL
DEACTIVATE COLUMN ACCESS CONTROL
APPEND NO YES
AUDIT NONE CHANGES ALL
VALIDPROC program-name
ENABLE ARCHIVE USE archive-table-name
DISABLE ARCHIVE

Notes:
1 The same clause must not be specified more than one time, except for the ADD COLUMN or
ALTER COLUMN clauses. If multiple ADD COLUMN clauses are specified in the same statement, at most one ADD COLUMN clause can contain a references-clause. If ALTER COLUMN SET DATA TYPE is specified, it must be specified first.

The ALTER COLUMN, ADD PARTITION, ALTER PARTITION, and ROTATE PARTITION clauses are mutually exclusive with each other.

If ADD CLONE, DROP CLONE, RENAME COLUMN, ADD ORGANIZE BY HASH, ALTER ORGANIZATION, DROP ORGANIZATION, ADD VERSIONING, DROP VERSIONING, DROP COLUMN, ACTIVATE, DEACTIVATE, ENABLE ARCHIVE, or DISABLE ARCHIVE is specified, no other clause is allowed on the ALTER TABLE statement.

The ADD keyword is optional for referential-constraint or unique-constraint if it is the first clause specified in the statement. Otherwise, ADD is required.

```
column-definition:
  column-name data-type
    default-clause
    NOT NULL
    column-constraint
    generated-clause
    IMPLICITLY HIDDEN
    AS SECURITY LABEL
      FIELDPROC program-name
        \const
    INLINE LENGTH integer
```

Notes:
1. **data-type** is optional if as-row-change-timestamp-clause is specified
2. The same clause must not be specified more than one time.
3. GENERATED must be specified if the column is to be an identity column.
4. IMPLICITLY HIDDEN must not be specified for a column defined as a ROWID, or a distinct type that is based on a ROWID.
5. AS SECURITY LABEL can be specified only for a CHAR(8) data type and requires that the NOT NULL and WITH DEFAULT clauses be specified.
6. INLINE LENGTH only applies to a column with a LOB data type or a distinct type that is based on a LOB data type.
data-type:

-built-in-type-

distinct-type-name

built-in-type:
Notes:
1 The \textit{cast-function-name} form of the DEFAULT value can only be used with a column that is defined as a distinct type.
as-identity-clause:

```
 AS IDENTITY
```

(1) START WITH numeric-constant
• INCREMENT BY 1
• INCREMENT BY numeric-constant
• NO MINVALUE
• MINVALUE numeric-constant
• NO MAXVALUE
• MAXVALUE numeric-constant
• NO CYCLE
• CYCLE
• CACHE 20
• NO CACHE
• CACHE integer-constant
• NO ORDER
• ORDER

Notes:
1. Separator commas can be specified between attributes when an identity column is defined.

as-row-change-timestamp-clause:
```
 FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
```

as-row-transaction-start-id-clause:
```
 AS TRANSACTION START ID
```
as-row-transaction-timestamp-clause:

\[ \text{AS ROW} \quad \text{BEGIN} \quad \text{END} \]

as-generated-expression-clause:

\[ \text{AS} \quad \left( \text{non-deterministic-expression} \right) \]

non-deterministic-expression:

\[ \text{DATA CHANGE OPERATION} \quad \text{special-register} \quad \text{session-variable} \]

special-register:

(1)

\[ \text{CURRENT CLIENT ACCTNG} \quad \text{CURRENT CLIENT APPLNAME} \quad \text{CURRENT CLIENT CORR_TOKEN} \quad \text{CURRENT CLIENT USERID} \quad \text{CURRENT CLIENT WRKSTNNAME} \quad \text{CURRENT SERVER} \quad \text{CURRENT SQLID} \quad \text{SESSION_USER} \]

Notes:

1. This definition of special register is specific to this context, as part of \textit{non-deterministic-expression}.
2. USER can be specified as a synonym for \texttt{SESSION\_USER}. 
**session-variable:**

(1)

SYSIBM.PACKAGE_NAME
SYSIBM.PACKAGE_SCHEMA
SYSIBM.PACKAGE_VERSION

Notes:
1 This definition of session variable is specific to this context, as part of \textit{non-deterministic-expression}.

**column-alteration:**

\texttt{column-name} \texttt{SET DATA TYPE altered-data-type}

\begin{itemize}
  \item \texttt{INLINE LENGTH} \texttt{integer} (1)
  \item \texttt{default-clause}
  \item \texttt{INLINE LENGTH} \texttt{integer}
  \item \texttt{GENERATED}
  \item \texttt{BY DEFAULT}
  \item identity-alteration \texttt{as-transaction-timestamp-clause}
  \item \texttt{as-transaction-id-clause}
  \item \texttt{DROP DEFAULT}
\end{itemize}

Notes:
1 \texttt{INLINE LENGTH} can only be specified for LOB columns in tables that are in universal table spaces. \texttt{INLINE LENGTH} cannot be specified if \texttt{FOR SBCS DATA} or \texttt{FOR MIXED DATA} is also specified.

**altered-data-type:**
XML-schema-specification:

```
ID—registered-XML-schema-name
URL—target-namespace
NO NAMESPACE
LOCATION—schema-location
```

identity-alteration:

```
(1)
RESTART
WITH—numeric-constant
SET INCREMENT BY—numeric-constant
SET NO MINVALUE
MINVALUE—numeric-constant
SET NO MAXVALUE
MAXVALUE—numeric-constant
SET NO CYCLE
CYCLE
SET NO CACHE
CACHE—integer-constant
SET NO ORDER
ORDER
```

Notes:
1. At least one option must be specified and the same clause must not be specified more than one time.

unique-constraint:

```
CONSTRAINT—constraint-name
PRIMARY KEY
UNIQUE
(column-name)
—BUSINESS_TIME—WITHOUT OVERLAPS
```
Notes:
1 For compatibility with prior releases, when the CONSTRAINT clause (shown above) is not specified, a constraint-name can be specified following FOREIGN KEY.

1038 SQL Reference
partition-expression:

```
column-name
  NULLS LAST
  ASC
  DESC
```

partition-element:

```
ENDING AT (constant)
  INCLUSIVE
  HASH SPACE integer K M G
```

partition-clause:

```
ENDING AT (constant)
  INCLUSIVE (1)

HASH SPACE integer K M G (2)
```

Notes:
1. The ENDING clause must not be specified for a partition-by-growth table space, but must be specified for a range partitioned table space.
2. The HASH SPACE clause can only be specified for the ALTER PARTITION clause.

partition-rotation:

```
ENDING AT (constant)
  INCLUSIVE RESET

SQL Reference
Description

table-name

Identifies the table to be altered. The name must identify a table that exists at the current server. The name must not identify a declared temporary table, view, or a table that was implicitly created for an XML column. If the name identifies a catalog table, DATA CAPTURE CHANGES is the only clause that can be specified.

If table-name identifies an auxiliary table, alterations are limited to the following clauses:

- APPEND

If table-name identifies a materialized query table, alterations are limited to the following clauses:

- AUDIT
- DATA CAPTURE
- ALTER MATERIALIZED QUERY
- DROP MATERIALIZED QUERY
- ADD RESTRICT ON DROP
- DROP RESTRICT ON DROP

ADD COLUMN

ADD COLUMN column-definition

Adds a column to the table. Except for the following columns, all values of the column in existing rows are set to its default value:

- ROWID column
- Identity column
- Row change timestamp column
- Row-begin column
- Row-end column
- Transaction-start-ID column

If the table has \( n \) columns, the ordinality of the new column is \( n+1 \). The value of \( n \) cannot be greater than 749. For a dependent table, \( n \) cannot be greater than 748.

The column cannot be added if the increase in the total byte count of the columns exceeds the maximum row size. The maximum row size for the table is eight less than the maximum record size as described in [Maximum record size](#).

If you add a LOB column and the table does not already have a ROWID column, DB2 creates an implicitly hidden ROWID column. For details about
adding a LOB column, such as the other objects that might be implicitly created or need to be explicitly created, see Creating a table with LOB columns. For more information about adding a ROWID column, see Adding a ROWID column.

For implicitly created LOB objects, the privilege set requires CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created) and the USE privilege on the buffer pool and the storage group that is used by the auxiliary table and the LOB table space. The implicitly created objects are owned by the owner of the base table.

If you add an XML column, the privilege set requires the CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created), INDEX on the base table for the first DOCID column that is added, and USE privilege on the buffer pool and the storage group that is used by the XML objects. These privileges are required for implicitly created XML objects. The implicitly created objects are owned by the owner of the base table.

When you add a column to a table, the table space is placed into advisory REORG-pending status.

The table must not be a history table or archive table.

If the table is a system-period temporal table, the column is also added to the associated history table. If the table is an archive-enabled table, the column is also added to the associated archive table. The following attributes of the column in the associated table are the same as the attributes of the corresponding column of the table that is being altered:

- Name
- Data type
- Length (including inline LOB lengths), precision, scale
- FOR BIT, SBCS, or MIXED DATA attribute for a character string column
- Null attribute
- Hidden attribute
- Field procedure

You cannot add the following columns:

- A column to a table that has an edit procedure that is defined as WITH ROW ATTRIBUTES.
- A ROWID column to a table that already has an explicitly defined ROWID column
- An identity column to a table that has an identity column
- A security label column to a table that already has a security label column
- A security label column to a system-period temporal table or archive-enabled table
- A row change timestamp column to a table that already has a row change timestamp column
- A LOB, ROWID, identity column, or row change timestamp column to a created temporary table
- A GRAPHIC, VARGRAPHIC, DBCLOB, or CHAR FOR MIXED DATA column, when the setting for installation option MIXED DATA is NO
- A Unicode column to an EBCDIC table (specifying CCSID 1208 or CCSID 1200) if the table is already defined with an EDITPROC or VALIDPROC.

If the column that is being added is a security label column, row permissions, including the default row permission, cannot exist for the table

```
column-name
```

Names of the column you want to add to the table. The name must not be
the same as the name of an existing column of the table or the name of a period in the table. A column named SYSTEM_TIME or BUSINESS_TIME cannot be added to a table that is defined as a system-period temporal table or a history table. Do not qualify column-name.

**built-in-type**

Specifies the data type of the column is one of the built-in data types. See `built-in-type` for information about the built-in data types that can be used when adding a column to a table.

**distinct-type-name**

Specifies the distinct type (user-defined data type) of the column. The length and scale of the column are respectively the length and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

**DEFAULT**

Specifies the default value that is assigned to the column in the absence of a value specified in a data change statement, or LOAD. Do not specify DEFAULT for the following types of columns:

- A ROWID column (DB2 generates default values)
- An identity column (DB2 generates default values)
- An XML column
- A row change timestamp column

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default for a security label column.

If a CCSID clause is specified for the column, do not specify a value after the DEFAULT keyword. Alternatively, DEFAULT NULL can be specified.

If a value is not specified after the DEFAULT keyword, the default value depends on the data type of the column as indicated in the following table:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character or graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string of length 0</td>
</tr>
<tr>
<td>Inline BLOB</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Inline CLOB</td>
<td>Blanks</td>
</tr>
<tr>
<td>Inline DBCLOB</td>
<td>Blanks</td>
</tr>
</tbody>
</table>
Date For existing rows, a date corresponding to 1 January 0001. For added rows, CURRENT DATE.

Time For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, CURRENT TIME.

Timestamp without time zone
For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision. For added rows, CURRENT_TIMESTAMP(p) WITHOUT TIME ZONE where p is the corresponding timestamp precision.

Timestamp with time zone
For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and zeros for fractional seconds up to the timestamp precision, 0 time zone hours, 0 time zone minutes. For added rows, CURRENT_TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.

If the column is defined as timestamp with time zone, the default value must include a time zone.

In a given column definition:
• DEFAULT and FIELDPROC cannot both be specified.
• NOT NULL and DEFAULT NULL cannot both be specified.
• Omission of NOT NULL and DEFAULT for a column other than an identity column is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

A default value other than the one that is listed above can be specified in one of the following forms:
• WITH DEFAULT for a default value of an empty string
• DEFAULT NULL for a default value of null

constant
Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or string constant must be short enough so that its UTF-8 representation requires no more than 1536 bytes. A hexadecimal graphic string (GX) constant cannot be specified.

In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD, as the default for the column. If SESSION_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37. For existing rows, the value is that of the SESSION_USER special register at the time the ALTER TABLE statement is processed.
CURRENT SQLID
Specifies the value of the SQL authorization ID of the process at the
time of an SQL data change statement or LOAD, as the default for the
column. If CURRENT SQLID is specified, the data type of the column
must be a character string with a length attribute greater than or equal
to the length attribute of the CURRENT SQLID special register. If the
data type of the column is an inline CLOB, the INLINE LENGTH
attribute must be greater than or equal to the length attribute of the
CURRENT SQLID special register. For existing rows, the value is the
SQL authorization ID of the process at the time the ALTER TABLE
statement is processed.

NULL
Specifies null as the default value for the column.

cast-function-name
The name of the cast function that matches the name of the distinct
type for the column. A cast function can be specified only if the data
type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified
or implicitly resolved through function resolution, must be the same as
the explicitly or implicitly specified schema name of the distinct type.

constant
Specifies a constant as the argument. The constant must conform to
the rules of a constant for the source type of the distinct type. The
length of the constant cannot be greater than the INLINE LENGTH
attribute for LOB columns.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register
at the time a row is inserted as the default for the column. The
source type of the distinct type of the column must be a CHAR,
VARCHAR, or inline CLOB with a length attribute (inline length
attribute for CLOB) that is greater than or equal to the length
attribute of the SESSION_USER special register.

CURRENT SQLID
Specifies the value of the CURRENT SQLID special register at the
time a row is inserted as the default for the column. The source
type of the distinct type of the column must be a CHAR,
VARCHAR, or inline CLOB with a length attribute (or inline length
attribute for CLOB) that is greater than or equal to the length
attribute of the CURRENT SQLID special register.

NULL
Specifies the NULL value as the argument.

GENERATED
Specifies that DB2 generates values for the column.

GENERATED is applicable only to the following columns:
- ROWID columns
- Identity columns
- Row change timestamp columns
- Row-begin columns
- Row-end columns
- Transaction-start-ID columns
• Generated expression columns

If the table is a system-period temporal table or an archive-enabled table, GENERATED must not be specified for the column that is to be added, unless the column is a ROWID column. The default is GENERATED ALWAYS.

**ALWAYS**

Specifies that DB2 will generate a value for the column when a row is inserted into the table. ALWAYS is the recommended value unless you are using data propagation.

**BY DEFAULT**

Specifies that DB2 will generate a value for the column when a row is inserted unless a value was specified for the column on the data change statement.

If a user-supplied value is specified for a ROWID column, DB2 uses the value only if both of the following conditions are true:

• The value is a valid row ID value that was previously generated by DB2.

• The column has a unique, single-column index.

Until this index is created on the ROWID column, the insert, and update operations and the LOAD utility cannot be used to add rows to the table. If the table space name is not specified on the CREATE TABLE statement, DB2 implicitly creates the necessary object to make the table complete, including the index. The name of this index is `I` followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, DB2 inserts a specified value but does not verify that it is a unique value for the column unless the identity column has a unique, single-column index.

If a user-supplied value is specified for an identity column, DB2 inserts the specified value but does not perform any special validation on that value beyond the normal validation that is performed for any column. DB2 does not check how the specified value affects the sequential properties that are defined for the identity column. To ensure the uniqueness of an identity column that is defined as GENERATED BY DEFAULT, define a unique index on the identity column.

BY DEFAULT is the recommended value only when you are using data propagation.

**AS IDENTITY**

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a distinct type that is based on one of these types). Separator commas between identity column attribute specifications are optional when the identity column is defined.
An identity column is implicitly NOT NULL. When adding an identity column to a table, you must also specify GENERATED ALWAYS or GENERATED BY DEFAULT.

Defining a column AS IDENTITY does not necessarily guarantee uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

**START WITH** `numeric-constant`
- Specifies the first value that is generated for the identity column. The value can be any positive or negative value that can be assigned to the column without non-zero digits to the right of the decimal point.

- If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after the maximum or minimum value for the identity column is reached. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range that is used for cycles is defined by MINVALUE and MAXVALUE.

**INCREMENT BY** `numeric-constant`
- Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant and can be assigned to the column without any non-zero digits to the right of the decimal point. The default is 1.

- If the value is positive or zero, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

**MINVALUE** or **NO MINVALUE**
- Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

**NO MINVALUE**
- Specifies that the minimum end point of the range of values for the identity column is not set. In this case, the default value for MINVALUE becomes one of the following values:
  - For an ascending identity column, the value is the START WITH value or 1 if START WITH was not specified.
  - For a descending identity column, the value is the minimum value of the data type of the column.

**MINVALUE** `numeric-constant`
- Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be less than or equal to the maximum value.

**MAXVALUE** or **NO MAXVALUE**
- Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.
NO MAXVALUE
Specifies that the minimum end point of the range of values for the identity column is not set. In such a case, the default value for MAXVALUE becomes one of the following values:
- For an ascending identity column, the value is the maximum value of the data type of the column.
- For a descending identity column, the value is the START WITH value or -1 if START WITH is not specified.

MAXVALUE numeric-constant
Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that can be assigned to this column without non-zero digits to the right of the decimal point. The value must be greater than or equal to the minimum value.

CYCLE or NO CYCLE
Specifies whether this identity column is to continue to generate values after reaching either its maximum or minimum value.

NO CYCLE
Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached. NO CYCLE is the default.

CYCLE
Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

CACHE or NO CACHE
Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

NO CACHE
Specifies that values for the identity column are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column results in synchronous I/O.

CACHE integer-constant
Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a system failure, all cached identity column values that are yet to be assigned might be lost and will not be used.
Therefore, the value that is specified for CACHE also represents the maximum number of values for the identity column that could be lost during a system failure.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

**ORDER or NO ORDER**

Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

**NO ORDER**

Specifies that the values do not need to be generated in order of request.

**ORDER**

Specifies that the values are generated in order of request. Specifying ORDER might disable the caching of values.

ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, suppose that members DB2A and DB2B are using the identity column, DB2A gets the cache values 1 to 20, and DB2B gets the cache values 21 to 40. If DB2A requested a value first, then DB2B requested, and then DB2A again requested, the actual order of values that are assigned would be 1,21,2. Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the ORDER option.

**AS TRANSACTION START ID**

Specifies that a timestamp value is assigned when the row is inserted or any column in the row is updated. If the value of the row-begin column is unique from row-begin column values that are generated for other transactions, the row-begin column value is assigned to the transaction-start-ID column. Otherwise, the value of the transaction-start-ID column is derived from the row-begin column value and adjusted to make it unique from transaction-start-ID column values that are generated for other transactions.

A transaction-start-ID column is intended to be used for a system-period temporal table.

A table can have only one transaction-start-id column. If data-type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If data-type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause.

A transaction-start-id column is not updatable.

**FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**

Specifies that the column is a timestamp and the values will be generated by DB2. DB2 generates a value for the column for each row.
as a row is inserted, and for any row for which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the time of the insert or update of the row. If multiple rows are inserted or updated with a single statement, the value of the row change timestamp column might be different for each row.

If data-type is specified, it must be TIMESTAMP WITHOUT TIME ZONE with a precision of 6. You must specify NOT NULL with a row change timestamp column.

AS ROW BEGIN
Specifies that a value for the data type of the column is assigned when a row is inserted or any column in the row is updated. The value that is assigned for a TIMESTAMP WITHOUT TIME ZONE column is TIMESTAMP value '9999-12-30-00.00.00.000000000000'. The value that is assigned for a TIMESTAMP WITH TIME ZONE COLUMN is TIMESTAMP value '9999-12-30.00.00.00.000000000000 +00:00'.

A row-begin column is intended to be used for a system-period temporal table.

A table can have only one row-begin column. If data-type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If data-type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause.

A row-begin column is not updatable.

AS ROW END
Specifies that a value for the data type of the column is assigned when a row is inserted or any column in the row is updated. The value that is assigned for a timestamp without time zone column is TIMESTAMP '9999-12-30-00.00.00.000000000000'. The value that is assigned for a timestamp with time zone column is TIMESTAMP '9999-12-30.00.00.00.000000000000 +00:00'.

A row-end column is intended to be used for a system-period temporal table.

For a table with system-period data versioning, when a row is deleted as the result of an update or delete operation, the value of the row-end column in the historical row reflects when the row was deleted. The value that is generated for the column in the historical row is a timestamp that corresponds to the most recent transaction start time that is associated with the transaction. If a row that is to be updated would result in a value for the row-end column that is less than or equal to the value for the corresponding row-begin column, the timestamp value for the row-end column is adjusted. If multiple rows are deleted with a single SQL statement, the values for the column in the historical rows are the same.

A table can have only one row-end column. If data-type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If data-type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is
defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. The column cannot have a DEFAULT clause.

A row-end column is not updatable.

**DATA CHANGE OPERATION**

Specifies that the database manager generates one of the following values, depending on the specified expression:

- **I** Insert operation
- **U** Update operation.
- **D** Delete operation.

A table can have only one DATA CHANGE OPERATION column. The column must be defined as CHAR(1). The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

**special-register**

Specifies the value of the special register. This column is to contain the value of the special register at the time of the data change statement that assigns the value to the column. If multiple rows are inserted or updated with a single SQL statement, the value for the column is the same for all of the rows.

**special-register** must be one of the following special registers, and the column must use the required data type.

<table>
<thead>
<tr>
<th>Special register</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_CLIENT_ACCTNG</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT_CLIENT_APPLNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT_CLIENT_CORR_TOKEN</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT_CLIENT_USERID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT_CLIENT_WRKSTNNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT_SERVER</td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>CURRENT_SQLID</td>
<td>VARCHAR((n)) where (n \geq 8)</td>
</tr>
<tr>
<td>SESSION_USER or USER</td>
<td>VARCHAR(128)</td>
</tr>
</tbody>
</table>

This column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC
Related information:
“Special registers” on page 159

session-variable
Specifies the value of a built-in session variable. The fully qualified name of the session variable must be specified. The value of the session variable is obtained from the GETVARIABLE function at the time of the data change operation that assigns the value to the column. If multiple rows are changed with a single SQL statement, the value for the column is the same for all of the rows.

session-variable must be one of the following session variables, and the column must use the required data type.

Table 104. Possible session variable values for non-deterministic expression columns

```
+----------------+-----------------------------+
<table>
<thead>
<tr>
<th>Session variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSIBM.PACKAGE_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_VERSION</td>
<td>VARCHAR(122)</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------</td>
</tr>
</tbody>
</table>
```

The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:
- CCSID 1200
- CCSID 1208
- FIELDPROC

Related information:
“Built-in session variables” on page 342

NOT NULL
Prevents the column from containing null values. If NOT NULL is specified, the DEFAULT clause must be used to specify a nonnull default value for the column unless the column has a row ID data type or is an identity column. For a ROWID column, NOT NULL must be specified, and DEFAULT must not be specified. For an identity column, although NOT NULL can be specified, DEFAULT must not be specified.

IMPLICITLY HIDDEN
Specifies that the column is not visible in the results of SQL statements unless you refer explicitly to the column by name. For example, assume that table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause. The result of SELECT * FROM T1 would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID.

references-clause
The references-clause of a column-definition provides a shorthand method of defining a foreign key composed of a single column. Thus, if references-clause is specified in the definition of column C, the effect is the
same as if that references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify references-clause in the definition of the following types of columns because these types of columns cannot be a foreign key:

- LOB columns
- ROWID columns
- XML columns
- DECIMAL columns
- Row change timestamp columns
- Security label columns
- Unicode columns in EBCDIC tables

**check-constraint**

The check-constraint of a column-definition has the same effect as specifying a check constraint in a separate ADD check-constraint clause. For conformance with the SQL standard, a check constraint specified in the definition of column C should not reference any columns other than C.

Do not specify a check constraint in the definition of the following types of columns:

- LOB columns
- ROWID columns
- XML columns
- DECIMAL columns
- Security label columns
- Unicode columns in EBCDIC tables

**FIELDPROC program-name**

Designates program-name as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with the TIMESTAMP WITH TIME ZONE data type
- Unicode columns in EBCDIC tables

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides DB2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the ALTER TABLE statement defines the data characteristics of the decoded values.

If you omit FIELDPROC, the column has no field procedure.
Related information:
[Field procedures (DB2 Administration Guide)]

**constant**

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The $n$th parameter specified in the FIELDPROC clause on ALTER TABLE corresponds to the $n$th parameter of the specified field procedure. The maximum length of the parameter list is 255 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

**AS SECURITY LABEL**

Specifies that the table is defined with multilevel security with row level granularity and specifies that the column will contain the security label values. A table can have only one security label column. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column does not have any field procedures, check constraints, or referential constraints.
- The column must be defined as NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not be specified with a default value (DB2 provides the default value).
- The table does not have an edit procedure that is defined as WITH ROW ATTRIBUTES.
- The table is not the source table for a materialized query table.

For existing rows in the table, the value of the security label column defaults to the security label of the user at the time the ALTER statement is executed.

**INLINE LENGTH integer**

 Specifies the maximum length for the column, if the column is a LOB column and the table is in a universal table space. INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB) or if the table is not in a universal table space.

For BLOB and CLOB columns, integer specifies the maximum number of bytes that are stored in the base table space for the column. integer must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, integer specifies the maximum number of double-byte characters that are stored in the table space for the column. integer must be between 0 and 16340 (inclusive) for a DBCLOB column.

If INLINE LENGTH is specified, the value of integer cannot be greater than the maximum length of the LOB column.

If the INLINE LENGTH clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the INLINE LENGTH attribute, the LOB column will use the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD as the default inline length when the value of LOB INLINE LENGTH does not exceed the maximum length of the LOB
column. If the value of LOB INLINE LENGTH exceeds the maximum length of the LOB column, the maximum length is the inline length of this LOB column.

- If a distinct type that has been created with the INLINE LENGTH attribute is used, the LOB column inherits the inline length from the distinct type.

Regardless of how the length is determined, the inline length of the LOB cannot be greater than its maximum length.

**ALTER COLUMN**

**ALTER COLUMN column-alteration**

Alters the definition of an existing column, including the attributes of an existing identity column. Only the attributes specified are altered. Other attributes remain unchanged. Only future values of the column are affected by the changes made with an ALTER TABLE ALTER COLUMN statement.

The table being altered must not be in an incomplete state because of a missing unique index on a unique constraint (primary or unique key). An ALTER TABLE ALTER COLUMN statement might not be processed in the same unit of work as a data change statement. A column cannot be altered if any of the following conditions are true:

- The table has an edit procedure that is defined as WITH ROW ATTRIBUTES or a validation exit procedure
- The table is used in a materialized query table definition
- The table is a materialized query table
- The table is a system-period temporal table that is enabled for system-period data versioning
- The table is a history table
- The table is an archive-enabled table or an archive table
- There is an extended index that depends on that column
- The column is referenced in a field procedure
- The column is referenced in a referential constraint
- The column is referenced in the definition of a SYSTEM_TIME or BUSINESS_TIME period
- The column is defined as a transaction-start-ID column
- The column is defined as a security label column
- The column is defined as a row change timestamp column
- The column is a Unicode column in an EBCDIC table
- The column is a generated expression column.

You can modify all the attributes of an existing identity column, except for the data type of the column. To change the data type of an identity column, drop the table containing the column and recreate it. When the attributes of an identity column are altered, the column of the specified column-name must exist in the specified table and must have been defined with the IDENTITY attribute.

**column-name**

Identifies the column to be altered. The name must not be qualified and must identify an existing column in the table being altered when the ALTER statement is processed. The name must not identify a column that is being added in the same ALTER TABLE statement.
A column can only be referenced in one ALTER COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

**SET DATA TYPE** *(altered-data-type)*

Specifies the new data type of the column to be altered. For a character column, you can also use the clause to change the definition of the subtype that is stored in the DB2 catalog and OBD.

The column cannot be an identity column. The new data type must be compatible with the existing data type of the column. The existing data type of the column cannot be a ROWID, date, time, or distinct type. When the source data type is a LOB, the target data type must be the same LOB data type. If the source data type is a LOB and the maximum length is altered, the new maximum length must be at least as large as the existing length attribute. If the column is a partitioning column, and the existing data type is CHAR or VARCHAR FOR BIT DATA, the new data type cannot be VARBINARY or BINARY. If the column is CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, or BINARY, the new data type cannot be VARBINARY if the column is part of an index and is defined with the DESC attribute. For more information on the compatibility of data types, see "Assignment and comparison" on page 123.

A TIMESTAMP column can only be altered to TIMESTAMP with a larger precision. A TIMESTAMP WITH TIME ZONE column can only be altered to TIMESTAMP WITH TIME ZONE with a larger precision. If the precision of a timestamp column is increased, the fractional seconds of existing data values are extended with zeros so that the number of fractional second digits matches the specified timestamp precision.

If the data type is a LOB and the maximum length is being changed, any packages or statements in the dynamic statement cache that reference the table are invalidated. Any views that reference the LOB column are regenerated.

If any numeric data type is being converted to DECFLOAT, the ALTER statement will fail if there is a partitioning key, check constraints, index, or a unique constraint on the column.

If *altered-data-type* is XML, the old data type of the altered column must also be XML:

- If the old data type has no XML type modifier and the new data type does, you should ensure that all values in the XML column are valid according to the XML schema that is specified in the type modifier. The XML table space for the column that is being changed is left in CHECK-pending status.
- If the old data type has the XML type modifier but the new data type has no type modifier, the existing values do not need to be re-validated. The state of the table space is not changed.
  
  If the XML schemas that are specified in the old XML type modifier are a subset of the XML schemas that are specified in the new XML type modifier, the existing values do not need to be re-validated. The state of the XML table space is not changed.
- If the XML schemas that are specified in the old XML type modifier are NOT a subset of the XML schemas that are specified in the new XML type modifier, the XML table space for the column that is being changed is left in the CHECK-pending status.
Changing an XML column to use a different type modifier does not result in the invalidation of dependent packages or statements in the dynamic statement cache. Also, changing an XML column to use a different type modifier will not generate a new version of the table.

If the data type is a character or graphic string, the new length attribute must be at least as large as the existing length attribute of the column. If the data type is a numeric data type, the specified precision and scale must be at least as large as the existing precision and scale. If a decimal fraction is being converted to floating point, the ALTER statement will fail if there is a unique index or a unique constraint on the column.

If the specified column has a default value, the existing default value must represent a value that could be assigned to a column with the new data type in accordance with the rules for assignment. The default value is updated to reflect the new data type.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the new column length must not exceed the limit on an index size. For PADDED indexes, the sum of the length attributes of the columns must not be greater than 2000-\(n\), where \(n\) is the number of columns that can contain null values. For NOT PADDED indexes, the sum of the length attributes of the columns must not be greater than 2000-\(n-2m\), where \(n\) is the number of nullable columns and \(m\) is the number of varying length columns.

The total byte count of columns after the alteration must not exceed the maximum row size. If the column is in the partitioning key, the new partitioning key cannot exceed 255-\(n\).

Table 105 shows the numeric data type alterations that are supported for SET DATA TYPE:

<table>

</tr>
</tbody>
</table>
When a SMALLINT, INTEGER, or DECIMAL column is altered to a BIGINT data type, and there is an index defined on that column, the index will be put in RBDP status.

In releases of DB2 prior to Version 9.1, use of the DECIMAL(19,0) data type for applications that work with BIGINT data was encouraged. For performance reasons, the DECIMAL(19,0) columns should be altered to BIGINT. Note that altering from DECIMAL(19,0) to BIGINT is provided only for DECIMAL(19,0) columns that are used for applications that work with BIGINT (thus, the data in those columns is within the range of the BIGINT).

When altering from DECIMAL(19,0) to BIGINT you should ensure that all values in the DECIMAL(19,0) column are within the range of BIGINT before the alter. The following query or a similar query can be run to determine which rows (if any) contain values that are outside of the range of BIGINT:

```
SELECT * FROM table_name
WHERE dec19_0_column > 9223372036854775807
  OR dec19_0_column < -9223372036854775808;
```

When a partitioning key column with a numeric data type is altered to a larger numeric data type, and the limit key value for the original numeric data type of the column is X'FF', the limit key value for the new numeric data type of the column is left-padded with X'FF'. For example, if a column is converted from SMALLINT to INTEGER, and a limit key value for the SMALLINT column is 32767 (which is 2 bytes of X'FF'), the limit key for the INTEGER column is 2147483647 (which is 4 bytes of X'FF').

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is neither all X'FF' nor all X'00', the limit key value for the new character data type of the column is right-padded with blank(s) of the encoding scheme of the table. For example, if a column is converted from CHAR(1) to VARCHAR(2), and a limit key value for the CHAR(1) column is 'A' (which is X'C1'), the limit key for the VARCHAR(2) column is 'A ' (which is X'C140' when the encoding scheme of the table is EBCDIC, or is X'C120' when the encoding scheme of the table is UNICODE or ASCII).

Table 106 on page 1059 shows the character data type alterations that are supported for SET DATA TYPE:
Table 106. Supported character data type alterations for SET DATA TYPE (x >=0).

<table>
<thead>
<tr>
<th>From/To</th>
<th>CHARACTER (n+x)</th>
<th>VARCHAR (n+x)</th>
<th>LONG VARCHAR</th>
<th>GRAPHIC (n+x)</th>
<th>VARGRAPHIC (n+x)</th>
<th>LONG VARGRAPHIC</th>

<tr>
<td>LONG VARGRAPHIC</td>
<td>N</td>
<td>N</td>
<td>N</td>
<td>N</td>
<td>Y</td>
<td>N</td>
</tr>
</tbody>
</table>

When columns are converted from CHAR to VARCHAR, normal assignment rules apply, which means that trailing blanks are kept instead of being stripped out. If you want varying length character strings without trailing blanks, use the STRIP function for data in the column after changing the data type to VARCHAR.

When a CHAR FOR BIT DATA column is converted to a BINARY data type, the following applies:
- The existing space characters in the table will not be changed to hexadecimal zeros (X'00')
- If the new length attribute is greater than current length attribute of the column, the values in the table are padded with hexadecimal zeros (X'00')

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, the existing default value will be cast as a binary string. The resulting binary string will be at least twice the original size. The alter will fail if the resulting binary string length exceeds 1536 UTF-8 bytes.

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, and there is an index defined on that column, the index will be put in RBDP.

Table 107. Supported binary data type alterations for SET DATA TYPE (x >=0)

<table>
<thead>
<tr>
<th>From/To</th>
<th>BINARy(n+x)</th>
<th>VARBINARY(n+x)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(n) FOR BIT DATA</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>VARCHAR(n) FOR BIT DATA</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>BINARY(n)</td>
<td>Y</td>
<td>Y</td>
</tr>
<tr>
<td>VARBINARY(n)</td>
<td>Y</td>
<td>Y</td>
</tr>
</tbody>
</table>

**Note:** ALTER from VARBINARY to BINARY is not allowed when the column is part of a unique index.

The table being altered must not be defined with an edit procedure that is defined as WITH ROW ATTRIBUTES or a valid procedure. There must not be a materialized query table defined on this table, and this table must not be defined as a materialized query table.

Changing the data type, precision, scale, or length of a column can affect a row permission or a column mask that is defined on the table. If the data type, length, precision, or scale for the column is changed and a column mask is defined for this column, or a row permission or a column mask
references this column, these row permissions and column masks are reevaluated using the new column attributes of the column. If an error is encountered during the reevaluation process, the ALTER statement returns the error.

During the reevaluation of the column mask or row permission, user-defined functions that are referenced in the definition of the column mask or the row permission must be resolved to the same functions that were resolved during the creation of the column mask or the row permission.

If the alteration results in the generation of a new table version, the table space that contains the table that is being changed is left in an advisory REORG-pending (AREO) status. If the column that is being changed is part of an index, an exception state might be set for the index as shown in Table 108:

Table 108. Informational settings for ALTER COLUMN when the column is in an index

</tbody>
</table>

For information on resetting informational or restrictive exception states, see DB2 Utility Guide and Reference.

FOR subtype DATA

Alters the subtype of a character column. This clause does not change the data. The clause only updates the definition of the subtype as it is stored in the DB2 catalog and the OBD. The length and data type that are specified must match the existing length and data type of the column.

Only character strings are valid when subtype is BIT.

For more information on the subtype values (SBCS, MIXED, and BIT), see the subtype information under built-in-type.

SET INLINE LENGTH integer

Specifies the new inline length for the column. SET INLINE LENGTH can only be specified for an inline LOB column in a table that is in a universal table space. INLINE LENGTH cannot be specified if FOR SBCS DATA or FOR MIXED DATA is also specified in the same ALTER TABLE statement.
Inline LOB columns cannot be added to a table that is in a table space that has basic row format. The new length can be smaller or larger than the original length. `integer` is a value between 0 and 32680 bytes (inclusive) for a BLOB or CLOB column or between 0 and 16340 characters (inclusive) for a DBCLOB column. The inline length cannot be changed in the following cases:

- The LOB column is referenced in an expression-based index or a spatial index.
- The new inline length is less than the default length for the column.
- The new inline length is greater than the maximum length of the LOB column.

If there are views that inherit the inline length from a LOB column and the inline length of that LOB column has been changed, the views (and any views that are dependent on those views) are recalculated to use the updated inline length.

If the inline length is changed, any packages or statements in the dynamic statement cache that reference the table are invalidated.

When the base table space is not empty, increasing the length puts the table space in an advisory REORG-pending state, and decreasing the length puts the table space in a REORG-pending state.

No expression-based indexes can be created after the inline length is changed until the REORG utility is run on the base table space.

**SET default-clause**

Specifies the new default value of the column to be altered. The new default value must conform to the current rules for assigning that value to the column. Existing rows will retain their current value. The new default value will only be reflected in the rows that are inserted after the alter. Sections that are dependent on the table that is being altered will be invalidated.

The table must not be referenced by an view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the default value might be altered to the same value as an existing row of that column. However, subsequent data change operations will fail in the absence of a value specified for that column on the insert operation.

For LOB columns, only the default for inline LOB columns can be changed. The new default length cannot be greater than the inline length.

**DROP DEFAULT**

Drops the current default value of the column. For columns that are not nullable, the specified column must be defined with a default value. For columns that are nullable, the specified column cannot have a null default value. For columns that are nullable, the new default value is the null value.

The table that contains the specified column must not be referenced in a view. The table must not be defined with the DATA CAPTURE CHANGES attribute when the subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES.
Follow these steps to remove the default value for a column that was defined using ALTER TABLE with the ADD COLUMN clause:

1. Run the REORG utility or the UPDATE statement to reset the AREO* state:
   - Run the REORG utility on the table space that contains the table
   - If the table is in a universal table space and the table does not have row access control activated, run an UPDATE statement without the SKIP LOCKED DATA or WHERE clauses specified. The update operation must be done with a searched UPDATE statement and the expression in the SET clause cannot be a scalar-fullselect or a row-fullselect. An update operation within a SELECT statement will not reset the AREO* status.

2. Issue the ALTER TABLE statement that specifies the DROP DEFAULT clause

If the REORG is not done before the ALTER TABLE, or the UPDATE statement does not reset the AREO* status, an error is returned for the ALTER TABLE statement.

**SET GENERATED**
Specifies that DB2 generates values for the column. SET GENERATED must not be specified for a column of a history table or for a column that already has the GENERATED attribute.

**ALWAYS**
Specifies that DB2 always generates a value for the column when a row is inserted or updated and a default value must be generated.

**BY DEFAULT**
Specifies that DB2 generates a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified. For a row change timestamp column, DB2 inserts or updates a specified value but does not verify that it is a unique value for the column unless the row change timestamp column has a unique constraint or a unique index that solely specifies the row change timestamp column.

**RESTART**
Specifies the next value for the identity column. If numeric-constant is not specified, the sequence is restarted at the value that is specified implicitly or explicitly as the starting value when the identity column was originally created.

**WITH numeric-constant**
Specifies that, when it is time to generate the next value for this identity column, numeric-constant will be used as the next value for the column. This value can be any positive or negative value (including 0) that could be assigned to this column without nonzero digits existing to the right of the decimal point.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values that are in effect for all the options after the ALTER statement is issued.

After an identity column is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated previously.
SET INCREMENT BY numeric-constant

For a definition, see the description of INCREMENT BY numeric-constant for defining an identity column.

SET MINVALUE or NO MINVALUE

For a definition, see the description of MINVALUE or NO MINVALUE for defining an identity column.

SET MAXVALUE or NO MAXVALUE

For a definition, see the description of MAXVALUE or NO MAXVALUE for defining an identity column.

SET CYCLE or NO CYCLE

For a definition, see the description of CYCLE or NO CYCLE for defining an identity column.

SET CACHE or NO CACHE

For a definition, see the description of CACHE or NO CACHE for defining an identity column.

SET ORDER or NO ORDER

For a definition, see the description of ORDER or NO ORDER for defining an identity column.

RENAME COLUMN:

RENAME COLUMN source-column-name TO target-column-name

 Renames the specified column. The names must not be qualified.

 source-column-name

 Identifies the column that is to be renamed. The name must identify an existing column of the table.

 target-column-name

 Specifies the new name for the column. The name must not identify a column that already exists in the table, or the name of a period that exists in the table.

You cannot rename a column if any of the following conditions apply:

• The column is referenced in a view
• The column is referenced in the expression of an index definition
• The column is referenced in the definition of a row permission or a column mask
• The column is referenced in an SQL table user-defined function
• The column has a check constraint defined
• The column has a field procedure defined
• The table has a trigger
• The table is a materialized query table or is referenced by a materialized query table
• The table has a valid procedure, or an edit procedure that is defined as WITH ROW ATTRIBUTES
• The table is a DB2 catalog table
• The table is a system-period temporal table or a history table
• The table is an archive-enabled table or an archive table
DROP COLUMN

DROP COLUMN `column-name`

Drops the identified column from the table. Any privileges that are associated with the column are revoked.

A column cannot be dropped if any of the following conditions are true:

- The containing table space is not a universal table space
- The table is a created global temporary table
- The table is a system-period temporal table
- The table is a history table
- The table is an archive-enabled table
- The table is an archive table
- The table has an edit procedure or a validation exit procedure
- The table contains check constraints
- The table is a materialized query table
- The table is referenced in a materialized query table definition
- The column is defined as a security label column
- The column is an XML column
- The column is a DOCID column
- The column is a hidden ROWID column
- The column is defined as ROWID GENERATED BY DEFAULT, and the table contains a hidden ROWID column
- The column is a ROWID column on which there is a dependent LOB column
- The column is part of the table partitioning key
- The column is part of the hash key
- All of the remaining columns in the table are hidden
- A view that is dependent on the table has INSTEAD OF triggers
- A trigger is defined on the table
- Any of the following objects are dependent on the table:
  - Extended indexes
  - Row permissions
  - Column masks
  - Inline SQL table functions

`column-name`

Identifies the column that is to be dropped. The column name must not be qualified. The name must identify a column of the specified table. The name must not identify the only column of the table or a column that is referenced in the definition of a period. The table definition must not be in an incomplete state.

If the column is a LOB column, any auxiliary tables that are associated with the column and the indexes on the auxiliary tables are also dropped. Any LOB table spaces that were implicitly created for the auxiliary tables are also dropped. If the column is the last LOB column in the table, any implicitly created ROWID column in the table is also dropped.

Dropping a column is a pending change to the definition of the table if the data sets of the table space are already created, otherwise, the change takes effect immediately.
If the change is a pending change to the definition of the table, the
definition of the containing table space must not be in an incomplete state.
Pending changes are not reflected in the definition or data at the time the
ALTER TABLE statement is issued. Instead, the entire table space is placed
in an advisory REORG-pending state (AREOR). A subsequent
reorganization of the entire table space will apply the pending definition
changes to the definition and data of the table. If the change is a pending
change, a new table version is generated.

RESTRICT
Specifies that the column cannot be dropped if any views, indexes, unique
constraints, or referential constraints are dependent on the column.

ADD PERIOD:

ADD PERIOD period-definition
Adds a period to the table.

The table must not be an archive-enabled table or an archive table.

begin-column-name must not be the same as end-column-name. The data type,
precision, and scale for begin-column-name must be the same as for
end-column-name.

SYSTEM_TIME(begin-column-name, end-column-name)
Names the period SYSTEM_TIME. The name must not identify an existing
column in the table. A table can have only one SYSTEM_TIME period.

A system generated check constraint named
DB2_GENERATED_CHECK_CONSTRAINT_FOR_SYSTEM_TIME is
generated to ensure that the value for end-column-name is greater than the
value for begin-column-name. begin-column-name and end-column-name must
be defined as TIMESTAMP(12) WITHOUT TIME ZONE.
DB2_GENERATED_CHECK_CONSTRAINT_FOR_SYSTEM_TIME cannot
be an existing check constraint.

The begin-column-name must specify a row-begin column and the
end-column-name must specify a row-end column. Both columns must be
defined as GENERATED ALWAYS. A column mask or row permission
must not be defined for the table.

BUSINESS_TIME(begin-column-name, end-column-name)
Names the period BUSINESS_TIME. The name must not identify an
existing column in the table. A table can have only one BUSINESS_TIME
period.

An implicit check constraint is generated to ensure that the value of
end-column-name is greater than the value of begin-column-name. The name
of the implicitly created check constraint is
DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME, and
that name must not be defined as the name of an existing check constraint.

The columns that are specified for begin-column-name and end-column-name
must be defined as DATE or TIMESTAMP(6) WITHOUT TIME ZONE, and
must be defined as NOT NULL. The columns that are specified for
begin-column-name and end-column-name must not identify a column that is
defined with a GENERATED clause.

begin-column-name
Identifies the column that records the start value for the period. The name
must identify an existing column in the table. \textit{begin-column-name} must not be the same as a column that is used in the definition of another period for the table.

\textit{end-column-name}

Identifies the column that records the end value for the period. The name must identify an existing column in the table. \textit{end-column-name} must not be the same as a column that is used in the definition of another period for the table.

\section*{ADD unique-constraint:}

\textbf{CONSTRAINT} \textit{constraint-name}

Names the primary key or unique key constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table. If the table space is implicitly created, the enforcing primary key and unique key indexes are also implicitly created.

\textbf{PRIMARY KEY}(\textit{column-name},...)

Defines a primary key composed of the identified columns. Each column name must be an unqualified name that identifies a column of the table. The same column must not be identified more than one time. The following types of columns cannot be specified in a PRIMARY KEY clause:

\begin{itemize}
  \item a LOB column
  \item a ROWID column
  \item a DECFLOAT column
  \item an XML column
  \item a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
  \item a row change timestamp column
  \item a Unicode column in an EBCDIC table
\end{itemize}

The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 -2m, where m is the number of varying-length columns in the key. The table must not have a primary key and the identified columns must be defined as NOT NULL.

The set of columns in the primary key cannot be the same as the set of columns of another unique key.

The table must have a unique index with a unique key that is identical to the primary key. The keys are identical only if they have the same number of columns and the \textit{n}th column name of one is the same as the \textit{n}th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, DB2 will automatically create a primary index. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created primary key index is owned by the owner of the base table.

The identified columns are defined as the primary key of the table. The description of the index is changed to indicate that it is a primary index. If the table has more than one unique index with a key that is identical to the primary key, the selection of the primary index is arbitrary.

\textbf{BUSINESS\_TIME WITHOUT OVERLAPS}

\textit{BUSINESS\_TIME WITHOUT OVERLAPS} can be specified as the last item
in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list
must include at least one column-name or key-expression. When WITHOUT
OVERLAPS is specified, the values for the rest of the specified keys are
unique with respect to the time for the BUSINESS_TIME period. When
BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the
BUSINESS_TIME period must not be specified as part of the constraint.
The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the
following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

**UNIQUE(column-name,...)**

Defines a unique key composed of the identified columns with the specified
constraint-name. If a constraint-name is not specified, a name is generated. Each
column name must be an unqualified name that identifies a column of the
table. The same column must not be identified more than one time. The
following types of columns cannot be specified in a UNIQUE clause:

- a LOB column
- a ROWID column
- a DEC_FLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DEC_FLOAT data
type
- a Unicode column in an EBCDIC table

Each identified column must be defined as NOT NULL. The number of
identified columns must not exceed 64. In addition, the sum of the length
attributes of the columns must not be greater than 2000 - n for padded indexes
and 2000 - n - 2m for nonpadded indexes, where n is the number of columns
that can contain null values and m is the number of varying-length columns in
the key.

The set of columns in the unique key cannot be the same as the set of columns
of the primary key or another unique key. A unique key is a duplicate if it is
the same as the primary key or a previously defined unique key. The
specification of a duplicate unique key is ignored with a warning.

The table must have a unique index with a key that is identical to the unique
key. The keys are identical only if they have the same number of columns and
the nth column name of one is the same as the nth column name of the other.
If the table is in a table space that is implicitly created, and no unique index is
defined on the identified columns, DB2 will automatically create a unique
index to enforce the unique key constraint. The privilege set must include the
INDEX privilege on the table and the USE privilege on the buffer pool and the
storage group. The implicitly created unique key index is owned by the owner
of the base table.

The identified columns are defined as a unique key of the table. The
description of the index is changed to indicate that it is enforcing a unique key
constraint. If the table has more than one unique index with a key that is
identical to the unique key, the selection of the enforcing index is arbitrary.

**BUSINESS_TIME WITHOUT OVERLAPS**

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item
in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list
must include at least one column-name or key-expression. When WITHOUT
OVERLAPS is specified, the values for the rest of the specified keys are
unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The start column of the BUSINESS_TIME period in ascending order

ADD referential-constraint:

CONSTRAINT constraint-name
Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

FOREIGN KEY (column-name,...) references-clause
Specifies a referential constraint with the specified constraint-name.

FOREIGN KEY cannot be specified if the table is a history table or an archive table.

Let T1 denote the object table of the ALTER TABLE statement.

The foreign key of the referential constraint is composed of the identified columns. Each column-name must be an unqualified name that identifies a column of T1. The same column must not be identified more than one time. The following types of columns cannot be specified in the FOREIGN KEY clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- a security label column
- a row change timestamp column
- a Unicode column in an EBCDIC table

The number of identified columns must not exceed 64 and the sum of their length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and the parent table are the same as the FOREIGN KEY and parent table of an existing referential constraint on T1. The specification of a duplicate referential constraint is ignored with a warning.

The foreign key of the referential constraint cannot reference a parent key that contains BUSINESS_TIME WITHOUT OVERLAPS.

REFERENCES table-name (column-name,...)
The table name specified after REFERENCES must identify a table that exists at the current server.

table-name must not identify a catalog table, a declared global temporary table, a history table, or an archive table.

Let T2 denote the identified parent table and let T1 denote the table that is being changed (T1 and T2 can be the same table).
T2 must have a unique index and the privilege set on T2 must include the
ALTER or REFERENCES privilege on the parent table, or the REFERENCES
privilege on the columns of the nominated parent key.

The parent key of the referential constraint is composed of the identified
columns. Each column-name must be an unqualified name that identifies a
column of T2. The same column must not be identified more than one time.
The following types of columns cannot be specified in a REFERENCES clause:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data
type
- a security label column
- a row change timestamp column
- a Unicode column in an EBCDIC table

The list of column names in the parent key must be identical to the list of
column names in a primary key or unique key in the parent table T2. The
column names must be specified in the same order as in the primary key or
unique key. If any of the referenced columns in T2 has a non-numeric data
type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, then T2 must have a primary key.
Omission of a list of column names is an implicit specification of the columns
of the primary key for T2.

The specified foreign key must have the same number of columns as the
parent key of T2 and, except for their names, default values, null attributes and
check constraints, the description of the nth column of the foreign key must be
identical to the description of the nth column of the nominated parent key. If
the foreign key includes a column defined as a distinct type, the corresponding
column of the nominated parent key must be the same distinct type. If a
column of the foreign key has a field procedure, the corresponding column of
the nominated parent key must have the same field procedure and an identical
field description. A field description is a description of the encoded value as it is
stored in the database for a column that has been defined to have an
associated field procedure.

The table space that contains T1 must be available to DB2. If T1 is populated,
its table space is placed in a check pending status. A table in a segmented table
space is populated if the table is not empty. A table in a table space that is not
segmented is considered populated if the table space has ever contained any
records.

The referential constraint specified by the FOREIGN KEY clause defines a
relationship in which T2 is the parent and T1 is the dependent. A description
of the referential constraint is recorded in the catalog.

ON DELETE
The delete rule of the relationship is determined by the ON DELETE clause.
For more on the concepts used here, see “Referential constraints” on page 25.

If T1 and T2 are the same table, CASCADE or NO ACTION must be specified.
SET NULL must not be specified unless some column of the foreign key allows
null values. Also, SET NULL must not be specified if any nullable column of
the foreign key is a column of the key of a partitioning index. The default
value for the rule depends on the value of the CURRENT RULES special
register when the ALTER TABLE statement is processed. If the value of the
register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'SQL', the
delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or
propagated delete operation and that row has dependents in T1. Let \( p \) denote
such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are
deleted.
- If CASCADE is specified, the delete operation is propagated to the
dependents of \( p \) in T1.
- If SET NULL is specified, each nullable column of the foreign key of each
dependent of \( p \) in T1 is set to null.

A cycle involving two or more tables must not cause a table to be
delete-connected to itself. Thus, if the relationship would form a cycle:

- The referential constraint cannot be defined if each of the existing
relationships that would be part of the cycle have a delete rule of
CASCADE.
- CASCADE must not be specified if T2 is delete-connected to T1.

If T1 is delete-connected to T2 through multiple paths, those relationships in
which T1 is a dependent and which form all or part of those paths must have
the same delete rule and it must not be SET NULL. For example, assume that
T1 is a dependent of T3 in a relationship with a delete rule of \( r \) and that one of
the following is true:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows
from that table cascades to both T2 and T3.

In this case, the referential constraint cannot be defined when \( r \) is SET NULL.
When \( r \) is other than SET NULL, the referential constraint can be defined, but
the delete rule that is implicitly or explicitly specified in the FOREIGN KEY
clause must be the same as \( r \).

**ENFORCED or NOT ENFORCED**

Indicates whether or not the referential constraint is enforced by DB2 during
normal operations, such as insert, update, or delete.

**ENFORCED**

Specifies that the referential constraint is enforced by DB2 during normal
operations (such as data change operations) and that it is guaranteed to be
correct. ENFORCED is the default.

**NOT ENFORCED**

Specifies that the referential constraint is not enforced by DB2 during
normal operations (such as data change operations). NOT ENFORCED
should only be used when the data that is stored in the table is verified to
conform to the constraint by some other method than relying on DB2.

**ENABLE QUERY OPTIMIZATION**

Specifies that the constraint can be used for query optimization. DB2 uses the
information in query optimization using materialized query tables with the
assumption that the constraint is correct. This is the default.
ADD check-constraint:

CONSTRAINT constraint-name

Names the check constraint. If constraint-name is not specified, a unique constraint name is derived from the name of the first column in the check-condition specified in the definition of the check constraint. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

CHECK (check-condition)

Defines a check constraint. At any time, check-condition must be true or unknown for every row of the table. A check-condition can evaluate to unknown if a column that is an operand of the predicate is null. A check-condition that evaluates to unknown does not violate the check constraint. A check-condition is a search condition, with the following restrictions:

• It can refer only to the columns of table table-name.
• The columns cannot be any of the following types of columns:
  – LOB columns
  – ROWID columns
  – DECFLOAT columns
  – XML columns
  – distinct type columns that are based on LOB, ROWID, and DECFLOAT data types
  – security label columns
  – Unicode columns in an EBCDIC table
• It can be up to 7400 bytes long, not including redundant blanks.
• It must not contain any of the following:
  – Subselects
  – Built-in or user-defined functions
  – CAST specifications
  – Cast functions other than those created when the distinct type was created
  – Host variables
  – Global variables
  – Parameter markers
  – Special registers
  – Columns that include a field procedure
  – CASE expressions
  – ROW CHANGE expressions
  – Row expressions
  – DISTINCT predicates
  – GX constants (hexadecimal graphic string constants)
  – Sequence references
  – OLAP specifications
• If a check-condition refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
• The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
• The first operand of every predicate must be the column name of a column in the table.
• The second operand in the check-condition must be either a constant or a column name of a column in the table.
  – If the second operand of a predicate is a constant, and if the constant is:
A floating-point number, then the column data type must be floating point.
- A decimal number, then the column data type must be either floating point or decimal.
- A big integer number, then the column data type must not be an integer or a small integer
- An integer number, then the column data type must not be a small integer.
- A small integer number, then the column data type must be small integer.
- A decimal constant, then its precision must not be larger than the precision of the column.
- If the second operand of a predicate is a column, then both columns of the predicate must have:
  - The same data type
  - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes.

**Effects of defining a check constraint on a populated table:** When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'DB2', the check constraint is not immediately enforced on the table. The check constraint is added to the description of the table, and the table space that contains the table is placed in a check pending status. For a description of the check pending status and the implications for utility operations, see *DB2 Utility Guide and Reference*.

When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'STD', the check constraint is checked against all rows of the table. If no violations occur, the check constraint is added to the table. If any rows violate the new check constraint, an error occurs and the description of the table is unchanged.

**DROP constraint:**

**DROP PRIMARY KEY**

Drops the definition of the primary key and all referential constraints in which the primary key is a parent key. The table must have a primary key and the privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table.

The description of the primary index is changed to indicate that it is not a primary index. If the table space was implicitly created, the corresponding enforcing index is dropped if the primary key is dropped.

**DROP UNIQUE constraint-name**

Drops the definition of the unique key constraint and all referential constraints in which the unique key is a parent key. The table must have a unique key. The privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table. The description of the enforcing index is changed to indicate that it is not enforcing a unique key constraint. If the table space is implicitly created, the corresponding enforcing index is dropped if the unique key is dropped.

**DROP FOREIGN KEY constraint-name**

Drops the referential constraint *constraint-name*. The *constraint-name* must identify a referential constraint in which the table is the dependent table, and
the privilege set must include the ALTER or REFERENCES privilege on the parent table of that relationship, or the REFERENCES privilege on the columns of the parent table of that relationship.

**DROP CHECK constraint-name**
Drops the check constraint constraint-name. The constraint-name must identify an existing check constraint defined on the table.

**DROP CONSTRAINT constraint-name**
Drops the constraint constraint-name. The constraint-name must identify an existing primary key, unique key, check, or referential constraint defined on the table.

DROP CONSTRAINT must not be used on the same ALTER TABLE statement as DROP PRIMARY KEY, DROP UNIQUE KEY, DROP FOREIGN KEY or DROP CHECK.

### ADD partitioning:

**ADD PARTITION BY RANGE**
Specifies the range partitioning scheme for the table (the columns used to partition the data). When this clause is specified, the table uses table-controlled partitioning. The number of partitions specified in the ADD PARTITION BY RANGE clause has to be the same as the number of partitions defined in the table space.

This clause applies only to tables in a partitioned table space. If the table is already complete by having established either table-controlled partitioning or index-controlled partitioning, the ADD PARTITION BY RANGE clause is not allowed. If this clause is used, then the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

**partition-expression**
Specifies the key data over which the range is defined to determine the target data partition of the data.

**column-name**
Specifies the columns of the key. Each column-name must identify a column of the table. Do not specify more than 64 columns, the same column more than one time, a qualified column name, or any of the following types of columns:

- a BINARY or VARBINARY column
- a LOB column
- a DECIMAL column
- an XML column
- a column with a distinct type that is based on any of the preceding data types
- a row change timestamp column
- a Unicode column in an EBCDIC table

The sum of length attributes of the columns must not be greater than 255 - n, where n is the number of columns that can contain null values.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.
**NULLS LAST**  
Specifies that null values are treated as positive infinity for purposes of comparison.

**ASC**  
Puts the entries in ascending order by the column. ASC is the default.

**DESC**  
Puts the entries in descending order by the column.

**partition-element**  
Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

**PARTITION integer**  
Specifies a number of a physical partition in the table space. A PARTITION clause must be specified for every partition of the table space. In the context, highest means highest in the sorting sequence of the columns. In a column that is defined as ascending (ASC), highest and lowest have the usual meanings. In a column that is defined as descending (DESC), the lowest actual value is the highest in the sorting sequence.

**ENDING AT (constant, MAXVALUE, or MINVALUE...)**  
Specifies the limit key for a partition boundary. Specify at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key for ascending and the lowest for descending.

**constant**  
Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**  
Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**  
Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.
The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

**INCLUSIVE**
Specifies that the specified range values are included in the data partition.

**HASH SPACE** integer\(_K\)\(_M\)\(_G\)
Specifies the amount of fixed hash space to preallocate for the partition that is associated with the partition element. If HASH SPACE is omitted from the partition element, the HASH SPACE value that is specified in the ORGANIZE BY CLAUSE is used.

The HASH SPACE keyword in the partition-element must only be specified if the table is defined to use hash organization.

\(K\)
Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

\(M\)
Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

\(G\)
Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 131072 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4\(_G\) is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

**ADD PARTITION:**

**ADD PARTITION**
Specifies that a partition is added to the table and each partitioned index on the table. The new partition is the next physical partition not being used until the maximum for the table space has been reached. ADD PARTITION must not be specified for nonpartitioned tables. Adding a partition is not allowed if the table is a materialized query table or a materialized query table is defined on the table. However, adding a partition is allowed if an accelerated query table is defined on the table. A partition cannot be added if the table space definition is incomplete because a partitioning key or partitioning index is missing. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

If the table is in a partition-by-growth table space, a new partition can be added until the number of partitions reaches the MAXPARTITIONS limit. The total number of table space partitions cannot exceed the value that is specified for MAXPARTITIONS for the table space.

The maximum number of partitions allowed depends on how the table space was originally created. If DSSIZE was specified when the table space was created, it is non-zero in the catalog. The maximum number of partitions allowed is shown in the following table.
Table 109. Maximum number of partitions allowed

<table>
<thead>
<tr>
<th>DSSIZE</th>
<th>Page size 4</th>
<th>Page size 8 KB</th>
<th>Page size 16 KB</th>
<th>Page size 32 KB</th>

</tbody>
</table>

If LARGE was specified when the table space was created, the maximum number of partitions is shown in the fourth row of Table 110. For more than 254 partitions when LARGE or DSSIZE is not specified, the maximum number of partitions is determined by the page size of the table space.

Table 110. Maximum number of partitions when DSSIZE = 0

</tbody>
</table>

The existing table space PRIQTY and SECQTY attributes of the previous logical partition are used for the space attributes of the new partition. For each partitioned index, the existing PRIQTY and SECQTY attributes of the previous partition are used.

To specify specific space attributes for the new partition, use additional ALTER TABLESPACE and ALTER INDEX statements.

HASH SPACE cannot be specified with ADD PARTITION. For partition-by-growth table spaces, the hash space value is not applicable at the partition level. For range-partitioned universal table spaces, the hash space value is inherited from base table.

**ENDING AT (constant, MAXVALUE, or MINVALUE, ...)**

Specifies the high key limit for the new partition. The new partition's key limit must be higher when partitioning is ascending and lower when it is descending. Specify at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in the PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. ENDING AT cannot be specified for a table in a partition-by-growth table space, but must be specified if the table is in a range-partitioned table space.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is
descending, the padding character is X'00'. The precision and scale of a
decimal constant must not be greater than the precision and scale of its
 Corresponding column. A hexadecimal string constant (GX) cannot be
 specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a
partition boundary (that is, all X'FF' regardless of whether the column is
ascending or descending). If all of the columns in the partitioning key are
ascending, a constant or the MINVALUE clause cannot be specified
following MAXVALUE. After MAXVALUE is specified, all subsequent
columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key
of a partition boundary (that is, all X'00' regardless of whether the column
is ascending or descending). If all of the columns in the partitioning key
are descending, a constant or the MAXVALUE clause cannot be specified
following MINVALUE. After MINVALUE is specified, all subsequent
columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value
to the second column, and so on. Using fewer values than there are columns
in the key has the same effect as using the highest or lowest values for the
omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest
value of the key in the next partition.
- The values specified for the last partition are enforced. The value specified
for the last partition is the highest value of the key that can be placed in the
table. If the limit was not previously enforced, any existing key values that
are greater than the value that is specified for the added partition are placed
into the discard data set when REORG is run.
- If a key includes a ROWID column or a column with a distinct type that is
based on a ROWID data type, 17 bytes of the constant that is specified for
the corresponding ROWID column are considered.
- The combination of the number of table space partitions and the
 corresponding limit key size cannot exceed the number of partitions * (106 +
 limit key size in bytes) < 65394
- If the concatenation of all the values exceeds 255 bytes, only the first 255
bytes are considered.

**INCLUSIVE**

Specifies that the specified range values are included in the data partition.

**ALTER PARTITION:**

**ALTER PARTITION**

Specifies that the partitioning limit key for the identified partition is to be
changed.

This clause applies only to tables in a partitioned table space. ALTER
PARTITION must not be specified for a table in a partition-by-growth table
space or for tables that have XML columns.

*integer*

If *integer* is specified, it must be in the range 1 to *n*, where *n* is the number
of partitions in the table. integer is the physical partition number. When this option is specified for any partition except for the last, both the identified partition and the partition following are placed in advisory REORG-pending (AREOR) status.

ENDING AT (constant, MAXVALUE, or MINVALUE...)

Specifies the highest value of the partitioning key for the identified partition.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT in each ALTER PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

constant

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

MAXVALUE

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

MINVALUE

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See [list of rules](#).

The value that is specified must not be equal to or beyond the range of the partition boundaries of the adjacent partitions.

INCLUSIVE

Specifies that the specified range values are included in the data partition.

HASH SPACE integerK|M|G

Specifies the amount of fixed hash space to preallocate for the partition
that is associated with the partition element. If HASH SPACE is omitted from the partition element, the HASH SPACE value that is specified in the ORGANIZE BY CLAUSE is used.

The HASH SPACE keyword in the partition-element must only be specified if the table is defined to use hash organization.

K
Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M
Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G
Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

**ROTATE PARTITION:**

**ROTATE PARTITION FIRST** or **integer** **TO LAST**

Specifies that the first logical partition or the physical partition that corresponds to integer is to be rotated to become the last partition. Processing resets the specified partition to empty, and the limit key that is associated with the partition is set to the constant that is specified with the boundary specification clause. For ascending limit keys, the new limit key must be higher than the limit key for the preexisting last logical partition prior to this statement being processed. For descending limit keys, the new limit must be lower than the limit for the preexisting last logical partition prior to this statement being processed.

The table definition must be complete and must contain more than one partition. This clause must be followed by the ENDING AT clause, which specifies the new high key limit for this partition, which is now logically last.

Rotating a partition occurs immediately. If there is a referential constraint with DELETE RESTRICT on the table, the ROTATE might fail. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

After an ALTER TABLE statement with the ROTATE PARTITION clause is run, the RUNSTATS utility or the REORG utility with the STATISTICS option should be run on the table space to ensure effective access paths are available for selection.

If the table has a security label column, the user must have a valid security label to rotate partitions. In addition, if write-down is in effect, the user must have the write-down privilege.

ROTATE PARTITION must not be specified in the following situations:
The table is a materialized query table or a materialized query table is defined on the table.

- The table is in a partition-by-growth table space.
- The table has XML columns.
- The table is a system-period temporal table or a history table.
- The table is an archive-enabled table or an archive table.

Adding a partition is allowed if an accelerated query table is defined on the table.

**integer**

Specifies a positive integer that represents a physical partition number as identified by the PARTITION column of the SYSIBM.SYSTABLEPART catalog table. The partition must be a data partition that exists in the table. The partition cannot be the last partition of the table.

**ENDING AT (constant, MAXVALUE, or MINVALUE...)**

The ENDING AT clause specifies the new high key limit for the existing partition holding the oldest data.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See [list of rules](#).
INCLUSIVE
Specifies that the specified range values are included in the data partition.

RESET
Specifies that the existing data in the first logical partition is deleted. In addition the key entries from the associated physical and logical index partitions are deleted. In a partitioned table with limit values that are in ascending sequence, ALTER TABLE ROTATE PARTITION FIRST TO LAST logically operates as if the partition with the lowest high key limit were dropped and then a new partition was added with the specified high key limit. The new key limit for the partition must be higher than any other partition in the table. For descending limit keys, the rotation operates as the partition with the highest limit values becomes the partition with the lowest limit values.

If the partition contains any of the following attributes, each data row in the partition must be deleted individually:

- Referential integrity parent relationships
- DATA CAPTURE logging enabled
- Delete row triggers

If the table resides in a range-partitioned universal table space and does not have any of the previous attribute, the data rows can be removed using mass delete processing (individual data rows are neither touched nor logged).

ADD organization:

ADD ORGANIZE BY HASH
Specifies that a hash is to be used for the data organization of the table.
ADD ORGANIZE BY HASH must not be specified if the table is already defined with the APPEND YES clause, or if the table space is defined with the MEMBER CLUSTER clause.

ALTER TABLE ADD ORGANIZE BY HASH is allowed only if the table is in either a partition-by-growth table space or a range-partitioned universal table space.

ADD ORGANIZE BY HASH must not be specified on tables that are using basic row format.

ADD ORGANIZE BY HASH must not be specified if a user specified clustering index exists.

ADD ORGANIZE BY HASH must not be specified for global temporary tables.

After ALTER TABLE with ADD ORGANIZE BY HASH runs:

- Any packages that are dependent on the table are invalidated.
- All columns that are part of the hash key are no longer updatable. SQL statements that update a column of the hash key return an error.
- The entire table space that contains the table must be reorganized.

UNIQUE
Specifies that DB2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

\((column-name,\ldots)\)
The list of column names defines the hash key that is used to determine where a row will be placed.
Each column-name must be an unqualified name that identifies a column of the table. The same column must not be specified more than one time and the specified columns must be defined as NOT NULL. The number of specified columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types of columns:

- a LOB column
- a DECFLOAT column
- an XML column
- a distinct type column that is based on one of the preceding data types
- a Unicode column in an EBCDIC table

If the table is defined as partition by range, the list of column names must specify all of the column names that are specified in the partition-expression for the table, and must specify the column names in the same order as partition-expression. If the ORGANIZE BY clause contains more columns than the partition-expression for the table, partition-expression determines the partition number.

**HASH SPACE integer K|M|G**

Specifies the amount of fixed hash space to preallocate for the table. If the table is range-partitioned, this is the space for each partition.

The default is 64M for a table in a partition-by-growth universal table space or 64M for each partition of a partition by range universal table space.

| K | Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456. |
| M | Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144. |
| G | Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table. |

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

**ALTER ORGANIZATION:**

**ALTER ORGANIZATION SET HASH SPACE integer**

Changes the fixed hash space that is used for the data organization for the table. The table must be defined to use hash organization.

If the table is defined as range-partitioned, the value specified by integer is per partition and applies to each partition of the table. For tables that are not range-partitioned, integer applies to the whole table.

The new hash space value will be applied when the table space is reorganized using the REORG utility.

**HASH SPACE integer K|M|G**

Specifies the amount of fixed hash space to preallocate for the table. If the table is range-partitioned, this is the space for each partition.
K Indicates that the integer value is to be multiplied by 1,024 to specify the hash space size in bytes. The integer must be between 256 and 67,108,864.

M Indicates that the integer value is to be multiplied by 1,048,576 to specify the hash space size in bytes. The integer must be between 1 and 65,536.

G Indicates that the integer value is to be multiplied by 1,073,741,824 to specify the hash space size in bytes. The integer must be between 1 and 64 for a range-partitioned table and must be between 1 and 131,072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

**DROP ORGANIZATION:**

**DROP ORGANIZATION**

Specifies that the data organization definition for the table is dropped. The entire table becomes inaccessible and is placed in REORG-pending status. REORG must be run to make the table accessible. If the table is in a partition by range universal table space, the entire table space must be reorganized at one time.

If any type of clustering is required, you must create the clustering index or add the MEMBER CLUSTER clause to the table.

After the next time the REORG utility is run, the hash space value will be cleared and the implicitly created hash overflow index will be dropped.

**DROP ORGANIZATION** must only be specified if the table is defined to use hash organization.

To change the columns that are specified for the hash key for a table that uses hash organization, the definition of the hash key must be dropped by using **ALTER DROP ORGANIZATION**, then the new columns for the hash key can be specified with **ALTER ADD organization-clause**.

**ADD VERSIONING:**

**ADD VERSIONING**

Specifies that the table is a system-period temporal table.

The table must not already be defined as a system-period temporal table, a history table, an archive-enabled table, or an archive table.

A SYSTEM_TIME period and a transaction-start-ID column must be defined for the table. The data type, length, precision, and scale for a transaction-start-ID column must be defined the same as the row-begin column and row-end column of the SYSTEM_TIME period in the table. The table must be the only table in the table space. The table must not be a materialized query table, an incomplete table, an auxiliary table, a table that is involved in a clone relationship, a table that was implicitly created for an XML column, or a table that contains a security label column. **ADD VERSIONING** must not be specified with other clauses on the **ALTER TABLE** statement.

The privilege set must include the privileges to issue an **ALTER TABLE** statement for the associated history table.
Historical versions of the rows in the table are retained by DB2. A system-period temporal table contains extra information that indicates when a row is inserted into the table, and when it is updated or deleted. An associated history table is used to store the historical rows of the table. When data in the system-period temporal table is updated, the previous version of the row is kept in the associated history table. When data in a system-period temporal table is deleted, the last version of the row is inserted into the history table.

References to the table can include a period clause to indicate which versions of the data are returned.

**USE HISTORY TABLE** `history-table-name`

Specifies a history table in which to keep the historical rows of the system-period temporal table.

If the history table contains data, ensure that the data accurately represents historical rows. If the data does not accurately represent historical rows, the results of temporal queries might be unexpected.

`history-table-name` must identify a table that exists at the current server and must not identify one of the following tables:

- A catalog table.
- A system-period temporal table. The table was defined as a system-period temporal table by a previous statement, or the current statement defines the table as a system-period temporal table.
- An existing history table.
- An archive-enabled table.
- An archive table.
- A declared global temporary table.
- A created global temporary table.
- A materialized query table.
- A view.
- An auxiliary table.
- A table that was implicitly created for an XML column.
- A table that is involved in a clone relationship.

The history table must be the only table in the table space. The history table must not contain any of the following columns:

- Identity column
- Row change timestamp column
- Row-begin column
- Row-end column
- Transaction-start-ID column
- Generated expression column
- Column mask
- Row mask
- Security label column.

The history table must not include a period and must not have an incomplete table definition.

The encoding scheme and CCSID for the system-period temporal table and identified history table must be the same.
The system-period temporal table and the identified history table must have the same number and order of columns. The following attributes of the corresponding columns of the two tables must be the same:

- name
- data type
- length (excluding inline LOB length), precision, and scale
- subtype and CCSID
- null attribute
- hidden attribute
- field procedure

If a column of the system-period temporal table is defined as ROWID GENERATED ALWAYS, the corresponding history column should be defined as ROWID GENERATED ALWAYS.

If a column of the system-period temporal table is defined as GENERATED ALWAYS FOR EACH ROW ON UPDATE OF ROW CHANGE TIMESTAMP or GENERATED AS IDENTITY, the corresponding column in the history table cannot be defined with a GENERATED attribute.

**ON DELETE ADD EXTRA ROW**

Specifies that an additional row is inserted into the associated history table when a row is deleted from a system-period temporal table. The content of the columns of the additional row in the history table are determined as follows:

- New values are generated for each column that corresponds to a non-deterministic generated expression column.
- The column that corresponds to the row-begin column is set to the same value as the column that corresponds to the row-end column.
- The other columns are set to the same value as in the row inserted into the history table for the delete.

The ON DELETE ADD EXTRA ROW clause is intended to be used when the system-period temporal table contains a non-deterministic generated expression column.

**Related information:**

[Temporal tables (DB2 Administration Guide)]

**DROP VERSIONING:**

**DROP VERSIONING**

Specifies that the table is no longer a system-period temporal table. *table-name* must identify a system-period temporal table. Historical data will no longer be recorded and maintained for the table. The definition of the columns and data of the table *table-name* are not changed, but the table is no longer treated as a system-period temporal table. The SYSTEM_TIME period is retained. The relationship between the system-period temporal table and history table is removed. The history table is not dropped, only the relationship between the two tables is removed. Subsequent queries that reference the table must not specify a SYSTEM_TIME period specification for the table.

Packages and statements in the dynamic statement cache that use the SYSTEM_TIME period are invalidated.
Versioning cannot be dropped if there are any views, materialized query table definitions, or inline SQL table functions that depend on the SYSTEM_TIME period.

DROP VERSIONING must not be specified with any other clauses on the ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated history table.

**ADD MATERIALIZED QUERY:**

**ADD MATERIALIZED QUERY** `materialized-query-definition`

Changes a base table to a materialized query table. Supplies a definition for a regular table to make it a materialized query table. The table specified by `table-name` and the result columns of the fullselect must not have the following characteristics:

- Be already defined as a materialized query table
- Have any primary keys, unique constraints (unique indexes), referential constraints (foreign keys), check constraints, or triggers defined
- Be referenced in the definition of another materialized query table
- Be directly or indirectly referenced in the `fullselect`
- Be in an incomplete state
- Be a system-period temporal table or a history table
- Be a base table that has been activated for the row access controls or column access controls
- Be a base table for which a row permission or a column mask has been defined
- Be an archive-enabled table or an archive table

If `table-name` does not meet these criteria, an error occurs.

The `fullselect` must not contain a period specification.

The object that is specified in the FROM clause of the `fullselect` cannot be a view with columns of length 0.

`fullselect`

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- Have the same number of columns
- Have exactly the same column definitions
- Have the same column names in the same ordinal positions

The `fullselect` must not directly or indirectly reference a base table that has been activated for the row access controls or column access controls or reference a base table for which a row permission or a column mask has been defined.

The outer SELECT clause of `fullselect` must not result in a column that is an array.

If fullselect is specified, the owner of the table being altered must have the SELECT privilege on the tables or views referenced in the fullselect.

Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the table of the fullselect reside

If the owner of the table does not have the SELECT privilege, the following authorization IDs must have SYSADM authority or DBADM authority for the database in which the tables of the fullselect reside:

- For embedded statements, the authorization ID of the owner of the plan or package
- For dynamically prepared statements, the SQL authorization ID of the process

For details about specifying fullselect for a materialized query table, see the definition of fullselect in the "CREATE TABLE" on page 1446 statement.

Altering a table to change it from a base table to a materialized query table with REFRESH DEFERRED causes any packages that are dependent on the table to be invalidated.

refreshable-table-options

Specifies the materialized query table options for altering a regular table to a materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED

Specifies that the data in the table is not validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

REFRESH DEFERRED

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or as updated by the user for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER

Specifies how the data in the materialized query table is maintained.

MAINTAINED BY SYSTEM

Specifies that the data in the materialized query table table-name is to be maintained by the system. Only the REFRESH TABLE statement is allowed on the table.

MAINTAINED BY USER

Specifies that the data in materialized query table table-name is to be maintained by the user, who can use LOAD utility or SQL data change statements and REFRESH TABLE statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION

Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the
restrictions for query optimization, an error occurs. For detailed rules to satisfy query optimization, see materialized-query-definition in the "CREATE TABLE" on page 1446 statement.

**DISABLE QUERY OPTIMIZATION**
Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

**ALTER MATERIALIZED QUERY:**

**ALTER MATERIALIZED QUERY** materialized-query-table-alteration
Changes attributes of a materialized query table. The table-name must identify a materialized query table.

**SET refreshable-table-alteration**
Changes how the table is maintained or whether the table can be used in query optimization.

**MAINTAINED BY SYSTEM**
Specifies that the data in a materialized query table table-name is to be maintained by the system.

**MAINTAINED BY USER**
Specifies that the data in the materialized query table table-name is to be maintained by the user.

**ENABLE QUERY OPTIMIZATION**
Specifies that materialized query table table-name can be used in query optimization. If the fullselect specified for the materialized query table does not satisfy the restrictions for automatic query optimization, an error occurs. For detailed rules to satisfy query optimization, see "CREATE TABLE" on page 1446.

**DISABLE QUERY OPTIMIZATION**
Specifies that materialized query table table-name cannot be used for query optimization. The table can still be queried directly.

**DROP MATERIALIZED QUERY:**

**DROP MATERIALIZED QUERY**
Changes a materialized query table so that it is no longer considered a materialized query table. The table specified by table-name must be defined as a materialized query table. The definition of columns and data of the name are not changed, but the table can no longer be used for query optimization and is no longer valid for use with the REFRESH TABLE statement.

Altering a table to change from a materialized query table to a base table with the DROP MATERIALIZED QUERY clause causes any packages dependent on the table to be invalidated.

**DATA CAPTURE:**

**DATA CAPTURE**
Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause)
- Changing columns (using the ALTER COLUMN clause)

For guidance on intended uses of the expanded log records, see:
The description of data propagation to IMS in *IMS DataPropagator: An Introduction*

The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*

The instructions for reading log records in *DB2 Administration Guide*

**NONE**

Do not record additional information to the log.

**CHANGES**

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available.

Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

The DATA CAPTURE CHANGES clause can be specified for a table for which row access controls or column access control are active. However, the access controls do not protect data that is written to the log.

For details about the recording of additional data for logged updates to catalog tables, see "Notes" on page 1022.

**VOLATILE:**

**VOLATILE or NOT VOLATILE**

Specifies how DB2 is to choose access to the table.

**VOLATILE**

Specifies that DB2 is to use index access to the table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques are disabled when VOLATILE is used.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows. Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation.

**NOT VOLATILE**

Specifies that DB2 is to base SQL access to the table on the current statistics.

**CARDINALITY**

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

**ADD CLONE:**

**ADD CLONE clone-table-name**

Specifies that a clone table, identified by *clone-table-name*, is created for the table that is being altered. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server. The name must not identify a table that exists in the SYSPENDINGOBJECTS catalog table. The clone table is created in the same
table space as the base table and has the same structure as the base table. This includes, but is not limited to, column names, data types, null attributes, check constraints, indexes. When ADD CLONE is used to create a clone of the specified base table, the base table must conform to the following rules:

- Reside in a DB2-managed universal table space
- If the table space or any of its dependent objects (LOBs, XMLs, or indexes) is created with the DEFINE NO clause, all data sets must already be created
- Be the only table in the table space
- Not be defined with a clone table
- Not be defined to use hash organization.
- Not be involved in any referential constraint
- Not be defined with any after triggers
- Not be a materialized query table
- Not have any pending changes
- Not have any active versioning
- Not have an incomplete definition
- Not be a created global temporary table or a declared global temporary table
- Not be a system-period temporal table or a history table
- Not be an archive-enabled table or an archive table

The base table and the clone table are considered unrelated with regard to access controls. Row access control or column access control can be activated independently for the base table, the clone table, or both.

**DROP CLONE:**

**DROP CLONE**

Specifies that the clone table that is associated with the specified base table is dropped. *table-name* must identify a base table that exists at the current server and the table must have a clone table defined.

When a clone table is dropped, any row permissions or column masks that are defined for the clone table are also dropped. If the clone table is referenced in the definition of a row permission or a column mask, the ALTER statement returns an error.

**RESTRICT ON DROP:**

**ADD RESTRICT ON DROP**

Restricts dropping the table and the database and table space that contain the table.

**DROP RESTRICT ON DROP**

Removes the restriction on dropping the table and the database and table space that contain the table.

**ROW ACCESS CONTROL:**

**ACTIVATE ROW ACCESS CONTROL**

Specifies that row access control should be activated for the table. If the table is an alias or a synonym, row access control is activated for the base table.

The table must not be one of the following tables:
- A created temporary table
A table that is directly or indirectly referenced in the definition of a materialized query table
A table that has a security label column
A system-period temporal table
A history table
An archive-enabled table
An archive table

If a trigger exists for the table, the trigger must be defined with the SECURED clause.

The table must not be referenced in the definition of a view if the following conditions are true:

- The view is defined with the WITH CHECK OPTION clause
- An INSTEAD OF trigger exists for the view and the trigger is not defined with the SECURED clause.

A default row permission is implicitly created for the table and allows no access to any of the rows of the table, unless there is another row permission that is enabled and that provides access for the authorization IDs or roles that are specified in the definition of the row permission. A query that references the table before such a row permission exists and is enabled will return a warning that there is no data in the table.

ACTIVATE ROW ACCESS CONTROL must not be specified if a period is defined for the table, because a default row permission cannot be defined for a table with a period specification.

When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, all row permissions that are enabled for the table, including the default row permission, are applied to control the set of rows that are accessible for the table. If any row permission that is enabled is invalid because a previous attempt to regenerate the row permission was unsuccessful, row access control cannot be activated.

ACTIVATE ROW ACCESS CONTROL is ignored if row access control is already activated for the table.

DEACTIVATE ROW ACCESS CONTROL

Specifies that row access control for the table is deactivated. When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, any existing row permissions for the table that are enabled are not applied to control the set of rows that are accessible for the table.

DEACTIVATE ROW ACCESS CONTROL is ignored if row access control is already defined as not activated for the table.

COLUMN ACCESS CONTROL:

ACTIVATE COLUMN ACCESS CONTROL

Specifies that column access control should be activated for the table. If the table is an alias or a synonym, column access control is activated for the base table.

The table must not be one of the following tables:

- A created temporary table
- A table that is directly or indirectly referenced in the definition of a materialized query table
• A system-period temporal table
• A history table
• An archive-enabled table
• An archive table

If a trigger exists for the table, the trigger must be defined with the SECURED clause.

The table must not be referenced in the definition of a view if the following conditions are true:
• The view is defined with the WITH CHECK OPTION clause
• An INSTEAD OF trigger exists for the view and the trigger is not defined with the SECURED clause.

When column access control is activated, access to the table is not restricted. However, when the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, all column masks that are enabled for the table are applied to mask the values that are returned for the columns that are referenced in the final result table or to determine the new values that are used in the SQL data change statements. If any enabled column mask is invalid because a previous attempt to regenerate it was unsuccessful, column access control cannot be activated

ACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already activated for the table.

DEACTIVATE COLUMN ACCESS CONTROL
Specifies that column access control for the table is deactivated. When the table is referenced in a SELECT, INSERT, UPDATE, DELETE, or MERGE statement, any existing column masks that are enabled for the table are not applied to control the values that are returned for the columns that are referenced in the final result table or to determine if the new values can be used in the SQL data change statements.

DEACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is already defined as not activated for the table.

APPEND:
APPEND NO or APPEND YES
Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition-by-growth table space, the APPEND attributes of LOB table will be inherited by each partition.

NO Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

YES Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.
**AUDIT:**

**AUDIT**
Alters the auditing attribute of the table. For information about audit trace classes, see *DB2 Administration Guide*.

**NONE**
Specifies that no auditing is to be done when the table is accessed.

**CHANGES**
Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

**ALL**
Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

The ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- **AUDIT** attribute is changed to **NONE**, **CHANGES**, or **ALL** on an audited or non-audited table.
- **AUDIT CHANGES** or **AUDIT ALL** is in effect.

**VALIDPROC:**

**VALIDPROC**
Names a validation procedure for the table or inhibits the execution of any existing validation procedure.

**program-name**
Designates **program-name** as the new validation exit routine for the table.

The validation procedure can inhibit a data change operation on any row of the table. Before the operation takes place, the row is passed to the procedure. The values that are represented by any LOB or XML columns in the table are not passed to the validation procedure. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. When you name a new procedure, any existing procedure is no longer used. The new procedure is not used to validate existing table rows. It is used only to validate rows that are loaded, inserted, updated, or deleted after execution of the ALTER TABLE statement.

The table must not be an EBCDIC table that includes a Unicode column.

**Related information:**

- [Validation routines (DB2 Administration Guide)]

**NULL**
Discontinues the use of any validation routine for the table.
ENABLE ARCHIVE:

ENABLE ARCHIVE

Specifies that the table is an archive-enabled table.

The table must satisfy the following criteria:

- The table must not already be defined as an archive-enabled table or an
  archive table.
- The table must not contain a period.
- The table must be the only table in the table space.
- The table must not have a column mask or row permission defined.
- The table must not be one of the following tables:
  - A materialized query table
  - An incomplete table
  - An auxiliary table
  - A table that is involved in a clone relationship
  - A table that was implicitly created for an XML column
  - A table that contains a security label column
  - A system-period temporal table
  - A history table

ENABLE ARCHIVE must not be specified with other clauses on the ALTER
TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE
statement for the associated archive table.

For archive-enabled tables, DB2 retains archived versions of the rows. When
data in an archive-enabled table is deleted, and the
SYSIBMADM.MOVE_TO_ARCHIVE global variable is set to Y, the last version
of the row is inserted into the archive table.

The SYSIBMADM.GET_ARCHIVE global variable and the
ARCHIVESENSITIVE bind option determine whether rows in the associated
archive table are included when an archive-enabled table is referenced in a
table-reference.

Related information:
- Archive-enabled tables and archive tables (Introduction to DB2 for z/OS)
- "Built-in global variables" on page 340
- ARCHIVESENSITIVE bind option (DB2 Commands)

USE archive-table-name

Specifies an archive table in which to keep archived rows of the
archive-enabled table.

archive-table-name must identify a table that exists at the current server. The
table must satisfy the following criteria:

- The table must be the only table in the table space.
- The table must not have an incomplete table definition.
- The table must not be defined as the parent or child in an existing referential
  constraint.
- The table must not include a period.
- The table must not include a row permission or column mask.
The table cannot be one of the following tables:
- A catalog table.
- An archive-enabled table. The table was defined as an archive-enabled table by a previous statement, or the current statement defines the table as an archive-enabled table.
- An existing archive table.
- A system-period temporal table.
- A history table.
- A declared global temporary table.
- A created global temporary table.
- A materialized query table.
- A view.
- An auxiliary table.
- A table that was implicitly created for an XML column.
- A clone table.
- A table that has a clone defined on it.

The table must not contain any of the following columns:
- An identity column
- A row-begin column
- A row-end column
- A transaction-start-ID column
- A generated expression column
- A security label column

The privilege set must include the privileges to issue an ALTER TABLE statement for the associated archive table.

The archive-enabled table and the associated archive table must have the same number and order of columns. The following attributes for the corresponding columns of the two tables must be the same:
- Name
- Data type
- Length (excluding inline LOB length or XML length in the base table), precision, and scale
- FOR BIT, SBCS, or MIXED DATA attribute for character string columns
- Null attribute
- Hidden attribute
- CCSID
- Field procedure

If a column of an archive-enabled table is defined as ROWID, the corresponding column of the archive table must also be defined as ROWID with the GENERATED ALWAYS attribute.

If a column of an archive-enabled table is defined as row change timestamp, the corresponding column of the archive table must also be defined as row change timestamp with the GENERATED ALWAYS attribute.
DISABLE ARCHIVE:

DISABLE ARCHIVE

Specifies that the table is no longer an archive-enabled table.

`table-name` must identify an archive-enabled table. The definition of the
columns and data of the table `table-name` are not changed, but the table is no
longer treated as an archive-enabled table. The relationship between the
archive-enabled table and the associated archive table is removed. The archive
table is not dropped. However, by removing the relationship between the
archive table and the archive-enabled table, the behavior of the archive-enabled
table changes as follows:

- Subsequent queries that reference the table do not consider rows in the
  archive table regardless of the setting of the `SYSIBMADM.GET_ARCHIVE`
global variable or the `ARCHIVESENSITIVE` bind option.
- Deleted rows are not moved to the archive table regardless of the setting of
  the `SYSIBMADM.MOVE_TO_ARCHIVE` global variable.

Packages and statements in the dynamic statement cache that reference the
table are invalidated.

DISABLE ARCHIVE must not be specified with any other clauses on the
ALTER TABLE statement.

The privilege set must include the privileges to issue an ALTER TABLE
statement for the associated archive table

Notes®

Order of processing of clauses:

When there is more than one clause, they are processed in the following
order:

1. VALIDPROC
2. AUDIT
3. DATA CAPTURE
4. ROTATE
5. VOLATILE clauses
6. APPEND clauses
7. DROP clauses
8. ALTER clauses
9. RENAME clause
10. ADD clauses

Within each of these stages, the order in which the user specifies the
clauses is the order in which they are performed.

Altering the data type, length, precision, or scale of a column:

When you change the data type, length, precision, or scale of a column, the
following information applies to indexes, limit keys, check constraints, and
invalidation:

- Restrictions. The ALTER TABLE statement is not allowed if any of the
  following conditions are true:
  - The column is referenced in a referential constraint.
  - The column has a field procedure routine.
  - The column is defined as an identity column.
  - The column is defined as an security label column.
- The table has an edit or validation routine.
- The subsystem parameter RESTRICT_ALT_COL_FOR_DCC is set to YES, the table is defined with DATA CAPTURE CHANGES, and the ALTER TABLE statement specifies an ALTER COLUMN clause that attempts to drop the default value for a column.
- The table is a created temporary table.
- The table is a materialized query table or the table is referenced by a materialized query table.
- The data type changed is not to a compatible data type.
- The new length or data type specification could result in a loss of significance because of a shorter length or less precision in the data type.
- For a conversion from decimal to float, a unique index or a unique constraint exists on the column.
- For a conversion from other numeric data type to DECFLOAT, a partitioning key, check constraint, index, or a unique constraint exists on the column.
- The existing default value for a column cannot be assigned to the new data type.
- Increasing the column length results in an existing index that references the column exceeding the maximum size of an index.
- Increasing the column length results in the partitioning key using that column exceeding the maximum size for a partitioning key.
- Table definition is incomplete because unique index for enforcing a unique constraint (primary key or unique key) is missing.

**Indexes.**
- If the index has a changed character column, the index is in advisory REORG-pending (AREO*) status.
- If the index has a changed numeric column, the index remains in REBUILD-pending (RBDP) status.
- If the index has a changed timestamp (with or without time zone) column, the index is in advisory REORG-pending (AREO*) status.

**Length of partitioned index keys.** When a table is altered and the length of a column in the PARTITIONING KEY is changed, DB2 changes the length of the limit key (the highest key value) for a partition too. The length of the limit key is increased by the same amount that the length of the column is increased.

**Check constraints.** If a check constraint refers to the column being altered, the length of the column is also changed in the check constraint.

**Statistics.** The RUNSTATS utility should be run to collect new COLUMN statistics for all altered columns. Even though the COLCARD value is valid, the HIGH2KEY and LOW2KEY values are invalid, and any SYSCOLSTATS catalog entries for the column are removed. Any frequencies or histogram statistics which include this column should also be collected again.

When you change a column from a fixed to varying length or change the length of a varying-length column, process the ALTER TABLE statements in the same unit of work or do a reorganization between the ALTER TABLE statements to avoid anomalies with the lengths and padding of individual values.
Referencing columns in ADD, ALTER, and RENAME clauses:
A column can only be referenced once in an ADD COLUMN, an ALTER COLUMN, or a RENAME COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB, ROWID, and DECIMAL columns apply to distinct type columns that are based on LOBs, row IDs, and DECIMALs. For example, if a table has an explicitly created ROWID column, you cannot add a column with a distinct type that is sourced on a row ID.

Adding a column to table T only changes the description of T. If the catalog description of T is used to create a table T' and a facility such as DSN1COPY is used to effectively copy T into T', queries that refer to the added column in T' will fail because the data does not match its description. To avoid this problem, run the REORG utility against the table space of T before making the copy.

Restrictions on a clone table:
Tables that are involved in a clone relationship (base tables and their associated clone tables) have the following restrictions:
• You cannot use the RUNSTATS utility on a clone table.
• Objects that are involved in a clone relationship do not use the FASTSWITCH naming convention when the REORG utility is run. This includes both the base table and the clone table objects (data and index), as well as LOB and XML objects.
• For a partitioned table, if a mixture of 'I' and 'J' data sets exists when a clone table is created, the mixture of 'I' and 'J' data sets can be changed only by first dropping the clone table.
• Catalog and directory tables cannot have clone tables.
• Indexes cannot be created on a clone table. When an index is created on a base table that is involved in a clone relationship, the index on the clone table will be created implicitly and will be put into rebuild-pending status.
• Implicitly created auxiliary table spaces (table spaces for LOB and XML columns) and auxiliary indexes for the base table are always created as DEFINE YES.
• Before triggers cannot be created on a clone table. Before triggers that are created on a base table apply to both the base table and the clone table.
• You cannot rename a base table that has a clone and you cannot rename a clone table.
• Real-time statistics tables cannot have clone tables.
• You cannot drop an auxiliary table or an auxiliary index of an object that is involved in a clone relationship.

If the table is involved in a clone relationship, no other table altering can take place. If a table change is required, the clone table objects must be dropped so that the base table object attributes can be modified. After the table and index changes and such are completed, the clone table objects can be recreated.
Size restriction for the object descriptor of a table in the SYSIBM.SYSOBDS catalog table:

The following cases might result in an error being returned if the ALTER TABLE statement results in a versioned object descriptor that is larger than 30,000 bytes being added (or updated) in the SYSIBM.SYSOBDS catalog table:

- An ALTER TABLE statement that results in the first version of the object descriptor being generated for the table
- An ALTER TABLE statement that results in the first version of the object descriptor being generated for one or more of the indexes that are defined on the table
- An ALTER TABLE ALTER COLUMN SET DATA TYPE statement on an existing decimal column on a versioned table

You might need to drop and recreate the table if the object descriptor for the table exceeds 30,000 bytes. Alternatively, you can reduce the size of the object descriptor for the table by reducing the size of the default value for varying-length columns in the table by issuing an ALTER TABLE ALTER COLUMN SET DEFAULT statement. You can also drop unnecessary column defaults to reduce the size of the object descriptor for the table.

Altering the attributes of an existing identity column:

Existing values for the identity column are unaffected by the ALTER TABLE statement. The changed identity column attributes affect values generated after the ALTER statement has executed. DB2 does not validate any of the existing identity column values against the new identity column attributes. For example, duplicate values might be generated even if NO CYCLE is in effect, such as when an ascending identity column altered to become a descending identity column.

Any existing values in the cache that have not yet been used might be lost. Loss of cached values can also occur if the ALTER statement returns an error or is rolled back.

Pending changes to the definition of a table:

Issuing the ALTER TABLE statement with certain options can cause a pending change to the definition of a table. When an ALTER TABLE statement that causes pending changes to the definition is executed, semantic validation and authorization checking are performed. However, changes to the table definition and data are not applied and the table space is placed in advisory REORG-pending state (AREOR). The pending changes are recorded in the SYSIBM.SYSPENDINGDDL catalog table. Run the REORG utility with the SHRLEVEL CHANGE or SHRLEVEL REFERENCE options on the table space to apply the pending changes to the definition and data of the table space. When the pending changes are applied, dependent packages are invalidated, the corresponding entries in the SYSIBM.SYSPENDINGDDL catalog table are removed, and the advisory REORG-pending state is removed.

The following ALTER TABLE options can cause pending changes to the definition of the table under certain conditions:

- DROP COLUMN, if the data sets of the table space are already created
- ALTER PARTITION, to change the limit keys for the following types of partitioned table spaces:
  - Range-partitioned universal table spaces
  - Partitioned table spaces (non-universal) with table-controlled partitioning
Restrictions when objects have pending definition changes:
The following statements cannot be executed if the table space, or any
objects within that table space, has pending definition changes:
- ALTER TABLE with immediate options
- CREATE INDEX on the table
- ALTER INDEX ADD COLUMN or ADD INCLUDE COLUMN of any
  index defined on the table
- ALTER INDEX REGENERATE of any index defined on the table

The following statements cannot be executed if the table has pending
definition changes:
- CREATE TRIGGER on the table
- CREATE TRIGGER of an INSTEAD OF trigger on a view that is
dependent the table
- CREATE PERMISSION on the table or that references the table
- CREATE MASK on the table or that references the table
- CREATE FUNCTION of an inline SQL table function that references the
table
- CREATE TABLE or ALTER TABLE that defines a materialized query
table that references the table

The following statements cannot be executed if the table contains any
columns with pending definition changes:
- CREATE VIEW that references a column with pending definition
  changes
- ALTER TABLE with the ADD VERSIONING clause that references a
  history table that contains columns with pending definition changes
- ALTER TABLE with the ENABLE ARCHIVE clause that references an
  archive table that contains columns with pending definition changes

Adding a LOB column:
If the table space that contains the table is implicitly created and you add a
LOB column to the table, the following object are implicitly created:
- A LOB table space
- An auxiliary table
- An auxiliary index

If the base table is involved in a clone relationship, implicitly created LOB
table spaces and implicitly created indexes are always created with the
DEFINE YES attribute.

Adding a ROWID column:
When you add a ROWID column to an existing table, DB2 ensures that the
same, unique row ID value is returned for a row whenever it is accessed. If
the table already has an implicitly hidden ROWID column, DB2 also
ensures that the values in the two ROWID columns are identical.

If the table space that contains the table is implicitly created and you add a
ROWID column that is defined as GENERATED BY DEFAULT to the table,
an enforcing index for the ROWID column is implicitly created. If the table
already has an implicitly hidden ROWID column and the ROWID column
that you add is defined as GENERATED BY DEFAULT, DB2 changes the
implicitly hidden ROWID column to have the GENERATED BY DEFAULT
attribute and does not implicitly create an enforcing index for the ROWID
column.
When you add a ROWID column that is defined as GENERATED BY DEFAULT and the ROWID index is implicitly created, the privilege set requires the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created ROWID index is owned by the owner of the table.

Reorganizing a table space has no effect on the values in a ROWID column.

**Adding an identity column:**
When you add an identity column to a table that is not empty, DB2 places the table space that contains the table in the REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the identity column in all existing rows and then removes the REORG pending status. These values are guaranteed to be unique, and their order is system-determined.

**Adding a row change timestamp column:**
When you add a row change timestamp column to an existing table, the initial value for existing rows is not stored at the time of the ALTER statement. DB2 places the table space into an advisory-REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the row change timestamp column in all existing rows and then removes the REORG pending status. These values will not change unless the row is updated.

**XML version support when adding an XML column:**
When an XML column is added to a table that is in a universal table space, the XML column and the associated XML table will support XML versions if it is the first XML column in the table or if all the other XML columns in the table support XML versions. Similarly, when a clone table is associated with the base table, any XML columns and associated XML tables will support XML versions if the existing XML columns in the base table support XML versions.

**Effect of adding a column on views:**
Adding a column to a table has no effect on existing views.

**Considerations for implicitly hidden columns:**
A column that is defined as implicitly hidden can be explicitly referenced on the ALTER statement. For example, an implicitly hidden column can be altered, can be specified as part of a referential constraint or a check constraint, or a materialized query table definition.

**Cascaded effects of adding or altering a column:**
Adding a column to a table has no cascaded effects to views that reference the table. For example, adding a column to a table does not cause the column to be added to any dependent views, even if those views were created with a SELECT clause. But altering a column can cause other cascaded effects. The following table lists the cascaded effect of altering the data type, precision, scale, or length of a column.
<table>
<thead>
<tr>
<th>Operation</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alter of a column referenced by a view</td>
<td>If the data type, length, precision, or scale for a column is altered, all the views that are dependent on the altered table are reevaluated at alter time with the new column attributes. If errors are encountered during the view regeneration process, the ALTER TABLE statement fails. The new internal structure of each dependent view is not saved at alter time, and subsequent references to a dependent view will cause the view to be regenerated again. Use the ALTER VIEW statement to regenerate a dependent view and have the new internal structure saved.</td>
</tr>
<tr>
<td>Alter of a column referenced in the key of an index or a unique constraint (unique key or primary key)</td>
<td>The alter is allowed unless DECIMAL with a fraction is being converted to a floating value. In this case, the loss of precision can result in a loss of uniqueness. For numeric data type conversions, the index is placed in REBUILD-pending status. For character data type conversions, the index key columns are converted on first-write access. The index is not placed in REBUILD-pending status.</td>
</tr>
<tr>
<td>Alter of a column referenced in a package</td>
<td>The alter is allowed. All packages dependent on the table in which the column is being altered are invalidated.</td>
</tr>
<tr>
<td>Alter of a column referenced in the body of a user-defined function or procedure</td>
<td>Alter is allowed. If there is a package associated with the function or procedure, it is invalidated.</td>
</tr>
<tr>
<td>Alter of a column referenced in the parameter list of a user-defined function or procedure</td>
<td>Alter is allowed. The attributes of the existing function or procedure are unchanged. To access the new definition of the column, the function or procedure must be dropped and recreated.</td>
</tr>
<tr>
<td>Alter of a column referenced by a trigger</td>
<td>Alter is allowed. All trigger packages that are dependent on the table of the column are invalidated.</td>
</tr>
<tr>
<td>Alter of a column referenced in a CHECK constraint</td>
<td>Alter is not allowed.</td>
</tr>
</tbody>
</table>

**Adding a partition:**
When you add a partition to a table, if the boundary for the last partition was not previously enforced, it is enforced after the partition is added, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before the new one is added was in REORG-pending status, the added partition is also placed in REORG-pending status.

**Adding a partition for a table that is in a partition-by-growth table space and has LOB columns:**
If a table resides in the partition-by-growth table space that has LOB columns, its associated LOB table spaces can be created either explicitly or implicitly when the base table is created, depending on value that is in effect for SQLRULES:
• When SQLRULES = STD, the LOB table space is created implicitly for the first partition or for the number of partitions in the NUMPARTS clause, if it is specified in the CREATE TABLESPACE statement.

• When SQLRULES = DB2, the table definition will remain incomplete until the LOB table space is explicitly created for the first partition or for the number of partitions in the NUMPARTS clause, if it is specified in the CREATE TABLESPACE statement. In this case, if the LOB table space is not created before the first SQL data change statement operates against the table, the table that resides in the partition-by-growth table space remains with its definition in incomplete state. The table cannot be updated through SQL or LOAD.

Attributes that are inherited from the previous LOB table space partition when a LOB table space is created implicitly:
The following attributes apply to implicitly created LOB table space:
• BUFFERPOOL
• DATASET
• ERASERULE
• GBPCACHE
• LOCKMAX
• LOG
• CLOSE
• DSSIZE
• LOCKSIZE

Row format for newly added partitions:
When the value of the RRF subsystem parameter is ENABLE, newly added partitions that are created using the ADD PARTITION clause (or partitions that are added because the table space is partition-by-growth) will be created in re-ordered row format. When the value of the RRF subsystem parameter is DISABLE, newly added partitions will be created in basic row format, except for the following table spaces:
• For table spaces that are already using basic row format and that contain tables with edit procedures, newly created partition will always be in basic row format regardless of value of the RRF parameter.
• For table spaces that are already using re-ordered row format and that contain tables with edit procedures, newly created partition will always be in re-ordered row format regardless of value of the RRF parameter.
• Newly created partitions of an XML table space will always be in re-ordered format.

Rotating a partition from first to last:
Running ALTER TABLE to rotate the first logical partition to become the last logical partition can be very time consuming. During the reset operation, all rows from the partition are deleted. In addition, the keys for the deleted rows are also deleted from all nonpartitioned indexes, which requires that each nonpartitioned index must be scanned.

When you rotate partitions, if the boundary for the last partition was not previously enforced, it is enforced after ROTATE FIRST TO LAST is issued, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before ROTATE FIRST TO LAST was issued was in REORG-pending status, the last two logical partitions are left in REORG-pending status.
Effect of changes on applications:
Applications might need to be changed to correspond to changes to the
columns in a table. For example, if you increase the length of a column,
you need to increase the length of variables into which that column is
fetched. If you change the data type of a column, you also might need to
change the data type of the corresponding variable to avoid performance
degradation.

If you rename or drop a column, you need to change any references to that
column to avoid unexpected results.

Invalidation of packages:
All of the packages that refer to the table are invalidated when any of the
following conditions are true:
• The table is a created temporary table or a materialized query table.
• The table is changed to add or drop a materialized query definition.
• The AUDIT attribute of the table is changed.
• A DATE, TIME, TIMESTAMP WITHOUT TIME ZONE, or TIMESTAMP
  WITH TIME ZONE column is added and its default value for added
  rows is CURRENT DATE, CURRENT TIME, CURRENT TIMESTAMP
  (with corresponding timestamp precision) WITHOUT TIME ZONE, or
  CURRENT TIMESTAMP (with corresponding timestamp precision)
  WITH TIME ZONE respectively.
• A security label is added.
• The length attribute of a CHAR, VARCHAR, GRAPHIC, VARGRAPHIC,
  BINARY, or VARBINARY column has changed. See Table 108 on page
  1060
• A column data type, precision, scale, or subtype is changed.
• A column is renamed.
• The table is partitioned and a partition is added or one of the existing
  partitions is changed or rotated
• An identity attribute of an identity column has changed
• A column is dropped

When a referential constraint is defined with a delete rule of CASCADE or
SET NULL, all packages that refer to the parent table of the constraint are
invalidated. Furthermore, all packages that refer to tables from which
deletes cascade to this parent table are also invalidated.

Altering a base table or a user-maintained materialized query table to
change it to a system-maintained materialized query table causes any
packages that are dependent on the table to be invalidated because data
change statements are not allowed on system-maintained materialized
query tables. Altering a materialized query table to change it to a base
table causes any packages that are dependent on the table to be invalidated
because the REFRESH TABLE statement is invalid on a base table.

Invalidation of packages by RENAME COLUMN:
ALTER TABLE RENAME COLUMN will invalidate any package that is
dependent on the table in which the column is renamed. Any attempt to
execute the invalidated package will trigger an automatic rebind of the
package.

The automatic rebind will fail if the column is referenced in the package
because the referenced column no longer exists in the table. In this case,
applications that reference the package need to be modified, recompiled,
and rebound to return the expected result.

The automatic rebind will succeed in either of the following cases:

- The package does not reference the column. In this case, the renaming of
  the column does not affect the query results that are returned by the
  package. The application does not need to be modified as a result of
  renaming the column.
- The package does reference the column, but after the column is
  renamed, another column with the name of the original column is added
  to the table. In this case, any query that references the name of the
  original column might return a different result set. In order to restore the
  expected results, the application would need to be modified to specify
  the new column name.

Example: The following scenario shows how renaming a column can cause
a package to return unexpected results:

```sql
CREATE TABLE MYTABLE (MYCOL1 INT);
INSERT INTO TABLE MYTABLE
VALUES (1);
SELECT MYCOL1 FROM MYTABLE -- this is the statement in
    -- the package MYPACKAGE,
    -- the query returns
    -- a value of 1

ALTER TABLE MYTABLE
    RENAME COLUMN
    MYCOL1 TO MYCOL2; -- MYPACKAGE is invalidated
        -- and automatic rebinding
        -- of MYPACKAGE will fail
        -- at this point

ALTER TABLE MYTABLE
    ADD COLUMN MYCOL1 VARCHAR(10); -- automatic rebinding
        -- of MYPACKAGE
        -- will be successful

INSERT INTO TABLE MYTABLE (MYCOL1)
VALUES ('ABCD');
```

At this point an application executes MYPACKAGE, which results in a
successful automatic rebind. However, the statement in the package will
return ‘ABCD’ instead of the expected ‘1’.

Dropping constraints and check pending status:
If a table space or partition is in check pending status because it contains a
table with rows that violate constraints, dropping the constraints removes
the check pending status.

Altering materialized query tables:
The ALTER TABLE statement can be used to register an existing table at
the current server as a materialized query table, change the attributes of an
existing materialized query table, or change an existing materialized query
table into a base table.

The isolation level at the time when a base table is first altered to become a
materialized query table by the ALTER TABLE statement is the isolation
level for the materialized query table.

Altering a table to change it to a materialized query table with query
optimization enabled makes the table eligible for use in query rewrite
immediately. Therefore, pay attention to the accuracy of the data in the
table. If necessary, the table should be altered to a materialized query table
with query optimization disabled, and then the table should be refreshed
and enabled with query optimization.
When a base table is altered into a materialized query table or a user-maintained query table is altered into a system-maintained one, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS contains the current timestamp. When a system-maintained materialized query table is altered into a user-maintained materialized query table, the REFRESH_TIME column of the row for the table in SYSIBM.SYSVIEWS does not change.

The LOAD utility is not allowed on a system-maintained query table, but it is allowed on a user-maintained materialized query table.

Considerations for running utilities while altering tables:
You cannot execute the ALTER TABLE statement while a utility has control of the table space that contains the table.

Restrictions on field procedures, edit procedures, and validation exit procedures:
Field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.
Consider using triggers to replace the functionality on field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

Restrictions on SQL data change statements in the same commit scope as ALTER TABLE:
SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER TABLE statements that affect that index.

Restrictions on DATA CAPTURE CHANGES:
If the table is in advisory REORG-pending state, you cannot alter the table to use the DATA CAPTURE CHANGES clause.

Capturing changes to the DB2 catalog:
To have logged changes to a DB2 catalog table augmented with information for data capture, specify ALTER TABLE xxx DATA CAPTURE CHANGES where xxx is the name of a catalog table (SYSIBM.xxx). Data capture of catalog table changes provides the possibility of creating and managing a shadow of the catalog.

When changes to the hash organization of a table take place:
An alter of the table that uses hash organization will take effect immediately in terms of enforcing the unique hash key. However, the physical organization of the table space is converted to hash organization after REORG.

In a range-partitioned universal table space, if individual partitions are altered to specify HASH SPACE, the new hash space values take effect after the REORG utility is run on the individual partitions.

Buffer pool, DSSIZE, and MAXPARTITIONS considerations for tables using hash organization:
DB2 will calculate an optimum buffer pool size for hash organization based on the definition of the table and validate the calculated buffer pool size with the buffer pool of the explicitly created table space. If the buffer pool sizes are different, DB2 will return an error.
If the table is a range-partitioned universal table space, the DSSIZE value for the table space must be large enough to fit the HASH SPACE specification for each partition.

If the table is in a partition-by-growth table space, the total space calculated from the DSSIZE and MAXPARTITIONS values for the table space must be large enough for the implicitly or explicitly specified HASH SPACE.

**Changing the hash space value:**
To change the HASH SPACE value for all partitions of a range-partitioned universal table space or to change the total HASH SPACE for a partition-by-growth table space, use the ALTER ORGANIZATION SET HASH SPACE (integer) clause. To change HASH SPACE value for more than one, but not all partitions of a range-partitioned universal table space you must specify separate ALTER TABLE statements for each partition and specify the ALTER PARTITION (integer) and HASH SPACE (integer) clauses.

**Hash space and DB2 page size:**
If the specified hash space is less than or equal to 64 MB (the DB2 default), DB2 will add extra space for DB2 system pages. If the specified hash space is greater than 64 MB, DB2 will use part of the hash space for DB2 system pages. The amount of space needed for DB2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/or PAGESIZE becomes, the larger the requirement for DB2 system pages. DB2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

**Hash space and DSSIZE:**
Depending on certain table space characteristics, DB2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. DB2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

**Specifying APPEND for tables that use hash organization:**
Append processing is not applicable to tables with hash organization since there is no key clustering in hash organization. For insert operations into tables with hash organization, DB2 will use the internal hash algorithm to determine the location of the row.

**Restrictions for tables with hash organization:**
Tables that use hash organization are subject to the following restrictions:
- If the table already uses hash organization, DB2 will returns an error.
- A table that is defined to use hash organization cannot be created in a LOB table space or XML table space.
- The data type of columns that are specified in a hash key cannot be changed.
- Partition level REORG is not allowed after the table is changed using the ALTER ADD HASH ORGANIZATION clause or the ALTER DROP ORGANIZATION clause.
- The MAXROWS clause is applicable only to the hash overflow area of the table space for tables with hash organization. The fixed hash area of each page will contain as many rows as it can hold, up to a maximum of 255.
DB2 implicitly creates a hash overflow index when hash organization is added to a table. The hash overflow index is in rebuild-pending state until the REORG utility is run.

**Restrictions for tables with dropped columns:**
Dropping of table columns is a pending definition change. A table space that contains a table with dropped columns cannot be recovered to a point in time before dropping of those columns was materialized.

**Row access control that is activated explicitly:**
The ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table. When this happens, a default row permission is implicitly created and allows no access to any rows of the table, unless later another enabled row permission exists that provides access for the authorization IDs or roles that are specified in the definition of the permission. The default row permission is always enabled.

When the table is referenced in a data manipulation statement, all enabled row permissions that have been created for the table, including the default row permission, are implicitly applied by DB2 to control which rows in the table are accessible. A row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. This derived search condition acts as a filter to the table before any user specified operations such as predicates, grouping, ordering, etc. are processed. This derived search condition permits the authorization IDs or roles that are specified in the permission definitions to access certain rows in the table. See the description of subselect for information on how the application of enabled row permissions affects the fetch operation. See the data change statements for information on how the application of enabled row permissions affects the data change operation.

When the ACTIVATE ROW ACCESS CONTROL clause is used, all the packages and dynamic cached statements that reference the table are invalidated.

Row access control remains enforced until the DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing it.

**Implicit object that is created when row access control is activated for a table:**
When the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table, DB2 implicitly creates a default row permission for the table. The default row permission prevents all access to the table. The implicitly created row permission is in the same schema of the base table and has a name in the form of `SYS_DEFAULT_ROW_PERMISSION__table-name ... up to 128 UTF-8 bytes. Notice two underscores after 'PERMISSION'. If this name is not unique, the last 4 bytes are reserved for a unique number 'nnnn', where 'nnnn' is a four alphanumeric characters starting at '0000' and is incremented by 1 value each time until a unique name is found. The owner of the default row permission is SYSIBM.

The default row permission is always enabled.

The default row permission is dropped when row access control is deactivated or when the table is dropped.

**Activating column access control:**
The ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for a table. The access to the table is not restricted but when the table is referenced in a data manipulation statement, all
enabled column masks that have been created for the table are applied to mask the column values referenced in the final result table of the queries or to determine the new values used in the data change statements.

When column masks are used to mask the column values, they determine the values in the final result table. If a column has a column mask and the column (a simple reference to a column name or embedded in an expression) appears in the outermost select list, the column mask is applied to the column to produce the values for the final result table. If the column does not appear in the outermost select list but it participates in the final result table, for example, it appears in a materialized table expression or view, the column mask is applied to the column in such a way that the masked value is included in the result table of the materialized table expression or view so that it can be used in the final result table.

The application of column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY. The rows returned in the final result table remain the same, except that the values in the resultant rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY sort-key, the order is based on the original column values and the masked values in the final result table might not reflect that order; similarly, the masked values might not reflect the uniqueness enforced by SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression can become different because the column mask is applied on the column before the expression evaluation can take place. If the expression in a query is the same as the expression used to mask the column value in the column mask definition, the result of the expression in the query might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR( SSN, 8, 4) and the same expression appears in the column mask definition. In this particular example, the user can replace the expression in the query with column SSN to avoid the same expression gets evaluated twice.

The following are the contexts where the column masks are used by DB2 to mask the column values for the result of a query. Certain restrictions might apply to some contexts. Those restrictions are described in a separate list.

- the outermost SELECT clause of a SELECT or SELECT INTO statement, or if the column does not appear in the outermost select list but it participates in the final result table, the outermost SELECT clause of the corresponding materialized table expression or view where the column appears.
- the outermost SELECT clause of a SELECT FROM INSERT, UPDATE, DELETE, or MERGE statement
- the outermost SELECT clause that are used to derive the new values for an INSERT, UPDATE, or MERGE statement, or a SET transition-variable assignment statement
- the same applies to a scalar-fullselect expression that does not use set operators and appears in the outermost SELECT clause of the above statements, the right side of a SET variable assignment statement, the VALUES INTO statement, or the VALUES statement.
• the same applies to the SQL statements or the equivalences such as the assignment statement that appears in a native SQL procedure or a non-inline user-defined SQL function.

If a CASE expression appears in the above contexts, the column masks are not applied in the search conditions of the WHEN clauses.

A column mask is created as a stand alone object without knowing all of the contexts in which it might be used. To mask a column value in the final result table, the column mask definition is merged into the statement by DB2. When the column mask definition is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of a column mask can return an error. The following describes when the error might be returned:

1. The column masks cannot be applied to the columns in the select lists that derive the final result table of set operations because one of the set operators that are used to derive the final result table is EXCEPT ALL, EXCEPT DISTINCT, INTERSECT ALL, or INTERSECT DISTINCT.

2. The column mask cannot be applied to the column in the select lists of a scalar-fullselect expression if the result of scalar-fullselect expression is derived from set operation EXCEPT or INTERSECT.

3. If the subselect contains a GROUP BY clause, the column mask cannot be applied to a column in the corresponding select list if none of the following conditions is satisfied:
   • The column must identify a column-name in the GROUP BY clause and the column must not be referenced in an expression in the GROUP BY clause. Furthermore, its column mask definition must satisfy the following condition:
     – any columns that are referenced in the column mask definition that come from the same table of the column to which the column mask is applied must identify a column-name in the GROUP BY clause
     – the column mask must not be referenced in an expression in the GROUP BY clause
   • The column must be specified under an aggregate function and its column mask definition must satisfy the following conditions:
     – The column mask definition must not reference a scalar-fullselect
     – The column mask definition must not reference an aggregate function

4. If the subselect contains a GROUP BY clause, and a column in the corresponding select list maps directly or indirectly to a column name or an expression in a materialized table expression or view, the column in the subselect where the GROUP BY is specified must be specified under an aggregate function.

5. If the subselect does not contain a GROUP BY clause, and a column in the corresponding select list is specified under an aggregate function, the column mask cannot be applied if the column mask definition references:
   • a scalar-fullselect
   • an aggregate function
6. If the FROM clause in a subselect references a recursive common table expression, and if the result of the recursive common table expression is used to derive the final result table, the column mask cannot be applied to a column that is referenced in the fullselect of the recursive common table expression.

7. If the FROM clause in a subselect contains a data-change-table-reference, and if an INCLUDE clause is specified as part of the SQL data change statement, the column mask cannot be applied to the columns that are used to derive the values for these additional columns in the outermost select list.

8. If the FROM clause in a subselect references an external table user-defined function or an inline SQL table user-defined function, and if the result of the function is used to derive the final result table, the column mask cannot be applied to the column that is an argument of the function.

9. If an OLAP specification is referenced in a select list that derives the final result table, the column mask cannot be applied to the column that is referenced in the partitioning expression or the sort key expression of the OLAP specification.

10. If a user-defined function is defined with the NOT SECURED option, the argument of the function must not reference a column for which a column mask is enabled and the column access control is activated for its table. This rule applies to user-defined functions that are referenced anywhere in the statement.

To avoid the above error situations at bind time, one of the following actions must be taken:

- modify or remove the above contexts from the statement
- disable the column mask
- drop the column mask, modify the definition, and recreate the column mask
- deactivate the column access control for the table

In other situations, if the statement contains a SELECT DISTINCT, and a column mask is applied to a column that directly or indirectly derives the result of SELECT DISTINCT, the statement might return a result that is not deterministic. The following examples illustrate when such results might be returned:

1. If the column mask definition references other columns from the same table of the column to which the column mask is applied, the result of SELECT DISTINCT can not be deterministic.

2. If the column is referenced in the argument of built-in scalar functions (such as COALESCE, IFNULL, NULLIF, MAX, MIN, LOCATE, TOTALORDER), the result of SELECT DISTINCT might not be deterministic.

3. If the column is referenced in the argument of an aggregation function, the result of SELECT DISTINCT might not be deterministic. If DISTINCT is specified, the argument of the function must not reference a column with a column mask.

4. If the column is embedded in an expression and the expression contains a function that is not deterministic or has an external action, the result of SELECT DISTINCT might not be deterministic.
With UNION DISTINCT, the elimination of the duplicate rows is based on the unmasked values in R1 and R2. Because all rows are from R1 or R2, the output values in the result table of the union may vary when one or more of the following conditions occur:

- The expression corresponding to the \( n \)th column in R1 references columns with column masks, but the expression corresponding to the \( n \)th column in R2 does not, or vice versa.
- The expressions corresponding to the \( n \)th column in R1 and R2 reference columns with different column masks.
- The column mask definition references columns that are not the same target column for which the column mask is defined, and those columns are not part of the UNION DISTINCT operation. It is recommended that the column mask definition does not reference other columns from the target table.

For example, a row in R1 is derived from the masked value, and a row in R2 is derived from the unmasked value. If the row in the result table is from R1, the masked value is returned. If the row in the result table is from R2, the unmasked value is returned.

EXCEPT and INTERSECT can be intermixed with UNION if the rows in R1 and R2 for EXCEPT and INTERSECT do not reference columns with column masks.

If the column is not nullable, most likely its column mask definition will not consider a null value for the column. After the column access control is activated for the target table, if the target table is the null-padded table in an outer join operation, the column value in the final result table might be a null.

When the columns are used to derive the new values for an INSERT, UPDATE, MERGE, or a SET transition-variable assignment statement, the original column values, not the masked values, are used. If the columns have column masks, those column masks are applied to ensure the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules described above for the final result table of a query. See the data change statements for how the column masks are used to affect the insertability and updatability.

A column mask can be applied only to a base table column. If a materialized table expression, materialized view, or common table expression column is involved in the final result table, the above error situations can occur inside the materialized table expression, materialized view, or common table expression definition.

Column access control does not affect the XMLTABLE built-in function. If the input to the XMLTABLE function is a column with a column mask, the column mask is not applied.

When the ACTIVATE COLUMN ACCESS CONTROL clause is used, all the packages and dynamic cached statements that reference the table are invalidated. However, if no enabled column mask exists for the table, the invalidation does not occur.
Column access control remains activated until the DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing it.

**Row and column access control are not enforced when EXPLAIN tables are populated by DB2:**
Row and column access control can be enforced for EXPLAIN tables. However, the enabled row permissions and column masks are not applied when DB2 inserts rows into those tables.

**Stop enforcing row or column access control:**
The DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing row access control for a table. The default row permission is dropped. Thereafter, when the table is referenced in a data manipulation statement, explicitly created row permissions are not applied. The table is accessible based on the granted privileges.

The DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing column access control for a table. Thereafter, when the table is referenced in a data manipulation statement, the column masks are not applied. The unmasked column values are used for the final result table.

The explicitly created row permissions or column masks, if any, remain but have no effect.

All the packages and dynamic cached statements that reference the table are invalidated when row or column access control is deactivated.

**Secure triggers for row and column access control:**
Triggers are used for database integrity, and as such a balance between row and column access control (security) and database integrity is needed. Enabled row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for any transition variables or transition tables referenced in the trigger body. To ensure there is no security concern for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created or altered with the SECURED option. If a trigger is not secure, row and column access control cannot be enforced for the triggering table.

**Secure user-defined functions for row and column access control:**
If a row permission or column mask definition references a user-defined function, the function must be altered with the SECURED option because the sensitive data might be passed as arguments to the function.

DB2 considers the SECURED option an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. It is assumed that such a control audit procedure is in place for all versions of the user-defined function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

**Database operations where row and column access control is not applicable:**
Row and column access control must not compromise database integrity. Columns involved in primary keys, unique keys, indexes, check constraints, and referential integrity (RI) must not be subject to row and column access control. Column masks can be defined for those columns but they are not applied during the process of key building or constraint or RI enforcement.

**Read-only cursors and read-only views:**
The rules that are used to determine a read-only cursor or a read-only
view remain unaffected by row and column access control because those rules are determined at bind time. The effect of application of enabled column masks is not known until run time. Therefore, the data change operation on a writable cursor or a writable view could still fail at run time.

Considerations for adding a column to a system-period temporal table or archive-enabled table:

- If the data type of the column is a distinct type:
  - The owner of the history table or archive table must implicitly or explicitly have the USAGE privilege on the distinct type.
  - If the distinct type is unqualified, its schema matches the schema for the following objects:
    - The implicit schema for the distinct type for the column in the history table is the same as the implicit schema that is determined for the distinct type in the system-period temporal table.
    - The implicit schema for the distinct type for the column in the archive table is the same as the implicit schema that is determined for the distinct type in the archive-enabled table.

- The syntax LONG VARCHAR or LONG VARGRAPHIC must not be specified when you add a column to these types of tables. Use VARCHAR or VARGRAPHIC instead.

- If the data type of the column is a LOB and the INLINE LENGTH clause is not specified, DB2 determines the length. The implicit inline length that is used for the column in the system-period temporal table or archive-enabled table is also used for the corresponding column in the history table or archive table.

- If the data type of the column is a LOB, auxiliary objects are implicitly created for it in the system-period temporal table or archive-enabled table. Auxiliary objects are also created for the corresponding column of the history table or archive table.

Effect of renaming a column on statistics profiles:

When you execute ALTER TABLE with RENAME COLUMN, statistics profiles that refer to that column are no longer valid. An error occurs when RUNSTATS is run with a profile that contains a renamed column. After you execute ALTER TABLE with RENAME COLUMN, complete these tasks:

1. Delete any statistics profiles that refer to the renamed column.
2. Create the statistics profiles again.

Related information:

- Syntax and options of the RUNSTATS control statement (DB2 Utilities)
- The statistics profile syntax (DB2 Utilities)
- Deleting statistics profiles (DB2 Performance)
- Creating statistics profiles (DB2 Performance)

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
• NOMINVALUE (single clause) as a synonym for NO MINVALUE
• NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
• NOORDER (single clause) as a synonym for NO ORDER
• PART integer VALUES can be specified as an alternative to PARTITION integer ENDING AT.
• VALUES as a synonym for ENDING AT
• DEFINITION ONLY as a synonym for WITH NO DATA
• SET MATERIALIZED QUERY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
• SET SUMMARY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
• SET MATERIALIZED QUERY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
• SET SUMMARY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
• TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Column DEPTNAME in table DSN8B10.DEPT was created as a VARCHAR(36). Increase its length to 50 bytes. Also, add the column BLDG to the table DSN8B10.DEPT. Describe the new column as a character string column that holds SBCS data.

```sql
ALTER TABLE DSN8B10.DEPT
ALTER COLUMN DEPTNAME SET DATA TYPE VARCHAR(50)
ADD BLDG CHAR(3) FOR SBCS DATA;
```

Example 2: Assign a validation procedure named DSN8EAEM to the table DSN8B10.EMP.

```sql
ALTER TABLE DSN8B10.EMP
VALIDPROC DSN8EAEM;
```

Example 3: Disassociate the current validation procedure from the table DSN8B10.EMP. After the statement is executed, the table no longer has a validation procedure.

```sql
ALTER TABLE DSN8B10.EMP
VALIDPROC NULL;
```

Example 4: Define ADMRDEPT as the foreign key of a self-referencing constraint on DSN8B10.DEPT.

```sql
ALTER TABLE DSN8B10.DEPT
FOREIGN KEY (ADMRDEPT) REFERENCES DSN8B10.DEPT ON DELETE CASCADE;
```

Example 5: Add a check constraint to the table DSN8B10.EMP which checks that the minimum salary an employee can have is $10,000.

```sql
ALTER TABLE DSN8B10.EMP
ADD CHECK (SALARY >= 10000);
```

Example 6: Alter the PRODINFO table to define a foreign key that references a non-primary unique key in the product version table (PRODVER_1). The columns of the unique key are VERNAME, RELNO.

```sql
ALTER TABLE PRODINFO
FOREIGN KEY (PRODNAMERO) REFERENCES PRODVER_1 (VERNAME, RELNO) ON DELETE RESTRICT;
```
Example 7: Assume that table DEPT has a unique index defined on column DEPTNAME. Add a unique key constraint named KEY_DEPTNAME consisting of column DEPTNAME to the DEPT table:

```
ALTER TABLE DSN8B10.DEPT
ADD CONSTRAINT KEY_DEPTNAME UNIQUE( DEPTNAME );
```

Example 8: Register the base table TRANSCOUNT as a materialized query table. The result of the fullselect must provide a set of columns that match the columns in the existing table (same number of columns, same column definitions, and same names). So that you can maintain the table with insert, update, and delete operations as well as the REFRESH TABLE statement, define the materialized query table as user-maintained.

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY
(SELECT ACCTID, LOCID, YEAR, COUNT(*) as cnt
 FROM TRANS
 GROUP BY ACCTID, LOCID, YEAR )
DATA INITIALLY DEFERRED
REFRESH DEFERRED
MAINTAINED BY USER;
```

Example 9: Assume that table TB1 has a column, COL1 that is defined as CHAR(4) FOR BIT DATA WITH DEFAULT 'AB'. The value that is stored in the table will be X'C1C24040'. After the following ALTER TABLE statement is run, the resulting value that is stored in the table will be BX'C1C240400000':

```
ALTER TABLE TB1
ALTER COLUMN COL1
SET DATA TYPE BINARY(6);
```

**Examples for column access controls**

Example 1:

Based on the data in the CUSTOMER table, the SELECT DISTINCT statement returns one row with the SALARY value 100,000. A column mask, SALARY_MASK, is created to mask the salary value. After column access control is activated for the CUSTOMER table, the column mask is applied to SALARY column. A user with the 'MGR' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of the SALARY column, but the value that is returned in that row is based on the masked SALARY value, which can be either 125,000 or 110,000.

The table CUSTOMER contains:

<table>
<thead>
<tr>
<th>SALARY</th>
<th>COMMISSION</th>
<th>EMPID</th>
</tr>
</thead>
<tbody>
<tr>
<td>100,000</td>
<td>25,000</td>
<td>123456</td>
</tr>
<tr>
<td>100,000</td>
<td>10,000</td>
<td>654321</td>
</tr>
</tbody>
</table>

CREATE MASK SALARY_MASK ON CUSTOMER
FOR COLUMN SALARY RETURN
CASE WHEN(SESSION_USER = 'MGR')
    THEN SALARY + COMMISSION
    ELSE SALARY
END
ENABLE;
COMMIT;
ALTER TABLE CUSTOMER
Example 2:
Based on the data in T1 and T2 tables, the SELECT DISTINCT statement using the COALESCE function returns one row with the T1.C1 value of 1. A column mask, C1_MASK, is created to mask the value of T1.C1. After column access control is activated for table T1, the column mask is applied to column C1 of table T1. A user with the 'EMP' ID (or role) issues a SELECT DISTINCT statement. The SELECT DISTINCT statement still returns one row because the removal of duplicates is based on the unmasked value of T1.C1 from the COALESCE function, but the value that is returned in that row is based on the masked value of T1.C1 from the COALESCE function. The returned value can be either 2 or 3.

Example 3:
Based on the data in the CUSTOMER table, the maximum income is the same in the states CA and IL, 50,000, thus, the SELECT DISTINCT statement returns one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column before the MAX aggregate function is evaluated. However, the INCOME_MASK column mask, masks the income value of 0 as 100,000 in state IL. As a result, the maximum income becomes 100,000 for state IL, but the maximum income is still 50,000 for state CA. X.B is used in a predicate in the SELECT DISTINCT statement, therefore, the original INCOME values and the original results of the MAX(INCOME) function must be preserved. So the SELECT DISTINCT statement still returns one row, but the value in that row might not be deterministic, that is, the value might be 50,000 from the 'CA' row or might be 100,000 from the 'IL' row.

The CUSTOMER table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA</td>
<td>40,000</td>
</tr>
<tr>
<td>CA</td>
<td>50,000</td>
</tr>
</tbody>
</table>
CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
CASE WHEN(INCOME = 0)
    THEN 100000
ELSE INCOME
    END
ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
    ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;

SELECT DISTINCT B FROM
    (SELECT STATE, MAX(INCOME) FROM CUSTOMER
        GROUP BY STATE)
    X(A, B)
WHERE B > 10000;

Example 4:

The expression INCOME + RAND() is not deterministic because the RAND function is not deterministic. Based on the data in the CUSTOMER table, the SELECT DISTINCT statement will, most likely, return two distinct rows. However, it could return only one row. A column mask, INCOME_MASK, is created to mask the income value. After column access control is activated for the CUSTOMER table, the column mask is applied to the INCOME column, which causes the masked value for both rows to be the same. Because the RAND function is not deterministic, the SELECT DISTINCT statement will, most likely, still return two distinct rows, but it could return only one row. The uncertainty caused by the RAND function causes the result of the SELECT DISTINCT statement to not be deterministic.

The CUSTOMER table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA</td>
<td>40,000</td>
</tr>
<tr>
<td>CA</td>
<td>50,000</td>
</tr>
</tbody>
</table>

CREATE MASK INCOME_MASK ON CUSTOMER
FOR COLUMN INCOME RETURN
CASE WHEN(INCOME = 40,000)
    THEN 500000
ELSE INCOME
    END
ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
    ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;
```sql
SELECT DISTINCT A FROM
(SELECT INCOME + RAND() FROM CUSTOMER)
X(A)
WHERE A > 10000;
```

*Example 5:*

A column mask, `STATE_MASK`, is created for the `STATE` column of the `CUSTOMER` table to return a value that shows the city name with the state if the city is SJ, SFO, or OKLD. Otherwise the city is not returned, just the state. After column access control is activated for the `CUSTOMER` table, a `SELECT` statement which groups results using the `STATE` column is issued. However, because the `CITY` column that is referenced in the `STATE_MASK` column mask is not a grouping column, a bind time error is returned to signify that the `STATE_MASK` column mask is not appropriate for this statement.

The `CUSTOMER` table contains:

<table>
<thead>
<tr>
<th>STATE</th>
<th>CITY</th>
<th>INCOME</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA</td>
<td>SJ</td>
<td>40,000</td>
</tr>
<tr>
<td>CA</td>
<td>SC</td>
<td>30,000</td>
</tr>
<tr>
<td>CA</td>
<td>SB</td>
<td>60,000</td>
</tr>
<tr>
<td>CA</td>
<td>SFO</td>
<td>80,000</td>
</tr>
<tr>
<td>CA</td>
<td>OKLD</td>
<td>50,000</td>
</tr>
<tr>
<td>CA</td>
<td>SJ</td>
<td>70,000</td>
</tr>
<tr>
<td>NY</td>
<td>NY</td>
<td>50,000</td>
</tr>
</tbody>
</table>

```sql
CREATE MASK STATE_MASK ON CUSTOMER
FOR COLUMN STATE RETURN
CASE WHEN(CITY = 'SJ')
    THEN CITY, ' '||STATE
WHEN(CITY = 'SFO')
    THEN CITY, ' '||STATE
WHEN(CITY = 'OKLD')
    THEN CITY, ' '||STATE
ELSE ' '||STATE
END
ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;

SELECT STATE, AVG(INCOME) FROM CUSTOMER
GROUP BY STATE
HAVING STATE = 'CA';
```
ALTER TABLESPACE

The ALTER TABLESPACE statement changes the description of a table space at the
current server.

Invocation

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared only if
DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
• Ownership of the table space
• DBADM authority for its database
• SYSADM or SYSCTRL authority
• System DBADM

If the database is implicitly created, the database privileges must be on the implicit
database or on DSNDB04.

If BUFFERPOOL or USING STOGROUP is specified, additional privileges might be
required, as explained in the description of those clauses.

Privilege set: If the statement is embedded in an application program, the
privilege set is the privileges that are held by the owner of the package. If the
statement is dynamically prepared, the privilege set is the union of the privilege
sets that are held by each authorization ID and role of the process.
Syntax

```
ALTER TABLESPACE table-space-name
  BUFFERPOOL bpname
  CCSID ccsid-value
  CLOSE YES
  CLOSE NO
  COMPRESS YES
  COMPRESS NO
  DROP PENDING CHANGES
  DSSIZE integer
  G
  LOCKMAX SYSTEM
  LOCKMAX integer
  LOCKSIZE ANY
  LOCKSIZE TABLESPACE
  LOCKSIZE TABLE
  LOCKSIZE PAGE
  LOCKSIZE ROW
  LOCKSIZE LOB
  LOGGED
  NOT LOGGED
  MAXROWS integer
  MAXPARTITIONS integer
  MEMBER CLUSTER YES
  MEMBER CLUSTER NO
  SEGSIZE integer
  TRACKMOD YES
  TRACKMOD NO
  using-block
  free-block
  gbpcache-block
```

Notes:

1. If you specify DROP PENDING CHANGES, DSSIZE, or SEGSIZE, no other clauses can be specified in the same ALTER TABLESPACE statement.

2. The same clause must not be specified more than one time in a single ALTER TABLESPACE statement. For example, if TRACKMOD YES is specified at the table space level, it must not be specified after ALTER PARTITION.

using-block:
USING VCAT—catalog-name
  USING STOGROUP—stogroup-name
    PRIQTY—integer
    SECQTY—integer
    ERASE YES
    ERASE NO

free-block:

FREEPAGE—integer
  PCTFREE 5
  PCTFREE smallint FOR UPDATE smallint

gbpcache-block:

GBPCACHE CHANGED
  GBPCACHE ALL
  GBPCACHE SYSTEM
  GBPCACHE NONE

Description

database-name.table-space-name

Identifies the table space that is to be altered. The name must identify a table space that exists at the current server. Omission of database-name is an implicit specification of DSNDB04.

If you identify a partitioned table space, you can use the PARTITION clause.

BUFFERPOOL bpname

Identifies the buffer pool that is to be used for the table space. bpname must identify an activated buffer pool.

The privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

If bpname specifies a buffer pool with a smaller page size than the current page size, the maximum record size of all tables in the table space must fit in the smaller page size.

If bpname specifies a buffer pool with a different page size, the table space can only be a universal table space (excluding XML table spaces) or a LOB table space. If the table space is a partition-by-growth universal table space, the page size must be valid depending on the values that are in effect for the MAXPARTITIONS and DSSIZE options of the table space. If the table space is a range-partitioned universal table space, the page size must be valid
depending on the values that are in effect for the current number of partitions and the DSSIZE option of the table space.

The buffer pool change is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or any objects within the base table space.
- The specified buffer pool has a different page size than the buffer pool that is currently being used for the table space.

Otherwise, the change is considered an immediate change.

For an immediate change where the page size of both buffer pools is the same, the table space and all data sets are immediately available. The data sets do not need to be closed and reopened for the table space to be available.

If the change is considered an immediate change, the change to the description of the table space takes effect the next time the data sets of the table space are opened. The data sets can be closed and reopened by using a STOP DATABASE command to stop the table space followed by a START DATABASE command to start the table space.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

When the pending page size change is applied, if the table space is a universal table space that uses partition-by-growth organization, the number of partitions is determined based on the amount of existing data and the new page size value. Changing the page size to be larger can cause automatic creation of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-created partitions independent of whether SQLRULES (DB2) or SQLRULES (STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

**CCSID ccsid-value**

Identifies the CCSID value to be used for the table space. `ccsid-value` must identify a CCSID value that is compatible with the current value of the CCSID for the table space. See "Notes" on page 882 for a list that shows the CCSID to which a given CCSID can be changed and details about changing it.

Do not specify CCSID for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

The CCSID of a table space cannot be changed if any of the following conditions are true:

- The table space contains any table that has an index that contains expressions.
- The table space contains a system-period temporal table or a history table.
- The table space contains an archive-enabled table or an archive table.
- The table space contains an EBCDIC table with a Unicode column.
CLOSE
When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

YES
Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

NO
Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified

COMPRESS
Specifies whether data compression applies to the rows of the table space or partition. Do not specify COMPRESS for a LOB table space or a table space in a work file database.

YES
Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition, or until an insert operation is performed through the INSERT statement or the MERGE statement.

NO
Specifies no data compression. Inserted rows will not be compressed. Updated rows will be decompressed. The dictionary used for compression will be erased when the LOAD REPLACE, LOAD RESUME NO, or REORG utility is run. See DB2 Performance Monitoring and Tuning Guide for more information about the dictionary and data compression.

DROP PENDING CHANGES
Drops pending changes to the definition of the table space and any objects within the table space. Pending changes to the definition of the table space or any object within the table space must exist.

When the DROP PENDING CHANGES clause is specified, no other options are allowed in the same ALTER TABLESPACE statement.

The DROP PENDING CHANGES clause also resets advisory REORG-pending (AREOR) status except for tables that are converting to hash access.

DSSIZE integer G
A value, in gigabytes, that indicates the maximum size for each partition, or for a LOB table space, the maximum size of each data set. DSSIZE can only be specified for a universal table space or a LOB table space. When DSSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.

The following are valid values for integer:

<table>
<thead>
<tr>
<th>integer</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 gigabyte</td>
</tr>
<tr>
<td>2</td>
<td>2 gigabytes</td>
</tr>
<tr>
<td>4</td>
<td>4 gigabytes</td>
</tr>
<tr>
<td>8</td>
<td>8 gigabytes</td>
</tr>
<tr>
<td>16</td>
<td>16 gigabytes</td>
</tr>
<tr>
<td>32</td>
<td>32 gigabytes</td>
</tr>
</tbody>
</table>
64 gigabytes
128G  128 gigabytes
256G  256 gigabytes

If integer is greater than 4, the data sets for the table space must be associated with a DFSMS data class that has been specified with an extended format and extended addressability.

If the table space is a partition-by-growth universal table space, the DSSIZE value must be valid depending on the values that are in effect for the MAXPARTITIONS option and the page size of the table space.

If the table space is a partition by range universal table space, the DSSIZE value must be valid depending on the values that are in effect for the current number of partitions and the page size of the table space.

The DSSIZE value must be valid depending on the maximum PIECESIZE of any associated non-partitioned secondary indexes.

The change to the DSSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and if one of the following conditions is true:

- Pending definition changes already exist for the table space or any associated indexes.
- The specified DSSIZE is different than the value that is currently being used for the table space.

Otherwise, the change takes effect immediately.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the table space is a partition-by-growth universal table space with the pending DSSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new DSSIZE value. Changing the DSSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

**LOCKMAX**

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX a for table space in a work file database, DB2 ignores the value because these types of locks are not used.

*integer*

Specifies the number of locks allowed before escalating, in the range 0 to 2,147,483,647.
Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

**SYSTEM**
Indicates that the value of field LOCKS PER TABLE(SPACE) on installation panel DSNTIPJ specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

If you change LOCKSIZE and omit LOCKMAX, the following results occur:

<table>
<thead>
<tr>
<th>LOCKSIZE</th>
<th>Resultant LOCKMAX</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLESPACE or TABLE</td>
<td>0</td>
</tr>
<tr>
<td>PAGE, ROW, or LOB</td>
<td>Unchanged</td>
</tr>
<tr>
<td>ANY</td>
<td>SYSTEM</td>
</tr>
</tbody>
</table>

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

**LOCKSIZE**
Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not specify LOCKSIZE for a table space in a work file database.

**ANY**
Specifies that DB2 can use any lock size.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (an installation parameter), the page or LOB locks are released and locking is set at the next higher level. If the table space is segmented, the next higher level is the table. If the table space is not segmented, the next higher level is the table space.

**TABLESPACE**
Specifies table space locks.

**TABLE**
Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

**PAGE**
Specifies page locks. Do not use PAGE for a LOB table space.

**ROW**
Specifies row locks. Do not use ROW for a LOB table space.

**LOB**
Specifies LOB locks. Use LOB only for a LOB table space.

The LOCKSIZE change affects a dynamic SQL statement if the statement is prepared and executed after the change. The LOCKSIZE change affects a static SQL statement if the statement is executed after the change.

**LOGGED or NOT LOGGED**
Specifies whether changes that are made to the data in the specified table space are recorded in the log.
LOGGED
Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This can affect the logging attribute of associated LOB table spaces. See “Notes” on page 1136 for more information.

If the base table space is in informational copy-pending status (meaning updates have been made to the table space) when you change from NOT LOGGED to LOGGED, the base table space is placed in copy-pending status. All indexes of tables in the table space are unchanged from their current state; that is, if an index is currently in informational copy-pending status, it will remain in information copy-pending status.

Specifying LOGGED for a LOB table space requires that the base table space also specifies the LOGGED parameter.

LOGGED cannot be specified for XML table spaces. The logging attribute of an XML table space is inherited from its base table space.

LOGGED cannot be specified for table spaces in DSND06 (the DB2 catalog) or in a work file database.

NOT LOGGED
Specifies that changes that are made to data in the specified table space are not recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This parameter can affect the logging attribute of associated LOB table spaces. See “Notes” on page 1136 for more information.

NOT LOGGED prevents undo and redo information from being recorded in the log for the base table space; however, control information for the specified base table space will continue to be recorded in the log. For a LOB table space, changes to system pages and to auxiliary indexes are logged.

NOT LOGGED is mutually exclusive with the DATA CAPTURE CHANGES parameter of CREATE TABLE and ALTER TABLE. NOT LOGGED will not be applied to the table space if any table in the table space specifies DATA CAPTURE CHANGES.

NOT LOGGED cannot be specified for XML table spaces.

NOT LOGGED cannot be specified for table spaces in the following databases:
- DSND06 (the DB2 catalog)
- a work file database

MAXROWS integer
Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255.
The change takes effect immediately for new rows added. However, the space class settings for some pages might be incorrect and could cause unproductive page visits. It is highly recommended to reorganize the table space after altering MAXROWS.

After ALTER TABLESPACE with MAXROWS is run, the table space is placed into an advisory REORG-pending status. Run the REORG TABLESPACE utility to remove the status.

Do not specify MAXROWS for a LOB table space, a table space that is implicitly created for an XML column, a table space in a work file database, or the DB2 catalog table spaces that are listed under “SQL statements allowed on the catalog” on page 2178.

MAXPARTITIONS integer

Specifies that the table space is partition-by-growth. integer specifies the maximum number of partitions to which the table space can grow or shrink. integer must be in the range of 1 to 4096, depending on the value that is in effect for DSSIZE and the page size of the table space, and must not be less than the number of physical partitions that are already allocated for the table space. See “CREATE TABLESPACE” on page 1517 for more information about how DSSIZE and the page size are related.

MAXPARTITIONS can only be specified for a simple table space that contains only one table, a segmented table space that contains only one table, or a partitioned-by-growth universal table space. The table space must have DB2-managed data sets.

Although physical data sets are not defined when the MAXPARTITIONS value is issued, there can be storage and cpu overhead. If an increase in the number of partitions is expected by using the MAXPARTITIONS clause, be aware that specifying an value larger than necessary, such as 4096 (the maximum value), as a default for all of your partition-by-growth table spaces can cause larger than expected storage requests.

The change to the value of MAXPARTITIONS is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending changes to the definition of the table space or associated indexes already exist.
- The table space is converted from a simple table space to a partition-by-growth universal table space.
- The table space is converted from a segmented table space to a partition-by-growth universal table space.
- The table space is changed to use a different page size by specifying the BUFFERPOOL option of ALTER TABLESPACE.
- The table space is changed to use a different DSSIZE by specifying the DSSIZE option of ALTER TABLESPACE.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.
If MAXPARTITIONS is specified on a simple or segmented table space, the table space is converted to a partition-by-growth universal table space that can grow to a maximum number of integer partitions. The SEGSIZE is set to the default of 32 if the SEGSIZE prior to conversion is less than 32. Otherwise, the value of SEGSIZE is inherited from the original table space. The DSSIZE is set to the default 4 gigabytes.

If the data sets of the table space are not defined, the number of partitions is set to 1 during the conversion to a partition-by-growth universal table space from a simple or segmented table space.

If the data sets of the table space are created, the number of partitions is determined based on amount of existing data at the time the pending change to the definition of the table space is applied. Partition growth can happen. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions, regardless of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and thereby authorization from the existing LOB objects.

If the table space is defined with LOCKSIZE TABLE, the lock size will be reset to LOCKSIZE TABLESPACE during conversion to a partition-by-growth universal table space.

**MEMBER CLUSTER YES or MEMBER CLUSTER NO**

Specifies whether the table space uses the MEMBER CLUSTER page set structure. The MEMBER CLUSTER clause can only be specified for a partition-by-growth or range-partitioned universal table space. Changing the MEMBER CLUSTER structure for a table space results in a pending definition change for the table space. The table space is placed in advisory REORG-pending state (AREOR). Running a utility like REORG with SHRLEVEL(CHANGE) or SHRLEVEL(REFERENCE) on the entire table space resets this state.

**MEMBER CLUSTER YES**

Specifies that the MEMBER CLUSTER page set structure is to be used for the specified table space when the table space is already defined as a partition-by-growth or range-partitioned universal table space.

MEMBER CLUSTER YES cannot be specified for LOB, workfile, or XML table spaces, or for table spaces that are organized for hash access.

**MEMBER CLUSTER NO**

Specifies that the table space does not use the MEMBER CLUSTER page set structure when the table space is already defined as a partition-by-growth or range-partitioned universal table space. If the universal table space is already defined to use the MEMBER CLUSTER page set structure, specifying MEMBER CLUSTER NO on the ALTER TABLESPACE statement removes the MEMBER CLUSTER page set structure from the table space.

MEMBER CLUSTER NO is the default.

**SEGSIZE integer**

Specifies that the table space is a universal table space, where integer specifies the number of pages that are to be assigned to each segment of the table space. integer must be a multiple of 4 between 4 and 64 (inclusive). When SEGSIZE is specified, no other options are allowed in the same ALTER TABLESPACE statement.
SEGSIZE can only be specified for a universal table space or a partitioned table space that uses table-controlled partitioning.

The change to the value of SEGSIZE is a pending change to the definition of the table space if the data sets of the table space are already created and one of the following conditions is true:

- Pending changes to the definition of the table space or its associated indexes already exist.
- The specified SEGSIZE value for a universal table space is different than the existing value.
- The table space is converted from a partitioned table space to a range-partitioned universal table space.

Otherwise, the change is an immediate change.

If the change is a pending change to the definition of the table space, the changes are not reflected in the definition or data at the time the ALTER TABLESPACE statement is issued. Instead, the entire table space is placed in an advisory REORG-pending state (AREOR). A subsequent reorganization of the entire table space will apply the pending definition changes to the definition and data of the table space.

If the existing FREEPAGE value (the number of pages to be left free) is greater than or equal to the new SEGSIZE value, the number of pages is adjusted to be one less than the new SEGSIZE value.

If the table space is a partitioned table space, the partitioned table space is converted to a range-partitioned universal table space with a segment size specified by integer. The MEMBER CLUSTER attribute is inherited from the original table space. The number of partitions is inherited from the original table space. If the original DSSIZE attribute has a value of 0, the DSSIZE is set to the original maximum partition size. Otherwise, the DSSIZE attribute is inherited from the original table space.

If the table space is a partition-by-growth universal table space when the pending SEGSIZE change is applied, the number of partitions is determined based on the amount of existing data in the table space and the new SEGSIZE value. Changing the SEGSIZE value to be smaller might cause automatic growth of additional partitions. If LOB columns exist, additional LOB table spaces and auxiliary objects are implicitly created for the newly-grown partitions independently of whether SQLRULES(DB2) or SQLRULES(STD) is in effect or whether the table space was explicitly or implicitly created. The new LOB objects inherit the buffer pool attribute and authorization from the existing LOB objects.

**TRACKMOD**

Specifies whether DB2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space or a table space in a work file database.

For the changed TRACKMOD option to take effect, the table space or partition needs to be stopped and restarted. The table space or partition can be stopped and restarted by running the STOP DATABASE command followed by the START DATABASE command, or by running the REORG utility on the table space or partition. See STOP DATABASE (DB2) (DB2 Commands) and START DATABASE (DB2) (DB2 Commands) or REORG TABLESPACE (DB2 Utilities) for information.

**YES**

DB2 tracks changed pages in the space map pages to improve the
performance of incremental image copy. For data sharing, changing TRACKMOD to YES causes additional SCA (shared communication area) storage to be used until after the next full or incremental image copy is taken or until TRACKMOD is set back to NO.

**NO** DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

**FREEPAGE integer**
Specifies how often to leave a page of free space when the table space is loaded or reorganized. One free page is left after every integer pages; integer can range from 0 to 255. FREEPAGE 0 leaves no free pages. Do not specify FREEPAGE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

**Related information:**
- Reserving free space for table spaces (DB2 Performance)
- Reserving free spaces for indexes (DB2 Performance)

**PCTFREE smallint**
Specifies what percentage of each page to leave as free space when the table space is loaded or reorganized. The default value is PCTFREE 5, which specifies that 5% of the space on each data page is reserved as free space. The first record on each page is loaded without restriction. When additional records are loaded, at least integer percent of free space is left on each page. integer can range from 0 to 99. Do not specify PCTFREE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

**FOR UPDATE smallint**
Specifies the percentage of space to reserve as free space on each page, for use by subsequent UPDATE operations. The smallint value is an integer in the range -1 to 99. FOR UPDATE -1 specifies that 5% of free space is reserved initially, and the amount of free spaces is calculated automatically based on certain real-time statistics values. The first record on each page is always loaded without restriction.

If this value is not specified, the value of the PCTFREE_UPD subsystem parameter is used.

The value is recorded in the PCTFREE_UPD column of the SYSIBM.SYSTABLEPART catalog table.

The FOR UPDATE smallint values do not apply to LOB table spaces, XML table spaces, or table spaces that use hash organization.

The sum of the values for PCTFREE smallint and FOR UPDATEsmallint must be less than or equal to 99.
If FOR UPDATEmallint is not specified and the sum of PCTFREE smallint and the PCTFREE_UPD subsystem parameter value is greater than or equal to 99, DB2 uses a smaller value for PCTFREE_UPD.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

Related information:
- Reserving free space for table spaces (DB2 Performance)
- Reserving free spaces for indexes (DB2 Performance)

**USING**
Specifies whether a data set for the table space or partition is managed by the user or is managed by the DB2 system. If the table space is partitioned, USING applies to the data set for the partition that is identified in the PARTITION clause. If the table space is a partition-by-growth table space, USING can only be specified at the table space level. If the table space is not partitioned, USING applies to every data set that is eligible for the table space. (A nonpartitioned table space can have more than one data set if PRIQTY+118 × SECQTY is at least 2 gigabytes.)

If the USING clause is specified, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. See [Altering storage attributes](#) to determine how and when changes take effect. Do not specify the USING clause if the table space is in a work file database.

**VCAT catalog-name**
Specifies a user-managed data set with a name that starts with catalog-name. The VCAT clause must not be specified if the table space is a partition-by-growth table space. You must specify the catalog name in the form of an SQL identifier. You must specify an alias28 if the name of the integrated catalog facility catalog is longer than eight characters. When the new description of the table space is applied, the integrated catalog facility catalog must contain an entry for the data set that conforms to the DB2 naming conventions set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for catalog-name that is not used by the other DB2 subsystems.

**STOGROUP stogroup-name**
Specifies a DB2-managed data set that resides on a volume of the identified storage group. stogroup-name must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCtrl authority, or the USE privilege for the storage group. When the new description of the table space is applied, the description of the storage group must include at least one volume serial number, each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

---

28. The alias of an integrated catalog facility catalog
If you specify USING STOGROUP and the current data set for the table space or partition is managed by DB2:

- Omission of the PRIQTY clause is an implicit specification of the current PRIQTY value.
- Omission of the SECQTY clause is an implicit specification of the current SECQTY value.
- Omission of the ERASE clause is an implicit specification of the current ERASE rule.

If you specify USING STOGROUP to convert from user-managed data sets to DB2-managed data sets:

- Omission of the PRIQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the SECQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the ERASE clause is an implicit specification of ERASE NO.

**PRIQTY** integer

Specifies the minimum primary space allocation for a DB2-managed data set of the table space or partition. integer must be a positive integer, or -1. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least \( n \) kilobytes, where \( n \) is the value of integer. However, the following exceptions exist:

For non-LOB table spaces, the exceptions are:

- For 4KB page sizes, if integer is greater than 0 and less than 12, \( n \) is 12.
- For 8KB page sizes, if integer is greater than 0 and less than 24, \( n \) is 24.
- For 16KB page sizes, if integer is greater than 0 and less than 48, \( n \) is 48.
- For 32KB page sizes, if integer is greater than 0 and less than 96, \( n \) is 96.
- For any page size, if integer is greater than 67108864, \( n \) is 67108864.

For LOB table spaces, the exceptions are:

- For 4KB page sizes, if integer is greater than 0 and less than 200, \( n \) is 200.
- For 8KB page sizes, if integer is greater than 0 and less than 400, \( n \) is 400.
- For 16KB page sizes, if integer is greater than 0 and less than 800, \( n \) is 800.
- For 32KB page sizes, if integer is greater than 0 and less than 1600, \( n \) is 1600.
- For any page size, if integer is greater than 67108864, \( n \) is 67108864.

The maximum value allowed for PRIQTY is 64GB (67108864 kilobytes).

If you specify PRIQTY with a value of -1, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If PRIQTY is omitted and USING STOGROUP is specified, the value of PRIQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)
If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of $p$ KB not less than $n$, where $p$ is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

At least one of the volumes of the identified storage group must have enough available space for the primary quantity. Otherwise, the primary space allocation will fail.

See Altering storage attributes to determine how and when changes to PRIQTY take effect.

**SECQTY integer**

Specifies the minimum secondary space allocation for a DB2-managed data set of the table space or partition. *integer* must be a positive integer, 0, or -1. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify SECQTY with a value of -1, DB2 uses a default value for the secondary space allocation.

If USING STOGROUP is specified and SECQTY is omitted, the value of SECQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or DB2 uses a default value, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of $p$ KB not less than *integer*, where $p$ is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs) for z/OS DFSMS Access Method Services for catalogs.

See Altering storage attributes to determine how and when changes to SECQTY take effect.

**ERASE**

Indicates whether the DB2-managed data sets for the table space or partition are to be erased before they are deleted during the execution of a utility or an SQL statement that drops the table space.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2.

**YES** Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.
This clause can be specified only if the data set is managed by DB2, and if one of the following is true:
- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify ERASE, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. If you specify ERASE for a partitioned table space, you must also specify the ALTER PARTITION clause. See [Altering storage attributes](#) to determine how and when changes take effect.

**GBPCACHE**

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or not). In addition, you cannot alter the GBPCACHE value of some DB2 catalog table spaces; for a list of these table spaces, see [“SQL statements allowed on the catalog”](#) on page 2178.

**CHANGED**

When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

**ALL**

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating DB2 when no other DB2 subsystems have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

**SYSTEM**

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

Use SYSTEM only for a LOB table space.

**NONE**

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status when the ALTER TABLESPACE statement is executed.
If you specify GBPCACHE in a data sharing environment, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed.

**ALTER PARTITION integer**

Specifies that the identified partition of the table space is to be changed. For a table space that has $n$ partitions, you must specify an integer in the range 1 to $n$. You must not use this clause for a nonpartitioned table space, for a LOB table space, or a partition-by-growth table space. At least one of the following clauses must be specified:

- COMPRESS
- ERASE
- FREEPAGE
- GBPCACHE
- PCTFREE
- PRIQTY
- SECQTY
- TRACKMOD
- USING

The changes specified by these clauses affect only the identified partition.

Do not specify the following clauses for ALTER PARTITION for partitions of a table space that is implicitly created for an XML column.

- CCSID
- FREEPAGE
- MAXROWS
- PCTFREE

**Notes**

**Running utilities:**

You cannot execute the ALTER TABLESPACE statement while a DB2 utility has control of the table space.

**Altering more than one partition:**

To change FREEPAGE, PCTFREE, USING, PRIQTY, SECQTY, COMPRESS, ERASE, or GBPCACHE for more than one partition, you must use separate ALTER TABLESPACE statements.

**Altering storage attributes:**

The USING, PRIQTY, SECQTY, and ERASE clauses define the storage attributes of the table space or partition. If you specify USING or ERASE when altering storage attributes, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. You can use a STOP DATABASE...SPACENAM... command to stop the table space or partition.

If the catalog name changes, the changes take effect after you move the data and start the table space or partition using the START DATABASE...SPACENAM... command. The catalog name can be implicitly or explicitly changed by the ALTER TABLESPACE statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *DB2 Administration Guide*.

Changes to the secondary space allocation (SECQTY) take effect the next time DB2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the table space or partition. The changes to the other storage attributes take effect the next time the page set is reset. For a
non-LOB table space, the page set is reset when you use the REORG, RECOVER, or LOAD REPLACE utilities on the table space or partition. For a LOB table space, the page set is reset when RECOVER is run on the LOB table space or LOAD REPLACE is run on its associated base table space. If there is not enough storage to satisfy the primary space allocation, a REORG might fail. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the table space or partition.

**Recommended GBPCACHE setting for LOB table spaces:**
For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

**Altering table spaces for tables that use hash organization:**
Certain attributes of the table space, such as buffer pool and page size, might affect performance of tables that use hash organization. Changes related to the hash organization of a table will be validated and might generate error messages as described in "CREATE TABLE" on page 1446 and "ALTER TABLE" on page 1027.

**Altering the logging attribute of a table space:**
If the logging attribute (specified with the LOGGED or NOT LOGGED parameter) of a table space is altered frequently, the size of SYSIBM.SYSCOPY might need to be increased.

The logging attribute of the table space cannot be altered if the table space has been updated in the same unit of recovery.

A full image copy of the table space should be taken:
- Before altering a table space to NOT LOGGED
- After altering a table space to LOGGED

If a table space has data changes after an image copy is taken (the table space is in informational COPY-pending state), and the table space is altered from NOT LOGGED to LOGGED, the table space is marked COPY-pending and a full image copy of the table space must be taken.

An XML table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the XML table space is said to be linked to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated XML table spaces are altered back to LOGGED, and all of these links are dissolved.

A LOB table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the LOB table space is said to be linked to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated LOB table spaces are altered back to LOGGED, and all of these links are dissolved.

You can dissolve the link between these logging attributes by altering the logging attribute of the LOB table space to NOT LOGGED, even though it has already been implicitly given this logging attribute. After such an alter,
the logging attribute of the LOB table space is unaffected when the logging attribute of the base table is altered back to LOGGED. A LOB table space with the NOT LOGGED logging attribute does not have this attribute changed in any way if the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When altered in this way, the logging attributes of the LOB table space and the base table space are not linked. If the base table space is altered back to LOGGED, the logging attribute of any LOB table spaces that are not linked to the logging attribute of the base table space remain unchanged.

**Altering table spaces for DB2 catalog tables:**
For details on altering options on catalog tables, see SQL statements allowed on the catalog on page 2178.

**Invalidation of packages:**
All of the packages that refer to that table space are invalidated when any of the following conditions are true:
- The SBCS CCSID attribute of a table space is changed.
- When increasing the MAXPARTITIONS attribute of a table space.
- The SEGSIZE attribute of a partitioned table space is changed to convert the table space to a range-partitioned universal table space.

**Pending changes to the definition of a table space:**
Issuing the ALTER TABLESPACE statement with certain options can cause a pending change to the definition of a table space. When an ALTER TABLESPACE statement that causes pending changes to the definition is executed, semantic validation and authorization checking are performed. However, changes to the table space definition and data are not applied and the table space is placed in advisory REORG-pending state (AREOR). The pending changes are recorded in the SYSIBM.SYSPENDINGDDL catalog table. The REORG utility that specifies SHRLEVEL CHANGE or REFERENCE should be run on the table space to apply the pending changes to the definition and data of the table space. When the pending changes are applied, dependent packages are invalidated, the corresponding entries in the SYSIBM.SYSPENDINGDDL catalog table are removed, and the advisory REORG-pending state is removed.

The following ALTER TABLESPACE options can cause pending changes to the definition of the table space under certain conditions:
- BUFFERPOOL
- DSSIZE
- MAXPARTITIONS
- SEGSIZE

The changes that are caused by all other options occur when the ALTER TABLESPACE statement is executed.

**Restrictions on ALTER TABLESPACE statements that cause pending changes:**
ALTER TABLESPACE statements that cause pending changes have the following restrictions:
- Options that cause pending changes cannot be specified with options that take effect immediately
- Options that cause pending changes cannot be specified for the following objects:
  - The catalog
  - System objects
- Objects in a workfile database

- The DROP PENDING CHANGES clause cannot be specified for a catalog table space

- If there are pending changes to the table space, you cannot use ALTER TABLESPACE to change from a DB2-managed data set to a user-managed data set

- If there are pending changes to the table space, you cannot specify the following clauses:
  - FREEPAGE
  - ALTER PARTITION FREEPAGE

- If there are pending changes to the table space, or to tables contained in the table space, you cannot specify the CCSID clause

- If the table space, or any table it contains is in an incomplete state, you cannot specify options that cause pending changes

**Alternative syntax and synonyms:**

For compatibility with previous releases of DB2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. DB2 treats all partitioned table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space.

- When altering the partitions of a partitioned table space, the ALTER keyword that precedes PARTITION keyword is optional and if ALTER keyword is omitted, then you can specify PART as a synonym for PARTITION.

- You can specify LOG YES as a synonym for LOGGED and LOG NO as a synonym for NOT LOGGED.

**Examples**

*Example 1:* Alter table space DSN8S11D in database DSN8D11A. BP2 is the buffer pool associated with the table space. PAGE is the level at which locking is to take place.

```
ALTER TABLESPACE DSN8D11A.DSN8S11D
  BUFFERPOOL BP2
  LOCKSIZE PAGE;
```

*Example 2:* Alter table space DSN8S11E in database DSN8D11A. The table space is partitioned. Indicate that the data sets of the table space are not to be closed when there are no current users of the table space. Also, change all of the partitions so that DB2 will use a formula to determine any secondary space allocations, and change partition 1 to use a PCTFREE value of 20.

```
ALTER TABLESPACE DSN8D11A.DSN8S11E
  CLOSE NO
  SECQTY -1
  ALTER PARTITION 1 PCTFREE 20;
```

*Example 3:* The following statement changes the maximum number of partitions in a partition-by-growth table space:

```
ALTER TABLESPACE TS01DB.TS01TS
  MAXPARTITIONS 30;
```
ALTER TRIGGER

The ALTER TRIGGER statement changes the description of a trigger at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- Ownership of the trigger
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). However, if the schema name is not the same as one of the authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM authority, SYSCTRL authority, or system DBADM authority.
- The authorization ID of the process has the ALTERIN privilege on the schema.

At least one of the following privileges is required if the SECURED option is specified:
- SECADM authority
- CREATE_SECURE_OBJECT privilege

Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

Syntax

```
ALTER TRIGGER trigger-name SECURED
```

```
ALTER TRIGGER trigger-name NOT SECURED
```
Description

`trigger-name`
Identifies the trigger that is to be changed. The trigger must exist at the current server.

SECURED or NOT SECURED

Specifies that the trigger is to be changed to be secure or not secure. Changing a trigger between SECURED and NOT SECURED causes an implicit rebind of the trigger package. If an error is encountered during the implicit rebind of the trigger package, the ALTER TRIGGER statement returns the error.

SECURED

Specifies the trigger is considered secure.

SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED

Specifies the trigger is considered not secure.

NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Notes

Changing a trigger from NOT SECURED to SECURED:

Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to the owner of the trigger. After the trigger is changed to SECURED, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the ALTER TRIGGER statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, DB2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

Altering a trigger from SECURED to NOT SECURED:

The ALTER TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.
ALTER TRIGGER statement and implicit rebind:
The trigger package is implicitly rebound when the trigger is changed by using the ALTER TRIGGER statement. No additional BIND related privileges are required for this implicit rebind. If an error is encountered during the implicit rebind, the ALTER TRIGGER statement fails and returns the error.

Row access control and column access control that is not enforced for transition variables and transition tables:
If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be changed to use the SECURED option. If a trigger is not secure, row access control and column access control cannot be enforced for the triggering table.

Examples

Example 1: Change the definition of trigger TRIGGER1 to secured:
```
ALTER TRIGGER TRIGGER1
SECURED;
```
ALTER TRUSTED CONTEXT

The ALTER TRUSTED CONTEXT statement modifies the definition of a trusted context at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- SYSADM authority
- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the union of the set of privileges that are held by each authorization ID of the process. If the statement is run in a trusted context with a role, the privilege set is the union of the set of privileges that are held by the role that is associated with the primary authorization ID and the set of privileges that are held by each authorization ID of the process.
Syntax

ALTER TRUSTED CONTEXT — context-name

(1) ALTER SYSTEM AUTHID — authorization-name
    NO DEFAULT ROLE
    DEFAULT ROLE — role-name
    WITHOUT ROLE AS OBJECT OWNER
    WITH ROLE AS OBJECT OWNER AND QUALIFIER
    ENABLE
    DISABLE
    NO DEFAULT SECURITY LABEL
    DEFAULT SECURITY LABEL — seclabel-name

(2) ATTRIBUTES ( ADDRESS — address-value )
    ENCRYPTION — encryption-value
    SERVAUTH — servauth-value
    JOBNAME — jobname-value

(3) ADD ATTRIBUTES ( ADDRESS — address-value )
    SERVAUTH — servauth-value
    JOBNAME — jobname-value

(4) DROP ATTRIBUTES ( ADDRESS )
    SERVAUTH — servauth-value
    JOBNAME — jobname-value

user-clause:

Notes:
1 These clauses can be specified in any order. Each clause must not be specified more than one time.
2 This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.
3 ENCRYPTION must not be specified more than one time.
4 JOBNAME must not be specified with ADDRESS, ENCRYPTION, or SERVAUTH.
5 Each pair of attribute name and corresponding value must be unique.
Description

context-name

Identifies the trusted context to alter. context-name must refer to a trusted context that exists at the current server.

ALTER

Specifies that changes are to be made to the definition of an existing trusted context.

SYSTEM AUTHID authorization-name

Specifies that authorization-name is the system authorization ID for the trusted context. The system authorization ID is the primary authorization ID of the DB2 system that establishes the connection. For a remote connection, the authorization ID is derived from the system used ID that is provided by the external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 112.

Table 112. System authorization ID for a local connection

<table>
<thead>
<tr>
<th>Source of local connection</th>
<th>System authorization ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Started task (RRSAF)</td>
<td>USER parameter on JOB statement or RACF USER.</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>USER parameter on JOB statement</td>
</tr>
</tbody>
</table>
authorization-name must not be associated with an existing trusted context.

NO DEFAULT ROLE or DEFAULT ROLE role-name
Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

NO DEFAULT ROLE
Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

DEFAULT ROLE role-name
Specifies that role-name is the role for the trusted context. role-name must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER
Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

WITHOUT ROLE AS OBJECT OWNER
Specifies that a role is not used as the owner of the objects that are created using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

WITH ROLE AS OBJECT OWNER AND QUALIFIER
Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context. That role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

AND QUALIFIER
Specifies that the role-name will be used as the default for the CURRENT SCHEMA special register. The role-name will also be included in the SQL PATH (in place of CURRENT SQLID).

When WITH ROLE AS OBJECT OWNER AND QUALIFIER is not specified, there is no change to the default of the CURRENT SCHEMA special register and SQL PATH.

DISABLE or ENABLE
Specifies whether the trusted context is in the enabled or disabled state.
DISABLE
   Specified that the trusted context is disabled. A trusted context that is
disabled is not considered when a trusted connection is established.

ENABLE
   Specifies that the trusted context is enabled.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL seclabel-name
   Specifies whether a default security label is associated with a trusted
connection that is based on this trusted context. If a trusted connection for the
specified context is active, the change goes into effect at the next connection
reuse attempt or when a new connection is requested.

NO DEFAULT SECURITY LABEL
   Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL seclabel-name
   Specifies that seclabel-name is the default security label for the trusted
context. seclabel-name is the security label that is used for multilevel
security verification. seclabel-name must identify one of the RACF
SECLABEL values that is defined for the SYSTEM AUTHID. This security
label is used in a trusted connection that is based on the specified trusted
context when the user does not have a specific security label defined as
part of the definition of this trusted context. In this case, seclabel-name must
also identify one of the RACF SECLABEL values that is defined for the
user.

ALTER ATTRIBUTES or ADD ATTRIBUTES
   Specifies a list of one or more connection trust attributes to change or add to
the definition of a trusted context. The connection trust attributes are used to
define the trusted context. If ALTER ATTRIBUTES is specified and the attribute
is not currently part of the definition of the specified trusted context, an error
is returned. Existing specifications for the specified attributes are changed to
the new value if ALTER is specified. Attributes that are not specified retain the
previously specified values.

ADDRESS address-value
   Specifies the actual communication address that is used by the connection
to communicate with the database manager. The protocol supported is only
for TCP/IP. Previously specified ADDRESS values are removed when
ALTER ATTRIBUTES is specified. The ADDRESS attribute can be specified
multiple times, but each address-value must be unique.

   When establishing a trusted connection, if multiple values are defined for
the ADDRESS attribute for a trusted context, a candidate connection is
considered to match this attribute if the address that is used by a
connection matches any of the values that are defined for the ADDRESS
attribute of the trusted context.

   address-value specifies a string constant that contains the value that is
associated with the ADDRESS trust attribute. address-value must be an IPv4
address, an IPv6 address, or a secure domain name with a length no
greater than 254 bytes. No validation of address-value is done at the time
the ALTER TRUSTED CONTEXT statement is processed. address-value must
be left justified within the string constant.

   • An IPv4 address is represented as a dotted decimal address. An example
of an IPv4 address is 9.112.46.111.
An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0008:0800:200C:417A. This address can also be expressed in a compressed form as 2001:DB8:8:0800:200C:417A.

A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

**ENCRIPTION** encryption-value

Specifies the minimum level of encryption of the data stream (network encryption) for the connection.

*encryption-value* specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- **NONE**, which specifies that no specific level of encryption is required.
- **LOW**, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- **HIGH**, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

**ENCRIPTION** cannot be specified if **ADD ATTRIBUTES** is specified. See “CREATE TRUSTED CONTEXT” on page 1562 for more information about the ENCRYPTION attribute.

**JOBNAME** jobname-value

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. Previously specified values for JOBNAME are removed when **ALTER ATTRIBUTES** is specified. The JOBNAME attribute can be specified multiple times, but each **jobname-value** must be unique.

*jobname-value* specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. **jobname-value** is an EBCDIC 8 byte job name or started task name. **jobname-value** must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that match the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space.

<table>
<thead>
<tr>
<th>Source of the address space</th>
<th>Job name</th>
</tr>
</thead>
<tbody>
<tr>
<td>RRSAF</td>
<td>Job name or started task name</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>Job name on JOB statement</td>
</tr>
</tbody>
</table>

**SERVAUTH** servauth-value

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2. Previously specified values for SERVAUTH are removed when **ALTER**
ATTRIBUTES is specified. The SERVAUTH attribute can be specified multiple times but each servauth-value must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. servauth-value is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. servauth-value must be left justified in the string constant. No validation of servauth-value is done at the time the ALTER TRUSTED CONTEXT statement is processed.

DROP ATTRIBUTES
Specifies that one or more attributes are dropped from the definition of a trusted context. If the attribute is not currently specified as part of the definition of a trusted context, an error is returned. The specification of DROP ATTRIBUTES must not attempt to drop all of the existing attributes for a trusted context.

ADDRESS address-value
Specifies that the identified communication address is removed from the definition of the trusted context. address-value specifies a string constant that contains the value of an existing ADDRESS trust attribute.

JOBNAME jobname-value
Specifies that the identified job name is removed from the definition of the trusted context. jobname-value specifies a string constant that contains the value of an existing JOBNAME trust attribute.

SERVAUTH servauth-value
Specifies that the identified servauth that is removed from the definition of the trusted context. servauth-value specifies a string constant that contains the value of an existing SERVAUTH trust attribute.

ADD USE FOR
 Specifies additional users who can use a trusted connection that is based on the specified trusted context.

authorization-name
Specifies that the trusted connection can be used by the specified authorization-name. This is the DB2 primary authorization ID. The authorization-name must not identify an authorization ID that is already defined to use the trusted context, and must not be specified more than one time in the ADD USE FOR clause.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is used by the specified authorization-name. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by the specified authorization-name. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE profile-name
Specifies that the trusted connection can be used by the DB2 primary authorization IDs that are permitted to use the specified profile-name in RACF. The profile-name must not already be defined to use the trusted connection.
context and must not be specified more than one time in the ADD USE FOR clause. After you specify an external security profile, any user who is permitted access to the RACF profile can use the trusted context in addition to any users that are specified using the ADD USE FOR authorization-name clause.

**ROLE role-name**
Specifies that role-name is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL seclabel-name**
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

**PUBLIC**
Specifies that a trusted connection that is based on the specified trusted context can be used by any user. PUBLIC must not already be defined to use the trusted context and must not be specified more than one time in the ADD USE FOR clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

The specifications for a user are determined in the following order of precedence:
- authorization-name
- EXTERNAL SECURITY PROFILE profile-name
- PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION (with JOE and SAM permitted to use the RACF PROFILE SPROFILE), and PUBLIC WITH AUTHENTICATION. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if the trusted connection is used by SALLY, authentication is required.

**REPLACE USE FOR**
Specifies a change to the specified user or PUBLIC for who can use the trusted context.
authorization-name
Specifies the authorization-name that is changed for use of the trusted context. The trusted context must already be defined to allow use by authorization-name, and authorization-name must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with authorization-name is changed as indicated.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is using the specified trusted context. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by the specified authorization-name. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

EXTERNAL SECURITY PROFILE profile-name
Specifies the profile-name to change attributes for use of the trusted connection. The trusted context must already be defined to allow use of profile-name. profile-name must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with the profile-name is changed as indicated.

ROLE role-name
Specifies that role-name is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The role-name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

SECURITY LABEL seclabel-name
Specifies that seclabel-name is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified profile-name in RACF. The seclabel-name must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

PUBLIC
Specifies that the attributes for use of the trusted connection by PUBLIC are to be changed. PUBLIC must already be defined to use the trusted context, and PUBLIC must not be specified more than one time in the REPLACE USE FOR clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of
the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

**WITHOUT AUTHENTICATION or WITH AUTHENTICATION**
Specifies whether use of the trusted connection requires authentication of the user.

**WITHOUT AUTHENTICATION**
Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

**WITH AUTHENTICATION**
Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user.

**DROP USE FOR**
Specifies who can no longer use the trusted context. The users that are removed from the definition of the trusted context are the specified users (or PUBLIC) that are currently allowed to use the trusted context. If multiple users are specified to be dropped, and one or more of those users cannot be dropped, those users that can be dropped are dropped and a warning is returned. If none of the specified users can be removed from the definition of the trusted context, an error is returned.

`authorization-name`
Specifies the `authorization-name` that will no longer be able to use this trusted context.

**EXTERNAL SECURITY PROFILE** `profile-name`
Removes the ability for the specified `profile-name` to use the trusted context.

**PUBLIC**
Specifies that PUBLIC users will no longer be able to use this trusted context. The system authorization ID and individual authorization IDs that have been explicitly enabled can still use the trusted context.

**Notes**

*Precedence for authorization-name and authentication requirements:* If the `authorization-name` that is specified in the SYSTEM AUTHID clause is the same authorization name that is specified in the ADD or REPLACE USE FOR `authorization-name` clauses, the role or the security label that is specified for the `authorization-name` takes precedence over the default value and the value that is specified for the EXTERNAL SECURITY PROFILE `profile-name` (if one is specified). If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the specified profile names and is not specified in ADD or REPLACE USE for `authorization-name`, the role or the security label that is specified for that `profile-name` takes precedence over the default value.

Authentication is required for SYSTEM AUTHID if the AUTHENTICATION clause is specified in the ADD or REPLACE USE FOR clauses, or if the subsystem parameter TCP/IP Already Verified is set to NO. For example, if `authorization-name` is the same as the authorization name that is specified in the SYSTEM AUTHID clause and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, authentication is required for SYSTEM AUTHID when the remote trusted connection is established. If `authorization-name` is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, authentication is required for SYSTEM AUTHID when the trusted connection is established.
YES, authentication is still required for SYSTEM AUTHID.

**Order of precedence for users of a trusted connection:** The specifications for a user are determined in the following order of precedence:

- `authorization-name`
- `EXTERNAL SECURITY PROFILE profile-name`
- `PUBLIC`

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

**User-clause SYSTEM AUTHID considerations:** If the `authorization-name` that is specified in the SYSTEM AUTHID clause is the same as the `authorization-name` that is specified in the user-clause `authorization-name`, the role or the security label that is specified for `authorization-name` takes precedence over the default value. The value that is specified for the `profile-name`, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in `authorization-name`, the role or the security label that is specified for that `profile-name` takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the user-clause or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if `authorization-name` is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If `authorization-name` is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

**Order of operations:** The order in which the clauses of the ALTER TRUSTED CONTEXT statement are applied are as follows:

- DROP ATTRIBUTES
- DROP USE FOR
- ALTER
- ADD ATTRIBUTES
- ADD USE FOR
- REPLACE USE FOR

**Effect of changes on existing trusted connections:** If trusted connections exist for the trusted context that is changed, the connections continue to use the unchanged definition of the trusted context until the connection is terminated or an attempt at reuse is made. If the trusted context is disabled while there are active trusted connections that are based on this trusted context, the connections continue to be
used until terminated or an attempt at reuse is made. If the trust attributes are
changed, trusted connections that exist at the time that the trusted context is
changed will continue to be used.

*When changes to a trusted context take place:* The changes to the definition of a
trusted context take effect after the ALTER TRUSTED CONTEXT statement is
committed. If the ALTER TRUSTED CONTEXT statement results in an error or is
rolled back, the trusted context is not changed.

*Role privileges:* If no role is associated with the user or the trusted context, only
the privileges that are associated with the user are applicable. This is the same as
not using a trusted context.

**Examples**

**Example 1:** The following statement updates the default role of the trusted context
CTX1:

```
ALTER TRUSTED CONTEXT CTX1
  ALTER DEFAULT ROLE CTXROLE2;
```

**Example 2:** The following statement changes the CTX3 trusted context to allow use
for BILL, and it also puts the trusted context into the disabled state:

```
ALTER TRUSTED CONTEXT CTX3
  DISABLE
  ADD USE FOR BILL;
```

**Example 3:** The following statement changes the CTX4 trusted context to allow the
previously defined user JOE to use the trusted context without authentication. The
statement also adds use for PUBLIC with authentication and TOM with a role of
SPLROLE:

```
ALTER TRUSTED CONTEXT CTX4
  REPLACE USE FOR JOE WITHOUT AUTHENTICATION
  ADD USE FOR PUBLIC WITH AUTHENTICATION,
    TOM ROLE SPLROLE;
```

**Example 4:** The following statement changes the REMOTECTX to use a different
IPv4 address than it was originally defined to use. It also changes the encryption
settings from NONE to LOW. After the ALTER statement is processed, the
connection will be considered trusted only when it is established from 9.12.155.200
with low encryption. The connection will no longer be considered trusted if it is
established from the previously defined addresses:

```
ALTER TRUSTED CONTEXT REMOTECTX
  ALTER ATTRIBUTES (ADDRESS '9.12.155.200',
    ENCRYPTION 'LOW');
```
The ALTER VIEW statement regenerates a view using an existing view definition at the current server. ALTER VIEW is primarily used during DB2 migration or when DB2 maintenance is applied. To change a view definition (for example, to add additional columns), you must drop the view and create a new view using the CREATE VIEW statement.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the view
- SYSADM authority
- SYSCTRL authority
- System DBADM

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

Syntax

```
ALTER VIEW view-name REGENERATE
```

Description

view-name

Identifies the view to be regenerated. The name must identify a view that exists at the current server.

REGENERATE

Specifies that the view is to be regenerated. The view definition in the catalog is used, and existing authorizations and dependent views are retained. The catalog is updated with the regenerated view definition. If the view cannot be successfully regenerated, an error is returned.

Examples

Check the catalog to find any views that were marked with view regeneration errors during catalog migration:

```
SELECT CREATOR,NAME FROM SYSIBM.SYSTABLES
WHERE TYPE = 'V' AND STATUS = 'R' AND TABLESTATUS = 'V';
```

Assume that the query returned MYVIEW as the name of a view with a regeneration error. Issue an ALTER VIEW statement to regenerate the view:
ALTER VIEW MYVIEW REGENERATE;
ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a stored procedure.

Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

Authorization

None required.

Syntax

```
ASSOCIATE RESULT SET LOCATORS
WITH PROCEDURE procedure-name
```

Description

rs-locator-variable

Identifies a result set locator variable that has been declared according to the rules for declaring result set locator variables.

WITH PROCEDURE procedure-name or host-variable

Identifies the stored procedure that returned one or more result sets. When the ASSOCIATE LOCATORS statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one-part, two-part, or three-part name. The procedure name in the ASSOCIATE LOCATORS statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the ASSOCIATE LOCATORS statement.

If a host variable is used to specify the name:

- It must be a character string variable with a length attribute that is not greater than 255.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable
Notes

Assignment of locator values: If the ASSOCIATE LOCATORS statement specifies multiple locator variables, locator values are assigned to the locator variables in the order that the associated cursors are opened regardless of whether they are still open or not at run time. Locator values are assigned to the locator variables in the same order that they would be placed in the SQLVAR entries in the SQLDA as a result of a DESCRIBE PROCEDURE statement.

Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later opened again before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values assigned for the following ASSOCIATE LOCATORS statement will be in the order A, C, B:

ASSOCIATE RESULT SET LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P1;
   -- assigns locators for result set cursors A, C, and B

More than one locator can be associated with a result set. You can issue multiple ASSOCIATE LOCATORS statements for the same stored procedure with different result set locator variables to associate multiple locators with each result set.

• If the number of result set locator variables specified in the ASSOCIATE LOCATORS statement is less than the number of result sets returned by the stored procedure, all locator variables specified in the statement are assigned a value, and a warning is issued. For example, assume procedure P1 exists and returns four result sets. Each of the following ASSOCIATE LOCATORS statement returns information on the first result set along with a warning that not enough locators were provided to obtain information about all the result sets.

  CALL P1;
  ASSOCIATE RESULT SET LOCATORS (:loc1) WITH PROCEDURE P1;
     -- :loc1 is assigned a value for first result set, and a warning is returned
  ASSOCIATE RESULT SET LOCATORS (:loc2) WITH PROCEDURE P1;
     -- :loc2 is assigned a value for first result set, and a warning is returned
  ASSOCIATE RESULT SET LOCATORS (:loc3) WITH PROCEDURE P1;
     -- :loc3 is assigned a value for first result set, and a warning is returned
  ASSOCIATE RESULT SET LOCATORS (:loc4) WITH PROCEDURE P1;
     -- :loc4 is assigned a value for first result set, and a warning is returned

• If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the stored procedure, the extra locator variables are assigned a value of 0.

Accessing result sets from multiple CALL statements: An application can access to result sets created by multiple CALL statements. The result sets can be created by different procedure or by the same procedure invoked multiple times.

• Invoking different procedures: Invoking different procedures with the same name can be done either explicitly by specifying the different collections or implicitly with the use of the PACKAGE PATH. For example, to identify the different collections explicitly, specify qualified names on the CALL statement. Although both procedures are named P2, they are different procedures. After the second CALL statement, result sets from both procedures are accessible to the application.
CALL X.P2;
CALL Y.P2;

The collections for the two different procedures can also be determined implicitly from the PACKAGE PATH when unqualified procedure names are specified as part of the CALL statement. For example, assume that procedure P4 exists in collections X and Z. An application contains two CALL statements to invoke procedure P4. The references to procedure P4 in the CALL statements are unqualified. So, the PACKAGE PATH special register is used to resolve the procedure name. Procedure X.P4 is invoked for the first CALL statement and procedure Z.P4 is invoked by the second CALL statement. Following the second CALL statement, result sets from both procedures are accessible to the application.

SET CURRENT PACKAGE PATH = X, Y, Z;
CALL P4;
SET CURRENT PACKAGE PATH = PATH Z, Y, X;
CALL P4;

• **Invoking the same procedure multiple times:** If the server and requester are both the same version of DB2, you can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors. For more information on this situation, see [Multiple calls to the same stored procedure](#).

When a procedure is invoked multiple times in an application and there is a need to process the result sets from the different instances at the same time, be sure to use the ASSOCIATE LOCATORS statement after each CALL statement to capture the locator values returned from each invocation of the procedure. For example, assume that procedure P exists in collection Z and that an application contains two CALL statements to invoke procedure P. The PACKAGE PATH is used to determine the collection for the procedure in the first CALL statement, and the collection is explicitly specified in the second CALL statement. Result sets from both procedures can be accessible to the application following both CALL statements if the locators for the result sets produced by the first CALL statement are captured with an ASSOCIATE LOCATOR statement before invoking the procedure the second time.

SET CURRENT PACKAGE PATH = X, Y, Z;
CALL P3;
ASSOCIATE LOCATORS ...;
CALL Z.P3;
ASSOCIATE LOCATORS ...
-- process the result sets using the locators

Using host variables: If the ASSOCIATE LOCATORS statement contains host variables, the following conditions apply:

• If the statement is executed statically, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

• If the statement is executed dynamically, the contents of the host variables are assumed to be in the encoding scheme that is specified in the APPLICATION ENCODING bind option.

Examples

The statements in the following examples are assumed to be in PL/I programs.
Example 1: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets returned by stored procedure P1. Assume that the stored procedure is called with a one-part name from current server SITE2.

   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL P1;
   EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)
       WITH PROCEDURE P1;

Example 2: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHEMA is used.

   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL MYSCHEMA.P1;
   EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)
       WITH PROCEDURE MYSCHEMA.P1;

Example 3: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets that are returned by the stored procedure named by host variable HV1. Assume that host variable HV1 contains the value SITE2.MYSCHEMA.P1 and the stored procedure is called with a three-part name.

   EXEC SQL CALL SITE2.MYSCHEMA.P1;
   EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
       WITH PROCEDURE :HV1;

The preceding example would be invalid if host variable HV1 had contained the value MYSCHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the ASSOCIATE LOCATORS statement.

   EXEC SQL CONNECT TO SITE2;
   EXEC SQL CALL SITE2.MYSCHEMA.P1;
   EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
       WITH PROCEDURE :HV1;
BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of an SQL declare section. An SQL declare section contains declarations of host variables that are eligible to be used as host variables in SQL statements in a program.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

BEGIN DECLARE SECTION

Description

The BEGIN DECLARE SECTION statement can be coded in the application program wherever variable declarations can appear in accordance with the rules of the host language. It is used to indicate the beginning of a host variable declaration section. A host variable section ends with an END DECLARE SECTION statement, described in "END DECLARE SECTION" on page 1695.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) SQL processing option is specified:

• A variable referred to in an SQL statement must be declared within a host variable declaration section of the source program in all host languages, other than Java and REXX. Furthermore, the declaration of each variable must appear before the first reference to the variable. Host variables are declared without the use of these statements in Java, and they are not declared at all in REXX.

• BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.

• Host variable declaration sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes

Host variable declaration sections are only required if the STDSQL(YES) option is specified or the host language is C. However, declare sections can be specified for any host language so that the source program can conform to IBM SQL. If declare sections are used, but not required, variables declared outside a declare section must not have the same name as variables declared within a declare section.
Example
EXEC SQL BEGIN DECLARE SECTION;
   -- host variable declarations
EXEC SQL END DECLARE SECTION;
The CALL statement invokes a stored procedure.

**Invocation**

This statement can be embedded in an application program. This statement can be executed interactively using the command line processor. Refer to *DB2 Application Programming and SQL Guide* for information about using the command line processor with the CALL statement. This statement can also be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements. IBM’s ODBC and CLI drivers provide this capability.

**Authorization**

Invoking a stored procedure requires the EXECUTE privilege on the following:

- The stored procedure
  
  You do not need the EXECUTE privilege on a stored procedure that was created prior to Version 6 of DB2 for z/OS.

- Additional authority is needed for the stored procedure package and most packages that run in the stored procedure.
  
  The authorization that is required for which packages is explained in detail in [Authorization to execute packages under the stored procedure](#).

**Authorization to execute the stored procedure**

The authorization ID or role that must have the EXECUTE privilege on the stored procedure depends on the form of the CALL statement:

- For static SQL programs that use the syntax CALL *procedure*, the owner of the plan or package that contains the CALL statement must have one of the following:
  
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - DATAACCESS authority
  - SYSADM authority

- For static SQL programs that use the syntax CALL *host-variable*, the authorization ID or role of the plan or package that contains the CALL statement must have one of the following:
  
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - DATAACCESS authority
  - SYSADM authority

The DYNAMICRULES behavior for the plan or package that contains the CALL statement determines both the authorization ID or role and the privilege set that is held by that authorization ID or role:

**Run behavior**

The privilege set is the union of the set of privileges that are held by the SQL authorization ID and each authorization ID or role of the process.

**Bind behavior**

The privilege set is the privileges that are held by the primary authorization ID of the owner of the package or plan.
Define behavior

The privilege set is the privileges that are held by the authorization ID or role of the owner (definer) of the stored procedure or user-defined function that issued the CALL statement.

Invoke behavior

The privilege set is the privileges that are held by the authorization ID or role of the invoker of the stored procedure or user-defined function that issued the CALL statement. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, the privilege set is the union of the set of privileges that are held by each authorization ID or role.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see [Table 6 on page 77](#).

Authorization to execute packages under the stored procedure (including nested stored procedures)

The authorization that is required to run the stored procedure package and any packages that are used under the stored procedure (including nested stored procedures) apply to any form of the CALL statement as follows:

- **Stored procedure package:** One of the authorization IDs or roles that are defined in [Set of authorization IDs](#) must have at least one of the following privileges or authorities on the stored procedure package:
  - The EXECUTE privilege
  - Ownership of the package
  - PACKADM authority for the package's collection
  - SYSADM authority

  A PKLIST entry is not required for the stored procedure package.

- **User-defined function packages and trigger packages:** If a stored procedure or any application under the stored procedure invokes a user-defined function, DB2 requires only the owner (the definer), and not the invoker of the user-defined function, to have EXECUTE authority on the user-defined function package. However, the authorization ID or role of the SQL statement that invokes the user-defined function must have EXECUTE authority on the function.

  Similarly, if a trigger is used under a stored procedure, DB2 does not require EXECUTE authority on the trigger package; however, the authorization ID or role of the SQL statement that activates the trigger must have EXECUTE authority on the trigger.

  For more information about the EXECUTE authority for user-defined functions, triggers, and user-defined function packages, see [DB2 Administration Guide](#).

  PKLIST entries are not required for any user-defined function packages or trigger packages that are used under the stored procedure.

- **Packages other than user-defined function, trigger, and stored procedure packages:** One of the authorization IDs or roles that is defined below under [Set of authorization IDs](#) must have at least one of the following privileges or authorities on any packages other than user-defined function and trigger packages that are used under the stored procedure:
  - The EXECUTE privilege
  - Ownership of the package
  - PACKADM authority for the package's collection
SYSADM authority

PKLIST entries are required for any of these packages that are used under the stored procedure.

For improved performance and simplicity, consider granting the EXECUTE ON PACKAGE privilege for the stored procedure package, and for any packages that run under the stored procedure, to the owner of the stored procedure.

Set of authorization IDs: DB2 checks the following authorization IDs, in the order in which they are listed, for the required authorization to execute the stored procedure package and any packages that run under the stored procedure other than user-defined function and trigger packages as described previously. Authorization checking ends after the first authorization ID that has EXECUTE ON PACKAGE privileges for the target package is found.

- The owner (the definer) of the stored procedure.
- The owner of the plan that contains the CALL statement that invokes the stored procedure if either of the following conditions is true:
  - The calling application (a package or a DBRM that is bound directly to the plan) is local.
  - The calling application is distributed, the DB2 subsystem is both the requester and the server, and the PRIVATE_PROTOCOL subsystem parameter is not set to NO.
- The owner of the package that contains the CALL statement that invokes the stored procedure if the calling application is distributed and either of the following conditions is true:
  - The DB2 subsystem is the server but not the requester.
  - The DB2 subsystem is both the server and the requester and the PRIVATE_PROTOCOL subsystem parameter is set to NO.
  - The calling application uses Recoverable Resources Management Services attachment facility (RRSAF) and has no plan.
- The authorization ID as determined by the value of the DYNAMICRULES bind option for the plan or package that contains the CALL statement if the CALL statement is in the form of CALL :host-variable.
  - If the calling application is bound with the DYNAMICRULES(RUN) option, DB2 checks either the authorization ID of the process at run time and its secondary authorization IDs or the single authorization ID that is determined by the other DYNAMICRULES bind option values.
  - If the calling application is bound with a value other than DYNAMICRULES(RUN), DB2 checks only a single authorization ID, even if that ID fails the EXECUTE ON PACKAGE authorization check.
  - If the calling application is a package and is bound with DYNAMICRULES(BIND), DB2 checks the authorization ID of the package owner. DB2 does not check the authorization ID of the plan owner.
### Syntax

```sql
CALL procedure-name variable
(expression, NULL, or TABLE transition-table-name) USING DESCRIPTOR descriptor-name
```

### Description

**procedure-name or host-variable**

Identifies the procedure to call by the specified `procedure-name` or the procedure name contained in the `host-variable`. The identified procedure must exist at the current server.

If `procedure-name` specifies any of the three special characters that are alphabetic extenders for national languages, $#@, specify the procedure name with a `host-variable`.

If a `host-variable` is used:
- It must be a `CHAR` or `VARCHAR` variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the `host-variable` is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the `host-variable`
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the `host-variable`

In addition, the specification can:
- Contain upper and lowercase characters. Lowercase characters are not folded to uppercase.
- Use a delimited identifier for any part of a three-part procedure name.

If the server is DB2 for z/OS, the specification must be a `procedure-name` as defined above.

When the CALL statement is executed, the `procedure-name` or `specification` must identify a stored procedure that exists at the server.

When the package that contains the CALL statement is bound, the stored procedure that is invoked must be created if `VALIDATE(BIND)` is specified. Although the stored procedure does not need to be created at bind time if `VALIDATE(RUN)` is specified, it must be created when the CALL statement is executed.

**expression, NULL, or TABLE transition-table-name**

Identifies a list of values to be passed as arguments to the stored procedure. The `n`th value corresponds to the `n`th parameter in the procedure. Each parameter that is defined using `CREATE PROCEDURE` as `OUT` or `INOUT` must be specified as a variable. An argument that is an array can be specified
only if the CALL statement is issued from SQL PL or Java (using IBM Data Server Driver for JDBC and SQLJ type 4 connectivity).

The number of arguments that are specified must be the same as the number of parameters of a procedure that is defined at the current server with the specified procedure name.

If USING DESCRIPTOR is specified, each host variable described by the identified SQLDA is an argument, or part of an expression that is an argument of the CALL statement. If host structures are not specified in the CALL statement, the \( n \)th argument of the CALL statement corresponds to the \( n \)th parameter in the stored procedure, and the number in each must be the same. Otherwise, each reference to a host structure is replaced by a reference to each of the variables contained in that host structure, and the resulting number of arguments must be the same as the number of parameters defined for the stored procedure.

However, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

The attributes of the parameters are determined by the current server. In addition to attributes such as data type and length, the description of each parameter indicates how the stored procedure uses it:

- IN means as an input value
- OUT means as an output value
- INOUT means both as an input and an output value

All parameters that are not variables are assumed to be input parameters (IN).

expression

The argument is the result of the specified expression, which is evaluated before the stored procedure is invoked.

If expression is a single variable, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. An expression can contain any of the following items:

- Variable
- Constant
- Special register
- Session global variable
- Cast function with a variable or constant argument

A variable can identify a structure. Any variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of the variables contained in the host structure.

If the result of the expression can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

expression must not reference an associative array value as an argument to a function if the procedure is remote.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:
• IN expression can contain references to multiple host variables. In
  addition to the rules stated in "Expressions" on page 243 for expression,
  expression cannot include a column name, a scalar subselect, a file
  reference variable, an aggregate function, or a user-defined function that
  is sourced on an aggregate function.
• INOUT or OUT expression can only be a single variable. expression cannot
  include a file reference variable or an array element.

NULL
The parameter is a null value. The corresponding parameter of the
procedure must be defined as IN and the description of the procedure
must allow for null parameters.

TABLE transition-table-name
The parameter is a transition table, and it is passed to the procedure as a
table locator. You can use the CALL statement with the TABLE clause only
within the definition of the triggered action of a trigger. The name of a
transition table must be specified in the CALL statement if the
 corresponding parameter of the procedure was defined in the TABLE LIKE
clause of the CREATE PROCEDURE statement. For information about
creating a trigger, see "CREATE TRIGGER" on page 1544 and DB2
Application Programming and SQL Guide.

There is no effect on the transition table on the return from the procedure
regardless of whether the parameter was defined as IN, INOUT, or OUT.

USING DESCRIPTOR descriptor-name
Identifies an SQLDA that contains a valid description of the host variables
that are to be passed as parameters to the stored procedure. If the stored
procedure has no parameters, an SQLDA is ignored.

Before the CALL statement is processed, the user must set the following
fields in the SQLDA:
• SQLN to indicate the number of SQLVAR occurrences provided in the
  SQLDA. This number must not be less than SQLD. This field is not part
  of the REXX SQLDA and therefore does not need to be set for REXX
  programs.
• SQLDABC to indicate the number of bytes of storage allocated for the
  SQLDA. This number must be not be less than SQLN*44+16. This field is
  not part of the REXX SQLDA and therefore does not need to be set for
  REXX programs.
• SQLD to indicate the number of variables used in the SQLDA when
  processing the statement. This number must be the same as the number
  of parameters of the stored procedure.
• SQLVAR occurrences to indicate the attributes of the variables.

There are additional considerations for setting the fields of the SQLDA
when a variable that is passed as a parameter to the stored procedure has
a LOB data type or is a LOB locator. For more information, see "SQL
descriptor area (SQLDA)" on page 2144.

The SQL CALL statement ignores distinct type information in the SQLDA.
Only the base SQL type information is used to process the input and
output parameters described by the SQLDA.

In REXX, only host variables USING DESCRIPTOR is supported. Since
global variables are not supported within the SQLDA, global variable are
not supported in REXX.
Notes

**Parameter assignments:** When the CALL statement is executed, the value of each of its arguments is assigned with storage assignment rules to the corresponding IN or INOUT parameter of the stored procedure. In cases where the arguments of the CALL statement are not an exact match to the data types of the parameters of the stored procedure, each argument specified in the CALL statement is converted to the data type of the corresponding parameter of the stored procedure at execution. The conversion occurs according to the same rules as assignment to columns.

Control is passed to the stored procedure according to the calling conventions of the host language.

When execution of the stored procedure is complete, the value of each parameter of the stored procedure defined as OUT or INOUT is assigned to the corresponding argument of the CALL statement. If an error is returned by the procedure, OUT arguments are undefined, and INOUT arguments are unchanged.

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

The following rules apply when the value of an array argument is assigned to the corresponding array parameter:

- **For a local procedure call:** The argument and the parameter must be defined as the same array type.

- **For a remote procedure call:** The data type of the elements of the array argument must be the same as the data type of the elements of the array parameter. In addition, for IN or OUT parameters, all of the relevant conditions in one of the rows in the following table must be true. For INOUT parameters, all of the relevant conditions in row 1 of the following table must be true, or all of the relevant conditions in rows 2 and 3 must be true. A relevant condition is indicated with Y.

<table>
<thead>
<tr>
<th>Relationship of argument to associated parameter</th>
<th>Relationship applies to IN parameter</th>
<th>Relationship applies to OUT parameter</th>
<th>Relationship applies to INOUT parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>The argument is an ordinary array, the parameter is an ordinary array, and the argument and parameter are defined with the same data type for the array indexes.</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>

</tbody>
</table>
### Relationship of argument to associated parameter

<table>
<thead>
<tr>
<th>Relationship of argument to associated parameter</th>
<th>Relationship applies to IN parameter</th>
<th>Relationship applies to OUT parameter</th>
<th>Relationship applies to INOUT parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>The argument is an ordinary array, the parameter is an associative array type, the parameter is an IN or INOUT parameter, and the data type of the array indexes is INTEGER. The associative array parameter is assigned an associative array value that is derived from the ordinary array argument value. The values of the array elements in the ordinary array are assigned to the target associative array parameter, in the same order as their order in the ordinary array argument. The index values in the target associative array parameter are assigned from 1 to the cardinality of the ordinary array argument value.</td>
<td>Y</td>
<td>Y</td>
<td></td>
</tr>
<tr>
<td>The argument is an ordinary array type, the parameter is an associative array type, and the parameter is an INOUT or OUT parameter. The argument is assigned an ordinary array value that is derived from the associative array parameter value. The values of the array elements in the associative array value are assigned to the target ordinary array, in an order determined by DB2. The index values in the target ordinary array argument are assigned from 1 to the cardinality of the associative array parameter value. The index values from the associative array parameter value are ignored.</td>
<td>Y</td>
<td>Y</td>
<td></td>
</tr>
</tbody>
</table>

For details on the rules used to assign parameters, see “Assignment and comparison” on page 123.

Conversion can occur when precision, scale, length, encoding scheme, or CCSID differ between the argument specified in the CALL statement and the data type of the corresponding parameter of the stored procedure. Conversion might occur for a character string argument specified in the CALL statement when the corresponding parameter of the stored procedure has a different encoding scheme or CCSID. For example, an error occurs when the CALL statement passes an argument of mixed data that actually contains DBCS characters as input for a parameter of the stored procedure that is defined as FOR SBCS DATA. Likewise, an error occurs when the
stored procedure returns mixed data that actually contains DBCS characters for an argument of the CALL statement that is defined as FOR SBCS DATA.

**Procedure signatures:** A procedure is identified by its schema, a procedure name, and its number of parameters. This is called a procedure signature, which must be unique within the database. DB2 for z/OS does not support overloaded procedure names (procedures with the same schema and procedure name, but with different numbers of parameters).

**SQL path:** A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments that are enclosed in parentheses. A procedure can also be invoked without the schema name, which results in a choice of possible procedures in different schemas that have the same procedure name and same number of parameters. In this case, the SQL path is used to assist in procedure resolution. The SQL path is a list of schemas that is searched to identify a procedure with the same name and number of parameters as the procedure in the CALL statement. For CALL statements that explicitly specify a procedure name, the SQL path is specified by using the platform-specific bind option. For CALL host-variable statements, the SQL path is the value of the CURRENT PATH special register when the procedure is invoked.

**Procedure resolution:** Given a procedure invocation, the database manager must decide which of the possible procedures that has the same name to call.

A procedure name is a qualified or unqualified name. Each part of the name must be composed of SBCS characters:

- A fully qualified procedure name is a three-part name. The first part is an SQL identifier that contains the location name that identifies the DBMS at which the procedure is stored. The second part is an SQL identifier that contains the schema name of the stored procedure. The last part is an SQL identifier that contains the name of the stored procedure. A period must separate each of the parts. Any or all of the parts can be a delimited identifier.

- A two-part procedure name has one implicit qualifier. The implicit qualifier is the location name of the current server. The two parts identify the schema name and the name of the stored procedure. A period must separate the two parts.

- An unqualified procedure name is a one-part name with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier depends on the server. If the server is DB2 for z/OS, the implicit qualifier is the schema name. DB2 uses the SQL path to determine the value of the schema name.
  - If the procedure name is specified as a string constant on the CALL statement (CALL procedure-name), the SQL path is the value of the PATH bind option that is associated with the calling package or plan.
  - If a host variable is specified for the procedure name on the CALL statement (CALL host-variable), the SQL path is the value of the CURRENT PATH special register.

DB2 searches the schema names in the SQL path from left to right until a stored procedure with the specified schema name is found in the DB2 catalog. When a matching schema.procedure-name is found, the search stops only if the following conditions are true:

- The user is authorized to call the stored procedure.
- The number of parameters in the definition of the stored procedure matches the number of parameters specified on the CALL statement.
If the list of schemas in the SQL path is exhausted before the procedure name is resolved, an error is returned.

When the procedure is resolved depends on how the procedure name is specified. For a CALL statement that specifies the procedure name using a host variable, procedure resolution occurs at run time. For a CALL statement that contains the name of the procedure as an identifier, procedure resolution occurs when the CALL statement is bound.

Procedure resolution is done by the database manager using the following steps:
1. Find all procedures from the catalog where all of the following conditions are true:
   - For invocations where the schema name is specified (qualified references), the schema name and the procedure name match the invocation name.
   - For invocations where the schema name is not specified (unqualified references), the procedure name matches the invocation name, and the procedure has a schema name that matches one of the schemas in the SQL path.
   - The number of defined parameters matches the number of arguments that are specified in the invocation.
   - The invoker has the EXECUTE privilege on the procedure.
2. Of the candidate procedures that remain from step 1, choose the procedure whose schema is first in the SQL path. If no candidate procedures remain after step 1, an error is returned.
3. For CALL statements that use a host variable to specify the procedure name, the CURRENT ROUTINE VERSION special register can affect which version of the native SQL procedure is invoked. If the CURRENT ROUTINE VERSION special register is set, check if there is a version of the procedure with that version name. If not, choose the currently active version of the procedure.
   - For CALL statements that do not use a host variable to specify the procedure name, choose the currently active version of the procedure.

**Version resolution:** Normally, the currently active version of a native SQL procedure will be used on a CALL statement. However, if the CALL statement is a recursive call inside the body of the same stored procedure, and the original CALL statement uses a version that is different from the currently active version, the active version will not be used. The version from the original CALL statement will be used for any recursive CALL statements until the entire stored procedure finishes executing. This preserves the semantics of the version that is used by the original CALL statement. This includes the case where the recursive call is indirect. For example, assume that procedure SP1 call procedure SP2, which in turn recursively calls SP1. The second invocation of procedure SP1 will use the version of the procedure that is active at the time of the original CALL statement that invoked procedure SP1.

Since the currently active version can be used at the next CALL statement, it is possible that two or more versions of the same procedure can run at the same time. There could be different versions of an SQL procedure loaded by a given thread. For example, a CALL SP1 statement in an application will cause the currently active version, SP1_V1, to load and execute. After this CALL statement has completed, an ALTER PROCEDURE ALTER ACTIVE VERSION could execute and change the active version of the procedure SP1 to version SP1_V2. Subsequent CALL SP1 statements from the same thread will load the currently active version of the procedure, SP1_V2, and execute it.
**Parameter assignments:** When the CALL statement is executed, the value of each of its parameters is assigned with storage assignment rules to the corresponding parameter of the procedure. Control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned with storage assignment rules to the corresponding parameter of the CALL statement defined as OUT or INOUT. If an error is returned by the procedure, OUT arguments are undefined and INOUT arguments are unchanged. For details on the assignment rules, see “Assignment and comparison” on page 123.

**Cursors and prepared statements in procedures:** All cursors opened in the called procedure that are not result set cursors are closed and all statements prepared in the called procedure are destroyed when the procedure ends.

**Result sets from procedures:** Any cursors specified using the WITH RETURN clause that the procedure leaves open when it returns identifies a result set. In a procedure written in Java, all cursors are implicitly defined WITH RETURN.

Results sets are returned only when the procedure is called from CLI, JDBC, or SQLJ. If the procedure was invoked from CLI or Java, and more than one cursor is left open, the result sets can only be processed in the order in which the cursors were opened. Only unread rows are available to be fetched. For example, if the result set of a cursor has 500 rows, and 150 of those rows have been read by the procedure at the time the procedure is terminated, then rows 151 through 500 will be returned to the procedure.

**Errors from procedures:** A procedure can return errors or warnings using an SQLSTATE like other SQL statements. Applications should be aware of the possible SQLSTATEs that can be expected when a procedure is invoked. The possible SQLSTATEs depend on how the procedure is coded. Procedures might also return SQLSTATEs such as those that begin with '38' or '39' if DB2 encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that can result from issuing a CALL statement.

**Improving performance:** The capability of calling stored procedures is provided to improve the performance of DRDA distributed access. The capability is also useful for local operations. The server can be the local DB2. In which case, packages are still required.

All values of all parameters are passed from the requester to the server. To improve the performance of this operation, host variables that correspond to OUT parameters and have lengths of more than a few bytes should be set to null before the CALL statement is executed.

**Using the CALL statement in a trigger:** When a trigger issues a CALL statement to invoke a stored procedure, the parameters that are specified in the CALL statement cannot be host variables and the USING DESCRIPTOR clause cannot be specified.

**Nesting CALL statements:** A program that is executing as a stored procedure, a user-defined function, or a trigger can issue a CALL statement. When a stored procedure, user-defined function, or trigger calls a stored procedure, user-defined function, or trigger, the call is considered to be nested. Stored procedures, user-defined functions, and triggers can be nested up to 64 levels deep on a single system. Nesting can occur within a single DB2 subsystem or when a stored procedure or user-defined function is invoked at a remote server.
If a stored procedure returns any query result sets, the result sets are returned to the caller of the stored procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, Figure 18 illustrates a scenario in which a client program calls stored procedure PROCA, which in turn calls stored procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets. The number of query result sets that PROCB returns does not count toward the maximum number of query results that PROCA can return.

Figure 18. Nested CALL statements

Some stored procedures cannot be nested. A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN attribute. Procedures that are defined with the AUTONOMOUS attribute cannot call other procedures that are defined with the AUTONOMOUS attribute.

Multiple calls to the same stored procedure: You can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors.

The application might receive a "resource unavailable message" if the CALL statement causes the values of the maximum number of active stored procedures or maximum number open cursors to be exceeded. The value of field MAX STORED PROCEDURES (on installation panel DSNTIPX) defines the maximum number of active stored procedures that are allowed per thread. The value of field MAX OPEN CURSORS (on installation panel DSNTIPX) defines the maximum number of open cursors (both result set cursors and regular cursors) that are allowed per thread.

If you make multiple calls to the same stored procedure within an application, be aware of the following considerations:

- A DESCRIBE PROCEDURE statement describes the last instance of the stored procedure.
- The ASSOCIATE LOCATORS statement works on the last instance of the stored procedure.
- The ALLOCATE CURSOR statement must specify a unique cursor name for a result set returned from an instance of the stored procedure. Otherwise, you will lose the data from the result sets that are returned from prior instances or calls to the stored procedure.
You should issue an ASSOCIATE LOCATORS statement (or DESCRIBE PROCEDURE statement) after each call to the stored procedure to get a unique locator value for each result set.

**Using host variables:** If the CALL statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Examples**

**Example 1:** A PL/I application has been precompiled on DB2 ALPHA and a package was created at DB2 BETA with the BIND subcommand. A CREATE PROCEDURE statement was issued at BETA to define the procedure SUMARIZE, which allows nulls and has two parameters. The first parameter is defined as IN and the second parameter is defined as OUT. Some of the statements that the application that runs at DB2 ALPHA might use to call stored procedure SUMARIZE include:

```sql
EXEC SQL CONNECT TO BETA;
V1 = 528671;
IV = -1;
EXEC SQL CALL SUMARIZE(:V1,:V2 INDICATOR :IV);
```

**Example 2:** Suppose that stored procedure MYPROC exists and produces several result sets. An application might include statements like the following to access the result sets produced by MYPROC:

```sql
-- Invoke stored procedure MYPROC that returns several result sets
EXEC SQL CALL MYPROC (....);
-- Copy the locator values for the result sets into result set locator variables
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:RS1, :RS2, :RS3) WITH PROCEDURE MYPROC;
-- Allocate cursors for the result set cursors
EXEC SQL ALLOCATE CSR1 CURSOR FOR RESULT SET :RS1;
EXEC SQL ALLOCATE CSR2 CURSOR FOR RESULT SET :RS2;
EXEC SQL ALLOCATE CSR3 CURSOR FOR RESULT SET :RS3;
-- Process data returned with the result set cursors
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH CSR1 INTO ........
END;
EXEC SQL CLOSE CSR1 INTO ......
-- do similar processing with other result sets
...
```

**Example 3:** Suppose that procedure FIND_CUSTOMERS has the following parameters:

- An IN parameter that is an array of phone numbers
- An IN parameter that is a prefix value to search for a match
- An OUT parameter that returns an array of phone numbers

FIND_CUSTOMERS searches the input array variable for phone numbers that match the prefix value, and returns an array that contains the phone numbers that match the prefix value.

FIND_CUSTOMERS looks like this:

```
-------------------------------------------------------------------------------------------------------------------------------
-- Create an SQL procedure with array parameters. The array parameters are defined
-- with the PHONENUMBERS array type. The procedure searches for numbers in
-- IN_PHONENUMBERS that begin with the given prefix, and returns the phone numbers
-- in the NUMBERS_OUT parameter.
```
CREATE PROCEDURE FIND_CUSTOMERS(
   IN NUMBERS_IN PHONENUMBERS,
   IN PREFIX CHAR(3),
   OUT NUMBERS_OUT PHONENUMBERS)
BEGIN
   DECLARE I, J INTEGER;
   SET I = 1;
   SET J = 1;
   -- Initialize NUMBERS_OUT to an empty array using an array constructor
   -- with no elements
   SET NUMBERS_OUT = ARRAY[ ];
   WHILE i < CARDINALITY(NUMBERS_IN) DO
      IF SUBSTR(NUMBERS_IN[I], 1, 3) = PREFIX THEN
         SET NUMBERS_OUT[J] = NUMBERS_IN[I];
         SET J = J + 1;
      END IF;
      SET I = I + 1;
   END WHILE;
END %

In the calling routine, declare array variables, and initialize the input array with values from an array constructor. Then invoke the procedure:

CREATE TYPE PHONENUMBERS AS VARCHAR(20) ARRAY[10]; -- Create an array type
DECLARE PNUMBER_ARRAY PHONENUMBERS; -- Declare input array variable
DECLARE PNUMBER_ARRAY_OUT PHONENUMBERS; -- Declare output array variable
SET PNUMBER_ARRAY = ARRAY['416-305-3745',
                           '905-414-4565',
                           '416-305-3746'];
CALL FIND_CUSTOMERS(PNUMBER_ARRAY, -- NUMBERS_IN parameter (IN parm)
                    '416', -- PREFIX parameter (IN parm)
                    PNUMBER_ARRAY_OUT); -- NUMBERS_OUT parameter (OUT parm)

The CALL statement returns an array value with the following information in the argument corresponding to the NUMBERS_OUT parameter, which sets the PNUMBER_ARRAY_OUT variable:

['416-305-3745',
 '416-305-3746']
CLOSE

The CLOSE statement closes a cursor. If a temporary copy of a result table was created when the cursor was opened, that table is destroyed.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See "DECLARE CURSOR" on page 1598 for the authorization required to use a cursor.

Syntax

```
CLOSE cursor-name
```

Description

cursor-name

Identifies the cursor to be closed. The cursor name must identify a declared cursor as explained in "DECLARE CURSOR" on page 1598. When the CLOSE statement is executed, the cursor must be in the open state.

Notes

Implicit cursor close: At the end of a unit of work, all open cursors declared without the WITH HOLD option that belong to an application process are implicitly closed.

Close cursors for performance: Explicitly closing cursors as soon as possible can improve performance.

Procedure considerations: Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see "CALL" on page 1163.

Allocated cursors: The cursor could have been allocated. See "ALLOCATE CURSOR" on page 879.

Example

A cursor is used to fetch one row at a time into the application program variables DNUM, DNAME, and MNUM. Finally, the cursor is closed. If the cursor is reopened, it is again located at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
     SELECT DEPTNO, DEPTNAME, MGRNO
     FROM DSN8810.DEPT
     WHERE ADMRDEPT = 'A00'
END-EXEC.
```
EXEC SQL OPEN C1 END-EXEC.
EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.

IF SQLCODE = 100
  PERFORM DATA-NOT-FOUND
ELSE
  PERFORM GET-REST-OF-DEPT
  UNTIL SQLCODE IS NOT EQUAL TO ZERO.

EXEC SQL CLOSE C1 END-EXEC.

GET-REST-OF-DEPT.
  EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.
The COMMENT statement adds or replaces comments in the descriptions of various objects in the DB2 catalog at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

For a comment on the following objects, the privilege set must include at least one of the listed authorities or privileges:

**Table, view, index, column, or alias for a table or view:**

- Ownership of the table, view, alias, or index
- DBADM authority for its database (tables and indexes only)
- SYSADM or SYSCTRL authority
- System DBADM
- SECADM authority (if the table has an activated row permission or column access control)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Distinct type, stored procedure, trigger, or user-defined function:**

- Ownership of the distinct type, stored procedure, trigger, or user-defined function
- The ALTERIN privilege on the schema (for the addition of comments)
- SYSADM or SYSCTRL authority
- System DBADM

**Secure trigger or secure user-defined function:**

- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Package:**

- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- System DBADM

**Role or a trusted context:**

- Ownership of the object
- SYSADM or SYSCTRL authority
- SECADM

If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

**Sequence or alias for a sequence:**

- Ownership of the sequence
• The ALTER privilege for the sequence if the target is a sequence
• The ALTERIN privilege on the schema
• SYSADM or SYSCTRL authority
• System DBADM

The authorization ID that matches the schema name implicitly has the
ALTERIN privilege on the schema.

Row permission or column mask:
SECADM authority

Privilege set: If the statement is embedded in an application program, the
privilege set is the privileges that are held by the owner of the plan or package. If
the statement is dynamically prepared, the privilege set is determined by the
DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is
summarized in Table 97 on page 873 (For more information on these behaviors,
including a list of the DYNAMICRULES bind option values that determine them,
see “Authorization IDs and dynamic SQL” on page 77.)

Syntax

```sql
COMMENT ON
  | alias-designator IS string-constant
  | COLUMN table-name [.column-name]
  | function-designator .ACTIVE VERSION
  | INDEX index-name .VERSION routine-version-id
  | PACKAGE collection-id.package-name .VERSION version-id
  | PLAN plan-name .ACTIVE VERSION
  | PROCEDURE procedure-name .VERSION routine-version-id
  | ROLE role-name .VERSION
  | SEQUENCE sequence-name .VERSION
  | TABLE table-name .view-name .VERSION
  | TRIGGER trigger-name .VERSION
  | TRUSTED CONTEXT context-name .VERSION
  | TYPE type-name .VERSION
  | MASK mask-name .VERSION
  | PERMISSION permission-name .VERSION
  | VARIABLE variable-name .VERSION
  | multiple-column-list
```

alias-designator
Notes:
1. If PUBLIC is specified, FOR SEQUENCE must also be specified.

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type that is based on a LOB data type.
**Description**

**alias-designator**

**ALIAS** *alias-name*

Indicates a comment will be added or replaced for an alias. The name must identify an alias that exists at the current server.

If the PUBLIC keyword is specified, *alias-name* must identify a public alias that exists at the current server. The comment is applied to a public alias.
FOR TABLE
Specifies that the alias is for a table or a view. The comment replaces the
value of the REMARKS column of the SYSIBM.SYSTABLES catalog table
for the row that describes the alias.

FOR SEQUENCE
Specifies that the alias is for a sequence. The comment replaces the value
of the REMARKS column of the SYSIBM.SYSSequences catalog table for
the row that describes the alias.

COLUMN table-name.column-name or view-name.column-name
Identifies the column to which the comment applies. The name must identify a
column of a table or view that exists at the current server. The name must not
identify a column of a declared temporary table. The comment is placed into
the REMARKS column of the SYSIBM.SYSCOLUMNS catalog table, for the row
that describes the column.

Do not use TABLE or COLUMN to comment on more than one column in a
table or view. Give the table or view name and then, in parentheses, a list in
the form:

    column-name IS string-constant,
    column-name IS string-constant,...

The column names must not be qualified, each name must identify a column
of the specified table or view, and that table or view must exist at the current
server.

FUNCTION or SPECIFIC FUNCTION
Identifies the function to which the comment applies. The function must exist
at the current server, and it must be a function that was defined with the
CREATE FUNCTION statement or a cast function that was generated by a
CREATE TYPE statement. The comment is placed in the REMARKS column of
the SYSIBM.SYSROUTINES catalog table for the row that describes the
function.

The function can be identified by its name, function signature, or specific
name. If the function was defined with a table parameter (the LIKE TABLE
was specified in the CREATE FUNCTION statement to indicate that one of the
input parameters is a transition table), you must identify the function with its
function name, if it is unique, or with its specific name.

FUNCTION function-name
Identifies the function by its function name. There must be exactly one
function with function-name in the schema. The function can have any
number of input parameters. If the schema does not contain a function
with function-name, or if the schema contains more than one function with
this name, and error is returned.

FUNCTION function-name (parameter-type,...)
Identifies the SQL function by its function signature, which uniquely
identifies the function. A function with the function signature must exist in
the explicitly or implicitly specified schema.

If function-name() is specified, the function that is identified must have zero
parameters.

function-name
Identifies the name of the function. If the function was defined with a
table parameter (the LIKE TABLE name AS LOCATOR clause was
specified in the CREATE FUNCTION statement to indicate that one of
the input parameters is a transition table), the function signature
cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or with its specific name.

\[(\text{parameter-type}, \ldots)\]
Specifies the number of input parameters of the function and the name and data type of each parameter.

\[(\text{data-type}, \ldots)\]
Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.
  For example, \(\text{DEC()}\) will be considered a match for a parameter of a function defined with a data type of \(\text{DEC(7,2)}\). Similarly \(\text{DECFLOAT()}\) will be considered a match for \(\text{DECFLOAT(16)}\) or \(\text{DECFLOAT(34)}\).
  FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).
- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.
  The specific value for \(\text{FLOAT(n)}\) does not have to exactly match the defined value of the source function because \(1 \leq n \leq 21\) indicates REAL and \(22 \leq n \leq 53\) indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.
- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the \text{FOR subtype DATA} clause or the \text{CCSID} clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

\text{AS LOCATOR}
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

\text{SPECIFIC FUNCTION specific-name}
Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. A function with the specific name must exist in the schema. If the specific name is not
qualified, it is implicitly qualified with a schema name as described in the
description for FUNCTION function-name.

**ACTIVE VERSION**
Specifies that the comment applies to the currently active version of the
routine that is specified by function-name.

**ACTIVE VERSION** is the default.

**VERSION** routine-version-id
Specifies that the comment applies only to the version of the routine that is
identified by routine-version-id. routine-version-id must identify a version of
the specified routine that already exists at the current server. If
routine-version-id is not specified, a null string is used as the version
identifier.

**INDEX** index-name
Identifies the index to which the comment applies. index-name must identify an
index that exists at the current server. The comment is placed in the REMARKS
column of the SYSIBM.SYSINDEXES catalog table for the row that describes
the index.

**MASK** mask-name
Identifies the column mask to which the comment applies. mask-name must
identify a column mask that exists at the current server. The comment is placed
in the REMARKS column of the SYSIBM.SYSCONTROLS catalog table for the
row that describes the column mask.

**PACKAGE** collection-id.package-name
Identifies the package to which the comment applies. You must qualify the
package name with a collection ID. collection-id.package-name must identify a
package that exists at the current server. The name plus the implicitly or
explicitly specified version-id must identify a package that exists at the current
server. Omission of the version-id is an implicit specification of the null version.
The name must not identify a trigger package or a package that is associated
with an SQL routine. Specify this clause to comment on a package that was
created as the result of a BIND COPY command used to deploy a version of a
native SQL procedure.

**VERSION** version-id
version-id is the version identifier that was assigned to the package's DBRM
when the DBRM was created. If version-id is not specified, a null version is
used as the version identifier.

Delimit the version identifier when it:
• Is generated by the VERSION(AUTO) precompiler option
• Begins with a digit
• Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an
application program for execution in *DB2 Application Programming and SQL
Guide*.

**PERMISSION** permission-name
Identifies the row permission to which the comment applies. permission-name
must identify a row permission that exists at the current server. The comment
is placed in the REMARKS column of the SYSIBM.SYSCONTROLS catalog
table for the row that describes the row permission.
PLAN plan-name
   Identifies the plan to which the comment applies. plan-name must identify a plan that exists at the current server.

PROCEDURE procedure-name
   Identifies the procedure to which the comment applies. procedure-name must identify a procedure that exists at the current server.

ACTIVE VERSION
   Specifies that the comment applies to the currently active version of the routine that is specified by procedure-name.
   ACTIVE VERSION is the default.

VERSION routine-version-id
   Specifies that the comment applies only to the version of the routine that is identified by routine-version-id. routine-version-id must identify a version of the specified routine that already exists at the current server. If routine-version-id is not specified, a null string is used as the version identifier.

ROLE role-name
   Identifies the role to which the comment applies. role-name must identify a role that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSROLES catalog table for the row that describes the role.

SEQUENCE sequence-name
   Identifies the sequence to which the comment applies.
   sequence-name must identify a sequence that exists at the current server.
   sequence-name must not be the name of an internal sequence object that is used by DB2. The comment is placed in the REMARKS column of the SYSIBM.SYSSSEQUENCES catalog table for the row that describes the sequence.

TABLE table-name or view-name
   Identifies the table or view to which the comment applies. table-name or view-name must identify a table, auxiliary table, or view that exists at the current server. table-name must not identify a declared temporary table. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

TRIGGER trigger-name
   Identifies the trigger to which the comment applies. trigger-name must identify a trigger that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTRIGGERS catalog table for the row that describes the trigger.

TRUSTED CONTEXT context-name
   Identifies the trusted context to which the comment applies. context-name must identify a trusted context that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSCONTEXT catalog table for the row that describes the trusted context.

TYPE type-name
   Identifies the user-defined type to which the comment applies. type-name must identify a user-defined type that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSDATATYPES catalog table for the row that describes the user-defined type.
VARIABLE variable-name

Identifies the global variable to which the comment applies. variable-name must identify a global variable that exists at the current server. variable-name must not identify a built-in global variable.

IS string-constant

Introduces the comment that you want to make. string-constant can be any SQL character string constant of up to 762 bytes.

multiple-column-list

To comment on more than one column in a table or view with a single COMMENT statement, specify the table or view name, followed by a list in parentheses of the form:

(column-name IS string-constant,
 column-name IS string-constant,
 ...
)

Each column name must not be qualified, and must identify a column of the specified table or view that exists at the current server.

Notes

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following syntax alternatives:

- DATA TYPE or DISTINCT TYPE as a synonym for TYPE
- COMMENT ON ALIAS SYSPUBLIC.name can be specified as an alternative to COMMENT ON PUBLIC ALIAS SYSPUBLIC.name

Examples

Example 1: Enter a comment on table DSN8B10.EMP.

```
COMMENT ON TABLE DSN8B10.EMP
  IS 'REFLECTS 1ST QTR 81 REORG';
```

Example 2: Enter a comment on view DSN8B10.VDEPT.

```
COMMENT ON TABLE DSN8B10.VDEPT
  IS 'VIEW OF TABLE DSN8B10.DEPT';
```

Example 3: Enter a comment on the DEPTNO column of table DSN8B10.DEPT.

```
COMMENT ON COLUMN DSN8B10.DEPT.DEPTNO
  IS 'DEPARTMENT ID - UNIQUE';
```

Example 4: Enter comments on the two columns in table DSN8B10.DEPT.

```
COMMENT ON DSN8B10.DEPT
  (MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',
   ADMRDEPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT');
```

Example 5: Assume that you are SMITH and that you created the distinct type DOCUMENT in schema SMITH. Enter comments on DOCUMENT.

```
COMMENT ON TYPE DOCUMENT
  IS 'CONTAINS DATE, TABLE OF CONTENTS, BODY, INDEX, and GLOSSARY';
```

Example 6: Assume that you are SMITH and you know that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Enter comments on ATOMIC_WEIGHT.
COMMENT ON FUNCTION CHEM.ATOMIC_WEIGHT
IS 'TAKES ATOMIC NUMBER AND GIVES ATOMIC WEIGHT';

Example 7: Assume that you are SMITH and that you created the function CENTER in schema SMITH. Enter comments on CENTER, using the signature to uniquely identify the function instance.

    COMMENT ON FUNCTION CENTER (INTEGER, FLOAT)
    IS 'USES THE CHEBYCHEV METHOD';

Example 8: Assume that you are SMITH and that you created another function named CENTER in schema JOHNSON. You gave the function the specific name FOCUS97. Enter comments on CENTER, using the specific name to identify the function instance.

    COMMENT ON SPECIFIC FUNCTION JOHNSON.FOCUS97
    IS 'USES THE SQUARING TECHNIQUE';

Example 9: Assume that you are SMITH and that procedure OSMOSIS is in schema BIOLOGY. Enter comments on OSMOSIS. Your comments will apply to the currently active version of the procedure OSMOSIS.

    COMMENT ON PROCEDURE BIOLOGY.OSMOSIS
    IS 'CALCULATIONS THAT MODEL OSMOSIS';

Example 11: Assume that you are SMITH and that trigger BONUS is in your schema. Enter comments on BONUS.

    COMMENT ON TRIGGER BONUS
    IS 'LIMITS BONUSES TO 10% OF SALARY';

Example 12: Provide a comment for package MYPKG, which is in collection COLLIDA.

    COMMENT ON COLLIDA.MYPKG
    IS 'THIS IS MY PACKAGE';

Example 14: Provide a comment on role ROLE1:

    COMMENT ON ROLE ROLE1
    IS 'Role defined for trusted context, ctx1';

Example 15: Provide a comment on trusted context CTX1:

    COMMENT ON TRUSTED CONTEXT CTX1
    IS 'WEBSHERE SERVER';

Example 15: Provide a comment on column mask M1:

    COMMENT ON MASK M1
    IS 'Column mask for column EMP.SALARY';
COMMIT

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It cannot be used in the IMS or CICS environment.

Authorization

None required.

Syntax

[Diagram: COMMIT and WORK]

Description

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work. For more information see Chapter 6, “Statements,” on page 865.

Notes

Recommended coding practices: Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK statement before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

Effect of COMMIT: All savepoints that are set within the unit of recovery are released, and all changes are committed for the following statements that are executed during the unit of recovery:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL
• MERGE
• RENAME
• REVOKE
• UPDATE
• SELECT INTO with an SQL data change statement
• subselect with an SQL data change statement

SQL connections are ended when any of the following conditions apply:
• The connection is in the release pending status
• The connection is not in the release pending status but it is a remote connection and:
  – The DISCONNECT(AUTOMATIC) bind option is in effect, or
  – The DISCONNECT(CONDITIONAL) bind option is in effect and an open
    WITH HOLD cursor is not associated with the connection.

For existing connections, all LOB locators are disassociated, except for those
locators for which a HOLD LOCATOR statement has been issued without a
 corresponding FREE LOCATOR statement. All open cursors that were declared
without the WITH HOLD option are closed. All open cursors that were declared
with the WITH HOLD option are preserved, along with any SELECT statements
that were prepared for those cursors.

Static and dynamic INSERT, UPDATE, DELETE, and MERGE statements that
 reference declared global temporary tables that were defined without ON
 COMMIT DROP TABLE and are bound with or use the RELEASE(DEALLOCATE)
 option are kept past commit points. The statement is not kept across the commit
point if one of the following conditions is true:
• The declared global temporary table is defined with the ON COMMIT DROP
  TABLE option.
• The statement uses the RELEASE(COMMIT) bind option.
• The statement also references a DB2 base object (for example, a table or view),
  and one of the following statements is true:
  – The base object reference is for a DB2 catalog table.
  – At the commit point, DB2 determines that another DB2 thread is waiting for
    an X-lock on the base object's database descriptor (DBD).
  – The statement references an XML function or operation, and at the commit
    point DB2 determines that the base object DBD S-lock for the XML operation
    must be released.
  – At the commit point, DB2 determines that a base object DBD S-lock that is
    used by the statement must be released and cannot be maintained across the
    commit point.
• DB2 determines that another DB2 thread is waiting for an X-lock on the DB2
  package that contains the statement.

Prepared dynamic statements are kept past commit points if one of the following
conditions is true:
• Dynamic caching is enabled for your system. In that case, all prepared SELECT
  and data change statements that are bound with KEEPDYNAMIC(YES) are kept
  past the commit point.
• The statements reference a declared global temporary table that was defined
  without ON COMMIT DROP TABLE, and the package was bound with or uses
the RELEASE(DEALLOCATE) option. In that case, all prepared INSERT, UPDATE, DELETE, and MERGE statements that reference the declared global temporary table are kept across the commit point.

Prepared statements cannot be kept past a commit if any of the following conditions is true:
- SQL RELEASE has been issued for that site.
- Bind option DISCONNECT(AUTOMATIC) was used.
- Bind option DISCONNECT(CONDITIONAL) was used and there are no open WITH HOLD cursors for that site.
- The statement references a declared global temporary table, has no open WITH HOLD cursor, and is in a package that is bound with the RELEASE(COMMIT) option.
- The statement references a declared global temporary table that was defined with the ON COMMIT DROP TABLE option. The statement also has no open WITH HOLD cursor, and the statement’s package is bound with or uses the RELEASE(DEALLOCATE) option.

All implicitly acquired locks are released, except for the following locks:
- Locks that are required for the cursors that were not closed
- Table and table space locks when the RELEASE parameter on the bind command was not RELEASE(COMMIT)
- LOB locks and LOB table space locks that are required for held LOB locators

For an explanation of the duration of explicitly acquired locks, see DB2 Performance Monitoring and Tuning Guide.

All rows of every created temporary table of the application process are deleted with the exception that the rows of a created temporary table are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table. In addition, if RELEASE(COMMIT) is in effect, the logical work files for the created temporary tables whose rows are deleted are also deleted.

All rows of every declared temporary table of the application process are deleted with these exceptions:
- The rows of a declared temporary table that is defined with the ON COMMIT PRESERVE ROWS attribute are not deleted.
- The rows of a declared temporary table that is defined with the ON COMMIT DELETE ROWS attribute are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table.

Implicit commit operations: In all DB2 environments, the normal termination of a process is an implicit commit operation.

Restrictions on the use of COMMIT: The COMMIT statement cannot be used in the IMS or CICS environment. To cause a commit operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these commit operations on DB2 data is the same as that of the SQL COMMIT statement.
The COMMIT statement cannot be used in a stored procedure if the procedure is in the calling chain of a user-defined function or a trigger or DB2 is not the commit coordinator.

*Effect of commit on special registers:* Issuing a COMMIT statement may cause special registers to be re-initialized. Whether one of these special registers is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see “CURRENT PATH” on page 190.

*Effect of commit on global variables:* Global variables are not controlled at the transaction level. Issuing a COMMIT statement does not effect the contents of a global variable.

**Example**

Commit all DB2 database changes made since the unit of recovery was started.

```
COMMIT WORK;
```
The CONNECT statement connects an application process to a database server. This server becomes the current server for the process. The CONNECT statement of DB2 for z/OS is equivalent to CONNECT (Type 2) in IBM DB2 SQL Reference for Cross-Platform Development.

Refer to "Distributed data" on page 38 for complete information about connections, the current server, commit processing, and distributed and remote units of work.

**Invocation**

This statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

The primary authorization ID of the process or the authorization ID that is specified in this statement must be authorized to connect to the specified server. The server performs the authorization check when the statement is executed, and determines the specific authorization that is required. See DB2 Administration Guide for further information.

**Syntax**

```
CONNECT
TO location-name

host-variable
authorization
RESET
authorization
```

**Description**

**TO** *location-name* or *host-variable*

Identifies the server by the specified location name or by the location name that is contained in the host variable. If a host variable is specified:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes long.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.
It must not contain lowercase characters.

If used with an SQL procedure language application, host variable must be a qualified SQL-variable name or a qualified SQL-parameter name.

When the CONNECT statement is executed:

- The location name must identify a server known to the local DB2 subsystem. Hence, the location name must be the location name of the local DB2 subsystem or it must appear in the LOCATION column of the SYSIBM.LOCATIONS table.
- The application process must not have an existing connection to the specified server, if the SQLRULES(STD) bind option is in effect.
- The application process must be in a connectable state, if the transaction is participating in a remote unit of work.

**RESET**

CONNECT RESET is equivalent to CONNECT TO \(x\) where \(x\) is the location name of the local DB2 subsystem.

- If the SQLRULES(DB2) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection.
- If the SQLRULES(STD) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection only if the connection does not exist.

**authorization**

Specifies an authorization ID and a password that is used to verify that the authorization ID is authorized to connect to the server. Authorization cannot be specified when the connection type is IMS or CICS for a connection to the local DB2 subsystem. An attempt to do so causes an SQL error.

**USER host-variable**

Identifies the authorization name to use when connecting to the server. The value of host-variable must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified within the host variable and must conform to the rules for forming an authorization name.
- The value must not be followed by an indicator variable.
- The value must be padded on the right with blanks if the length of the authorization name is less than the length of the host variable.

For a connection to the local DB2 subsystem, a user ID that is longer than 8 characters causes an SQL error.

**USING host-variable**

Identifies the password of the authorization name to use when connecting to the server. The value of host-variable must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified.
- The value must not include an indicator variable.
- The value must be padded on the right with blanks if the length of the password is less than the length of the host variable.
- The value must not contain lowercase characters.

For a connection to a DB2 subsystem, a password that is longer than 8 characters causes an SQL error.
CONNECT USER/USING is equivalent to CONNECT TO x USER/USING where x is the location name of the local DB2 subsystem (which has the semantic of CONNECT RESET).

CONNECT with no operand
This form of the CONNECT statement returns information about the current server in the SQLERRP field of the SQLCA. SQLERRP returns blanks if the application process is in the unconnected state.

Executing a CONNECT with no operand has no effect on connection states.

In a remote unit of work, this form of CONNECT does not require the application process to be in a connectable state.

Notes
Successful connection: With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is successful:

• One of the following scenarios takes place in a distributed unit of work:
  – If the location name does not identify a server to which the application process is already connected, an SQL connection to the server is created and placed in the current and held state. The previously current SQL connection, if any, is placed in the dormant state.
  – If the location name identifies a server to which the application process is already connected, the associated SQL connection is dormant, and the SQLRULES(DB2) option is in effect, the SQL connection is placed in the current state. The previously current SQL connection, if any, is placed in the dormant state.
  – If the location name identifies a server to which the application process is already connected, the associated SQL connection is current, and the SQLRULES(DB2) option is in effect, the states of all SQL connections of the application process are unchanged.

• The following actions occur in a remote unit of work:
  – The application process is connected to the specified server.
  – An existing SQL connection of the application process is ended. As a result, all cursors of that SQL connection are closed, all prepared statements of that connection are destroyed, and so on.

• The location name is placed in the CURRENT SERVER special register.
• When CONNECT is used to connect back to the local DB2 subsystem, the CURRENT SQLID special register is reinitialized if the USER/USING clause is specified.
• Information about the server is placed in the SQLERRP field of the SQLCA. If the server is a DB2 product, the information has the form `ppp`vvr"rm. The format is `ppp`vvr"rm. It contains the following information:

  `ppp`  The product identifier:
  'AQT' IBM DB2 Analytics Accelerator for z/OS
  'ARI' DB2 Server for VSE & VM
  DSN' DB2 for z/OS
  'JCC' IBM Data Server Driver for JDBC and SQLJ
  'QSQ' DB2 for i
  'SQL' DB2 for Linux, UNIX, and Windows
The version identifier such as '11' for Version 11.

The release identifier such as '01'.

The modification level:
- Values '0', '1', '2', '3', and '4' identify modification levels in conversion and enabling-new-function mode from Version 10 (CM10, CM10*, ENFM10, and ENFM10*)
- Values '5', '6', '7', '8', and '9' identify modification levels in new-function mode.

For example, if the identified product is Version 11 of DB2 for z/OS in new-function mode, the value is ‘DSN11015’.

Additional information about the connection is placed in the SQLERRMC field of the SQLCA. The contents are product-specific.

Tip: Use the GET DIAGNOSTICS statement to get detailed diagnostic information about the last SQL statement that was executed.

Unsuccessful connection: With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is unsuccessful:

- In a distributed unit of work, the connection state of the application process and the states of its SQL connections are unchanged unless the failure was because an authorization check failed. If this is the case, the connection is placed in the connectable and unconnected state.
- In a remote unit of work, the SQLERRP field of the SQLCA is set to the name of the DB2 requester module that detected the error.

If execution of the CONNECT statement is unsuccessful because the application process is not in the connectable state, the connection state of the application process is unchanged. If execution of the CONNECT statement is unsuccessful for any other reason, CURRENT SERVER is set to blanks and the application process is placed in the connectable and unconnected state.

Authorization: If the server is a DB2 subsystem, a user is authenticated in the following way:

- DB2 invokes RACF via the RACROUTE macro with REQUEST=VERIFY to verify the password.
- If the password is verified, DB2 then invokes RACF again via the RACROUTE macro with REQUEST=AUTH, to check whether the authorization ID is allowed to use DB2 resources defined to RACF.
- DB2 then invokes the connection exit routine if one has been defined.
- The connection then has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID.

If the server is a remote DB2 subsystem, the requester generates authentication tokens and sends them to the remote site in the following way:

- The SECURITY_OUT column in SYSIBM.LUNAMES for SNA or the SECURITY_OUT column in SYSIBM.IPNAMES for TCP/IP must have one of the following values:
  - 'A' (already verified)
  - 'D' (userid and security-sensitive data encryption; TCP/IP only)
  - 'E' (userid, password, and security-sensitive data encryption; TCP/IP only)
  - 'P' (password)
When the value is 'A', the user ID and password specified on the CONNECT is still sent.

When the value is 'D', 'E', 'or 'P', the requester encrypts the user ID and password specified on the CONNECT for TCP/IP. However, if the Integrated Cryptographic Service Facility (ICSF) is not configured at the requester or if the server does not support encryption, one of the following actions occurs:

- If the value of SECURITY_OUT in SYSIBM.IPNAMES is 'D' or 'E', SQLCODE -904 is returned if ICSF is not configured at the requester, and SQLCODE -30082 is returned if the server does not support encryption.
- If the value of SECURITY_OUT in SYSIBM.IPNAMES is 'P', the requester does not encrypt the user ID and password and flows the tokens in clear text.

- For SNA, the ENCRYPTPSWDS column in SYSIBM.SYSLUNAMES must be not contain 'Y'.
- The authorization ID and password are verified at the server.
- In all cases, outbound translation—as specified in SYSIBM.USERNAMES—is not done.

Distributed unit of work: In general, the following are true:

- A CONNECT statement with the TO clause and the USER/USING clause can be executed only if no current or dormant connection to the named server exists. However, if the named server is the local DB2 subsystem and the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.
- A CONNECT statement without the TO clause but with the USER/USING clause can be executed only if no current or dormant connection to the local DB2 subsystem exists. However, if the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.

Remote unit of work: If the authorization check fails, the connection is placed in the connectable and unconnected state.

Precompiler options: Regardless of whether a program is precompiled with the CONNECT(1) or CONNECT(2) option, DB2 for z/OS negotiates with the remote server during the connection process to determine how to perform commits. If the remote server does not support the two-phase commit protocol, DB2 downgrades to perform one-phase commits.

Programs containing CONNECT statements that are precompiled with different CONNECT precompiler options cannot execute as part of the same application process. An error occurs when an attempt is made to execute the invalid CONNECT statement.

Host variables: If a CONNECT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Error processing: A CONNECT statement can return and indicate a successful execution even when no physical connection yet exists. DB2 delays the physical connection process, when possible, to economize on the number of messages it sends to a server. Therefore, errors in CONNECT statement processing can be reported following the next executable SQL statement, not immediately following the CONNECT statement.
Restrictions on array types and array variables: In any SQL statement other than a CALL statement, array types and array variables must not be referenced after a connection at a remote server has been established. This restriction includes an SQL statement that executes at a remote server as a result of a three-part name or alias that resolves to an object at a remote server. An exception is that an array element can be the target of a FETCH, SELECT INTO, SET assignment-statement, or VALUES INTO statement in an SQL routine even when the statement is executed at a remote server.

Examples

Example 1: Connect an application to a DBMS. The location name is in the character-string variable LOCNAME, the authorization identifier is in the character-string variable AUTHID, and the password is in the character-string variable PASSWORD.

```
EXEC SQL CONNECT TO :LOCNAME USER :AUTHID USING :PASSWORD;
```

Example 2: Obtain information about the current server.

```
EXEC SQL CONNECT;
```

Example 3: Execute SQL statements in a distributed unit of work. The first CONNECT statement creates a connection to the EASTDB server. The second CONNECT statement creates a connection to the WESTDB server, and places the SQL connection to EASTDB in the dormant state.

```
EXEC SQL CONNECT TO EASTDB;
  -- execute statements referencing objects at EASTDB
EXEC SQL CONNECT TO WESTDB;
  -- execute statements referencing objects at WESTDB
```

Example 4: Connect the application to a DBMS whose location identifier is in the character-string variable LOC using the authorization identifier in the character-string variable AUTHID and the password in the character-string variable PASSWORD. Perform work for the user, and then release the connection and connect again using a different user ID and password.

```
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
  -- execute SQL statements accessing data on the server
RELEASE :LOC;
EXEC SQL COMMIT;
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
  -- set AUTHID and PASSWORD to new values
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
  -- execute SQL statements accessing data on the server
```

Example 5: Change servers in a remote unit of work. Assume that the application connected to a remote DB2 server, opened a cursor, and fetched rows from the cursor's result table. Subsequently, to connect to the local DB2 subsystem, the application executes the following statements:

```
EXEC SQL COMMIT WORK;
EXEC SQL CONNECT RESET;
```

The COMMIT is required because opening the cursor caused the application to enter the unconnectable and connected state.

If the cursor was declared with the WITH HOLD clause and was not closed with a CLOSE statement, it would still be open even after execution of the COMMIT statement. However, it would be closed with the execution of the CONNECT statement.

Related concepts:
Explicit CONNECT statements (Introduction to DB2 for z/OS)

"Distributed data” on page 38

Related tasks:

- Reusing a local trusted connection through the SQL CONNECT statement (Managing Security)
CREATE ALIAS

The CREATE ALIAS statement defines an alias for a table, a view, or a sequence. The definition is recorded in the DB2 catalog at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

To create an alias, the privilege set must include at least one of the listed authorities or privileges:

To create an alias for a table or a view:
- The CREATEALIAS privilege
- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES
- System DBADM

To create an alias for a sequence:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner of the plan or package is a role, this role must hold the privileges for the privilege set. If the specified alias name includes a qualifier that is not the same as this authorization ID, the privilege set must include one of the following authorities:
- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:
- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.
If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. If the process is not running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause and the specified alias name includes a qualifier that is not the same as this authorization ID:

- The privilege set must include SYSADM or SYSCTRL authority.
- The privilege set must include DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES.
- The qualifier must be the same as one of the authorization IDs of the process and the privileges that are held by that authorization ID must include the CREATEALIAS privilege. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

Syntax

```
CREATE ALIAS table-alias
PUBLIC sequence-alias
```

```
table-alias
PUBLIC sequence-alias
```

```
table-alias
PUBLIC sequence-alias
```

Description

**PUBLIC**

Specifies that the alias is an object in the system schema SYSPUBLIC.

The PUBLIC keyword is used to create a public alias. If the keyword PUBLIC is not specified, the alias that is created is a private alias.

PUBLIC can be specified only for a sequence.

**alias-name**

Names the alias.

For a table alias, the name, including the implicit or explicit qualifier, must not identify a table, view, or table alias that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.
For a sequence alias, the name, including the implicit or explicit qualifier, must not identify a sequence or sequence alias that exists at the current server.

If a two-part name is specified, the schema name cannot begin with 'SYS', except if PUBLIC is specified, in which case the schema name must be SYSPUBLIC. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

When an application uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names.

**FOR TABLE** table-name, view-name, or alias-name2
Identifies the table, view, or table alias for which alias-name is defined. If another alias name is specified (alias-name2), it must not be the same as the new alias-name that is being defined (in its fully-qualified form). If a table is identified, it must not be an auxiliary table, a declared temporary table, or a table that is implicitly created for an XML column.

The table or view need not exist at the time the alias is defined. If it does not exist when the alias is created, a warning is returned. However, the referenced object must exist when a SQL statement that contains the alias is used, otherwise an error is returned. If it does exist, the referenced object can be at the current server or at another server. The referenced name must not be an alias that exists at the current server.

**FOR SEQUENCE** sequence-name
Identifies the sequence for which alias-name is defined. The sequence-name must not be a sequence that is generated by the DB2 subsystem for an identity column or a DOCID column. The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'. sequence-name must not be an existing alias for a sequence.

The sequence need not exist at the time the alias is defined. If sequence-name does not exist when the alias is created, a warning is returned. However, the referenced object must exist when a SQL statement that contains the alias is used, otherwise an error is returned.

**Notes**

**Owner privileges:**
There are no specific privileges on an alias. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

**PUBLIC aliases:**
If the PUBLIC keyword is specified or if SYSPUBLIC is explicitly specified as the schema qualifier for alias-name, a public alias is created.

**Resolving an unqualified alias name:**
When an unqualified alias name is resolved, private aliases are considered before public aliases.

**Conservative binding for aliases for synonyms:**
The timestamp for creation of an alias for a synonym must be older than
the timestamp that results from an explicit bind for the package that
contains the reference to the alias for the synonym. During the automatic
bind process, aliases for synonyms that are created in a release of the DB2
subsystem that is later than the release that was used to explicitly bind the
package are not considered for resolution of an alias for a synonym.

Example

Example 1: Create an alias for a catalog table at a DB2 with location name
DB2USCALABOA5281.

    CREATE ALIAS LATABLES FOR DB2USCALABOA5281.SYSIBM.SYSTABLES;

Example 2: Create a public alias called SEQS for a sequence named JOE.JOESSEQ.

    CREATE PUBLIC ALIAS SEQS FOR JOE.JOESSEQ;

The alias can be referenced as SYSPUBLIC.SEQS, or simply as SEQS if a private
sequence or alias named SEQS does not exist.
CREATE AUXILIARY TABLE

The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

Invocation

This statement can be embedded in an application program or issued interactively if the value of special register CURRENT RULES is 'DB2' and the table space is explicitly created when the statement is executed. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Do not use this statement if the value of special register CURRENT RULES is 'STD' or if the table space is implicitly created. When the values of the CURRENT RULES special register is 'STD' and a base table is created with LOB columns or altered such that LOB columns are added, DB2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column. DB2 also automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column if the table space is implicitly created. DB2 chooses the names and characteristics of these objects. For more information about the names and the characteristics, see Creating a table with LOB columns.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database implicitly or explicitly specified by the IN clause
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specifies, a role is the owner. Otherwise, an authorization ID is the owner. If the specified table name includes a qualifier that is not the same as this authorization ID, the privilege set must include SYSADM or SYSCTRL authority, DBADM authority for the database, or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case,
the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. If the process is in a trusted context, any authorization ID can be the qualifier. However, if the process is not in a trusted context and if the specified table name includes a qualifier that is not the same as the SQL authorization ID of the process, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the table.

**Syntax**

```sql
CREATE AUXILIARY TABLE aux-table-name IN database-name.

STORES table-name COLUMN column-name
```

**Description**

**AUXILIARY or AUX**

Specifies a table that is used to store the LOB data for a LOB column (or a column with a distinct type that is based on a LOB data type).

**aux-table-name**

Names the auxiliary table. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

**IN database-name.table-space-name or IN table-space-name**

Identifies the table space in which the auxiliary table is created. The name must identify an empty LOB table space that currently exists at the current server. The LOB table space must be in the same database as the associated base table.

If you specify a database and a table space, the table space must belong to the specified database. If you specify only a table space, it must belong to the database that contains the specified table space. If you specify only a table space, this table space must belong to DSNDB04. This type of table space is only created when SET CURRENT RULES='DB2' is specified.

**STORES table-name COLUMN column-name**

Identifies the base table and the column of that table that is to be stored in the auxiliary table. If the base table is nonpartitioned, an auxiliary table must not

---

29. Exception: The CREATETAB privilege is checked on the SQL authorization ID of the process.
already exist for the specified column. If the base table is partitioned, an auxiliary table must not already exist for the specified column and specified partition.

The encoding scheme for the LOB data stored in the auxiliary table is the same as the encoding scheme for the base table. It is either ASCII, EBCDIC, or UNICODE depending on the value of the CCSID clause when the base table was created.

**APPEND NO or APPEND YES**

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition-by-growth table space, the APPEND attributes of LOB table will be inherited by each partition.

**APPEND NO**

Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

APPEND NO is the default

**APPEND YES**

Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

**PART integer**

Specifies the partition of the base table for which the auxiliary table is to store the specified column. You can specify PART only if the base table is defined in a partitioned table space, and no other auxiliary table exists for the same LOB column of the base table.

**Notes**

Owner privileges: There are no specific privileges on an auxiliary table. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

Determining the number of auxiliary tables to create: If the base table is nonpartitioned, you might need to create one LOB table space and one auxiliary table for each LOB column in the base table. If the base table is partitioned, for each LOB column, you might need to create one LOB table space and one auxiliary table for each partition. For example if your base table has three partitions and two LOB columns, you might need to create three LOB table spaces and three auxiliary tables for each LOB column. In other words, you might need a total of six LOB table spaces and six auxiliary tables.

Auxiliary tables in LOB table spaces that are logged: When you create an auxiliary table in a LOB table space that is LOGGED, and the associated base table space is NOT LOGGED, the logging attribute of the LOB table space is implicitly changed to NOT LOGGED and the logging attributes of the base table space and the LOB table space are linked.

Append processing and unused free space in a table: An update or delete of LOB data creates some free space in the LOB table that can be used by the next insert.
the table uses append processing, any free space that is not at the end of the table space will not be reused during the insert operation. Any unused free space in the table can be reclaimed by running the REORG utility with either the SHRLEVEL REFERENCE or SHRLEVEL CHANGE keywords. The REORG utility is not influenced by the APPEND option.

**Example**

Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to sample employee table DSN8B10.EMP for each employee's photo. Create auxiliary table EMP_PHOTO_ATAB to store the BLOB data for the BLOB column in LOB table space DSN8D11A.PHOTOLTS.

```sql
CREATE AUX TABLE EMP_PHOTO_ATAB
  IN DSN8D11A.PHOTOLTS
  STORES DSN8B10.EMP
  COLUMN EMP_PHOTO;
```
CREATE DATABASE

The CREATE DATABASE statement defines a DB2 database at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEDBA privilege
- The CREATEDBC privilege
- SYSADM or SYSCTRL authority
- System DBADM

If the database is created as a workfile database, the privilege set that is defined below must include SYSADM authority.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process.

See “Notes” on page 1210 for the authorization effect of a successful CREATE DATABASE statement.

Syntax

```
CREATE DATABASE database-name
  BUFFERPOOL bpname
  INDEXBP bpname
  AS WORKFILE
  FOR member-name
  STOGROUP stogroup-name
  CCSID ASCII
  EBCDIC
  UNICODE
```

Notes:

1. The same clause must not be specified more than one time.
Description

database-name

Names the database. The name must not start with DSNDDB and must not identify a database that exists at the current server. database-name must not be in the form of eight characters that start with DSN followed by exactly five digits. If the database is to be a work file database in a data sharing environment, DSNDB07 is an acceptable work file database name. However, only one member of a data sharing group can use DSNDB07 as the name of its work file database.

BUFFERPOOL bpname

Specifies the default buffer pool name to be used for table spaces created within the database. If the database is a work file database, 8KB and 16KB buffer pools cannot be specified. See “Naming conventions” on page 59 for more details about bpname.

If you omit the BUFFERPOOL clause, the default 4-KB buffer pool for user data that is specified on installation panel DSNTIP1 is used.

INDEXBP bpname

Specifies the default buffer pool name to be used for the indexes created within the database. The name can identify a 4KB, 8KB, 16KB, or 32KB buffer pool. See “Naming conventions” on page 59 for more details about bpname.

If you omit the INDEXBP clause, the buffer pool specified for user indexes on installation panel DSNTIP1 is used. The default value for the user indexes field on that panel is BP0.

AS WORKFILE

Specifies the database is a work file database. AS WORKFILE can be specified only in a data sharing environment. Only one work file database can be created for each DB2 subsystem. The work file database is used for work files, created global temporary table, declared temporary tables, and sensitive static scrollable cursors.

PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority) to define a declared temporary table in the work file database. This implicit privilege is not recorded in the DB2 catalog and cannot be revoked.

The CCSID clause is not supported for a work file database. If you specify AS WORKFILE, do not use the CCSID clause.

FOR member-name

Specifies the member for which this database is to be created. Specify FOR member-name only in a data sharing environment.

If FOR member-name is not specified, the member is the DB2 subsystem on which the CREATE DATABASE statement is executed.

STOGROUP stogroup-name

Specifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. The default is SYSDEFLT.

CCSID encoding-scheme

Specifies the default encoding scheme for data stored in the database. The default applies to table spaces created in the database. All tables stored within a table space must use the same encoding scheme.

ASCII Specifies that the data must be encoded using the ASCII CCSIDs of the server.
EBCDIC
Specifies that the data must be encoded using the EBCDIC CCSIDs of the server.

UNICODE
Specifies that the data must be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

The option defaults to the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Do not use the CCSID clause if you specify the AS WORKFILE clause.

Notes
If the statement is embedded in an application program, the owner of the plan or package is the owner of the database. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the database.

If the owner of the database has the CREATEDBA, SYSADM, or SYSCTRL authority, the owner acquires DBADM authority for the database. DBADM authority for a database includes table privileges on all tables in that database. Thus, if a user with SYSCTRL authority creates a database, that user has table privileges on all tables in that database. This is an exception to the rule that SYSCTRL authority does not include table privileges.

If the owner of the database has the CREATEDBC privilege, but not the CREATEDBA privilege, the owner acquires DBCTRL authority for the database. In this case, no authorization ID has DBADM authority for the database until it is granted by an authorization ID with SYSADM authority.

Examples

Example 1: Create database DSN8D11P. Specify DSN8G110 as the default storage group to be used for the table spaces and indexes in the database. Specify 8KB buffer pool BP8K1 as the default buffer pool to be used for table spaces in the database, and BP2 as the default buffer pool to be used for indexes in the database.

```sql
CREATE DATABASE DSN8D11P
STOGROUP DSN8G110
BUFFERPOOL BP8K1
INDEXBP BP2;
```

Example 2: Create database DSN8TEMP. Use the defaults for the default storage group and default buffer pool names. Specify ASCII as the default encoding scheme for data stored in the database.

```sql
CREATE DATABASE DSN8TEMP
CCSID ASCII;
```
**CREATE FUNCTION**

The CREATE FUNCTION statement registers a user-defined function with a database server. Each type of function that you can register with this statement is described separately.

**External scalar**

The function is written in a programming language and returns a scalar value. The external executable routine is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external scalar)” on page 1239.

**External table**

The function is written in a programming language. It returns a table to the subselect from which it was started by returning one row at a time, each time that the function is started. The external executable routine is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external table)” on page 1264.

**Sourced**

The function is implemented by starting another function (either built-in, external, SQL, or sourced) that exists at the server. The function inherits the attributes of the underlying source function. See “CREATE FUNCTION (sourced)” on page 1294.

**SQL scalar**

The function is written exclusively in SQL statements and returns a scalar value. The body of an SQL scalar function is written in the SQL procedural language. The function is defined at the current server along with various attributes of the function.

See “CREATE FUNCTION (compiled SQL scalar)” on page 1212 and “CREATE FUNCTION (inlined SQL scalar)” on page 1283.

**SQL table**

The function is written exclusively as an SQL RETURN statement and returns a set of rows. The body of an SQL table function is written in the SQL procedural language. The function is defined at the current server along with various attributes of the function. See “CREATE FUNCTION (SQL table)” on page 1308.

Related concepts:

- “User-defined functions” on page 235
- “Sample user-defined functions” on page 2683

Related tasks:

- Defining a user-defined function (DB2 Application programming and SQL)
CREATE FUNCTION (compiled SQL scalar)

The CREATE FUNCTION (compiled SQL scalar) statement defines a compiled SQL scalar function at the current server and specifies the source statements for the function. The body of the function is written in the SQL procedural language. The function returns a single value each time it is invoked.

A package is created for a compiled SQL scalar function.

For compiled SQL scalar functions, you can define multiple versions of the function. Use CREATE FUNCTION (compiled SQL scalar) to define the initial version, and ALTER FUNCTION to define subsequent versions. For information about the SQL statements that are supported in SQL functions, refer to "SQL-procedure-statement" on page 2034.

Invocation

For a compiled SQL function, this statement can only be dynamically prepared but the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package, depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a user-defined type is referenced (as the data type of a parameter or an SQL variable), the privilege set must also include at least one of the following:

- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- SYSADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:

- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege
Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

```
CREATE FUNCTION function-name(
  parameter-declaration
)
RETURNS data-type
  VERSION V1
  VERSION routine-version-id
  option-list
  SQL-routine-body
```

```
parameter-declaration:
```
```
  parameter-name parameter-type
```

```
parameter-type:
```
```
data-type
  TABLE LIKE table-name
  AS LOCATOR
  view-name
```
**built-in-type:**

```
- SMALLINT
- INTEGER
- BIGINT
- DECIMAL (5, 0)
- NUMERIC (integer, integer)
- DECIMAL (integer)
- REAL (integer)
- DOUBLE (34)
- DECIMAL (integer)
- CHARACTER (integer) CCSID ASCII FOR SBCS DATA
- CHARACTER VARYING (integer) EBCDIC MIXED
- CHARACTER large OBJECT (integer) CCSID ASCII FOR SBCS DATA
- CLOB K EBCDIC MIXED
- GRAPHIC (integer) CCSID ASCII
- VARGRAPHIC (integer) EBCDIC
- DBCLOB (integer)
- BINARY (integer)
- BINARY VARYING (integer)
- VARBINARY (integer)
- BINARY LARGE OBJECT (integer)
- BLOB (integer)
- DATE
- TIME
- TIMESTAMP WITHOUT TIME ZONE
- ROWID
- XML
```
option-list: (The options in the option-list can be specified in any order, but each one can only be specified one time)
Description

function-name

Names the function. If function-name already exists with the specified signature, an error is returned even if VERSION is specified with a routine-version-id that is different from any existing version identifier for the function that is specified in function-name.\(^{30}\)

(parameter-declaration,...)

Specifies the number of input parameters of the function and the name and data type of each parameter. Each parameter-declaration specifies an input parameter for the function. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All of the parameters for a function are input parameters and are nullable. If the function has more than 30 parameters, only the first 30 parameters are used to determine if the function is unique.

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

If you specify the name of the distinct type without a schema name, DB2 resolves the distinct type by searching the schemas in the SQL path.

TABLE LIKE table-name AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This value is a locator for the table, which the function uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the triggered action of a trigger.

\(^{30}\) If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
array-type-name
The data type of the input parameter is a user-defined array type.

If you specify array-type-name without a schema name, DB2 resolves
the array type by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the
parameters with a character or graphic string data type must be the
same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or
explicitly specified subtype (BIT, SBCS, or MIXED), the function program
can receive character data of any subtype. Therefore, conversion of the
input data to the subtype of the parameter might occur when the function
is invoked. An error occurs if mixed data that actually contains DBCS
characters is used as the value for an input parameter that is declared with
an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the
function as a different data type:

• A datetime type parameter is passed as a character data type, and the
data is passed in ISO format.
  The encoding scheme for a datetime type parameter is the same as the
implicitly or explicitly specified encoding scheme of any character or
graphic string parameters. If no character or graphic string parameters
are passed, the encoding scheme is the value of field DEF ENCODING
SCHEME on installation panel DSNTIPF.

• A distinct type parameter is passed as the source type of the distinct
type.

RETURNS
Identifies the output of the function.

data-type2
Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as
described under array-type-name apply to the data type of the output of the
function.

VERSION routine-version-id
Specifies the version identifier for the first version of the function that is to be
generated. You can use an ALTER FUNCTION statement with the ADD
VERSION clause or the BIND DEPLOY command to create additional versions
of the function.

routine-version-id
An SQL identifier of up to 64 EBCDIC bytes that designates a version
of a routine. The UTF-8 representation of the name must not exceed
122 bytes.

V1 is the default version identifier.

LANGUAGE SQL
Specifies that the function is written exclusively in SQL.

SPECIFIC specific-name
Specifies a unique name for the function. The name is implicitly or explicitly
qualified with a schema name. The name, including the schema name, must
not identify the specific name of another function that exists at the current
server.
The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSTABLES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

**NOT DETERMINISTIC** must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. **NOT DETERMINISTIC** is the default.

**DETERMINISTIC**

The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. **DETERMINISTIC** is not the default. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.
EXTERNAL ACTION

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from the function. For the data access classification of each statement, see Table 167 on page 2096.

MODIFIES SQL DATA

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

READS SQL DATA

Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.
**READS SQL DATA** is the default.

**CONTAINS SQL**
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

**CALLED ON NULL INPUT or RETURNS NULL ON NULL INPUT**
Specifies whether the function is invoked if any of the input arguments is null at execution time.

**CALLED ON NULL INPUT**
Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

**CALLED ON NULL INPUT** is the default.

**RETURNS NULL ON NULL INPUT**
Specifies that the function is not invoked and returns the null value if any of the input argument values is null.

**STATIC DISPATCH**
At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

**ALLOW PARALLEL or DISALLOW PARALLEL**
Specifies if the function can be run in parallel. The default is DISALLOW PARALLEL, if you specify one or more of the following clauses:

- NOT DETERMINISTIC
- EXTERNAL ACTION
- MODIFIES SQL DATA

Otherwise, ALLOW PARALLEL is the default.

**ALLOW PARALLEL**
Specifies that the function can be run in parallel.

**DISALLOW PARALLEL**
Specifies that the function cannot be run in parallel.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**
Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

**ALLOW DEBUG MODE**
Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

**DISALLOW DEBUG MODE**
Specifies that this version of the routine cannot be run in debugging mode.

You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

**DISABLE DEBUG MODE**
Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has
been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

**PARAMETER CCSID**
Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

If the data type for a parameter is a user-defined array type that is defined with character or graphic string array elements, or a character string array index, the CCSID of these array attributes must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER schema-name**
Specifies the implicit qualifier that is used for unqualified names of tables, views, indexes, and aliases that are referenced in the routine body. The default value is the same as the default schema.

**PACKAGE OWNER authorization-name**
Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body and must contain the necessary bind privileges. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, authorization-name must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, authorization-name can be any authorization ID that contains the necessary bind privileges.

**ASUTIME**
Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.
NO LIMIT
Specifies that there is no limit on the service units.

NO LIMIT is the default.

LIMIT integer
The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine.

INHERIT SPECIAL REGISTERS
Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 40 on page 212.

INHERIT SPECIAL REGISTERS is the default.

DEFAULT SPECIAL REGISTERS
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 40 on page 212.

WLM ENVIRONMENT FOR DEBUG MODE name
Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

CURRENT DATA YES or CURRENT DATA NO
Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA YES also determines whether block fetch can be used for distributed, ambiguous cursors.

CURRENT DATA YES
Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

CURRENT DATA NO
Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You
receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

**CURRENT DATA NO** is the default.

**DEGREE**

Specifies whether to attempt to run a query using parallel processing to maximize performance.

- **1** Specifies that parallel processing should not be used.
  
  1 is the default.

- **ANY** Specifies that parallel processing can be used.

**CONCURRENT ACCESS RESOLUTION**

Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**

Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

**USE CURRENTLY COMMITTED**

Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

**DYNAMICRULES** also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the **DYNAMICRULES** clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the **DYNAMICRULES** value and the run time
environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**
- Specifies that dynamic SQL statements are to be processed using run behavior.
  - **RUN** is the default.

**BIND**
- Specifies that dynamic SQL statements are to be processed using bind behavior.

**DEFINEBIND**
- Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

**DEFINERUN**
- Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

**INVOKEBIND**
- Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

**INVOKE_RUN**
- Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See "Authorization IDs and dynamic SQL" on page 77 for information on the effects of these options.

**APPLICATION ENCODING SCHEME**
- Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

**ASCII**
- Specifies that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**
- Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**
- Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

**WITH EXPLAIN or WITHOUT EXPLAIN**
- Specifies whether information will be provided about how SQL statements in the routine will execute.

**WITHOUT EXPLAIN**
- Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the
EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

WITH EXPLAIN
  Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table owner PLAN_TABLE. owner is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as owner PLAN_TABLE that points to the base table, PLAN_TABLE. owner must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. PLAN_TABLE must have a base table and can have multiple aliases with the same table name, PLAN_TABLE, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to owner PLAN_TABLE, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables if they exist: DSN_STATEMNT_TABLE and DSN_FUNCTION_TABLE. DSN_STATEMNT_TABLE contains an estimate of the processing cost for an SQL statement. See DB2 Application Programming and SQL Guide for more information. DSN_FUNCTION_TABLE contains information about function resolution. See DB2 Application Programming and SQL Guide for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see “EXPLAIN” on page 1706.

WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE
  Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. DB2 Command Reference shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

WITHOUT IMMEDIATE WRITE
  Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

WITH IMMEDIATE WRITE
  Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

ISOLATION LEVEL RR, RS, CS, or UR
  Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see DB2 Performance Monitoring and Tuning Guide.

RR  Specifies repeatable read.
RS  Specifies read stability.
CS Specifies cursor stability. **CS** is the default.

**UR** Specifies uncommitted read.

**OPTHINT** *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

*string-constant* is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See DB2 Installation Guide for information about enabling optimization hints.

**SQL PATH**

Specifies the SQL path that the DB2 subsystem uses to resolve unqualified user-defined data types, functions, and procedure names (in CALL statements) in the body of the routine. The maximum length of the SQL path is 2048 bytes. DB2 calculates the length by taking each *schema-name* that is specified and removing any trailing blanks from it, adding a delimiter on the left and right sides, and adding one comma after each schema name except for the last name. The length of the resulting string cannot exceed 2048 bytes.

*schema-name*

Identifies a schema. DB2 does not verify that the schema exists when the CREATE statement is processed. The same schema name should not appear more than one time in the list of schema names.

SYSPUBLIC must not be specified for the SQL path.

**SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBADM".

**SESSION_USER or USER**

Specifies the value of the SESSION_USER (or USER) special register. At the time the CREATE statement is processed, the actual length is included in the total length of the list of schema names that is specified for the SQL PATH option.

**REOPT**

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

**NONE**

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

**NONE** is the default.

**ALWAYS**

Specifies that DB2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

**ONCE**

Specifies that DB2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access
path is used until the prepared statement is invalidated or removed from
the dynamic statement cache and need to be prepared again.

**QUERY ACCELERATION**

Specifies whether a static SQL query is bound for acceleration, and if so, with
what behavior.

**NONE**

Specifies that no static SQL query in the application is bound for
acceleration or will be accelerated when the application is run.

**ENABLE**

Specifies that a static SQL query is bound for acceleration if it satisfies the
acceleration criteria, including the cost and heuristics criteria. The query is
routed to an accelerator when the application runs. Otherwise, if the static
query does not satisfy the acceleration criteria, the query is bound for
execution in DB2.

If an error condition, such as one of the following examples, occurs while
executing the accelerated static query when the application is run, DB2
fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
- The accelerator returns an error for the query.
- The accelerator is not started and DB2 cannot route the static query to
  the accelerator for execution.

**ENABLE WITH FAILBACK**

Results in the same behavior as ENABLE, except if one of the error
conditions occurs on the first OPEN of the accelerated static query when
the application is run. In this case, instead of failing the static query and
returning a negative SQL code to the application, DB2 performs a
temporary *statement-level* incremental bind of the query and runs the query
in DB2. The application does not see the acceleration failure. Failback to
DB2 is not possible after the application does a successful OPEN for the
query on the accelerator.

**ELIGIBLE**

Specifies that a static SQL query is bound for acceleration if the query
meets the basic acceleration criteria, regardless of the cost or heuristics
criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.

**ALL**

Specifies that all of the static SQL queries in the application are to be
bound for acceleration and routed to the accelerator when the application
runs. If DB2 determines that a static query cannot be bound to run on the
accelerator and the query references a user base table or view, the BIND or
REBIND PACKAGE operation fails with an error message for that query.
(A failure exception is made for declared global temporary tables (DGTTs)
and created global temporary tables and (CGTTs) because these tables
cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.
This bind option does not apply to a `fullselect` or `WITH common-table-expression` that is specified in a RETURN statement for the routine, or in a SET `host-variable-assignment` that is used in the routine. The queries that are specified in these cases cannot be accelerated.

**GET_ACCEL_ARCHIVE**

Specifies whether a static SQL query that is bound for acceleration retrieves archived data on the accelerator, instead of active data.

**NO**

Specifies that no static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2.

If the static query is bound for acceleration because the `QUERYACCELERATION` bind option was specified, the query is routed to the accelerator when the application runs; however, the query does not retrieve any archived data.

**YES**

Specifies that if all of the following criteria are met, the query is bound for acceleration and retrieves the archived data on the accelerator when the application runs:

- The `QUERYACCELERATION` bind option is also specified.
- The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
- The static query satisfies the acceleration criteria that is specified by the `QUERYACCELERATION` bind option.

If the static query does not satisfy the acceleration criteria that is specified by the `QUERYACCELERATION` bind option, the `BIND` or `REBIND PACKAGE` operation fails with an error message for that query.

This bind option does not apply to a `fullselect` or `WITH common-table-expression` that is specified in a RETURN statement for the routine, or in a SET `host-variable-assignment` that is used in the routine. The queries that are specified in these cases cannot be accelerated.

**VALIDATE RUN or VALIDATE BIND**

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

**VALIDATE RUN**

Specifies that if needed objects or privileges do not exist when the `CREATE` statement is processed, warning messages are returned, but the `CREATE` statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the `CREATE` statement. The authorization checks the use of the authorization ID of the owner of the routine.

**VALIDATE RUN** is the default.

**VALIDATE BIND**

Specifies that if needed objects or privileges do not exist at the time the `CREATE` statement is processed, an error is issued and the `CREATE` statement fails.
ROUNDING
 specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDBING MODE in DECP.

**DEC_ROUND_CEILING**
 specifies numbers are rounded towards positive infinity.

**DEC_ROUND_DOWN**
 specifies numbers are rounded towards 0 (truncation).

**DEC_ROUND_FLOOR**
 specifies numbers are rounded towards negative infinity.

**DEC_ROUND_HALF_DOWN**
 specifies numbers are rounded to nearest; if equidistant, round down.

**DEC_ROUND_HALF_EVEN**
 specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

**DEC_ROUND_HALF_UP**
 specifies numbers are rounded to nearest; if equidistant, round up.

**DEC_ROUND_UP**
 specifies numbers are rounded away from 0.

DATE FORMAT ISO, EUR, USA, JIS, or LOCAL
 specifies the date format for result values that are string representations of date or time values. See “String representations of datetime values” on page 103 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)
 specifies the maximum precision that is to be used for decimal arithmetic operations. See “Arithmetic with two decimal operands” on page 247 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form pp.s is specified, s must be a number between 1 and 9. s represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED
 specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

**FOR UPDATE CLAUSE REQUIRED**
 specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

**FOR UPDATE CLAUSE REQUIRED** is the default.

**FOR UPDATE CLAUSE OPTIONAL**
 specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE
OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

**TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 103 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

**NOT SECURED or SECURED**

Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

**NOT SECURED**

Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

**SECURED**

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

**BUSINESS_TIME SENSITIVE**

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

**YES**

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

**NO**

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

Related information:

“CURRENT TEMPORAL BUSINESS_TIME” on page 201

**SYSTEM_TIME SENSITIVE**

Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**YES**

References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

**NO**

References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.
Related information:
“CURRENT TEMPORAL SYSTEM_TIME” on page 203

ARCHIVE SENSITIVE
Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

YES
References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

NO
References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

Related information:
“Built-in global variables” on page 340

APPLCOMPAT compatibility-level
Specifies the package compatibility level behavior for static SQL. If this option is not specified then the behavior is determined, in priority order, by the compatibility-level of the last BIND or REBIND of the package or the APPLCOMPAT system parameter. The following values of compatibility-level can be specified:

V10R1
The static SQL statements in the package have V10R1 compatibility behavior.

V11R1
The static SQL statements in the package have V11R1 compatibility behavior.

Related information:
APPL_COMPAT_LEVEL field (APPLCOMPAT subsystem parameter) (DB2 Installation and Migration)

SQL-routine-body
Specifies a single SQL control statement, including a compound-statement. See Chapter 7, “SQL control statements for SQL routines,” on page 2029 for more information about defining SQL functions.

An error is issued if an SQL function calls a procedure and the procedure issues a COMMIT, ROLLBACK, CONNECT, RELEASE, or SET CONNECTION statement.

If the SQL-routine-body is a compound statement, it must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.

SQL-routine-body must not contain a period specification or period clause.

An ALTER FUNCTION (compiled SQL scalar) statement or an ALTER PROCEDURE (SQL native) statement with an ADD VERSION clause or a REPLACE clause is not allowed in an SQL-routine-body.

Notes
Choosing data types for parameters:
When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See Promotion of data types on page 112). For example,
a constant that is one of the input arguments to the function might have a
built-in data type that is different from the data type that the function
expects, and more significantly, might not be promotable to that expected
data type. Based on the rules of promotion, consider using the following
data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do
not use the following data types, which might have different
representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

**Specifying the encoding scheme for parameters:**
The implicitly or explicitly specified encoding scheme of all of the
parameters with a character or graphic string data type (both input and
output parameters) must be the same—either all ASCII, all EBCDIC, or all
UNICODE.

**Identifier resolution:**
See Chapter 7, “SQL control statements for SQL routines,” on page 2029 for
information on how names are resolved to columns, SQL variables, or SQL
parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and
parameters, qualify the duplicate names by using the table designator for
columns, the routine name for parameters, and the label name for SQL
variables.

**Determining the uniqueness of functions in a schema:**
At the current server, the function signature of each function, which is the
qualified function name combined with the number and data types of the
input parameters, must be unique. If the function has more than 30 input
parameters, only the data types of the first 30 are used to determine
uniqueness. This means that two different schemas can each contain a
function with the same name that have the same data types for all of their
corresponding data types. However, a single schema must not contain
multiple functions with the same name that have the same data types for
all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not
consider any length, precision, or scale attributes in the comparison. DB2
considers the synonyms of data types as a match. For example, REAL and
FLOAT, and DOUBLE and FLOAT are considered a match. Therefore,
CHAR(8) and CHAR(35) are considered to be the same, as are
DECIMAL(11,2), DECIMAL(4,3), DECIMAL(16) and DECIMAL(34),
TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE
and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and
graphic types, and the timestamp types are considered to be the same. For
example, the following are considered to be the same type: CHAR and
GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB,
TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME
ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type.
An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

- `CREATE FUNCTION PART (INT, CHAR(15)) ...`
- `CREATE FUNCTION PART (INTEGER, CHAR(40)) ...`
- `CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...`
- `CREATE FUNCTION ANGLE (DEC(10,7)) ...`

**Overriding a built-in function:**

Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

**Self-referencing function:**

The body of an SQL function (that is, the expression or NULL in the RETURN statement in the body of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

**Scrollable cursors specified with user-defined functions:**

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

**Versions of a function:**

The CREATE FUNCTION statement for an SQL function defines the initial version of the function. You can define additional versions using the ADD VERSION clause of the ALTER FUNCTION statement. All versions of a function share the same function signature and the same specific name. However, the parameters names can differ between versions of a function. Only one version of the function can be considered to be the active version of the function.

**Considerations for packages:**

A package is generated for compiled SQL scalar functions. The package that is associated with the first version of a function is named as follows:

- `location` is set to the value of the CURRENT SERVER special register.
- `collection-id` (schema) for the package is the same as the schema qualifier of the function.
- `package-id` is the same as the specific name of the function.
- `version-id` is the same as the version identifier for the initial version of the function.
The package is generated using the bind options that correspond to the implicitly or explicitly specified function options. In addition to the corresponding bind options, the package is generated using the following bind options:
- FLAG(I)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

Correspondence of function options to bind command options:
The following table lists options for CREATE FUNCTION and ALTER FUNCTION and the corresponding bind command option. See BIND and REBIND options for packages and plans (DB2 Commands) for information about the BIND command options.

Considerations for SQL processor programs:
SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (DB2 Application programming and SQL).

Lines within definitions of an SQL function:
When a compiled SQL function is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

Considerations for functions defined with EXTERNAL ACTION or MODIFIES SQL DATA:
If a function is specified in the select-list of a select-statement and is the function specifies EXTERNAL ACTION or MODIFIES SQL DATA, the function will only be invoked for each row that is returned. Otherwise, the function might be invoked for rows that are not selected.

Error handling in SQL functions:
You should consider the possible exceptions that can occur for each SQL statement in the body of a compiled SQL function. Any exception SQLSTATE that is not handled within the function (using a handler), results in the exception SQLSTATE being returned for the SQL statement that caused the function to be invoked.

Dependent objects:
An SQL routine is dependent on objects that are referenced in the routine body.

Considerations for a function that is defined using a TABLE LIKE name AS LOCATOR clause:
If a function is defined with a table parameter (the TABLE LIKE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function cannot be changed with an ALTER FUNCTION statement if the change...
requires that the parameter list be specified. For example, to add or replace a version of an SQL scalar function, the function must be dropped and re-created.

Functions and global variables:
The content of global variables that are referenced in functions is inherited from the caller.

Considerations for a function with a parameter that is defined as an array type:
A function that is defined with a parameter or RETURNS data-type2 that is an array type can be invoked only from within an SQL PL context.

Creating a secure function:
Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages. If the function is a compiled SQL function, DB2 assumes that such a control audit procedure is in place for all versions of the function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

Invoking other user-defined functions in a secure function:
When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:
The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

Deploying a compiled SQL scalar function:
When a BIND DEPLOY command is issued to deploy a compiled SQL scalar function to a target location, the SECURED and NOT SECURED options are included in the deployment process.

When deploying a compiled SQL scalar function, if a function with the same target name does not exist at the target location, the deployed function is created as a new function at the target location with the same SECURED or NOT SECURED option that is specified (or the default of NOT SECURED is used) in the source of the deployment.

When deploying a compiled SQL scalar function, if a function with the same target name already exists at the target location, the deployed function is either added as a new version of the function, or the deployed function is used to replace an existing version of the function. The SECURED or NOT SECURED option of the deployed function must be the same as that of the existing function at the target location.
Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example: Define a scalar function that returns the text of an input string, in reverse order:

```sql
CREATE FUNCTION REVERSE(INSTR VARCHAR(4000))
RETURNS VARCHAR(4000)
DETERMINISTIC NO EXTERNAL ACTION CONTAINS SQL
BEGIN
DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
DECLARE LEN INT;
IF INSTR IS NULL THEN
RETURN NULL;
END IF;
SET (RESTSTR, LEN) = (INSTR, LENGTH(INSTR));
WHILE LEN > 0 DO
SET (REVSTR, RESTSTR, LEN) =
(SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR,
SUBSTR(RESTSTR, 2, LEN - 1),
LEN - 1);
END WHILE;
RETURN REVSTR;
END#
This CREATE FUNCTION statement registers a user-defined external scalar function with a database server. A scalar function returns a single value each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified

- SECADM authority
- CREATE_SECURE_OBJECT privilege

When LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
• The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

```
CREATE FUNCTION function-name (parameter-declaration)

(1)

RETURNS data-type2

(2)

AS LOCATOR

data-type3

CAST FROM data-type4

AS LOCATOR

option-list
```

Notes:
1. This clause and the clauses that follow in the `option-list` can be specified in any order.
2. `AS LOCATOR` can be specified only for a LOB data type or a distinct type based on a LOB data type.

**parameter-declaration:**

```
parameter-name data-type

(1)

AS LOCATOR

TABLE LIKE table-name

AS LOCATOR

view-name
```

Notes:
1. `AS LOCATOR` can be specified only for a LOB data type or a distinct type based on a LOB data type.

**data-type:**

```
built-in-type

distinct-type-name
```

**built-in-type:**
option-list: (The clauses in the option list can be specified in any order)
Notes:

1. The same clause must not be specified more than one time.

2. If NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, DISALLOW PARALLEL is the default.
**Description**

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

<table>
<thead>
<tr>
<th>ALL</th>
<th>LIKE</th>
<th>UNIQUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>MATCH</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>ANY</td>
<td>NOT</td>
<td>=</td>
</tr>
<tr>
<td>BETWEEN</td>
<td>NULL</td>
<td>=~</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>ONLY</td>
<td>&lt;</td>
</tr>
</tbody>
</table>

Notes:
1. The slash (/) is supported for compatibility with previous release of DB2 for z/OS.
2. The exclamation point (!) is supported for compatibility with other products in the DB2 family.
The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameters-declaration,...)

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

CREATE FUNCTION WOOFER();

parameter-name

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

data-type

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

built-in-type

The data type of the input parameter is a built-in data type.

For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function...
is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.
  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.
- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE table-name or view-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name or view-name* must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option.
when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.

- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see DB2 Application Programming and SQL Guide.

RETURNS

Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

data-type2

Specifies the data type of the output. The output parameter is nullable.

The same considerations that apply to the data type and nullability of input parameter, as described under data-type, apply to the data type of the result of the function.

AS LOCATOR

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

data-type3 CAST FROM data-type4

Specifies the data type of the output of the function (data-type4) and the data type in which that output is returned to the invoking statement (data-type3). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which DB2 converts to a DECIMAL value and then passes to the statement that invoked the function:

```
CREATE FUNCTION SQRT(DECIMAL(15,0))
RETURNS DECIMAL(15,0) CAST FROM DOUBLE
...
```

The value of data-type4 can be any built-in data type and must be castable to data-type3. The value for data-type3 can be any built-in data type. (For information on casting data types, see “Casting between data types” on page 113.) The encoding scheme of the parameters, if they are string data types, must be the same.
If the PARAMETER VARCHAR clause is specified, data-type3 and data-type4 should be specified as VARCHAR.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the value. You can specify AS LOCATOR only if data-type4 is a LOB data type or a distinct type based on a LOB data type.

**SPECIFIC specific-name**

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of specific-name is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (function-name). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

$$SQLxxxxxxxxxxxx$$

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID or VARCHAR**

Specifies the encoding scheme for character and graphic string parameters, and in the case of LANGUAGE C, specifies that representation of variable length string parameters.

**CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for all string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.
VARCHAR
Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

NULTERM
Specifies that variable length character string parameters are represented in a NUL-terminated string form.

STRUCTURE
Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with the PARAMETER CCSID clause. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

EXTERNAL
Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

EXTERNAL
EXTERNAL NAME PKJVSP1
EXTERNAL NAME 'PKJVSP1'

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

EXTERNAL PKJVSP1

NAME external-program-name or identifier
Identifies the user-written code that implements the user-defined function.

If LANGUAGE is JAVA, external-program-name must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid external-java-routine-name. If multiple external-program-names are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a JAVA function for which NO SQL is also specified.

An external-java-routine-name contains the following parts:
**jar-name**
Identifies the name given to the JAR file when it was installed in the database. The name contains `jar-id`, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified `jar-id` is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If `jar-name` is specified, it must exist when the CREATE FUNCTION statement is processed.

If `jar-name` is not specified, the function is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed function.

**method-name**
Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

**package-id**
Identifies a package. The concatenated list of `package-ids` identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

**class-id**
Identifies the class identifier of the Java object.

**method-id**
Identifies the method identifier with the Java class to be invoked.

**method-signature**
Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the `method-signature` if the user-defined function involves any input or output parameters that can be NULL. When the function being created is called, DB2 searches for a Java method with the exact `method-signature`. The number of `java-datatype` elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for `method-signature`. If a Java `method-signature` is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE FUNCTION statement.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for
load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

If you do not specify the NAME clause, 'NAME function-name' is implicit. In this case, function-name must not be longer than 8 characters.

**LANGUAGE**

Specifies the language interface convention to which the body of the function is written. All programs must be designed to run in IBM's Language Environment environment.

**ASSEMBLE**

The function is written in Assembler.

**C**

The function is written in C or C++.

**COBOL**

The function is written in COBOL, including the object-oriented language extensions.

**JAVA**

The user-defined function is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must also be specified with a valid external-java-routine-name and PARAMETER STYLE must be specified with JAVA.

Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is in effect.

**PLI**

The function is written in PL/I.

**PARAMETER STYLE**

Specifies the conventions for passing parameters to and returning a value from the function.

**SQL**

Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- $n$ parameters for the input parameters that are specified for the function
- A parameter for the result of the function
- $n$ parameters for the indicator variables for the input parameters
- A parameter for the indicator variable for the result
- The SQLSTATE to be returned to DB2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to DB2
- The function can also pass from zero to three additional parameters:
  - The scratchpad, if SCRATCHPAD is specified
  - The call type, if FINAL CALL is specified
  - The DBINFO structure, if DBINFO is specified

**JAVA**

Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications.
PARAMETER STYLE JAVA can be specified only if LANGUAGE is specified as JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE JAVA is specified.

**NOT DETERMINISTIC or DETERMINISTIC**
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**
The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

Some functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

**DETERMINISTIC**
The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**FENCED**
Specifies that the external function runs in an external address space to prevent the function from corrupting DB2 storage.

FENCED is the default.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**
Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**
The function is not called if any of the input arguments is null. The result is the null value. RETURNS NULL ON INPUT is the default.

**CALLED ON NULL INPUT**
The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**
Specifies the classification of SQL statements that the function can execute. DB2 verifies that the SQL statements that the function issues are consistent with this specification. For the data access classification of each statement, see Table 167 on page 2096.
**MODIFIES SQL DATA**

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data. The default is READS SQL DATA.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

**NO SQL**

Specifies that the function can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA function that uses a JAR file.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for external functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

**EXTERNAL ACTION**

Specifies that the function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, DB2:

- Materializes the views and table expressions in SELECT or data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.
NO EXTERNAL ACTION
Specifies that the function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

NO PACKAGE PATH or PACKAGE PATH package-path
Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

NO PACKAGE PATH
Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see DB2 Application Programming and SQL Guide.

PACKAGE PATH package-path
Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The package-path value that is provided when the function is created is checked when the function is invoked. If package-path contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the package-path value is checked.

NO SCRATCHPAD or SCRATCHPAD
Specifies whether DB2 is to provide a scratchpad for the function. It is strongly recommended that external functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

NO SCRATCHPAD
Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

SCRATCHPAD length
Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- length must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00' s).
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:
SELECT A, UDFX(A) FROM TABLEB
WHERE UDFX(A) > 103 OR UDFX(A) < 19;

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the DISALLOW PARALLEL clause for functions that will not work correctly with parallelism.

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2 initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.
- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, DB2:
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

Do not specify SCRATCHPAD when LANGUAGE JAVA is in effect.

**NO FINAL CALL or FINAL CALL**

*NO FINAL CALL*  
Specifies whether a final call is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resource and anchors them in the scratchpad.

*FINAL CALL*  
Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call. NO FINAL CALL is the default.

*First call*  
Specifies that the first call to the function for this reference to the function in this SQL statement. A first call is a normal call—SQL arguments are passed and the function is expected to return a result.

*Normal call*  
Specifies that SQL arguments are passed and the function is expected to return a result.
Final call

Specifies that the last call to the function to enable the function to free resources. A final call is not a normal call. If an error occurs, DB2 attempts to make the final call unless the function abended. A final call occurs at these times:

- **End of statement**: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
- **End of a parallel task**: When the function is executed by parallel tasks.
- **End of transaction**: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

Do not specify FINAL CALL when LANGUAGE JAVA is in effect.

**ALLOW or DISALLOW PARALLEL**

For a single reference to the function, specifies whether parallelism can be used when the function is invoked. Although parallelism can be used for most scalar functions, some functions such as those that depend on a single copy of the scratchpad cannot be invoked with parallel tasks.

Consider these characteristics when determining which clause to use:

- If all invocations of the function are completely independent from one another, specify ALLOW PARALLEL.
- If each invocation of the function updates the scratchpad, providing values that are of interest to the next invocation, such as incrementing a counter, specify DISALLOW PARALLEL.
- If the scratchpad is used only so that some expensive initialization processing is performed a minimal number of times, specify ALLOW PARALLEL.
- If the function performs some external action that should apply to only one partition, specify DISALLOW PARALLEL.
- If the function is defined with MODIFIES SQL DATA, specify DISALLOW PARALLEL, not ALLOW PARALLEL.

ALLOW PARALLEL is the default unless NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, in which case, DISALLOW PARALLEL is the default.

**ALLOW PARALLEL**

Specifies that DB2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.
DISALLOW PARALLEL
   Specifies that DB2 does not consider parallelism for the function.

NO DBINFO or DBINFO
   Specifies whether additional status information is passed to the function when it is invoked.

   NO DBINFO
      No additional information is passed. NO DBINFO is the default.

   DBINFO
      An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see DB2 Application Programming and SQL Guide.

      Do not specify DBINFO when LANGUAGE JAVA is in effect.

NO COLLID or COLLID collection-id
   Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

NO COLLID
   The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in DB2 Application Programming and SQL Guide.

   NO COLLID is the default.

   COLLID collection-id
      The name of the package collection that is to be used when the function is executed.

WLM ENVIRONMENT
   Identifies the WLM (workload manager) application environment in which the function is to run. The name of the WLM environment is an SQL identifier.

   If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time. When LANGUAGE is JAVA, you must specify WLM ENVIRONMENT, and the WLM environment in which the function is to run must be Java-enabled.

   name
      The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

   (name,*)
      When an SQL application program directly invokes the function, the WLM environment in which the function runs.
If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see Running external functions in WLM environments.

**ASUTIME**
Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**
There is no limit on the service units. NO LIMIT is the default.

**LIMIT integer**
The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**
Specifies whether the load module for the function is to remain resident in memory when the function ends. This option is ignored if LANGUAGE JAVA is specified.

**NO**
The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

**YES**
The load module remains resident in memory after the function ends. Use YES for reentrant functions.

**PROGRAM TYPE**
Specifies whether the function program runs as a main routine or a subroutine.

**SUB**
The function runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option. SUB is the default.

**MAIN**
The function runs as a main routine.

**SECURITY**
Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**
The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.
DB2 is the default.

**USER**
An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**
An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE**
Specifies whether the routine is to be put in a stopped state after some number of failures.

**STOP AFTER SYSTEM DEFAULT FAILURES**
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

**STOP AFTER nn FAILURES**
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURE**
Specifies that this routine should not be placed in a stopped state after any failure.

**RUN OPTIONS runtime-options**
Specifies the Language Environment runtime options to be used for the function. You must specify runtime-options as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment runtime options, see z/OS Language Environment Programming Reference.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**
Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**
Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 40 on page 212.

**DEFAULT SPECIAL REGISTERS**
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 40 on page 212.

**STATIC DISPATCH**
At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.
NOT SECURED or SECURED
Specifies if the function is considered secure for row access control and column access control.

NOT SECURED
Specifies that the function is not considered as secure for row access control and column access control.

NOT SECURED is the default.
When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED
Specifies that the function is considered secure for row access control and column access control.
The function must be defined with SECURED when it is referenced in a row permission or a column mask.

Notes
Owner privileges:
The owner is authorized to execute the function (EXECUTE privilege) and has the ability to grant these privileges to others. For more information, see “GRANT (function or procedure privileges)” on page 1768. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 72.

Choosing data types for parameters:
When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 112). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:
• INTEGER instead of SMALLINT
• DOUBLE instead of REAL
• VARCHAR instead of CHAR
• VARGRAPHIC instead of GRAPHIC
• VARBINARY instead of BINARY
For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:
• FLOAT. Use DOUBLE or REAL instead.
• NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:
The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:
At the current server, the function signature of each function, which is the
qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMPTIME(6) WITH TIME ZONE and TIMESTAMPTIME(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMPTIME WITHOUT TIME ZONE and TIMESTAMPTIME WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...  
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...  
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...  
CREATE FUNCTION ANGLE (DEC(10,7)) ...  
```

**Character string representation considerations:**
The PARAMETER VARCHAR clause is specific to LANGUAGE C functions because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external function. For example, a CREATE FUNCTION statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the function, the specific name of the function, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.
Considerations for accessing message tokens and DBINFO:

DB2 returns system-generated parameters from a routine, such as message tokens and DBINFO. The message tokens and DBINFO are character string data. The CCSID for system-generated string parameters is determined from the CCSID that is in effect for string parameters that are defined for the routine. If the parameter list for the routine does not include any character or graphic string parameters, the CCSID for system-generated string parameters is determined from the PARAMETER CCSID option that is in effect for the routine. For example, with a Unicode database, you can specify PARAMETER CCSID EBCDIC to have the system-generated string parameters returned to the invoking application in EBCDIC.

Overriding a built-in function:

Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

Running external functions in WLM environments:

You can use the WLM ENVIRONMENT clause to identify the address space in which a function or is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with data, such as employee salaries.

To prevent a user from defining functions in sensitive WLM environments, DB2 invokes the external security manager to determine whether the user has authorization to issue CREATE FUNCTION statements that refer to the specified WLM environment. The following example shows the RACF command that authorizes DB2 user DB2USER1 to register a function on DB2 subsystem DB2A that runs in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.
Invoking other user-defined functions in a secure function:
If a secure user-defined function invokes other user-defined functions, DB2 does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access the sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:
If a row permission or a column mask definition references a user-defined function, the user-defined function must be secure because the sensitive data might be passed as arguments to the function. The column SECURE in the EXPLAIN table DSN_FUNCTION_TABLE indicates whether a user-defined function is considered secure.

Functions and global variables:
The content of global variables that are referenced in functions is inherited from the caller.

Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Assume that you want to write an external function program in C that implements the following logic:
\[ \text{output} = 2 \times \text{input} - 4 \]

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement or allow it to be the default. Write the statement needed to register the function, using the specific name MINENULL1.

```sql
CREATE FUNCTION NTEST1 (SMALLINT)
RETURNS SMALLINT
EXTERNAL NAME 'NTESTMOD'
SPECIFIC MINENULL1
LANGUAGE C
DETERMINISTIC
NO SQL
FENCED
PARAMETER STYLE SQL
RETURNS NULL ON NULL INPUT
NO EXTERNAL ACTION;
```

Example 2: Assume that user Smith wants to register an external function named CENTER in schema SMITH. The function program will be written in C and will be reentrant. Write the statement that Smith needs to register the function, letting DB2 generate a specific name for the function.

```sql
```
CREATE FUNCTION CENTER (INTEGER, FLOAT)
    RETURNS FLOAT
    EXTERNAL NAME 'MIDDLE'
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    FENCED
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
    STAY RESIDENT YES;

Example 3: Assume that user McBride (who has administrative authority) wants to register an external function named CENTER in the SMITH schema. McBride plans to give the function specific name FOCUS98. The function program uses a scratchpad to perform some one-time only initialization and save the results. The function program returns a value with a FLOAT data type. Write the statement McBride needs to register the function and ensure that when the function is invoked, it returns a value with a data type of DECIMAL(8,4).

CREATE FUNCTION SMITH.CENTER (FLOAT, FLOAT, FLOAT)
    RETURNS DECIMAL(8,4) CAST FROM FLOAT
    EXTERNAL NAME 'CMOD'
    SPECIFIC FOCUS98
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    FENCED
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
    SCRATCHPAD
    NO FINAL CALL;

Example 4: The following example registers a Java user-defined function that returns the position of the first vowel in a string. The user-defined function is written in Java, is to be run fenced, and is the FINDVWL method of class JAVAUDFS.

CREATE FUNCTION FINDV (CLOB(100K))
    RETURNS INTEGER
    FENCED
    LANGUAGE JAVA
    PARAMETER STYLE JAVA
    EXTERNAL NAME 'JAVAUDFS.FINDVWL'
    NO EXTERNAL ACTION
    CALLED ON NULL INPUT
    DETERMINISTIC
    NO SQL;
CREATE FUNCTION (external table)

This CREATE FUNCTION statement registers a user-defined external table function with a database server. A user-defined external table function can be used in the FROM clause of a subselect. It returns a table to the subselect by returning one row at a time each time it is invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

At least one of the following additional privileges is required if the SECURED option is specified
- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.
**Syntax**

```plaintext
CREATE FUNCTION function-name()

parameter-declaration

RETURNS TABLE(column-name data-type)

option-list

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
2. This clause and the clauses that follow in the option-list can be specified in any order.

parameter-declaration:

```plaintext
parameter-name parameter-type

parameter-type:

```plaintext
data-type

Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

data-type:

```plaintext
built-in-type

distinct-type-name
```
option-list: (The clauses in the option-list can be specified in any order.)
Description

`function-name`

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

Notes:
1. The same clause must not be specified more than one time.
The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server. You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of function-name must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

```
ALL   LIKE   UNIQUE
AND   MATCH UNKNOWN
ANY   NOT   =
BETWEEN NULL   =~
DISTINCT ONLY   <
EXCEPT OR   <=
EXISTS OVERLAPS   <=
FALSE   SIMILAR   >
FOR   SOME    >=
FROM   TABLE   <>
IN   TRUE    <=
IS   TYPE
```

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

```
(parameter-declaration,...)
```

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

**parameter-name**

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name. The same name cannot be used for a parameter name and a column name.

**data-type**

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

**built-in-type**

The data type of the input parameter is a built-in data type.

For information on the data types, see [built-in-type](https://www.example.com).

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**distinct-type-name**

The data type of the input parameter is a distinct type. Any length,

---

31. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE table-name or view-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.
table-name or view-name must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see DB2 Application Programming and SQL Guide.

**RETURNS TABLE**

Identifies that the output of the function is a table. The parentheses that follow the keyword enclose the list of names and data types of the columns of the table.

- **column-name** Specifies the name of the column. The name is an SQL identifier and must be unique within the RETURNS TABLE clause for the function.
- **data-type** Specifies the data type of the column. The column is nullable.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only for a LOB data type or a distinct type based on a LOB data type.

**RETURNS GENERIC TABLE**

Specifies that the output of the function is a generic table. This option can only be specified if LANGUAGE C is also specified.

The names and data types of the columns must be declared when the table function is references using the typed-correlation-clause of the subselect.

Related information:

[“typed-correlation-clause” on page 806](#)
**SPECIFIC** *specific-name*

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID or VARCHAR**

**CCSID**

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS TABLE clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**VARCHAR**

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

**NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.
**STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS TABLE clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

**EXTERNAL**

Specifies that the function being registered is based on code that is written in an external programming language and adheres to the documented linkage conventions and interface of that language.

If you do not specify the NAME clause, 'NAME function-name' is implicit. In this case, function-name must not be longer than 8 characters.

**NAME string or identifier**

Identifies the name of the load module that contains the user-written code that implements the logic of the function.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

```sql
EXTERNAL
EXTERNAL NAME PKJVSP1
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

```sql
EXTERNAL PKJVSP1
```

**LANGUAGE**

Specifies the application programming language in which the function program is written. All programs must be designed to run in IBM's Language Environment environment.

**ASSEMBLE**

The function is written in Assembler.

**C**

The function is written in C or C++. The VARCHAR clause can only be specified is LANGUAGE C is specified.
COBOL
The function is written in COBOL, including the object-oriented language extensions.

PLI
The function is written in PL/I.

PARAMETER STYLE SQL
Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

PARAMETER STYLE SQL specifies the parameter passing convention that supports passing null values both as input and for output.

If the RETURNS TABLE clause is specified, the parameters that are passed between the invoking SQL statement and the function include:
• \( n \) parameters for the input parameters that are specified for the function
• \( m \) parameters for the result columns of the function that are specified on the RETURNS TABLE clause
• \( n \) parameters for the indicator variables for the input parameters
• \( m \) parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause
• The SQLSTATE to be returned to DB2
• The qualified name of the function
• The specific name of the function
• The SQL diagnostic string to be returned to DB2
• The scratchpad, if SCRATCHPAD is specified
• The call type
• The DBINFO structure, if DBINFO is specified

If the RETURNS GENERIC TABLE clause is specified, the parameters that are passed between the invoking SQL statement and the function include:
• \( n \) parameters for the input parameters that are specified for the function
• \( n \) parameters for the indicator variables for the input parameters
• \( m \) parameters for the result columns of the function that are specified on the RETURNS GENERIC TABLE clause
• A result table descriptor that contains the following:
  – \( m \) result columns of the function that are specified in the typed-correlation-clause of the table-function-reference in a SELECT statement
  – An array of \( m \), 4-byte addresses to the values of the result columns
  – An array of \( m \), null indicators of the result columns
• The SQLSTATE to be returned to DB2
• The qualified name of the function
• The specific name of the function
• The SQL diagnostic string to be returned to DB2
• The scratchpad, if SCRATCHPAD is specified
• The call type
• The DBINFO structure, if DBINFO is specified

For complete details about the structure of the parameter list that is passed, see DB2 Application Programming and SQL Guide.
NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

NOT DETERMINISTIC
The function might not return the same results each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

DETERMINISTIC
The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function.
DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

FENCED
Specifies that the function runs in an external address space to prevent the function from corrupting DB2 storage.
FENCED is the default.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT
Specifies whether the function is called if any of the input arguments is null at execution time.

RETURNS NULL ON NULL INPUT
The function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON NULL INPUT is the default.

CALLED ON NULL INPUT
The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

READS SQL DATA, CONTAINS SQL, or NO SQL
Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function. The default is READS SQL DATA. For the data access classification of each statement, see Table 167 on page 2096.

READS SQL DATA
Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.
CONTAINS SQL
Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

NO SQL
Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

EXTERNAL ACTION
The function can take an action that changes the state of an object that DB2 does not manage.

If you specify EXTERNAL ACTION, DB2:

• Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.

• Does not move the function from one task control block (TCB) to another between FETCH operations.

• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

NO PACKAGE PATH or PACKAGE PATH package-path
Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

NO PACKAGE PATH
Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function.
If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see DB2 Application Programming and SQL Guide.

**PACKAGE PATH**

`package-path`

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The `package-path` value that is provided when the function is created is checked when the function is invoked. If `package-path` contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the `package-path` value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether DB2 provides a scratchpad for the function. It is strongly recommended that functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

**NO SCRATCHPAD**

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

**SCRATCHPAD**

`length`

Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- `length` must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00' s).
- The scope of a scratchpad is the SQL statement. Each reference to the function in an SQL statement has a scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

```
SELECT *
FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2 initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function is invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, DB2:

- Does not move the function from one task control block (TCB) to another between FETCH operations.
• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

**NO FINAL CALL or FINAL CALL**
Specifies whether a *first call* and a *final call* are made to the function.

**NO FINAL CALL**
A first call and final call are not made to the function. NO FINAL CALL is the default.

**FINAL CALL**
A first call and final call are made to the function in addition to one or more *open, fetch, or close calls.*

The types of calls are:

**First call**
A *first call* occurs only if the function was defined with FINAL CALL. Before a first call, the scratchpad is set to binary zeros. Argument values are passed to the function, and the function might acquire memory or perform other one-time only resource initialization. However, the function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments.

**Open call**
An *open call* occurs unless the function returns an error. The scratchpad is set to binary zeros only if the function was defined with NO FINAL CALL. Argument values are passed to the function, and the function might perform any one-time initialization actions that are required. However, the function should not return any data to DB2.

**Fetch call**
A *fetch call* occurs unless the function returns an error during the first call or open call. Argument values are passed to the function, and DB2 expects the function to return a row of data or the end-of-table condition. If a scratchpad is also passed to the function, it remains untouched from the previous call.

**Close call**
A *close call* occurs unless the function returns an error during the first call, open call, or fetch call. No SQL-argument or SQL-argument-ind values are passed to the function, and if the function attempts to examine these values, unpredictable results might occur. If a scratchpad is also passed to the function, it remains untouched from the previous call.

The function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments. Also on close call, a function that is defined with NO FINAL CALL should release any system resources that it acquired. (A function that is defined with FINAL CALL should release any acquired resources on the final call.)

**Final**
The *final call* balances the first call, and like the first call, occurs only if the function was defined with FINAL CALL. The function can set return values for the SQL-state and diagnostic-message arguments. The function should also release any system resources that it acquired. A final call occurs at these times:
• **End of statement:** When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.

• **End of transaction:** When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

**DISALLOW PARALLEL**

Specifies that DB2 does not consider parallelism for the function.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the function when it is invoked.

**NO DBINFO**

No additional information is passed. NO DBINFO is the default.

**DBINFO**

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application run time authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

**CARDINALITY integer**

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must range from 0 to 2147483647.

If you do not specify CARDINALITY, DB2 assumes a finite value. The finite value is the same value that DB2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality—the function never returns the “end-of-table” condition and always returns a row, then a query that requires the “end-of-table” to work correctly will need to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

**NO COLLID or COLLID collection-id**

Identifies the package collection that is to be used when the external is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

**NO COLLID**

The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGSET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID collection-id**

The name of the package collection that is to be used when the external is executed.
**WLM ENVIRONMENT**

Identifies the WLM (workload manager) application environment in which the function is to run. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time.

**name**

The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

**(name,*)**

When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see [Running external functions in WLM environments](#).

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *[z/OS MVS Initialization and Tuning Guide](#)*.

**NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

**LIMIT integer**

The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends.

**NO**

The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

**YES**

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

**PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.
The function runs as a subroutine. SUB is the default.

The function runs as a main routine.

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

DB2 is the default.

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

Specifies the Language Environment run time options to be used for the function. You must specify runtime-options as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

Specifies how special registers are set on entry to the routine.

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 40 on page 212.

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 40 on page 212.

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

Specifies whether the routine is to be put in a stopped state after some number of failures.
STOP AFTER SYSTEM DEFAULT FAILURES
   Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

STOP AFTER nn FAILURES
   Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
   Specifies that this routine should not be placed in a stopped state after any failure.

NOT SECURED or SECURED
   Specifies if the function is considered secure for row access control and column access control.

   NOT SECURED
      Specifies that the function is not considered as secure for row access control and column access control.
      NOT SECURED is the default.
      When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

   SECURED
      Specifies that the function is considered secure for row access control and column access control.
      The function must be defined with SECURED when it is referenced in a row permission or a column mask.

Notes

See “Notes” on page 1259 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Determining the uniqueness of functions in a schema
- Character string representation considerations
- Overriding a built-in function
- Scrollable cursors specified with user-defined functions
- Creating a secure function
- Invoking other user-defined functions in a secure function
- SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table
- Functions and global variables

Example

Example 1: The following example registers a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.
Within the context of a single session, the table function always returns the same table; therefore, it is defined as DETERMINISTIC. In addition, the DISALLOW PARALLEL keyword is added because table functions cannot operate in parallel.

Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value and is specified to help DB2.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
RETURNS TABLE (DOC_ID CHAR(16))
EXTERNAL NAME ABC
LANGUAGE C
PARAMETER STYLE SQL
NO SQL
DETERMINISTIC
NO EXTERNAL ACTION
FENCED
SCRATCHPAD
FINAL CALL
DISALLOW PARALLEL
CARDINALITY 20;
```

Example 2: The following example registers a generic table function:

```
CREATE FUNCTION tf6(p1 VARCHAR(10))
RETURNS GENERIC TABLE
EXTERNAL NAME 'tf6'
LANGUAGE C
PARAMETER STYLE SQL
DETERMINISTIC
NO EXTERNAL ACTION
FENCED
SCRATCHPAD
FINAL CALL;
```

Note that LANGUAGE C must be specified, and the names and data type of the result columns must be declared when the table function is referenced in the SELECT clause.
CREATE FUNCTION (inlined SQL scalar)

The CREATE FUNCTION (inlined SQL scalar) statement defines an SQL scalar function at the current server and specifies an SQL procedural language RETURN statement for the body of the function. The function returns a single value each time it is invoked.

A package is not created for an inlined SQL scalar function.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a user-defined type is referenced (as the data type of a parameter), the privilege set must also include at least one of the following:

- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.
Syntax

```sql
CREATE FUNCTION function-name ( parameter-declaration )
RETURNS data-type LANGUAGE SQL option-list SQL-routine-body
```

Notes:
1. The RETURNS clause, the RETURN-statement, and the clauses in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

parameter-declaration:

```sql
parameter-name data-type
```

Notes:
1. Note that the parameter-name is required for SQL functions.

data-type:

```sql
built-in-type distinct-type-name
```
### built-in-type:

- **SMALLINT**
- **INTEGER**
- **BIGINT**
- **DECIMAL**
- **NUMERIC**
- **FLOAT**
- **REAL**
- **DOUBLE**
- **DECIMAL**
- **CHARACTER**
- **CHAR**
- **CHARACTER VARYING**
- **CHARACTER LARGE OBJECT**
- **GRAPHIC**
- **VARGRAPHIC**
- **DBCLOB**
- **BINARY**
- **BINARY VARYING**
- **DATE**
- **TIME**
- **TIMESTAMP**
- **ROWID**
- **XML**

### option-list:

- **CCSID**
- **ASCII**
- **EBCDIC**
- **UNICODE**
- **FOR SBCS DATA**
- **MIXED**
- **BIT**
Notes:
1. This clause and the other clauses in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

SQL-routine-body

Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of name, schema name, the number of parameters, and the data type of each parameter\(^{32}\) (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* is an SQL identifier.

The name must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

\[
\begin{array}{ccc}
\text{ALL} & \text{LIKE} & \text{UNIQUE} \\
\text{AND} & \text{MATCH} & \text{UNKNOWN} \\
\text{ANY} & \text{NOT} & = \\
\text{BETWEEN} & \text{NULL} & \text{~=} \\
\text{DISTINCT} & \text{ONLY} & < \\
\text{EXCEPT} & \text{OR} & <= \\
\text{EXISTS} & \text{OVERLAPS} & << \\
\text{FALSE} & \text{SIMILAR} & > \\
\text{FOR} & \text{SOME} & >= \\
\text{FROM} & \text{TABLE} & => \\
\text{IN} & \text{TRUE} & <>
\end{array}
\]

\(^{32}\) If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(\textit{parameter-declaration,...})

Specifies the number of input parameters of the function and the name and data type of each parameter. Each \textit{parameter-declaration} specifies an input parameter for the function. A function can have zero or more input parameters. There must be one entry in the list for each parameter that the function expects to receive. All of the parameters for a function are input parameters and are nullable. If the function has more than 30 parameters, only the first 30 parameters are used to determine if the function is unique.

\textit{parameter-name}

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

\textit{data-type}

Specifies the data type of the input parameter. The data type can be a built-in data type or a user-defined type.

\textit{built-in-type}

The data type of the input parameter is a built-in data type.

For information on the data types, see \texttt{built-in-type}.

For parameters with a character or graphic data type, the \texttt{PARAMETER CCSID} clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

\textit{distinct-type-name}

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

If you specify the name of the distinct type without a schema name, DB2 resolves the distinct type by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.
The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**RETURNS**

Identifies the output of the function.

\[\text{data-type2}\]

Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as described under [data-type](#), apply to the data type of the output of the function.

**LANGUAGE SQL**

Specifies that the function is written exclusively in SQL.

**SPECIFIC specific-name**

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of specific-name is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (function-name). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are
specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

**EXTERNAL ACTION**

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
• Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

NO EXTERNAL ACTION
The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

READS SQL DATA or CONTAINS SQL
Specifies which SQL statements, if any, can be executed in the function or any routine that is called from the function. For the data access classification of each statement, see Table 167 on page 2096.

READS SQL DATA
Specifies that the function can execute statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL
Specifies that the function can execute only SQL statements with a data access classification of CONTAINS SQL or NO SQL. The function cannot execute SQL statements that read or modify data.

STATIC DISPATCH
At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

CALLED ON NULL INPUT
Specifies that the function is to be invoked if any, or if all, of the argument values are null. Specifying CALLED ON NULL INPUT means that the body of the function must be coded to test for null argument values.

CALLED ON NULL INPUT is the default.

NOT SECURED or SECURED
Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.
NOT SECURED
Specifies that the function is not considered secure for row access control and column access control.

NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED
Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body
Specifies a single RETURN statement, see “RETURN statement” on page 2069

Notes

Choosing data types for parameters:
When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 112). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:
The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:
At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.
When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, TIMESTAMP WITHOUT TIME ZONE and TIMESTAMP WITH TIME ZONE. CHAR(13) and GRAPHIC(8) are considered to be the same type. An error is returned if the signature of the function being created is a duplicate of a signature for an existing user-defined function with the same name and schema.

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```sql
CREATE FUNCTION PART (INT, CHAR(15)) ... 
CREATE FUNCTION PART (INTEGER, CHAR(40)) ... 
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ... 
CREATE FUNCTION ANGLE (DEC(10,7)) ... 
```

**Overriding a built-in function:**
Giving a function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create a function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

**Self-referencing function:**
The body of an SQL function (that is, the `expression` or `NULL` in the `RETURN` clause of the CREATE FUNCTION (inlined SQL scalar) statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

**Dependent objects:**
An SQL routine is dependent on objects that are referenced in the routine body.

**Functions and global variables:**
The content of global variables that are referenced in functions is inherited from the caller.

**Creating a secure function:**
Typically, the security administrator will examine the data that is accessed by a function, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who currently requires...
the privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT privilege from the function owner.

DB2 treats the SECURED attribute as an assertion that declares that the security administrator has established an audit procedure for all changes to the user-defined function. DB2 assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages. If the function is a non-inline SQL function, DB2 assumes that such a control audit procedure is in place for all versions of the function, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

**Invoking other user-defined functions in a secure function:**

When a secure user-defined function is referenced in an SQL data change statement that references a table that is using row access control or column access control, and if the secure user-defined function invokes other user-defined functions, the nested user-defined functions are not validated as secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

**The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:**

The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table indicates if a user-defined function is considered secure.

**Alternative syntax and synonyms:**

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- TIMEZONE can be specified as an alternative to TIME ZONE.

For an inlined SQL scalar function, the RETURNS clause and the clauses in the option-list can be specified in any order.

**Examples**

*Example 1: Define a scalar function that returns the tangent of a value using existing SIN and COS built-in functions:*

```sql
CREATE FUNCTION TAN (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X);
```
CREATE FUNCTION (sourced)

This CREATE FUNCTION statement registers a user-defined function that is based on an existing scalar or aggregate function with a database server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

Additional privileges are required for the source function, and other privileges are also needed if the function uses a table as a parameter, or refers to a distinct type. These privileges are:
- The EXECUTE privilege for the function that the SOURCE clause references.
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.
Syntax

CREATE FUNCTION function-name (parameter-declaration) RETURNS data-type2 AS LOCATOR SPECIFIC specific-name

Notes:
1  RETURNS, SPECIFIC, and SOURCE can be specified in any order.
2  AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

parameter-declaration:

parameter-name parameter-type

parameter-type:

data-type (1) AS LOCATOR
TABLE LIKE table-name AS LOCATOR (2)

Notes:
1  AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
2  The TABLE LIKE name AS LOCATOR clause can only be specified for the parameter list of the function that is being defined.
data-type:

### Description

**function-name**

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

If the function is sourced on an existing function to enable the use of the existing function with a distinct type, the name can be the same name as the existing function. In general, more than one function can have the same name if the function signature of each function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of **function-name** must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

```plaintext
ALL LIKE UNIQUE
AND MATCH UNKNOWN
ANY NOT =
BETWEEN NULL ~=
DISTINCT ONLY <
EXCEPT OR <=
EXISTS OVERLAPS <<
FALSE SIMILAR >
FOR SOME >=
FROM TABLE ->
IN TRUE <>
IS TYPE
```

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

**(parameter-declaration,...)**

Specifies the number of input parameters of the function and the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

**parameter-name**

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

**data-type**

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

**built-in-type**

The data type of the input parameter is a built-in data type.

---

33. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.
For information on the data types, see built-in-type.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

distinct-type-name
The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.
  
  The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

You can specify any built-in data type or distinct type that matches or can be cast to the data type of the corresponding parameter of the source function (the function that is identified in the SOURCE clause). (For information on casting data types, see Casting between data types on page 113.) Length, precision, or scale attributes do not have to be specified for data types with these attributes. When specifying data types with these attributes, follow these rules:

- An empty set of parentheses can be used to indicate that the length, precision, or scale is the same as the source function.
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default values are used.

AS LOCATOR
Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.
TABLE LIKE table-name or view-name AS LOCATOR

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

table-name or view-name must identify a table or view that exists at the current server. A view cannot have columns of length 0. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see DB2 Application Programming and SQL Guide.

RETURNS

Identifies the output of the function.

data-type2

Specifies the data type of the output. The output is nullable.
You can specify any built-in data type or distinct type that can be cast from the data type of the result of the source function. (For information on casting data types, see "Casting between data types" on page 113.) For additional rules that apply to the data type that you can specify, see Rules for creating sourced functions.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

**SPECIFIC specific-name**

Provides a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of `specific-name` is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (`function-name`). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

```
SQLxxxxxxxxxxxx
```

where `xxxxxxxxxxxx` is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSRoutines catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as `ALTER FUNCTION`, `COMMENT`, `DROP`, `GRANT`, and `REVOKE`) and in DB2 commands (`START FUNCTION`, `STOP FUNCTION`, and `DISPLAY FUNCTION`). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**SOURCE**

Specifies that the new function is being defined as a sourced function. A sourced function is implemented by another function (the source function). The
source function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement for a distinct type
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the built-in functions shown in Table 115 (if a particular syntax is shown, only the indicated form cannot be specified).

Table 115. Built-in functions that cannot be the source function. When listed with specific conditions, the function cannot be a source function under those conditions. Otherwise, the function cannot be a source function regardless of its arguments.

If you base the sourced function directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example, assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes that are specified on the EXTERNAL clause of the CREATE FUNCTION statement for function C.

**function-name**

Identifies the function that is to be used as the source function. The source function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If you specify an unqualified function-name, DB2 searches the schemas of the SQL path. DB2 selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found or a schema has more than one function with this name.

**function-name (parameter-type,...)**

Identifies the function that is to be used as the source function by its function signature, which uniquely identifies the function. The function-name (parameter-type,...) must identify a function with the specified signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. DB2 uses the number of data types and the logical concatenation of the data types to identify the specific function instance. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If function-name() is specified, the identified function must have zero parameters.

**function-name**

Identifies the function name of the source function. If you specify an unqualified name, DB2 searches the schemas of the SQL path. Otherwise, DB2 searches for the function in the specified schema.

**parameter-type,...**

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision, or scale attribute, use one of the following specifications:

- Empty parentheses indicate that DB2 ignores the attribute when determining whether the data types match. For example, DEC() is considered a match for a parameter of a function that is defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parentheses because its parameter value indicates a specific data type (REAL or DOUBLE).
• If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not need to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

• If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

If you omit the FOR subtype DATA clause or the CCSID clause for data types with a subtype or encoding scheme attribute, DB2 is to ignore the attribute when determining whether the data types match. An exception to ignoring the attribute is FOR BIT DATA. A character FOR BIT DATA parameter of the new function cannot correspond to a parameter of the source function that is not defined as character FOR BIT DATA. Likewise, a character parameter of the new function that is not FOR BIT DATA cannot correspond to a parameter of the source function that is defined as character FOR BIT DATA.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

AS LOCATOR
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or distinct type that is based on a LOB.

SPECIFIC specific-name
Identifies the function to be used as the source function by its specific name.

If you specify an unqualified specific-name, DB2 searches the SQL path to locate the schema. DB2 selects the first schema that contains a function with this specific name for which the user has EXECUTE authority. DB2 returns an error if it cannot find a function with the specific name in one of the schemas in the SQL path.

If you specify a qualified specific-name, DB2 searches the named schema for the function. DB2 returns an error if it cannot find a function with the specific name.

Notes
Owner privileges:
The owner is authorized to execute the function (EXECUTE privilege) in the following cases:

• If the underlying function is a user-defined function, and the owner is authorized with the grant option to execute the underlying function, the privilege on the new function includes the grant option. Otherwise, the owner can execute the new function but cannot grant others the privilege to do so.
• If the underlying function is a built-in function, the owner is authorized with the grant option to execute the underlying built-in function and the privilege on the new function includes the grant option.

For more information, see “GRANT (function or procedure privileges)” on page 1768. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 72.

Choosing data types for parameters:

When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 112). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, consider using the following data types for parameters:

• INTEGER instead of SMALLINT
• DOUBLE instead of REAL
• VARCHAR instead of CHAR
• VARGRAPHIC instead of GRAPHIC
• VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

• FLOAT. Use DOUBLE or REAL instead.
• NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters:

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Determining the uniqueness of functions in a schema:

At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, or scale attributes in the comparison. DB2 considers the synonyms of data types as a match. For example, REAL and FLOAT, and DOUBLE and FLOAT are considered a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), DECFLOAT(16) and DECFLOAT(34), TIMESTAMP(6) and TIMESTAMP(9), and TIMESTAMP(6) WITH TIME ZONE and TIMESTAMP(9) WITH TIME ZONE. Furthermore, the character and graphic types, and the timestamp types are considered to be the same. For example, the following are considered to be the same type: CHAR and
GRAPHIC, VARCHAR and VARGRAPHIC, CLOB and DBCLOB, 
TIMESTAMP WITHOUT TIME ZONE and TIMEST MP WITH TIME 
ZONE, CHAR(13) and GRAPHIC(8) are considered to be the same type. 
An error is returned if the signature of the function being created is a 
duplicate of a signature for an existing user-defined function with the same 
name and schema.

Assume that the following statements are executed to create four functions 
in the same schema. The second and fourth statements fail because they 
create functions that are duplicates of the functions that the first and third 
statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ... 
CREATE FUNCTION PART (INTEGER, CHAR(40)) ... 
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ... 
CREATE FUNCTION ANGLE (DEC(10,7)) ... 
```

**Rules for creating sourced functions:**

Assume that the function that is being created is named NEWF and the 
source function is named SOURCEF. Consider the following rules when 
creating a sourced function:

- The unqualified names of the sourced function and source function can 
  be different (NEWF and SOURCEF).
- The number of input parameters for NEWF and SOURCEF must be the 
  same.
- When specifying the input parameters and output for NEWF, you can 
  specify a value for the precision, scale, subtype, or encoding scheme for 
  a data type with any of these attributes or use empty parentheses. 
  Empty parentheses, such as VARCHAR(), indicate that the value of the 
  attribute is the same as the attribute for the corresponding parameter of 
  SOURCEF, or that is determined by data type promotion. If you specify 
  any values for the attributes, DB2 checks the values against the 
  corresponding input parameters and returned output of SOURCEF as 
  described next.

- When the CREATE FUNCTION statement is executed, DB2 checks the 
  input parameters of NEWF against those of SOURCEF. The data type of 
  each input parameter of NEWF function must be either the same as, or 
  promotable to, the data type of the corresponding parameter of 
  SOURCEF. (For information on the promotion of data types, see 
  "Casting between data types" on page 113.)

This checking does not guarantee that an error will not occur when 
NEWF is invoked. For example, an argument that matches the data type 
and length or precision attributes of a NEWF parameter might not be 
promotable if the corresponding SOURCEF parameter has a shorter 
length or less precision. In general, do not define the parameters of a 
sourced function with length or precision attributes that are greater than 
the attributes of the corresponding parameters of the source function.

- When the CREATE FUNCTION statement is executed, DB2 checks the 
  data type identified in the RETURNS clause of NEWF against the data 
  type that SOURCEF returns. The data type that SOURCEF returns must 
  be either the same as, or promotable to, the RETURNS data type of 
  NEWF.

This checking does not guarantee that an error will not occur when 
NEWF is invoked. For example, the value of a result that matches the 
data type and length or precision attributes of those specified for 
SOURCEF's result might not be promotable if the RETURNS data type
of NEWF has a shorter length or less precision. Consider the possible effects of defining the RETURNS data type of a sourced function with length or precision attributes that are less than the attributes defined for the data type returned by source function.

**Scrollable cursors specified with user-defined functions:**
A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

**SECURED functions:**
The sourced user-defined function inherits the SECURED or NOT SECURED attribute from the source function in which only the topmost user-defined function is considered. If the topmost user-defined function is secure, any nested user-defined functions are also considered secure. DB2 does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the security administrator needs to ensure that those functions are allowed to access sensitive data and should ensure that a change control audit procedure has been established for all changes to those functions.

If the sourced function is using the VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER function as its source, the sourced function must specify only two input parameters.

**Functions and global variables:**
The content of global variables that are referenced in functions is inherited from the caller.

If the function references global variables, the level of SQL data access must be at least CONTAINS SQL. If the function contains SQL statements that make modifications to global variables, the level of SQL data access must be MODIFIES SQL DATA.

**Examples**

**Example 1:** Assume that you created a distinct type HATSIZE, which you based on the built-in data type INTEGER. You want to have an AVG function to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```sql
CREATE FUNCTION AVE (HATSIZE) RETURNS HATSIZE
SOURCE SYSIBM.AVG (INTEGER);
```

When you created distinct type HATSIZE, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

**Example 2:** After Smith registered the external scalar function CENTER in his schema, you decide that you want to use this function, but you want it to accept two INTEGER arguments instead of one INTEGER argument and one FLOAT argument. Create a sourced function that is based on CENTER.

```sql
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
RETURNS FLOAT
SOURCE SMITH.CENTER (INTEGER, FLOAT);
```
The CREATE FUNCTION (SQL table) statement creates an SQL table function at the current server. The function returns a set of rows.

**Invocation**

This statement can only be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

The privilege set that is defined below must include at least one of the following privileges or authorities:
- The CREATEIN privilege on the schema
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the function has installation SYSADM authority, the function is identified as system-defined function.

If a distinct type is referenced (i.e. as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following:
- Ownership of the distinct type
- The USAGE privilege on the distinct type
- SYSADM authority
- SYSDBADM authority

If the function uses a table as a parameter, the privilege set must also include at least one of the following:
- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

At least one of the following additional privileges is required if the SECURED option is specified
- SECADM authority
- CREATE_SECURE_OBJECT privilege

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package. If the owner is a role, matching of the implicit schema name does not apply and the role must include one of the previously listed privileges or authorities.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the
set of privileges that are held by the SQL authorization ID of the process. If the
schema name is not the same as the SQL authorization ID of the process, one of
the following conditions must be met:

- The privilege set includes SYSADM authority
- The privilege set includes SYSCTRL authority
- The SQL authorization ID of the process has the CREATEIN privilege on the
  schema

Syntax

```
CREATE FUNCTION function-name (
  parameter-declaration
)
RETURNS TABLE (column-name data-type2)
option-list

  PARAMETER CCSID ASCII EBCDIC UNICODE

Notes:
1 The options in the option-list can be specified in any order. However, the same clause cannot be specified more than one time.

SQL-routine-body:

RETURN statement
  BEGIN ATOMIC RETURN statement END

Description

function-name
Names the user-defined function. The name is implicitly or explicitly qualified
by a schema name. The combination of the name, the schema name, the
number of parameters, and the data type of each parameter (without regard to
any length, precision, scale, subtype, or encoding scheme attribute of the data
type) must not identify a user-defined function that exists at the current server.

(parameter-declaration,...)
Identifies the number of input parameters of the function, and specifies the
name and data type of each parameter. All of the parameters for a function are
input parameters and are nullable. There must be one entry in the list for each
parameter that the function expects to receive.

parameter-name
Specifies the name of the input parameter. Each name in the parameter list
must not be the same as any other name.
Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR subtype DATA clause), see built-in types. However, the varying length string data types have different maximum lengths for this statement than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows:

- VARCHAR or VARBINARY: 32704
- VARGRAPHIC: 16352

For parameters with a character or graphic data type, the PARAMETER CCSID clause or the CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of the CCSID clauses, the encoding scheme is the value of the DEF ENCODING SCHEME field on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

The data type of the parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type for the distinct type.

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This value is a locator for the table, which the function uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns.

A function with a table parameter can only be invoked from the triggered action of a trigger.

Specifies that the output of the function is a table. The RETURN statement in an SQL table function must return a table result. The parentheses that follow the RETURNS TABLE keyword delimit a list of name and data type pairs of the columns of the output table. All parameters for a function are input parameters and are nullable.

Specifies the name of the column. The name cannot be qualified, and must be unique within the RETURNS TABLE clause for the function.

Specifies the data type and attributes of the column of the output table.
For SQL table functions, the result table of the function might include multiple encoding schemes – similar to what a view definition can include.

**LANGUAGE SQL**
Specifies that the function is written exclusively in SQL.

**SPECIFIC specific-name**
Specifies a unique name for the function.

**NOT DETERMINISTIC or DETERMINISTIC**
Specifies whether the function returns the same results each time that the function is invoked with the same input arguments. DB2 does not verify that the function program is consistent with the specification of NOT DETERMINISTIC or DETERMINISTIC.

**NOT DETERMINISTIC**
Specifies that the function might not return the same result table each time that the function is invoked with the same input arguments, even when the referenced data in the database has not changed. The function depends on some state values that might affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a table function that is not deterministic is one which references special registers, other functions that are not deterministic, or a sequence in a way that affects the table function’s result table. **NOT DETERMINISTIC** is the default.

**DETERMINISTIC**
Specifies that the function always returns the same result table each time that the function is invoked with the same input arguments (provided that the referenced data in the database has not changed). DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function.

**EXTERNAL ACTION or NO EXTERNAL ACTION**
Specifies whether the function contains an external action. DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**EXTERNAL ACTION**
The function performs some external action (outside the scope of the function program). Thus, the function must be invoked with each successive function invocation. EXTERNAL ACTION must be specified if the function invokes another function that has external actions. **EXTERNAL ACTION** is the default.

**NO EXTERNAL ACTION**
The function does not perform any external action. It need not be called with each successive function invocation. Functions that are defined with NO EXTERNAL ACTION might perform better than functions that are defined with EXTERNAL ACTION because the function might not be invoked for each successive function invocation.

Although the scope of global variables are beyond the scope of the routine, global variables can be set in the routine body when NO EXTERNAL ACTION is specified.

**READS SQL DATA or CONTAINS SQL**
Specifies the classification of SQL statements that the function (any routine that is invoked from this function) can execute. DB2 verifies that the SQL statements that the function issues are consistent with this specification.
READS SQL DATA
Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

READS SQL DATA is the default.

CONTAINS SQL
Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The function cannot execute statements that read or modify data.

CALLED ON NULL INPUT
Specifies that the function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

CALLED ON NULL INPUT is the default.

INHERIT SPECIAL REGISTERS
Specifies that existing values of special registers are inherited upon entry to the function. INHERIT SPECIAL REGISTERS is the default.

STATIC DISPATCH
At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

CARDINALITY integer
Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of integer must be between 0 and 2147483647.

If you do not specify CARDINALITY, DB2 assumes a finite value. The finite value is the same value that DB2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality (the function never returns the end-of-table condition and always returns a row), a query that requires the end-of-table condition to work correctly will need to be interrupted.

PARAMETER CCSID
Specifies the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or RETURNS clause, or in the DEF ENCODING SCHEME field on installation panel DSNTIPF. This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause. This clause also specifies the encoding scheme that is used for system-generated parameters of the routine such as message tokens and DBINFO.

NOT SECURED or SECURED
Specifies if the function is considered secure for row access control and column access control. The SECURED or NOT SECURED option applies to all future versions of the function.

NOT SECURED
Specifies that the function is not considered secure for row access control and column access control.
NOT SECURED is the default.

When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled when the table is using active column access control.

SECURED

Specifies that the function is considered secure for row access control and column access control.

The function must be secure when it is referenced in a row permission or a column mask.

SQL-routine-body

RETURN-statement

Specifies the return value of the function. A RETURN statement must be specified for an SQL table function.

ATOMIC

ATOMIC indicates that an unhandled exception condition within the RETURN statement causes the statement to be rolled back.

Notes

Identifier resolution:

See Chapter 7, “SQL control statements for SQL routines,” on page 2029 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Referencing date and time special registers:

If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. In addition, this value is the same value that is returned by the register invocation in the statement that invoked the function.

Scrollable cursors specified with user-defined functions:

A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

Dependent objects:

An SQL routine is dependent on objects that are referenced in the routine body.

Considerations for columns that are defined with a field procedure:

The body of an SQL table function must not reference a column that is defined with a field procedure, and the RETURNS clause of an SQL table function must not reference a column that is defined with a field procedure. An SQL table function must not be invoked with an expression that is derived from a column that is defined with a field procedure.

Creating a secure function:

Typically, the security administrator will examine the data that is accessed
by a function, ensure that it is secure, and grant the
CREATE_SECURE_OBJECT privilege to someone who currently requires
the privileges to create a secure user-defined function. After the function is
created, they will revoke the CREATE_SECURE_OBJECT privilege from the
function owner.

DB2 treats the SECURED attribute as an assertion that declares that the
security administrator has established an audit procedure for all changes to
the user-defined function. DB2 assumes that such a control audit procedure
is in place for all subsequent ALTER FUNCTION statements or changes to
external packages. If the function is a compiled SQL function, DB2 assumes
that such a control audit procedure is in place for all versions of the
function, and that all subsequent ALTER FUNCTION statements or
changes to external packages are being reviewed by this audit process.

**Invoking other user-defined functions in a secure function:**
When a secure user-defined function is referenced in an SQL data change
statement that references a table that is using row access control or column
access control, and if the secure user-defined function invokes other
user-defined functions, the nested user-defined functions are not validated
as secure. If those nested functions can access sensitive data, the security
administrator needs to ensure that those functions are allowed to access
sensitive data and should ensure that a change control audit procedure has
been established for all changes to those functions.

**The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table:**
The SECURE column in the DSN_FUNCTION_TABLE EXPLAIN table
indicates if a user-defined function is considered secure.

**Functions and global variables:**
The content of global variables that are referenced in functions is inherited
from the caller.

**Restrictions involving pending definition changes:**
CREATE FUNCTION is not allowed if the function is an inline SQL table
function that references a table that has pending definition changes.

**Alternative syntax and synonyms:**
To provide compatibility with previously releases of DB2 or other products
in the DB2 family, DB2 supports the following keywords:
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

**Examples**

*Example 1:* Define a table function, JTABLE, to return a table with 3 columns:

```sql
CREATE FUNCTION JTABLE (COLD_VALUE CHAR(9), T2_FLAG CHAR(1))
RETURNS TABLE (COLA INT, COLB INT, COLC INT)
LANGUAGE SQL
SPECIFIC DEPTINFO
NOT DETERMINISTIC
READS SQL DATA
RETURN
SELECT A.COLA, B.COLB, B.COLC
FROM TABLE1 AS A
LEFT OUTER JOIN
TABLE2 AS B
ON A.COL1 = B.COL1 AND T2_FLAG = 'Y'
WHERE A.COLD = COLD_VALUE;
```
Example 2: Define a table function that returns the employees in a specified department number. The function simply returns the employees for the requested department:

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
RETURNS TABLE (EMPNO CHAR(6), LASTNAME VARCHAR(15), FIRSTNAME VARCHAR(12))
LANGUAGE SQL
READS SQL DATA
NO EXTERNAL ACTION
DETERMINISTIC
RETURN
SELECT EMPNO, LASTNAME, FIRSTNAME
FROM YEMP
WHERE YEMP.WORKDEPT = DEPTEMPLOYEES.DEPTNO;
```
CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETMTAB system privilege
- The CREATETAB database privilege for any database
- DBADM, DBCTRL, or DBMAINT authority for any database
- SYSADM or SYSCTRL authority
- System DBADM

However, DBADM, DBCTRL, or DBMAINT authority is not sufficient authority if you are creating a temporary table for someone else and the table qualifier is not your authorization ID.

Additional privileges might be required when the data type of a column is a distinct type or the LIKE clause is specified. See the description of distinct-type and LIKE for the details.

Privilege set: The privilege set is the same as the privilege set for the CREATE TABLE statement. See Privilege Set for details.

Syntax

```
CREATE GLOBAL TEMPORARY TABLE table-name
    (column-definition)
    LIKE table-name
    view-name

CCSID ASCII EBCDIC UNICODE
```

column-definition:
Chapter 6. Statements

Description

`table-name`
Names the temporary table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, synonym, or temporary table that exists at the database server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The qualification rules for a temporary table are the same as for other tables.

The owner acquires ALL PRIVILEGES on the table WITH GRANT OPTION and the authority to drop the table.

`column-definition`
Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32714 bytes. The maximum row size must not exceed 32706 bytes (8 bytes less than the maximum record size).

`column-name`
Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

`data-type`
Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

`built-in-type`
The data type of the column is a built-in data type.

For more information on and the rules that apply to the data types, see `built-in-type`.

`distinct-type`
Any distinct type except one that is based on a LOB or ROWID data type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

`NOT NULL`
Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

`LIKE table-name or view-name`
Specify that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table, view, or temporary table that exists at the current server. A view cannot contain columns of length 0.

`table-name or view-name` must not contain a Unicode column in an EBCDIC table.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If any column of the identified table or view has an attribute value that is not allowed for a column in a temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.
- If any column of the identified table or view allows a default value other than null, that default value is ignored and the corresponding column in the
new temporary table has no default value. A default value other than null is not allowed for any column in a temporary table.

**CCSID encoding-scheme**

Specifies the encoding scheme for string data stored in the table.

**ASCII**

Specifies that the data must be encoded by using the ASCII CCSIDs of the server.

An error occurs if a valid ASCII CCSID has not been specified for the installation.

**EBCDIC**

Specifies that data must be encoded by using the EBCDIC CCSIDs of the server.

An error occurs if a valid EBCDIC CCSID has not been specified for the installation.

**UNICODE**

Specifies that data must be encoded by using the CCSIDs of the server for Unicode.

An error occurs if a valid CCSID for Unicode has not been specified for the installation.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used. An error occurs if CCSIDs have not been defined.

For the creation of temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause.

**Notes**

*Owner privileges:* The owner of the table has all table privileges (see [“GRANT (table or view privileges)” on page 1786](#) with the ability to grant these privileges to others. For more information about ownership of the object, see [“Authorization, privileges, permissions, masks, and object ownership” on page 72](#).

*Instantiation and termination:* Let T be a temporary table defined at the current server and let P denote an application process:

- An empty instance of T is created as a result of the first implicit or explicit reference to T in an OPEN, SELECT INTO or SQL data change operation that is executed by any program in P.
- Any program in P can reference T and any reference to T by a program in P is a reference to that instance of T.

  When a commit operation terminates a unit of work in P and no program in P has an open WITH HOLD cursor that is dependent on T, the commit includes the operation DELETE FROM T.
- When a rollback operation terminates a unit of work in P, the rollback includes the operation DELETE FROM T.
- When the connection to the database server at which an instance of T was created terminates, the instance of T is destroyed. However, the definition of T remains. A DROP TABLE statement must be executed to drop the definition of T.
Restrictions and extensions: Let T denote a temporary table:

- Columns of T cannot have default values other than null.
- A column of T cannot have a LOB or ROWID data type (or a distinct type based on one).
- T cannot have unique constraints, referential constraints, or check constraints.
- T cannot be defined as the parent in a referential constraint.
- T cannot be referenced in:
  - A CREATE INDEX statement.
  - A LOCK TABLE statement.
  - As the object of an UPDATE statement in which the object is T or a view of T. However, you can reference T in the WHERE clause of an UPDATE statement (including the update operation of the MERGE statement).
  - DB2 utility commands.
- If T is referenced in the fullselect of a CREATE VIEW statement, you cannot specify a WITH CHECK OPTION clause in the CREATE VIEW statement.
- ALTER TABLE T is valid only if the statement is used to add a column to T. Any column that you add to T must have a default value of null. When you alter T, any packages that refer to the table are invalidated, and DB2 automatically rebinds the packages the next time they are run.
- DELETE FROM T or a view of T is valid only if the statement does not include a WHERE or WHERE CURRENT OF clause. In addition, DELETE FROM view of T is valid only if the view was created (CREATE VIEW) without the WHERE clause. A DELETE FROM statement deletes all the rows from the table or view.
- You can refer to T in the FROM clause of any subselect. If you refer to T in the first FROM clause of a select-statement, you cannot specify a FOR UPDATE clause.
- You cannot use a DROP DATABASE statement to implicitly drop T. To drop T, reference T in a DROP TABLE statement.
- A temporary table instantiated by an SQL statement using a three-part table name can be accessed by another SQL statement using the same name in the same application process for as long as the DB2 connection which established the instantiation is not terminated.
- GRANT ALL PRIVILEGES ON T is valid, but you cannot grant specific privileges on T. Of the ALL privileges, only the ALTER, INSERT, DELETE, and SELECT privileges can actually be used on T.
- REVOKE ALL PRIVILEGES ON T is valid, but you cannot revoke specific privileges from T.
- A COMMIT operation deletes all rows of every temporary table of the application process, but the rows of T are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on T. In addition, if RELEASE(COMMIT) is in effect and no open WITH HOLD cursors are dependent on T, all logical work files for T are also deleted.
- A ROLLBACK operation deletes all rows and all logical work files of every temporary table of the application process.
- You can reuse threads when using a temporary table, and a logical work file for a temporary table name remains available until deallocation. A new logical work file is not allocated for that temporary table name when the thread is reused.
- You can refer to T in the following statements:
<table>
<thead>
<tr>
<th>ALTER FUNCTION</th>
<th>CREATE PROCEDURE</th>
<th>DECLARE TABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER PROCEDURE</td>
<td>CREATE SYNONYM</td>
<td>DELETE (if it does not</td>
</tr>
<tr>
<td>COMMENT</td>
<td>CREATE TABLE LIKE</td>
<td>include a WHERE clause)</td>
</tr>
<tr>
<td>CREATE ALIAS</td>
<td>CREATE VIEW</td>
<td>DROP TABLE</td>
</tr>
<tr>
<td>CREATE FUNCTION</td>
<td>DESCRIBE TABLE</td>
<td>INSERT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>LABEL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT INTO</td>
</tr>
</tbody>
</table>

*Alternative syntax and synonyms:* For compatibility with previous releases of DB2, you can specify LONG VARCHAR as a synonym for VARCHAR(integer) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(integer) when defining the data type of a column. However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

**Examples**

*Example 1:* Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, column MEANING has a subtype of SBCS:

```sql
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP
    (CODE INTEGER NOT NULL, MEANING VARCHAR(254) NOT NULL);
```

*Example 2:* Create a temporary table, EMP:

```sql
CREATE GLOBAL TEMPORARY TABLE EMP
    (TMPDEPTNO CHAR(3) NOT NULL,
     TMPDEPTNAME VARCHAR(36) NOT NULL,
     TMPMGRNO CHAR(6),
     TMPLOCATION CHAR(16));
```
CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The INDEX privilege on the table
- Ownership of the table
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the index is created using an expression, the EXECUTE privilege is required on any user-defined function that is invoked in the index expression.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the specified index name includes a qualifier that is not the same as this owner, the privilege set must include SYSADM or SYSCTRL authority, or DBADM or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. However, if the specified index name includes a qualifier that is not the same as this authorization ID, the following rules apply:
• If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.

• If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the index. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

Syntax

```sql
CREATE UNIQUE INDEX index-name ON table-name (column-name ASC)
WHERE NOT NULL
ON key-expression DESC
, BUSINESS_TIME WITHOUT OVERLAPS
RANDOM
other-options
```

other-options:
Notes:

1. The same clause must not be specified more than one time.

2. The value of field PAD INDEXES BY DEFAULT (on installation panel DSNTIPE) determines the default. When the value is NO, NOT PADDED is the default. When the value is YES, PADDED is the default. For more information, see the description of the PADDED or NOT PADDED options.
XML-pattern-clause:

prolog:

pattern-expression:

Notes:
1  pattern-expression cannot be an empty string.
**Notes:**

1. The same clause must not be specified more than once.

**free-specification:**

**Notes:**

1. The same clause must not be specified more than one time.

**gbpcache-specification:**

**partition-element:**

**Notes:**

1. The same clause must not be specified more than once.
**Description**

**UNIQUE**

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

**UNIQUE WHERE NOT NULL**

Prevents the table from containing two or more rows with the same value of the index key where all null values for a column are not considered equal. Multiple null values are allowed. Otherwise, this is identical to **UNIQUE**.

**INDEX index-name**

Names the index. The name must not identify an index that exists at the current server or in the SYSIBM.SYSPENDINGOBJECTS catalog table.

The associated index space also has a name. That name appears as a qualifier in the names of data sets defined for the index. If the data sets are managed by the user, the name is the same as the second (or only) part of index-name. If this identifier consists of more than eight characters, only the first eight are used.

The name of the index space must be unique among the names of the index spaces and table spaces of the database for the identified table. If the data sets are defined by DB2, DB2 derives a unique name.

If the index is an index on a declared temporary table, the qualifier, if explicitly specified, must be SESSION. If the index name is unqualified, DB2 uses SESSION as the implicit qualifier.

**ON table-name or aux-table-name**

Identifies the table on which the index is created. The name can identify a base table, a materialized query table, a declared temporary table, or an auxiliary table.

**table-name**

Identifies the base table, materialized query table, or declared temporary table on which the index is created. The name must identify a table that exists at the current server. (The name of a declared temporary table must be qualified with SESSION.)

The name must not identify a clone table. The name must not identify a created temporary table or a table that is implicitly created for an XML column. If the index that is being created is for XML values, the table can contain an XML column, otherwise, the table must not contain an XML column. The name cannot identify a catalog table or declared temporary table if the index is created using expressions.

If the table has enforced row or column access controls, the row permissions and column masks are not applied during key generation.

**column-name,...**

Specifies the columns of the index key.

Each column-name must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. Do not qualify column-name.
Do not specify a column for column-name that is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a DECIMAL column (or a column with a distinct type that is based on a DECIMAL data type)
- a BINARY or VARBINARY column (or a column with a distinct type that is based on a BINARY or VARBINARY data type) when the PARTITION BY RANGE clause is also specified
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type) when the PADDED clause is also specified
- a row change timestamp column when the PARTITION BY RANGE clause is also specified.
- a timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) when the PARTITION or PARTITION BY RANGE clause is also specified.

A column with an XML type can only be specified if the XMLPATTERN clause is also specified. If the XMLPATTERN clause is specified, only one column can be identified and the column must be an XML type. The resulting index is an XML index.

If the column is a Unicode column in an EBCDIC table, the index key is converted to Unicode and the index is treated as an expression-based index, subject to the same restrictions as other expression-based indexes.

The sum of the length attributes of the columns must not be greater than the following limits, where \( n \) is the number of columns that can contain null values and \( m \) is the number of varying-length columns in the key:

- \( 2000 - n \) for a padded, nonpartitioning index
- \( 2000 - n - 2m \) for a nonpadded, nonpartitioning index
- \( 255 - n \) for a partitioning index (padded or nonpadded)
- \( 255 - n - 2m \) for a nonpadded, partitioning index

**key-expression**

Specifies an expression that returns a scalar value. An index with a key that includes one or more expressions consisting of more than just a column name is an expression-based index. key-expression cannot be specified with the GENERATE KEY USING clause or the INCLUDE clause. key-expression has the following restrictions:

- Each key-expression must contain as least one reference to a column of table-name.
  - All references to columns of table-name must be unqualified.
  - Referenced columns cannot be LOB, XML, or DECIMAL data types or a distinct type that is based on one of these data types.
  - Referenced columns cannot include any FIELDPROCs or a SECURITY LABEL. Referenced columns cannot be implicitly hidden (that is, defined with the IMPLICITLY HIDDEN attribute).

- key-expression must not include any of the following:
  - A subquery
  - An aggregate function
  - A function that is not deterministic function
  - A function that has an external action
- A user-defined function
- The VERIFY_GROUP_FOR_USER or VERIFY_ROLE_FOR_USER functions
- A sequence reference
- A host variable
- A parameter marker
- A special register
- An expression for which implicit time zone value apply (or example, cast a timestamp to a timestamp with time zone)
- A CASE expression
- An OLAP specification

- If `key-expression` references a cast function, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type.
- If `key-expression` references the LOWER or UPPER functions, the input `string-expression` cannot be FOR BIT DATA, and the function invocation must contain the `locale-name` argument.
- If `key-expression` references the TRANSLATE function, the function invocation must contain the `to-string` argument.
- If `key-expression` references the SUBSTR function, the function can reference the inline portion of a LOB column.
- The same expression cannot be used more than one time in the same index.
- The data type of the result of the expression cannot be a LOB, XML, DECFLOAT, or array value. However, the data type of the intermediate result can be a LOB value, but not an XML or DECFLOAT value.
- If a Unicode column in an EBCDIC table is referenced in a `key-expression`, the encoding scheme of the index keys must either be all Unicode or all EBCDIC. Otherwise, the encoding scheme of the result of a `key-expression` must be the same encoding scheme as the table.

The maximum length of the text string of each `key-expression` is 4000 bytes after conversion to UTF-8. The maximum number of `key-expression` in an extended index is 64.

**ASC**

Puts the index entries in ascending order by the column. ASC cannot be specified with the GENERATE KEY USING clause.

ASC is the default.

**DESC**

Puts the index entries in descending order by the column. DESC cannot be specified with the GENERATE KEY USING clause or if the ON clause contains `key-expression`.

DESC cannot be specified if the column is a Unicode column in an EBCDIC table.

**RANDOM**

Index entries are put in a random order by the column. RANDOM cannot be specified in the following cases:
- A varying length column is part of the index key and the index is defined with the NOT PADDED option
- A column of the index key is defined as TIMESTAMP WITH TIME ZONE
- The index is an XML index. An XML index is defined with the GENERATE KEY USING clause
- The index is part of the partitioning key
- A column of the index key is a Unicode column in an EBCDIC table
- The index is an expression-based index

**BUSINESS_TIME WITHOUT OVERLAPS**

`BUSINESS_TIME WITHOUT OVERLAPS` can only be specified for an index that is defined as UNIQUE. When `BUSINESS_TIME WITHOUT OVERLAPS` is specified, the values for the rest of the specified keys are unique with respect to any period of time.

`BUSINESS_TIME WITHOUT OVERLAPS` can be specified as the last item in the list. The list must include at least one `column-name` or `key-expression`.

When `BUSINESS_TIME WITHOUT OVERLAPS` is specified, the columns of the `BUSINESS_TIME` period must not be specified as `key-expressions`.

When `BUSINESS_TIME WITHOUT OVERLAPS` is specified, the following columns are added to the index:

- The end column of the `BUSINESS_TIME` period in ascending order
- The start column of the `BUSINESS_TIME` period in ascending order

`aux-table-name`

Identifies the auxiliary table on which the index is created. The name must identify an auxiliary table that exists at the current server. If the auxiliary table already has an index, do not create another one. An auxiliary table can only have one index.

Do not specify any columns for the index key. The key value is implicitly defined as a unique 19 byte value that is system generated.

If qualified, `table-name` or `aux-table-name` can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field `DB2 LOCATION NAME` of installation panel `DSNTIPR` at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the `CURRENT SERVER` special register.) Whether the name is two-part or three-part, the authorization ID that qualifies the name is the owner of the index.

The table space that contains the named table must be available to DB2 so that its data sets can be opened. If the table space is EA-enabled, the data sets for the index must be defined to belong to a DFSMS data class that has the extended format and addressability attributes.

**GENERATE KEY USING**

Along with `XMLPATTERN`, `GENERATE KEY USING` is required to generate an XML index.

**XMLPATTERN**

When an XML column is indexed, only parts of the documents will be indexed. To identify those parts, a path expression that follows the `XMLPATTERN` clause is specified. Only values of those element, attribute, or text nodes which match the specified pattern are indexed. An XML pattern can be specified using an optional namespace declaration where namespace
prefixes are mapped to namespace URIs and by providing a path expression.
The path expression is similar to a path expression in XQuery except that the
paths that are specified for the XML index can support child axis,
self-or-descendant axis, wildcard expressions, or attribute only. The maximum
length of an XML pattern text is 4000 bytes after being converted to UTF-8.
Refer to DB2 XML Guide for more information about XQuery.

prolog
To use qualified names in the pattern-expression, namespace prefixes need to be
declared. A default namespace can also be declared for use with unqualified
names.

\texttt{declare namespace NCName=StringLiteral}
The namespace prefix, \texttt{NCName}, is mapped to a namespace URI that is
identified in \texttt{StringLiteral}. Multiple namespaces can be declared, but each
namespace prefix must be unique within the list of namespace
declarations. \texttt{NCName} is an XML name as defined by the XML 1.0
standard. \texttt{NCName} cannot include a colon character. The namespace URI
xmlns/.

\texttt{declare default element namespace StringLiteral}
Specifies the default namespace URI for unqualified names of elements and
types. \texttt{StringLiteral} is a namespace URI. If no default element namespace is
declared, unqualified names of element and types are in no namespace.
Only one default namespace can be declared.

pattern-expression
Pattern-expression is used to identify those nodes in an XML document that are
indexed. Pattern-expression cannot be an empty or invalid string, and the
XQuery expression cannot be nested more than 50 levels. pattern-expression
cannot be an XQuery updating expression.

\texttt{// (forward slash)}
Separates path expression steps.

\texttt{// (double forward slash)}
Abbreviated syntax for /descendant-or-self::node/.

\texttt{. (dot)}
Abbreviated syntax for /self::node/.

\texttt{child::}
Specifies children of the context node. child:: is the default if no forward
axis is specified.

\texttt{descendant::}
Specifies the descendants of the context node.

\texttt{self::}
Specifies the current context node.

\texttt{descendant-or-self::}
Specifies the context node and the descendents of the context node.

\texttt{element-name}
Identifies an element in an XML document. element-name is an XML
QName that can have one of the following forms:

\texttt{nsprefix:NCName}
nsprefix explicitly specifies a namespace prefix that must be
declared.
**NCName**
An unqualified XML name that uses the default namespace.

* (an asterisk)
Indicates any element name. If * is prefixed by attribute:: or @, * indicates any attribute name.

nsprefix:*
Indicates any NCName within the specified namespace.

*:NCName
Indicates a specific XML name in any of the currently declared namespaces.

attribute:: or @
Specifies attributes of the context node.

attribute-name
Identifies an attribute in an XML document. attribute-name is an XML QName that can have one of the following forms:

nsprefix:NCName
nsprefix explicitly specifies a namespace prefix that must be declared.

NCName
An unqualified XML name that uses the default namespace.

text()
Matches any text node.

fn:upper-case()
Specifies an element node or an attribute node that identifies the key value for the index for each node that is specified by the context step (the part of pattern-expression that is specified prior to fn:upper-case).

The context step of fn:upper-case() must specify an element node or an attribute node. The argument of fn:upper-case() must be a self step. The key values of an XML value index must be specified as the SQL data type VARCHAR. The length of the VARCHAR value can be any value that is allowed in DB2.

fn:exists()
Specifies an element node that identifies the key value for the index for each node that is specified by the context step (the part of pattern-expression that is specified prior to fn:exists).

The context step of fn:exists() must specify an element node. The argument of fn:exists() must be either a single step of a child element node or an attribute node. The name test part can be a wildcard character for either the namespace prefix or NCName. The key values of an XML value index for an XPath expression that ends with fn:exists() must be specified as the SQL data type VARCHAR(1). The key value will be "T" or "F". "T" implies that fn:exists() evaluates to true and "F" implies that fn:exists() evaluates to false.

**AS SQL** data-type
Specifies that indexed values are stored as an instance of the specified SQL data type. Casting to the specified data type can result in a loss of precision of the values. For example, a loss of precision can occur when an XML integer value is cast to the SQL data type DECFLOAT. If the cast causes a loss of precision, the result will be rounded to the approximate value when it is stored.
in the index. The cast result cannot be outside of the range that is supported by the SQL data type. If the value cannot be cast to the specified data type, the document is still inserted into the table, but the index entry for that value is not created. No error or warning code is returned.

If the index is unique, the uniqueness is enforced on the value after it is cast to the specified type. Because rounding can occur during the cast to the SQL data type, if a value is cast to the same key value as a document that the table already contains, DB2 will return duplicate key errors at insert time, or fail to create the index.

**VARCHAR** *(integer)*

The length integer is a value in the range of 1 to 1000 bytes. If VARCHAR is specified with a length, the specified length is treated as a constraint. If documents are inserted into a table (or exist in the table at create index time) that have nodes with values that are longer than the specified length, the insert or index creation will fail.

**DECFLOAT**

DEC_FLOAT can be specified to index numeric values. For the cast to succeed, the string must be a valid XML numeric type. Otherwise the value will be ignored and no insert to the index will occur. The result of the cast cannot be outside of the range that DEC_FLOAT can represent. Because the XML Schema data type for numeric values allows greater precision than the SQL data type, the result might be rounded to fit into the SQL data type. The DEC_FLOAT values that are stored in the index are the normalized numeric values.

**DATE**

The SQL DATE data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. For invalid xs: date values, the value will be ignored without being inserted into the index. The XML schema data type for DATE allows for greater precision than the SQL data type. If an out-of-range value is encountered, an error is returned.

**TIMESTAMP** *(12)*

The SQL TIMESTAMP data type values will be normalized to UTC (Coordinated Universal Time) before being stored in the index. If the value that is specified in the document does not specify the time zone, DB2 will use the implicit time zone to normalize the value to UTC. For invalid xs: dateTime values, the value will be ignored without being inserted into the index. The XML schema data type for timestamps allows for greater precision than the SQL data type. If an out-of-range value is encountered, an error is returned. Only a precision of 12 fractional digits is allowed for an SQL TIMESTAMP index key.

**INCLUDE** *(column-name)*

Specifies additional columns to append to the set of index key columns of a unique index. Any column that is specified using INCLUDE column-name is not used to enforce uniqueness. The included columns might improve performance for some queries using index only access.

The UNIQUE clause must be specified when INCLUDE is specified. Columns that are specified in the INCLUDE clause count towards the limits for the number of columns and the limits on the sum of the length attributes of the columns that are specified in the index. The total number of columns for the index cannot exceed 64.

*column-name* must be distinct from the columns that are used to enforce uniqueness and from other columns specified in the INCLUDE clause.
column-name must be unqualified, must identify a column of the specified
table, and must not be one of the existing columns of the index. column-name
must not identify a LOB or DECFLOAT column (or a distinct type that is
based on one of those types).

The INCLUDE clause cannot be specified for the following types of indexes:
• A non-unique index
• A partitioning index when index-controlled partitioning is used
• An auxiliary index
• An XML index
• An extended index
• An expression-based index

Columns in the INCLUDE list that are defined as character or graphic string
data types must be defined with the same encoding scheme as other key
columns with character or graphic string data types.

CLUSTER or NOT CLUSTER

Specifies whether the index is the clustering index for the table. This clause
must not be specified for an index on an auxiliary table, or on a table that is
defined to use hash organization.

CLUSTER

The index is to be used as the clustering index of the table. CLUSTER
cannot be specified if XMLPATTERN or key-expression is specified.

NOT CLUSTER

The index is not to be used as the clustering index of the table.

PARTITIONED

Specifies that the index is data partitioned (that is, partitioned according to the
partitioning scheme of the underlying data). A partitioned index can be created
only on a partitioned table space, not on a partition-by-growth table space.
PARTITIONED cannot be specified if XMLPATTERN is specified. The types of
partitioned indexes are partitioning and secondary.

An index is considered a partitioning index if the specified index key columns
match or comprise a superset of the columns specified in the partitioning key,
are in the same order, and have the same ascending or descending attributes.

If PARTITION BY was not specified when the table was created, the CREATE
INDEX statement must have the ENDING AT clause specified to define a
partitioning index and use index-controlled partitioning. This index is created
as a partitioned index even if the PARTITIONED keyword is not specified.
When a partitioning index is created, if both the PARTITIONED and ENDING
AT keywords are omitted, the index will be non-partitioned. If PARTITIONED
is specified, the USING specification with PRIQTY and SECQTY specifications
are optional. If these space parameters are not specified, default values are
used.

A secondary index is any index defined on a partitioned table space that does
not meet the definition of the partitioning index. For partitioned secondary
indexes (data-partitioned secondary indexes), the ENDING AT clause is not
allowed because the partitioning scheme of the index is predetermined by that
of the underlying data. UNIQUE and UNIQUE WHERE NOT NULL are not
allowed unless the columns in the index are a superset of the partitioning
columns. If a partitioned secondary index is created on a table that uses
index-controlled partitioning, the table is converted to use table-controlled
partitioning.
Index-controlled partitioning cannot be used if the
PREVENT_NEW_IXCTRL_PART subsystem parameter is set to YES.

Related information:
PREVENT INDEX PART CREATE field (PREVENT_NEW_IXCTRL_PART
subsystem parameter) (DB2 Installation and Migration)

NOT PADDED or PADDDED
Specifies how varying-length string columns are to be stored in the index. If
the index contains no varying-length columns, this option is ignored, and a
warning message is returned. Indexes that do not have varying-length string
columns are always created as physically padded indexes.

NOT PADDED
Specifies that varying-length string columns are not to be padded to their
maximum length in the index. The length information for a varying-length
column is stored with the key.

NOT PADDED must be used if the definition of the index refers to a
Unicode column in an EBCDIC table.

NOT PADDED is ignored and has no effect if the index is being created on
an auxiliary table. Indexes on auxiliary tables are always padded.

PADDDED
Specifies that varying-length string columns within the index are always
padded with the default pad character to their maximum length. PADDLED
cannot be specified if XMLPATTERN is specified. PADDLED cannot be
specified for indexes that are defined on VARBINARY columns.

When the index contains at least one varying-length column, the default for
the option depends on the value of field PAD INDEXES BY DEFAULT on
installation panel DSNTIPE:
• When the value of this field is NO, new indexes are not padded unless
PADDLED is specified.
• When the value of this field is YES, new indexes are padded unless NOT
PADDLED is specified.

The components of the USING clause are discussed below, first for
non-partitioned indexes and then for partitioned indexes.

Using clause for non-partitioned indexes
For non-partitioned indexes, the USING clause indicates whether the data sets
for the index are to be managed by the user or managed by DB2. If DB2
definition is specified, the clause also gives space allocation parameters
(PRIQTY and SECQTY) and an erase rule (ERASE).

If you omit USING, the data sets will be managed by DB2 on volumes listed in
the default storage group of the database that is associated with the table. That
default storage group must exist. With no USING clause, PRIQTY, SECQTY,
and ERASE assume their default values.

VCAT catalog-name
Specifies that the first data set for the index is managed by the user, and
that following data sets, if needed, are also managed by the user.
The data sets defined for the index are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by `catalog-name`. An alias must be used if `catalog-name` is longer than eight characters.

Conventions for index data set names are given in Data set naming conventions (DB2 Administration Guide). `catalog-name` is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for `catalog-name` that is not used by the other DB2 subsystems.

Do not specify VCAT in any of the following circumstances:

- For an index on a declared temporary table.
- If the table space is partition-by-growth, and the table space is not part of the DB2 catalog.

**STOGROUP** `stogroup-name`

Specifies that DB2 will define and manage the data sets for the index. Each data set will be defined on a volume listed in the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. If `PRIQTY+118×SECQTY` is 2 gigabytes or greater, more than one data set could eventually be used, but only the first is defined during execution of this statement.

To use USING STOGROUP, the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. Moreover, `stogroup-name` must identify a storage group that exists at the current server and includes in its description at least one volume serial number. The description can indicate that the choice of volumes will be left to Storage Management Subsystem (SMS). Each volume specified in the storage group must be accessible to z/OS for dynamic allocation of the data set, and all these volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must not contain an entry for the first data set of the index. If the catalog is password protected, the description of the storage group must include a valid password.

The storage group supplies the data set name. The first level qualifier is also the name of, or an alias for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming convention for the data set is the same as if the data set is managed by the user.

**PRIQTY** `integer`

Specifies the minimum primary space allocation for a DB2-managed data set. `integer` must be a positive integer, or -1. When you specify PRIQTY with a positive integer value, the primary space allocation is at least `n` kilobytes, where `n` is:

- **12** If `integer` is greater than 0 and less than 12.
- `integer` If `integer` is between 12 and 4194304.
- **2097152** If both of the following conditions are true:
  - `integer` is greater than 2097152.
The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.

4194304

If integer is greater than 4194304.

If you do not specify PRIQTY, or you specify a PRIQTY value of -1, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of 4KB not less than \( n \). The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by DB2 for purposes other than storing index entries.

**SECQTY** \( \text{integer} \)

Specifies the minimum secondary space allocation for a DB2-managed data set. \( \text{integer} \) must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify a SECQTY value of -1, DB2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of 4KB not less than \( \text{integer} \). The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

**ERASE**

Indicates whether the DB2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index.

**NO**

Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.

**YES**

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

**USING clause for partitioned indexes:**

If the index is partitioned, there is a PARTITION clause for each partition. Within a PARTITION clause, a USING clause is optional. If a USING clause is present, it applies to that partition in the same way that a USING clause for a secondary index applies to the entire index.
When a USING specification is absent from a PARTITION clause, the USING clause parameters for the partition depend on whether a USING clause is specified before the PARTITION clauses.

- If the USING clause is specified, it applies to every PARTITION clause that does not include a USING clause.
- If the USING clause is not specified, the following defaults apply to the partition:
  - Data sets are managed by DB2
  - The default storage group for the database is used
  - A value of 12 is used for PRIQTY and SECQTY
  - A value of NO is used for ERASE

**VCAT** catalog-name

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify an alias for the integrated catalog facility catalog if the name of the integrated catalog facility catalog is longer than eight characters.

If \( n \) is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the \( n \)th data set of the index, conforming to the DB2 naming convention for data sets set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for catalog-name that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

**STOGROUP** stogroup-name

If USING STOGROUP is used, explicitly or by default, for a partition \( n \), DB2 defines the data set for the partition during the execution of the CREATE INDEX statement, using space from the named storage group. The privilege set must include SYSADM authority, SYSCtrl authority, or the USE privilege for that storage group. The integrated catalog facility catalog used for the storage group must NOT contain an entry for the \( n \)th data set of the index.

stogroup-name must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCtrl authority, or the USE privilege for the storage group.

If you omit PRIQTY, SECQTY, or ERASE from a USING STOGROUP clause for some partition, their values are given by the next USING STOGROUP clause that governs that partition: either a USING clause that is not in any PARTITION clause, or a default USING clause. DB2 assumes one and only one data set for each partition.

**FREEPAGE** integer

Specifies how often to leave a page of free space when index entries are created as the result of executing a DB2 utility or when creating an index for a table with existing rows. One free page is left for every integer pages. The value of integer can range from 0 to 255. The default is 0, leaving no free pages.

Do not specify FREEPAGE for an index on a declared temporary table.
PCTFREE integer
Determines the percentage of free space to leave in each nonleaf page and leaf
page when entries are added to the index or index partition as the result of
executing a DB2 utility or when creating an index for a table with existing
rows. The first entry in a page is loaded without restriction. When additional
entries are placed in a nonleaf or leaf page, the percentage of free space is at
least as great as integer.

The value of integer can range from 0 to 99, however, if a value greater than 10
is specified, only 10 percent of free space will be left in nonleaf pages. The
default is 10.

Do not specify PCTFREE for an index on a declared temporary table.

If the index is partitioned, the values of FREEPAGE and PCTFREE for a
particular partition are given by the first of these choices that applies:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for
that partition. Do not use more than one free-specification in any PARTITION
clause.
- The values given in a free-specification that is not in any PARTITION clause.
- The default values FREEPAGE 0 and PCTFREE 10.

GBPCACHE
In a data sharing environment, specifies what index pages are written to the
group buffer pool. In a non-data-sharing environment, the option is ignored
unless the index is on a declared temporary table. Do not specify GBPCACHE
for an index on a declared temporary table in either environment (data sharing
or non-data-sharing).

CHANGED
Specifies that updated pages are written to the group buffer pool, when
there is inter-DB2 R/W interest on the index or partition. When there is no
inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W
interest exists when more than one member in the data sharing group has
the index or partition open, and at least one member has it open for
update. GBPCACHE CHANGED is the default.

If the index is in a group buffer pool that is defined as GBPCACHE(NO),
CHANGED is ignored and no pages are written to the group buffer pool.

ALL
Indicates that pages are written to the group buffer pool as they are read in
from DASD.

Exception: In the case of a single updating DB2 subsystem when no other
DB2 subsystems have any interest in the page set, no pages are written to
the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO),
ALL is ignored and no pages are written to the group buffer pool.

NONE
Indicates that no pages are written to the group buffer pool. DB2 uses the
group buffer pool only for cross-validation.

If the index is partitioned, the value of GBPCACHE for a particular partition
is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition.
   Do not use more than one gbpcache-specification in any PARTITION clause.
2. The value given in a gbpcache-specification that is not in any PARTITION clause.
3. GBPCACHE CHANGED is the default value.

**DEFINE**
Specifies when the underlying data sets for the index are physically created. The SPACE column in catalog table SYSINDEXPART is used to record the status of the data sets (undefined or allocated). If the DEFINE keyword is not specified, the define attribute is inherited from the current state of the base table space.

**YES**
The data sets are created when the index is created (the CREATE INDEX statement is executed).

**NO**
The data sets are not created until data is inserted into the index.

DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). Use DEFINE NO especially when performance of the CREATE INDEX statement is important or DASD resource is constrained.

Do not use DEFINE NO on an index if you use a program outside of DB2 to propagate data into a table on which that index is defined. If you use DEFINE NO on an index of a table and data is then propagated into the table from a program that is outside of DB2, the index space data sets are allocated, but the DB2 catalog will not reflect this fact. As a result, DB2 treats the data sets for the index space as if they have not yet been allocated. The resulting inconsistency causes DB2 to deny application programs access to the data until the inconsistency is resolved.

DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DEFINE NO is also ignored if the index is being created on a table that is not empty or on an auxiliary table.

Do not specify DEFINE NO if the index is created on a base table that is involved in a clone relationship.

Do not specify DEFINE NO for an index on a declared temporary table.

**COMPRESS NO or COMPRESS YES**
Specifies whether compression for index data will be used. If the index is partitioned, the clause will apply to all partitions.

**COMPRESS NO**
Specifies that no index compression will be used.

COMPRESS NO is the default.

**COMPRESS YES**
Specifies that index compression will be used. The bufferpool that is used to create the index must be 8K, 16K, or 32K in size. The physical page size on disk will be 4K. The index compression will take place immediately.

Index compression is recommended for applications that do sequential insert operations with few or no delete operations. Random inserts and deletes can adversely effect compression. Index compress is also recommended for applications where the indexes are created primarily for scan operations.

**INCLUDE NULL KEYS or EXCLUDE NULL KEYS**
Specifies whether an index entry will be created when every key column contains the NULL value.
INCLUDE NULL KEYS
Specifies that an index entry will be created when every key column
contains the NULL value.

INCLUDE NULL KEYS is the default.

EXCLUDE NULL KEYS
Specifies that no index entry will be created when every key column
contains the NULL value. If any key column is not null the index entry
will be created.

EXCLUDE NULL KEYS must not be specified with the following:
- UNIQUE
- BUSINESS_TIME WITHOUT OVERLAPS
- XML-index-specification
- key-expression
- INCLUDE (column-name)

EXCLUDE NULL KEYS must also not be specified if any of the columns
that are identified by column-name are defined as NOT NULL, or if the
index is defined as a partitioning index for use with index-controlled
partitioning.

PARTITION BY RANGE
Specifies the partitioning index for the table, which determines the partitioning
scheme for the data in the table.

PARTITION BY RANGE should only be specified if the table space is
partitioned and the partitioning schema has not already been established.

PARTITION BY RANGE must not be specified if the index is an extended
index, is defined with the BUSINESS_TIME WITHOUT OVERLAPS, or if the
table is in a universal table space (ranged-partitioned or partition-by-growth
table space).

partition-element
Specifies the range for each partition.

PARTITION integer
A PARTITION clause specifies the highest value of the index key in
one partition of a partitioning index. In this context, highest means
highest in the sorting sequences of the index columns. In a column
defined as ascending (ASC), highest and lowest have their usual
meanings. In a column defined as descending (DESC), the lowest actual
value is highest in the sorting sequence.

If you use CLUSTER, and the table is contained in a partitioned table
space, you must use exactly one PARTITION clause for each partition
(defined with NUMPARTS on CREATE TABLESPACE). If there are p
partitions, the value of integer must range from 1 through p.

The length of the highest value of a partition (also called the limit key)
is the same as the length of the partitioning index.

ENDING AT(constant, MAXVALUE, or MINVALUE...)
Specifies that this is the partitioning index and indicates how the data
will be partitioned. The table space is marked complete after this
partitioning index is created. You must use at least one value (constant,
MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION
clause. You can use as many as there are columns in the key. The
concatenation of all the values is the highest value of the key in the
corresponding partition of the index unless the VALUES statement was already specified when the table or previous index was created.

**constant**

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in the last partition depends on how the table space is defined. For table spaces that are created without the LARGE or DSSIZE options, the values that you specify after VALUES are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key. For large partitioned table space, the values you specify are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value that is specified for the last partition are out of range.
ENDING AT can be specified only if the ENDING AT clause was not specified on a previous CREATE or ALTER TABLE statement for the underlying table.

**INCLUSIVE**
Specifies that the specified range values are included in the data partition.

**BUFFERPOOL bpname**
Identifies the buffer pool that is to be used for the index. The bpname must identify an activated 4KB, 8KB, 16KB, or 32KB buffer pool and the privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

The default is the default 4KB buffer pool for indexes in the database. A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

See “Naming conventions” on page 59 for more details about bpname. See DB2 Command Reference for a description of active and inactive buffer pools.

**CLOSE**
Specifies whether or not the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached.

**YES**
Eligible for closing. This is the default unless the index is on a declared temporary table.

**NO**
Not eligible for closing.

If the limit on the number of open data sets is reached and there are no page sets that specify CLOSE YES to close, page sets that specify CLOSE NO will be closed.

For an index on a declared temporary table, DB2 uses CLOSE NO regardless of the value specified.

**DEFER**
Indicates whether the index is built during the execution of the CREATE INDEX statement. Regardless of the option specified, the description of the index and its index space is added to the catalog. If the table is determined to be empty and DEFER YES is specified, the index is neither built nor placed in a rebuild-pending status. Refer to DB2 Administration Guide for more information about using DEFER. Do not specify DEFER for an index on a declared temporary table or an auxiliary table.

**NO**
The index is built. This is the default.

**YES**
The index is not built. If the table is populated, the index is placed in a rebuild-pending status and a warning message is issued; the index must be rebuilt by the REBUILD INDEX utility.

**PIECESIZE integer**
Specifies the maximum addressability of each data set for a non-partitioned index. The subsequent keyword K, M, or G, indicates the units of the value that is specified in integer.
Indicates that the integer value is to be multiplied by 1024 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 268435456.

Indicates that the integer value is to be multiplied by 1048576 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 262144.

Indicates that the integer value is to be multiplied by 1073741824 to specify the maximum data set size in bytes. integer must be a power of two between 1 and 256.

Table 116 shows the valid values for the data set size, which depend on the size of the table space.

<td>DSSIZE 256G</td>
</tr>
</tbody>
</table>

PIECESIZE has no effect on primary and secondary space allocation as it is only a specification of the maximum amount of data that a data set can hold and not the actual allocation of storage.

If you change the PIECESIZE value with the ALTER INDEX statement, the index is put into REBUILD-pending status.

See the following for additional information:

- Number of pieces and maximum piece size for non-partitioned indexes and data-partitioned secondary indexes
- Choosing a value for PIECESIZE
COPY

Indicates whether the COPY utility is allowed for the index. Do not specify COPY for an index on a declared temporary table.

**NO**

Does not allow full image or concurrent copies or the use of the RECOVER utility on the index. NO is the default.

**YES**

Allows full image or concurrent copies and the use of the RECOVER utility on the index.

**Notes**

**Owner privileges:**

The owner of the table has all table privileges (see "GRANT (table or view privileges)" on page 1786) with the ability to grant these privileges to others. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

**Effects of the DEFER clause:**

If DEFER NO is implicitly or explicitly specified, the CREATE INDEX statement cannot be executed while a DB2 utility has control of the table space that contains the identified table.

If the identified table already contains data and if the index build is not deferred, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.

**Errors evaluating the expressions for an index:**

Errors that occur during the evaluation of an expression for an index are returned when the expression is evaluated. This can occur on an SQL data change statement, SELECT from an SQL data change statement, or the REBUILD INDEX utility. For example, the evaluation of the expression 10 / column_1 returns an error if the value in column_1 is 0. The error is returned during CREATE INDEX processing if the table is not empty and contains a row with a value of zero in column_1, otherwise the error is returned during the processing of the insert or update operation when a row with a value of zero in column_1 is inserted or updated.

**Result length of expressions that return a string type:**

If the result data type of key-expression is a string type and the result length cannot be calculated at bind time, the length is set to the maximum allowable length of that data type or the largest length that DB2 can estimate. In this case, the CREATE INDEX statement can fail because the total key length might exceed the limit of an index key.

For example, the result length of the expression REPEAT('A', CEIL(1.1)) is VARCHAR(32767) and the result length of the expression SUBSTR(DESCRIPTION, 1, INTEGER(1.2)) is the length of the DESCRIPTION column. Therefore, a CREATE INDEX statement that uses any of these expressions as a key-expression might not be created because the total key length might exceed the limit of an index key.

**Use of ASC or DESC on key columns:**

There are no restrictions on the use of ASC or DESC for the columns of a parent key or foreign key. An index on a foreign key does not have to have the same ascending and descending attributes as the index of the corresponding parent key.
EBCDIC, ASCII, and UNICODE encoding schemes for an index:

An index has the same encoding scheme as its associated table.

Number of pieces and maximum piece size for non-partitioned indexes

The largest amount of data that an index can hold is the maximum number of pieces for the index times the maximum amount of data that a piece can hold.

For a non-partitioned index, the maximum amount of data that an index can hold is defined by using the PIECESIZE parameter.

The default piece size for an index is as follows:

- 2 GB (PIECESIZE 2 G) for indexes of table spaces created without the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for indexes of table spaces created with the LARGE or DSSIZE option
- 4 GB (PIECESIZE 4 G) for auxiliary indexes

The following tables list the maximum number of pieces and the default index piece size for various table spaces.

Table 117. Maximum number of pieces and the default index piece size for a partitioned table space that is created without the LARGE or DSSIZE clauses and has a NUMPART value of less than or equal to 64

<table>
<thead>
<tr>
<th>Definition of partitioned table space (non-large), NUMPART value</th>
<th>Maximum number of pieces in a non-partitioned index</th>
<th>Default index piece size for a non-partitioned index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMPARTS &lt;= 16</td>
<td>32</td>
<td>2G</td>
</tr>
<tr>
<td>NUMPART &gt;= 17 but</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NUMPARTS &lt;= 32</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NUMPART &gt;= 33</td>
<td>32</td>
<td>2G</td>
</tr>
</tbody>
</table>

Table 118. Maximum number of pieces and the default index piece size for a partitioned table space that is created with the LARGE or DSSIZE clauses or has a NUMPART value of greater than or equal to 65

<table>
<thead>
<tr>
<th>Definition of partitioned table space (large)</th>
<th>Maximum number of pieces for a non-partitioned index</th>
<th>Default index piece size for a non-partitioned index</th>
</tr>
</thead>
<tbody>
<tr>
<td>• LARGE clause - specified</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
<tr>
<td>• DSSIZE clause - not specified</td>
<td>- see [1]</td>
<td></td>
</tr>
<tr>
<td>• LARGE clause - not specified</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
<tr>
<td>• DSSIZE clause - not specified</td>
<td>- see [1]</td>
<td></td>
</tr>
<tr>
<td>• NUMPARTS clause - greater than 64 but less than 256</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
<tr>
<td>• LARGE clause - not specified</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
<tr>
<td>• DSSIZE clause - specified or NUMPARTS clause - greater than or equal to 256</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
<tr>
<td>• NUMPARTS clause - greater than or equal to 256</td>
<td>MIN(4096, 2^32 / (x/y))</td>
<td>4G</td>
</tr>
</tbody>
</table>

Note:

1. For a non-partitioned index, the formula \(\text{MIN}(4096, 2^{32} / (x / y))\), determines the maximum number of pieces for the non-partitioned index, where \(x\) and \(y\) have the following values:
   - \(x\) is the piece size of the index (stored in the PIECESIZE column of the SYSIBM.SYSINDEXES catalog table)
   - \(y\) is the page size of the index (stored in the PGSIZE column of the SYSIBM.SYSINDEXES catalog table)
Table 119. Maximum number of pieces and the default index piece size for a non-partitioned table space

<table>
<thead>
<tr>
<th>Type of non-partitioned table space</th>
<th>Maximum number of pieces</th>
<th>Default index piece size</th>
</tr>
</thead>

<tr>
<td>LOB, auxiliary, or XML table space</td>
<td>32</td>
<td>4G</td>
</tr>
</tbody>
</table>

Choosing a value for PIECESIZE:

To choose a value for PIECESIZE, divide the size of the non-partitioned index by the number of data sets that you want. For example, to ensure that you have five data sets for the non-partitioned index, and your index is 10MB (and not likely to grow much), specify PIECESIZE 2 M. If your non-partitioned index is likely to grow, choose a larger value.

Remember that 32 data sets is the limit if the underlying table space is not defined as LARGE or with a DSSIZE parameter and that the limit is 4096 for objects with greater than 254 parts. For a non-partitioned index on a table space that is defined as LARGE or with a DSSIZE parameter, the maximum is MIN(4096, $2^{32}$ / (index piece size / index page size)).

Keep the PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, the value of your primary quantity plus the secondary quantities should be evenly divisible into PIECESIZE.

Dropping an index:

Partitioning indexes can be dropped. If the table space is using index-controlled partitioning, the table space is converted to table-controlled partitioning. Secondary indexes that are not indexes on auxiliary tables can be dropped simply by dropping the indexes. An empty index on an auxiliary table can be explicitly dropped; a populated index can be dropped only by dropping other objects. For details, see Dropping an index on an auxiliary table and an auxiliary table.

If the index is a unique index that enforces a primary key, unique key, or referential constraint, the constraint must be dropped before the index is dropped. See "DROP" on page 1672.

Unique indexes and enforcement of UNIQUE or PRIMARY KEY specifications for a table:

A table requires a unique index (that is not defined as UNIQUE WHERE NOT NULL) if you use the UNIQUE or PRIMARY KEY clause in the CREATE or ALTER TABLE statements, or if there is a ROWID column that is defined as GENERATED BY DEFAULT. DB2 implicitly creates those unique indexes if the table space is explicitly created and the CREATE or ALTER TABLE statement is processed by the schema processor or if the table space is implicitly created; otherwise, you must explicitly create them.

If any of the unique indexes that must be explicitly defined do not exist, the definition of the table is incomplete, and the following rules apply:

- Let K denote a key for which a required unique index does not exist and let n denote the number of unique indexes that remain to be created before the definition of the table is complete. (For a new table that has no indexes, K is its primary key or any of the keys defined in the CREATE or ALTER TABLE statement as UNIQUE and n is the number
of such keys. After the definition of a table is complete, an index cannot be dropped if it is enforcing a primary key or unique key.)

- The creation of the unique index reduces \( n \) by one if the index key is identical to \( K \). The keys are identical only if they have the same columns in the same order.
- If \( n \) is now zero, the creation of the index completes the definition of the table.
- If \( K \) is a primary key, the description of the index indicates that it is a primary index. If \( K \) is not a primary key, the description of the index indicates that it enforces the uniqueness of a key defined as UNIQUE in the CREATE or ALTER TABLE statement.

A unique index cannot be created on a materialized query table.

**Unique indexes and XML columns:**

If the index is an XML index on a unique XML column, the uniqueness applies to values of the specified pattern across all documents of that column, and the uniqueness is enforced on the value after the value is cast to the specified SQL data type. Because the data type conversion might result in a loss of precision and normalization, multiple values that appear unique in the XML document might still result in duplicate errors. If the index is defined using an expression, the uniqueness is enforced against the values that are stored in the index, not against the original values of the columns. The **WHERE NOT NULL** specification is ignored with a warning if XMLPATTERN is also specified, and the index is treated as if **UNIQUE** had been specified.

**Defining an XML index using an XPath pattern-expression that includes functions:**

An XPath **pattern-expression** that includes functions (including fn:exists() or fn:upper-case()) will have two parts. The first part is referred to as the **context step** and specifies the XPath of the element node or attribute node for which an index entry will be created (the element or attributes NodeID will be included in the index). The context step follows the same syntax as the XPath **pattern-expression** for an XML index, except that for fn:exists() it has to specify an element node, and for fn:upper-case() it has to specify an element node or an attribute node.

The second part is referred to as the **function expression step** and specifies the fn:exists() or fn:upper-case() XPath function. The function expression step is the right-most part of an XPath **pattern-expression**. For each node specified by the context step, the function expression step specifies the key value for the index. For example, in the XPath **pattern-expression** `/purchaseOrder/items/item/fn:exists(shipDate)`, the context step is `/purchaseOrder/items/item`, and the function expression step is fn:exists(shipDate).

**Use of PARTITIONED keyword:**

When a partitioned index is created and no additional keywords are specified, the index is non-partitioned. If the keyword PARTITIONED is specified, the index is partitioned. If PARTITION BY RANGE is specified, the index is both data-partitioned and key-partitioned because it is defined on the partitioning columns of the table. Any index on a partitioned table space that does not meet the definition of a partitioning index is a secondary index. When a secondary index is created and no additional keywords are specified, the secondary index is non-partitioned (NPSI). If the keyword PARTITIONED is specified, the index is a data-partitioned secondary index (DPSI).
Creating a partitioning index for a table created without partition boundaries:
When a table is created without specifying partition boundaries using the ENDING AT clause, the table is incomplete until a partitioning index is created. The first index that is created for a table must specify both the PARTITION and the ENDING AT clauses.

When the PARTITION clause is specified while creating an index, either the PARTITIONED clause, or the ENDING AT clause must also be specified.

Considerations for tables that are involved in a clone relationship:
If an index is created on a base table that is involved in a clone relationship, an index with the same name is also created on the clone table. The index on the clone table will be placed in rebuild-pending status unless the clone table is empty when the index is created.

Considerations for tables that contain a row change timestamp column:
To create an index that refers to a row change timestamp column in the table, values must already exist in the column for all rows. Values are stored in row change timestamp columns whenever a row is inserted or updated in the table. If the row change timestamp column is added to an existing table that contains rows, the values for the row change timestamp column is not materialized and stored at the time of the ALTER TABLE statement. Values are materialized for these rows when they are updated, or when a REORG or a LOAD REPLACE utility is run on the table or table space.

Restriction on table spaces when there are pending changes to the definition:
A CREATE INDEX statement is not allowed if there are pending changes to the definition of the table space or to any objects in the table space. In addition, an index that references an expression cannot be created on a table where the inline length of a LOB column has been changed and the table space has not been reorganized.

Effects of DEFINE NO and INCLUDE NULL KEYS or EXCLUDE NULL KEYS:
When INCLUDE NULL KEYS is specified (implicitly or explicitly) with DEFINE NO and the table that is being indexed is populated, a warning is returned, the index is created, and the data set is defined. When EXCLUDE NULL KEYS is specified, it is possible that the data set will not be defined if the all rows for the table that is being indexed contain the NULL value for all key columns. The index will be empty after the CREATE INDEX statement. However, if DEFINE NO is specified with EXCLUDE NULL KEYS a warning is returned.

Creating indexes on DB2 catalog tables:
For details on creating indexes on catalog tables, see "SQL statements allowed on the catalog" on page 2178.

EA-enabled index data sets:
If an index is created for an EA-enabled table space, the data sets for the index must be set up to belong to a DFSMS data class that has the extended format and extended addressability attributes.

Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when creating a partitioned index:
• **PART integer VALUES** as an alternative syntax for **PARTITION integer ENDING**. The **PARTITION BY RANGE** keyword that precedes the `partition-element` clause is optional.

Although these keywords are supported as alternatives, they are not the preferred syntax.

**User-defined indexes on catalog tables:**

If you issue CREATE INDEX for an index on a catalog table, and you specify the USING clause, DB2 ignores that clause. Instead, DB2 defines and manages the index data sets. The data sets are defined in the same SMS environment that is used for the catalog data sets with default space attributes.

**Examples**

*Example 1:* Create a unique index, named DSN8B10.XDEPT1, on table DSN8B10.DEPT. Index entries are to be in ascending order by the single column DEPTNO. DB2 is to define the data sets for the index, using storage group DSN8G110. Each data set should hold 1 megabyte of data at most. Use 512 kilobytes as the primary space allocation for each data set and 64 kilobytes as the secondary space allocation. These specifications enable each data set to be extended up to 8 times before a new data set is used—512KB + (8*64KB)= 1024KB. Make the index padded.

The data sets can be closed when no one is using the index and do not need to be erased if the index is dropped.

```
CREATE UNIQUE INDEX DSN8B10.XDEPT1 ON DSN8B10.DEPT (DEPTNO ASC) PADDED USING STOGROUP DSN8G110 PRIQTY 512 SECQTY 64 ERASE NO BUFFERPOOL BP1 CLOSE YES PIECESIZE 1M;
```

For the above example, the underlying data sets for the index will be created immediately, which is the default (DEFINE YES). Assuming that table DSN8B10.DEPT is empty, if you wanted to defer the creation of the data sets until data is first inserted into the index, you would specify DEFINE NO instead of accepting the default behavior. Specifying PADDED ensures that the varying-length character string columns in the index are padded with blanks.

*Example 2:* Create a cluster index, named XEMP2, on table EMP in database DSN8B10. Put the entries in ascending order by column EMPNO. Let DB2 define the data sets for each partition using storage group DSN8G110. Make the primary space allocation be 36 kilobytes, and allow DB2 to use the default value for SECQTY, which for this example is 12 kilobytes (3 times 4KB). If the index is dropped, the data sets need not be erased.

There are to be 4 partitions, with index entries divided among them as follows:

- Partition 1: entries up to H99
- Partition 2: entries above H99 up to P99
- Partition 3: entries above P99 up to Z99
- Partition 4: entries above Z99
Associate the index with buffer pool BP1 and allow the data sets to be closed when no one is using the index. Enable the use of the COPY utility for full image or concurrent copies and the RECOVER utility.

```sql
CREATE INDEX DSN8B10.XEMP2
ON DSN8B10.EMP
  (EMPNO ASC)
USING STOGROUP DSN8G110
PRIQTY 36
ERASE NO
CLUSTER
PARTITION BY RANGE
  (PARTITION 1 ENDING AT('H99'),
   PARTITION 2 ENDING AT('P99'),
   PARTITION 3 ENDING AT('Z99'),
   PARTITION 4 ENDING AT('999'))
BUFFERPOOL BP1
CLOSE YES
COPY YES;
```

Example 3: Create a secondary index, named DSN8B10.XDEPT1, on table DSN8B10.DEPT. Put the entries in ascending order by column DEPTNO. Assume that the data sets are managed by the user with catalog name DSNCAT and each data set is to hold 1GB of data, at most, before the next data set is used.

```sql
CREATE UNIQUE INDEX DSN8B10.XDEPT1
ON DSN8B10.DEPT
  (DEPTNO ASC)
USING VCAT DSNCAT
PIECESIZE 1048576K;
```

Example 4: Assume that a column named EMP_PHOTO with a data type of BLOB(110K) was added to the sample employee table for each employee’s photo and auxiliary table EMP_PHOTO_ATAB was created in LOB table space DSN8D11A.PHOTOLTS to store the BLOB data for the column. Create an index named XPHOTO on the auxiliary table. The data sets are to be user-managed with catalog name DSNCAT.

```sql
CREATE UNIQUE INDEX DSN8B10.XPHOTO
ON DSN8B10.EMP_PHOTO
  (EMP_PHOTO_ATAB)
USING VCAT DSNCAT
COPY YES;
```

In this example, no columns are specified for the key because auxiliary indexes have implicitly generated keys.
CREATE MASK

The CREATE MASK statement creates a column mask at the current server. A column mask is used for column access control and specifies the value that should be returned for a specified column.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

SECADM authority can create a column mask in any schema. Additional privileges are not needed to reference other objects in the mask definition. For example, the SELECT privilege is not needed to query a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role that is in effect.

Syntax

```
CREATE MASK mask-name
ON table-name
AS correlation-name
FOR COLUMN column-name
RETURN case-expression
DISABLE
ENABLE
```

Description

- **mask-name**
  Specifies the names the column mask. The name, including the implicit or explicit qualifier, must not identify a column mask or a row permission that already exists at the current server.

- **ON table-name**
  Identifies the table for which the column mask is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:
  - An auxiliary table
• A created or declared temporary table
• A view
• A catalog table
• An alias
• A synonym
• A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
• A table that was implicitly created for an XML column
• A table that contains a period
• A history table
• An archive-enabled table
• An archive table

correlation-name
Specifies a correlation name that can be used within case-expression to designate the table. For information about correlation-name, see “Correlation names” on page 216.

FOR COLUMN column-name
Identifies the column to which the mask applies. column-name must be an unqualified name that identifies a column of the specified table. A mask must not already exist for the column. The column must not be:
• a LOB column or a distinct type column that is based on a LOB
• an XML column
• defined with a FIELDPROC
• a Unicode column in an EBCDIC table

RETURN case-expression
Specifies a CASE expression that determines the value that is returned for the column. The result of the CASE expression is returned in place of the column value in a row. The result data type, null attribute, data length, subtype, encoding scheme, and CCSID of the CASE expression must be identical to those attributes of the column that is specified by column-name. If the data type of column-name is a user-defined data type, the result data type of the CASE expression must be the same user-defined type. The CASE expression must not reference any of the following objects:
• A remote object
• The table for which the column mask is being defined
• A created global temporary table or a declared global temporary table
• An auxiliary table
• A table that was implicitly created for an XML column
• A column that is defined with a FIELDPROC
• A LOB column or a distinct type column that is based on a LOB
• An XML column
• A select list notation * or name.* in the SELECT clause
• A table function
• A collection-derived table (UNNEST)
• A user-defined function that is defined as not secure
• A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
• An aggregate function, unless it is specified in a subquery
• A built-in table function
• An XMLTABLE table function
• An XML EXISTS predicate
• An OLAP specification
• A ROW CHANGE expression
• A sequence reference
• A host variable, SQL variable, SQL parameter, or trigger transition variable
• A parameter marker
• A table reference that contains a period specification
• A view that includes any of the preceding restrictions in its definition

The encoding scheme of the specified table is used to evaluate the CASE expression. Tables and language elements that require multiple encoding scheme evaluation must not be referenced in the CASE expression. See “Determining the encoding scheme and CCSID of a string” on page 50 for language elements that require multiple evaluation.

If the CASE expression references tables for which row or column access control is active, access controls for those tables are not cascaded.

**DISABLE or ENABLE**

Specifies that the column mask is to be enabled or disabled for column access control.

**DISABLE**

Specifies that the column mask is to be disabled for column access control. The column mask will remain disabled regardless of whether column access control is activated for the table.

**DISABLE** is the default.

**ENABLE**

Specifies that the column mask is to be enabled for column access control. If column access control is not currently active for the table, the column mask will become enabled when column access control is activated for the table. If column access control is currently active for the table, the column mask becomes enabled immediately and all packages and statements in the dynamic statement cache that reference the table are invalidated.

**Notes**

**How column masks affect queries:**

The application of enabled column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, or ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY clause with a sort-key expression, the order is based on the original values of the column and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by a SELECT DISTINCT statement. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, a column mask on
column SSN might change the result of the aggregate function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the unmasked values.

Conflicts between the definition of a column mask and SQL:
A column mask is created as a stand alone object, without knowing all of the contexts in which it might be used. To mask the value of a column in the final result table, the definition of the column mask is merged into a query by DB2. When the definition of the column mask is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask can return an error. When this happens, either the statement needs to be modified or the column mask must be dropped or re-created with a different definition. See "ALTER TABLE" on page 1027 for those situations in which a bind time error might be issued for the statement.

Column masks and null columns:
If the column is not nullable, the definition of its column mask will not, most likely, consider a null value for the column. After the column access control is activated for the table, if the table is the null-padded table in an outer join, the value of he column in the final result table might be a null. To ensure that the column mask can mask a null value, if the table is the null-padded table in an outer join, DB2 will add "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition. This forces a null value to always be masked as a null value. For a nullable column, this removes the ability to mask a null value as something else. Example 5 shows this added WHEN clause.

Column mask values for SQL data change statements
When columns are used to derive new values for an INSERT, UPDATE, MERGE, or a SET transition-variable assignment statement, the original values of the column, not the masked values, are used to derive the new values. If the columns have column masks, those column masks are applied to ensure that the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure that the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time. The rules that are used to apply column masks in order to derive the new values follow the same rules for the final result table of a query.

Column masks that are created before column access control is activated:
The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have one mask only.

The definition of a mask is stored in the DB2 catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. SECADM authority is required to issue such an ALTER TABLE statement. A disabled column mask remains ineffective.
even when column access control is activated for the table. The ALTER
MASK statement can be used to alter between ENABLE and DISABLE.

After column access control is activated for a table, when the table is
referenced in a data manipulation statement, all enabled column masks
that have been created for the table are implicitly applied by DB2 to mask
the values returned for the columns referenced in the final result table of
the queries or to determine the new values used in the data change
statements.

Creating column masks before activating column access control for a table
is the recommended sequence to avoid multiple invalidations of packages
and dynamic cached statements that reference the table.

**Column masks that are created after column access control is activated:**
The enabled column masks become effective as soon as they are
committed. All the packages and dynamic cached statements that reference
the table are invalidated. Thereafter, when the table is referenced in a data
manipulation statement, all enabled column masks are implicitly applied
by DB2 to the statement. Any disabled column mask remains ineffective
even when column access control is activated for the table.

**No cascaded effect when column or row access control enforced tables are
referenced in column mask definitions:**
A column mask definition may reference tables and columns that are
currently enforced by row or column access control. Access control from
those tables and columns are ignored when the table for which the column
mask is being created is referenced in a data manipulation statement.

**Multiple column masks and row permissions sharing the same environment
variables:**
Multiple column masks and row permissions can be created for a table.
They must use the same set of environment variables. The set of
environment variables is determined when the first column mask or row
permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment
variables. The following table shows which environment variable must be
the same among the multiple column masks and row permissions.

<table>
<thead>
<tr>
<th>Environment variables shown as SYSENVIRONMENT columns</th>

**Note:** In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

**Ordinary SQL identifiers specified in a static CREATE MASK statement in a COBOL application:**
If the CREATE MASK statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the column mask definition must not follow the rules for naming COBOL words. They must follow the rules for naming SQL identifiers on page 57. For example, the COBOL word 1ST-TIME is not allowed as an ordinary SQL identifier in a column mask definition; change it to FIRST_TIME or put it in the delimiters.

**Encoding scheme and CCSIDs of the data manipulation statement after column masks are applied:**
The encoding scheme and CCSIDs of the data manipulation statement is not affected by the column masks that are implicitly applied by DB2 for the column access control. The column mask definition is evaluated using its target table's encoding scheme and CCSIDs.

**Consideration for DB2 limits:**
If the data manipulation statement already approaches some DB2 limits in the statement, it should be noted that the more enabled column masks and
enabled row permissions are created, the more likely they would impact some limits. For example, they may cause the statement to exceed the maximum total length (32600 bytes) of columns of a query operation requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT and GROUP BY). This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "Limits in DB2 for z/OS" in SQL Reference for the limits of a statement.

Restrictions involving pending definition changes:
CREATE MASK is not allowed if the mask is defined on a table or references a table that has pending definition changes.

Examples

Example 1:
After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see the last four characters only of the social security number. Peter who is neither cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
  FOR COLUMN SSN RETURN
    CASE
      WHEN (VERIFY_GROUP_FOR_USER(SSESSION_USER,'PAYROLL') = 1)
        THEN SSN
      WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR') = 1)
        THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
      ELSE NULL
    END
  END;
COMMIT;
ALTER TABLE EMPLOYEE
  ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;
SELECT SSN FROM EMPLOYEE
  WHERE EMPNO = 123456;
```

Example 2:
In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression gets evaluated twice.

```
CREATE MASK SSN_MASK ON EMPLOYEE
  FOR COLUMN SSN RETURN
    CASE
      WHEN (1 = 1)
        THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
      ELSE NULL
    END
  END;
COMMIT;
```
ALTER TABLE EMPLOYEE
   ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT 'XXX-XX-' || SUBSTR(SSN,8,4) FROM EMPLOYEE
   WHERE EMPNO = 123456;

Example 3:
A state government conducted a survey for the library usage of the households in each city. Fifty households in each city were sampled in the survey. Each household was given an option, opt-in or opt-out, whether to show their usage in any reports generated from the result of the survey.

A SELECT statement is used to generate a report to show the average hours used by households in each city. Column mask CITY_MASK is created to mask the city name based on the opt-in or opt-out information chosen by the sampled households. However, after column access control is activated for table LIBRARY_USAGE, the SELECT statement receives a bind time error. This is because column mask CITY_MASK references another column LIBRARY_OPT and LIBRARY_OPT does not identify a grouping column.

CREATE MASK CITY_MASK ON LIBRARY_USAGE
   FOR COLUMN CITY RETURN
      CASE
         WHEN (LIBRARY_OPT = 'OPT-IN')
            THEN CITY
         ELSE ''
      END
   ENABLE;

COMMIT;

ALTER TABLE LIBRARY_USAGE
   ACTIVATE COLUMN ACCESS CONTROL;

COMMIT;

SELECT CITY, AVG(LIBRARY_TIME) FROM LIBRARY_USAGE
   GROUP BY CITY;

Example 4:
Employee with EMPNO 123456 earns bonus $8000 and salary $80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

CREATE MASK SALARY_MASK ON EMPLOYEE
   FOR COLUMN SALARY RETURN
      CASE
         WHEN (BONUS < 10000)
            THEN SALARY
         ELSE NULL
      END
   ENABLE;

COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
   FOR COLUMN BONUS RETURN
      CASE
         WHEN (BONUS > 5000)
            THEN NULL
         ELSE BONUS
      END

Chapter 6. Statements 1363
END
ENABLE;
COMMIT;
ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;
SELECT SALARY FROM EMPLOYEE
    WHERE EMPNO = 123456;

Example 5:
This example shows DB2 adds "WHEN target-column IS NULL THEN NULL" as the first WHEN clause to the column mask definition then merges the column mask definition into the statement.

CREATE EMPLOYEE (EMPID INT,
    DEPTID CHAR(8),
    SALARY DEC(9,2) NOT NULL,
    BONUS DEC(9,2));

CREATE MASK SALARY_MASK ON EMPLOYEE
    FOR COLUMN SALARY RETURN
    CASE
    WHEN SALARY < 10000
    THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
    END
    ENABLE;
COMMIT;

CREATE MASK BONUS_MASK ON EMPLOYEE
    FOR COLUMN BONUS RETURN
    CASE
    WHEN BONUS > 1000
    THEN BONUS
    ELSE NULL
    END
    ENABLE;
COMMIT;
ALTER TABLE EMPLOYEE
    ACTIVATE COLUMN ACCESS CONTROL;
COMMIT;

SELECT SALARY FROM DEPT
    LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;

/* When SALARY_MASK is merged into the above statement,
   'WHEN SALARY IS NULL THEN NULL' is added as the
   first WHEN clause, as follows:
*/

SELECT CASE WHEN SALARY IS NULL THEN NULL
    WHEN SALARY < 10000 THEN CAST(SALARY*2 AS DEC(9,2))
    ELSE COALESCE(CAST(SALARY/2 AS DEC(9,2)), BONUS)
    END SALARY
    FROM DEPT
    LEFT JOIN EMPLOYEE ON DEPTNO = DEPTID;
CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission for row access control at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include the following authority:

- SECADM authority

SECADM authority can create a row permission in any schema. Additional privileges are not needed to reference other objects in the permission definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to invoke a user-defined function.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. However, if it is running in a trusted context defined with the ROLE AS OBJECT OWNER AND QUALIFIER clause, the privilege set is the set of privileges that are held by the role in effect.

Syntax

```
CREATE PERMISSION permission-name
ON table-name
AS correlation-name
FOR ROWS WHERE search-condition
ENFORCED FOR ALL ACCESS
DISABLE
ENABLE
```

Description

(permission-name)

Names the row permission for row access control. The name, including the implicit or explicit qualifier, must not identify a row permission or a column mask that already exists at the current server.

(ON table-name)

Identifies the table on which the row permission is created. The name must identify a table that exists at the current server. It must not identify any of the following objects:

- An auxiliary table
- A created or declared temporary table
- A view
• A catalog table
• An alias
• A synonym
• A materialized query table or table that is directly or indirectly referenced in the definition of a materialized query table
• A table that was implicitly created for an XML column
• A table that contains a period
• A history table
• An archive-enabled table
• An archive table
• A table that has a security label column.

correlation-name
Can be used within search-condition to designate the table. For the explanation of correlation-name, see "Correlation names" on page 216.

FOR ROWS WHERE
Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition
Specifies a condition that can be true, false, or unknown for a row of the table. search-condition follows the same rules that are used by the search condition in a WHERE clause of a subselect. In addition, the search condition must not reference any of the following objects:
• A remote object
• The table for which the row permission is being defined
• A table that has a security label column
• A created global temporary table or a declared global temporary table
• An auxiliary table
• A table that was implicitly created for an XML column
• A collection-derived table (UNNEST)
• A table function
• A host variable, SQL variable, SQL parameter, or trigger transition variable
• A user-defined function that is defined as not secure
• A function that is not deterministic or that has an external action or is defined with the MODIFIES SQL DATA option
• A parameter marker
• A column that is defined with a FIELDPROC
• A LOB column or a distinct type column that is based on a LOB
• An XML column
• A Unicode column in an EBCDIC table
• An XML EXISTS predicate
• An OLAP specification
• A ROW CHANGE expression
• A sequence reference
• A select list notation * or name.* in the SELECT clause
• A table reference that contains a period specification
• A view that includes any of the preceding restrictions in its definition
The encoding scheme of the table is used to evaluate the search-condition. Tables and language elements that require multiple encoding scheme evaluation must not be referenced in the search-condition. See “Determining the encoding scheme and CCSID of a string” on page 50 for those language elements.

If the search-condition references tables for which row or column access control is activated, access control from those tables is not cascaded.

**ENFORCED FOR ALL ACCESS**
Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, DB2 implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed are insertable or updatable by the user who requested the data change operation.

**DISABLE or ENABLE**
Specifies that the row permission is to be enabled or disabled for row access control.

**DISABLE**
Specifies that the row permission is to be disabled for row access control. The row permission will remain ineffective regardless the row access control is activated for the table or not.

**DISABLE** is the default.

**ENABLE**
Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

**Notes**

**How row permission are applied and how they affect certain statements:**
See the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause for information on how to activate row access control and how row permissions are applied. See the description of subselect for information on how the application of row permissions affects the fetch operation. See the data change statements for information on how the application of row permissions affects the data change operation.

**Row permissions that are created before row access control is activated for a table:**
The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

The definition of the row permission is stored in the DB2 catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A row permission can be created as enabled or disabled for row access control. An enabled row
Permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by DB2 to control access to the table.

Creating row permissions before activating row access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.

**Row permissions that are created after row access control is activated for a table:** An enabled row permission becomes effective as soon as it is committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permission remains ineffective even when row access control is activated for the table.

**No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:** A row permission definition may reference tables and columns that are currently enforced by row or column access control. Access control from those tables are ignored when the table for which the row permission is being created is referenced in a data manipulation statement.

**Multiple column masks and row permissions sharing the same environment variables:**

Multiple column masks and row permissions can be created for a table. They must use the same set of environment variables. The set of environment variables is determined when the first column mask or row permission is created for the table.

The catalog table SYSENVIRONMENT contains the list of environment variables. The following table shows which environment variable must be the same among the multiple column masks and row permissions.

<table>
<thead>
<tr>
<th>Environment variables shown as SYSENVIRONMENT columns</th>

</table>

Note: In a data sharing environment, if a separate DSNHDECP module is provided for each member of the group, the DSNHDECP settings for each environment variable should be the same in all members of the data sharing group, otherwise an error might be issued when multiple column masks or row permissions are created.

Ordinary SQL identifiers specified in a static CREATE PERMISSION statement in a COBOL application:

If the CREATE PERMISSION statement is a static statement in a COBOL application, the ordinary SQL identifiers used in the row permission definition must not follow the rules for naming COBOL words (DSNH20474, reason code 14). They must follow the rules for naming SQL identifiers as described in the topic “SQL identifiers” in DB2 SQL Reference. For example, the COBOL word 1ST-TIME is not allowed as an
ordinary SQL identifier in a row permission definition; change it to 
FIRST_TIME or put it in the delimiters.

Encoding scheme and CCSIDs of the data manipulation statement after row 
permissions are applied:
The encoding scheme and CCSIDs of the data manipulation statement is 
not affected by the row permissions that are implicitly applied by DB2 for 
the row access control. The row permission definition is evaluated using its 
target table’s encoding scheme and CCSIDs.

Consideration for DB2 limits:
If the data manipulation statement already approaches some DB2 limits in 
the statement, it should be noted that the more enabled row permissions 
and enabled column masks are created, the more likely they would impact 
some limits. For example, they may cause the statement to exceed the 
maximum total length (32600 bytes) of columns of a query operation 
requiring sort and evaluating aggregate functions (MULTIPLE DISTINCT 
and GROUP BY). This is because the enabled column mask and enabled 
row permission definitions are implicitly merged into the statement when 
the table is referenced in a data manipulation statement. See "Limits in 
DB2 for z/OS" in SQL Reference for the limits of a statement.

Restrictions involving pending definition changes:
CREATE PERMISSION is not allowed if the permission is defined on a 
table or references a table that has pending definition changes.

Examples

Example 1:
Secure user-defined function ACCOUNTING_UDF in row permission 
SALARY_ROW_ACCESS processes the sensitive data in column SALARY. 
After row access control is activated for table EMPLOYEE, Accountant Paul 
retrieves the salary of employee with EMPNO 123456 who is making 
$100,000 a year. Paul may or may not see the row depending on the output 
value from user-defined function ACCOUNTING_UDF.

CREATE PERMISSION SALARY_ROW_ACCESS ON EMPLOYEE 
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR','ACCOUNTING') = 1 
  AND 
  ACCOUNTING_UDF(SALARY) < 120000 
  ENFORCED FOR ALL ACCESS 
  ENABLE;

COMMIT;

ALTER TABLE EMPLOYEE 
  ACTIVATE ROW ACCESS CONTROL;

COMMIT;

SELECT SALARY FROM EMPLOYEE 
  WHERE EMPNO = 123456;

Example 2:
The tellers in a bank can only access customers from their branch. All 
tellers have secondary authorization ID TELLER. The customer service 
representatives are allowed to access all customers of the bank. All 
customer service representatives have secondary authorization ID CSR. A 
row permission is created for each group of personnel in the bank 
accordingly to the access rule defined by SECADM authority. After row 
access control is activated for table CUSTOMER, in the SELECT statement
the search conditions of both row permissions are merged into the statement and they are combined with the logic OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
    FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1
    AND
    BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
        WHERE EMP_ID = SESSION_USER)
    ENFORCED FOR ALL ACCESS
ENABLE;
COMMIT;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
    FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'CSR') = 1
    ENFORCED FOR ALL ACCESS
ENABLE;
COMMIT;

ALTER TABLE CUSTOMER
    ACTIVATE ROW ACCESS CONTROL;
COMMIT;

SELECT * FROM CUSTOMER;
```
CREATE PROCEDURE

The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

External
The procedure is written in a programming language such as C, COBOL, or Java. The external executable is referenced by a procedure defined at the server along with various attributes of the procedure.

See “CREATE PROCEDURE (external)” on page 1374.

SQL
The procedure is written exclusively in SQL statements. The body of an SQL procedure is written in the SQL procedural language. The procedure body is defined at the current server along with various attributes of the procedure.

See “CREATE PROCEDURE (SQL - external)” on page 1393 and “CREATE PROCEDURE (SQL - native)” on page 1405.
CREATE PROCEDURE (external)

The CREATE PROCEDURE statement defines an external stored procedure at the
current server.

Invocation

This statement can be embedded in an application program or issued interactively.
It is an executable statement that can be dynamically prepared only if
DYNAMICRULES run behavior is specified implicitly or explicitly.

Authorization

The privilege set that is defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN
privilege on the schema.

If the authorization ID that is used to create the procedure has installation
SYSADM authority, the procedure is identified as system-defined procedure.

When LANGUAGE is JAVA and a jar-name is specified in the EXTERNAL NAME
clause, the privilege set must include USAGE on the JAR file, the Java archive file.

Privilege set: If the statement is embedded in an application program, the
privilege set is the privileges that are held by the owner of the plan or package. If
the owner is a role, the implicit schema match does not apply and this role needs
to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for
which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the
set of privileges that are held by the SQL authorization ID of the process. If the
schema name is not the same as the SQL authorization ID of the process, one of
the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the
  schema.

The authorization ID that is used to create the stored procedure must have
authority to define programs that run in the specified WLM environment. In
addition, if the stored procedure uses a user-defined type as a parameter, this
authorization ID must have the USAGE privilege on each parameter that is defined
as a user-defined type.
Syntax

CREATE PROCEDURE procedure-name (parameter-declaration) option-list

parameter-declaration:

IN parameter-name parameter-type

OUT parameter-name parameter-type

INOUT parameter-name parameter-type

Notes:
1 For a REXX stored procedure, only one parameter can have type OUT or INOUT. That parameter must be declared last.

parameter-type:

data-type

TABLE LIKE table-name AS LOCATOR

view-name AS LOCATOR

Notes:
1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

data-type:

built-in-type

distinct-type-name

built-in-type:
option-list: (The options can be specified in any order.)
Notes:
1. The same clause must not be specified more than one time.
2. The VARCHAR clause can only be specified if LANGUAGE C is specified.
3. With LANGUAGE JAVA, use a valid external-java-routine-name.
external-java-routine-name:
  jar-name : method-name method-signature

jar-name:
  schema-name : jar-id

method-name:
  package-id : class-id method-id

method-signature:
  (java-datatype)

Notes:
1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

Description

procedure-name

Names the stored procedure. The name cannot be a single asterisk, even if you specify it as a delimited identifier ("*"). The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

The schema name can be 'SYSIBM' or 'SYSPROC'. It can also be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

(parameter-declaration,...)

Specifies the number of parameters of the stored procedure and the data type of each parameter, and optionally, the name of each parameter. A parameter for a stored procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.
All parameters are nullable except for numeric parameters in Java procedures, where numeric parameters, other than the DECIMAL types are not nullable in order to conform to the SQL/JRT standard.

**IN**
Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**
Identifies the parameter as an output parameter that is returned by the stored procedure.

**INOUT**
Identifies the parameter as both an input and output parameter for the stored procedure.

**parameter-name**
Names the parameter for use as an SQL variable. The name cannot be the same as any other parameter-name for the procedure.

**data-type**
Specifies the data type of the parameter. The data type can be a built-in data type or a user-defined type.

If you specify the name of a user-defined type without a schema name, DB2 resolves the user-defined type by searching the schemas in the SQL path.

**built-in-type**
The data type of the parameter is a built-in data type.

For more information on the data types, see [built-in-type](#).

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**distinct-type-name**
The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input argument on the CALL statement can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.
The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

**TABLE LIKE table-name or view-name AS LOCATOR**

 Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the stored procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACES. The number of columns and the attributes of those columns are determined at the time the CREATE PROCEDURE statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the procedure.

*table-name or view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE PROCEDURE statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE PROCEDURE statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the procedure is called, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length,
precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE PROCEDURE statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE PROCEDURE statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see DB2 Application Programming and SQL Guide.

FENCED
Specifies that the procedure runs in an external address space.

DYNAMIC RESULT SETS integer
Specifies the maximum number of query result sets that the stored procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE
Specifies whether the procedure can be run in debugging mode. When DYNAMICRULES run behavior is in effect, the default is determined by using the value of the CURRENT DEBUG MODE special register. Otherwise the default is DISALLOW DEBUG MODE.

Do not specify this option unless LANGUAGE JAVA is in effect.

ALLOW DEBUG MODE
Specifies that the JAVA procedure can be run in debugging mode.

DISALLOW DEBUG MODE
Specifies that the JAVA procedure cannot be run in debugging mode.

You can use an ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

DISABLE DEBUG MODE
Specifies that the JAVA procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE once the procedure has been created or altered using DISABLE DEBUG MODE. To change this option, you must drop and re-create the procedure using the option that you want.

PARAMETER CCSID or PARAMETER VARCHAR
Specifies the encoding scheme for string parameters, and in the case of LANGUAGE C, specifies the representation of variable length string parameters.

CCSID
Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER
CCSID clause, the value specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**VARCHAR**

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

**NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

**STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

**EXTERNAL**

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure that is based on code written in an external programming language. If the NAME clause is not specified, 'NAME procedure-name' is assumed. The NAME clause is required for a LANGUAGE JAVA procedure because the default name is not valid for a Java procedure. In some cases, the default name will not be valid. To avoid invalid names, specify the NAME clause for the following types of procedures:

- A procedure that is defined as LANGUAGE JAVA
- A procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

**NAME string or identifier**

Identifies the user-written code that implements the stored procedure.

If LANGUAGE is JAVA, string must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid external-java-routine-name. If multiple strings are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break.

An external-java-routine-name contains the following parts:

**jar-name**

Identifies the name given to the JAR file when it was installed in the database. The name contains jar-id, which can optionally be qualified.
with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified jar-id is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If jar-name is specified, it must exist when the CREATE PROCEDURE statement is processed. Do not specify a jar-name for a JAVA procedure for which NO SQL is also specified.

If jar-name is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

method-name
Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

package-id
Identifies a package. The concatenated list of package-ids identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

class-id
Identifies the class identifier of the Java object.

method-id
Identifies the method identifier with the Java class to be invoked.

method-signature
Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the method-signature if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact method-signature. The number of java-datatype elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for method-signature. If a Java method-signature is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE PROCEDURE statement.

For other values of LANGUAGE, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.
LANGUAGEN
This mandatory clause is used to specify the language interface convention to
which the procedure body is written. All programs must be designed to run in
the server’s environment. Assembler, C, COBOL, and PL/I programs must be
designed to run in IBM’s Language Environment.

ASSEMBLE
  The stored procedure is written in Assembler.

C
  The stored procedure is written in C or C++.

COBOL
  The stored procedure is written in COBOL, including the OO-COBOL
  language extensions.

JAVA
  The stored procedure is written in Java and is executed in the Java Virtual
  Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME
  clause must be specified with a valid external-java-routine-name and
  PARAMETER STYLE must be specified with JAVA. The procedure must be
  a public static method of the specified Java class.

  Do not specify LANGUAGE JAVA when DBINFO, PROGRAM TYPE
  MAIN, or RUN OPTIONS is specified.

PL/I
  The stored procedure is written in PL/I.

REXX
  The stored procedure is written in REXX. Do not specify LANGUAGE
  REXX when PARAMETER STYLE SQL is in effect. When REXX is
  specified, the procedure must use PARAMETER STYLE GENERAL or
  GENERAL WITH NULLS.

MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL
  Specifies which SQL statements, if any, can be executed in the procedure or
  any routine that is called from this procedure. The default is MODIFIES SQL
  DATA. For the data access classification of each statement, see [Table 167 on
  page 2096]

MODIFIES SQL DATA
  Specifies that the procedure can execute any SQL statement except
  statements that are not supported in procedures.

READS SQL DATA
  Specifies that the procedure can execute statements with a data access
  indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The
  procedure cannot execute SQL statements that modify data.

CONTAINS SQL
  Specifies that the procedure can execute only SQL statements with an
  access indication of CONTAINS SQL or NO SQL. The procedure cannot
  execute statements that read or modify data.

NO SQL
  Specifies that the procedure can execute only SQL statements with a data
  access classification of NO SQL. Do not specify NO SQL for a JAVA
  procedure that uses a JAR file.

PARAMETER STYLE
  Identifies the linkage convention used to pass parameters to and return values
  from the stored procedure. All of the linkage conventions provide arguments to
the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see DB2 Application Programming and SQL Guide.

**SQL**

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first \( n \) parameters that are specified on the CREATE PROCEDURE statement.
- \( n \) parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If DBINFO is specified, the DBINFO structure.

PARAMETER STYLE SQL is the default. Do not specify PARAMETER STYLE SQL when LANGUAGE REXX or LANGUAGE JAVA is in effect.

**GENERAL**

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

**GENERAL WITH NULLS**

Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short INTS. The indicator array enables the stored procedure to accept or return null parameter values.

**JAVA**

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

For REXX stored procedures (LANGUAGE REXX), GENERAL and GENERAL WITH NULLS are the only valid values for PARAMETER STYLE; therefore, specify one of these values and do not allow PARAMETER STYLE to default to SQL.

**DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

**DETERMINISTIC**

The stored procedure always returns the same results each time the stored
procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

**NOT DETERMINISTIC**

The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed. NOT DETERMINISTIC is the default.

DB2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**NO PACKAGE PATH or PACKAGE PATH package-path**

Specifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the procedure is the same as the list of package collection IDs for the calling program. If the calling program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

**PACKAGE PATH package-path**

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the routine is invoked.

The package-path value that is provided when the procedure is created is checked when the CALL statement is prepared. If package-path contains SESSION_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the package-path value is checked.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the stored procedure when it is invoked.

**NO DBINFO**

Additional information is not passed. NO DBINFO is the default.

**DBINFO**

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the name of the current server, the application run time authorization ID and identification of the version and release of the database manager that invoked the procedure. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

DBINFO can be specified only if PARAMETER STYLE SQL is specified.

**NO COLLID or COLLID collection-id**

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

**NO COLLID**

The package collection for the stored procedure is the same as the package
collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in DB2 Application Programming and SQL Guide.

NO COLLID is the default.

**COLLID** *collection-id*

The package collection for the stored procedure is the one specified.

For REXX stored procedures, *collection-id* can be DSNREXRR, DSNREXRS, DSNREXCR, or DSNREXCS.

**WLM ENVIRONMENT**

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the stored procedure runs in the default WLM-established stored procedure address space specified at installation time.

**name**

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

**(name,*)**

When an SQL application program directly calls a stored procedure, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To define a stored procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

**LIMIT** *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than
the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**
Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends. This option is ignored if LANGUAGE JAVA is specified.

**NO**  
The load module is deleted from memory after the stored procedure ends. NO is the default.

**YES**  
The load module remains resident in memory after the stored procedure ends.

**PROGRAM TYPE**
Specifies whether the stored procedure runs as a main routine or a subroutine.

**SUB**  
The stored procedure runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option.

**MAIN**  
The stored procedure runs as a main routine. With LANGUAGE REXX, PROGRAM TYPE MAIN is always in effect.

The default for PROGRAM TYPE is:
- MAIN with LANGUAGE REXX
- SUB with LANGUAGE JAVA
- For other languages, the default depends on the value of the CURRENT RULES special register:
  - MAIN when the value is DB2
  - SUB when the value is STD

**SECURITY**
Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**  
The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space. DB2 is the default.

**USER**  
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

**DEFINER**  
An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE**
Specifies whether the routine is to be put in a stopped state after some number of failures.
STOP AFTER SYSTEM DEFAULT FAILURES
Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTPX. This is the default.

STOP AFTER nn FAILURES
Specifies that this routine should be placed in a stopped state after nn failures. The value nn can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any failure.

RUN OPTIONS runtime-options
Specifies the Language Environment run time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run time options to be passed to the REXX language interface to DB2. You must specify runtime-options as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

COMMIT ON RETURN
Indicates whether DB2 commits the transaction immediately on return from the stored procedure.

NO DB2 does not issue a commit when the stored procedure returns. NO is the default.

YES DB2 issues a commit when the stored procedure returns if the following statements are true:
• The SQLCODE that is returned by the CALL statement is not negative.
• The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS
Specifies how special registers are set on entry to the routine. The default is INHERIT SPECIAL REGISTERS.

INHERIT SPECIAL REGISTERS
Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 40 on page 212.

DEFAULT SPECIAL REGISTERS
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 40 on page 212.
CALLED ON NULL INPUT

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values. CALLED ON NULL INPUT is the default.

Notes

Owner privileges: The owner is authorized to call the procedure (EXECUTE privilege) and grant others the privilege to call the procedure. See "GRANT (function or procedure privileges)" on page 1768. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

Choosing data types for parameters: When you choose the data types of the parameters for your stored procedure, consider the rules of promotion that can affect the values of the parameters. (See "Promotion of data types" on page 112). For example, a constant that is one of the input arguments to the stored procedure might have a built-in data type that is different from the data type that the procedure expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

Specifying the encoding scheme for parameters: The encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using the PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that they all agree.

Character string representation considerations: The PARAMETER VARCHAR clause is specific to LANGUAGE C routines because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.
PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external procedure. For example, a CREATE PROCEDURE statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the procedure, the specific name of the procedure, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

**Running stored procedures:** You can use the WLM ENVIRONMENT clause to identify the address space in which a stored procedure is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with sensitive data, such as employee salaries.

Regardless of where the stored procedure is to run, DB2 invokes RACF to determine whether you have appropriate authorization. You must have authorization to issue CREATE PROCEDURE statements that refer to the specified WLM environment or the DB2-established stored procedure address space. For example, the following RACF command authorizes DB2 user DB2USER1 to define stored procedures on DB2 subsystem DB2A that run in the WLM environment named PAYROLL.

```plaintext
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

**Accessing result sets from nested stored procedures:** When another stored procedure or a user-defined function calls a stored procedure, only the calling routine can access the result sets that the stored procedure returns. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

When a stored procedure is nested, the result sets that are returned by the stored procedure are accessible only by the calling routine. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

**Restrictions for nested stored procedures:** A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN clause.

**Stored procedures and user-defined session global variables:**

The content of user-defined session global variables that are referenced in routines is inherited from the caller. User-defined session global variables can be modified in stored procedures, except when the stored procedure is called by a trigger or a function.

If the procedure contains references to user-defined session global variables, the level of SQL data access must be at least CONTAINS SQL. If the procedure contains SQL statements that modify user-defined session global variables, the level of SQL data access must be MODIFIES SQL DATA.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET as a synonym for DYNAMIC RESULT SET
- RESULT SETS as a synonym for DYNAMIC RESULT SETS
Examples

Example 1: Create the definition for a stored procedure that is written in COBOL. The procedure accepts an assembly part number and returns the number of parts that make up the assembly, the total part cost, and a result set. The result set lists the part numbers, quantity, and unit cost of each part. Assume that the input parameter cannot contain a null value and that the procedure is to run in a WLM environment called PARTSA.

```sql
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
  LANGUAGE COBOL
  EXTERNAL NAME MYMODULE
  PARAMETER STYLE GENERAL
  WLM ENVIRONMENT PARTSA
  DYNAMIC RESULT SETS 1;
```

Example 2: Create the definition for the stored procedure described in Example 1, except use the linkage convention that passes more information than the parameter specified on the CALL statement. Specify Language Environment run time options HEAP, BELOW, ALL31, and STACK.

```sql
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
  LANGUAGE COBOL
  EXTERNAL NAME MYMODULE
  PARAMETER STYLE SQL
  WLM ENVIRONMENT PARTSA
  DYNAMIC RESULT SETS 1
  RUN OPTIONS 'HEAP(,,ANY),BELOW(4K,,),ALL31(ON),STACK(,,ANY,);'
```

Example 3: Create the procedure definition for a stored procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that is currently available.

```sql
CREATE PROCEDURE PARTS_ON_HAND(IN PARTNUM INT, 
  OUT COST DECIMAL(7,2), 
  OUT QUANTITY INT)
  LANGUAGE JAVA
  EXTERNAL NAME 'PARTS.ONHAND'
  PARAMETER STYLE JAVA;
```
CREATE PROCEDURE (SQL - external)

The CREATE PROCEDURE statement defines an external SQL procedure at the current server and specifies the source statements for the procedure. This is the only type of SQL procedure that is available for versions of DB2 prior to Version 9.

For information about the SQL control statements that are supported in external SQL procedures, refer to the SQL control statements for external SQL procedures on page 2098.

Invocation

This statement can only be dynamically prepared, but the DYNAMICRULES run behavior must be specified implicitly or explicitly. It is intended to be processed using one of the following methods:

- JCL
- The DB2 for z/OS SQL procedure processor (DSNTPSMP) (IBM Optim™ Development Studio uses this method.)

Issuing the CREATE PROCEDURE statement from another context will result in an incomplete procedure definition even though the statement processing returns without error. For more information on preparing SQL procedures for execution, see DB2 Application Programming and SQL Guide.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If the authorization ID that is used to create the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

The authorization ID that is used to create the stored procedure must have authority to create programs that are to be run in the specified WLM environment.
The owner of the procedure is determined by how the CREATE PROCEDURE statement is invoked:

- If the statement is embedded in a program, the owner is the authorization ID of the owner of the plan or package.
- If the statement is dynamically prepared, the owner is the SQL authorization ID in the CURRENT SQLID special register.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

**Syntax**

```
CREATE PROCEDURE procedure-name (parameter-declaration)
(option-list SQL-routine-body)
```

**parameter-declaration:**

```
IN OUT INOUT parameter-name parameter-type
```

**parameter-type:**

```
built-in-type TABLE LIKE table-name AS LOCATOR
```

**built-in-type:**
option-list: (The options can be specified in any order, but each option can be specified only one time)
Notes:

1 Either the FENCED or EXTERNAL NAME clause must be specified to indicate that the definition is for an external SQL procedure.

Description

procedure-name

Names the procedure. The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

(parameter-declaration,...)

Specifies the number of parameters of the procedure, the data type of each parameter, and the name of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. If an
error is returned by the procedure, OUT parameters are undefined, and
INOUT parameters are unchanged. All of the parameters are nullable.

**IN**
Identifies the parameter as an input parameter to the procedure. The value
of the parameter on entry to the procedure is the value that is returned to
the calling SQL application, even if changes are made to the parameter
within the procedure.

IN is the default.

**OUT**
Identifies the parameter as an output parameter that is returned by the
procedure. If the parameter is not set within the procedure, the null value
is returned.

**INOUT**
Identifies the parameter as both an input and output parameter for the
procedure. If the parameter is not set within the procedure, its input value
is returned.

*parameter-name*
Names the parameter for use as an SQL variable. *parameter-name* is an SQL
identifier and must not be a delimited identifier that includes lowercase
letters or special characters. A parameter name cannot be the same as the
name of any other parameter for this version of the procedure.

*parameter-type*
Specifies the data type of the parameter.

*built-in-type*

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of
character data types (the FOR *subtype* DATA clause), see *built-in-type*
For external SQL procedures, the maximum limit for VARCHAR is
32767 and for VARGRAPHIC is 16382.

For parameters with a character or graphic data type, the
PARAMETER CCSID clause or CCSID clause indicates the encoding
scheme of the parameter. If you do not specify either of these clauses,
the encoding scheme is the value of field DEF ENCODING SCHEME
on installation panel DSNTIPF.

Although an input parameter with a character data type has an
implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the
value that is actually passed in the input parameter can have any
subtype. Therefore, conversion of the input data to the subtype of the
parameter might occur when the procedure is called. With ASCII or
EBCDIC, an error occurs if mixed data that actually contains DBCS
characters is used as the value for an input parameter that is declared
with an SBCS subtype.

A parameter with a datetime data type is passed to the SQL procedure
as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is determined as
follows:

- If there are one or more parameters with a character or graphic data
type, the encoding scheme of the datetime type parameter is the
same as the encoding scheme of the character or graphic parameters.
• Otherwise, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**TABLE LIKE table-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The transition table includes columns that are defined as implicitly hidden in the table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns.

For more information about the TABLE LIKE clause, see [TABLE LIKE](#).

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

**LANGUAGE**

Specifies the application programming language in which the procedure is written.

**SQL**

The procedure is written in DB2 SQL procedural language.

**FENCED**

Specifies that the procedure runs in an external address space. FENCED also specifies that the SQL procedure program is an MVS load module with an external name.

**DYNAMIC RESULT SETS integer**

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that the procedure can return no result sets. The value of integer must be between 0 and 32767.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that is to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**PARAMETER VARCHAR**

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

**NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

NULTERM is the default.
**STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified, the routine will encounter different parameter forms depending on which group member invokes the routine.

**EXTERNAL NAME 'string' or identifier**

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

EXTERNAL NAME procedure-name is the default. In some cases, the default name will not be valid. To avoid an invalid name, specify EXTERNAL NAME for a procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

**NOT DETERMINISTIC**

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**CALLED ON NULL INPUT**

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or non-null values.

CALLED ON NULL INPUT is the default.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements that the procedure can execute.

For the data access classification of each statement, see Table 167 on page 2096.

Statements that are not supported in any procedure return an error.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.
MODIFIES SQL DATA is the default.

**READS SQL DATA**
Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**
Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**NO DBINFO**
Specifies that no additional status information that is known by DB2 is passed to the procedure when it is invoked.

**NO COLLID or COLLID collection-id**
Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

**NO COLLID**
Specifies that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in DB2 Application Programming and SQL Guide.

NO COLLID is the default.

**COLLID collection-id**
Specifies the package collection for the procedure.

**WLM ENVIRONMENT name or (name,*)**
Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The name of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the procedure runs in the default WLM-established stored procedure address space that is specified at installation time.

**name**
The WLM environment in which the procedure must run. If another procedure or a user-defined function calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

**(name,*)**
When an SQL application program directly calls a procedure, name specifies the WLM environment in which the procedure runs.

If another procedure or a user-defined function calls the stored procedure, the procedure runs in the same WLM environment that the calling routine uses.
To define a procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

- **NO LIMIT**
  - There is no limit on the number of CPU service units that the procedure can run.
  - NO LIMIT is the default.

- **LIMIT integer**
  - The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**STAY RESIDENT**

Specifies whether the load module for the procedure remains resident in memory when the procedure ends.

- **NO**
  - The load module is deleted from memory after the procedure ends.
  - NO is the default.

- **YES**
  - The load module remains resident in memory after the procedure ends.

**PROGRAM TYPE**

Specifies whether the procedure runs as a main routine or a subroutine.

- **MAIN**
  - The procedure runs as a main routine.
  - MAIN is the default.

- **SUB**
  - The procedure runs as a subroutine.

**SECURITY**

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

- **DB2**
  - The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.
  - DB2 is the default.

- **USER**
  - An external security environment should be established for the procedure.
If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

**DEFINER**
An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

**RUN OPTIONS run-time-options**
Specifies the Language Environment run time options that are to be used for the procedure. You must specify run-time-options as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any run time options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment run time options, see z/OS Language Environment Programming Reference.

**COMMIT ON RETURN**
Indicates whether DB2 commits the transaction immediately on return from the procedure.

**NO**
DB2 does not issue a commit when the procedure returns.

NO is the default.

**YES**
DB2 issues a commit when the procedure returns if the following statements are true:
- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**
Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**
Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 40 on page 212.

INHERIT SPECIAL REGISTERS is the default.

**DEFAULT SPECIAL REGISTERS**
Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 40 on page 212.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURE**
Specifies the routine is stopped after failures.
STOP AFTER SYSTEM DEFAULT FAILURES
Specifies that this routine should be placed in a stopped state after the
number of failures indicated by the value of field MAX ABEND COUNT
on installation panel DSNTIPX.

STOP AFTER SYSTEM DEFAULT FAILURES is the default.

STOP AFTER \( nn \) FAILURES
Specifies that this routine should be placed in a stopped state after \( nn \)
failures. The value \( nn \) can be an integer from 1 to 32767.

CONTINUE AFTER FAILURE
Specifies that this routine should not be placed in a stopped state after any
failure.

SQL-routine-body
Specifies the statements that define the body of the SQL procedure. For
information on the SQL control statements that are supported in external SQL
procedures, see “SQL control statements for external SQL procedures” on page
2098.

Notes
See “Notes” on page 1390 for information about:
• Owner privileges
• Choosing data types for parameters
• Specifying the encoding scheme for parameters
• Environments for running stored procedures
• Accessing result sets from nested stored procedures

Error handling in SQL procedures: You should consider the possible exceptions that
can occur for each SQL statement in the body of a procedure. Any exception
SQLSTATE that is not handled within the procedure using a handler within a
compound statement results in the exception SQLSTATE being returned to the
caller of the procedure.

Stored procedures and user-defined session global variables:
The content of user-defined session global variables that are referenced in
routines is inherited from the caller. User-defined session global variables
can be modified in stored procedures, except when the stored procedure is
called by a trigger or a function.

If the procedure contains references to user-defined session global
variables, the level of SQL data access must be at least CONTAINS SQL. If
the procedure contains SQL statements that modify user-defined session
global variables, the level of SQL data access must be MODIFIES SQL
DATA.

Alternative syntax and synonyms: To provide compatibility with previous releases
of DB2 or other products in the DB2 family, DB2 supports the following keywords:
• RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
• VARIANT as a synonym for NOT DETERMINISTIC
• NOT VARIANT as a synonym for DETERMINISTIC
Examples

Example 1: Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```sql
CREATE PROCEDURE UPDATESALARY
    (IN EMPLOYEE_NUMBER CHAR(10),
    IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY1'
MODIFIES SQL DATA
UPDATE EMP
    SET SALARY = SALARY * RATE
    WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2: Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The procedure runs in a WLM environment called PARTSA.
- The same input always produces the same output.
- SQL work is committed on return to the caller.
- The Language Environment run time options to be used when the SQL procedure executes are 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'.

```sql
CREATE PROCEDURE UPDATESALARY
    (IN EMPLOYEE_NUMBER CHAR(10),
    IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY2'
MODIFIES SQL DATA
WLM ENVIRONMENT PARTSA
DETERMINISTIC
RUN OPTIONS 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'
COMMIT ON RETURN YES
UPDATE EMP
    SET SALARY = SALARY * RATE
    WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see "SQL control statements for external SQL procedures" on page 2098.
CREATE PROCEDURE (SQL - native)

The CREATE PROCEDURE statement defines an SQL procedure at the current server and specifies the source statements for the procedure. You can define multiple versions of the procedure. CREATE PROCEDURE is used to define the initial version, and ALTER PROCEDURE is used to define subsequent versions.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 7, “SQL control statements for SQL routines,” on page 2029.

Invocation

This statement can only be dynamically prepared, and the DYNAMICRULES run behavior must be specified implicitly or explicitly.

Authorization

The privilege set that is defined below must include at least one of the following:
- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM authority
- SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

If a user-defined type is referenced (as the data type of a parameter or SQL variable), the privilege set must also include at least one of the following privileges or authorities:
- Ownership of the user-defined type
- The USAGE privilege on the user-defined type
- SYSADM authority

If the procedure uses a table as a parameter, the privilege set must also include at least one of the following privileges or authorities:
- Ownership of the table
- The SELECT privilege on the table
- SYSADM authority

If the authorization ID that is used to create the procedure has installation SYSADM authority, the procedure is identified as system-defined procedure.

Privilege set: The privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process and the owner is that role.

If the statement is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that
are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

The privilege set must also include the privileges required to execute the statements in SQL-routine-body.

If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must have authority to define programs that run in the specified WLM environment.

The owner of the procedure is the SQL authorization ID in the CURRENT SQLID special register unless the process is running within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the owner of the procedure is the role that is associated with the primary authorization ID of the process.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

**Syntax**

```
CREATE PROCEDURE procedure-name
  (parameter-declaration)
  VERSION V1
  VERSION routine-version-id
  option-list
  SQL-routine-body
```

Parameter-declaration:

```
IN OUT INOUT parameter-name parameter-type
```

Parameter-type:
data-type:

TABLE LIKE table-name AS LOCATOR

view-name

built-in-type:

distinct-type-name

array-type-name
option-list: (The options can be specified in any order, but each one can only be specified one time.)

**Notes:**

1. An ALTER FUNCTION statement (SQL scalar) or an ALTER PROCEDURE statement (SQL native) with an ADD VERSION or REPLACE clause are not allowed in an SQL-routine-body.

### Description

**procedure-name**

Names the procedure. If `procedure-name` already exists, an error is returned even if VERSION is specified with a `version-id` that is different from any existing version identifier for the procedure that is specified in `procedure-name`.

**(parameter-declaration,...)**

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the
procedure that is being defined. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

**IN**
Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**
Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

**INOUT**
Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

**parameter-name**
Names the parameter for use as an SQL variable. A parameter name cannot be the same as the name of any other parameter for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

**built-in-type**
The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR subtype DATA clause), see [built-in-type](#). However, the varying length string data types have different maximum lengths than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows: 32704 for VARCHAR or VARBINARY, and 16352 for VARGRAPHIC.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format. The encoding scheme for a datetime type
parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

**distinct-type-name**

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type. The distinct type must not be based on a LOB data type.

**array-type-name**

The data type of the input parameter is a user-defined array type.

If you specify array-type-name without a schema name, DB2 resolves the array type by searching the schemas in the SQL path.

**TABLE LIKE table-name AS LOCATOR**

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. A procedure with a table parameter can only be invoked from the triggered action of a trigger. For additional information about using table locators, refer to DB2 Application Programming and SQL Guide.

**VERSION routine-version-id**

Specifies the version identifier for the first version of the procedure that is to be generated. See “Naming conventions” on page 59 for information about specifying routine-version-id. You can use an ALTER PROCEDURE statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the procedure.

V1 is the default version identifier.

See Versions of a procedure for more information about the use of versions for procedures.

**LANGUAGE SQL**

Specifies that the procedure is written in the DB2 SQL procedural language.

**DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.
DETERMINISTIC
The procedure always returns the same results each time it is called with
the same IN and INOUT arguments if the data that is referenced in the
database has not changed.

NOT DETERMINISTIC
The procedure might not return the same result each time it is called with
the same IN and INOUT arguments, even when the data that is referenced
in the database has not changed.

NOT DETERMINISTIC is the default.

DB2 does not verify that the procedure code is consistent with the specification
of DETERMINISTIC or NOT DETERMINISTIC.

MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL
Specifies the classification of SQL statements that the procedure can execute.

MODIFIES SQL DATA
Specifies that the procedure can execute any SQL statement except
statements that are not supported in procedures.
MODIFIES SQL DATA is the default.

READS SQL DATA
Specifies that the procedure can execute statements with a data access
indication of READS SQL DATA or CONTAINS SQL. The procedure
cannot execute SQL statements that modify data.

CONTAINS SQL
Specifies that the procedure can execute only SQL statements with a data
access indication of CONTAINS SQL. The procedure cannot execute
statements that read or modify data.

CALLED ON NULL INPUT
Specifies that the procedure will be called if any, or even if all parameter
values are null.

DYNAMIC RESULT SETS integer
Specifies the maximum number of query result sets that the procedure can
return. The default is DYNAMIC RESULT SETS 0, which indicates that there
are no result sets. The value must be between 0 and 32767.

ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE
Specifies whether this version of the routine can be run in debugging mode.
The default is determined using the value of the CURRENT DEBUG MODE
special register.

ALLOW DEBUG MODE
Specifies that this version of the routine can be run in debugging mode.
When this version of the routine is invoked and debugging is attempted, a
WLM environment must be available.

DISALLOW DEBUG MODE
Specifies that this version of the routine cannot be run in debugging mode.
You can use an ALTER statement to change this option to ALLOW DEBUG
MODE for this initial version of the routine.

DISABLE DEBUG MODE
Specifies that this version of the routine can never be run in debugging
mode.
This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the option that you want. An alternative to dropping and recreating the routine is to create a version of the routine that uses the option that you want and making that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

**PARAMETER CCSID**
Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

If the data type for a parameter is a user-defined distinct type that is defined as a character or graphic type string, the CCSID of the distinct type must be the same as the value that is specified in this clause.

If the data type for a parameter is a user-defined array type that is defined with character or graphic string array elements, or a character string array index, the CCSID of these array attributes must be the same as the value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER schema-name**
Specifies the implicit qualifier that is used for unqualified names of tables, views, indexes, and aliases that are referenced in the routine body. The default value is the same as the default schema.

**PACKAGE OWNER authorization-name**
Specifies the owner of the package that is associated with the version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body and must contain the necessary bind privileges. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, **authorization-name** must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, **authorization-name** can be any authorization ID that contains the necessary bind privileges.

**ASUTIME**
Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.
When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

**NO LIMIT**

Specifies that there is no limit on the service units.

**NO LIMIT** is the default.

**LIMIT** integer

The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the procedure uses more service units than the specified value, DB2 cancels the procedure. The CPU cycles that are consumed by parallel tasks in a procedure do not contribute towards the specified ASUTIME LIMIT.

**COMMIT ON RETURN NO, COMMIT ON RETURN YES, or AUTONOMOUS**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**COMMIT ON RETURN NO**

DB2 does not issue a commit when the procedure returns. NO is the default.

**COMMIT ON RETURN YES**,

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**AUTONOMOUS**

DB2 executes the SQL procedure in a unit of work that is independent from the calling application. When this option is specified the procedure follows the rules of the COMMIT ON RETURN YES option before returning to the calling application. However, it does not commit changes in the calling application. When autonomous is specified:

- DYNAMIC RESULT SETS 0 must be in effect.
- Stored procedure parameters must not be defined as:
  - A LOB type
  - The XML data type
  - A distinct data type that is based on a LOB or XML value
  - An array type that is defined with array elements that are a LOB type

A value must not be assigned to a global variable when an autonomous procedure is executing.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 40 on page 212.
**INHERIT SPECIAL REGISTERS** is the default.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 40 on page 212.

**WLM ENVIRONMENT FOR DEBUG MODE** *name*

Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

**DEFER PREPARE or NODEFER PREPARE**

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value in effect for the REOPT option. If REOPT NONE is in effect, the default is inherited from the plan at run time. Otherwise, the default is DEFER PREPARE.

**DEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in DB2 Command Reference for considerations with distributed processing.

**NODEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

**CURRENT DATA YES or CURRENT DATA NO**

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

**CURRENT DATA YES**

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

**CURRENT DATA NO**

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA NO is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:
- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

**CURRENT DATA NO** is the default.

**DEGREE**
Specifies whether to attempt to run a query using parallel processing to maximize performance.

1 Specifies that parallel processing should not be used.

1 is the default.

**ANY**
Specifies that parallel processing can be used.

**CONCURRENT ACCESS RESOLUTION**
Specifies the whether processing uses only committed data or whether it will wait for commit or rollback of data that is in the process of being updated.

**WAIT FOR OUTCOME**
Specifies that processing will wait for the commit or rollback of data that is in the process of being updated.

**USE CURRENTLY COMMITTED**
Specifies that processing use the currently committed version of the data when data that is in the process of being updated is encountered. **USE CURRENTLY COMMITTED** is applicable on scans that access tables that are defined in universal table spaces with row or page level lock size.

When there is lock contention between a read transaction and an insert transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS or RS. Applicable scans include intent read scans for read-only and ambiguous queries and for updatable cursors. **USE CURRENTLY COMMITTED** is also applicable to scans initiated from WHERE predicates of UPDATE or DELETE statements and the subselect of INSERT statements.

When there is lock contention is between a read transaction and a delete transaction, **USE CURRENTLY COMMITTED** is applicable to scans with isolation level CS and when CURRENT DATA NO is specified.

**DYNAMICRULES**
Specifies the values that apply, at run time, for the following dynamic SQL attributes:
- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the run time environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the run time environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:
RUN
Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

BIND
Specifies that dynamic SQL statements are to be processed using bind behavior.

DEFINEBIND
Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

DEFINERUN
Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

INVOKEBIND
Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

INVOKERUN
Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See "Authorization IDs and dynamic SQL" on page 77 for information on the effects of these options.

APPLICATION ENCODING SCHEME
Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

ASCII
Specifies that the data is encoded using the ASCII CCSIDs of the server.

EBCDIC
Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

UNICODE
Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in DB2 Command Reference for information about how the default for this option is determined.

WITH EXPLAIN or WITHOUT EXPLAIN
Specifies whether information will be provided about how SQL statements in the routine will execute.

WITHOUT EXPLAIN
Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.
**WITH EXPLAIN**

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table `owner.PLAN_TABLE`. `owner` is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as `owner.PLAN_TABLE` that points to the base table, `PLAN_TABLE`. `owner` must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. `PLAN_TABLE` must have a base table and can have multiple aliases with the same table name, `PLAN_TABLE`, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to `owner.PLAN_TABLE`, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables if they exist: `DSN_STATEMNT_TABLE` and `DSN_FUNCTION_TABLE`. `DSN_STATEMNT_TABLE` contains an estimate of the processing cost for an SQL statement. See DB2 Application Programming and SQL Guide for more information. `DSN_FUNCTION_TABLE` contains information about function resolution. See DB2 Application Programming and SQL Guide for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1706.

**WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. DB2 Command Reference shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

**WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

**WITHOUT IMMEDIATE WRITE** is the default.

**WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see DB2 Performance Monitoring and Tuning Guide.

**RR** Specifies repeatable read.

**RS** Specifies read stability.

**CS** Specifies cursor stability. **CS** is the default.

**UR** Specifies uncommitted read.
WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC

Specifies whether DB2 keeps dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC

Specifies that DB2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

WITH KEEP DYNAMIC

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread timeouts, as described in DB2 Installation Guide for installation panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The DB2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

OPTHINT string-constant

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

string-constant is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See DB2 Installation Guide for information about enabling optimization hints.

SQL PATH

Specifies the SQL path that DB2 uses to resolve unqualified user-defined type, function, and procedure names in the procedure body. The default value is "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", and the value of the QUALIFIER option, which is the qualifier for the procedure that is the target of the statement.
Schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM" do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path.

DB2 calculates the length by taking each schema-name specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed the length of the CURRENT SCHEMA special register. If you do not specify the "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM", schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT PATH special register, DB2 returns an error for the CREATE statement.

Related information:
- “SQL path” on page 66
- “CURRENT SCHEMA” on page 198
- “CURRENT PATH” on page 190

schema-name
- Specifies a schema. DB2 does not validate that the specified schema actually exists when the CREATE statement is processed.
  - SYSPUBLIC must not be specified for the SQL path.

schema-name-list
- Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.
  - SYSPUBLIC must not be specified for the SQL path.

SYSTEM PATH
- Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".

SESSION_USER or USER
- Specifies the value of the SESSION_USER or USER special register, which represents a maximum 8 byte (in EBCDIC) schema-name. At the time the CREATE statement is processed, this length is included in the total length of the list of schema names that is specified for the PATH bind option.

RELEASE AT
- Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

COMMIT
- Specifies that resources will be released at each commit point.
  - COMMIT is the default.

DEALLOCATE
- Specifies that resources will be released only when the thread terminates.
  - DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.
Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan.

Related information:

Choosing a RELEASE option (DB2 Performance)

REOPT
Specifies if DB2 will determine the access path at runtime by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE
Specifies that DB2 does not determine the access path at runtime by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

ALWAYS
Specifies that DB2 always determines the access path at runtime each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

ONCE
Specifies that DB2 determines the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

QUERY ACCELERATION
Specifies whether a static SQL query is bound for acceleration, and if so, with what behavior.

NONE
Specifies that no static SQL query in the application is bound for acceleration or will be accelerated when the application is run.

ENABLE
Specifies that a static SQL query is bound for acceleration if it satisfies the acceleration criteria, including the cost and heuristics criteria. The query is routed to an accelerator when the application runs. Otherwise, if the static query does not satisfy the acceleration criteria, the query is bound for execution in DB2.

If an error condition, such as one of the following examples, occurs while executing the accelerated static query when the application is run, DB2 fails the static query and returns a negative SQL code to the application:

- A failure occurs while running the static query on the accelerator.
• The accelerator returns an error for the query.
• The accelerator is not started and DB2 cannot route the static query to
  the accelerator for execution.

**ENABLE WITH FAILBACK**
Results in the same behavior as ENABLE, except if one of the error
conditions occurs on the first OPEN of the accelerated static query when
the application is run. In this case, instead of failing the static query and
returning a negative SQL code to the application, DB2 performs a
temporary *statement-level* incremental bind of the query and runs the query
in DB2. The application does not see the acceleration failure. Failback to
DB2 is not possible after the application does a successful OPEN for the
query on the accelerator.

**ELIGIBLE**
Specifies that a static SQL query is bound for acceleration if the query
meets the basic acceleration criteria, regardless of the cost or heuristics
criteria. The query is routed to the accelerator when the application runs.

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.

**ALL**
Specifies that all of the static SQL queries in the application are to be
bound for acceleration and routed to the accelerator when the application
runs. If DB2 determines that a static query cannot be bound to run on the
accelerator and the query references a user base table or view, the BIND or
REBIND PACKAGE operation fails with an error message for that query.
(A failure exception is made for declared global temporary tables (DGTIs)
and created global temporary tables and (CGTTIs) because these tables
cannot be accelerated.)

Like the behavior for ENABLE, if an error condition occurs while executing
the accelerated static query when the application is run, DB2 fails the static
query and returns a negative SQL code to the application.

This bind option does not apply to a *fullselect* or WITH *common-table-expression*
that is specified in a RETURN statement for the routine, or in a SET
*host-variable-assignment* that is used in the routine. The queries that are
specified in these cases cannot be accelerated.

**GET_ACCEL_ARCHIVE**
Specifies whether a static SQL query that is bound for acceleration retrieves
archived data on the accelerator, instead of active data.

**NO** Specifies that no static SQL query is bound to retrieve archived data from
the accelerator. If the static query also is not bound for acceleration, the
query is bound to run in DB2.

If the static query is bound for acceleration because the
QUERYACCELERATION bind option was specified, the query is routed to
the accelerator when the application runs; however, the query does not
retrieve any archived data.

**YES**
Specifies that if all of the following criteria are met, the query is bound for
acceleration and retrieves the archived data on the accelerator when the
application runs:
• The QUERYACCELERATION bind option is also specified.
• The static SQL query references an accelerated table that has partitioned data archived on an accelerator.
• The static query satisfies the acceleration criteria that is specified by the QUERYACCELERATION bind option.

If the static query does not satisfy the acceleration criteria that is specified by the QUERYACCELERATION bind option, the BIND or REBIND PACKAGE operation fails with an error message for that query.

This bind option does not apply to a fullselect or WITH common-table-expression that is specified in a RETURN statement for the routine, or in a SET host-variable-assignment that is used in the routine. The queries that are specified in these cases cannot be accelerated.

**VALIDATE RUN or VALIDATE BIND**

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

**VALIDATE RUN**

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

**VALIDATE RUN** is the default.

**VALIDATE BIND**

Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.

**ROUNDING**

Specifies the rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in DECP.

**DEC_ROUND_CEILING**

Specifies numbers are rounded towards positive infinity.

**DEC_ROUND_DOWN**

Specifies numbers are rounded towards 0 (truncation).

**DEC_ROUND_FLOOR**

Specifies numbers are rounded towards negative infinity.

**DEC_ROUND_HALF_DOWN**

Specifies numbers are rounded to nearest; if equidistant, round down.

**DEC_ROUND_HALF_EVEN**

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

**DEC_ROUND_HALF_UP**

Specifies numbers are rounded to nearest; if equidistant, round up.

**DEC_ROUND_UP**

Specifies numbers are rounded away from 0.
DATE FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the date format for result values that are string representations of date or time values. See “String representations of datetime values” on page 103 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)

Specifies the maximum precision that is to be used for decimal arithmetic operations. See “Arithmetic with two decimal operands” on page 247 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form \texttt{pp.s} is specified, \texttt{s} must be a number between 1 and 9. \texttt{s} represents the minimum scale that is to be used for division.

FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

FOR UPDATE CLAUSE REQUIRED

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

\textbf{FOR UPDATE CLAUSE REQUIRED} is the default.

FOR UPDATE CLAUSE OPTIONAL

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are identified in the FOR UPDATE clause and to specify the acquisition of update locks.

TIME FORMAT ISO, EUR, USA, JIS, or LOCAL

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 103 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

BUSINESS_TIME SENSITIVE

Determines whether references to application-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

YES

References to application-period temporal tables are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. YES is the default value.

NO

References to application-period temporal tables are not affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register.
Related information:

“CURRENT TEMPORAL BUSINESS_TIME” on page 201

**SYSTEM_TIME SENSITIVE**
Determines whether references to system-period temporal tables in both static and dynamic SQL statements are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

**YES**
References to system-period temporal tables are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. YES is the default value.

**NO**
References to system-period temporal tables are not affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

Related information:

“CURRENT TEMPORAL SYSTEM_TIME” on page 203

**ARCHIVE SENSITIVE**
Determines whether references to archive-enabled tables in SQL statements are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

**YES**
References to archive-enabled tables are affected by the value of the SYSIBMADM.GET_ARCHIVE global variable. YES is the default value.

**NO**
References to archive-enabled tables are not affected by the value of the SYSIBMADM.GET_ARCHIVE global variable.

Related information:

“Built-in global variables” on page 340

**APPLCOMPAT compatibility-level**
Specifies the package compatibility level behavior for static SQL. If this option is not specified then the behavior is determined, in priority order, by the compatibility-level of the last BIND of the package or the APPLCOMPAT system parameter. The following values of compatibility-level can be specified:

**V10R1**
The static SQL statements in the package have V10R1 compatibility behavior.

**V11R1**
The static SQL statements in the package have V11R1 compatibility behavior.

Related information:

APPLCOMPAT LEVEL field (APPLCOMPAT subsystem parameter) (DB2 Installation and Migration)

**SQL-routine-body**
Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 7, “SQL control statements for SQL routines,” on page 2029. If an SQL-procedure-statement is the only statement in the procedure body, the statement must not end with a semicolon.
Notes

Additional Notes:
See "Notes" on page 1390 for information about:
- Owner privileges
- Choosing data types for parameters
- Environments for running stored procedures
- Accessing result sets from nested stored procedures

Versions of a procedure:
The CREATE PROCEDURE statement for an SQL procedure defines the initial version of the procedure. You can define additional versions using the ADD VERSION clause of the ALTER PROCEDURE statement. All versions of a procedure share the same procedure signature and the same specific name. However, the parameters names can differ between versions of a procedure. Only one version of the procedure can be considered to be the active version of the procedure.

Characteristics of the package that is generated for a procedure:
The package that is associated with the first version of a procedure is named as follows:
- location is set to the value of the CURRENT SERVER special register
- collection-id (schema) for the package is the same as the schema qualifier of the procedure.
- package-id is the same as the specific name of the procedure
- version-id is the same as the version identifier for the initial version of the procedure.

If you want to change the collection-id for the name of the package, you need to make a copy of the package.

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See "Implicit rebinding and regeneration that occurs because of an ALTER PROCEDURE statement" in Chapter 7, "SQL control statements for SQL routines," on page 2029 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:
- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(*)

See Table 101 on page 1012 for additional information about the correspondence of procedure options to bind options.

Considerations for SQL processor programs:
SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the routine body that end with semicolons. These processor programs accept multiple SQL statements as input, with each statement separated with a terminator character. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE FUNCTION statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see DB2 Application Programming and SQL Guide.
Identifier resolution:
See Chapter 7, “SQL control statements for SQL routines,” on page 2029 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the routine name for parameters, and the label name for SQL variables.

Lines within the SQL procedure definition:
When a procedure is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the new line control character.

Error handling in SQL procedures:
You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement or a compound statement that is nested within that compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

Stored procedures and user-defined session global variables:
The content of user-defined session global variables that are referenced in routines is inherited from the caller. User-defined session global variables can be modified in stored procedures, except when the stored procedure is called by a trigger or a function.

If the procedure contains references to user-defined session global variables, the level of SQL data access must be at least CONTAINS SQL. If the procedure contains SQL statements that modify user-defined session global variables, the level of SQL data access must be MODIFIES SQL DATA.

Specifying the encoding scheme for parameters:
The encoding scheme of all of the parameters with a character or graphic string data type, distinct type with a CCSID, or an array type with a CCSID (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that all encoding schemes agree.

Stored procedures with a parameter that is defined as an array type:
A procedure that is defined with a parameter that is an array type, other than an array global variable, can be invoked only from within an SQL PL context, or from a Java application program that uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

Compatibilities:
For compatibility with previous versions of DB2, the following clauses can be specified, but they will be ignored and a warning will be issued:
• STAY RESIDENT
• PROGRAM TYPE
• RUN OPTIONS
• NO DBINFO
• COLLID or NOCOLLID
• SECURITY
• PARAMETER STYLE GENERAL WITH NULLS
• STOP AFTER SYSTEM DEFAULT FAILURES
• STOP AFTER \textit{nn} FAILURES
• CONTINUE AFTER FAILURES
• PARAMETER VARCHAR

If the FENCED or EXTERNAL clause is specified, an external SQL procedure will be generated. See "CREATE PROCEDURE (SQL - external)" on page 1393 for more information.

If WLM ENVIRONMENT is specified without the FOR DEBUG MODE keywords, and error is returned. If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:
• RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
• VARIANT as a synonym for NOT DETERMINISTIC
• NOT VARIANT as a synonym for DETERMINISTIC
• NULL CALL as a synonym for CALLED ON NULL

Examples

Example 1: Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:
• Calculate the employee’s new salary.
• Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 2: Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:
• The same input always produces the same output.
• SQL work is committed on return to the caller.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
DETERMINISTIC
COMMIT ON RETURN YES
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

Example 3: Create the definition for an SQL procedure that uses arrays as IN and OUT parameters. The procedure is named GETWEEKENDS. It accepts an array of
DATE values as input, and returns an array that contains only the dates that fall
on a Saturday or Sunday. For example, if the input dates are a Saturday, a Friday,
and a Sunday, the procedure returns only the dates that fall on Saturday and
Sunday.

Suppose that the following user-defined array type has been defined:

```sql
CREATE TYPE DATEARRAY AS DATE ARRAY[100];
```

After the array type is created, any references to it need to specify the fully
qualified user-defined array type name. Otherwise, the schema for the type needs
to be in the CURRENT PATH.

Suppose that the SQL procedure is defined like this:

```sql
CREATE PROCEDURE GETWEEKENDS(IN MYDATES DATEARRAY, OUT WEEKENDS DATEARRAY)
BEGIN
    -- ARRAY INDEX VARIABLES
    DECLARE DATEINDEX, WEEKENDINDEX INT DEFAULT 1;
    -- VARIABLE TO STORE THE ARRAY LENGTH OF MYDATES,
    -- INITIALIZED USING THE CARDINALITY FUNCTION.
    DECLARE DATESCOUNT INT;
    SET DATESCOUNT = CARDINALITY(MYDATES);
    -- FOR EACH DATE IN MYDATES, IF THE DATE IS A SUNDAY OR SATURDAY,
    -- ADD IT TO THE OUTPUT ARRAY NAMED "WEEKENDS"
    WHILE DATEINDEX <= DATESCOUNT DO
        IF DAYOFWEEK(MYDATES[DATEINDEX]) IN (1, 7) THEN
            SET WEEKENDS[WEEKENDINDEX] = MYDATES[DATEINDEX];
            SET WEEKENDINDEX = WEEKENDINDEX + 1;
        END IF;
        SET DATEINDEX = DATEINDEX + 1;
    END WHILE;
END
```

Also suppose that input array MYDATES contains the following content:

```
['2012-04-28', '2012-02-10', '2012-03-18']
```

After the procedure returns, output array WEEKENDS contains the following
content:

```
['2012-04-28', '2012-03-18']
```

Example 4: Create the definition for an SQL procedure that uses arrays as OUT
parameters. The procedure is named GET_PHONES. It returns an array that
contains phone numbers for employee 1775. If more than five phone numbers exist
for the employee, an error is returned because the array is defined for only five
elements.

Suppose that the following user-defined array type and table have been defined:

```sql
CREATE TYPE PHONELIST AS DECIMAL(10, 0) ARRAY[5];
CREATE TABLE EMP_PHONES(ID INTEGER, PHONENUMBER DECIMAL(10,0));
```

The SQL procedure is defined like this:

```sql
CREATE PROCEDURE GET_PHONES(OUT EPHONES PHONELIST)
BEGIN
    SELECT ARRAY_AGG(PHONENUMBER)
    INTO EPHONES
    FROM EMP_PHONES
    WHERE ID = 1775;
END
```
For more examples of SQL procedures, see Chapter 7, “SQL control statements for SQL routines,” on page 2029.
CREATE ROLE

The CREATE ROLE statement creates a role at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following authorities:
- SYSADM authority
- SYSCTRL authority
- SECADM

Privilege set: If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process or by the role that is associated with the primary authorization ID, if the statement is run in a trusted context and the ROLE AS OBJECT OWNER clause is specified.

Syntax

```
CREATE ROLE role-name
```

Description

`role-name`

Names the role. The name must not identify a role that exists at the current server. The name must not begin with the characters 'SYS' and must not be 'DBADM', 'NONE', 'NULL', 'PUBLIC', or 'SECADM'.

Examples

The following statement creates a role named TELLER.

```
CREATE ROLE TELLER;
```
CREATE SEQUENCE

The CREATE SEQUENCE statement creates a sequence at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

If the data type of the sequence is a distinct type, the privilege set must include the USAGE privilege on the distinct type.
Syntax

```
CREATE SEQUENCE sequence-name (1)
    AS data-type
    START WITH numeric-constant
    INCREMENT BY 1
    INCREMENT BY numeric-constant
    NO MINVALUE numeric-constant
    NO MAXVALUE numeric-constant
    NO CYCLE
    CYCLE CACHE 20
    NO CACHE
    CACHE integer-constant
    NO ORDER
    ORDER
```

Notes:
1. The same clause must not be specified more than once. Separator commas can be specified between sequence attributes when a sequence is defined.

**data-type:**

```
built-in-type distinct-type-name
```

**built-in-type:**

```
SMALLINT
    INTEGER
    INT
    BIGINT
    DECIMAL
    (5,0)
    DEC
    NUMERIC
    (integer, integer)
```

**Description**

*sequence-name*

Names the sequence. The name, including the implicit or explicit qualifiers, must not identify an existing sequence at the current server, including the sequence names that are generated by DB2.
The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

**AS data-type**

Specifies the data type to be used for the sequence value. The data type can be any exact numeric data type (SMALLINT, INTEGER, BIGINT, or DECIMAL with a scale of zero), or a user-defined distinct type for which the source type is an exact numeric data type with a scale of zero. The default, when AS is not specified, is INTEGER. If DECIMAL is specified, the default is DECIMAL(5,0).

**START WITH numeric-constant**

Specifies the first value for the sequence. The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If the START WITH clause is not explicitly specified with a value, the default is the MINVALUE for ascending sequences and MAXVALUE for descending sequences.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

**INCREMENT BY numeric-constant**

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point. The default is 1.

If INCREMENT BY is positive, the sequence ascends. If INCREMENT BY is negative, the sequence descends. If INCREMENT is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

**MINVALUE or NO MINVALUE**

Specifies the minimum value at which a descending sequence either cycles or stops generating values or an ascending sequence cycles to after reaching the maximum value. The default is NO MINVALUE.

**MINVALUE numeric-constant**

Specifies the minimum end of the range of values for the sequence. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

For the effects of defining MINVALUE and MAXVALUE with the same value, see [Defining a constant sequence](#).

**NO MINVALUE**

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MINVALUE becomes one of the following:
• For an ascending sequence, the value is the START WITH value or 1 if START WITH is not specified.
• For a descending sequence, the value is the minimum value of the data type that is associated with the sequence.

**MAXVALUE or NO MAXVALUE**
Specifies the maximum value at which an ascending sequence either cycles or stops generating values or an descending sequence cycles to after reaching the minimum value. The default is NO MAXVALUE.

**MAXVALUE numeric-constant**
Specifies the maximum end of the range of values for the sequence. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

For the effects of defining MAXVALUE and MINVALUE with the same value, see [Defining a constant sequence](#).

**NO MAXVALUE**
Specifies the maximum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MAXVALUE becomes one of the following:
• For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence.
• For a descending sequence, the value is the START WITH value or -1 if START WITH is not specified.

To find the maximum possible value for a given data type, see the "Limits in DB2 for z/OS" on page 2078.

**CYCLE or NO CYCLE**
Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it. The default is NO CYCLE.

**CYCLE**
Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

**NO CYCLE**
Specifies that the sequence cannot generate more values once the
maximum or minimum value for the sequence has been reached. The NO CYCLE option (the default) can be altered to CYCLE at any time during the life of the sequence.

When the next value is being generated for a sequence if the maximum value (for an ascending sequence) or the minimum value (for a descending sequence) of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, an error occurs.

**CACHE or NO CACHE**

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

**CACHE integer-constant**

Specifies the maximum number of values of the sequence that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2. The default is CACHE 20.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

**NO CACHE**

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O.

**ORDER or NO ORDER**

Specifies whether the sequence numbers must be generated in order of request. The default is NO ORDER.

**ORDER**

Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

**NO ORDER**

Specifies that the sequence numbers do not need to be generated in order of request.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to
20 and DB2B gets the cache values 21 to 40, the actual order of values assigned
would be 1,21,2 if DB2A requested for next value first, then DB2B requested,
and then DB2A again requested. Therefore, to guarantee that sequence
numbers are generated in strict numeric order among multiple DB2 members
using the same sequence concurrently, specify the ORDER option.

**Notes**

Owner privileges: The owner is authorized to change (ALTER privilege) or use
(USAGE privilege) the sequence and grant others these privileges. See “GRANT
(sequence privileges)” on page 1779. For more information about ownership of the
object see “Authorization, privileges, permissions, masks, and object ownership”
on page 72.

*Relationship of MINVALUE and MAXVALUE:* MINVALUE must not be greater
than MAXVALUE. Although MINVALUE is typically less than MAXVALUE,
MINVALUE can equal MAXVALUE. If START WITH were the same value as
MINVALUE and MAXVALUE, the sequence would be constant. The request for the
next value in a constant sequence appears to have no effect because all of the
values that are generated by the sequence are in fact the same value.

*Defining sequences that cycle:* When you define a sequence, you can choose to
have it cycle automatically or not when the maximum or minimum value for the
sequence has been reached.

- Implicitly or explicitly defining a sequence with NO CYCLE causes the sequence
to not cycle automatically after the boundary is reached. However, you can use
the ALTER SEQUENCE statement to cycle the sequence manually. ALTER
SEQUENCE allows you to restart or extend the sequence, which causes sequence
values to continue to be generated.

- Explicitly defining a sequence with CYCLE causes the sequence to cycle
automatically after the boundary is reached. Sequence values continue to be
generated after the sequence cycles.

When a sequence is defined to cycle automatically, the maximum or minimum
value that is generated for a sequence might not be the actual MAXVALUE or
MINVALUE value that is specified if the increment is a value other than 1 or -1.
For example, the sequence defined with START WITH=1, INCREMENT=2,
MAXVALUE=10 will generate a maximum value of 9, and will not generate the
value 10.

When a sequence is defined with CYCLE, any application conversion tools (for
converting applications from other vendor platforms to DB2) should also
explicitly specify MINVALUE, MAXVALUE, and START WITH.

*Defining a constant sequence:* You can define a sequence such that it always
returns the same (or a constant) value. To create a constant sequence, use either of
these techniques when defining the sequence:

- Specify an INCREMENT value of zero and a START WITH value that does not
  exceed MAXVALUE.
- Specify the same value for START WITH, MINVALUE, and MAXVALUE, and
  specify CYCLE.

A constant sequence can be used as a numeric global variable. You can use ALTER
SEQUENCE to adjust the values that are generated for a constant sequence.

*Consumed values of a sequence:* After DB2 generates a value for a sequence, that
value can be said to be "consumed" regardless of whether or not that value is used
by the application or not. The value is not reused within the current cycle. A consumed value might not be used when the statement that caused the value to be generated fails for some reason or is rolled back after the value was generated. Generated but unused values can constitute gaps in a sequence.

**Gaps in a sequence:** Consecutive values in a sequence differ by the constant INCREMENT BY value specified for the sequence. However, gaps can occur in the values that are assigned to a sequence object by DB2.

The following situations are some examples of how gaps can be introduced in the sequence values:

- A transaction has advanced the sequence and then rolls back.
- The SQL statement leading to the generation of the next value fails after the value was generated.
- The NEXT VALUE expression is used in the SELECT statement of a cursor in a DRDA environment where the client uses block-fetch and not all retrieved rows are fetched by the application.
- The sequence is altered and then the alteration is rolled back.
- The sequence (or an identity column table) is dropped and then the drop is rolled back.
- The SYSIBM.SYSSEQ table space is stopped or closed for any reason (including when DSMAK is reached)
- The DB2 subsystem is stopped or goes down

Values of such gaps are not available for the current cycle, unless the sequence is altered and restarted in a specific way to make them available.

A sequence is incremented independently of a transaction. Thus, a given transaction increments the sequence two times might see a gap in the two numbers that it receives if other transactions concurrently increment the same sequence. Most applications can tolerate these instances as these are not really gaps.

**Duplicate sequence values:** It is possible the duplicate values can be generated for a sequence. Duplicate values are most likely to occur when a sequence is defined with the CYCLE option, is defined as a constant sequence, or is altered. For example, the following situations could cause duplicate sequence values:

- A sequence is defined with the attributes START WITH=2, INCREMENT BY 2, MINVALUE=2, MAXVALUE=10, and CYCLE.
- The ALTER SEQUENCE statement is used to restart the sequence with a value that has already been generated.
- The ALTER SEQUENCE statement is used to reverse the ascending direction of a sequence by changing the INCREMENT BY value from a positive to a negative.

**Using sequences:** A sequence can be referenced using a sequence-reference. A sequence reference can appear in most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value or the previously generated value. A NEXT VALUE sequence expression is used to generate a new value. A PREVIOUS VALUE sequence expression is used to obtain the last assigned value of a sequence. For more information, see "Sequence reference" on page 294.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:
• NOMINVALUE (single key word) as a synonym for NO MINVALUE
• NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
• NOCYCLE (single key word) as a synonym for NO CYCLE
• NOCACHE (single key word) as a synonym for NO CACHE
• NOORDER (single key word) as a synonym for NO ORDER

Examples

Example 1: Create a sequence names "org_seq" that starts at 1 increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORDER_SEQ
    START WITH 1
    INCREMENT BY 1
    NO MAXVALUE
    NO CYCLE
    CACHE 24;
```

INCREMENT 1, NO MAXVALUE, and NO CYCLE are defaults and do not need to be specified.

Example 2: The following example shows how to create and use a sequence named "order_seq" in a table named 'orders':

```
CREATE SEQUENCE ORDER_SEQ
    START WITH 1
    INCREMENT BY 1
    NO MAXVALUE
    NO CYCLE
    CACHE 20;

INSERT INTO ORDERS (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
```

or to update the orders:

```
UPDATE ORDERS
SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
WHERE CUSTNO = 123456;
```

Example 3: The following example shows how to use the same sequence number as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row to generate the sequence value and with a PREVIOUS VALUE expression for the other rows to refer to the sequence value most recently generated.

```
INSERT INTO ORDERS (ORDERNO, CUSTNO)
VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEMS (ORDERNO, PARTNO, QUANTITY)
VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 100);
```

If NEXT VALUE is invoked in the same statement as the PREVIOUS VALUE, then regardless of their order in the statement, PREVIOUS VALUE returns the previous (unincremented) value and NEXT VALUE returns the next value.
CREATE STOGROUP

The CREATE STOGROUP statement creates a storage group at the current server. Storage from the identified volumes can later be allocated for table spaces and index spaces.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATESG privilege
- SYSADM or SYSCTRL authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

Syntax

```
CREATE STOGROUP stogroup-name
  VOLUMES (
    volume-id
  )
  VCAT catalog-name
```

Notes:

1. The same volume-id must not be specified more than once.

Description

**stogroup-name**
Names the storage group. The name must not identify a storage group that exists at the current server.
**VOLUMES**(volume-id,...) or **VOLUMES('*,...)

Defines the volumes of the storage group. Each volume-id is a volume serial number of a storage volume. The volume serial number can have a maximum of six characters and is specified as an identifier or a string constant.

If the data set that is associated with the storage group is not managed by Storage Management Subsystem (SMS), VOLUMES must be specified. Asterisks are recognized only by SMS. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended. If one or more of the DATACLAS, MGMTCLAS, or STORCLAS clauses are specified, VOLUMES can be omitted. If the VOLUMES clause is omitted, the volume selection is controlled by SMS.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

**VCAT** catalog-name

Identifies the integrated catalog facility catalog for the storage group. You must specify an alias\(^{35}\) if the name of the integrated catalog facility catalog is longer than 8 characters.

The designated catalog is the one in which entries are placed for the data sets created by DB2 with the aid of the storage group. These are linear VSAM data sets for associated table or index spaces or for their partitions. For each such space or partition, association is made through a USING clause in a CREATE TABLESPACE, CREATE INDEX, ALTER TABLESPACE, or ALTER INDEX statement. For more on the association, see the descriptions of those statements in this chapter.

Conventions for data set names are given in *DB2 Administration Guide*. catalog-name is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for catalog-name that is not used by the other DB2 subsystems.

**DATACLAS** dc-name

Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

**MGMTCLAS** mc-name

Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

**STORCLAS** sc-name

Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The

\(^{35}\) The alias of an integrated catalog facility catalog.
SMS storage administrator defines the storage class that can be used. 
STORCLAS must not be specified more than one time.

Notes

Device types: When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

Number of volumes: There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

z/OS imposes a limit on the number of volumes that can be allocated per data set (currently, 59 volumes). For the latest information on that restriction, see z/OS DFSMS Access Method Services for Catalogs.

Storage group owner: If the statement is embedded in an application program, the owner of the plan or package is the owner of the storage group. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the storage group. The owner has the privilege of altering and dropping the storage group.

Specifying volume IDs: A new storage group must have either specific volume IDs or non-specific volume IDs. You cannot create a storage group that contains a mixture of specific and non-specific volume IDs.

Verifying the existence of volumes and classes: When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the existence of the volumes or classes or determine the types of devices that are identified or if SMS is active. Later, when the storage group allocates data sets, the list of volumes is passed to Data Facilities (DFSMsdfp) in the physical order of the data sets in the SYSIBM.SYSVOLUMNS catalog table.

Related information:

Implementing DB2 storage groups (DB2 Administration Guide)

Example

Create storage group, DSN8G110, of volumes ABC005 and DEF008. DSNCAT is the integrated catalog facility catalog name.

```
CREATE STOGROUP DSN8G110
  VOLUMES (ABC005,DEF008)
  VCAT DSNCAT;
```
CREATE SYNONYM (deprecated)

The CREATE SYNONYM statement defines a synonym for a table or view at the current server.

Important: Synonyms are deprecated. Use aliases instead. Synonyms are similar to aliases, but are supported only for compatibility with previous releases. Synonyms might not be available in future releases of DB2. Synonyms behave differently with DB2 for z/OS than with the other DB2 family products. Do not create or use synonyms when writing new SQL statements or when creating portable applications.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified. The statement cannot be processed in a trusted context that is defined with a role as the object owner.

Authorization

None required.

Syntax

```sql
CREATE SYNONYM synonym FOR authorization-name.table-name

OR

CREATE SYNONYM synonym FOR authorization-name.view-name
```

Description

**synonym**
Names the synonym. The name must not identify a synonym, table, view, or alias that exists at the current server and that is owned by the owner of the synonym that is being created and must not identify a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

**FOR authorization-name.table-name or authorization-name.view-name**
Identifies the object to which the synonym applies. The name must consist of two parts and must identify a table, view, or alias that exists at the current server. If a table is identified, it must not be an auxiliary table or a declared temporary table. If an alias is identified, it must be an alias for a table or view at the current server and the synonym is defined for that table or view. The name must not identify a table that was implicitly created for an XML column.

Notes

**Owner privileges:** There are no specific privileges on a synonym. For more information about ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.
If an alias is used to denote the table or view, the name of that table or view, not the alias, is recorded in the catalog as the definition of the synonym. That severs the connection between the synonym and alias, and even if the alias is dropped and redefined, the synonym is still in effect and names the original table or view.

Example

Define DEPT as a synonym for the table DSN8B10.DEPT.

```
CREATE SYNONYM DEPT
FOR DSN8B10.DEPT;
```
CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database explicitly specified by the IN clause.
  - If the IN clause is not specified, the CREATETAB privilege on database DSNDDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDDB04 is required.
- SYSADM or SYSCtrl authority
- System DBADM

If the table space is created implicitly, the privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database explicitly specified by the IN clause.
  - If the IN clause is not specified, the CREATETS privilege on database DSNDDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDDB04 is required.
- SYSADM or SYSCtrl authority

The privilege set must also have the USE privilege for the default buffer pool and default storage group of the database if the database is specified in the IN clause.

For tables that are created in an implicit database, the database authority must be held on DSNDDB04.

Additional privileges might be required in the following conditions:

- The clause IN, LIKE or FOREIGN KEY is specified.
- The data type of a column is a distinct type.
- The table space is implicitly created.
- A fullselect is specified.
- A column is defined as a security label column.

See the description of the appropriate clauses for details about these privileges.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the package.
If the application is bound in a trusted context with the ROLE AS OBJECT
OWNER clause specified:

- A role is the owner of the table that is being created
- The privilege set is the set of privileges that are held by that role
- The schema qualifier (implicit or explicit) must be the same as the role, unless
  the role has the CREATEIN privilege on the schema, or SYSADM, SYSCTRL, or
  system DBADM authority

Otherwise, an authorization ID is the owner of the package, and the following
rules apply:

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM
  authority, SYSCTRL authority, and System DBADM authority, the schema
  qualifier (implicit or explicit) must be the same as the authorization ID of the
  owner of the package.
- If the privilege set lacks SYSADM authority, SYSCTRL authority, and System
  DBADM authority, and the table is explicitly qualified, the authorization ID that
  is the same as the schema name must have all the necessary privileges to create
  the table, and that authorization ID is the owner of the table. Otherwise, the
  authorization ID of the owner of the package must have all the necessary
  privileges to create the table, and that authorization ID is the owner of the table.
- If the privilege set includes SYSADM authority, SYSCTRL authority, or system
  DBADM authority, the schema qualifier (implicit or explicit) can be any schema
  name. However, if the table is explicitly qualified, the authorization ID that is
  the same as the schema name is the owner of the table. Otherwise, the
  authorization ID of the owner of the package is the owner of the table.
- If the privilege set includes DBADM authority and DBCTRL authority for the
  database, the schema qualifier (implicit or explicit) can be any schema name.
  However, if the table is explicitly qualified, the authorization ID that is the same
  as the schema name is the owner of the table. Otherwise, the authorization ID of
  the owner of the package is the owner of the table.

If the statement is dynamically prepared, the privilege set is the privileges that are
held by the SQL authorization ID of the process unless the process is within a
trusted context and the ROLE AS OBJECT OWNER clause is in effect. When ROLE
AS OBJECT OWNER is in effect, the privileges set is the privileges that are held by
the role that is associated with the primary authorization ID of the process, and the
owner of the table is that role. The schema qualifier (implicit or explicit) must be
the same as that role, unless the role has CREATEIN privilege on the schema, or
SYSADM authority, SYSCTRL authority, or System DBADM authority.

For the case where the SQL authorization ID of the process holds the privileges,
the following rules apply:

- If the privilege set lacks CREATEIN privilege on the schema, SYSADM authority,
  SYSCTRL authority, and System DBADM authority, the schema qualifier must be
  the same as one of the authorization IDs of the process.
- If the privilege set lacks SYSADM authority, SYSCTRL authority, and System
  DBADM authority, and the table is explicitly qualified, then the authorization ID
  that is the same as the schema name must have all the necessary privileges to
  create the table, and that authorization ID is the owner of the table. Otherwise,
  the SQL authorization ID of the process must include all privileges that are
  needed to create the table, and that authorization ID is the owner of the table.
- If the privilege set includes SYSADM authority, SYSCTRL authority, or System
  DBADM authority, the schema qualifier can be any schema name. However, if
the table is explicitly qualified, then the authorization ID that is the same as the
schema name is the owner of the table. Otherwise, the SQL authorization ID of
the process is the owner of the table.

Syntax
Notes:
1 The same clause must not be specified more than once.

column-definition:
Notes:
1 Data type is optional if `as-row-change-timestamp-clause` is specified
2 The same clause must not be specified more than one time.
3 This form of the DEFAULT value can only be used with columns that are defined as a distinct type.
4 AS SECURITY LABEL can be specified only for a CHAR(8) data type and requires that the NOT NULL and WITH DEFAULT clauses be specified.
5 IMPLICITLY HIDDEN must not be specified for a column defined as a ROWID, or a distinct type that is based on a ROWID.
6 INLINE LENGTH only applies to a column with a LOB data type or a distinct type that is based on a LOB data type.
XML-type-modifier:

XML-schema-specification:

generated-clause:

as-identity-clause:
as-row-change-timestamp-clause:

```sql
(1) AS IDENTITY
( START WITH numeric-constant
  INCREMENT BY 1
  INCREMENT BY numeric-constant
  NO MINVALUE
  MINVALUE numeric-constant
  NO MAXVALUE
  MAXVALUE numeric-constant
  NO CYCLE
  CYCLE
  CACHE 20
  NO CACHE
  CACHE integer-constant
  NO ORDER
  ORDER
```

Notes:
1. Separator commas can be specified between attributes when an identity column is defined.

as-row-change-timestamp-clause:

```sql
FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
```

as-row-transaction-start-id-clause:

```sql
AS TRANSACTION START ID
```

as-row-transaction-timestamp-clause:

```sql
AS ROW BEGIN
  END
```

as-generated-expression-clause:

```sql
AS ( non-deterministic-expression )
```

non-deterministic-expression:
special-register:

(1)

CURRENT CLIENT_ACCTNG
CURRENT CLIENT_APPLNAME
CURRENT CLIENT_CORR_TOKEN
CURRENT CLIENT_USERID
CURRENT CLIENT_WRKSTNNAME
CURRENT SERVER
CURRENT SQLID
SESSION_USER

Notes:
1. This definition of special register is specific to this context, as part of non-deterministic-expression.
2. USER can be specified as a synonym for SESSION_USER.

session-variable:

(1)

SYSIBM.PACKAGE_NAME
SYSIBM.PACKAGE_SCHEMA
SYSIBM.PACKAGE_VERSION

Notes:
1. This definition of session variable is specific to this context, as part of non-deterministic-expression.

column-constraint:

CONSTRANTR constraint-name
PRIMARY KEY
UNIQUE
references-clause
CHECK(check-condition)

period-definition:
**unique-constraint:**

```
CONSTRAINT constraint-name PRIMARY KEY (column-name)
```

(1)

**Notes:**

1. If **BUSINESS_TIME WITHOUT OVERLAPS** is specified, the BUSINESS TIME period will not overlap in time periods for the same column-name values.

**referential-constraint:**

```
CONSTRAINT constraint-name FOREIGN KEY (column-name) REFERENCES table-name
```

**references-clause:**

```
ON DELETE RESTRICT
```

**check-constraint:**

```
ENFORCED
```

Chapter 6. Statements 1455
as-result-table:

```
AS (fullselect) WITH NO DATA
```

copy-options:

```
(1) EXCLUDING IDENTITY
(2) EXCLUDING COLUMN DEFAULTS
(3) EXCLUDING XML TYPE MODIFIERS
```

Notes:
1. These clauses can be specified in any order and must not be specified more than one time.
2. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.
3. EXCLUDING XML TYPE MODIFIERS must be specified with the LIKE clause if the identified table has an XML type modifier and none of the XML columns of the new table has an XML type modifier. EXCLUDING XML TYPE MODIFIERS is not supported when a view is identified in a LIKE clause and the view contains XML columns.
refreshable-table-options:

DATA INITIALLY DEFERRED—REFRESH DEFERRED

MAINTAINED BY SYSTEM
MAINTAINED BY USER
ENABLE QUERY OPTIMIZATION
DISABLE QUERY OPTIMIZATION

Notes:
1 The same clause must not be specified more than one time.

partitioning-clause:

PARTITION BY

RANGE
SIZE
EVERY integer-constant

partition-expression:

column-name
NULLS LAST
ASC

partition-element:
organization-clause

organize-by-hash-unique

Description

table-name
Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

column-definition

column-name
Names a column of the table. For a dependent table, up to 749 columns can be named. For a table that is not a dependent, this number is 750. Do not qualify column-name and do not use the same name for more than one column of the table.

built-in-type
Specifies the data type of the column as one of the following built-in data types, and for character string data types, specifies the subtype. For more information about defining a table with a LOB column (CLOB, BLOB, or DBCLOB), see Creating a table with LOB columns.

SMALLINT
For a small integer.

INTEGER or INT
For a large integer.
**BIGINT**

For a big integer.

**DECIMAL(integer, integer) or DEC(integer, integer)**

**DECIMAL(integer) or DEC(integer)**

**DECIMAL or DEC**

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(p) for DECIMAL(p,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

**DECFLOAT(integer)**

For a decimal floating-point number. The value of integer must be either 16 or 34 and represents the number of significant digits that can be stored. If integer is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

**FLOAT(integer)**

**FLOAT**

For a floating-point number. If integer is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

**REAL**

For single precision floating-point.

**DOUBLE or DOUBLE PRECISION**

For double precision floating-point

**CHARACTER(integer) or CHAR(integer)**

**CHARACTER or CHAR**

For a fixed-length character string of length integer, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

**VARCHAR(integer), CHAR VARYING(integer), or CHARACTER VARYING(integer)**

For a varying-length character string of maximum length integer, which can range from 1 to the maximum record size minus 10 bytes. See Table 126 on page 1510 to determine the maximum record size.

**CCSID 1208**

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

**FOR subtype DATA**

Specifies a subtype for a character string column, which is a column with a data type of CHAR, VARCHAR, or CLOB. Do not use the FOR subtype DATA clause with columns of any other data type (including any distinct type). subtype can be one of the following:

**SBCS**

Column holds single-byte data.
**MIXED**
Column holds mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNCODE clause is also specified, or the table is being created in a Unicode table space or database.

**BIT**
Column holds BIT data. Do not specify BIT for a CLOB column.

Only character strings are valid when subtype is BIT.

If you do not specify the FOR clause, the column is defined with a default subtype. For ASCII or EBCDIC data:

- The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
- The default is MIXED when the value is YES.

For Unicode data, the default subtype is MIXED.

A security label column is always considered SBCS data, regardless of the encoding scheme of the table.

**CLOB**(integer [K|M|G]), **CHAR LARGE OBJECT**(integer [K|M|G]), or **CHARACTER LARGE OBJECT**(integer [K|M|G])

CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT
For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2,147,483,647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 99.

When integer is not specified, the default length is 1M. The maximum value that can be specified for integer depends on whether a units indicator is also specified as shown in the following list.

- integer: The maximum value for integer is 2,147,483,647. The maximum length of the string is integer.
- integer K: The maximum value for integer is 2,097,152. The maximum length is 1024 times integer.
- integer M: The maximum value for integer is 2048. The maximum length is 1,048,576 times integer.
- integer G: The maximum value for integer is 2. The maximum length is 1,073,741,824 times integer.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), DB2 uses a value that is one byte less, or 2,147,483,647.

**GRAPHIC**(integer)

For a fixed-length graphic string of length integer, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

**VARGRAPHIC**(integer)

For a varying-length graphic string of maximum length integer, which must range from 1 to \( n/2 \), where \( n \) is the maximum row size minus 2 bytes.
CCSID 1200
Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

DBCLOB(integer [K|M|G])

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1 073 741 823. A DBCLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 99.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

CCSID 1200
Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

BINARY(integer)
A fixed-length binary string of length integer. The integer can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(integer) or VARBINARY(integer)
A varying-length binary string of maximum length integer, which can range from 1 through 32704. The length is limited by the page size of the table space.

BLOB (integer [K|M|G] or BINARY LARGE OBJECT(integer [K|M|G])

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 99.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is the same as for CLOB.

DATE
For a date.

TIME
For a time.

TIMESTAMP(integer) WITHOUT TIME ZONE
For a timestamp. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(integer) WITH TIME ZONE
For a timestamp with time zone. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID
For a row ID type.
A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

**XML**

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

**XMLSCHEMA**

Specifies one or more XML schemas that are used to validate the XML value. The same XML schema cannot be specified more than one time.

If the XML value has already been validated, for example, the XML value is the result of the DSN_XMLVALIDATE function or from an XML column with a type modifier, and the XML schema against which the XML value is validated is one of the schemas specified in the XML-type-modifier, DB2 accepts the XML value without revalidation.

**XML-schema-specification**

Specifies one XML schema. The XML schema can be identified by using either the registered XML-schema-name or the schema's target namespace followed by an optional schema location. Any XML schema that is referenced in this clause must be registered in the XML schema repository prior to use.

**ID registered-XML-schema-name**

Identifies an XML schema by using its registered-XML-schema-name. The name must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists, an error is returned.

The schema qualifier must be SYSXSR.

**URI target-namespace**

Specifies the target namespace URI of the XML schema. The value for the target-namespace URI is a character string constant which is not empty. The URI must be the target namespace of a registered XML schema and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema.

**NO NAMESPACE**

Specifies that the XML schema has no target namespace. There must be a registered XML schema that has no target namespace. If no LOCATION clause is specified, there must be only one such registered XML schema.

**LOCATION schema-location**

Specifies the XML schema location URI of the XML schema. The value of schema-location is a character string constant that is not empty. The schema location URI, combined with the target namespace URI, must identify a registered XML schema.

**ELEMENT element-name**

Specifies the name of the global element declaration. element-name must match the local name of the root element node in the instance XML document. The namespace name of the root element node must be the same as the target namespace URI.
**distinct-type-name**

Specifies the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table. The subtype for the distinct type, if it has the attribute, is the subtype with which the distinct type was created.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

**NOT NULL**

Prevents the column from containing null values. Omission of NOT NULL implies that the column can contain null values.

**column-constraint**

The column-constraint of a column-definition provides a shorthand method of defining a constraint composed of a single column. Thus, if a column-constraint is specified in the definition of column C, the effect is the same as if that constraint were specified as a unique-constraint, referential-constraint, or check-constraint in which C is the only identified column.

**CONSTRAINT constraint-name**

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If the name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**PRIMARY KEY**

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. PRIMARY KEY cannot be specified more than one time in a column definition, and must not be specified if the UNIQUE clause is specified in the definition. This clause must also not be specified if the definition is for one of the following types of columns:

- a LOB column
- a ROWID column
- a DECIMAL column
- a distinct type column that is based on a LOB, ROWID, or DECIMAL data type
- an XML column
- a row change timestamp column
- a Unicode column in an EBCDIC table

The table is marked as unavailable until its primary index is explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates an index to enforce the uniqueness of the
primary key and the table definition is considered complete. (For more information about implicitly created indexes, see [Implicitly created indexes].)

**UNIQUE**

Provides a shorthand method of defining a unique key composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. UNIQUE cannot be specified more than one time in a column definition and must not be specified if the PRIMARY KEY clause is specified in the column definition or if the definition is for one of the following types of columns:
- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a Unicode column in an EBCDIC table

The table is marked as unavailable until all the required indexes are explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see [Implicitly created indexes].)

**references-clause**

The references-clause of a column-definition provides a shorthand method of defining a foreign key composed of a single column. Thus, if references-clause is specified in the definition of column C, the effect is the same as if the references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify references-clause in the definition of the following types of columns because these types of columns cannot be a foreign key:
- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT data type
- an XML column
- a row change timestamp column
- a security label column
- a Unicode column in an EBCDIC table

**CHECK (check-condition)**

CHECK (check-condition) provides a shorthand method of defining a check constraint that applies to a single column. For conformance with the SQL standard, if CHECK is specified in the column definition of column C, no
columns other than C should be referenced in the check condition of the check constraint. The effect is the same as if the check condition were specified as a separate clause.

**DEFAULT**

Specifies the default value that is assigned to the column in the absence of a value specified on an insert or update operation or LOAD. DEFAULT must not be specified more than one time in the same column-definition. Do not specify DEFAULT for the following types of columns because DB2 generates default values:

- An identity column (a column that is defined AS IDENTITY)
- A ROWID column (or a distinct type that is based on a ROWID)
- A row change timestamp column
- A row-begin column
- A row-end column
- A transaction-start-id column
- An XML column

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default value for a security label column.

Do not specify a value after the DEFAULT keyword for a Unicode column in an EBCDIC table. Alternatively, DEFAULT NULL can be specified.

If a value is not specified after DEFAULT, the default value depends on the data type of the column, as follows:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Big integer</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string of length 0</td>
</tr>
<tr>
<td>Inline BLOB</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Inline CLOB</td>
<td>Blanks</td>
</tr>
<tr>
<td>Inline DBCLOB</td>
<td>Blanks</td>
</tr>
<tr>
<td>Date</td>
<td>CURRENT DATE</td>
</tr>
<tr>
<td>Time</td>
<td>CURRENT TIME</td>
</tr>
<tr>
<td><code>TIMESTAMP(integer)</code> WITHOUT TIME ZONE</td>
<td>CURRENT TIMESTAMP(p) WITHOUT TIME ZONE where p is the corresponding timestamp precision.</td>
</tr>
<tr>
<td><code>TIMESTAMP(integer)</code> WITH TIME ZONE</td>
<td>CURRENT TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.</td>
</tr>
</tbody>
</table>

If the column is defined as timestamp with time zone the default value must include a time zone.
Distinct type
The default of the source data type

A default value other than the one that is listed above can be specified in one of the following forms:
- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

Omission of NOT NULL and DEFAULT from a column-definition, for a column other than an identity column, is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

constant
Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or graphic string constant must be short enough so that its UTF-8 representation requires no more than 1536. A hexadecimal graphic string constant (GX) cannot be specified.

In addition, the length of the constant value cannot be greater than the INLINE LENGTH attribute for LOB columns.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the time of an SQL data change statement or LOAD as the default value for the column. If SESSION_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to 8 characters when the value is expressed as CCSID 37.

CURRENT SQLID
Specifies the value of the SQL authorization ID of the process at the time of an insert or update operation or LOAD as the default value for the column. If CURRENT SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT SQLID special register. If the data type of the column is an inline CLOB, the INLINE LENGTH attribute must be greater than or equal to the length attribute of the CURRENT SQLID special register.

NULL
Specifies NULL as the default value for the column. If NOT NULL is specified, DEFAULT NULL must not be specified with the same column-definition.

cast-function-name
The name of the cast function that matches the name of the distinct type for the column. A cast function can only be specified if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

constant
Specifies a constant as the argument. The constant must conform to the
rules of a constant for the source type of the distinct type. The length of the constant cannot be greater than the INLINE LENGTH attribute for LOB columns.

**SESSION_USER or USER**
Specifies the value of the SESSION_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the SESSION_USER special register.

**CURRENT SQLID**
Specifies the value of the CURRENT SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR, VARCHAR, or inline CLOB with a length attribute (inline length attribute for CLOB) that is greater than or equal to the length attribute of the CURRENT SQLID special register.

**NULL**
Specifies the NULL value as the argument.

In a given column definition:
- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.

Table 122 summarizes the effect of specifying the various combinations of the NOT NULL and DEFAULT clauses on the CREATE TABLE statement column-description clause.

<table>
<thead>
<tr>
<th>If NOT NULL is:</th>
<th>And DEFAULT is:</th>
<th>The effect is:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specified</td>
<td>Omitted</td>
<td>An error occurs if a value is not provided for the column on an insert or update operation or LOAD.</td>
</tr>
<tr>
<td>Specified without an operand</td>
<td>constant</td>
<td>The system defined nonnull default value is used.</td>
</tr>
<tr>
<td>Specified without an operand</td>
<td>SESSION_USER</td>
<td>The value of the SESSION_USER special register at the time of an insert or update operation or LOAD is used as the default value.</td>
</tr>
<tr>
<td>Specified without an operand</td>
<td>CURRENT SQLID</td>
<td>The SQL authorization ID of the process at the time of an insert or update operation or LOAD is used as the default value.</td>
</tr>
<tr>
<td>Specified without an operand</td>
<td>NULL</td>
<td>An error occurs during the execution of CREATE TABLE.</td>
</tr>
</tbody>
</table>

Table 122. Effect of specifying combinations of the NOT NULL and DEFAULT clauses
<table>
<thead>
<tr>
<th>If NOT NULL is:</th>
<th>And DEFAULT is:</th>
<th>The effect is:</th>
</tr>
</thead>
<tbody>

<td>CURRENT SQLID</td>
<td>The SQL authorization ID of the process is used as the default value.</td>
</tr>
<tr>
<td>Specified without an operand</td>
<td>NULL</td>
<td>Null is used as the default value.</td>
</tr>
</tbody>
</table>

**Note:** The table does not apply to a column with a ROWID data type or to an identity column.

**GENERATED**

Specifies that DB2 generates values for the column. GENERATED must be specified if the column is to be considered one of the following types of columns:

- An identity column
- A row change timestamp column.
- A ROWID column
- A row-begin column
- A row-end column
- A transaction-start-id column
- A generated expression column

GENERATED must only be specified for these types of columns. GENERATED must not be specified with default-clause in a column definition.

GENERATED must not be specified if the column definition references global variables.

**ALWAYS**

Specifies that DB2 always generates a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the default and recommended value. A column that is defined as GENERATED ALWAYS is not updatable.

**BY DEFAULT**

Specifies that DB2 will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a row change timestamp column, DB2 inserts or updates a specified value but does not verify that the value is unique for the column unless the row change timestamp column has a unique constraint or a unique index that specifies only the row change timestamp column.

For a ROWID column, DB2 uses a specified value only if it is a valid row ID value that was previously generated by DB2 and the column has a unique, single-column index. Until this index is created on the ROWID
column, the SQL insert or update operation and the LOAD utility cannot be used to add rows to the table. If the table space is explicitly created and the value of the CURRENT RULES special register is ‘STD’ when the CREATE TABLE statement is processed, or if the table space is implicitly created, DB2 implicitly creates the index on the ROWID column. The name of this index is ‘I’ followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, DB2 inserts a specified value but does not verify that it a unique value for the column unless the identity column has a unique, single-column index.

BY DEFAULT is the recommended value only when you are using data propagation.

**FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**

Specifies that the column is a timestamp column for the table. DB2 generates a value for the column for each row as the row is inserted, and for any row in which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the insert or update time of the row. If multiple rows are inserted or updated with a single statement, the value for the row change timestamp column might be different for each row.

A table can only have one row change timestamp column.

If `data-type` is specified, it must be `TIMESTAMP WITHOUT TIME ZONE` with a precision of 6.

A row change timestamp column cannot have a DEFAULT clause. NOT NULL must be specified for a row change timestamp column.

**AS TRANSACTION START ID**

Specifies that the value is assigned by DB2 whenever a row is inserted into the table or any column in the row is updated. DB2 assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated using the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or when a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table.

A table can have only one transaction-start-ID column. If a data type is not specified, the column is defined as `TIMESTAMP(12) WITHOUT TIME ZONE`. If a data type is specified, it must be `TIMESTAMP(12) WITHOUT TIME ZONE` or `TIMESTAMP(12) WITH TIME ZONE`. If the column is defined as `TIMESTAMP WITH TIME ZONE`, the values are stored in UTC, with a time zone of +00:00. A transaction-start-ID column cannot have a DEFAULT clause. A transaction-start-ID column is not updatable.
A value for a transaction-start-ID column is composed of a TIMESTAMP(9) value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

**AS ROW BEGIN**
Specifies that the column contains timestamp data and that the values are generated by DB2. DB2 generates a value for the column for each row as the row is inserted, and for every row in which any column is updated. The generated value is a timestamp that corresponds to the start time that is associated with the most recent transaction. If multiple rows are inserted with a single SQL statement, the values for the transaction start timestamp column are the same.

For a system-period temporal table, DB2 ensures the uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted or updated within a single SQL transaction, the values for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period.

A table can have only one column defined as AS ROW BEGIN. If a data type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP(12) WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. If no data type is specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. A column defined as a row-begin column cannot have a DEFAULT clause, and must be defined as NOT NULL. A row-begin column is not updatable.

A value for a row-begin column is composed of a TIMESTAMP(9) value that is unique per transaction per data sharing member followed by 3 digits that indicate the data sharing member number.

**AS ROW END**
Specifies that a value for the data type of the column is assigned by DB2 whenever a row is inserted or any column in the row is updated. The value that is assigned for a TIMESTAMP WITHOUT TIME ZONE column is the TIMESTAMP value '9999-12-30-00.00.00.000000000000'. The value that is assigned for a TIMESTAMP WITH TIME ZONE column is the TIMESTAMP value '9999-12-30-00.00.00.000000000000 +00:00'.

A row-end column is required as the second column of a SYSTEM_TIME period.

A table can have only one row-end column. If a data type is not specified, the column is defined as TIMESTAMP(12) WITHOUT TIME ZONE. If a data type is specified, it must be TIMESTAMP(12) WITHOUT TIME ZONE or TIMESTAMP(12) WITH TIME ZONE. If the column is defined as TIMESTAMP WITH TIME ZONE, the values are stored in UTC, with a time zone of +00:00. A row-end column cannot have a DEFAULT clause and must be defined as NOT NULL. A row-end column is not updatable.

**DATA CHANGE OPERATION**
Specifies that the database manager generates one of the following values, depending on the specified expression:

- **I** Insert operation.
- **U** Update operation.
Delete operation.

A table can have only one DATA CHANGE OPERATION column. The column must be defined as CHAR(1). The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

**special-register**

Specifies the value of the special register. The column is to contain the value of the special register at the time of the data change statement that assigns the value to the column. If multiple rows are inserted or updated with a single SQL statement, the value for the column is the same for all of the rows.

special-register must be one of the following special registers, and the column must use the required data type.

<table>
<thead>
<tr>
<th>Special register</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT CLIENT_ACCTNG</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_APPLNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_CORR_TOKEN</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_USERID</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT CLIENT_WRKSTNNAME</td>
<td>VARCHAR(255)</td>
</tr>
<tr>
<td>CURRENT SERVER</td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>CURRENT SQLID</td>
<td>VARCHAR($n$) where $n$ ≥ 8</td>
</tr>
<tr>
<td>SESSION_USER or USER</td>
<td>VARCHAR(128)</td>
</tr>
</tbody>
</table>

The column cannot have a DEFAULT clause and must not be defined as NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

**Related information:**

“Special registers” on page 159

**session-variable**

Specifies the value of a built-in session variable. The fully qualified name of the session variable must be specified. The value of the session variable is obtained from the GETVARABLE function at the time of the data change operation that assigns the value to the column. If multiple rows are changed with a single SQL statement, the value for the column is the same for all of the rows.
session-variable must be one of the following session variables, and the
column must use the required data type.

Table 124. Possible session variable values for non-deterministic expression columns

<table>
<thead>
<tr>
<th>Session variable</th>
<th>Data type for the column</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSIBM.PACKAGE_NAME</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_SCHEMA</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>SYSIBM.PACKAGE_VERSION</td>
<td>VARCHAR(122)</td>
</tr>
</tbody>
</table>

The column cannot have a DEFAULT clause and must not be defined as
NOT NULL.

The column is a non-deterministic column.

Do not specify any of the following clauses for the column:

- CCSID 1200
- CCSID 1208
- FIELDPROC

Related information:

"Built-in session variables” on page 342

AS IDENTITY

Specifies that the column is an identity column for the table. A table can
have only one identity column. AS IDENTITY can be specified only if the
data type for the column is an exact numeric type with a scale of zero
(SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a
distinct type based on one of these types).

An identity column is implicitly NOT NULL. An identity column cannot
have a WITH DEFAULT clause.

Defining a column AS IDENTITY does not necessarily ensure the
uniqueness of the values. To ensure uniqueness of the values, define a
unique, single-column index on the identity column.

START WITH numeric-constant

Specifies the first value that is generated for the identity column. The
value can be any positive or negative value that could be assigned to
the column without non-zero digits existing to the right of the decimal
point.

If a value is not explicitly specified when the identity column is
defined, the default is the MINVALUE for an ascending identity
column and the MAXVALUE for a descending identity column. This
value is not necessarily the value that would be cycled to after
reaching the maximum or minimum value for the identity column. The
START WITH clause can be used to start the generation of values
outside the range that is used for cycles. The range used for cycles is
defined by MINVALUE and MAXVALUE.

INCREMENT BY numeric-constant

Specifies the interval between consecutive values of the identity
column. The value can be any positive or negative value (including 0)
that does not exceed the value of a large integer constant, and could be
assigned to the column without any non-zero digits existing to the
right of the decimal point.
If this value is negative, the values for the identity column descend. If this value is 0 or positive, the values for the identity column ascend. The default is 1.

**MINVALUE** or **NO MINVALUE**

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

**NO MINVALUE**

Specifies that the minimum end point of the range of values for the identity column has not been set. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

The default is NO MINVALUE.

**MINVALUE numeric-constant**

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

**MAXVALUE** or **NO MAXVALUE**

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

**NO MAXVALUE**

Specifies that the minimum end point of the range of values for the identity column has not been set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending identity column, the value is the maximum value of the data type associated with the column.
- For a descending identity column, the value is the START WITH value -1 if START WITH is not specified.

The default is NO MAXVALUE.

**MAXVALUE numeric-constant**

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

**CYCLE** or **NO CYCLE**

Specifies whether this identity column should continue to generate values after reaching either its maximum or minimum value. The default is NO CYCLE.

**NO CYCLE**

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached.
**CYCLE**
Specifies that values continue to be generated for the identity column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

**CACHE integer-constant or NO CACHE**
Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

**NO CACHE**
Specifies that values for the identity column and sequences are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column or sequence results in synchronous I/O.

In a data sharing environment, use NO CACHE if you need to guarantee that the identity column and sequence values are generated in the order in which they are requested.

**CACHE integer-constant**
Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a DB2 shutdown, all cached identity column values and sequence values that are yet to be assigned will be lost and will not be used. Therefore, the value that is specified for CACHE also represents the maximum number of identity column values and sequence values that will be lost during a DB2 shutdown.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

**ORDER or NO ORDER**
Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

**NO ORDER**
Specifies that the values do not need to be generated in order of request.

**ORDER**
Specifies that the values are generated in order of request. Specifying ORDER might disable the caching of values. ORDER applies only to a single-application process.
In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the identity column, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested a value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the ORDER option.

**FIELDPROC** program-name

Designates program-name as the field procedure exit routine for the column. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data types. The column must not be one of the following:

- a LOB column
- a security label column
- a row change timestamp column
- a column with theTIMESTAMP WITH TIME ZONE data type
- a Unicode column in an EBCDIC table

The field procedure encodes and decodes column values: before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides DB2 with the column's field description. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

**Related information:**

- Field procedures (DB2 Administration Guide)
- "Character and graphic string comparisons" on page 138

**constant**

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The n-th parameter specified in the FIELDPROC clause on CREATE TABLE corresponds to the n-th parameter of the specified field procedure. The maximum length of the parameter list is 254 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

If you omit FIELDPROC, the column has no field procedure.

**AS SECURITY LABEL**

Specifies that the column will contain security label values. This also indicates that the table is defined with multilevel security with row level granularity. A table can have only one security label column. To define a table with a security
label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column must be defined with the NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not specify a default value (DB2 determines the default value).
- No field procedures, check constraints, or referential constraints are defined on the column.
- No edit procedure for the table can be defined with row attribute sensitivity.

For information about using multilevel security, see DB2 Administration Guide.

**IMPLICITLY HIDDEN**

Specifies that the column is not visible in the result for SQL statements unless you explicitly refer to the column by name. For example, assuming that the table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID. IMPLICITLY HIDDEN must not be specified for all columns of a table.

**INLINE LENGTH integer**

Specifies the maximum length for the column, if the column is a LOB column and the table is in a universal table space. INLINE LENGTH cannot be specified if the column is not a LOB column (or a distinct type that is based on a LOB) or if the table is not in a universal table space.

For BLOB and CLOB columns, integer specifies the maximum number of bytes that are stored in the base table space for the column. integer must be between 0 and 32680 (inclusive) for a BLOB or CLOB column.

For a DBCLOB column, integer specifies the maximum number of double-byte characters that are stored in the table space for the column. integer must be between 0 and 16340 (inclusive) for a DBCLOB column.

If INLINE LENGTH is specified, the value of integer cannot be greater than the maximum length of the LOB column.

If the INLINE LENGTH clause is not specified, the maximum length of the LOB column depends on the following conditions:

- If a distinct type is not used or the distinct type that is used has been created without the INLINE LENGTH attribute, the LOB column will use the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD as the default inline length when the value of LOB INLINE LENGTH does not exceed the maximum length of the LOB column. If the value of LOB INLINE LENGTH exceeds the maximum length of the LOB column, the maximum length is the inline length of this LOB column.
- If a distinct type that has been created with the INLINE LENGTH attribute is used, the LOB column inherits the inline length from the distinct type.

Regardless of how the length is determined, the inline length of the LOB cannot be greater than its maximum length.
**period-definition**

**PERIOD**

Defines a period for the table. `begin-column-name` must not be the same as `end-column-name`. The data type, length, precision, and scale for `begin-column-name` must be the same as for `end-column-name`.

**SYSTEM_TIME (begin-column-name, end-column-name)**

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME. A table can have only one SYSTEM_TIME period. `begin-column-name` must be defined as AS ROW BEGIN and `end-column-name` must be defined as AS ROW END.

**BUSINESS_TIME (begin-column-name, end-column-name)**

Defines an application period with the name BUSINESS_TIME. There must not be a column in the table with the name BUSINESS_TIME. A table can have only one BUSINESS_TIME period. `begin-column-name` and `end-column-name` must be defined as DATE or TIMESTAMP(6) WITHOUT TIME ZONE, and the columns must be defined as NOT NULL. `begin-column-name` and `end-column-name` must not identify a column that is defined with a GENERATED clause.

An implicit check constraint is generated to ensure that the value of `end-column-name` is greater than the value of `begin-column-name`. The name of the implicitly created check constraint is `DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME`, and that name must not be defined as the name of an existing check constraint.

**begin-column-name**

Identifies the column that records the beginning of the period of time in which a row is valid. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table. `begin-column-name` must not be the same as `end-column-name`. The data type and precision for `begin-column-name` must be the same as for `end-column-name`.

For a SYSTEM_TIME period, `begin-column-name` must be defined as AS ROW BEGIN.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

**end-column-name**

Identifies the column that records the end of the period of time in which a row is valid. In the history table that is associated with a system-period temporal table, the history table column that corresponds to `end-column-name` in the system-period temporal table is set to reflect the deletion of the row. The name must identify a column that exists in the table and must not be the same as a column that is used in the definition of another period for the table.

For a SYSTEM_TIME period, `end-column-name` must be defined as AS ROW END.

For a BUSINESS_TIME period, the column must not be defined with a GENERATED clause.

**unique-constraint**

**CONSTRAINT constraint-name**

Names the constraint. If a constraint name is not specified, a unique constraint
name is generated. If a name is specified, it must be different from the names
of any referential, check, primary key, or unique key constraints previously
specified on the table.

**PRIMARY KEY**(column-name,...)

Defines a primary key composed of the identified columns. The clause must
not be specified more than one time and the same column must not be
identified more than one time. The identified columns must be defined as NOT
NULL. Each column-name must be an unqualified name that identifies a
column of the table except for the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT
- an XML column
- a row change timestamp column
- a Unicode column in an EBCDIC table

The number of identified columns must not exceed 64. In addition, the sum of
the length attributes of the columns must not be greater than 2000 - 2m, where
m is the number of varying-length columns in the key.

The table is marked as unavailable until its primary index is explicitly created
unless the table space is explicitly created and the CREATE TABLE statement is
processed by the schema processor, or the table space is implicitly created. In
that case, DB2 implicitly creates an index to enforce the uniqueness of the
primary key and the table definition is considered complete. (For more
information about implicitly created indexes, see [implicitly created indexes](#))

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in
the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must
include at least one column-name or key-expression. When WITHOUT
OVERLAPS is specified, the values for the rest of the specified keys are unique
with respect to the time for the BUSINESS_TIME period. When
BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the
BUSINESS_TIME period must not be specified as part of the constraint. The
specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to
the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

**UNIQUE**(column-name,...)

Defines a unique key composed of the identified columns. Each column-name
must be an unqualified name that identifies a column of the table. Each
identified column must be defined as NOT NULL. The same column must not
be identified more than one time. The following types of columns cannot be
identified:

- a LOB column
- a ROWID column
- a DECFLOAT column
- a distinct type column that is based on a LOB, ROWID, or DECFLOAT
- a row change timestamp column
- a Unicode column in an EBCDIC table
The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than 2000 - 2m, where m is the number of varying-length columns in the key.

A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table is marked as unavailable until all the required indexes are explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In these cases, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see [implicitly created indexes].)

BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one column-name or key-expression. When WITHOUT OVERLAPS is specified, the values for the rest of the specified keys are unique with respect to the time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint. The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

**referential-constraint**

**CONSTRAINT** constraint-name

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**FOREIGN KEY (column-name,...) references-clause**

Each specification of the FOREIGN KEY clause defines a referential constraint.

The foreign key of the referential constraint is composed of the identified columns. Each column-name must be an unqualified name that identifies a column of the table. The same column cannot be identified more than one time. The column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column
- a Unicode column in an EBCDIC table

The number of identified columns must not exceed 64. The sum of the column length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and parent table are the same as the FOREIGN KEY and parent table of a previously defined referential constraint. The specification of a duplicate referential constraint is ignored with a warning.
The foreign key of the referential constraint cannot reference a parent key that contains BUSINESS_TIME WITHOUT OVERLAPS.

**REFERENCES table-name (column-name,...)**

The table name that is specified after REFERENCES must identify a table that exists at the current server\(^{36}\). The table name must not identify one of the following tables:

- A catalog table
- A declared global temporary table
- A history table
- An archive table

In the following discussion, let T2 denote an identified table and let T1 denote the table that you are creating (T1 and T2 cannot be the same table\(^{36}\)).

T2 must have a unique index. The privilege set must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key.

The parent key of the referential constraint is composed of the identified columns. Each column-name must be an unqualified name that identifies a column of T2. The same column must not be identified more than one time. The identified column cannot be any of the following types of columns:

- a LOB column
- a ROWID column
- a DECFLOAT column
- an XML column
- a row change timestamp column
- a security label column
- a Unicode column in an EBCDIC table

The list of column names in the parent key must match the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the same order as in the primary key or unique key. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2. The description of the \(n\)th column of the foreign key must be identical to the description of the \(n\)th column of the nominated parent key. The exception is that their names, default values, null attributes, and check constraints do not have to match. If the foreign key includes a column that is defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A field description is a description of the encoded value as it is stored in the database for a column that is defined to have an associated field procedure.

---

\(^{36}\) This restriction is relaxed when the statement is processed by the schema processor and the other table is created within the same CREATE SCHEMA.
The referential constraint that is specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

**ON DELETE**

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see "Referential constraints" on page 25.

SET NULL must not be specified unless some column of the foreign key allows null values. The default value for the rule depends on the value of the CURRENT RULES special register when the CREATE TABLE statement is processed. If the value of the register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'STD', the delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let \( p \) denote such a row of T2. Then:

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of \( p \) in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of \( p \) in T1 is set to null.

Let T3 denote a table identified in another FOREIGN KEY clause (if any) of the CREATE TABLE statement. The delete rules of the relationships involving T2 and T3 must be the same and must not be SET NULL if:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendents of the same table and the deletion of rows from that table cascades to both T2 and T3.

**ENFORCED or NOT ENFORCED**

Indicates whether or not the referential constraint is enforced by DB2 during normal operations, such as insert, update, or delete.

**ENFORCED**

Specifies that the referential constraint is enforced by the DB2 during normal operations (such as insert, update, or delete) and that it is guaranteed to be correct. This is the default.

**NOT ENFORCED**

Specifies that the referential constraint is not enforced by DB2 during normal operations, such as insert, update, or delete. This option should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on the database manager.

**ENABLE QUERY OPTIMIZATION**

Specifies that the constraint can be used for query optimization. DB2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

**check-constraint**

**CONSTRAINT constraint-name**

Names the check constraint. The constraint name must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.
If `constraint-name` is not specified, a unique constraint name is derived from the name of the first column in the `check-condition` specified in the definition of the check constraint.

**CHECK** *(check-condition)*

Defines a check constraint. At any time, the `check-condition` must be true or unknown for every row of the table. A `check-condition` can evaluate to unknown if a column that is an operand of the predicate is null. A `check-condition` that evaluates to unknown does not violate the check constraint. A `check-condition` is a search condition, with the following restrictions:

- It can refer only to columns of table `table-name`.
- The columns cannot be the following types of columns:
  - LOB columns
  - ROWID columns
  - DECIMAL columns
  - distinct type columns that are based on LOB, ROWID, and DECIMAL data types
  - XML columns
  - security label columns
  - Unicode columns in an EBCDIC table
- It can be up to 3800 bytes long, not including redundant blanks.
- It must not contain any of the following:
  - Subselects
  - Built-in or user-defined functions
  - CAST specifications
  - Cast functions other than those created when the distinct type was created
  - Host variables
  - Parameter markers
  - Special registers
  - Global variables
  - Columns that include a field procedure
  - CASE expressions
  - ROW CHANGE expressions
  - Row expressions
  - DISTINCT predicates
  - GX constants (hexadecimal graphic string constants)
  - Sequence references
  - OLAP specifications
- If a `check-condition` refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the `check-condition` must be either a constant or a column name of a column in the table.
  - If the second operand of a predicate is a constant, and if the constant is:
- A floating-point number, then the column data type must be floating point.
- A decimal number, then the column data type must be either floating point or decimal.
- An integer number, then the column data type must not be a small integer.
- A small integer number, then the column data type must be small integer.
- A decimal constant, then its precision must not be larger than the precision of the column.
- If the second operand of a predicate is a column, then both columns of the predicate must have:
  - The same data type.
  - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes.

LIKE

```
table-name or view-name
```

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view.

The name that is specified after LIKE must identify a table or view that exists at the current server or a declared temporary table. A view cannot contain columns of length 0.

```
table-name
```

must not contain a Unicode column in an EBCDIC table.

The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view. If the identified table or view contains a column with a distinct type, the USAGE privilege on the distinct type is also needed. An identified table must not be an auxiliary table or a clone table. An identified view must not include a column that is an explicitly defined ROWID column (including a distinct type that is based on a ROWID), an identity column, or a row change timestamp column.

The use of LIKE is an implicit definition of \( n \) columns, where \( n \) is the number of columns in the identified table (including implicitly hidden columns) or view. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition includes all attributes of the \( n \) columns as they are described in SYSCOLUMNS with the following exceptions:

- When a table is identified in the LIKE clause and a column in the table has a field procedure, the corresponding column of the new table has the same field procedure and the field description. However, the field procedure is not invoked during the execution of the CREATE TABLE statement. When a view is identified in the LIKE clause, none of the columns of the new table will have a field procedure. This is true even in the case that a column of a base table underlying the view has a field procedure defined.
- When a table is identified in the LIKE clause and a column in the table is an identity column, the corresponding column of the new table inherits only the data type of the identity column; none of the identity attributes of the column are inherited unless the INCLUDING IDENTITY clause is specified.
• When a table is identified in the LIKE clause and a column in the table is a security label column, the corresponding column of the new table inherits only the data type of the security label column; none of the security label attributes of the column are inherited.

• When a table is identified in the LIKE clause and the table contains a ROWID column (explicitly-defined or implicitly hidden), the corresponding columns of the new table inherit the ROWID columns.

• When a table is identified in the LIKE clause and the table contains row change timestamp column, a transaction-start-ID column, a row-begin column, or a row-end column, the corresponding column of the new table inherits only the data type of the original column. The new column is not considered a generated column.

• When a table is identified in the LIKE clause and a column in the table is a generated expression column, the corresponding column of the new table inherits only the data type of the original column. The new column is not considered a generated column.

• When a table is identified in the LIKE clause and the table contains an inline LOB column, the corresponding columns of the new table will inherit the inline attribute if the table is in an universal table space. Otherwise, the inline attribute of the table identified in the LIKE clause is ignored.

• When a view is identified in the LIKE clause, the default value that is associated with the corresponding column of the new table depends on the column of the underlying base table for the view. If the column of the base table does not have a default, the new column does not have a default. If the column of the base table has a default, the default of the new column is:
  – Null if the column of the underlying base table allows nulls.
  – The default for the data type of the underlying base table if the underlying base table does not allow nulls.

The above defaults are chosen regardless of the current default of the base table column. The existence of an INSTEAD OF trigger does not affect the inheritance of default values.

• When a table that uses table-controlled partitioning is identified in the LIKE clause, the new table does not inherit partitioning scheme of that table. You can add these partition boundaries by specifying ALTER TABLE with the ADD PARTITION BY RANGE clause.

• The CCSID of the column is determined by the implicit or explicit CCSID clause. For more information, see the CCSID clause.

• When a table is identified in the LIKE clause and the table includes a period, the new table does not inherit the period.

• When the table that is identified in the LIKE clause is a system-period temporal table, the new table is not a system-period temporal table.

• When the table that is identified in the LIKE clause has row access controls or column access controls activated, the new table does not inherit the row access controls or the column access controls.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.
**copy-options**

Specifies whether identity column attributes, row change timestamp attributes, and column defaults are inherited from the definition of the source of the result table.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited from the definition of the source of the result table.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that identity column attributes are not inherited from the definition of the source of the result table. This is the default.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that, if available, identity column attributes (such as START WITH, INCREMENT BY, and CACHE values) are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or fullselect is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table with the identity attribute. In other cases, the columns of the new temporary table do not inherit the identity attributes. The columns of the new table do not inherit the identity attributes in the following cases:

- The select list of the fullselect includes multiple instances of an identity column name (that is, selecting the same column more than one time).
- The select list of the fullselect includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The fullselect includes a set operation.

**EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies whether row change timestamp column attributes are inherited from the definition of the source of the result table.

**EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies that row change timestamp column attributes are not inherited from the source result table definition. This is the default.

**INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies that, if available, row change timestamp column attributes are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or fullselect is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table defined as a row change timestamp column. In other cases, the columns of the new temporary table do not inherit the row change timestamp column attributes. The columns of the new table do not inherit the row change timestamp attributes in the following cases:

- The select list of the fullselect includes multiple instances of a row change timestamp column name (that is, selecting the same column more than one time).
- The select list of the `fullselect` includes multiple row change timestamp column names (that is, it involves a join).
- The row change timestamp column is included in an expression in the select list.
- The `fullselect` includes a set operation (such as union).

**EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS**

Specifies whether column defaults are inherited from the source result table definition. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

**EXCLUDING COLUMN DEFAULTS**

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert or update operation, or LOAD for the new table.

**INCLUDING COLUMN DEFAULTS**

Specifies that column defaults for each updatable column of the definition of the source table are inherited. Columns that are not updatable do not have a default defined in the corresponding column of the created table. The existence of an INSTEAD OF trigger for a view does not affect the inheritance of default values.

**USING TYPE DEFAULTS**

Specifies that the default values for the table depend on data type of the columns that result from `fullselect`, as follows:

- **Data type**
  - Default value

  **Numeric**
  - 0
  **Fixed-length character string**
  - Blanks
  **Fixed-length graphic string**
  - Blanks
  **Fixed-length binary string**
  - Hexadecimal zeros
  **Varying-length string**
  - A string of length 0
  **Fixed-length char or fixed-length graphic**
  - A string of blanks
  **Fixed-length binary**
  - Hexadecimal zeros

- **Date**
  - CURRENT DATE

- **Time**
  - CURRENT TIME

- **Timestamp** without time zone
  - CURRENT TIMESTAMP(p) WITHOUT TIME ZONE where p is the corresponding timestamp precision.

- **Timestamp** with time zone
  - CURRENT TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.
as-result-table

Specifies that the column definitions of the table are based on the result of the fullselect.

column-name

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each column-name must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the fullselect.

A list of column names must be specified if the result table of the fullselect has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause.

AS (fullselect)

Specifies that the table definition is based on the column definitions from the result of the fullselect. The use of AS (fullselect) is an implicit definition of n columns for the table, where n is the number of columns that would result from the fullselect. The columns of the new table are defined by the columns that result from the fullselect. Every select list element must have a unique name. The AS clause can be used in the select-clause to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of fullselect. The length of each column must not be 0. Other column attributes, such as DEFAULT and IDENTITY, are not inherited from the fullselect. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the fullselect is not considered hidden in the new table. The generated column attributes are not inherited from the fullselect. That is, a new column of the table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the fullselect is a column that can be mapped to a column of a base table or a view. The new table contains a security label column if only one table in the fullselect contains a security label column and the primary authorization ID of the statement has a valid security label.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations:

• Ownership of the tables or views referenced in the fullselect
• The SELECT privilege on the tables and views referenced in the fullselect
• SYSADM authority
• DBADM authority for the database in which the tables of the fullselect reside

The fullselect must not:
• Result in a column having a ROWID, BLOB, CLOB, DBCLOB, or XML data type or a distinct type based on these data types.
• Include multiple security label columns.
• Include a PREVIOUS VALUE or a NEXT VALUE expression.
• Refer to host variables or include parameter markers.
• Include an SQL data change statement in the FROM clause.
• Reference data that is encoded with different CCSID sets.
• Result in a column that is an array.
• Reference a remote object.

WITH NO DATA
Specifies that the query is used only to define the attributes of the new table. The table is not populated using the results of the fullselect and the REFRESH TABLE statement cannot be used.

If the tables that are specified in the use row access controls or column access controls, the row access controls and the column access controls are not defined for the new table.

materialized-query-definition

materialized-query-definition
Specifies that the column definitions of the materialized query table are based on the result of a fullselect. If materialized-query-table-options are specified, the REFRESH TABLE statement can be used to populate the table with the results of the fullselect.

column-name
Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each column-name must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the fullselect.

A list of column names must be specified if the result table of the fullselect has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

AS (fullselect)
Specifies that the table definition is based on the column definitions from the result of the fullselect. The use of AS (fullselect) is an implicit definition of n columns for the table, where n is the number of columns that would result from the fullselect. The columns of the new table are defined by the columns that result from the fullselect. Every select list element must have a unique name. The AS clause can be used in the select-clause to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of fullselect. The length of each column must not be a 0. Other column attributes, such as DEFAULT, IDENTITY, and unique constraints, are not inherited from the fullselect. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the fullselect is
not considered hidden in the new table. The generated column attributes are not inherited from the \textit{fullselect}. That is, the new column of the materialized query table is not considered as a generated column. A \texttt{FIELDPROC} is inherited for a column if the corresponding select item of the \textit{fullselect} is a column that can be directly mapped to a column of a base table or a view in the FROM clause of the \textit{fullselect}. The materialized query table contains a security label column if only one table in the \textit{fullselect} contains a security label column and the primary authorization ID of the statement has a valid security label.

\textbf{Authorization for creating materialized query tables:}

The owner of the table being created must have the \texttt{SELECT} privilege on the tables or views referenced in the \textit{fullselect}, or the privilege set must include \texttt{SYSADM} or \texttt{DBADM} authority for the database in which the tables of the \textit{fullselect} reside. Having \texttt{SELECT} privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the \textit{fullselect}
- The \texttt{SELECT} privilege on the tables and views referenced in the \textit{fullselect}
- \texttt{SYSADM} authority
- \texttt{DBADM} authority for the database in which the tables of the \textit{fullselect} reside

The rules for establishing the qualifiers for names used in the \textit{fullselect} are the same as the rules used to establish the qualifiers for \textit{table-name}.

The following restrictions apply when creating materialized query tables. When \textit{fullselect} does not satisfy the restrictions, an error occurs:

\textbf{General restrictions:} The following restrictions apply:

- The length of each result column of the \textit{fullselect} must not be 0.
- The \textit{fullselect} cannot contain a column of a LOB or XML data type.
- No more than one table in the \textit{fullselect} can contain a security label column.
- The \textit{fullselect} must not contain a period specification.
- The object that is specified in the FROM clause of the \textit{fullselect} cannot be a view with columns of length 0.
- The \textit{fullselect} cannot contain a reference to a created global temporary table, a declared global temporary table, or another materialized query table.
- The \textit{fullselect} cannot directly or indirectly reference a base table that has been activated for the row or column access control or a base table for which a row permission or a column mask has been defined.
- The \textit{fullselect} must not refer to host variables or include parameter markers.
- The \textit{fullselect} must not refer to global variables.

\textbf{Additional restrictions when ENABLE QUERY OPTIMIZATION is in effect:}

- The \textit{fullselect} must be a subselect.
- The outermost SELECT list of the subselect must not reference data that is encoded with different CCSID sets.
• The subselect cannot include the following:
  - A special register
  - A scalar fullselect
  - A row change timestamp column
  - A ROW CHANGE expression
  - An expression for which implicit time zone values apply (for example, cast a timestamp to a timestamp with time zone)
  - The RAND built-in function
  - The RID built-in function
  - A user-defined scalar or table function that is not deterministic or that has external actions
  - Any predicates that include a subquery
  - A row expression predicate
  - A join using the INNER JOIN syntax, or an outer join
  - A lateral correlation
  - A nested table expression or view that requires temporary materialization
  - A direct or indirect reference to a table that uses activated row or column access controls, or a table for which row or column access controls have been defined.
  - A FETCH FIRST clause
  - A reference to a global variable
  - A collection-derived table (UNNEST)
  - A GROUPING SETS or super-groups clause

• If a table with a security label is referenced, the security label column must be referenced in the outer select list of the subselect.

• If the subselect references a view, the fullselect in the view definition must satisfy all other restrictions.

refreshable-table-options
Specifies the options for a refreshable materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

DATA INITIALLY DEFERRED
Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a user-maintained materialized query table.

REFRESH DEFERRED
Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated for a user-maintained materialized query table.

MAINTAINED BY SYSTEM or MAINTAINED BY USER
Specifies how the data in the materialized query table is maintained.
MAINTAINED BY SYSTEM
Specifies that the materialized query table is maintained by the system. Only the REFRESH statement is allowed on the table. This is the default.

MAINTAINED BY USER
Specifies that the materialized query table is maintained by the user, who can use the LOAD utility, an SQL data change statement, a SELECT from data change statement, or REFRESH TABLE SQL statements on the table.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION
Specifies whether this materialized query table can be used for optimization.

ENABLE QUERY OPTIMIZATION
Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs.

ENABLE QUERY OPTIMIZATION is the default.

The fullselect must not contain a period specification.

DISABLE QUERY OPTIMIZATION
Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

IN
Identifies the database and table space in which the table is created. Both forms are optional.

If you specify both a database and a table space, the database must be described in the catalog on the current server. The database must not be DSNDB06 or a work file database. The table space must belong to the database that you specify and must not be an XML table space.

If you specify a database but not a table space, a table space is implicitly created in database-name. The name of the table space is derived from the name of the table. The qualifier of the table space is the same as the qualifier of the table. The buffer pool that is used is the default buffer pool for user data that is specified on installation panel DSNTIP1. If you specify a table space but not a database, the database that contains the table space is used.

If you specify neither a table space or a database, a database is implicitly created with the name DSNxxxxx, where xxxx is a five-digit number. A table space is also implicitly created.

If you specify a table space, it cannot be one of the following table spaces:

- A table space that was created implicitly
- A partitioned or a partition-by-growth table space that already contains a table
- A LOB table space
- A table space that already contains a system-period temporal table, a history table, an archive-enabled table, or an archive table

If you specify a partitioned table space, you cannot load or use the table until its partitioned scheme is created.
You cannot specify the name of an implicitly created database. That is, you specify a database name that is eight characters, DSNxxxx, where xxxx is a five-digit number.

To create a table space implicitly, the privilege set must have: SYSADM or SYSCTRL authority; DBADM, DBCTRL, or DBMAINT authority for the database; or the CREATETS privilege for the database. You must also have the USE privilege for the default buffer pool in the database and default storage group.

If you specify a table space name, you must have SYSADM or SYSCTRL authority, DBADM authority for the database, or the USE privilege for the table space.

**partitioning-clause block**

**PARTITION BY RANGE or PARTITION BY SIZE**

Specifies the partitioning scheme for the table.

**PARTITION BY RANGE**

Specifies the range partitioning scheme for the table (the columns that are used to partition the data). When this clause is specified, the table space is complete, and it is not necessary to create a partitioned index on the table. If this clause is used, the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

If this clause is specified, the IN `database-name.table-space-name` clause is required. This clause applies only to tables in a partitioned table space. PARTITION BY RANGE must not be specified for a table that is created in a partition-by-growth table space.

**partition-expression**

Specifies the key data over which the range is defined to determine the target data partition of the data.

**column-name**

Specifies the columns of the key. Each `column-name` must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. The sum of length attributes of the columns must not be greater than 255 - n, where n is the number of columns that can contain null values. Do not specify a qualified column name.

A timestamp with time zone column (or a column with a distinct type that is based on the timestamp with time zone data type) can only be specified as the last column in a partitioning key.

Do not specify a column for `column-name` if the column is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a BINARY column (or a column with a distinct type that is based on a BINARY data type)
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- an XML column
- a row change timestamp column
nulls last
  specifies that null values are treated as positive infinity for
  purposes of comparison.

asc
  puts the entries in ascending order by the column. asc is the
default.

desc
  puts the entries in descending order by the column.

partition-element
  specifies ranges for a data partitioning key and the table space where
  rows of the table in the range will be stored.

partition integer
  integer is the physical number of a partition in the table space. a
  partition clause must be specified for every partition of the
  table space. in this context, highest means highest in the sorting
  sequences of the columns. in a column defined as ascending (asc),
  highest and lowest have their usual meanings. in a column defined
  as descending (desc), the lowest actual value is highest in the
  sorting sequence.

ending at (constant, maxvalue, or minvalue, ...)
  defines the limit key for a partition boundary. specify at least one
  value (constant, maxvalue, or minvalue) after ending at in
  each partition clause. you can use as many values as there are
  columns in the key. the concatenation of all values is the highest
  value of the key for ascending and the lowest for descending.

constant
  specifies a constant value with a data type that must conform
  to the rules for assigning that value to the column. if a string
  constant is longer or shorter than required by the length
  attribute of its column, the constant is either truncated or
  padded on the right to the required length. if the column is
  ascending, the padding character is x'ff'. if the column is
  descending, the padding character is x'00'. the precision and
  scale of a decimal constant must not be greater than the
  precision and scale of its corresponding column. a hexadecimal
  string constant (gx) cannot be specified.

maxvalue
  specifies a value greater than the maximum value for the limit
  key of a partition boundary (that is, all x'ff' regardless of
  whether the column is ascending or descending). if all of the
  columns in the partitioning key are ascending, a constant or
  the minvalue clause cannot be specified following
  maxvalue. after maxvalue is specified, all subsequent
  columns must be maxvalue.

minvalue
  specifies a value that is smaller than the minimum value for
  the limit key of a partition boundary (that is, all x'00'
  regardless of whether the column is ascending or descending).
  if all of the columns in the partitioning key are descending, a
  constant or the maxvalue clause cannot be specified
following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:
- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition for ascending cases.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value specified for the last partition are out of range.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- If a null value is specified for the partitioning key and the key is ascending, an error is returned unless MAXVALUE is specified. If the key is descending, an error is returned unless MINVALUE is specified.

**HASH SPACE** integerK|M|G

Specifies the amount of fixed hash space to preallocate for the partition that is associated with the partition-element. If HASH SPACE is omitted from the partition element, the HASH SPACE value from the ORGANIZE BY clause is used.

If HASH SPACE is not specified, each partition will use the HASH SPACE value specified in organization-clause.

The HASH SPACE keyword in partition-element must only be specified if organization-clause is also specified.

K Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

M Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

G Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 256 for a partition by range table and must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.
INCLUSIVE
Specifies that the specified range values are included in the data partition.

PARTITION BY SIZE
Specifies that the table is created in a partition-by-growth table space. If the IN clause is also specified, the IN clause must identify a partition-by-growth table space.

EVERY integer G
Specifies that the table is to be partitioned by growth, every integer G bytes. integer must not be greater than 256. If the IN clause identifies a table space, integer must be the same as the DSSIZE value that is in effect for the table space that will contain the table.

organization-clause

ORGANIZE BY HASH
Specifies that a hash is to be used for the data organization of the table.

If PARTITION BY RANGE is specified, and the IN clause specifies a table space, the table space must be a partition by range universal table space.

If PARTITION BY RANGE is not specified, and an IN clause is specified, the IN clause must identify a partition-by-growth universal table space.

ORGANIZE BY HASH must not be specified if the table is defined with APPEND YES.

ORGANIZE BY HASH must not be specified if the table is using basic row format.

UNIQUE
Specifies that DB2 enforces uniqueness of the hash key columns, preventing the table from containing two or more rows with the same value of the hash key.

(column-name,...)

The list of column names defines the hash key that is used to determine where a row will be placed. Each column-name must be an unqualified name that identifies a column of the table. The same column must not be specified more than once and the specified columns must be defined as NOT NULL. The number of specified columns must not exceed 64, and the sum of their length attributes must not exceed 255. A specified column cannot be any of the following types:

- a LOB column
- a DECFLOAT column
- a XML column
- a distinct type column that is based on one of the preceding data types
- a Unicode column in an EBCDIC table

If PARTITION BY RANGE is also specified, the list of column names must specify all of the column names that are specified in partition-expression for the table, and must specify the column names in the same order as partition-expression. If the ORGANIZE BY clause contains more columns than partition-expression, partition-expression determines the partition number.
HASH SPACE \textit{integer}K|M|G

Specifies the amount of fixed hash space to preallocate for the table. If the table is partitioned by range, this is the space for each partition.

The default is 64M for a table in a partition-by-growth universal table space or 64M for each partition of a partition by range universal table space.

\textbf{K} Indicates that the integer value is to be multiplied by 1024 to specify the hash space size in bytes. The integer must be between 256 and 268435456.

\textbf{M} Indicates that the integer value is to be multiplied by 1048576 to specify the hash space size in bytes. The integer must be between 1 and 262144.

\textbf{G} Indicates that the integer value is to be multiplied by 1073741824 to specify the hash space size in bytes. The integer must be between 1 and 131072 for a non-partitioned table.

If a value greater than 4G is specified, the data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

\textbf{Other options}

\textbf{EDITPROC} \textit{program-name}

Identifies the user-written code that implements the edit procedure for the table. The edit procedure must exist at the current server. The procedure is invoked during the execution of an SQL data change statement or LOAD and all row retrieval operations on the table.

An edit routine receives an entire table row, and can transform that row in any way. Also, it receives a transformed row and must change the row back to its original form.

You must not specify an edit routine for a table with a LOB column, or for an EBCDIC table with a Unicode column.

For information on writing an EDITPROC exit routine, see \textit{Edit procedures} (DB2 Administration Guide).

\textbf{WITH ROW ATTRIBUTES}

Specifies that the edit procedure parameter list contains an address for the description of a row. \text{WITH ROW ATTRIBUTES} must not be specified for a table with an identity, LOB, XML, ROWID, or SECURITY LABEL column. \text{WITH ROW ATTRIBUTES} is the default. When \text{WITH ROW ATTRIBUTES} is specified, the column names in the table must not be longer than 18 EBCDIC SBCS characters in length.

\textbf{WITHOUT ROW ATTRIBUTES}

Specifies that the description of the row is not provided to the edit procedure. On entry to the edit procedure, the address for the row description in the parameter list contains a value of zero.

\textbf{VALIDPROC} \textit{program-name}

Designates \textit{program-name} as the validation exit routine for the table. Writing a validation exit routine is described in \textit{Validation routines} (DB2 Administration Guide).
The validation routine can inhibit a load, insert, update, or delete operation on any row of the table: before the operation takes place, the procedure is passed the row. The values that are represented by any LOB or XML columns in the table are not passed to the validation routine. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. In an ALTER TABLE statement, you can designate a replacement procedure or discontinue the use of a validation procedure.

If you omit VALIDPROC, the table has no validation routine.

You must not specify a validation routine for an EBCDIC table with a Unicode column.

**AUDIT**

Identifies the types of access to this table that causes auditing to be performed. For information about audit trace classes, see *DB2 Administration Guide*.

If a materialized query table is refreshed with the REFRESH TABLE statement, the auditing also occurs during the REFRESH TABLE operation. **AUDIT** works as usual for LOAD and SQL data change operations on a user-maintained materialized query table.

**NONE**

Specifies that no auditing is to be done when this table is accessed. This is the default.

**CHANGES**

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

**ALL**

Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

If the table is subsequently altered with an ALTER TABLE statement, the ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- **AUDIT** attribute is changed to **NONE**, **CHANGES**, or **ALL** on an audited or non-audited table.
- **AUDIT CHANGES** or **AUDIT ALL** is in effect.

**OBID integer**

Identifies the OBID to be used for this table. An OBID is the identifier for an object's internal descriptor. The integer must be greater than 1 and must not identify an existing or previously used OBID of the database. If you omit OBID, DB2 generates a value.

The following statement retrieves the value of OBID:

```sql
SELECT OBID
FROM SYSIBM.SYSTABLES
WHERE CREATOR = 'ccc' AND NAME = 'nnn';
```
Here, \textit{nnn} is the table name and \textit{ccc} is the creator of the table.

\textbf{DATA\ CAPTURE}\n
Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause of the ALTER TABLE statement)
- Changing columns (using the ALTER COLUMN clause of the ALTER TABLE statement)

For guidance on intended uses of the expanded log records, see:

- The description of data propagation to IMS in \textit{IMS DataPropagator: An Introduction}
- The instructions for using Remote Recovery Data Facility (RRDF) in \textit{Remote Recovery Data Facility Program Description and Operations}
- The instructions for reading log records in \textit{DB2 Administration Guide}

If a materialized query table is refreshed with the \texttt{REFRESH\ TABLE} statement, the logging of the augmented information occurs during the \texttt{REFRESH\ TABLE} operation. DATA\ CAPTURE\ works as usual for insert, update, and delete operations on a user-maintained materialized query table.

\textbf{NONE}\n
Do not record additional information to the log. This is the default.

\textbf{CHANGES}\n
Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA\ CAPTURE\ CHANGES for tables that reside in table spaces that specify NOT\ LOGGED.

\textbf{WITH\ RESTRICT\ ON\ DROP}\n
Indicates that the table can be dropped only by using REPAIR\ DBD\ DROP. In addition, the database and table space that contain the table can be dropped only by using REPAIR\ DBD\ DROP.

The WITH\ RESTRICT\ ON\ DROP clause can be removed using the ALTER TABLE statement with the DROP\ RESTRICT\ ON\ DROP clause. After the WITH\ RESTRICT\ ON\ DROP clause is removed from the definition of the table, the table, the database, and the containing table space can be dropped using the DROP\ statement.

\textbf{CCSID\ encoding\-scheme}\n
Specifies the encoding scheme for string data stored in the table. If the IN clause is specified with a table space, the value must agree with the encoding scheme that is already in use for the specified table space. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the table space or database specified in the IN clause. If the IN clause is not specified, the value specified is used for the table being created as well as for the table space that DB2 implicitly creates. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

If the CCSID clause is not specified, the encoding scheme for the table depends on the IN clause:

- If the IN clause is specified, the encoding scheme already in use for the table space or database specified in the IN clause is used.
• If the IN clause is not specified, the encoding scheme of the new table is the same as the scheme for the table that is specified in the LIKE clause.

If the CCSID clause is specified for a materialized query table, the encoding scheme specified in the clause must be the same as the scheme for the result CCSID of the fullselect. The CCSID must also be the same as the CCSID of the table space for the table being created.

**VOLATILE or NOT VOLATILE**

Specifies how DB2 is to choose access to the table.

**VOLATILE**

Specifies that index access should be used on this table whenever possible for SQL operations.

One instance in which you might want to use VOLATILE is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows. Another instance in which you might want to use VOLATILE is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation.

**NOT VOLATILE**

Specifies that SQL access to this table should be based on the current statistics. NOT VOLATILE is the default.

**CARDINALITY**

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

**LOGGED or NOT LOGGED**

Specifies whether changes that are made to the data in the implicitly created table space are recorded in the log. This parameter applies to the implicitly created table space and to all indexes of this table. XML table spaces and indexes associated with the XML table spaces inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

Do not specify LOGGED or NOT LOGGED if the table space name is specified by using the IN table-space-name clause.

**LOGGED**

Specifies that changes that are made to the data in the implicitly created table space are recorded in the log.

**LOGGED** is the default.

**NOT LOGGED**

Specifies that changes that are made to data in the implicitly created table space are not recorded in the log.

**NOT LOGGED** prevents undo and redo information from being recorded in the log. However, control information for the implicitly created table space will continue to be recorded in the log.
**COMPRESS YES or COMPRESS NO**

Specifies whether data compression applies to the rows of the implicitly created table space. The default is specified by the value of the subsystem parameter USE DATA COMPRESSION.

Do not specify **COMPRESS YES** or **COMPRESS NO** if the table space name is specified by using the **IN table-space-name** clause.

**COMPRESS YES**

Specifies that data compression applies to the rows of the implicitly created table space. The rows are not compressed until the LOAD or REORG utility is run on the table in the implicitly created table space.

**COMPRESS NO**

Specifies that data compression is not used for the rows of the implicitly created table space.

**APPEND NO or APPEND YES**

Specifies whether append processing is used for the table. The **APPEND** clause must not be specified for a table that is created in a work file table space.

**NO**

Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row’s cluster key column.

**NO** is the default.

**YES**

Specifies that data rows are to be placed into the table by disregarding the clustering during insert and LOAD operations.

**DSSIZE integer G**

Specifies the maximum size for the implicitly created partition-by-growth or range-partitioned universal table space. This value is only applied to the implicitly created base table space, not to any associated implicitly created XML or LOB table spaces.

Do not specify **DSSIZE integer G** if any of the following conditions are true:

- The table space name is specified by using the **IN table-space-name** clause.
- The **PARTITION BY** clause includes the **EVERY integer-constant G** clause.

The default is specified by the value of the subsystem parameter MAXIMUM PARTITION SIZE.

For more detailed information about the **DSSIZE** clause, refer to "CREATE TABLESPACE" on page 1517.

**BUFFERPOOL bpname**

Specifies the buffer pool be use for the implicitly created table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively.

**bpname** must identify an activated buffer pool. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege on the buffer pool.

Do not specify **BUFFERPOOL bpname** if the table space name is specified by using the **IN table-space-name** clause.

If you do not specify the **BUFFERPOOL** clause for an implicitly created table space, the default buffer pool of the database is used unless the record length
exceeds the page size. If the record length exceeds the page size, do not specify the BUFFERPOOL clause. In this case, DB2 will choose a suitable buffer pool for the implicitly table space.

Refer to “Naming conventions” on page 59 for more information about bpname.

**MEMBER CLUSTER**

Specifies that data that is inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. DB2 places the data in the implicitly created table space based on available space.

Do not specify **MEMBER CLUSTER** if the table space name is specified by using the IN table-space-name clause.

**TRACKMOD YES or TRACKMOD NO**

Specifies whether DB2 tracks modified pages in the space map pages of the implicitly created table space. The default is specified by the value of the subsystem parameter TRACK MODIFIED PAGES.

Do not specify **TRACKMOD YES** or **TRACKMOD NO** if the table space name is specified by using the IN table-space-name clause.

**TRACKMOD YES**

Changed pages are tracked in the space map pages to help improve performance of incremental image copies.

**TRACKMOD NO**

Changed pages are not tracked in the space map pages. DB2 uses the LRSN value in each page to determine whether a page has been changed.

**Notes**

**Owner privileges:**

The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 1786) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, permissions, masks, and object ownership” on page 72.

**Table design:**

Designing tables is part of the process of database design. For information on design, see *Introduction to DB2 for z/OS*.

**Creating a table in a segmented table space:**

A table cannot be created in a segmented table space if any of the following conditions are true:

- The available space in the data set is less than the segment size specified for the table space, and
- The data set cannot be extended.

**Creating a table with graphic and mixed data columns:**

You cannot create an ASCII or EBCDIC table with a GRAPHIC, VARGRAPHIC, or DBCLOB column or a CHAR, VARCHAR, or CLOB column defined as FOR MIXED DATA when the setting for installation option MIXED DATA is NO.

**Creating a table with distinct type columns based on LOB, ROWID, and DECFLOAT columns:**

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB columns (CLOB, DBCLOB, and BLOB), ROWID columns, and DECFLOAT columns apply to distinct type
columns that are based on LOBs, row IDs, and DECFLOATs. For example, a table cannot have both an explicitly defined ROWID column and a column with a distinct type that is based on a row ID.

Tables with inline LOB columns:
If the 32K page size is exceeded for a table in an universal table space, DB2 recalculates the record size using 0 as the inline length for LOB columns that do not specify the INLINE LENGTH clause. After the recalculation, if the 32K page size is still exceeded, the CREATE TABLE statement returns an error.

You cannot create a table with an inline LOB column in a table space that has basic row format.

Creating a table with LOB columns:
A table with a LOB column (CLOB, DBCLOB, or BLOB) must also have a ROWID column and one or more auxiliary tables. When you create the table, DB2 implicitly generates a ROWID column for you. This is called an implicitly hidden ROWID column, and DB2:

- Creates the column with a name of DB2_GENERATED_ROWID_FOR_LOBSnn.
  DB2 appends nn only if the column name already exists in the table, replacing nn with 00 and incrementing by 1 until the name is unique within the row.
- Defines the column as GENERATED ALWAYS.
- Appends the implicitly hidden ROWID column to the end of the row after all the other explicitly defined columns.

For example, assume that DB2 generated an implicitly hidden ROWID column named DB2_GENERATED_ROWID_FOR_LOBS for table MYTABLE. The result table for a SELECT * statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2_GENERATED_ROWID_FOR_LOBS would include the implicitly hidden ROWID column.

If the MIXED DATA subsystem parameter is set to yes, and a lowercase or mixed case hexadecimal constant is specified as the default value for a LOB column, the CREATE TABLE statement returns an error.

The definition of the table is marked incomplete until an auxiliary table is created in a LOB table space for each LOB column in the base table and index is created on each auxiliary table. The auxiliary table stores the actual values of a LOB column. If you create a table with a LOB column in a partitioned table space, there must be one auxiliary table defined for each partition of the base table space.

Unless DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table, you need to create these objects using the CREATE TABLESPACE, CREATE AUXILIARY TABLE, and CREATE INDEX statements.

If the table space that contains the table is explicitly created and the value of the CURRENT RULES special register is ‘STD’ when the CREATE TABLE statement is processed, or the table space that contains the table is implicitly created, DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table.

The privilege set must include the following privileges:
The USE privilege on the buffer pool and the storage group that is used by the XML objects
If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

DB2 chooses the names of implicitly created objects using these conventions:

LOB table space
Name is 8 characters long, consisting of an ‘L’ followed by 7 random characters.

auxiliary table
Name is 18 characters long. The first five characters of the name are the first five characters of the name of the base table. The second five characters are the first five characters of the name of the LOB column. The last eight characters are randomly generated. If a base table name or a LOB column name is less than five characters, DB2 adds underscore characters to the name to pad it to a length of five characters.

index on the auxiliary table
Name is 18 characters long. The first character of the name is an ‘I’. The next ten characters are the first ten characters of the name of the auxiliary table. The last seven characters are randomly generated. The index has the COPY NO attribute.

The other attributes of these implicitly created objects are those that would have been created by their respective CREATE statements with all optional clauses omitted, with the following exceptions:
• The database name is the database name of the base table.
• If the LOB table space is implicitly created, the buffer pool is determined by the DEFAULT BUFFER POOL FOR USER LOB DATA fields of installation panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

Utility REPORT TABLESPACESET identifies the LOB table spaces that DB2 implicitly created.

Creating a table with an XML column:
When a table is created with an XML column, an XML table space, XML table, and a node ID index and document ID index are implicitly created. The privilege set must include the following privileges:
• The USE privilege on the buffer pool and the storage group that is used by the XML objects
• If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

The buffer pool for the XML table space is determined by the DEFAULT BUFFER POOL FOR USER XML DATA fields of installation panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

The XML table space will have a larger DSSIZE than the base table space if the base table space is partitioned by range. If the base table space is partitioned by growth, the default DSSIZE of 4GB will be used for the XML table space. The DSSIZE for an XML table space that is associated with a partitioned by range base table space is determined as follows.
Table 125. Default DSSIZE for XML table spaces, given base table space DSSIZE and page size

<table>
<thead>
<tr>
<th>Base table space DSSIZE</th>
<th>4KB base page size</th>
<th>8KB base page size</th>
<th>16KB base page size</th>
<th>32KB base page size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1GB - 4GB</td>
<td>4GB</td>
<td>4GB</td>
<td>4GB</td>
<td>4GB</td>
</tr>
<tr>
<td>8GB</td>
<td>32GB</td>
<td>16GB</td>
<td>16GB</td>
<td>16GB</td>
</tr>
<tr>
<td>16GB</td>
<td>64GB</td>
<td>32GB</td>
<td>16GB</td>
<td>16GB</td>
</tr>
<tr>
<td>32GB</td>
<td>64GB</td>
<td>64GB</td>
<td>32GB</td>
<td>16GB</td>
</tr>
<tr>
<td>64GB</td>
<td>64GB</td>
<td>64GB</td>
<td>64GB</td>
<td>32GB</td>
</tr>
<tr>
<td>128GB</td>
<td>256GB</td>
<td>256GB</td>
<td>128GB</td>
<td>64GB</td>
</tr>
<tr>
<td>256GB</td>
<td>256GB</td>
<td>256GB</td>
<td>256GB</td>
<td>128GB</td>
</tr>
</tbody>
</table>

For example: for a base table space that has a DSSIZE of 8GB and a page size of 8KB, the XML table space will have a DSSIZE of 16GB.

**Naming convention for implicitly created XML objects:**
- Implicitly created XML table spaces names will be Xyyyyyynnnn, where yyy is derived from the first three bytes of the base table name (if the name is shorter than 3, yyy is padded with X). nnn is a numeric string that will start at 0000 and be incremented by 1 until a unique number is found.
- Implicitly created XML table names will be Xyyyyyyyyyyyyyyyyyyyyyyyyyy, where yyyyyyyyyyyyyyyyyyyyyy is the first 18 UTF-8 bytes of the base table name or of the entire name if it is less than 18. nnn will only be appended if the name already exists in the table. If the name already exists, nnn will be replaced with 000 and will be incremented by 1 until the name is unique.
- Implicitly created document ID index names will be I_DOCIDyyyyyyyyyyyyyyyyyyyyyyyy, where yyyyyyyyyyyyyyyyyyyyy is the first 18 UTF-8 bytes of the base table name or the entire name if it is less than 18. nnn will only be appended if the index already exists in the table. If the index already exists, nnn will be replaced with 000 and will be incremented by 1 until the name is unique.
- Implicitly created node ID index names will be I_NODEIDyyyyyyyyyyyyyyyyyyyyyyyy, where yyyyyyyyyyyyyyyyyyyyy is the first 18 UTF-8 bytes of the XML table name or the entire name if it is less than 18. nnn will only be appended if the index already exists in the table. If the index already exists, nnn will be replaced with 000 and will be incremented by 1 until the name is unique.

**Creating a table with an identity column:**
- When a table has an identity column, DB2 can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys. Identity columns and ROWID columns are similar in that both types of columns contain values that DB2 generates. ROWID columns are used in large object (LOB) table spaces and can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40 byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that is not LOB data and that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing
numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time, it is possible that a large gap in the generated values for the identity column might result. For example, assume a table has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and DB2 subsequently generates values up to 1000. Now, assume that the table space is recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

If you want to ensure that an identity column has unique values, create a unique index on the column.

Creating a table with a LONG VARCHAR or LONG VARGRAPHIC column:
Although the syntax LONG VARCHAR and LONG VARGRAPHIC is allowed for compatibility with previous releases of DB2, its use is not encouraged. VARCHAR(integer) and VARGRAPHIC(integer) is the recommended syntax, because after the CREATE TABLE statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

When a column is defined using the LONG VARCHAR or LONG VARGRAPHIC syntax, DB2 determines the length attribute of the column. You can use the following information, which is provided for existing applications that require the use of the LONG VARCHAR or LONGVARGRAPHIC syntax, to calculate the byte count and the character count of the column.

To calculate the byte count, use this formula:

\[
2^{\text{INTEGER}((\text{INTEGER}((m-i-k)/j))/2)}
\]

Where:

- \(m\) is the maximum row size (8 less than the maximum record size)
- \(i\) is the sum of the byte counts of all columns in the table that are not LONG VARCHAR or LONG VARGRAPHIC
- \(j\) is the number of LONG VARCHAR and LONG VARGRAPHIC columns in the table
- \(k\) is the number of LONG VARCHAR and LONG VARGRAPHIC columns that allow nulls

To find the character count:
1. Find the byte count.
2. Subtract 2.
3. If the data type is LONG VARGRAPHIC, divide the result by 2. If the result is not an integer, drop the fractional part.

Considerations for a Unicode column in an EBCDIC table:
A column in an EBCDIC table can be defined for data encoded as Unicode UTF8 or UTF16. Specify the CCSID clause as the last part of the built-in-type specification to define a Unicode column. The CCSID clause can only be specified with the VARCHAR or VARGRAPHIC keywords as indicated, where \(n\) is the declared length:
If the **IN DATABASE** clause is specified:
If you specify **IN DATABASE** (either explicitly or by default), but do not specify a table space, a table space is implicitly created in *database-name*. The name of the table space is derived from the table name. The qualifier of the table space is the same as the qualifier of the table. The owner of the table space is SYSIBM.

If range-partitioning is not specified, the implicitly created table space is a partition-by-growth table space with MAXPARTITIONS 256, SEG SIZE 32, and DSSIZE 4G.

If range-partitioning is specified, the table space will be partitioned based on the number of parts specified on the CREATE TABLE statement with defaults of SEG SIZE 32, LOCK SIZE ROW, and LOCKMAX SYSTEM.

If the **IN** clause is not specified:
If you do not specify the **IN** clause, the DB2 subsystem will implicitly create a table space as described previously, but the DB2 subsystem will also choose a database. The DB2 subsystem creates a name in the form of DSNnnnnn, where nnnnn is between 00001 and the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, which has a default of 10000, inclusive. The owner of the database is SYSIBM.

- If DSNnnnnn already exists and is an implicitly created database, the DB2 subsystem creates the table in that database.
- If DSNnnnnn does not exist, the DB2 subsystem creates a database with the name DSNnnnnn.

If DSNnnnnn cannot be created because of a deadlock, timeout, or resource unavailable condition, the DB2 subsystem increments nnnnn by one and tries the resultant database name. If the DB2 subsystem reaches the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, and the corresponding database name is not available, the DB2 subsystem sets nnnnn to 00001 and tries the resultant database name. If the DB2 subsystem attempts to create the table a number of times that is equal to the maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB without success, an error occurs.

**Implicitly created table space attributes:**
The attributes of the implicitly created table space can be changed by using the ["ALTER TABLESPACE" on page 1120](#) statement.

**Defining a system-period temporal table:**
A system-period temporal table definition includes the following:
- A system period named SYSTEM_TIME which is defined using a row-begin column and a row-end column.
- A transaction-start-ID column.
- A system-period data versioning definition which includes the name of the associated history table.

To ensure that the history table cannot be implicitly dropped when a system-period temporal table is dropped, use the **WITH RESTRICT ON DROP** clause in the definition of the history table.
Defining an application-period temporal table:
An application-period temporal table definition includes an application period named BUSINESS_TIME. The application period is defined using a begin timestamp column and an end timestamp column.

Data change operations on an application-period temporal table might result in an automatic insert of one or two additional rows when a row is updated or deleted. When an update or delete of a row in an application-period temporal table is specified for a portion of the period that is represented by that row, the row is updated or deleted and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of an update or delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index, in which case an error is returned.

Bitemporal tables:
A table that is defined for system-period data versioning and contains a BUSINESS_TIME period is referred to as a bitemporal table.

Considerations for transaction-start-ID columns:
A transaction-start-ID column contains a null value if the column allows null values. A row-begin column which is unique from other row-begin column values that are generated for other transactions exists with the transaction-start-ID column. Given that the column might contain null values, consider using one of the following methods when retrieving a value from the column:

COALESCE (transaction_start_id_col, row_begin_col)
CASE WHEN transaction_start_id_col IS NOT NULL THEN transaction_start_id_col ELSE row_begin_col END

If the IN clause is specified with ORGANIZE BY HASH:
If you specify IN DATABASE (either explicitly or by default), and ORGANIZE BY HASH, DB2 will calculate an optimum buffer pool for hash organization based on the definition of the table and validate the calculated buffer pool with the buffer pool of the explicitly created table space. If the buffer pool sizes are different, DB2 will return an error.

If the table is in a range-partitioned universal table space, the DSSIZE value for the table space must be large enough to fit the HASH SPACE specification for each partition.

If the table is in a partition-by-growth table space, the total space calculated from the DSSIZE and MAXPARTITIONS values for the table space must be large enough for the implicitly or explicitly specified HASH SPACE.

If the IN clause is not specified with ORGANIZE BY HASH:
If you do not specify IN DATABASE (either explicitly or by default), DB2 will use the default DSSIZE of 4G for each partition for a range-partition universal table space or use the value that is specified in the partitioning clause. The hash space value that is specified on CREATE TABLE will be validated, per part, to ensure that the specified DSSIZE is adequate. If the DSSIZE is not adequate, an error will be returned.
If the maximum number of partitions needed for the specified hash space is more than the maximum number of partitions allowed, DB2 will return an error.

If the selected buffer pool is not available, an error will be returned.

**Creating a table with hash organization and LOB columns:**
If the table space is a partition-by-growth universal table space, DB2 will preallocate as many partitions as needed depending on the value specified for HASH SPACE. If DB2 needs to implicitly create the LOB object in a new partition, the privilege set for the implicitly created LOB objects must include the USE privilege on the buffer pool for the LOB table space.

**Hash space and DB2 page size:**
If the specified hash space is less than or equal to 64 MB (the DB2 default), DB2 will add extra space for DB2 system pages. If the specified hash space is greater than 64 MB, DB2 will use part of the hash space for DB2 system pages. The amount of space needed for DB2 system pages depends on SEGSIZE and PAGESIZE. The larger the SEGSIZE and/OR PAGESIZE becomes, the larger the requirement for DB2 system pages. DB2 can reserve up to 5 MB for system pages for the highest SEGSIZE value (64) and PAGESIZE value (32K).

**Hash space and DSSIZE:**
Depending on certain table space characteristics, DB2 needs to reserve space for the hash overflow area. Therefore, the amount of hash space cannot be equal to the DSSIZE value. The maximum amount of hash space that can be specified is approximately 20% less than the DSSIZE value. DB2 returns an error if the amount of hash space is too large. If the amount of hash space is too large, specify a larger value of DSSIZE, or decrease the amount of hash space.

**Specifying APPEND with ORGANIZE BY HASH:**
Append processing is not applicable to tables with hash organization since there is no key clustering in hash organization. For insert operations into tables with hash organization, DB2 will use the internal hash algorithm to determine the location of the row.

**Restrictions for tables with hash organization:**
Tables that use hash organization are subject to the following restrictions:
- A table that is defined to use hash organization cannot be created in a LOB table space or XML table space.
- ORGANIZE BY HASH must not be specified if the table space is defined with the MEMBER CLUSTER clause.
- The MAXROWS clause is applicable only to the hash overflow area of the table space for tables with hash organization. The fixed hash area of each page will contain as many rows as it can hold, up to a maximum of 255.
- The ORGANIZE BY HASH UNIQUE (column-list) clause is required when specifying HASH SPACE integer K|M|G in the partition-element. The organization-clause applies to the entire table and the partition-element clause applies at the partition level.
- DB2 will automatically create a hash overflow index when a table is created with hash organization.

**Implicitly created table spaces:**
If the table space is implicitly created, all of the following required system objects will also be implicitly created:
- The enforcing primary key index
- The enforcing unique key index
- Any necessary LOB table spaces, auxiliary table spaces, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

When DB2 implicitly creates a base table space for a table with LOB columns that can have inline LOBs, DB2 creates the base table space in reordered row format, regardless of the value of the RRF subsystem parameter.

When DB2 implicitly creates a table space for a table with hash organization, DB2 creates the table space in reordered row format, regardless of the value of the RRF subsystem parameter.

**Implicitly created indexes:**

When the PRIMARY KEY or UNIQUE clause is used in the CREATE TABLE statement and the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the primary or unique keys.

When a ROWID column is defined as GENERATED BY DEFAULT in the CREATE TABLE statement, and the CREATE TABLE statement is processed by SET CURRENT RULES = 'STD' or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the ROWID column.

The privilege set must include the USE privilege of the buffer pool.

Each index is created as if the following CREATE INDEX statement were issued:

```sql
CREATE UNIQUE INDEX xxx ON table-name (column1,...)
```

Where:
- `xxx` is the name of the index that DB2 generates.
- `table-name` is the name of the table specified in the CREATE TABLE statement.
- `(column1,...)` is the list of column names that were specified in the UNIQUE or PRIMARY KEY clause of the CREATE TABLE statement, or the column is a ROWID column that is defined as GENERATED BY DEFAULT.

For more information about the schema processor, see *DB2 Administration Guide*.

In addition, if the table space that contains the table is implicitly created, DB2 will check the DEFINE DATA SET subsystem parameter to determine whether to define the underlying data set for the index space of the implicitly created index on the base table.

If DEFINE DATA SET is NO, the index is created as if the following CREATE INDEX statement is issued:

```sql
CREATE UNIQUE INDEX xxx ON table-name (column1,...) DEFINE NO
```

**Maximum record size:**

The maximum record size of a table depends on the page size of the table...
space, whether the table space is organized for hash access, and whether the EDITPROC clause is specified, as shown in Table 126.

The initial page size of the table space is the size of its buffer, which is determined by the BUFFERPOOL clause that was explicitly or implicitly specified when the table space was created. When the record size reaches 90 percent of the maximum record size for the page size of the table space, the next largest page size is automatically used.

<table>
<thead>
<tr>
<th>Page Size = 4KB</th>
<th>Page Size = 8KB</th>
<th>Page Size = 16KB</th>
<th>Page Size = 32KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-hash table</td>
<td>4056</td>
<td>8138</td>
<td>16330</td>
</tr>
<tr>
<td>Non-hash table with EDITPROC=YES</td>
<td>4046</td>
<td>8128</td>
<td>16320</td>
</tr>
<tr>
<td>Hash table (hash home page)</td>
<td>3817</td>
<td>7899</td>
<td>16091</td>
</tr>
<tr>
<td>Hash table with EDITPROC=YES (hash home page)</td>
<td>3807</td>
<td>7889</td>
<td>16081</td>
</tr>
</tbody>
</table>

Table 126. Maximum record size, in bytes

The maximum record size corresponds to the maximum length of a VARCHAR column if that column is the only column in the table.

If the table space that contains the table is implicitly created, the proper buffer pool size is chosen according to the actual record size. If the record size reaches 90% of the maximum record size for the page size of the table space, the next largest page size will be used. Table 127 shows 90% of the maximum record size:

<table>
<thead>
<tr>
<th>Page Size = 4KB</th>
<th>Page Size = 8KB</th>
<th>Page Size = 16KB</th>
<th>Page Size = 32KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-hash table</td>
<td>3650</td>
<td>7324</td>
<td>14697</td>
</tr>
<tr>
<td>Non-hash table with EDITPROC=YES</td>
<td>3641</td>
<td>7315</td>
<td>14688</td>
</tr>
<tr>
<td>Hash table (hash home page)</td>
<td>3435</td>
<td>7109</td>
<td>14482</td>
</tr>
<tr>
<td>Hash table with EDITPROC=YES (hash home page)</td>
<td>3426</td>
<td>7100</td>
<td>14473</td>
</tr>
</tbody>
</table>

Table 127. 90% of Maximum record size, in bytes

Byte counts:
The sum of the byte counts of the columns must not exceed the maximum row size of the table. The maximum row size is eight less than the maximum record size.
For columns that do not allow null values, Table 128 gives the byte counts of columns by data type. For columns that allow null values, the byte count is one more than shown in the table.

Table 128. Byte counts of columns by data type

Related information:

Creating a materialized query table:
If the fullselect in the CREATE TABLE statement contains a SELECT *, the select list of the subselect is determined at the time the materialized query table is created. In addition, any references to user-defined functions are
resolved at the same time. The isolation level at the time when the
CREATE TABLE statement is executed is the isolation level for the
materialized query table. After a materialized query table is created, the
REFRESH_TIME column of the row for the table in the SYSIBM.SYSEVIEWS
catalog table contains the default timestamp.

The owner of a materialized query table has all the table privileges with
the grant option on the table irrespective of whether the owner has the
necessary privileges on the base tables, views, functions, and sequences.

No unique constraints or unique indexes can be created for materialized
query tables. Thus, a materialized query table cannot be a parent table in a
referential constraint.

When you are creating user-maintained materialized query tables, you
should create the materialized query table with query optimization
disabled and then enable the table for query optimization after it is
populated. Otherwise, DB2 might rewrite queries to use the empty
materialized query table, and you will not get accurate results.

**Considerations for implicitly hidden columns:**
A column that is defined as implicitly hidden is not part of the result table
of a query that specifies * in a SELECT list. However, an implicitly hidden
column can be explicitly referenced in a query. For example, an implicitly
hidden column can be referenced in the SELECT list or in a predicate in a
query. Additionally, an implicitly hidden column can be explicitly
referenced in a COMMENT, CREATE INDEX statement, ALTER TABLE
statement, INSERT statement, MERGE statement, UPDATE statement, or
RENAME statement. An implicitly hidden column can be referenced in a
referential constraint. A REFERENCES clause that does not contain a
column list refers implicitly to the primary key of the parent table. It is
possible that the primary key of the parent table includes a column defined
as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition
explicitly refers to an implicitly hidden column, that column will be part of
the materialized query table.

If the SELECT list of the fullselect of a view definition (CREATE VIEW
statement) explicitly refers to an implicitly hidden column, that column
will be part of the view, however the view column is not considered
‘hidden’.

**Restrictions on field procedures, edit procedures, and validation exit procedures:**
Field procedures, edit procedures, and validation exit procedures cannot be
used on tables that have column names that are larger than 18 EBCDIC
bytes. If you have tables that have field procedures or validation exit
procedures and you add a column where the column name is larger than
18 bytes, the field procedures and validation exit procedures for the table
will be invalidated.

Consider using triggers to replace the functionality on field procedures,
edit procedures, and validation exit procedures on tables where the column
names are larger than 18 EBCDIC bytes.

**Restrictions on SQL data change statements in the same unit of work as
CREATE TABLE:**
SQL data change statements cannot follow, in the same unit of work,
CREATE TABLE statements that specify the PARTITION BY clause.
Creating a table while a utility runs:
You cannot use CREATE TABLE while a DB2 utility has control of the table space implicitly or explicitly specified by the IN clause.

Restrictions involving pending definition changes:
A CREATE TABLE statement is not allowed if there are pending changes to the definition of the table space, if the CREATE TABLE statement specifies a FOREIGN KEY clause that reference a column for which there are pending definition changes, or if the CREATE TABLE statement specifies a materialized query table definition that references a table for which there are pending definition changes.

Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:
- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART integer VALUES can be specified as an alternative to PARTITION integer ENDING AT.
- VALUES as a synonym for ENDING AT
- DEFINITION ONLY as a synonym for WITH NO DATA
- SUMMARY between CREATE and TABLE
- TIMEZONE can be specified as an alternative to TIME ZONE.

Examples

Example 1: Create a table named DSN8B10.DEPT in the table space DSN8S11D of the database DSN8D11A. Name the five columns DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, and LOCATION, allowing only MGRNO and LOCATION to contain nulls, and designating DEPTNO as the only column in the primary key. All five columns hold character string data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, all five columns have the subtype SBCS.

```
CREATE TABLE DSN8B10.DEPT
(DEPTNO CHAR(3) NOT NULL,
 DEPTNAME VARCHAR(36) NOT NULL,
 MGRNO CHAR(6) ,
 ADMRDEPT CHAR(3) NOT NULL,
 LOCATION CHAR(16) ,
 PRIMARY KEY(DEPTNO) )
IN DSN8D11A.DSN8S11D;
```

Example 2: Create a table named DSN8B10.PROJ in an implicitly created table space of the database DSN8D11A. Assign the table a validation procedure named DSN8EAPR.

```
CREATE TABLE DSN8B10.PROJ
(PROJNO CHAR(6) NOT NULL,
 PROJNAME VARCHAR(24) NOT NULL,
 DEPTNO CHAR(3) NOT NULL,
 RESPEMP CHAR(6) NOT NULL,
 PRSTAFF DECIMAL(5,2) ,
 PRSTDATE DATE ,
```
Example 3: Assume that table PROJECT has a non-primary unique key that consists of columns DEPTNO and RESPEMP (the department number and employee responsible for a project). Create a project activity table named ACTIVITY with a foreign key on that unique key.

```sql
CREATE TABLE ACTIVITY
(PROJNO CHAR(6) NOT NULL,
ACTNO SMALLINT NOT NULL,
ACTDEPT CHAR(3) NOT NULL,
ACTOWNER CHAR(6) NOT NULL,
ACSTAFF DECIMAL(5,2),
ACSTDATE DATE NOT NULL,
ACENDATE DATE,
FOREIGN KEY (ACTDEPT,ACTOWNER)
    REFERENCES PROJECT (DEPTNO,RESPEMP) ON DELETE RESTRICT)
IN DSN8D11A.DSN8S11D;
```

Example 4: Create an employee photo and resume table EMP_PHOTO_RESUME that complements the sample employee table. The table contains a photo and resume for each employee. Put the table in table space DSN8D11A.DSN8S11E. Let DB2 always generate the values for the ROWID column.

```sql
CREATE TABLE DSN8B10.EMP_PHOTO_RESUME
(EMPNO CHAR(6) NOT NULL,
EMP_ROWID ROWID NOT NULL GENERATED ALWAYS,
EMP_PHOTO BLOB(110K),
RESUME CLOB(5K),
PRIMARY KEY (EMPNO))
IN DSN8D11A.DSN8S11E
CCSID EBCDIC;
```

Example 5: Create an EMPLOYEE table with an identity column named EMPNO. Define the identity column so that DB2 will always generate the values for the column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

```sql
CREATE TABLE EMPLOYEE
(EMPNO INTEGER GENERATED ALWAYS AS IDENTITY,
ID SMALLINT,
NAME CHAR(30),
SALARY DECIMAL(5,2),
DEPTNO SMALLINT)
IN DSN8D11A.DSN8S11D;
```

Example 6: Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contain daily summary data for the date and amount of a transaction.

```sql
CREATE TABLE STRANS AS
(SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
FROM TRANS
GROUP BY YEAR, MONTH, DAY)
DATA INITIALLY DEFERRED REFRESH DEFERRED;
```

Example 7: The following example creates a table in a partition-by-growth table space and includes the APPEND option:
CREATE TABLE TS01TB
   (C1 SMALLINT,
    C2 DECIMAL(9,2),
    C3 CHAR(4))
APPEND YES
IN TS01DB.TS01TS;

Example 8: The following example creates a table in a partition-by-growth table space where the table space is implicitly created:

CREATE TABLE TS02TB
   (C1 SMALLINT,
    C2 DECIMAL(9,2),
    C3 CHAR(4))
PARTITION BY SIZE EVERY 4G
IN DATABASE DSNDB04;

Example 9: Create a table, EMP_INFO, that contains a phone number and address for each employee. Include a row change timestamp column in the table to track the modification of employee information:

CREATE TABLE EMP_INFO
   (EMPNO CHAR(6) NOT NULL,
    EMP_INFOCHANGE NOT NULL
    GENERATED ALWAYS FOR EACH ROW ON UPDATE
    AS ROW CHANGE TIMESTAMP,
    EMP_ADDRESS VARCHAR(300),
    EMP_PHONENO CHAR(4),
    PRIMARY KEY (EMPNO));

Example 10: Create a table, TB01, that uses a range partitioning scheme with a segment size of 4 and 4 partitions.

CREATE TABLE TB01
   (ACCT_NUM INTEGER,
    CUST_LAST_NM CHAR(15),
    LAST_ACTIVITY_DT VARCHAR(25),
    COL2 CHAR(10),
    COL3 CHAR(25),
    COL4 CHAR(25),
    COL5 CHAR(25),
    COL6 CHAR(55),
    STATE CHAR(55))
IN DBB.TS01
PARTITION BY (ACCT_NUM)
   (PARTITION 1 ENDING AT (199),
    PARTITION 2 ENDING AT (299),
    PARTITION 3 ENDING AT (399),
    PARTITION 4 ENDING AT (MAXVALUE));

Example 11: Create a table, policy_info, that uses a SYSTEM_TIME period and create a history table, hist_policy_info. Then issue an ALTER TABLE statement to associate the policy_info table with the hist_policy_info table.

CREATE TABLE policy_info
   (policy_id CHAR(10) NOT NULL,
    coverage INT NOT NULL,
    sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
    sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
    create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
    PERIOD SYSTEM_TIME(sys_start,sys_end));
CREATE TABLE hist_policy_info
  (policy_id CHAR(10) NOT NULL,
   coverage INT NOT NULL,
   sys_start TIMESTAMP(12) NOT NULL,
   sys_end TIMESTAMP(12) NOT NULL,
   create_id TIMESTAMP(12));

ALTER TABLE policy_info
ADD VERSIONING USE HISTORY TABLE hist_policy_info;

Example 12: Create a table, policy_info, that uses a BUSINESS_TIME period.

CREATE TABLE policy_info
  (policy_id CHAR(4) NOT NULL,
   coverage INT NOT NULL,
   bus_start DATE NOT NULL,
   bus_end DATE NOT NULL,
   PERIOD BUSINESS_TIME(bus_start, bus_end));

Example 13: Create a table, policy_info, that uses both a SYSTEM_TIME period and
a BUSINESS_TIME period to keep historical rows and track a user-specified time
period. A table that specifies both a SYSTEM_TIME period and a BUSINESS_TIME
period is sometimes referred to as a bitemporal table. To enable retention of
historical rows, a history table, hist_policy_info, also needs to be created and
associated (using the ALTER TABLE statement) with the policy_info table.

CREATE TABLE policy_info
  (policy_id CHAR(4) NOT NULL,
   coverage INT NOT NULL,
   bus_start DATE NOT NULL,
   bus_end DATE NOT NULL,
   sys_start TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW BEGIN,
   sys_end TIMESTAMP(12) NOT NULL GENERATED ALWAYS AS ROW END,
   create_id TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID,
   PERIOD BUSINESS_TIME(bus_start, bus_end),
   PERIOD SYSTEM_TIME(sys_start, sys_end));

CREATE TABLE hist_policy_info
  (policy_id CHAR(4) NOT NULL,
   coverage INT NOT NULL,
   bus_start DATE NOT NULL,
   bus_end DATE NOT NULL,
   sys_start TIMESTAMP(12) NOT NULL,
   sys_end TIMESTAMP(12) NOT NULL,
   create_id TIMESTAMP(12));

ALTER TABLE policy_info
ADD VERSIONING USE HISTORY TABLE hist_policy_info;

CREATE TABLESPACE

The CREATE TABLESPACE statement defines a segmented, partitioned, or universal table space at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
• The CREATETS privilege for the database
• DBADM, DBCTRL, or DBMAINT authority for the database
• SYSADM or SYSCCTRL authority
• System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.
Syntax

CREATE LOB TABLESPACE table-space-name
     DSNI04
     IN database-name
     (1)
     using-block:
     free-block
     gbpcache-block
     DEFINE YES
     DEFINE NO
     NOT LOGGED
     TRACKMOD YES
     TRACKMOD NO
     DSSIZE integer
     partition-by-growth-specification
     partition-by-range-specification
     SEGSIZE integer

BUFFERPOOL bpname
CCSID ASCII
     EBCDIC
     UNICODE
CLOSE YES
CLOSE NO
COMPRESS NO
COMPRESS YES
LOCKMAX SYSTEM
     integer
LOCKSIZE ANY
     LOCKSIZE TABLESPACE
     LOCKSIZE TABLE
     LOCKSIZE PAGE
     LOCKSIZE ROW
     LOCKSIZE LOB
MAXROWS integer
SEGSIZE integer

Notes:
1 The same clause must not be specified more than one time.
Notes:
1. USING VCAT must not be specified if MAXPARTITIONS is also specified.
2. The same clause must not be specified more than one time.

Notes:
1. The same clause must not be specified more than one time.
### Description

**LOB**

Identifies the table space as LOB table space. A LOB table space is used to hold LOB values.

The LOB table space must be in the same database as its associated base table space. Do not specify LOB for a table space in a work file database.

**table-space-name**

Names the table space. The name, qualified with the `database-name` implicitly or explicitly specified by the IN clause, must not identify a table space, index space, or LOB table space that exists at the current server or that exists in the SYSPEINDINGOBJECTS catalog table.

A table space that is for declared temporary tables must be in the work file database. PUBLIC implicitly receives the USE privilege (without GRANT authority) on any table space created in the work file database. This implicit privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**IN database-name**

Specifies the database in which the table space is created. `database-name` must identify a database that exists at the current server and must not specify the following:

- DSNDB06 for any type of table space
- A work file database for a LOB table space
A TEMP database

An implicitly created database

If the table space is for declared temporary tables or static scrollable cursors, the name of the work file database must be specified.

DSNDB04 is the default.

The components of the USING clause are discussed below, first for nonpartitioned table spaces and then for partitioned table spaces. If you omit USING, the default storage group of the database must exist.

**USING clause for nonpartitioned table spaces:**

For nonpartitioned table spaces, the USING clause indicates whether the data set for the table space is defined by you or by DB2. If DB2 is to define the data set, the clause also gives space allocation parameters and an erase rule.

If you omit USING, DB2 defines the data sets using the default storage group of the database and the defaults for PRIQTY, SECQTY, and ERASE.

**VCAT catalog-name**

Specifies that the first data set for the table space is managed by the user, and following data sets, if needed, are also managed by the user.

The data sets defined for the table space are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by *catalog-name*. An alias 37 must be used if the catalog name is longer than eight characters.

Conventions for table space data set names are given in DB2 Administration Guide. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

VCAT must not be specified if MAXPARTITIONS is also specified.

**STOGROUP stogroup-name**

 Specifies that DB2 will define and manage the data sets for the table space. Each data set will be defined on a volume of the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. The storage group supplies the name of a volume for the data set and the first-level qualifier for the data set name. The first-level qualifier is also the name of, or an alias 37 for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming conventions for the data set are the same as if the data set is managed by the user. As was mentioned above for VCAT, the first-level qualifier could cause naming conflicts if the local DB2 can share integrated catalog facility catalogs with other DB2 subsystems.

*stogroup-name* must identify a storage group that exists at the current server. SYSADM or SYSCtrl authority, or the USE privilege on the storage group, is required.

The description of the storage group must include at least one volume serial number, or it must indicate that the choice of volumes is left to Storage Management Subsystem (SMS). If volume serial numbers appear in

---

37. The alias of an integrated catalog facility catalog.
the description, each must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must not contain an entry for the first data set of the table space. If the integrated catalog facility catalog is password protected, the description of the storage group must include a valid password.

**PRIQTY integer**

Specifies the minimum primary space allocation for a DB2-managed data set. integer must be a positive integer, or -1. In general, when you specify PRIQTY with a positive integer value, the primary space allocation is at least $n$ kilobytes, where $n$ is the value of integer.

However, the following exceptions exist:

For non-LOB table spaces, the exceptions are:

- For 4KB page sizes, if integer is greater than 0 and less than 12, $n$ is 12.
- For 8KB page sizes, if integer is greater than 0 and less than 24, $n$ is 24.
- For 16KB page sizes, if integer is greater than 0 and less than 48, $n$ is 48.
- For 32KB page sizes, if integer is greater than 0 and less than 96, $n$ is 96.
- For any page size, if integer is greater than 67108864, $n$ is 67108864.

For LOB table spaces, the exceptions are:

- For 4KB page sizes, if integer is greater than 0 and less than 200, $n$ is 200.
- For 8KB page sizes, if integer is greater than 0 and less than 400, $n$ is 400.
- For 16KB page sizes, if integer is greater than 0 and less than 800, $n$ is 800.
- For 32KB page sizes, if integer is greater than 0 and less than 1600, $n$ is 1600.
- For any page size, if integer is greater than 67108864, $n$ is 67108864.

If you do not specify PRIQTY, or specify PRIQTY with a value of -1, DB2 uses a default value for the primary space allocation; for information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY, and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of $p$ KB not less than $n$, where $p$ is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see DEFINE CLUSTER command (DFSMS Access Method Services for Catalogs).

Executing this statement causes only one data set to be created.

However, you might have more data than this one data set can hold.
DB2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, DB2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow DB2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

\[
\text{PRIQTY} + (\text{number of extents} \times \text{SECQTY}) \leq \text{DSSIZE (implicit or explicit)}
\]

**SECQTY integer**

Specifies the minimum secondary space allocation for a DB2-managed data set. `integer` must be a positive integer, 0, or -1. If you do not specify SECQTY, or specify SECQTY with a value of -1, DB2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see [Rules for primary and secondary space allocation](#). If you specify SECQTY, and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of \( p \) KB not less than `integer`, where \( p \) is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see [DEFINE CLUSTER command](#) (DFSMS Access Method Services for Catalogs).

**ERASE**

Indicates whether the DB2-managed data sets for the table space or partition are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

- **NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.
- **YES** Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

**USING clause for partitioned table spaces:**

If the table space is partitioned, there is a USING clause for each partition; either one you give explicitly or one provided by default. Except as explained below, the meaning of the clause and the rules that apply to it are the same as for a nonpartitioned table space.

The USING clause for a particular partition is the first of these choices that can be found:

- A USING clause in the PARTITION clause for the partition
- A USING clause that is not in any PARTITION clause
- An implicit USING STOGROUP clause that identifies the default storage group of the database and accepts the defaults for PRIQTY, SECQTY, and ERASE

**VCAT catalog-name**

Indicates that the data set for the partition is managed by the user using the naming conventions set forth in *DB2 Administration Guide*. As was true
for the nonpartitioned case, *catalog-name* identifies the catalog for the data set and supplies the first-level qualifier for the data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

**STOGROUP stogroup-name**

Indicates that DB2 will create a data set for the partition with the aid of a storage group named *stogroup-name*. The data set is defined during the execution of this statement. DB2 assumes one and only one data set for each partition.

The *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. The integrated catalog facility catalog used for the storage group must not contain an entry for that data set.

When USING STOGROUP is specified for a partition, the defaults for PRIQTY, SECQTY, and ERASE are the values specified in the USING STOGROUP clause that is not in any PARTITION clause. If that USING STOGROUP clause is not specified, the defaults are those specified in the description of PRIQTY, SECQTY, and ERASE.

**FREEPAGE integer**

Specifies how often to leave a page of free space when the table space or partition is loaded or reorganized. You must specify an integer in the range 0 to 255. If you specify 0, no pages are left as free space. Otherwise, one free page is left after every *n* pages, where *n* is the specified *integer* value. However, if the table space is segmented and the integer you specify is not less than the segment size, *n* is one less than the segment size.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

The default is FREEPAGE 0, leaving no free pages. Do not specify FREEPAGE for a LOB table space or a table space in a work file database.

For XML table spaces, this change has no effect until data in the table space is reorganized.

FREEPAGE does not apply to hash-organized table spaces.

**Related information:**

- Reserving free space for table spaces (DB2 Performance)
- Reserving free spaces for indexes (DB2 Performance)

**PCTFREE smallint**

Indicates what percentage of each page to leave as free space when the table is loaded or reorganized. *smallint* in the range from 0 to 99. The first record on each page is loaded without restriction. When additional records are loaded, at least *smallint* percent of free space is left on each page.
The default is PCTFREE 5, which means that 5% of the space on each page is reserved as free space. Do not specify PCTFREE for a LOB table space or a table space in a work file database.

For XML table spaces, this change has no effect until data in the table space is reorganized.

PCTFREE does not apply to table spaces for hash-organized tables except when AUTOESTSPACE(YES) is specified in a REORG TABLESPACE invocation.

**FOR UPDATE smallint**
Specifies the percentage of space to reserve as free space on each page, for use by subsequent UPDATE operations. The *smallint* value is an integer in the range -1 to 99. FOR UPDATE -1 specifies that 5% of free space is reserved initially, and the amount of free spaces is calculated automatically based on certain real-time statistics values. The first record on each page is loaded always loaded without restriction.

If this value is not specified, the value of the PCTFREE_UPD subsystem parameter is used.

The value is recorded in the PCTFREE_UPD column of the SYSIBM.SYSTABLEPART catalog table.

The FOR UPDATE *smallint* values do not apply to LOB table spaces, XML table spaces, or table spaces that use hash organization.

The sum of the values for PCTFREE *smallint* and FOR UPDATE*smallint* must be less than or equal to 99.

**If the table space is partitioned**, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that apply:
- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition
- The values given in a free-block that is not in any PARTITION clause
- The default values are FREEPAGE 0 and PCTFREE 5.

**Related information:**
- Reserving free space for table spaces (DB2 Performance)
- Reserving free spaces for indexes (DB2 Performance)

**GBPCACHE**
In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or non-data-sharing).

**CHANGED**
When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.
If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

**ALL**

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating DB2 when no other DB2s have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-invalidation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

**SYSTEM**

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

Use SYSTEM only for a LOB table space.

**NONE**

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-invalidation.

If you specify NONE, the table space or partition must not be in recover pending status and must be in the stopped state when the CREATE TABLESPACE statement is executed.

If the table space is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one gbpcache-block in any PARTITION clause.
2. The value given in a gbpcache-block that is not in any PARTITION clause.
3. The default value CHANGED.

**DEFINE**

Specifies when the underlying data sets for the table space are physically created.

**YES**

The data sets are created when the table space is created (the CREATE TABLESPACE statement is executed). YES is the default.

If MAXPARTITIONS is also specified, only the first partition is created when the table space is created. Additional partitions are created as needed.

**NO**

The data sets are not created until data is inserted into the table space. DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DB2 uses the SPACE column in catalog table SYSTABLEPART to record the status of the data sets (undefined or allocated).

Do not specify DEFINE NO for a table space in a work file database. DEFINE NO is not recommended if you intend to use any tools outside of DB2 to manipulate data, such as to load data, because data sets might then exist when DB2 does not expect them to exist. When DB2 encounters this inconsistent state, applications will receive an error.
For table spaces that are created with DEFINE NO, point-in-time recover will not work before data sets exist and before a recovery copy exists.

**LOGGED or NOT LOGGED**

Specifies whether changes that are made to the data in the specified table space are recorded in the log.

**LOGGED**

Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables that are created in the specified table space and to all indexes of those tables. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

LOGGED cannot be specified for table spaces in DSNDB06 (the DB2 catalog) or in a work file database.

LOGGED is the default.

**NOT LOGGED**

Specifies that changes that are made to data in the specified table space are not recorded in the log. This parameter applies to all tables that are created in the specified table space and to all indexes of those tables. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

NOT LOGGED cannot be specified for table spaces in the following databases:
- DSNDB06 (the DB2 catalog)
- a work file database

**TRACKMOD**

Specifies whether DB2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space. Do not specify TRACKMOD for a table space in a work file database.

**YES**

DB2 tracks changed pages in the space map pages to improve the performance of incremental image copy.

**NO**

DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

If the table space is partitioned, the value of TRACKMOD for a particular partition is given by the first of these choices that applies:
1. The value of TRACKMOD given in the PARTITION clause for that partition.
2. The value given in a trackmod-block that is not in any PARTITION clause.
3. The default value YES.

If TRACKMOD is not specified, the default value as specified in the subsystem parameter IMPTKMOD is used.

**DSSIZE integer G**

Specifies the maximum size for each partition, or for LOB table spaces, each...
If you specify DSSIZE, you must also specify the NUMPARTS, MAXPARTITIONS, or LOB clause. Do not specify DSSIZE for a table space in a work file database unless MAXPARTITIONS is also specified.

The following values are valid:

1G  1 gigabyte
2G  2 gigabytes
4G  4 gigabytes
8G  8 gigabytes
16G 16 gigabytes
32G 32 gigabytes
64G 64 gigabytes
128G 128 gigabytes
256G 256 gigabytes

To specify a value greater than 4G, the data sets for the table space must be associated with a DFSMS data class that has been specified with extended format and extended addressability.

If NUMPARTS is also specified, the maximum size of each partition depends on the value of NUMPARTS, as shown in the following table. Otherwise, the maximum size of each partition is 4G.

Table 129. Maximum partition size depending on value of NUMPARTS

<table>
<thead>
<tr>
<th>Value of NUMPARTS</th>
<th>Maximum partition size (default for DSSIZE)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 to 16</td>
<td>4GB (4G)</td>
</tr>
<tr>
<td>17 to 32</td>
<td>2GB (2G)</td>
</tr>
<tr>
<td>33 to 64</td>
<td>1GB (1G)</td>
</tr>
<tr>
<td>65 to 254</td>
<td>4GB (4G)</td>
</tr>
</tbody>
</table>

If NUMPARTS is greater than 254, the maximum partition size (and the default for DSSIZE) depends on the page size of the table space, as shown in the following table. The partition size shown is not necessarily the actual number of bytes used or allocated for any one partition; it is the largest number that can be logically addressed. Each partition occupies one data set.

Table 130. Maximum partition size depending on page size

<table>
<thead>
<tr>
<th>Page size</th>
<th>Maximum partition size (default for DSSIZE)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4K</td>
<td>4GB (4G)</td>
</tr>
<tr>
<td>8K</td>
<td>8GB (8G)</td>
</tr>
<tr>
<td>16K</td>
<td>16GB (16G)</td>
</tr>
<tr>
<td>32K</td>
<td>32GB (32G)</td>
</tr>
</tbody>
</table>

If DSSIZE is explicitly specified, the maximum number of partitions that can be specified or is the default is limited by the maximum table space size. For example:

- For a partitioned table space with a 4K page size, if DSSIZE 64GB is specified, the maximum NUMPARTS value is 256.
- For a partitioned table space with an 8K page size, if DSSIZE 64GB is specified, the maximum NUMPARTS value is 512.
- For a partitioned table space with a 32K page size, if DSSIZE 128GB is specified, the maximum NUMPARTS value is 1024.
See Table 132 on page 1530 for more information on the relationship between DSSIZE, NUMPARTS, and the table space size.

For LOB table spaces, if DSSIZE is not specified, the default for the maximum size of each data set is 4GB. The maximum number of data sets is 254.

For a description of the maximum size of a LOB table space (or the maximum size of LOB data for each column of a base table), see Large object table spaces (Introduction to DB2 for z/OS).

MAXPARTITIONS integer

Specifies that the table space is a partition-by-growth table space. The data set for the first partition is allocated unless the DEFINE NO clause is specified for the partition. The data sets for additional partitions are not allocated until they are needed.

integer specifies the maximum number of partitions to which the table space can grow. integer must be in the range of 1 to 4096, depending on the corresponding value of the DSSIZE clause. The following table shows the maximum value for MAXPARTITIONS in relation to the page size or DSSIZE value for the table space.

Table 131. Maximum value for MAXPARTITIONS given the page size or DSSIZE value for the table space

<table>

</tbody>
</table>

If MAXPARTITIONS is specified for a table space in a work file database, the table space will be a partition-by-growth table space. If the DSSIZE or NUMPARTS clauses are not specified in addition to the MAXPARTITIONS clause for a table space in a work file database, the default values for DSSIZE and NUMPARTS will be used. If MAXPARTITIONS is not specified for a table space in a work file database, the table space will be a segmented table space.

Although physical data sets are not defined when the MAXPARTITIONS value is issued, there can be storage and cpu overhead. If an increase in the number of partitions is expected by using the MAXPARTITIONS clause, be aware that specifying an value larger than necessary, such as 4096 (the maximum value), as a default for all of your partition-by-growth table spaces can cause larger than expected storage requests.

MEMBER CLUSTER

Specifies that data inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. Instead, DB2 chooses where to locate the data in the table space based on available space.

Do not specify MEMBER CLUSTER for segmented table spaces.
Do not specify MEMBER CLUSTER for a LOB table space or a table space in a work file database.

MEMBER CLUSTER can be specified with MAXPARTITIONS.

**NUMPARTS integer**

*integer*

Specifies the number of partitions. If *n* is specified for a partition-by-growth table space, *integer* indicates the number of partitions that are initially created unless DEFINE NO is specified. *integer* must be a value between 1 and 4096 inclusive and must be less than or equal to the value that is specified for the MAXPARTITIONS clause.

The maximum size of each partition depends on the value that is specified for DSSIZE. If DSSIZE is not specified, the number of partitions that are specified determines the maximum size of each partition. For a summary of the values for the maximum size of each partition, see Table 129 on page 1528 and Table 130 on page 1528.

The maximum number of partitions that a table space can have depends on the page size and DSSIZE. The total table space size depends on how many partitions it has and DSSIZE. Page size affects table size because it affects how many partitions a table space can have. The following table shows the maximum number of partitions for DSSIZE and page size and total table space size for both EA-enabled (extended addressability) and non-EA-enabled data sets. (Specifying a DSSIZE greater than 4GB requires EA-enabled data sets.)

</table>

For a description of the maximum size of a LOB table space (or the maximum size of LOB data for each column of a base table), see the Large object table spaces [Introduction to DB2 for z/OS](#).

If you omit NUMPARTS and MAXPARTITIONS, the table space is segmented with a SEGSIZE of 4, LOCKSIZE ANY (unless it is explicitly specified), is not partitioned, and initially occupies one data set.

Do not specify NUMPARTS for a LOB table space. Do not specify NUMPARTS for a table space in a work file database unless the MAXPARTITIONS clause is also specified.

**PARTITION** *integer*

Specifies to which partition the following using-block or free-block applies. *integer* can range from 1 to the number of partitions given by NUMPARTS.

You can code the PARTITION clause (and any using-block or free-block that follows it) as many times as needed. If you use the same partition number more than once, only the last specification for that partition is used.

The PARTITION clause must not be specified if the table space is a partition-by-growth table space.

**BUFFERPOOL** *bpname*

Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The *bpname* must identify an activated buffer pool, and the privilege set must include SYSADM
or SYSCTRL authority, or the USE privilege on the buffer pool. If the table space is to be created in a work file database, you cannot specify 8KB and 16KB buffer pools.

If you do not specify the BUFFERPOOL clause, the default buffer pool of the database is used unless the table space that is being created is a LOB table space. If you do not specify the BUFFERPOOL clause and the table space that is being created is a LOB table space, the default buffer pool is the buffer pool that is specified in the DEFAULT BUFFER POOL FOR USER LOB DATA field on installation panel DSNTIP1.

See “Naming conventions” on page 59 for more details about bpname. See ALTER BUFFERPOOL (DB2) (DB2 Commands) for a description of active and inactive buffer pools.

LOCKSIZE
Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not use this clause for a table space in a work file database.

ANY
Specifies that DB2 can use any lock size.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (the NUMLKT parameter), the page or LOB locks are released and locking is set at the next higher level.

If the table space is segmented, the next higher level is the table. If the table space is segmented and not partitioned, the next higher level is the table. If the table space is partitioned, the next higher level is the partition.

If the table space is implicitly created, DB2 uses LOCKSIZE ROW.

TABLESPACE
Specifies table space locks.

TABLE
Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

PAGE
Specifies page locks. Do not use PAGE for a LOB table space.

ROW
Specifies row locks. Do not use ROW for a LOB table space.

LOB
Specifies LOB locks. Use LOB only for a LOB table space.

LOCKMAX
Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX for a table space in a work file database, DB2 ignores the value because these types of locks are not used.

integer
Specifies the number of locks allowed before escalating, in the range 0 to 2,147,483,647.
Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

**SYSTEM**

Indicates that the value of LOCKS PER TABLE(SPACE), on installation panel DSNTIPJ, specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

<table>
<thead>
<tr>
<th>LOCKSIZE</th>
<th>Resultant LOCKMAX</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY</td>
<td>SYSTEM</td>
</tr>
<tr>
<td>TABLESPACE, TABLE, PAGE,</td>
<td>0</td>
</tr>
<tr>
<td>ROW, or LOB</td>
<td></td>
</tr>
</tbody>
</table>

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

**CLOSE**

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

**YES**

Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

**NO**

Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified.

**COMPRESS**

Specifies whether data compression applies to the rows of the table space or partition. Do not specify COMPRESS for a LOB table space or a table space in a work file database.

For partitioned table spaces, the COMPRESS attribute for each partition is the value from the first of the following conditions that apply:

- The value specified in the COMPRESS clause in the PARTITION clause for the partition
- The value specified in the COMPRESS clause that is not in any PARTITION clause
- An implicit COMPRESS NO by default.

For more information about data compression, see [Compressing your data][1](DB2 Performance).

**YES**

Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition, or until an insert operation is performed through the INSERT statement or the MERGE statement.

**NO**

Specifies no data compression for the table space or partition.

**CCSID encoding-scheme**

Specifies the encoding scheme for tables stored in the table space.
If you do not specify a CCSID when it is allowed, the default is the encoding scheme of the database in which the table space resides, except for table spaces in database DSNDDB04; for table spaces in DSNDDB04, the default is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**ASCII**  Specifies that the data is to be encoded using ASCII CCSIDs. If the database in which the table space is to reside is already defined as ASCII, the ASCII CCSIDs associated with that database are used. Otherwise, the default ASCII CCSIDs of the server are used.

**EBCDIC**  Specifies that the data is to be encoded using EBCDIC CCSIDs.

**UNICODE**  Specifies that the data is to be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used.

All data stored within a table space must use the same encoding scheme unless the table space is in a work file database.

Do not specify CCSID for a LOB table space or a table space in a work file database. The encoding scheme for a LOB table space is inherited from the base table space. A table space in a work file database does not have an associated encoding scheme because the table space can contain created and declared temporary tables with a mixture of encoding schemes.

**MAXROWS**  integer  Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255. This value is considered for insert operations, LOAD, and REORG. For LOAD and REORG (which do not apply for a table space in the work file database), the PCTFREE specification is considered before MAXROWS; therefore, fewer rows might be stored than the value you specify for MAXROWS.

If you do not specify MAXROWS, the default number of rows is 255.

Do not use MAXROWS for a LOB table space or a table space in a work file database.

**SEGSIZE**  integer  Specifies the type of table space that will be created depending on the values of the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses. integer specifies the number of pages that are to be assigned to each segment of the table space. integer must be a multiple of 4 between 0 and 64 (inclusive). integer cannot be 0 for an XML table space. Do not specify SEGSIZE for a LOB table space.

If SEGSIZE is not specified and only the NUMPARTS clause is specified, either a partitioned table space or a range-partitioned universal table space is created depending on the value of the DPSEGSZ subsystem parameter:

- If the value of DPSEGSZ is greater than 0 (zero), the table space will be a range-partitioned universal table with a SEGSIZE value that is equal to the value of DPSEGSZ.
- If the value of DPSEGSZ is equal to 0 (zero), the table space will be a partitioned table space.

If SEGSIZE is not specified and only the MAXPARTITIONS clause is specified, a partition-by-growth universal table space is created with a SEGSIZE that depends on the value of the DPSEGSZ subsystem parameter.
• If the value of DPSEGSZ is greater than 0 (zero), the table space will have a 
  SEGSIZE value that is equal to the value of DPSEGSZ.
• If the value of DPSEGSZ is equal to 0 (zero), the table space will have a 
  SEGSIZE value of 32.

The DPSEGSZ subsystem parameter has no effect on segmented table spaces.

The following table lists the type of table space depending on the specification 
of the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses:

<table>
<thead>
<tr>
<th>SEGSIZE clause</th>
<th>MAXPARTITIONS clause</th>
<th>NUMPARTS clause</th>
<th>Type of table space</th>
</tr>
</thead>
<tbody>
<tr>
<td>specified</td>
<td>specified</td>
<td>not specified</td>

</tbody>
</table>

Notes

Segmented table spaces:
If neither LOB, NUMPARTS, nor SEGSIZE are specified, the table space that is created is a segmented table space.

Related links: [Types of DB2 table spaces (Introduction to DB2 for z/OS)]

Universal table spaces:
If NUMPARTS and SEGSIZE are specified, the table space that is created is a range-partitioned universal table space. If MAXPARTITIONS or MAXPARTITIONS and SEGSIZE are specified, the table space that is created is a partition-by-growth universal table space. If a range-partitioned universal table space contains an XML column, the corresponding XML table space will be range-partitioned universal as well.

Related links: [Universal table spaces (Introduction to DB2 for z/OS)]

Applications that use currently committed access with table spaces that specify LOCKSIZE PAGE:
To ensure that readers of data in a table space that is defined with LOCKSIZE PAGE can always access currently committed data, set MAXROWS to 8 or less. If MAXROWS is greater than 8, readers might need to wait for insert or delete operations on tables in the table space to commit before the readers can access rows in the tables.

Related links: [Accessing currently committed data to avoid lock contention (DB2 Performance)]

Table spaces in a work file database:
The following restrictions apply to table spaces created in a work file database:

- They can be created for another member only if both the executing DB2 subsystem and the other member can access the work file data sets. That is required whether the data sets are user-managed or in a DB2 storage group.
- They cannot use 8 KB or 16 KB page sizes. (The buffer pool in which you define the table space determines the page size. For example, a table space that is defined in a 4 KB buffer pool has 4 KB page sizes.)
- When you create a table space in a work file database, the following clauses are not allowed:
Table spaces for declared temporary tables:
Declared temporary tables and sensitive static scrollable cursors must reside in segmented table spaces in the work file database. At least one table space with a 32KB page size must exist in the work file database before a declared temporary table can be defined and used or before sensitive static scrollable cursors are opened.

Table spaces in the work file database are shared by work files, created and declared global temporary tables and sensitive static scrollable cursor result tables. You cannot specify which table space is to be used for any specific object.

When you create table spaces in the work file database, it is recommended that you give each table space the same segment size, with the same minimum primary and secondary space allocation values for the data sets, to maximize the use of all the table spaces for all objects in all application processes.

Creating LOB table spaces:
When you create a LOB table space, the following clauses are not allowed:

Recommended GBPCACHE setting for LOB table spaces:
For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

Altering the logging attribute of a table space:
See "Notes" on page 1136 of "ALTER TABLESPACE" on page 1120 for information about altering the logging attributes of a table space.

Table space row formats:
Depending on the value of the RRF subsystem parameter, newly created table spaces will be in either re-ordered row format or basic row format. When the value of the RRF parameter is ENABLE, table spaces will be created in re-ordered row format. When the value of the RRF parameter is DISABLE, newly created table spaces will be created in basic row format. This includes universal table spaces, except for XML table spaces, which are always created in re-ordered row format, regardless of the value of the RRF parameter.

Making a partitioned table space larger:
Depending on the needs of your application, you might need to increase the size of a partitioned table space to hold more data by either adding more partitions or by increasing the size of the existing partitions:
To add more partitions, use the ALTER TABLE statement with the ADD PARTITION clause.

To increase the size of the partitions, use the following steps:

- If the table space is a range-partitioned universal table space, specify a larger DSSIZE using the ALTER TABLESPACE statement if the DSSIZE of the table space is not already at the maximum.
- If the table space is not a range-partitioned universal table space:
  1. Convert the table space to a range-partitioned universal table space by specifying a SEGSIZE value and a NUMPARTS value using the ALTER TABLESPACE statement
  2. Run the REORG utility with the SHRLEVEL CHANGE or SHRLEVEL REFERENCE option on the table space to apply the new SEGSIZE value
  3. Specify a larger DSSIZE using the ALTER TABLESPACE statement

Related links:

“ALTER TABLESPACE” on page 1120
REORG TABLESPACE (DB2 Utilities)

Redistributing data between existing partitions:

If you need to redistribute the data between the existing partitions to make better use of the space within the existing table, you can use either of these two methods:

- Use the ALTER TABLE statement with the ALTER PARTITION clause. You can alter the partitions to specify new partition boundaries to explicitly specify how to redistribute the data. Any affected partitions are set to REORG-pending status.
- Use the REORG utility with the REBALANCE keyword. REBALANCE specifies that the data is evenly redistributed across the partitions that are reorganized. See [REORG TABLESPACE (DB2 Utilities)] for information about using the REORG utility.

Rules for primary and secondary space allocation:

You can specify the primary and secondary space allocation for table spaces and indexes or allow DB2 to choose them. Having DB2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents.

In the following rules that describe how allocation works, these terms are used:

PRIQTY, SECQTY

The keywords for CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, and ALTER INDEX.

specified-priqty
The user-specified value for PRIQTY.

specified-secqty
The user-specified value for SECQTY.

actual-priqty
The actual primary space allocation, in kilobytes.

actual-priqty-cylinders
The actual primary space allocation, in cylinders.
The actual secondary space allocation, in kilobytes.

The actual secondary space allocation, in cylinders.

A value that is calculated by DB2 using a sliding scale. A sliding scale means that the first secondary extent allocations are smaller than later secondary allocations. For example, Figure 19 shows the sliding scale of secondary extent allocations that DB2 uses for a 64-GB data set. The size of each secondary extent is larger for each secondary extent that is allocated up to the 127th extent. For the 127th secondary extent and any subsequent extents, the secondary size allocation is 559 cylinders.

The rules are:

- **Rule 1 (for primary space allocation)**
  
  If PRIQTY is specified and specified-priqty is not equal to -1, actual-priqty is at least specified-priqty KB.
  
  If PRIQTY is not specified or specified-priqty is equal to -1, actual-priqty is determined as follows:
  
  - For a table space, if the TSQTY subsystem parameter value is specified and is greater than 0, actual-priqty is at least the value of TSQTY.
  
  If the TSQTY subsystem parameter is not specified or is 0, actual-priqty is one cylinder for a non-LOB table space. actual-priqty is 10 cylinders for a LOB table space.
  
  - For an index, if the IXQTY subsystem parameter value is specified and is greater than 0, actual-priqty is at least the value of IXQTY.
If the IXQTY subsystem parameter is not specified or is 0, actual-priqty is one cylinder.

**Rule 2 (for secondary space allocation)**

If SECQTY is not specified, the following formulas determine actual-secqty:

- If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:
  \[
  \text{actual-secqty-cylinders} = \max(0.1 \times \text{actual-priqty-cylinders}, \min(\text{calculated-extent-cylinders}, 127))
  \]

- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:
  \[
  \text{actual-secqty-cylinders} = \max(0.1 \times \text{actual-priqty-cylinders}, \min(\text{calculated-extent-cylinders}, 559))
  \]

**Rule 3 (for secondary space allocation)**

If SECQTY is 0, actual-secqty is 0.

**Rule 4 (for secondary space allocation)**

This is the only rule that depends on the value of subsystem parameter MGEXTSZ (field OPTIMIZE EXTENT on installation panel DSNTIP7).

If MGEXTSZ is YES:

- If SECQTY is specified and specified-secqty is not equal to -1 or 0, the following formulas determine actual-secqty:
  - If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:
    \[
    \text{actual-secqty-cylinders} = \max(0.1 \times \text{specified-secqty-cylinders}, \min(\text{calculated-extent-cylinders}, 127), \text{specified-secqty-cylinders})
    \]
  - If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:
    \[
    \text{actual-secqty-cylinders} = \max(0.1 \times \text{specified-secqty-cylinders}, \min(\text{calculated-extent-cylinders}, 559), \text{specified-secqty-cylinders})
    \]

If MGEXTSZ is NO:

- For a table space, if SECQTY is \( n \), the secondary space allocation is at least \( n \) kilobytes, with the following exceptions:
  - If SECQTY is greater than 4194304, \( n \) is 4194304 kilobytes.
  - For LOB table spaces:
    - For 4KB page sizes, if \( \text{integer} \) is greater than 0 and less than 200, \( n \) is 200.
    - For 8KB page sizes, if \( \text{integer} \) is greater than 0 and less than 400, \( n \) is 400.
    - For 16KB page sizes, if \( \text{integer} \) is greater than 0 and less than 800, \( n \) is 800.
    - For 32KB page sizes, if \( \text{integer} \) is greater than 0 and less than 1600, \( n \) is 1600.
    - For any page size, if \( \text{integer} \) is greater than 4194304, \( n \) is 4194304.
- For an index, if SECQTY is \( \text{integer} \), the secondary space allocation is at least \( n \) kilobytes, where \( n \) is:
  - 12 if SECQTY and PRIQTY are omitted
  - 4194304 if \( \text{integer} \) is greater than 4194304
  - \( \text{integer} \) if \( \text{integer} \) is not greater than 4194304
• **Rule 5 (for secondary space allocation):** When a table space requires a new piece, the primary allocation quantity of the new piece is determined as follows:
  – If the value of subsystem parameter MGEXTSZ is NO, the primary quantity from rule 1 is used.
  – Otherwise, the maximum of the following values is used:
    - The quantity that is calculated through sliding scale methodology
    - The primary quantity from rule 1
    - The specified SECQTY value

**Alternative syntax and synonyms:**
For compatibility with previous releases of DB2, the following keywords are supported:

• You can specify the LOCKPART clause, but it has no effect. DB2 treats all table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space. LOCKSIZE TABLESPACE and LOCKPART YES are mutually exclusive.

• When creating a partitioned table space, you can specify PART as a synonym for PARTITION.

• When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.

• You can specify the LARGE clause when creating partitioned table spaces, but DSSIZE is the preferred clause to use when specifying the partition size.

Although these keywords are supported as alternatives, they are not the preferred syntax.

**Examples**

*Example 1:* Create table space DSN8S11D in database DSN8D11A. Let DB2 define the data sets, using storage group DSN8G110. The primary space allocation is 52 kilobytes; the secondary, 20 kilobytes. The data sets need not be erased before they are deleted.

Locking on tables in the space is to take place at the page level. Associate the table space with buffer pool BP1. The data sets can be closed when no one is using the table space.

```
CREATE TABLESPACE DSN8S11D
  IN DSN8D11A
  USING STOGROUP DSN8G110
  PRIQTY 52
  SECQTY 20
  ERASE NO
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE YES;
```

For the above example, the underlying data sets for the table space will be created immediately, which is the default (DEFINE YES). If you want to defer the creation of the data sets until data is first inserted into the table space, you would specify DEFINE NO instead of accepting the default behavior.
Example 2: Assume that a large query database application uses a table space to record historical sales data for marketing statistics. Create large table space SALESHX in database DSN8D11A for the application. Create it with 82 partitions, specifying that the data in partitions 80 through 82 is to be compressed.

Let DB2 define the data sets for all the partitions in the table space, using storage group DSN8G110. For each data set, the primary space allocation is 4000 kilobytes, and the secondary space allocation is 130 kilobytes. Except for the data set for partition 82, the data sets do not need to be erased before they are deleted.

Locking on the table is to take place at the page level. There can only be one table in a partitioned table space. Associate the table space with buffer pool BP1. The data sets cannot be closed when no one is using the table space. If there are no CLOSE YES data sets to close, DB2 might close the CLOSE NO data sets when the DSMAX is reached.

```
CREATE TABLESPACE SALESHX 
IN DSN8D11A 
USING STOGROUP DSN8G110 
PRIQTY 4000 
SECQTY 130 
ERASE NO 
NUMPARTS 82 
(PARTITION 80 
COMPRESS YES, 
PARTITION 81 
COMPRESS YES, 
PARTITION 82 
COMPRESS YES 
ERASE YES) 
LOCKSIZE PAGE 
BUFFERPOOL BP1 
CLOSE NO;
```

Example 3: Assume that a column named EMP_PHOTO with a data type of BLOB(110K) has been added to the sample employee table for each employee's photo. Create LOB table space PHOTOLTS in database DSN8D11A for the auxiliary table that will hold the BLOB data.

Let DB2 define the data sets for the table space, using storage group DSN8G110. For each data set, the primary space allocation is 3200 kilobytes, and the secondary space allocation is 1600 kilobytes. The data sets do not need to be erased before they are deleted. (Because ERASE NO is the default, the clause does not have to be explicitly specified to get that behavior.)

```
CREATE LOB TABLESPACE PHOTOLTS 
IN DSN8D11A 
USING STOGROUP DSN8G110 
PRIQTY 3200 
SECQTY 1600 
LOCKSIZE LOB 
BUFFERPOOL BP16K0 
GBPCACHE SYSTEM 
NOT LOGGED 
CLOSE NO;
```

Example 4: The following example creates a range-partitioned universal table space, TSI, in database DSN8D11A using storage group DSN8G110. The table space has 16 pages per segment and has 55 partitions. It specifies LOCKSIZE ANY.
CREATE TABLESPACE TS1
  IN DSN8D11A
  USING STOGROUP DSN8G110
  NUMPARTS 55
  SEGSIZE 16
  LOCKSIZE ANY;

Example 5: The following example creates a range-partitioned universal table space, TS2, in database DSN8D11A using storage group DSN8G110. The table space has 64 pages per segment and has seven defer-defined partitions, where every other partition is compressed.

CREATE TABLESPACE TS2
  IN DSN8D11A
  USING STOGROUP DSN8G110
  NUMPARTS 7
  ( PARTITION 1 COMPRESS YES,
    PARTITION 3 COMPRESS YES,
    PARTITION 5 COMPRESS YES,
    PARTITION 7 COMPRESS YES
  )
  SEGSIZE 64
  DEFINE NO;

Example 6: The following example creates a partition-by-growth table space that has a maximum size of 2 GB for each partition, four pages per segment with a maximum of 24 partitions for the table space.

CREATE TABLESPACE TS01TS IN TS01DB USING STOGROUP SG1
  DSSIZE 2G
  MAXPARTITIONS 24
  LOCKSIZE ANY
  SEGSIZE 4;
CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger in a schema and builds a trigger package at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

In defining a trigger on a table, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the table on which the trigger is defined
- The SELECT privilege on any table or view in the search-condition of the triggered-action
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the table, which must include at least one of the following:
  - The TRIGGER privilege on the table on which the trigger is defined
  - The ALTER privilege on the table on which the trigger is defined
  - DBADM authority on the database that contains the table
  - SYSCTRL authority
  - System DBADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

In defining a trigger on a view, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the view on which the trigger is defined, if the REFERENCING clause is included in the trigger definition
- The SELECT privilege on any table or view in the search-condition of the triggered-action
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the view, which must include at least one of the following:
  - Ownership of the view on which the trigger is defined
  - SYSCTRL authority
  - System DBADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If
the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

At least one of the following privileges is required if the SECURED option is specified:

- SECADM authority
- CREATE_SECURE_OBJECT privilege

Note: If the SEPARATE SECURITY subsystem parameter is set to NO, SYSADM authority has implicit SECADM authority.

**Syntax**

```sql
CREATE TRIGGER trigger-name
(NO CASCADE BEFORE
AFTER
INSTEAD OF
| trigger-event | ON table-name | view-name |

REFERENCING | (1) AS
OLD correlation-name AS NEW correlation-name
| OLD_TABLE AS table-identifier |
| NEW_TABLE AS table-identifier |

MODE DB2SQL
NOT SECURED SECURED

triggered-action
```

**Notes:**

1. The same clause must not be specified more than one time.
Description

trigger-name

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger that exists at the current server.

The name is also used to create the trigger package; therefore, the name must also not identify a package that is already described in the catalog. The schema name becomes the collection-id of the trigger package. Although trigger-name can be specified as an ordinary or delimited identifier, the name should conform to the rules for an ordinary identifier. Refer to The implicitly created trigger package for additional information.

The schema name must not begin with ‘SYS’ unless the name is ‘SYSADM’, or the schema name is ‘SYSTOOLS’ and the user who executes the CREATE statement has SYSADM or SYSCTRL privilege.

NO CASCADE BEFORE

Specifies that the trigger is a before trigger. DB2 executes the triggered action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered action does not activate other triggers because the triggered action of a before trigger cannot contain any updates.

NO CASCADE BEFORE must not be specified when view-name is also specified. FOR EACH ROW must be specified for a BEFORE trigger.

AFTER

Specifies that the trigger is an after trigger. DB2 executes the triggered action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified if view-name is also specified.
INSTEAD OF
Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each type of operation on a given subject view. DB2 executes the triggered-action instead of the insert, update, or delete operation on the subject view.

INSTEAD OF must not be specified when table-name is also specified. The WHEN clause can not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

ON table-name
Identifies the subject table of the BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server. It must not identify a materialized query table, a clone table, a temporary table, an auxiliary table, an alias, a synonym, a real-time statistics table, or a catalog table.

ON view-name
Identifies the subject view of the INSTEAD OF trigger definition. The name must identify a view that exists at the current server.

view-name must not specify a view where any of the following conditions are true:

• The view is defined with the WITH CASCADED CHECK option (a symmetric view)
• The view on which a symmetric view has been defined
• The view references data that is encoded with different encoding schemes or CCSID values
• The view has a column that is a ROWID column
• The view has a column that is based on an underlying column of any of the following types:
  – A LOB, XML, or ROWID column
  – An identity column
  – A security label column
  – A row change timestamp column
  – A row-begin column
  – A row-end column
  – A transaction start ID column
• The view has columns that have field procedures
• All of the underlying tables of the view are catalog tables
• All of the underlying tables of the view are created global temporary tables
• All of the underlying tables of the view are clone tables
• The view has other views that are dependent on it

REFERENCING
Specifies the correlation names for the transition variables and the table names for the transition tables. For the rows in the subject table that are modified by the triggering SQL operation (insert, delete, or update), a correlation name identifies the columns of a specific row. table-identifiers identify the complete set of affected rows. Transition variables with XML types cannot be referenced inside of a trigger. If the column of a transition table is referenced, the data type of the column cannot be XML.
Each row that is affected by the triggering SQL operation is available to the triggered action by qualifying column names with correlation-names that are specified as follows:

**OLD AS correlation-name**
Specifies the correlation name that identifies the values in the row prior to the triggering SQL operation.

**NEW AS correlation-name**
Specifies the correlation name that identifies the values in the row as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

The complete set of rows that are affected by the triggering operation is available to the triggered action by using table-identifiers that are specified as follows:

**OLD_TABLE AS table-identifier**
Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

**NEW_TABLE AS table-identifier**
Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

Only one OLD and one NEW correlation-name can be specified for a trigger. Only one OLD_TABLE and one NEW_TABLE table-identifier can be specified for a trigger. All of the correlation-names and table-identifiers must be unique from one another.

[Table 134 on page 1549](#) summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD correlation-name and the OLD_TABLE table-identifier are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD correlation-name captures the values of the columns in the deleted row, and the OLD_TABLE table-identifier captures the values in the set of deleted rows. For an update operation, the OLD correlation-name captures the values of the columns of a row before the update operation, and the OLD_TABLE table-identifier captures the values in the set of updated rows.

The NEW correlation-name and the NEW_TABLE table-identifier are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW correlation-name captures the values of the columns in the inserted or updated row and the NEW_TABLE table-identifier captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any SET statements in the triggered action of BEFORE triggers.
Table 134. Allowable combinations of attributes in a trigger definition

</table>

Note:
1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each correlation-name and each table-identifier is the entire trigger definition.

FOR EACH ROW or FOR EACH STATEMENT
Specifies the conditions for which DB2 executes the triggered action.

FOR EACH ROW
Specifies that DB2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed.

FOR EACH STATEMENT
Specifies that DB2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.
MODE DB2SQL
Specifies the mode of the trigger. MODE DB2SQL triggers are activated after all of the row operations have occurred.

ASUTIME
Specifies the total amount of processor time, in CPU service units, that a single invocation of a trigger can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see z/OS MVS Initialization and Tuning Guide.

NO LIMIT
Specifies that there is no limit on the service units.
NO LIMIT is the default.

LIMIT integer
The limit on the number of CPU service units is a positive integer in the range of 1 to 2,147,483,647. If the trigger uses more service units than the specified value, DB2 cancels the trigger. The CPU cycles that are consumed by parallel tasks in a trigger do not contribute towards the specified ASUTIME LIMIT.

NOT SECURED or SECURED
Specifies whether the trigger is considered secure. NOT SECURED is the default.

SECURED
Specifies the trigger is considered secure.
SECURED must be specified for a trigger if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

NOT SECURED
Specifies the trigger is considered not secure.
NOT SECURED must not be specified for a trigger whose subject table is using row access control or column access control. NOT SECURED must also not be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

trigger-event
Specifies that the triggered action that is associated with the trigger is to be executed when the trigger event is applied to the subject table or view.

INSERT
Specifies that the trigger is an insert trigger. DB2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by DB2 adding a row to the table, the triggered action is not to be executed.

DELETE
Specifies that the trigger is a delete trigger. DB2 executes the triggered action whenever there is a delete operation on the subject table.
**UPDATE**

Specifies that the trigger is an update trigger. DB2 executes the triggered action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered action.

**OF column-name,...**

Each column-name that you specify must be a column of the subject table and must appear in the list only once. An update operation on any of the listed columns activates the triggered action.

UPDATE OF column-name cannot be specified for an INSTEAD OF trigger.

**triggered-action**

Specifies the action to be performed when the trigger is activated. The triggered-action is composed of one or more SQL statements and an optional condition that controls whether the statements are executed.

**WHEN (search-condition)**

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the search-condition evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed.

The WHEN clause must not be specified for an INSTEAD OF trigger.

search-condition must not reference the following items:

- A system-period temporal table if the trigger package is generated with the SYSTIMSENSITIVE(YES) bind option
- An archive-enabled table if the trigger package is generated with the ARCHIVESSENSITIVE(YES) bind option

**SQL-trigger-body**

Specifies the SQL statements that are to be executed for the triggered action.

**triggered-SQL-statement**

Specifies the SQL statements that can be specified as the only statement in a trigger body (with optional BEGIN ATOMIC and END block syntax).

**BEGIN ATOMIC triggered-SQL-statement,... END**

Specifies a list of SQL statements that are to be executed for the triggered action. The statements are executed in the order in which they are specified.

Only certain SQL statements can be specified in the SQL-trigger-body:

- A statement in the trigger body must not refer to host variables, parameter markers, undefined transition variables, or declared temporary tables.
- A statement in the trigger body must only refer to a table or view that is at the current server.
- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that contains one of the following statements:
  - COMMIT
  - CONNECT
  - RELEASE connection
– ROLLBACK (without TO SAVEPOINT)
– SET CONNECTION

- The trigger body must not, directly or indirectly, issue a CALL statement for a procedure that is defined with the COMMIT ON RETURN option.
- If the trigger is a before trigger:
  - The trigger body must not contain a DELETE, INSERT, MERGE, REFRESH TABLE, TRUNCATE, UPDATE statement, or SELECT FROM data-change-statement, and must not reference a procedure or function that is defined as MODIFIES SQL DATA.
  - The trigger body must not, directly or indirectly, issue a CALL statement for a procedure containing one of the following statements:
    - ALTER
    - COMMENT
    - CREATE
    - DELETE
    - DROP
    - EXCHANGE
    - GRANT
    - LABEL
    - LOCK TABLE
    - MERGE
    - REFRESH TABLE
    - RENAME
    - REVOKE
    - TRUNCATE
    - UPDATE

The body of a trigger must not reference a declared temporary table or a column of a BUSINESS_TIME period.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

A CREATE TRIGGER statement cannot contain a hexadecimal graphic string (GX) constant.

All tables, views, aliases, sequences, roles, user-defined types, user-defined functions, and procedures referenced in the triggered-action must exist at the current server when the trigger is created. The table or view that an alias refers to must also exist when the trigger is created.

Notes

Owner privileges:
When an INSTEAD OF trigger is defined, the associated privilege (INSERT, UPDATE, or DELETE on the view) is given to the owner of the view. The owner is granted the privilege with the ability to grant that privilege to others. For more information about ownership of an object, see “Authorization, privileges, permissions, masks, and object ownership” on page 72.
Execution authorization:
The user executing the triggering SQL operation does not need authority to execute a SQL-trigger-body. An SQL-trigger-body executes using the authority of the owner of the trigger.

Activating a trigger:
Only insert, delete, or update operations can activate a trigger. The activation of a trigger might cause trigger cascading. Trigger cascading is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which can result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing a significant change to the database as a result of a single insert, delete, or update operation.

Loading a table with the LOAD utility does not activate any triggers that are defined for the table if the SHRLEVEL NONE option is specified or accepted as the default. If the LOAD statement includes the SHRLEVEL CHANGE option, triggers are activated when loading a table with the LOAD utility.

Adding triggers to enforce constraints:
Adding a trigger on a table that already has rows in it will not cause the triggered-action to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

Multiple triggers:
Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated in the order in which they were created. For example, the trigger that was created first is executed first; the trigger that was created second is executed second.

Transition variables and transition tables:
The triggered-action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

A transition variable has the same name and data type as the corresponding column of the table that the trigger is defined on, and is nullable. A transition variable contains the value of a column in an affected row. A transition variable is qualified by a correlation name that identifies whether the reference is to the old value (before the update) or the new value (after the update). A transition variable can be referenced in the search condition, or in an SQL statement in the trigger body, wherever a variable would be allowed if the reference was made outside the body of a trigger. A new transition variable can be assigned a value in a before update or insert trigger. The values of the updated rows include the changes from any assignments to transition variables in the triggered-action of a before trigger.

A transition table contains the complete set of affected rows: either the old values (before the update) or the new values (after the update). A transition table is read-only, and can be referenced in the triggered-action of an after or instead of trigger. A column of a transition table has the same name, data type, and null attribute as the corresponding column of the table that the trigger is defined on. A transition table is referenced using an
associated table identifier that allows the complete set of affected rows to be treated as a table. A transition table can be referenced in a search condition, or in an SQL statement in the trigger body, wherever a table would be allowed if the reference was made outside the body of a trigger. In addition, a transition table can be passed as an argument to a user-defined function or procedure, specifying the TABLE keyword before the table identifier for the transition table. When the function or procedure is invoked, a table locator is passed for the transition table.

**Considerations for implicitly hidden columns:**
In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced. A transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table. Likewise, a transition variable will exist for the column that is defined as implicitly hidden. A transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

**Identifier resolution:**
Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, a transition variable, or a global variable. If the name is not qualified or is qualified but is still ambiguous, the following rules describe how the name is resolved. If correlation names are specified for both old and new transition variables, a reference to a transition variable must be qualified with the associated correlation name. The name is resolved by checking for a match in the following order:

- If the tables and views specified in the trigger body exist at the time the trigger is created, the name is first checked as a column name at the current server. If the name is found as a column name, but the privilege set that is used to issue the CREATE statement does not have the proper authority to access the table or view, an error is returned.
- If the name is not found as a column, the name is checked as a transition variable name.
- If the name is not found as a transition variable, the name is checked as a global variable.
- If the name is still not resolved, an error is returned.

**Considerations for transition variables in AFTER and INSTEAD OF triggers:**
Transition variables cannot be modified in an AFTER or INSTEAD OF trigger.

**Considerations for INSTEAD OF triggers:**
The addition of an INSTEAD OF trigger for a view affects the read only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

The creation of an INSTEAD OF trigger causes dependent packages, plans, and statements in the dynamic statement cache to be marked invalid if the view definition is not read-only.

The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:
- If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
• If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
  – the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  – otherwise, the null value
If a view column is not nullable and does not have a default, the value must be explicitly specified in the insert operation.

The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:
• If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value
• If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:
  – the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  – otherwise, the null value
If a view column is not nullable and does not have a default, the value must be explicitly specified in the update operation.
• Otherwise, the corresponding new transition variable is the existing value of the column in the row.

**Considerations for a MERGE statement:**
The MERGE statement can execute insert and update operations. The applicable UPDATE or INSERT triggers are activated for the MERGE statement when an insert or update operation is executed.

**Considerations for triggers that are defined on tables that contain XML columns:**
Although a trigger can be defined on a table that contains an XML column:
• An XML column cannot be referenced with a trigger transition variable in the trigger body. An SQL-procedure-statement cannot reference a transition variable that is an XML data type.
• An XML column of a transition table cannot be referenced in the trigger body. An SQL-procedure-statement cannot reference a column in a transition table that is an XML data type.

**Creating a trigger with the SECURED option:**
Typically, the security administrator will examine the data that is accessed by a trigger, ensure that it is secure, and grant the CREATE_SECURE_OBJECT privilege to someone who requires the privileges to create a secured trigger. After the trigger is created, the security administrator will revoke the CREATE_SECURE_OBJECT privilege from the owner of the trigger.

The trigger is considered secure after the CREATE TRIGGER statement is executed. DB2 treats the SECURED attribute as an assertion that declares that the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, DB2 assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure that those functions are allowed to access that data and that an audit procedure is in place for all versions of those functions, and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.
A trigger must be secure if its subject table is using row access control or column access control. SECURED must also be specified for a trigger that is created for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

**Creating a trigger with the NOT SECURED option:**

The CREATE TRIGGER statement returns an error if the subject table of the trigger is using row access control or column access control, or if the trigger is for a view and one or more of the underlying tables in the view definition is using row access control or column access control.

**Row and column access control that is not enforced for transition variables and transition tables:**

If row access control or column access control is enforced for the subject table of the trigger, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row access control and column access control is enforced for the triggering table, but is ignored for transition variables and transition tables that are referenced in the body of the trigger body or are passed as arguments to user-defined functions that are invoked in the body of the trigger. To ensure that there are no security concerns for SQL statements accessing sensitive data in transition variables and transition tables in the trigger action, the trigger must be created with the SECURED option. If a trigger is not secure, the CREATE TRIGGER statement returns an error.

**Restrictions involving pending definition changes:**

CREATE TRIGGER is not allowed if the trigger is defined on a table for which there are pending definition changes.

**Considerations for the special plan, statement, and function tables for EXPLAIN:**

You can create a trigger on PLAN_TABLE, DSN_STATEMENT_TABLE, or DSN_FUNCTION_TABLE. However, insert triggers that are defined on these tables are not activated when DB2 adds rows to the tables.

**Dependent objects:**

A trigger is dependent on the triggering table and objects that are referenced in the trigger body.

**Adding a column to a subject table or a table referenced in the triggered-action:**

If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an update trigger that was defined without an explicit list of column names, an update to the new column activates the trigger.
- If the subject table is referenced in the triggered-action, the new column is not accessible to the SQL statements until the trigger package is rebound.
- The OLD_TABLE and the NEW_TABLE transition tables contain the new column, but the column cannot be referenced unless the trigger is re-created. If the transition tables are passed to a user-defined function or a stored procedure, the user-defined function or stored procedure must be re-created with the new definition of the table (that is, the function or procedure must be dropped and re-created), and the package for the user-defined function or stored procedure must be rebound.

If a column is added to any table that is referenced in the triggered-action, the new column is not accessible to the SQL statements until the trigger package is rebound.
Dropping a column from a subject table or a table referenced in the triggered-action:
A column cannot be dropped from a table for which a trigger is defined.

Altering the attributes of a column that the triggered action references:
If a column is altered in the table on which the trigger is defined (the subject table), the alter is processed, and the dependent trigger packages are invalidated.

Renaming the table for which the trigger is defined, or tables referenced in the triggered-action:
You cannot rename a table for which a trigger is defined (the subject table). Except for the subject table, you can rename any table to which the SQL statements in the triggered action refer. After renaming such a table, drop the trigger and then re-create the trigger so that it refers to the renamed table.

Dropping the table for which a trigger is defined:
If the table that a trigger is defined on is dropped, the trigger is also dropped.

Effects of dropping or revoking privileges on an object referenced in the triggered-action:
Dropping an object that is referenced in the body of a trigger, or revoking a privilege to an object that is referenced in the body of a trigger, might have the following results:
- Dropping the table on which the trigger is defined causes the trigger and its package to also be dropped.
- Dropping any table, view, alias, or index that is referenced or used within the SQL statements in the triggered action causes the trigger and its package to be invalidated. Dropping a synonym that is referenced does not have any effect on the trigger or its package.
- Dropping a user-defined function that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Dropping a sequence that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Revoking a privilege on which the trigger depends causes the trigger and its package to be invalidated. If the appropriate privilege does not exist when the trigger package is rebound, the SQL statement that references the object fails.

Error handling in triggers:
A trigger can return errors, like other SQL statements. Applications need to account for the possible errors that can be expected when a trigger is invoked. Any exception SQLSTATE that is not handled within the trigger body (using a handler) results in the return of the exception SQLSTATE to the statement that caused the trigger to be activated. For example, if a SIGNAL statement (RESIGNAL statement or RAISE_ERROR function) raises a non-severe error in the SQL-trigger-body, and the condition is not handled within the trigger body, SQLCODE -438 and the corresponding SQLSTATE are returned. Other non-severe errors are returned with SQLCODE -723 and SQLSTATE 09000. Severe errors that occur during the execution of triggered SQL statements are returned with SQLCODE -901, -906, -911, or -913, and the corresponding SQLSTATE. Warnings are not returned.

Triggers and global variables:
The content of a global variable that is referenced by a trigger is inherited
from the triggering SQL operation (delete, insert, or update). Global
variables cannot be modified in or by a trigger.

Special registers:
The values of the special registers that are used in the trigger body are
determined when the trigger is activated. The value of the CURRENT
PACKAGESET special register is set to the schema name of the trigger, and
the values of the other special registers are inherited from the triggering
SQL operation (insert, update, or delete). These values are saved before a
trigger is activated, and are restored on return from the trigger. The
CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP special
registers are not restored on return from the trigger.

Result sets for stored procedures:
If a trigger invokes a stored procedure that returns result sets, the
application that activated the trigger cannot access those result sets.

Transaction isolation:
All of the statements in the SQL-trigger-body run under the isolation level
that is in effect for the trigger.

Limiting processor time:
The DB2 resource limit facility allows you to specify the maximum amount
of processor time for a dynamic, manipulative SQL statement such as
SELECT or SQL data change statements. The execution of a trigger is
counted as part of the triggering SQL statement. The ASUTIME routine
option can be used to specify such a limit.

Errors binding triggers:
When a CREATE TRIGGER statement is bound, the SQL statements within
the triggered action might not be fully parsed. Syntax errors in those
statements might not be caught until the CREATE TRIGGER statement is
executed.

Characteristics of the package that is generated for a trigger:
The package that is associated with the trigger is named as follows:

- location is set to the value of the CURRENT SERVER special register.
- collection-id (schema) for the package is the same as the schema qualifier
  of the trigger.
- package-id is the same as the name of the trigger.
- version-id is an empty string.

The package is generated with the bind options that correspond to the
implicitly or explicitly specified trigger options.

Multiple versions of a trigger package are not allowed. Use the REBIND
command to explicitly rebind the trigger package. To specify the name of a
trigger package for the bind commands, the trigger name must conform to
the rules for an ordinary identifier.

A trigger package becomes invalid if an object or privilege on which it
depends is dropped or revoked. The next time that the trigger is activated,
DB2 attempts to rebind the invalid trigger package. If the automatic rebind
is unsuccessful, the trigger package remains invalid.

You cannot create another package from the trigger package, such as with
the BIND COPY command. The only way to drop a trigger package is to
drop the trigger or the subject table. Dropping the trigger drops the trigger
package; dropping the subject table drops the trigger and the trigger
package.
Considerations for SQL processor programs:

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the triggered action that are ended with semicolons. These processor programs accept multiple SQL statements, each separated with a terminator character, as input. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE TRIGGER statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see Setting the SQL terminator character in a SPUFI input data set (DB2 Application programming and SQL) and DSNTEP2 and DSNTEP4 (DB2 Application programming and SQL).

Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- OLD TABLE as a synonym for OLD_TABLE
- NEW TABLE as a synonym for NEW_TABLE

Examples

Example 1: Create two triggers that track the number of employees that a company manages. The subject table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY_STATS table. The tables have these columns:

- EMPLOYEE table: ID, NAME, ADDRESS, and POSITION
- COMPANY_STATS table: NBEMP, NBPRODUCT, and REVENUE

This example shows the use of transition variables in a row trigger to maintain summary data in another table.

Create the first trigger, NEW_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMPLOYEE
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
  UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
END
```

Create the second trigger, FORM_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY_STATS by 1.

```
CREATE TRIGGER FORM_EMP
AFTER DELETE ON EMPLOYEE
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
  UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
END
```

Example 2: Create a trigger, REORDER, that invokes user-defined function ISSUE_SHIP_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE_SHIP_REQUEST orders a
quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity; the function also ensures that the request is sent to the appropriate supplier.

The parts records are in the PARTS table. Although the table has more columns, the trigger is activated only when columns ON_HAND and MAX_STOCKED are updated.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW AS NROW
  FOR EACH ROW MODE DB2SQL
  WHEN (NROW.ON_HAND < 0.10 * NROW.MAX_STOCKED)
  BEGIN ATOMIC
    VALUES(ISSUE_SHIP_REQUEST(NROW.MAX_STOCKED - NROW.ON_HAND, NROW.PARTNO));
  END
```

**Example 3:** Repeat the scenario in Example 2 except use a fullselect instead of a VALUES statement to invoke the user-defined function. This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW_TABLE AS NTABLE
  FOR EACH STATEMENT MODE DB2SQL
  BEGIN ATOMIC
    SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
    FROM NTABLE
    WHERE (ON_HAND < 0.10 * MAX_STOCKED);
  END
```

**Example 4:** Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of '75001' and a description. This example shows that the SIGNAL statement is useful for restricting changes that violate business rules.

```
CREATE TRIGGER SAL_ADJ
  AFTER UPDATE OF SALARY ON EMPLOYEE
  REFERENCING OLD AS OLD_EMP
      NEW AS NEW_EMP
  FOR EACH ROW MODE DB2SQL
  WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY * 1.20))
  BEGIN ATOMIC
    SIGNAL SQLSTATE '75001' ('Invalid Salary Increase - Exceeds 20%');
  END
```

**Example 5:** Assume that the following statements create a table, WEATHER (which stores temperature values in Fahrenheit), and a view, CELSIUS_WEATHER for users who prefer to work in Celsius instead of Fahrenheit:

```
CREATE TABLE WEATHER
  (CITY VARCHAR(25),
   TEMPF DECIMAL(5,2));
CREATE VIEW CELSIUS_WEATHER (CITY, TEMPC) AS
  SELECT CITY, (TEMPF-32)/1.8
  FROM WEATHER;
```

The following INSTEAD OF trigger is used on the CELSIUS_WEATHER view to convert Celsius values to Fahrenheit values and then insert the Fahrenheit value into the WEATHER table:
CREATE TRIGGER CW_INSERT INSTEAD OF INSERT ON CELSIUS_WEATHER
REFERENCING NEW AS NEWCW
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
    INSERT INTO WEATHER VALUES
    (NEWCW.CITY,
    1.8*NEWCW.TEMPC+32)
END;

<table>
<thead>

</tbody>
</table>
CREATE TRUSTED CONTEXT

The CREATE TRUSTED CONTEXT statement defines a trusted context at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:

- SYSADM authority
- SECADM authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.
Syntax

CREATE TRUSTED CONTEXT—context-name—

BASED UPON CONNECTION USING SYSTEM AUTHID—authorization-name—

NO DEFAULT ROLE

DEFAULT ROLE—role-name—

WITHOUT ROLE AS OBJECT OWNER

WITH ROLE AS OBJECT OWNER AND QUALIFIER

NO DEFAULT SECURITY LABEL

DEFAULT SECURITY LABEL—seclabel-name—

ATTRIBUTES

ADDRESS—address-value—

ENCRYPTION—encryption-value—

SERVAUTH—servauth-value—

JOBNAME—jobname-value—

WITH USE FOR

authorization-name—

EXTERNAL SECURITY PROFILE—profile-name—

PUBLIC

WITHOUT AUTHENTICATION

WITH AUTHENTICATION

Notes:

1 This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.

2 ENCRYPTION must not be specified more than one time.

3 Each pair of attribute name and corresponding value must be unique.

user-options:
Description

context-name
Names the trusted context. The name must not identify a trusted context that exists at the current server.

BASED UPON CONNECTION USING SYSTEM AUTHID authorization-name
Specifies that the context is a connection that is established by the authorization ID that is specified by authorization-name. The system authorization ID is the primary authorization ID. For a remote connection, it is derived from the system user ID that is provided by an external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 135.

Table 135. System authorization ID for a local connection

<table>
<thead>
<tr>
<th>Source of local connection</th>
<th>System authorization ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Started task (RRSAF)</td>
<td>USER parameter on JOB statement or RACF USER.</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>USER parameter on JOB statement</td>
</tr>
</tbody>
</table>

authorization-name must not be associated with an existing trusted context.

NO DEFAULT ROLE or DEFAULT ROLE role-name
Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context.

NO DEFAULT ROLE
Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

NO DEFAULT ROLE is the default.

DEFAULT ROLE role-name
Specifies that role-name is the role for the trusted context. role-name must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER
Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context.

WITHOUT ROLE AS OBJECT OWNER
Specifies that a role is not used as the owner of the objects that are created...
using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

WITH ROLE AS OBJECT OWNER AND QUALIFIER
Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context and that role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

AND QUALIFIER
Specifies that role-name will be used as the default for the CURRENT SCHEMA special register. The role-name will also be included in the SQL PATH (in place of CURRENT SQLID).

When WITH ROLE AS OBJECT OWNER AND QUALIFIER is not specified, there is no change to the default for the CURRENT SCHEMA special register and the SQL PATH.

DISABLE or ENABLE
Specifies whether the trusted context is created in the enabled or disabled state.

DISABLE
Specified that the trusted context is disabled when it is created. A trusted context that is disabled is not considered when a trusted connection is established. DISABLE is the default.

ENABLE
Specifies that the trusted context is enabled when it is created.

NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL seclabel-name
Specifies whether the trusted connection has a default security label.

NO DEFAULT SECURITY LABEL
Specifies that the trusted context does not have a default security label.

DEFAULT SECURITY LABEL seclabel-name
Specifies that seclabel-name is the default security label for the trusted context and is the security label that is used for multilevel security verification. seclabel-name must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used for a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, seclabel-name must also identify one of the RACF SECLABEL values that is defined for the user.

ATTRIBUTES
Specifies a list of one or more connection trust attributes that are used to define the trusted context.

ADDRESS address-value
Specifies the actual communication address that is used by the connection
to communicate with the database manager. The protocol supported is only for TCP/IP. The ADDRESS attribute can be specified multiple times, but each address-value must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. address-value must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of address-value is done at the time the CREATE TRUSTED CONTEXT statement is processed. address-value must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111
- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0008:0800:200C:417A. This address can also be express in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

**ENCRYPTION encryption-value**

Specifies the minimum level of encryption of the data stream (network encryption).

encryption-value specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. encryption-value must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. encryption-value must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

The following table summarizes when a trusted context can be used depending on the encryption that is used by the existing connection. If the trusted context cannot be used for the connection, a warning is returned.

<table>
<thead>
<tr>
<th>Encryption that is used by the existing connection</th>
<th>Value of the ENCRYPTION clause for the trusted context</th>
<th>Can the trusted context be used for the connection?</th>
</tr>
</thead>
<tbody>
<tr>
<td>No encryption</td>
<td>NONE</td>
<td>Yes</td>
</tr>
<tr>
<td>No encryption</td>
<td>LOW</td>
<td>No</td>
</tr>
<tr>
<td>No encryption</td>
<td>HIGH</td>
<td>No</td>
</tr>
<tr>
<td>Low encryption (64-bit)</td>
<td>NONE</td>
<td>Yes</td>
</tr>
<tr>
<td>Low encryption (64-bit)</td>
<td>LOW</td>
<td>Yes</td>
</tr>
<tr>
<td>Low encryption (64-bit)</td>
<td>HIGH</td>
<td>No</td>
</tr>
</tbody>
</table>
Table 136. Summary of when trusted context can be used by an existing connection (continued)

<table>
<thead>
<tr>
<th>Encryption that is used by the existing connection</th>
<th>Value of the ENCRYPTION clause for the trusted context</th>
<th>Can the trusted context be used for the connection?</th>
</tr>
</thead>
<tbody>
<tr>
<td>High encryption (128-bit)</td>
<td>NONE</td>

</tr>
<tr>
<td>High encryption (128-bit)</td>
<td>LOW</td>
<td>Yes</td>
</tr>
<tr>
<td>High encryption (128-bit)</td>
<td>HIGH</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**JOBNAME value**

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. The JOBNAME attribute can be specified multiple times, but each jobname-value must be unique.

jobname-value specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. jobname-value is an EBCDIC 8 byte value that specifies the job name or the started task name. The value must be left justified within the string constant. The last character in the name can be a wildcard character (*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that begin with the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space.

Table 137. Job name for local connection

<table>
<thead>
<tr>
<th>Source of the address space</th>
<th>Job name</th>
</tr>
</thead>
<tbody>
<tr>
<td>RRSASF</td>
<td>Job name or started task name</td>
</tr>
<tr>
<td>TSO</td>
<td>TSO logon ID</td>
</tr>
<tr>
<td>BATCH</td>
<td>Job name on JOB statement</td>
</tr>
</tbody>
</table>

**SERVAUTH servauth-value**

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2. The SERVAUTH attribute can be specified multiple times but each servauth-value must be unique.

servauth-value specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. servauth-value is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. servauth-value must be left justified in the string constant. No validation of servauth-value is done at the time the CREATE TRUSTED CONTEXT statement is processed.

**WITH USE FOR**

Specifies who can use a trusted connection that is based on the specified trusted context.

authorization-name

Specifies that the trusted connection can be used by the specified authorization-name. This is the DB2 primary authorization ID. The authorization-name must not be specified more than one time in the WITH USE FOR clause.

**ROLE role-name**

Specifies that role-name is the role that is used when a trusted
connection is used by the specified authorization-name. The role-name
must identify a role that exists at the current server. The role that is
explicitly specified for the user overrides any default role that is
associated with the trusted context.

**SECURITY LABEL seclabel-name**

Specifies that seclabel-name is the security label to use for multilevel
security verification when the trusted connection is used by the
specified authorization-name. The seclabel-name must be one of the RACF
SECLABEL values that is defined for the user. The security label that is
explicitly specified for the user overrides any default security label that is
associated with the trusted context.

***WITHOUT AUTHENTICATION or WITH AUTHENTICATION***

Specifies whether use of the trusted connection requires authentication
of the user.

**WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not
require authentication. WITHOUT AUTHENTICATION is the
default.

**WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the
authentication token with the authorization ID to authenticate the
user. If a trusted connection is established locally, the
authentication token is the password that is provided by the
CONNECT statement with the USER and USING clauses. If the
trusted connection is established from a remote client, the
authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

**EXTERNAL SECURITY PROFILE profile-name**

Specifies that the trusted connection can be used by the DB2 primary
authorization IDs that are permitted to use the specified profile-name in
RACF. The profile-name must not be specified more than one time in the
WITH USE FOR clause.

**ROLE role-name**

Specifies that role-name is the role that is used when a trusted
connection is used by any authorization ID permitted to use the
specified profile-name in RACF. The role-name must identify a role that
exists at the current server. The role that is explicitly specified for the
profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL seclabel-name**

Specifies that seclabel-name is the security label to use for multilevel
security verification when the trusted connection is used by any
authorization ID that is permitted to use the specified profile-name in
RACF. The seclabel-name must be one of the RACF SECLABEL values
that is defined for the user. The security label that is explicitly specified
for the profile overrides any default security label that is associated
with the trusted context.
WITHOUT AUTHENTICATION or WITH AUTHENTICATION
  Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION
  Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION
  Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:
    • password
    • RACF Passticket
    • Kerberos token

PUBLIC
  Specifies that a trusted connection that is based on the specified trusted context can be used by any user. All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION
  Specifies whether use of the trusted connection requires authentication of the user.

WITHOUT AUTHENTICATION
  Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

WITH AUTHENTICATION
  Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:
    • password
    • RACF Passticket
    • Kerberos token
Notes

Owner privileges: There are no specific privileges on a trusted context.

Requirement for trusted connections: To use trusted connections, you cannot set the ALL subsystem parameter to ALL and set the RESTART subsystem parameter to DEFER on installation panel DSNTIPS.

Order of precedence for users of a trusted connection: The specifications for a user are determined in the following order of precedence:

1. authorization-name
2. EXTERNAL SECURITY PROFILE profile-name
3. PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

User-clause SYSTEM AUTHID considerations: If the authorization-name that is specified in the SYSTEM AUTHID clause is the same as the authorization-name that is specified in the user-clause authorization-name, the role or the security label that is specified for authorization-name takes precedence over the default value. The value that is specified for the profile-name, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in authorization-name, the role or the security label that is specified for that profile-name takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the user-clause or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if authorization-name is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If authorization-name is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

Specifying a role in the definition of a trusted context: The definition of a trusted context can designate a role for a specific authorization ID, and a default role for use for an authorization ID for which a specific role has not been specified in the definition of the trusted context. This role can be used with a trusted connection that is based on the trusted context, but it does not make the role available outside of a trusted connection that is based on the trusted context. When an SQL statement that is not a CREATE, GRANT, or REVOKE statement is issued using a trusted connection, the privileges that are held by a role that is in effect for the authorization ID within the definition of the associated trusted context are considered in addition to other privileges that are directly held by the
authorization ID of the statement. The CREATE, GRANT, and REVOKE statements only consider the privileges of the role that is in effect for the trusted connection, or the authorization ID of the statement if a role is not in effect for the trusted connection. If ROLE AS OBJECT OWNER is in effect for a trusted connection, the role that is in effect for the authorization ID for the trusted connection becomes the owner of any object that is created while using the trusted connection.

When a newly created trusted context takes effect: The newly created trusted context takes effect after the CREATE TRUSTED CONTEXT statement is committed. If the CREATE TRUSTED CONTEXT statement results in an error or is rolled back, no trusted context is created.

Examples

Example 1: The following statement creates a trusted context called CTX1, which is based on a connection and can only be used by users JOE and SAM. Authentication information is required for JOE to use the trusted connection. The trusted context specifies a default role called CTXROLE. However, when JOE uses the trusted connection, the default role is overridden by the user role, ROLE1. When SAM uses the trusted connection, SAM uses the default role. CTX1 is enabled when it is created.

```
CREATE TRUSTED CONTEXT CTX1
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
  ATTRIBUTES (ADDRESS '9.30.131.203',
               ENCRYPTION 'LOW')
  DEFAULT ROLE CTXROLE
  ENABLE
  WITH USE FOR SAM, JOE ROLE ROLE1 WITH AUTHENTICATION;
```

Example 2: The following statement creates a trusted context, CTX2, for a started task, WASPROD. CTX2 is based on a connection, can be used by user SALLY, specifies a default role CTXROLE, and is enabled when it is created. SALLY uses the default role that is associated with the trusted context.

```
CREATE TRUSTED CONTEXT CTX2
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF002
  ATTRIBUTES (JOBNAME 'WASPROD')
  DEFAULT ROLE CTXROLE WITH ROLE AS OBJECT OWNER AND QUALIFIER
  ENABLE
  WITH USE FOR SALLY;
```
The CREATE TYPE statement defines a user-defined data type at the current server.

The following types of user-defined data types can be defined:

**Array**  
A user-defined data type that is an ordinary array or an associative array. The elements of an array type are based on one of the built-in data types. See “CREATE TYPE (array)” on page 1573.

**Distinct**  
A user-defined data type that shares a common representation with one of the built-in data types. Functions that cast between the user-defined distinct type and the source built-in data type are generated when the user-defined distinct type is created. Optionally, support for comparison operations to use with the user-defined distinct type can be generated when the user-defined distinct type is created. See “CREATE TYPE (distinct)” on page 1578.
CREATE TYPE (array)

The CREATE TYPE (array) statement defines an array type at the current server. An array type is a user-defined data type that is an ordinary array or an associative array. The elements of an array type are based on one of the built-in data types.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package.

Authorization

The privilege set that is defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is running under a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the owner is a role. The implicit schema match does not apply, and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Syntax

```
CREATE TYPE array-type-name AS built-in-type ARRAY [integer-constant] data-type2
```
Description

array-type-name

Names the array type. The name, including the implicit or explicit qualifier, must not identify any other built-in or user-defined type that exists at the current server.
The unqualified form of `array-type-name` must not be any of the following system-reserved keywords, even if you specify them as delimited identifiers:

```
ALL
LIKE
UNIQUE
AND
MATCH
UNKNOWN
ANY
NOT
BETWEEN
NULL
= ¬=
DISTINCT
ONLY
<
EXCEPT
OR
<=
EXISTS
OVERLAPS
<=
FALSE
SIMILAR
>
FOR
SOME
>=
FROM
TABLE
=>
IN
TRUE
<>
IS
TYPE
```

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

`built-in-type`

Specifies the built-in data type of the array elements. The data type must not be ROWID or XML. For more information on built-in data types, see [built-in-type in CREATE TABLE](#).

`CCSID ASCII, EBCDIC, or UNICODE in a built-in-type specification`

If the data type is a character string, and a CCSID clause is not specified for `built-in-type`, the default CCSID is determined as follows:

- If `data-type2` is a character string data type with an explicit CCSID clause, that same CCSID value is used for `built-in-type`.
- If `data-type2` is a character string data type without an explicit CCSID clause, the CCSID for `built-in-type` is determined from the encoding scheme that is indicated by the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

If a CCSID clause is specified for `built-in-type` and for `data-type2`, the CCSID values must be the same.

`FOR SBCS, MIXED, or BIT DATA in a built-in-type specification`

Specifies a subtype for a character string data type (VARCHAR). Do not use this clause with any other data type.

- **SBCS** Single-byte data.
- **MIXED** Mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified.
- **BIT** Bit data.

If you do not specify the FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA clause, the default value is determined as follows:

- For ASCII or EBCDIC data:
  - The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO.
  - The default is MIXED when the value is YES.
- For Unicode data, the default subtype is MIXED.

`ARRAY[integer-constant]`

Specifies that the type is an ordinary array with a maximum cardinality of `integer-constant`. The value must be an integer that is greater than 0 and less
than or equal to the largest positive integer value (2147483647). The default is
2147483647. Each varying-length string array element is allocated as its
maximum length.

The cardinality of an array value is determined by the highest element position
that is assigned to the array value. The maximum cardinality of an array is
limited by the total amount of memory that is available to DB2 applications.
Therefore, although an array with a large cardinality can be created, not all
elements might be available for use. An attempt to assign a value to an array
element when there is not enough memory results in an error.

**ARRAY[**data-type2**]**

Specifies that the type is an associative array that is indexed by values of data
type **data-type2**. The data type must be the INTEGER or VARCHAR data type.
The value that is specified as the index during assignment of a value to an
array element must be assignable to a value of **data-type2**.

The cardinality of an array value is determined by the number of unique index
values that are used when during assignment of array elements.

**CCSID ASCII, EBCDIC, or UNICODE in a **data-type2** specification**

If the data type is a character string, and a CCSID clause is not specified for
**data-type2**, the default CCSID is determined as follows:

- If **built-in-type** is a character string data type with an explicit CCSID clause,
  that same CCSID value is used for **data-type2**.
- If **built-in-type** is a character string data type without an explicit CCSID
  clause, the CCSID for **data-type2** is determined from the encoding scheme
  that is indicated by the value of field DEF ENCODING SCHEME on
  installation panel DSNTIPF.

If a CCSID clause is specified for **built-in-type** and for **data-type2**, the CCSID
values must be the same.

**FOR SBCS, MIXED, or BIT DATA in a **data-type2** specification**

Specifies a subtype for a character string data type (VARCHAR). Do not use
this clause with any other data type.

**SBCS** Single-byte data.
**MIXED**
**BIT** Bit data.

If you do not specify the FOR SBCS DATA, FOR MIXED DATA, or FOR BIT
DATA clause, the default value is determined as follows:

- For ASCII or EBCDIC data:
  - The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified.
  - The default is MIXED when the value is YES.
- For Unicode data, the default subtype is MIXED.

**Notes**

**Array type usage:** A user-defined array type can only be used as the data type of:
- An SQL variable
- A parameter or RETURNS **data-type** of an SQL scalar function
- A parameter of a native SQL procedure
- The target data type for a CAST specification

**Generated cast functions:** The successful execution of the CREATE TYPE (array)
statement causes the DB2 database manager to generate cast functions for the
user-defined array type. Those cast functions are recorded in the DB2 catalog. The
unqualified names of the two cast functions are ARRAY and the name of the array
type. A generated cast function cannot be explicitly dropped. The cast functions
that are generated for an array type are implicitly dropped when the array type is
dropped with the DROP statement.

**Examples**

*Example 1:* Create an ordinary array user-defined type named PHONENUMBERS,
with a maximum of 50 elements. The elements are of the DECIMAL(10,0) data
type.

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0) ARRAY[50];
```

*Example 2:* Create an ordinary array user-defined type named NUMBERS, in the
schema GENERIC. You do not know the maximum number of elements, so you
use the default value. The elements are of the DECFLOAT(34) data type.

```
CREATE TYPE GENERIC.NUMBERS AS DECFLOAT(34) ARRAY[];
```

*Example 3:* Create an associative array user-defined type named
PERSONAL_PHONENUMBERS. The elements are of the DECIMAL(16, 0) data
type. The array type is indexed by strings such as 'Home', 'Work', or 'Cell', so the
index data type must be VARCHAR.

```
CREATE TYPE PERSONAL_PHONENUMBERS AS DECIMAL(16,0) ARRAY[VARCHAR(8)];
```

*Example 4:* Create an associative array user-defined type named CAPITALSARRAY.
The elements are capital cities. The index values are province, territory, or country
names, so the index data type must be VARCHAR.

```
CREATE TYPE CAPITALSARRAY AS VARCHAR(30) ARRAY[VARCHAR(20)];
```

*Example 5:* Create an associative array user-defined type named PRODUCTS. The
elements are product descriptions of up to 40 characters. The index values are
product numbers, which have the INTEGER data type.

```
CREATE TYPE PRODUCTS AS VARCHAR(40) ARRAY[INTEGER];
```
CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type, which is a data type that a user defines. A distinct type must be based on one of the built-in data types.

Successful execution of the statement also generates:
• A function to cast between the distinct type and its source type
• A function to cast between the source type and its distinct type
• As appropriate, support for the use of comparison operators with the distinct type

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
• The CREATEIN privilege on the schema
• SYSADM or SYSCTRL authority
• System DBADM

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
• The privilege set includes SYSADM or SYSCTRL authority.
• The SQL authorization ID of the process has the CREATEIN privilege on the schema.
Syntax

```
CREATE TYPE distinct-type-name AS source-data-type
```

Notes:
1. INLINE LENGTH can only be specified when `source-data-type` is a LOB data type.

source-data-type

```
SMALLINT
INTEGER
BIGINT
DECIMAL (5,0)
REAL
DOUBLE PRECISION
DECIMAL (integer)
NUMERIC (integer)
FLOAT (integer)
DOUBLE PRECISION
DECFLOAT (16)
CHARACTER (integer) CCSID: ASCII FOR SBCS DATA
CHARACTER VARYING (integer) EBCDIC MIXED
CHARACTER LARGE OBJECT
CHAR (integer) CCSID: ASCII FOR SBCS DATA
CLOB EBCDIC MIXED
GRAPHIC (integer) CCSID: ASCII
VARGRAPHIC (integer) EBCDIC UNICODE
DBCLOB (integer)
BINARY (integer)
BINARY VARYING (integer)
VARBINARY (integer)
BINARY LARGE OBJECT
BLOB (integer)
DATE
TIME
TIMESTAMP (integer) WITHOUT TIME ZONE
ROWID
```
**Description**

*distinct-type-name*

Names the distinct type. The name, including the implicit or explicit qualifier, must not identify a distinct type that exists at the current server.

- The unqualified form of *distinct-type-name* must not be the name of a built-in data type, BOOLEAN, or any of following system-reserved keywords even if you specify them as delimited identifiers:

```
ALL   LIKE   UNIQUE
AND   MATCH  UNKNOWN
ANY   NOT    =
BETWEEN NULL   ^=
DISTINCT ONLY   <
EXCEPT OR     <=
EXISTS OVERLAPS ^<
FALSE SIMILAR >
FOR SOME    >=
FROM TABLE  ->
IN   TRUE   <>
IS   TYPE
```

- The qualified form of *distinct-type-name* is an SQL identifier (the schema name) followed by a period and an SQL identifier.

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

*source-data-type*

Specifies the data type that is used as the basis for the internal representation of the distinct type. The data type must be a built-in data type. For more information on built-in data types, see [built-in-type](#).

If the distinct type is based on a character or graphic string data type, the FOR clause indicates the subtype. If you do not specify the FOR clause, the distinct type is defined with the default subtype. For ASCII or EBCDIC data, the default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO. The default is MIXED when the value is YES. For UNICODE character data, the default subtype is mixed.

If the distinct type is based on a string data type, the CCSID clause indicates whether the encoding scheme of the data is ASCII, EBCDIC or UNICODE. If you do not specify CCSID ASCII, CCSID EBCDIC, or UNICODE, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**INLINE LENGTH** *integer*

Specifies the default inline length for columns that reference the distinct type. INLINE LENGTH can only be specified when *source-data-type* is a LOB data type. Only columns in a table that is in a universal table space can inherit the specified inline length for the distinct type. If the table is not in a universal table space, the specified inline length is ignored.

Where *source-data-type* is BLOB and CLOB, *integer* specifies the maximum number of bytes that are stored in the base table space for columns that reference this distinct type. *integer* must be between 0 and 32680 (inclusive) for a BLOB or CLOB *source-data-type*.

Where *source-data-type* is DBCLOB, *integer* specifies the maximum number of double-byte characters that are stored in the table space for columns that reference the distinct type. *integer* must be between 0 and 16340 (inclusive) for a DBCLOB *source-data-type*. 
If INLINE LENGTH is specified with a value of 0 for integer, any column that references the distinct type will not have an inline length unless the CREATE TABLE or ALTER TABLE ADD statement specifies an inline length for the column.

If INLINE LENGTH is not specified, any column that reference the distinct type takes its default value from the value of the LOB INLINE LENGTH parameter on installation panel DSNTIPD.

integer cannot be greater than the maximum length of the distinct type.

Notes

Owner privileges:
The owner of the distinct type is authorized to define columns, parameters, or variables with the distinct type (USAGE privilege) with the ability to grant these privileges to others. See "GRANT (type or JAR file privileges)" on page 1790. The owner is also authorized to invoke the generated cast function (EXECUTE privilege; see "GRANT (function or procedure privileges)" on page 1768). The owner is given the USAGE and EXECUTE privileges with the GRANT option. For more information about ownership of the object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

Source data types with DBCS or mixed data:
When the implicit or explicit encoding scheme is ASCII or EBCDIC and the source data type is graphic or a character type is MIXED DATA, then the value of field FOR MIXED DATA on installation panel DSNTIPF must be YES; otherwise, an error occurs.

Generated cast functions:
The successful execution of the CREATE TYPE (distinct) statement causes DB2 to generate the following cast functions:

• A function to convert from the distinct type to its source data type
• A function to convert from the source data type to the distinct type
• A function to cast from a data type A to distinct type DT, where A is promotable to the source data type S of distinct type DT

For some source data types, DB2 supports an additional function to convert from:

– INTEGER to the distinct type if the source type is SMALLINT
– VARCHAR to the distinct type if the source type is CHAR
– VARGRAPHIC to the distinct type if the source type is GRAPHIC
– VARBINARY to the distinct type if the source type is BINARY
– DOUBLE to the distinct type if the source type is REAL

The cast functions are created as if the following statements were executed:

```
CREATE FUNCTION source-type-name (distinct-type-name)
  RETURNS source-type-name ...
CREATE FUNCTION distinct-type-name (source-type-name)
  RETURNS distinct-type-name ...
```

Even if you specified a length, precision, or scale for the source data type in the CREATE TYPE (distinct) statement, the name of the cast function that converts from the distinct type to the source type is simply the name of the source data type. The data type of the value that the cast function returns includes any length, precision, or scale values that you specified for the source data type. (See Table 138 on page 1582 for details.)
The name of the cast function that converts from the source type to the distinct type is the name of the distinct type. The input parameter of the cast function has the same data type as the source data type, including the length, precision, and scale.

For example, assume that a distinct type named T_SHOESIZE is created with the following statement:

```
CREATE TYPE (distinct) CLAIRE.T_SHOESIZE AS VARCHAR(2)
```

When the statement is executed, DB2 also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.VARCHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T_SHOESIZE has an input parameter with a data type of VARCHAR(2).

The schema of the generated cast functions is the same as the schema of the distinct type. No other function with the same name and function signature must already exist in the database.

In the preceding example, if T_SHOESIZE had been sourced on a SMALLINT, CHAR, or GRAPHIC data type instead of a VARCHAR data type, another cast function would have been generated in addition to the two functions to cast between the distinct type and the source data type. For example, assume that T_SHOESIZE is created with this statement:

```
CREATE TYPE (distinct) CLAIRE.T_SHOESIZE AS CHAR(2)
```

When the statement is executed, DB2 generates these cast functions:

```
FUNCTION CLAIRE.CHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.CHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.CHAR (2)) RETURNS CLAIRE.T_SHOESIZE
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that the third function enables the casting of a VARCHAR(2) to T_SHOESIZE. This additional function is created to enable casting a constant, such as 'AB', directly to the distinct type. Without the additional function, you would have to first cast 'AB', which has a data type of VARCHAR, to a data type of CHAR and then cast it to the distinct type.

You cannot explicitly drop a generated cast function. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the source data type for a distinct type, the following table gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

Notes: NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. Use DECIMAL and DOUBLE (or REAL) instead.

**Built-in functions:**
When a distinct type is defined, the built-in functions (such as AVG, MAX, and LENGTH) are not automatically supported for the distinct type. You can use a built-in function on a distinct type only after a sourced user-defined function, which is based on the built-in function, has been created for the distinct type. For information on defining sourced user-defined functions, see "CREATE FUNCTION (sourced)" on page 1294.

**Arithmetic operators with distinct type operands:**
A distinct type cannot be used with arithmetic operators even if its source data type is numeric.
For additional information see "Arithmetic with distinct type operands" on page 253.

**Alternative syntax and synonyms:**
The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement. Use WITH COMPARISONS only if it is required for compatibility with other products in the DB2 family. If the source data type is either BLOB, CLOB, or DBCLOB and WITH COMPARISONS is specified, a warning occurs as in previous releases.

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:
- DISTINCT TYPE as a synonym for TYPE
- TIMEZONE can be specified as an alternative to TIME ZONE

Examples

Example 1: Create a distinct type named SHOESIZE that is based on an INTEGER data type.

    CREATE TYPE SHOESIZE AS INTEGER;

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

Example 2: Create a distinct type named MILES that is based on a DOUBLE data type.

    CREATE TYPE MILES AS DOUBLE;

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.
CREATE VARIABLE

The CREATE VARIABLE statement creates a global variable at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following:
- The CREATEIN privilege on the schema
- System DBADM authority
- SYSADM authority
- SYSCTRL authority

Privilege set: The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema. If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the owner is a role, the implicit schema does not apply and this role needs to include one of the previously listed privileges or authorities.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER AND QUALIFIER clause is in effect. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

When the ROLE AS OBJECT OWNER AND QUALIFIER clause is in effect, the privilege set is the set privileges that are held by the role. If the schema name does not match this role, one of the following conditions must be met:
- The privilege set includes SYSADM or SYSCTRL authority.
- This role has the CREATEIN privilege on the schema.

Syntax

```
CREATE VARIABLE variable-name data-type
```

data-type:
### Description

**variable name**

Names the global variable. The name, including the implicit or explicit qualifier, must not identify a global variable that exists at the current server. If the qualifier is not specified, the contents of the CURRENT SCHEMA special register is used.

**data-type**

Specifies the data type of the global variable.

**built-in-type**

The data type of the global variable is a built-in type. For information
about the data types, see built-in-type. The data type cannot be a LOB data
type, ROWID, or XML. If the data type is a string data type, it must be
Unicode.

**DEFAULT, DEFAULT NULL, DEFAULT constant, or DEFAULT special-register**
The default value that is assigned to the global variable if a value is not
explicitly specified. Specifies a value for the global variable when it is first
referenced in the session. The default value is determined on this first
reference. If the DEFAULT clause is not specified, the default for the global
variable is the null value.

**DEFAULT NULL**
Specifies null as the default value for the global variable. The value of a
global variable is always nullable.

**DEFAULT constant**
Specifies that the value of the constant is the default value for the global
variable. The value of the constant must conform to the rules for assigning
that value to the global variable. constant cannot be any of the constants
NAN, SNAN, or INFINITY.

**DEFAULT special-register**
Specifies that the value of the special register, when the global variable is
instantiated, is used as the default value of the global variable. The value
of the specified special register must conform to the rules for assigning that
value to the global variable. The following special registers must not be
specified:
- CURRENT GET_ACCEL_ARCHIVE
- CURRENT QUERY_ACCELERATION
- CURRENT TEMPORAL BUSINESS_TIME
- CURRENT TEMPORAL SYSTEM_TIME

**Notes**

**Session scope:**
global variables have a session scope. Although they are available for use
to all sessions that are active at the current server, the value of the global
variable is private for each session.

**Modifications to the value of a global variable:**
global variables are not under transaction control. Modifications to the
value of a global variable are not preserved when the transaction ends
with either a COMMIT or ROLLBACK statement.

**Privileges to use a global variable:**
Reading from or writing to a global variable requires that the authorization
ID or role that is in effect have the appropriate privileges on the global
variable. The owner of the variable is implicitly granted all privileges on
the variable.

**Setting the default value:**
After a global variable has been created, it is instantiated to its default
value when it is first referenced within a given scope. If a global variable is
referenced within a statement, it is instantiated independently from the
execution of that statement.

**Using a newly created global variable:**
If a global variable is created within a session, it cannot be used by other
sessions until the unit of work has committed. However, the newly created
global variable can be used within the session in which it is created before
the unit of work commits.

**Examples**

*Example 1:* Create a global variable to indicate what printer to use for the session.

```sql
CREATE VARIABLE MYSCHEMA.MYJOB_PRINTER VARCHAR(30)
  DEFAULT 'Default printer';
```

*Example 2:* Create a global variable to indicate the department where an employee
works.

```sql
CREATE VARIABLE SCHEMA1.GV_DEPTNO INTEGER
  DEFAULT 'Unassigned';
```
CREATE VIEW

The CREATE VIEW statement creates a view on tables or views at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

For every table or view identified in the fullselect, the privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SQLADM authority (catalog tables only)
- System DBADM authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- SYSCTRL authority (catalog tables only)
- SECADM authority (catalog tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDDB04.

Authority requirements depend in part on the choice of the owner of the view. For information on how to choose the owner, see the description of view-name in "Description" on page 1155.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the of the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

- If this privilege set includes SYSADM authority, the owner of the view can be any authorization ID. If that set includes SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.

- If the privilege set includes system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the creator must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.
• If the privilege set lacks system DBADM, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be any authorization ID if all of the following conditions are true:
  – The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
  – The view is not based only on views.

Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

• If the privilege set lacks SYSADM, SYSCTRL, system DBADM, and DBADM authority, or if the authorization ID of the application plan or package fails to meet any of the previous conditions, the owner of the view must be the owner of the application plan or package.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:
• If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, system DBADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
• If the privilege set includes system DBADM authority, SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the following rules apply:
• If the SQL authorization ID of the process has SYSADM authority, the owner of the view can be any authorization ID. If that authorization ID has SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)
  If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.
• If the SQL authorization ID of the process has system DBADM authority, the owner of the view can be any authorization ID. However, to create a view on a user table, either the owner of the view or the SQL authorization ID must have the SELECT privilege on all the tables or views in the CREATE VIEW statement.
• If SQL authorization ID of the process lacks system DBADM authority, SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be different from the SQL authorization ID if all of the following conditions are true:
  – The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
  – The view is not based only on views.
Note: The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

If the SQL authorization ID of the process lacks SYSADM, SYSCTRL, system DBADM authority, or DBADM authority, or if the SQL authorization ID of the process fails to meet any of the previous conditions, only the authorization IDs of the process can own the view. In this case, the privilege set is the privileges that are held by the authorization ID selected for ownership.

Syntax

```
CREATE VIEW view-name AS
(fullselect)
WITH common-table-expression
```

Description

`view-name`
Names the view. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table. The unqualified name must not be the same as an existing synonym.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

`column-name,...`
Names the columns in the view. If you specify a list of column names, it must consist of as many names as there are columns in the result table of the fullselect. Each name must be unique and unqualified. If you do not specify a list of column names, the columns of the view inherit the names of the columns of the result table of the fullselect.

You must specify a list of column names if the result table of the fullselect has duplicate column names or an unnamed column (a column derived from a constant, function, or expression that was not given a name by the `AS` clause). For more details about unnamed columns, see the information about names of result columns under "select-clause" on page 785.

`AS` Identifies the view definition.

`WITH common-table-expression`
Defines a common table expression for use with the fullselect that follows. The fullselect must not contain a period specification. For an explanation of common table expression, see "common-table-expression" on page 852.
fullselect
Defines the view. At any time, the view consists of the rows that would result if the fullselect were executed.

The fullselect must conform to the following rules:

- The fullselect must not refer to any host variables or parameter markers (question marks), but can refer to global variables.
- The fullselect must not refer to any declared temporary tables.
- The fullselect must not include an invocation of the UNPACK function.
- The fullselect must not contain a period specification.
- The FROM clause of the fullselect must not include a data-change-table-reference.
- The FROM clause of the fullselect must not include a view for which an INSTEAD OF trigger is defined.
- The outer SELECT list of the outer fullselect must not result in a column that is an array.

For an explanation of fullselect, see “fullselect” on page 843.

WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTIONS

 Specifies that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

The CHECK OPTION clause must not be specified if the view is read-only, includes a subquery, references a function that is not deterministic or has an external action, or if the fullselect of the view refers to a created temporary table. If the CHECK OPTION clause is specified for an updatable view that does not allow inserts, it applies to updates only.

If the CHECK OPTION clause is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes the CHECK OPTION clause. Because the definition of the view is not used, rows might be inserted or updated through the view that do not conform to the definition of the view.

The difference between the two forms of the check option, CASCADED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCADED. The view on which another view is directly or indirectly defined is an underlying view.

CASCADED
Update and insert operations on view V must satisfy the search conditions of view V and all underlying views, regardless of whether the underlying views were defined with a check option. Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V) as a constraint on insert or update operations. WITH CASCADED CHECK OPTION must not be specified if a view on which the specified view definition is dependent has an INSTEAD OF trigger defined.

LOCAL
Update and insert operations on view V must satisfy the search conditions of view V and underlying views that are defined with a check option (either WITH CASCADED CHECK OPTION or WITH LOCAL CHECK OPTION). Furthermore, every updatable view that is directly or indirectly
defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V that are defined with a check option) as a constraint on insert or update operations.

The LOCAL form of the CHECK option lets you update or insert rows that do not conform to the search condition of view V. You can perform these operations if the view is directly or indirectly defined on a view that was defined without a check option.

Table 139 illustrates the effect of using the default check option, CASCADED. The information in Table 139 is based on the following views:

- CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
- CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CASCADED CHECK OPTION
- CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Description of result</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSERT INTO V1 VALUES(5)</td>
<td>Succeeds because V1 does not have a check option and it is not dependent on any other view that has a check option.</td>
</tr>
<tr>
<td>INSERT INTO V2 VALUES(5)</td>
<td>Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly part of the definition of V2.</td>
</tr>
<tr>
<td>INSERT INTO V3 VALUES(5)</td>
<td>Results in an error because the inserted row does not conform to the search condition of V1.</td>
</tr>
<tr>
<td>INSERT INTO V3 VALUES(200)</td>
<td>Succeeds even though it does not conform to the definition of V3 (V3 does not have the view check option specified); it does conform to the definition of V2 (which does have the view check option specified).</td>
</tr>
</tbody>
</table>

The difference between CASCADED and LOCAL is shown best by example. Consider the following updatable views, where x and y represent either LOCAL or CASCADED:

- V1 is defined on Table T0.
- V2 is defined on V1 WITH x CHECK OPTION.
- V3 is defined on V2.
- V4 is defined on V3 WITH y CHECK OPTION.
- V5 is defined on V4.

This example shows V1 as an underlying view for V2 and V2 as dependent on V1.

Table 140 shows the views in which search conditions are checked during an insert or update operation:

<table>
<thead>
<tr>
<th>View used in INSERT or UPDATE operation</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>V1</td>
<td>None</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>V2</td>
<td>V2</td>
<td>V2, V1</td>
<td>V2</td>
<td>V2, V1</td>
</tr>
<tr>
<td>V3</td>
<td>V2</td>
<td>V2, V1</td>
<td>V2</td>
<td>V2, V1</td>
</tr>
<tr>
<td>V4</td>
<td>V4, V2</td>
<td>V4, V3, V2, V1</td>
<td>V4, V3, V2, V1</td>
<td>V4, V2, V1</td>
</tr>
</tbody>
</table>
Table 140. Views in which search conditions are checked during insert and update operations (continued)

<table>
<thead>
<tr>
<th>View used in INSERT or UPDATE operation</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
<th>x = LOCAL</th>
<th>x = CASCADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>V5</td>
<td>V4, V2</td>
<td>V4, V3, V2, V1</td>
<td>V4, V3, V2, V1</td>
<td>V4, V2, V1</td>
</tr>
</tbody>
</table>

Notes

Owner privileges

The owner of a view always acquires the SELECT privilege on the view and the authority to drop the view. If all of the privileges that are required to create the view are held with the GRANT option before the view is created, the owner of the view receives the SELECT privilege with the GRANT option. Otherwise, the owner receives the SELECT privilege without the GRANT option. For example, assume that a view definition also refers to a user-defined function. If the owner's EXECUTE privilege on the user-defined function is held without the GRANT option, the owner acquires the SELECT privilege on the view without the GRANT option.

The owner can also acquire INSERT, UPDATE, and DELETE privileges on the view. Acquiring these privileges is possible if the view is not "read-only", which means a single table of view is identified in the first FROM clause of the fullselect. For each privilege that the owner has on the identified table or view (INSERT, UPDATE, and DELETE) before the new view is created, the owner acquires that privilege on the view. The owner receives the privilege with the GRANT option if the privilege is held on the table or view with the GRANT option. Otherwise, the owner receives the privileges without the GRANT option.

With appropriate DB2 authority, a process can create views for those who have no authority to create the views themselves. The owner of such a view has the SELECT privilege on the view, without the GRANT option, and can drop the view.

For more information on the ownership of an object, see "Authorization, privileges, permissions, masks, and object ownership" on page 72.

Authorization for views created for other users:

When a process with appropriate authority creates a view for another user that does not have authorization for the underlying table or view, the SELECT privilege for the created view is implicitly granted to the user.

Considerations for row access control and column access control:

The view definition might reference a table for which row access control or column access control is activated. If the view definition references a table for which row access control or column access control is activated, the WITH CHECK OPTION clause must not be specified if the search conditions from the view or from the underlying views will be checked during an insert or update operation. Note that the WITH CHECK OPTION clause is ignored if such search conditions do not exist.

Read-only views:

A view is read-only if one or more of the following statements is true of its definition:

- The first FROM clause identifies more than one table or view, or
- identifies a table function, a nested table expression, a common table expression, or a collection-derived table.
The first SELECT clause specifies the keyword DISTINCT.
The outer fullselect contains a GROUP BY clause.
The outer fullselect contains a HAVING clause.
The first fullselect contains an aggregate function.
It contains a subquery such that the base object of the outer fullselect, and of the subquery, is the same table.
The first FROM clause identifies a read-only view.
The first FROM clause identifies a system-maintained materialized query table.
The outer fullselect is not a subselect (contains a set operator).

A read-only view cannot be the object of an SQL data change statement or a TRUNCATE statement. A view that includes GROUP BY or HAVING cannot be referred to in a subquery of a basic predicate.

Insertable views:
A view is insertable if an INSTEAD OF trigger for the insert operation has been defined for the view, or if at least one column of the view is updatable (independent of an INSTEAD OF trigger for update).

Considerations for implicitly hidden columns:
It is possible that the result table of the fullselect will include a column of a base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

Testing a view definition:
You can test the semantics of your view definition by executing SELECT * FROM view-name.

The two forms of a view definition:
Both the source and the operational form of a view definition are stored in the DB2 catalog. Those two forms are not necessarily equivalent because the operational form reflects the state that exists when the view is created. For example, consider the following statement:
CREATE VIEW V AS SELECT * FROM S;

In this example, S is a synonym or alias for A.T, which is a table with columns C1, C2, and C3. The operational form of the view definition is equivalent to:
SELECT C1, C2, C3 FROM A.T;

Adding columns to A.T using ALTER TABLE and dropping S does not affect the operational form of the view definition. Thus, if columns are added to A.T or if S is redefined, the source form of the view definition can be misleading.

View restrictions:
A view definition cannot contain references to remote objects. A view definition cannot map to more than 15 base table instances. A view definition cannot reference a declared global temporary table.

Restrictions involving pending definition changes:
CREATE VIEW is not allowed if the view references a column on which there are pending definition changes.
Considerations for inline LOB columns:
If the view references a table that contains an inline LOB column and DB2 determines that the inline attribute can be passed on to the view, the view will then inherit the inline attribute, otherwise the inline attribute is not inherited by the view.

Considerations for XML columns:
If the view has an XML column and the column of the underlying base table for the view has an XML type modifier, the view column has the same type modifier. However, if there is an instead of trigger defined on the view, validation of the column, according to XML schemas in the type modifier, is not enforced during insert or update to this view.

Examples

Example 1: Create the view DSN8B10.VPROJRE1. PROJNO, PROJNAME, PROJDEP, RESPEMP, FIRSTNME, MIDINIT, and LASTNAME are column names. The view is a join of tables and is therefore read-only.

```
CREATE VIEW DSN8B10.VPROJRE1
(PROJNO,PROJNAME,PROJDEP,RESPEMP,
 FIRSTNME,MIDINIT,LASTNAME)
AS SELECT ALL
PROJNO,PROJNAME,DEPTNO,EMPNO,
FIRSTNME,MIDINIT,LASTNAME
FROM DSN8B10.PROJ, DSN8B10.EMP
WHERE RESPEMP = EMPNO;
```

In the example, the WHERE clause refers to the column EMPNO, which is contained in one of the base tables but is not part of the view. In general, a column named in the WHERE, GROUP BY, or HAVING clause need not be part of the view.

Example 2: Create the view DSN8B10.FIRSTQTR that is the UNION ALL of three full selects, one for each month of the first quarter of 2000. The common names are SNO, CHARGES, and DATE.

```
CREATE VIEW DSN8B10.FIRSTQTR (SNO, CHARGES, DATE) AS
SELECT SNO, CHARGES, DATE
FROM MONTH1
WHERE DATE BETWEEN '01/01/2000' and '01/31/2000'
UNION ALL
SELECT SNO, CHARGES, DATE
FROM MONTH2
WHERE DATE BETWEEN '02/01/2000' and '02/29/2000'
UNION ALL
SELECT SNO, CHARGES, DATE
FROM MONTH3
WHERE DATE BETWEEN '03/01/2000' and '03/31/2000';
```
DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

Authorization

For each table or view identified in the SELECT statement of the cursor, the privilege set must include at least one of the following:
- The SELECT privilege
- Ownership of the object
- DBADM authority for the corresponding database (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- DATAACCESS authority

If the select-statement contains an SQL data change statement, the authorization requirements of that statement also apply to the DECLARE CURSOR statement.

The SELECT statement of the cursor is one of the following:
- The prepared select statement identified by statement-name
- The specified select-statement

If statement-name is specified:
- The privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on page 873. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 77.)
- The authorization check is performed when the SELECT statement is prepared.
- The cursor cannot be opened unless the SELECT statement is successfully prepared.

If select-statement is specified:
- The privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package.
- If the plan or package is bound with VALIDATE(BIND), the authorization check is performed at bind time, and the bind is unsuccessful if any required privilege does not exist.
- If the plan or package is bound with VALIDATE(RUN), an authorization check is performed at bind time, but all required privileges need not exist at that time. If all privileges exist at bind time, no authorization checking is performed when the cursor is opened. If any privilege does not exist at bind time, an authorization check is performed the first time the cursor is opened within a unit of work. The OPEN is unsuccessful if any required privilege does not exist.
Syntax

DECLARE cursor-name
  
  AS
  
  INS
  
  DS
  
  SS
  
  C

(1)

FOR select-statement
  
  holdability
  
  returnability
  
  rowset-positioning

Notes:
1. The same clause must not be specified more than once.

holdability:

- WITHOUT HOLD
- WITH HOLD

returnability:

- WITHOUT RETURN
- WITH RETURN
  - TO CALLE
  - TO CLIENT

rowset-positioning:

- WITHOUT ROWSET POSITIONING
- WITH ROWSET POSITIONING

Description

cursor-name

Names the cursor. The name must not identify a cursor that has already been
declared in the source program. The name is usually VARCHAR(128); however, if the cursor is defined WITH RETURN, the name is limited to VARCHAR(30).

**NO SCROLL or SCROLL**

Specifies whether the cursor is scrollable or not scrollable.

**NO SCROLL**

Specifies that the cursor is not scrollable. This is the default.

**SCROLL**

Specifies that the cursor is scrollable. For a scrollable cursor, whether the cursor has sensitivity to inserts, updates, or deletes depends on the cursor sensitivity option in effect for the cursor. If a sensitivity option is not specified, ASENSITIVE is the default.

**ASENSITIVE**

Specifies that the cursor should be as sensitive as possible. This is the default.

A cursor that defined as ASENSITIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 1840.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

**INSENSITIVE**

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or attribute-string of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

**SENSITIVE**

Specifies that the cursor has sensitivity to changes that are made to the database after the result table is materialized. The cursor is always sensitive to updates and deletes that are made using the cursor (that is, positioned updates and deletes using the same cursor). When the current value of a row no longer satisfies the select-statement or statement-name, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

If DB2 cannot make changes visible to the cursor, then an error is issued at bind time for OPEN CURSOR. DB2 cannot make changes visible to the cursor when the cursor implicitly becomes read-only. For example, when the result table must be materialized, as when the FROM clause of the SELECT statement contains more than one table or view. The current list of conditions that result in an implicit read-only cursor can be found in Read-only cursors.

The default is DYNAMIC.

**DYNAMIC**

Specifies that the result table of the cursor is dynamic, meaning that the size of the result table might change after the cursor is
opened as rows are inserted into or deleted from the underlying
table, and the order of the rows might change. Rows that are
inserted, deleted, or updated by statements that are executed by
the same application process as the cursor are visible to the cursor
immediately. Rows that are inserted, deleted, or updated by
statements that are executed by other application processes are
visible only after the statements are committed. If a column for an
ORDER BY clause is updated via a cursor or any means outside
the process, the next FETCH statement behaves as if the updated
row was deleted and re-inserted into the result table at its correct
location. At the time of a positioned update, the cursor is
positioned before the next row of the original location and there is
no current row, making the row appear to have moved.

If a SENSITIVE DYNAMIC cursor is not possible, an error is
returned. For example, if a temporary table is needed an error is
returned. The SELECT statement of a cursor that is defined as
SENSITIVE DYNAMIC cannot contain an SQL data change
statement.

The FETCH FIRST \emph{n} ROWS ONLY clause must not be specified for
the outermost fullselect for a sensitive dynamic cursor.

\textbf{STATIC}

Specifies that the size of the result table and the order of the rows
do not change after the cursor is opened. Rows inserted into the
underlying table are not added to the result table regardless of
how the rows are inserted. Rows in the result table do not move if
columns in the ORDER BY clause are updated in rows that have
already been materialized. Positioned updates and deletes are
allowed if the result table is updatable. The SELECT statement of a
cursor that is defined as SENSITIVE STATIC cannot contain an
SQL data change statement.

A STATIC cursor has visibility to changes made by \emph{this} cursor
using positioned updates or deletes. Committed changes made
outside this cursor are visible with the SENSITIVE option of the
FETCH statement. A FETCH SENSITIVE can result in a hole in the
result table (that is, a difference between the result table and its
underlying base table). If an updated row in the base table of a
cursor no longer satisfies the predicate of its SELECT statement, an
update hole occurs in the result table. If a row of a cursor was
deleted in the base table, a delete hole occurs in the result table.
When a FETCH SENSITIVE detects an update hole, no data is
returned (a warning is issued), and the cursor is left positioned on
the update hole. When a FETCH SENSITIVE detects a delete hole,
no data is returned (a warning is issued), and the cursor is left
positioned on the delete hole.

Updates through a cursor result in an automatic re-fetch of the
row. This re-fetch means that updates can create a hole themselves.
The re-fetched row also reflects changes as a result of triggers
updating the same row. It is important to reflect these changes to
maintain the consistency of data in the row.

Using a function that is not deterministic (built-in or user-defined)
in the WHERE clause of the \emph{select-statement} or \emph{statement-name} of a
SENSITIVE STATIC cursor can cause misleading results. This
situation occurs because DB2 constructs a temporary result table
and retrieves rows from this table for FETCH INSENSITIVE statements. When DB2 processes a FETCH SENSITIVE statement, rows are fetched from the underlying table and predicates are re-evaluated. Using a function that is not deterministic can yield a different result on each FETCH SENSITIVE of the same row, which could also result in the row no longer being considered a match.

A FETCH INSENSITIVE on a SENSITIVE STATIC SCROLL cursor is not sensitive to changes made outside the cursor, unless a previous FETCH SENSITIVE has already refreshed that row; however, positioned updates and delete changes with the cursor are visible.

STATIC cursors are insensitive to insertions.

WITHOUT HOLD or WITH HOLD

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

WITHOUT HOLD

Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

WITH HOLD

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared with WITH HOLD is closed at commit time if one of the following is true:

- The connection associated with the cursor is in the release pending status.
- The bind option DISCONNECT(AUTOMATIC) is in effect.
- The environment is one in which the option WITH HOLD is ignored.

When WITH HOLD is specified, a commit operation commits all of the changes in the current unit of work. For example, with a non-scrollable cursor, an initial FETCH statement is needed after a COMMIT statement to position the cursor on the row that follows the row that the cursor was positioned on before the commit operation.

WITH HOLD has no effect on an SQL data change statement within a SELECT statement. When a COMMIT is issued, the changes caused by the SQL data change statement are committed, regardless of whether or not the cursor is declared WITH HOLD.

All cursors are implicitly closed by a connect (Type 1) or rollback operation. A cursor is also implicitly closed by a commit operation if WITH HOLD is ignored or not specified.

Cursors that are declared with WITH HOLD in CICS or in IMS non-message-driven programs will not be closed by a rollback operation if the cursor was opened in a previous unit of work and no changes have been made to the database in the current unit of work. The cursor cannot be closed because CICS and IMS do not broadcast the rollback request to DB2 for a null unit of work.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the option WITH HOLD.

WITH HOLD is ignored in IMS message driven programs (MPP, IFP, and message-driven BMP). WITH HOLD maintains the cursor position in a CICS pseudo-conversational program until the end-of-task (EOT).
For details on restrictions that apply to declaring cursors with WITH HOLD, see DB2 Application Programming and SQL Guide.

**WITHOUT RETURN or WITH RETURN**

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is **WITHOUT RETURN**.

**WITHOUT RETURN**

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

**WITH RETURN**

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the DECLARE CURSOR statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has no effect.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although DB2 will automatically close any cursors that are not declared using with a WITH RETURN clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

**TO CALLER**

Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, WITH RETURN TO CALLER specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

**TO CLIENT**

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

**rowset-positioning**

Specifies whether multiple rows of data can be accessed as a rowset on a single FETCH statement for the cursor. The default is WITHOUT ROWSET POSITIONING.
WITHOUT ROWSET POSITIONING

Specifies that the cursor can be used only with row-positioned FETCH
statements. The cursor is to return a single row for each FETCH statement
and the FOR n ROWS clause cannot be specified on a FETCH statement
for this cursor. WITHOUT ROWSET POSITIONING or single row access
refers to how data is fetched from the database engine. For remote access,
data might be blocked and returned to the client in blocks.

WITH ROWSET POSITIONING

Specifies that the cursor can be used with either row-positioned or
rowset-positioned FETCH statements. This cursor can be used to return
either a single row or multiple rows, as a rowset, with a single FETCH
statement. ROWSET POSITIONING refers to how data is fetched from the
database engine. For remote access, if any row qualifies, at least 1 row is
returned as a rowset. The size of the rowset depends on the number of
rows specified on the FETCH statement and on the number of rows that
qualify. Data might be blocked and returned to the client in blocks.

DB2 REXX applications do not support cursors that are declared WITH
ROWSET POSITIONING. To allow a cursor for a SELECT statement in a
DB2 REXX application to be used with row-positioned or
rowset-positioned FETCH statements, specify WITH ROWSET
POSITIONING in the attribute string of the PREPARE statement for the
SELECT statement.

select-statement

Specifies the result table of the cursor. See "select-statement" on page 851 for
an explanation of select-statement.

The select-statement must not include parameter markers (except for REXX), but
can include references to host variables. In host languages, other than REXX,
the declarations of the host variables must precede the DECLARE CURSOR
statement in the source program. In REXX, parameter markers must be used in
place of host variables and the statement must be prepared.

The USING clause of the OPEN statement can be used to specify host variables
that will override the values of the host variables or parameter markers that
are specified as part of the statement in the DECLARE CURSOR statement.

The select-statement must not contain an SQL data change statement if the
cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

The outer select list of the select-statement of a scrollable cursor must not be an
array value.

statement-name

Identifies the prepared select-statement that specifies the result table of the
cursor whenever the cursor is opened. The statement-name must not be identical
to a statement name specified in another DECLARE CURSOR statement of the
source program. For an explanation of prepared SELECT statements, see
"PREPARE" on page 1846

The prepared select-statement must not contain an SQL data change statement if the
cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

Notes

A cursor in the open state designates a result table and a position relative to the
rows of that table. The table is the result table specified by the SELECT statement
of the cursor.
Read-only cursors: If the result table is read-only, the cursor is read-only. The cursor that references a view with instead of triggers are read-only since positioned UPDATE and positioned DELETE statements are not allowed using those cursors. The result table is read-only if one or more of the following statements is true about the select-statement of the cursor:

- The first FROM clause identifies or contains any of the following:
  - More than one table or view
  - A catalog table with no updatable columns
  - A read-only view
  - A nested table expression
  - A table function
  - A system-maintained materialized query table
  - A single table that is a system-period temporal table, and a period specification for SYSTEM_TIME is used
  - A single view that directly or indirectly references a system-period temporal table in the FROM clause of the outer fullselect of the view definition, and a period specification for SYSTEM_TIME is used
- The first SELECT clause specifies the keyword DISTINCT, contains an aggregate function, or uses both
- It contains an SQL data change statement
- The outer subselect contains a GROUP BY clause, a HAVING clause, or both clauses
- It contains a subquery such that the base object of the outer subselect, and of the subquery, is the same table
- Any of the following operators or clauses are specified:
  - A set operator
  - An ORDER BY clause (except when the cursor is declared as SENSITIVE STATIC scrollable)
  - A FOR READ ONLY clause
- It is executed with isolation level UR and a FOR UPDATE clause is not specified.
- It is a VALUES clause.

If the result table is not read-only, the cursor can be used to update or delete the underlying rows of the result table.

Tables for which row or column access controls are enforced: The select-statement of the cursor can reference a table for which row or column access controls are enforced. The row or column access controls do not effect the determination of whether the cursor is read-only and do not effect the cursor sensitivity.

Work file database requirement for static scrollable cursors: To use a static scrollable cursor, you must first create a work file database and at least one table space with a 32KB page size in this database because a static scrollable cursor requires a temporary table for its result table while the cursor is open. DB2 chooses a table space to use for the temporary result table. Dynamic scrollable cursors do not require a declared temporary table.

For static scrollable cursor declarations that contain empty strings, DB2 assigns one byte in the temporary table space for each empty string. The following example shows a scrollable cursor declaration with an empty string:
EXEC SQL DECLARE CSROWSTAT SENSITIVE STATIC SCROLL CURSOR
    WITH ROWSET POSITIONING WITH HOLD FOR
    SELECT ID1,''
    FROM TB;

**Cursors in COBOL and Fortran programs:** In COBOL and Fortran source programs, the DECLARE CURSOR statement must precede all statements that explicitly refer to the cursor by name. This rule does not necessarily apply to the other host languages because the precompiler provides a two-pass option for these languages. This rule applies to other host languages if the two-pass option is not used.

**Cursors in REXX:** If host variables are used in a DECLARE CURSOR statement within a REXX procedure, the DECLARE CURSOR statement must be the object of a PREPARE and EXECUTE.

**Scope of a cursor:** The scope of cursor-name is the source program in which it is defined; that is, the application program submitted to the precompiler. Thus, you can only refer to a cursor by statements that are precompiled with the cursor declaration. For example, a COBOL program called from another program cannot use a cursor that was opened by the calling program. Furthermore, a cursor defined in a Fortran subprogram can only be referred to in that subprogram. Cursors that specify WITH RETURN in a procedure and are left open are returned as result sets.

Although the scope of a cursor is the program in which it is declared, each package (or DBRM of a plan) created from the program includes a separate instance of the cursor, and more than one instance of the cursor can be used in the same execution of the program. For example, assume a program is precompiled with the CONNECT(2) option and its DBRM is used to create a package at location X and a package at location Y. The program contains the following SQL statements:

```sql
    DECLARE C CURSOR FOR ...  
    CONNECT TO X
    OPEN C
    FETCH C INTO ...
    CONNECT TO Y
    OPEN C
    FETCH C INTO ...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C. The same notion applies to a single location if the packages are in different collections.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results can be different. If the SELECT statement of the cursor contains CURRENT DATE, CURRENT TIME or CURRENT TIMESTAMP, all references to these special registers yields the same respective datetime value on each FETCH operation. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

**Blocking of data:** To process data more efficiently, DB2 might block data for read-only cursors. If a cursor is not going to be used in a positioned UPDATE or positioned DELETE statement, define the cursor as FOR READ ONLY.
Positioned deletes and isolation level UR: Specify FOR UPDATE if you want to
use the cursor for a positioned DELETE and the isolation level is UR because of a
BIND option. In this case, the isolation level is CS.

Returning a result set from a stored procedure: A cursor that is declared in a stored
procedure returns a result set when all of the following conditions are true:
- The cursor is declared with the WITH RETURN option. In a distributed
  environment, blocks of each result set of the cursor's data are returned with the
  CALL statement reply.
- The cursor is left open after exiting from the stored procedure. A cursor declared
  with the SCROLL option must be left positioned before the first row before
  exiting from the stored procedure.
- The cursor is declared with the WITH HOLD option if the stored procedure is
defined to commit on return.

The result set is the set of all rows after the current position of the cursor after
exiting the stored procedure. The result set is assumed to be read-only. If that same
procedure is reinvoked, open result set cursors for a stored procedure at a given
site are automatically closed by the database management system.

Scrollable cursors specified with user-defined functions: A row can be fetched more
than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a
function that is not deterministic in the select list of the cursor, a row can be
fetched multiple times with different results for each fetch. (However, the value of
a function that is not deterministic in the WHERE clause of a scrollable cursor is
captured when the cursor is opened and remains unchanged until the cursor is
closed.) Similarly, if a scrollable cursor is defined with a user-defined function with
external action, the action is executed with every fetch.

Multiple instances of a cursor that is defined with RETURN TO CLIENT: If the
cursor is declared in a native SQL procedure, a cursor that is declared as WITH
RETURN TO CLIENT can be opened even when a cursor with the same name is
already in the open state. In this case, the already open cursor becomes a result set
cursor and is no longer accessible by using its cursor name. A new cursor is
opened and becomes accessible by using the cursor name. When a CLOSE
statement is issued, the last instance of the cursor will be closed. Closing the new
cursor does not make the cursor that was previously accessible by that name
accessible by the cursor name again. Cursors that become result set cursors in this
way cannot be accessed at the server and can be processed only at the client.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Declare C1 as the cursor of a query to retrieve data from the table
DSN8B10.DEPT. The query itself appears in the DECLARE CURSOR statement.

EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8B10.DEPT
  WHERE ADMRDEPT = 'A00';

Example 2: Declare C1 as the cursor of a query to retrieve data from the table
DSN8810.DEPT. Assume that the data will be updated later with a searched update
and should be locked when the query executes. The query itself appears in the
DECLARE CURSOR statement.
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO
   FROM DSN8B10.DEPT
   WHERE ADMRDEPT = 'A00'
   FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;

Example 3: Declare C2 as the cursor for a statement named STMT2.
   EXEC SQL DECLARE C2 CURSOR FOR STMT2;

Example 4: Declare C3 as the cursor for a query to be used in positioned updates of
the table DSN8B10.EMP. Allow the completed updates to be committed from time
to time without closing the cursor.
   EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
      SELECT * FROM DSN8B10.EMP
      FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;

Instead of specifying which columns should be updated, you could use a FOR
UPDATE clause without the names of the columns to indicate that all updatable
columns are updated.

Example 5: In stored procedure SP1, declare C4 as the cursor for a query of the
table DSN8B10.PROJ. Enable the cursor to return a result set to the caller of SP1,
which performs a commit on return.
   EXEC SQL DECLARE C4 CURSOR WITH HOLD WITH RETURN FOR
      SELECT PROJNO, PROJNAME
      FROM DSN8B10.PROJ
      WHERE DEPTNO = 'A01';

Example 6: In the following example, the DECLARE CURSOR statement associates
the cursor name C5 with the results of the SELECT and specifies that the cursor is
scrollable. C5 allows positioned updates and deletes because the result table can be
updated.
   EXEC SQL DECLARE C5 SENSITIVE STATIC SCROLL CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DSN8B10.DEPT
      WHERE ADMRDEPT = 'A00';

Example 7: In the following example, the DECLARE CURSOR statement associates
the cursor name C6 with the results of the SELECT and specifies that the cursor is
scrollable.
   EXEC SQL DECLARE C6 INSENSITIVE SCROLL CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DSN8B10.DEPT
      WHERE DEPTNO;

Example 8: The following example illustrates how an application program might
use dynamic scrollable cursors. First create and populate a table.

CREATE TABLE ORDER
   (ORDERNUM INTEGER,
    CUSTNUM INTEGER,
    CUSTNAME VARCHAR(20),
    ORDERDATE CHAR(8),
    ORDERAMT DECIMAL(8,3),
    COMMENTS VARCHAR(20));

Populate the table by inserting or loading about 500 rows.
EXEC SQL DECLARE CURSOR ORDERSCROLL
   SENSITIVE DYNAMIC SCROLL FOR
   SELECT ORDERNUM, CUSTNAME, ORDERAMT, ORDERDATE FROM ORDER
   WHERE ORDERAMT > 1000
   FOR UPDATE OF COMMENTS;

Open the scrollable cursor.
   OPEN CURSOR ORDERSCROLL;

Fetch forward from the scrollable cursor.
   -- Loop-to-fill-screen
   -- do 10 times
      FETCH FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
   -- end

Fetch RELATIVE from the scrollable cursor.
   -- Skip-forward-100-rows
      FETCH RELATIVE +100
      FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
   -- Skip-backward-50-rows
      FETCH RELATIVE -50
      FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;

Fetch ABSOLUTE from the scrollable cursor.
   -- Re-read-the-third-row
      FETCH ABSOLUTE +3
      FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;

Fetch RELATIVE from scrollable cursor.
   -- Read-the-third-row-from current position
      FETCH SENSITIVE RELATIVE +3
      FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;

Do a positioned update through the scrollable cursor.
   -- Update-the-current-row
      UPDATE ORDER SET COMMENTS = "Expedite"
      WHERE CURRENT OF ORDERSCROLL;

Close the scrollable cursor.
   CLOSE CURSOR ORDERSCROLL;

Example 9: Declare C1 as the cursor of a query to retrieve a rowset from the table DEPT. The prepared statement is MYCURSOR.

   EXEC SQL DECLARE C1 CURSOR
      WITH ROWSET POSITIONING FOR MYCURSOR;
DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table resides in the work file database and its description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description and instance of the temporary table. When the application process terminates, the temporary table is dropped.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None are required, unless the LIKE clause is specified when additional privileges might be required.

PUBLIC implicitly has the following privileges without GRANT authority for declared temporary tables:

- The CREATETAB privilege to define a declared temporary table in the database that is defined AS WORKFILE, which is the database for declared temporary tables.
- The USE privilege to use the table spaces in the database that is defined as WORKFILE.
- All table privileges on the table and authority to drop the table. (Table privileges for a declared temporary table cannot be granted or revoked.)

These implicit privileges are not recorded in the DB2 catalog and cannot be revoked.
Syntax

```
DECLARE GLOBAL TEMPORARY TABLE table-name
  ( column-definition )
LIKE table-name
  copy-options
  view-name
  as-result-table
```

Notes:
1. The same clause must not be specified more than one time.

```
column-definition:

```
column-name data-type
  WITH
  DEFAULT
  constant
  SESSION_USER
  USER
  CURRENT_SQLID
  NULL
  GENERATED ALWAYS
  BY DEFAULT
  identity-options
```

Notes:
1. The same clause must not be specified more than one time.

```
data-type:
```
Notes:

1. These clauses can be specified in any order and must not be specified more than one time.
2. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.

identity-options:

Notes:

1. Separator commas can be specified between the attributes when an identity column is defined.

Description

`table-name`

Names the temporary table. The qualifier, if specified explicitly, must be SESSION. If the qualifier is not specified, it is implicitly defined to be SESSION.

If a table, view, synonym, or alias already exists with the same name and an implicit or explicit qualifier of SESSION:

- The declared temporary table is still defined with SESSION.`table-name`. An error is not issued because the resolution of a declared temporary table name does not include the persistent and shared names in the DB2 catalog tables.
Any references to SESSION.table-name will resolve to the declared temporary
table rather than to any existing SESSION.table-name whose definition is
persistent and is in the DB2 catalog tables.

column-definition
Defines the attributes of a column for each instance of the table. The number of
columns defined must not exceed 750. The maximum record size must not
exceed 32683 bytes. The maximum row size must not exceed 32675 bytes (8
bytes less than the maximum record size).

column-name
Names the column. The name must not be qualified and must not be the same
as the name of another column in the table.

data-type
Specifies the data type of the column. The data type can be any built-in data
type that can be specified for the CREATE TABLE statement except for a LOB
(BLOB, CLOB, and DBCLOB), ROWID, or XML type. The FOR subtype DATA
clause can be specified as part of data-type. For more information on the data
types and the rules that apply to them, see built-in-type.

DEFAULT
Specifies a default value for the column. This clause must not be specified
more than once in the same column-definition.

Omission of NOT NULL and DEFAULT from a column-definition is an implicit
specification of DEFAULT NULL.

If DEFAULT is specified without a value after it, the default value of the
column depends on the data type of the column, as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character string</td>
<td>A string of blanks</td>
</tr>
<tr>
<td>Fixed-length graphic string</td>
<td>A string of blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string of length 0</td>
</tr>
<tr>
<td>Date</td>
<td>CURRENT DATE</td>
</tr>
<tr>
<td>Time</td>
<td>CURRENT TIME</td>
</tr>
<tr>
<td>Timestamp</td>
<td>CURRENT TIMESTAMP(p) where p is the corresponding timestamp precision.</td>
</tr>
<tr>
<td>Timestamp with time zone</td>
<td>CURRENT TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.</td>
</tr>
</tbody>
</table>

A default value other than the one that is listed above can be specified in one
of the following forms:

constant
Specifies a constant as the default value for the column. The value of the
constant must conform to the rules for assigning that value to the column.
A hexadecimal graphic string constant (GX) cannot be specified.
SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the
time of an insert or update operation or LOAD as the default value for the
column. The data type of the column must be a character string with a
length attribute greater than or equal to the length attribute of the
SESSION_USER special register.

CURRENT SQLID
Specifies the value of the SQL authorization ID of the process at the time
of an SQL data change statement or LOAD as the default value for the
column. The data type of the column must be a character string with a
length attribute greater than or equal to the length attribute of the
CURRENT SQLID special register.

NULL
Specifies null as the default value for the column. If NOT NULL was
specified, DEFAULT NULL must not be specified within the same
column-definition.

GENERATED
Specifies that DB2 generates values for the column. GENERATED must be
specified if the column is to be considered an IDENTITY column. If DEFAULT
is specified for the column for an update operation, DB2 generates a value for
both GENERATED ALWAYS and GENERATED BY DEFAULT.

ALWAYS
Specifies that DB2 always generates a value for the column when a row is
inserted into the table.

BY DEFAULT
Specifies that DB2 generates a value for the column when a row is inserted
into the table unless a value is specified. BY DEFAULT is the
recommended value only when you are using data propagation.

Defining a column as GENERATED BY DEFAULT does not necessarily
guarantee the uniqueness of the values. To ensure uniqueness of the
values, define a unique, single-column index on the column.

AS IDENTITY
Specifies that the column is an identity column for the table. A table can have
only one identity column. AS IDENTITY can be specified only if the data type
for the column is an exact numeric type with a scale of zero (SMALLINT,
INTEGER, BIGINT, DECIMAL with a scale of zero).

An identity column is implicitly NOT NULL. An identity column cannot have
a DEFAULT clause. For the descriptions of the identity attributes, see the
description of the AS IDENTITY clause in "CREATE TABLE" on page 1446.

NOT NULL
Specifies that the column cannot contain nulls. Omission of NOT NULL
indicates that the column can contain nulls.

LIKE table-name or view-name
Specifies that the columns of the table have the same name, data type, and
nullability attributes as the columns of the identified table or view. If a table is
identified, the column default attributes are also defined by that table. If row
permissions or column access control is enforced for the table specified by
table-name, row and column access controls are not inherited by the new table.
The name specified must identify a table, view, synonym, or alias that exists at
the current server. The identified table must not be an auxiliary table.

`table-name` or `view-name` must not contain a Unicode column in an EBCDIC table.

The privilege set must include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If LIKE results in a column having a LOB data type, a ROWID data type, or distinct type, the DECLARE GLOBAL TEMPORARY TABLE statement fails.
- In addition to these data type restrictions, if any column has any other attribute value that is not allowed in a declared temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.

When the identified object is a table, the column name, data type, nullability, and default attributes are determined from the columns of the specified table; any identity column attributes are inherited only if the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified.

**as-result-table**

Specifies that the table definition is based on the column definitions from the result of a query expression.

The behavior of these column attributes is controlled with the INCLUDING or USING TYPE DEFAULTS clauses, which are defined below.

**AS** *(fullselect)*

Specifies an implicit definition of *n* columns for the declared global temporary table, where *n* is the number of columns that would result from the fullselect. The columns of the new table are defined by the columns that result from the fullselect. Every select list element must have a unique name. The AS clause can be used in the select-clause to provide unique names. The implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of fullselect. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the fullselect is not considered hidden in the new table. Row and column access controls that are enforced on the base table are not inherited by the new table.

The result table of the fullselect must not contain a column that has a LOB data type, a ROWID data type, an XML data type or a distinct type.

If fullselect results in other column attributes that are not applicable for a declared temporary table, those attributes are ignored in the implicit definition for the declared temporary table.

If fullselect results in a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.

The fullselect must not refer to variables or include parameter markers (question marks), but can refer to global variables. The outermost SELECT list of the outermost fullselect must not reference data that is encoded with different encoding schemes, and must not result in a column that is an array.

**WITH NO DATA**

Specifies that the fullselect is not executed. You can use the INSERT INTO
statement with the same `fullselect` specified in the AS clause to populate the declared temporary table with the set of rows from the result table of the `fullselect`.

`copy-options`
Specifies whether identity column attributes and column defaults are inherited from the definition of the source of the result table.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES**
Specifies whether identity column attributes are inherited from the columns resulting from the `fullselect`, `table-name`, or `view-name`.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**
Specifies that the table does not inherit the identity attributes of the columns resulting from the `fullselect`, `table-name`, or `view-name`.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**
Specifies that the table inherits the identity attributes, if any, of the columns resulting from the `fullselect` or `table-name`. In general, the identity attributes are copied if the element of the corresponding column in the table or `fullselect` is the name of a table column that directly or indirectly maps to the name of a base table column that is an identity column.

If the `INCLUDING IDENTITY COLUMN ATTRIBUTES` clause is specified with the AS `fullselect` clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the `fullselect` includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the `fullselect` includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The `fullselect` includes a set operation.

If `INCLUDING IDENTITY COLUMN ATTRIBUTES` is not specified, the new table will not have an identity column.

If the LIKE clause identifies a view, `INCLUDING IDENTITY COLUMN ATTRIBUTES` must not be specified.

**EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS**
Specifies whether the table inherits the default values of the columns of the `fullselect`. `EXCLUDING COLUMN DEFAULTS`, `INCLUDING COLUMN DEFAULTS`, and `USING TYPE DEFAULTS` must not be specified if the LIKE clause is specified.

**EXCLUDING COLUMN DEFAULTS**
Specifies that the table does not inherit the default values of the columns of the `fullselect`. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert operation for the new table.

**INCLUDING COLUMN DEFAULTS**
Specifies that the table inherits the default values of the columns of the `fullselect`. A default value is the value that is assigned to the column
when a value is not specified on an insert operation or LOAD. Columns resulting from the fullselect that are not updatable will not have a default defined in the corresponding column of the created table.

**USING TYPE DEFAULTS**

Specifies that the default values for the declared temporary table depend on the data type of the columns that result from `fullselect`, as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string of length 0</td>
</tr>
<tr>
<td>Date</td>
<td>CURRENT DATE</td>
</tr>
<tr>
<td>Time</td>
<td>CURRENT TIME</td>
</tr>
<tr>
<td>Timestamp</td>
<td>CURRENT TIMESTAMP(p) where (p) is the corresponding timestamp precision.</td>
</tr>
<tr>
<td><strong>Timestamp(integer) with time zone</strong></td>
<td>CURRENT TIMESTAMP(p) WITH TIME ZONE where (p) is the corresponding timestamp precision.</td>
</tr>
</tbody>
</table>

**CCSID encoding-scheme**

Specifies the encoding scheme for string data that is stored in the table. For declared temporary tables, the encoding scheme for the data cannot be specified for the table space or database, and all data in one table space or the database need not use the same encoding scheme. Because there can be only one work file database for all declared temporary tables for each DB2 member, there can be a mixture of encoding schemes in both the database and each table space.

For the creation of temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause or as the scheme for the table identified by the AS (fullselect) clause.

**ASCII** Specifies that the data is encoded by using the ASCII CCSIDs of the server.

**EBCDIC** Specifies that the data is encoded by using the EBCDIC CCSIDs of the server.

**UNICODE** Specifies that the data is encoded by using the UNICODE CCSIDs of the server.
An error occurs if the CCSIDs for the encoding scheme have not been defined. Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

**ON COMMIT**

Specifies what happens to the table for a commit operation. The default is ON COMMIT DELETE ROWS.

**DELETE ROWS**

Specifies that all of the rows of the table are deleted if there is no open cursor that is defined as WITH HOLD that references the table.

**PRESERVE ROWS**

Specifies that all of the rows of the table are preserved. Thread reuse capability is not available to any application process or thread that contains, at its most recent commit, an active declared temporary table that was defined with the ON COMMIT PRESERVE ROWS clause.

**DROP TABLE**

Specifies that the table is implicitly dropped at commit if there is no open cursor that is defined as WITH HOLD that references the table. If there is an open cursor defined as WITH HOLD on the table at commit, the rows are preserved.

**LOGGED or NOT LOGGED**

Specifies whether operations for the table are to be logged. This option also applies to any indexes that are associated with the table. Indexes inherit the logging attribute from their associated tables.

**LOGGED**

Specifies that insert, update, or delete operations for the declared temporary table are logged. Create and drop actions for the table are also logged. This is the default option.

**NOT LOGGED**

Specifies that insert, update, or delete operations for the declared temporary table are not logged. However, create and drop actions for the table are logged.

**ON ROLLBACK DELETE ROWS**

Specifies that when a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, all rows of the global temporary table are deleted. This is the default.

**ON ROLLBACK PRESERVE ROWS**

Specifies that when a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, all rows of the global temporary table are preserved.

If a ROLLBACK or ROLLBACK TO SAVEPOINT statement is issued, the following actions occur for tables that were created or dropped:

- If the table was created within the unit of work or savepoint, the table is dropped.
- If the table was dropped within the unit of work or savepoint, the table is re-created without any data.

For statements that insert multiple rows, the ATOMIC and NOT ATOMIC CONTINUE ON SQLEXCEPTION options of the INSERT statement determine the result of an error. If ATOMIC is specified, an error during insertion causes all rows in the global temporary table to be deleted. If NOT ATOMIC CONTINUE ON SQLEXCEPTION is
specified, an error during insertion causes all rows in the table to be
deleted, but the next insert is processed. At the end of the insert, the
table includes only the rows that were inserted after the last error.

Restriction: In CREATE TABLESPACE and ALTER TABLESPACE statements,
LOG YES and LOG NO can be used as syntax alternatives for LOGGED and
NOT LOGGED, respectively. These syntax alternatives cannot be used in a
DECLARE GLOBAL TEMPORARY TABLE statement.

Notes

Instantiation, scope, and termination: For the following explanations, P denotes an
application process, and T is a declared temporary table executed in P:

- An empty instance of T is created when a DECLARE GLOBAL TEMPORARY
  TABLE statement is executed in P.
- Any SQL statement in P can reference T, and any of those references to T in P is
  a reference to that same instance of T.()

If a DECLARE GLOBAL TEMPORARY statement is specified within an SQL PL
compound statement, the scope of the declared temporary table is the
application process and not just the compound statement. A declared temporary
table cannot be defined multiple times by the same name in other compound
statements in that application process, unless the table has been dropped
explicitly.

- If T was declared at a remote server, the reference to T must use the same DB2
  connection that was used to declare T and that connection must not have been
terminated after T was declared. When the connection to the database server at
  which T was declared terminates, T is dropped.

- If T was defined with the ON COMMIT DELETE ROWS clause specified
  implicitly or explicitly, when a commit operation terminates a unit of work in P
  and there is no open WITH HOLD cursor in P that is dependent on T, the
  commit deletes all rows from T.

- If T is defined with the ON COMMIT DROP TABLE clause, when a commit
  operation terminates a unit of work in P and no program in P has a WITH
  HOLD cursor open that is dependent on T, the commit includes the operation
  DROP TABLE T.

- When a rollback operation terminates a unit of work or savepoint in P, and that
  unit of work or savepoint includes the declaration of SESSION.T, the changes to
  table T are undone.

  When a rollback operation terminates a unit of work or savepoint in P, and that
  unit of work or savepoint includes the declaration of SESSION.T, the rollback
drops table T.

  When a rollback operation terminates a unit of work or savepoint in P, and that
  unit of work or savepoint includes the drop of the declaration of declared
  temporary table SESSION.T, the rollback undoes the drop of table T.

- When the application process that declared T terminates, T is dropped.

- When a rollback operation terminates a unit of work or a savepoint in P, and
  that unit of work or savepoint includes a modification to SESSION.T the
  following actions occur:

  – If NOT LOGGED was specified, all rows from SESSION.T are deleted unless
    ON ROLLBACK PRESERVE ROWS was also specified.

  – If NOT LOGGED was not specified, the changes to table T are undone.
If NOT LOGGED was specified and an INSERT, UPDATE or DELETE statement fails during execution (not a compilation error), all rows from SESSION.T are deleted.

When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback includes the operation DROP SESSION.T.

When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the drop of a declared temporary table SESSION.T, the rollback undoes the drop of the table. If NOT LOGGED was specified, the table is also emptied.

When the application process that declared T terminates or disconnects from the database, T is dropped and its instantiated rows are destroyed.

Privileges: When a declared temporary table is defined, PUBLIC is implicitly granted all table privileges on the table and authority to drop the table. These implicit privileges are not recorded in the DB2 catalog and cannot be revoked. This enables any SQL statement in the application process to reference a declared temporary table that has already been defined in that application process.

Referring to a declared temporary table in other SQL statements: Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, you must qualify the table name with SESSION. You can either specify SESSION explicitly in the table name or use the QUALIFIER bind option to specify SESSION as the qualifier for all SQL statements in the plan or package.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, DB2 assumes that you are not referring to a declared temporary table. DB2 resolves such table references to a table whose definition is persistent and appears in the DB2 catalog tables.

With the exception of the DECLARE GLOBAL TEMPORARY TABLE statement, any static SQL statement that references a declared temporary table is incrementally bound at run time. This is because the definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY statement is executed in the application process that contains those SQL statements and the definition does not persist when the application process finishes running.

When a plan or package is bound, any static SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) that references a table-name that is qualified by SESSION, regardless of whether the reference is for a declared temporary table, is not completely bound. However, the bind of the plan or package succeeds if there are no other errors. These static SQL statements are then incrementally bound at run time when the static SQL statement is issued. Object dependencies are not recorded in SYSIBM.SYSPLANDEP or SYSIBM.SYSPACKDEP tables. These incremental binds are necessary because:

- The definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY TABLE statement for the table is executed in the same application process that contains those SQL statements. Therefore, DB2 must wait until the plan or package is run to determine if SESSION.table-name refers to a base table or a declared temporary table.
- The definition of a declared temporary table does not persist after the table it is explicitly dropped (DROP statement), implicitly dropped (ON COMMIT DROP TABLE), or the application process that defined it finishes running. When the
application process terminates or is re-used as a reusable application thread, the
instantiated rows of the table are deleted and the definition of the declared
temporary table is dropped if it has not already been explicitly or implicitly
dropped.

After the plan or package is bound, any static SQL statement that refers to a
table-name that is qualified by SESSION has a new statement status of M in the
DB2 catalog table (STATUS column of SYSIBM.SYSSMT or
SYSIBM.SYSPACKSTM).

 Thread reuse: If a declared temporary table is defined in an application process that
is running as a local thread, the application process or local thread that declared
the table qualifies for explicit thread reuse if:
  - The table was defined with both the default ON COMMIT DELETE ROWS
    attribute and the NOT LOGGED ON ROLLBACK DELETE ROWS attribute.
  - The table was defined with PRESERVE ROWS specified on either the ON
    COMMIT or NOT LOGGED ON ROLLBACK option and the table was explicitly
    dropped with the DROP TABLE statement before the thread’s commit operation.
  - The table was defined with the ON COMMIT DROP TABLE attribute. When a
declared temporary table is defined with the ON COMMIT DROP TABLE and a
commit occurs, the table is implicitly dropped if there are no open cursors
defined with the WITH HOLD option.

When the thread is reused, the declared temporary table is dropped and its rows
are destroyed. However, if you do not explicitly or implicitly drop all declared
temporary tables before or when your thread performs a commit and the thread
becomes idle waiting to be reused, as with all thread reuse situations, the idle
thread holds resources and locks. This includes some declared temporary table
resources and locks on the table spaces and the database descriptor (DBD) for the
work file database. So, instead of using the implicit drop feature of thread reuse to
drop your declared temporary tables, it is recommended that you:
  - Use the DROP TABLE statement to explicitly drop your declared temporary
tables before the thread performs a commit and becomes idle.
  - Define the declared temporary tables with ON COMMIT DROP TABLE clause so
that the tables are implicitly dropped when a commit occurs.

Explicitly dropping the tables before a commit occurs or having them implicitly
dropped when the commit occurs enables you to maximize the use of declared
temporary table resources and release locks when multiple threads are using
declared temporary table.

Remote threads qualify for thread reuse differently than local threads. If a declared
temporary table is defined (with or without ON COMMIT DELETE ROWS) in an
application process that is running as a remote or DDF thread (also known as
Database Access Thread or DBAT), the remote thread qualifies for thread reuse
only when the declared temporary table is explicitly dropped before the thread
performs a commit operation. Dropping the declared temporary table enables the
remote thread to qualify for the implicit thread reuse that is supported for DDF
threads via connection pooling and to become an inactive DBAT (type 1 inactive
thread) or an inactive connection (type 2 inactive thread).

 Parallelism support: Only I/O and CP parallelism are supported. Any query that
involves a declared temporary table is limited to parallel tasks on a single CPC.
Restrictions on the use of declared temporary tables: Declared temporary tables cannot:

- Be specified in referential constraints.
- Be referenced in any SQL statements that are defined in an SQL function body (CREATE FUNCTION or ALTER FUNCTION statements), a trigger body (CREATE TRIGGER statement). If you refer a table name that is qualified with SESSION in a trigger body, DB2 assumes that you are referring to a base table.
- Be referenced in a CREATE INDEX statement unless the schema name of the index is SESSION.

In addition, do not refer to a declared temporary table in any of the following statements.

```
ALTER INDEX
ALTER TABLE
COMMENT
CREATE ALIAS
CREATE FUNCTION (TABLE LIKE clause)
CREATE PROCEDURE (TABLE LIKE clause)
CREATE TRIGGER
CREATE VIEW
GRANT (table or view privileges)
LABEL
LOCK TABLE
REFRESH TABLE
RENAME
REVOKE (table or view privileges)
```

Declared global temporary tables and dynamic statement caching: The DB2 dynamic statement cache feature does not support dynamic SQL statements that reference declared temporary tables, even if the SQL statement also includes references to base or persistent tables. DB2 will not insert such statements into the dynamic statement cache. Instead, these dynamic statements are processed as if statement caching is not in effect. Declared temporary tables are unique and specific to an application process or DB2 thread, cannot be shared across threads, are not described in the DB2 catalog, and do not persist beyond termination of the DB2 thread or application process. These attributes prevent the use of the dynamic statement cache feature where tables and SQL statements are shared across threads or application processes.

Table space requirements in the work file database: DB2 stores all declared temporary tables in the work file database. You cannot define a declared temporary table unless a table space with at least an 32KB page size exists in the work file database.

Alternative syntax and synonyms: To provide compatibility with previous releases, DB2 allows you to specify:

- LONG VARCHAR as a synonym for VARCHAR(integer) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(integer) when defining the data type of a column.

However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

- DEFINITION ONLY as a synonym for WITH NO DATA.
- TIMEZONE can be specified as an alternative to TIME ZONE.
Examples

Example 1: Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```sql
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
(EMPNO CHAR(6) NOT NULL,
SALARY DECIMAL(9, 2),
BONUS DECIMAL(9, 2),
COMM DECIMAL(9, 2))
CCSID EBCDIC
ON COMMIT PRESERVE ROWS;
```

Example 2: Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```sql
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
LIKE USER1.EMPTAB
INCLUDING IDENTITY
ON COMMIT PRESERVE ROWS;
```

In the above example, DB2 uses SESSION as the implicit qualifier for TEMPTAB1.
DECLARE STATEMENT

The DECLARE STATEMENT statement is used for application program documentation. It declares names that are used to identify prepared SQL statements.

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

```
DECLARE statement-name STATEMENT
```

Description

`statement-name STATEMENT`

Lists one or more names that are used in your application program to identify prepared SQL statements.

Example

This example shows the use of the DECLARE STATEMENT statement in a PL/I program.

```
EXEC SQL DECLARE OBJECT_STATEMENT STATEMENT;
EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE C1 CURSOR FOR OBJECT_STATEMENT;

( SOURCE_STATEMENT IS "SELECT DEPTNO, DEPTNAME,
  MGRNO FROM DSN8B10.DEPT WHERE ADMRDEPT = 'A00'"
)

EXEC SQL PREPARE OBJECT_STATEMENT FROM SOURCE_STATEMENT;
EXEC SQL DESCRIBE OBJECT_STATEMENT INTO SQLDA;

/* Examine SQLDA */
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 USING DESCRIPTOR SQLDA;
/* Print results */
END;
EXEC SQL CLOSE C1;
```
DECLARE TABLE

The DECLARE TABLE statement is used for application program documentation. It also provides the precompiler with information used to check your embedded SQL statements. (The DCLGEN subcommand can be used to generate declarations for tables and views described in any accessible DB2 catalog.

For more on DCLGEN, see DB2 Application Programming and SQL Guide and DB2 Command Reference.)

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

```
DECLARE table-name [ view-name ]

, TABLE( column-name built-in-type distinct-type-name [ NOT NULL ] [ NOT NULL WITH DEFAULT ])

built-in-type:
```

```sql
1626 SQL Reference
```
Description

**table-name or view-name**

Specifies the name of the table or view to document. If the table is defined in your application program, the description of the table in the SQL statement in which it is defined (for example, CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement) and the DECLARE TABLE statement must be identical.

**column-name**

Specifies the name of a column of the table or view.

The precompiler uses these names to check for consistency of names within your SQL statements. It also uses the data type to check for consistency of names and data types within your SQL statements.

**built-in-type**

Specifies the built-in data type of the column. Use one of the built-in data types.

**SMALLINT**

For a small integer.

**INTEGER or INT**

For a large integer.

**BIGINT**

For a big integer.

**DECIMAL(integer, integer) or DEC(integer, integer)**

**DECIMAL(integer) or DEC(integer)**

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(p) for DECIMAL(p,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

**FLOAT(integer)**

**FLOAT**

For a floating-point number. If integer is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

**REAL**

For single precision floating-point.

**DOUBLE or DOUBLE PRECISION**

For double precision floating-point

**DECFLOAT( integer)**

For a decimal floating-point number. The value of integer must be either 16
or 34 and represents the number of significant digits that can be stored. If integer is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

**CHARACTER(integer) or CHAR(integer)**

**CHARACTER or CHAR**

For a fixed-length character string of length integer, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

**VARCHAR(integer), CHAR VARYING(integer), or CHARACTER VARYING(integer)**

For a varying-length character string of maximum length integer, which can range from 1 to the maximum record size minus 10 bytes. See Table 126 on page 1510 to determine the maximum record size.

**CCSID 1208**

Specifies that the column is a Unicode column encoded in UTF-8. This clause must not be specified for an ASCII or Unicode table.

**CLOB(integer [K|M|G]), CHAR LARGE OBJECT(integer [K|M|G]), or CHARACTER LARGE OBJECT(integer [K|M|G])**

**CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT**

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2,147,483,647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 99.

When integer is not specified, the default length is 1M. The maximum value that can be specified for integer depends on whether a units indicator is also specified as shown in the following list.

**integer**

The maximum value for integer is 2,147,483,647. The maximum length of the string is integer.

**integer K**

The maximum value for integer is 2,097,152. The maximum length is 1024 times integer.

**integer M**

The maximum value for integer is 2048. The maximum length is 1,048,576 times integer.

**integer G**

The maximum value for integer is 2. The maximum length is 1,073,741,824 times integer.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), DB2 uses a value that is one byte less, or 2,147,483,647.

**GRAPHIC(integer)**

**GRAPHIC**

For a fixed-length graphic string of length integer, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

**VARGRAPHIC(integer)**

For a varying-length graphic string of maximum length integer, which must range from 1 to n/2, where n is the maximum row size minus 2 bytes.
CCSID 1200
Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

DBCLOB(integer [K|M|G])

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1,073,741,823. A DBCLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 99.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

CCSID 1200
 Specifies that the column is a Unicode column encoded in UTF-16. This clause must not be specified for an ASCII or Unicode table.

BINARY(integer)
A fixed-length binary string of length integer. The integer can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

BINARY VARYING(integer) or VARBINARY(integer)
A varying-length binary string of maximum length integer, which can range from 1 through 32,704. The length is limited by the page size of the table space.

BLOB (integer [K|M|G] or BINARY LARGE OBJECT(integer [K|M|G]))

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2,147,483,647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 99.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is the same as for CLOB.

DATE
For a date.

TIME
For a time.

TIMESTAMP(integer) WITHOUT TIME ZONE
For a timestamp. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

TIMESTAMP(integer) WITH TIME ZONE
For a timestamp with time zone. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

ROWID
For a row ID type.
A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

**XML**

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.

**distinct-type-name**

Specifies the distinct type (user-defined data type) of the column. An implicit or explicit schema name qualifies the name.

**NOT NULL**

Specifies that the column does not allow null values and does not provide a default value.

**NOT NULL WITH DEFAULT**

Specifies that the column does not allow null values but provides a default value.

**Notes**

*Error handling during processing:* If an error occurs during the processing of the DECLARE TABLE statement, a warning message is issued, and the precompiler continues processing your source program.

*Documenting a distinct type column:* Although you can specify the name of a distinct type as the data type of a column in the DECLARE TABLE statement, use the built-in data type on which the distinct type is based instead. Using the base type enables the precompiler to check the embedded SQL statements for errors; otherwise, error checking is deferred until bind time.

To determine the source data type of the distinct type, check the value of column SOURCETYPE in catalog table SYSDATATYPES.

**Examples**

*Example 1:* Declare the sample employee table, DSN8B10.EMP.

```
EXEC SQL DECLARE DSN8B10.EMP TABLE
  (EMPNO CHAR(6) NOT NULL,
   FIRSTNAME VARCHAR(12) NOT NULL,
   MIDINIT CHAR(1) NOT NULL,
   LASTNAME VARCHAR(15) NOT NULL,
   WORKDEPT CHAR(3)
   PHONENO CHAR(4)
   HIREDATE DATE
   JOB CHAR(8)
   EDLEVEL SMALLINT
   SEX CHAR(1)
   BIRTHDATE DATE
   SALARY DECIMAL(9,2)
   BONUS DECIMAL(9,2)
   COMM DECIMAL(9,2));
```

*Example 2:* Assume that table CANADIAN_SALES keeps information for your company’s sales in Canada. The table was created with the following definition:
CREATE TABLE CANADIAN_SALES
(PRODUCT_ITEM INTEGER,
MONTH INTEGER,
YEAR INTEGER,
TOTAL CANADIAN_DOLLAR);

CANADIAN_DOLLAR is a distinct type that was created with the following statement:

CREATE TYPE CANADIAN_DOLLAR AS DECIMAL(9,2);

Declare the CANADIAN_SALES table, using the source type for CANADIAN_DOLLAR instead of the distinct type name.

DECLARE TABLE CANADIAN_SALES
(PRODUCT_ITEM INTEGER,
MONTH INTEGER,
YEAR INTEGER,
TOTAL DECIMAL(9,2);
 DECLARE VARIABLE

The DECLARE VARIABLE statement defines a CCSID for a host variable and the subtype of the variable. When it appears in an application program, the DECLARE VARIABLE statement causes the DB2 precompiler to tag a host variable with a specific CCSID. When the host variable appears in an SQL statement, the DB2 precompiler places this CCSID into the structures that it generates for the SQL statement.

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

```
DECLARE host-variable VARIABLE
  CCSID ASCII FOR SBCS DATA
  CCSID EBCDIC
  CCSID UNICODE FOR MIXED DATA
  CCSID integer-constant
```

Description

`host-variable`

Identifies a character or graphic string host variable defined in the program. An indicator variable cannot be specified for the host-variable.

`CCSID ASCII, EBCDIC, or UNICODE`

Specifies that the appropriate default CCSID for the specified encoding scheme of the server should be used.

`CCSID ASCII`

Specifies that the default ASCII CCSID for the type of the variable at the server should be used.

`CCSID EBCDIC`

Specifies that the default EBCDIC CCSID for the type of the variable at the server should be used. CCSID EBCDIC is the default if this option is not specified.

`CCSID UNICODE`

Specifies that the default UNICODE CCSID for the type of the variable at the server should be used.

`FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA`

Specifies the type of data contained in the variable `host-variable`. The FOR clause cannot be specified when declaring a graphic host variable.
For ASCII or EBCDIC data, if this clause is not specified when declaring a
code host variable, the default is FOR SBCS DATA if MIXED DATA = NO
on the installation panel DSNTIPF. The default is FOR MIXED DATA if MIXED
DATA = YES on the installation panel DSNTIPF.

For UNICODE data, the default is always FOR MIXED DATA, regardless of
the setting of MIXED DATA on the installation panel DSNTIPF.

**FOR SBCS DATA**
Specifies that the values of the host variable can contain only SBCS
(single-byte character set) data.

**FOR MIXED DATA**
Specifies that the values of the host variable can contain both SBCS data
and DBCS data.

**FOR BIT DATA**
Specifies that the values of the host-variable are not associated with a
coded character set and, therefore, are never converted. The CCSID of a
FOR BIT DATA host variable is 65535.

**CCSID integer-constant**
Specifies that the values of the host variable contain data that is encoded using
CCSID integer-constant. If the integer is an SBCS CCSID, the host variable is
SBCS data. If the integer is a mixed data CCSID, the host variable is mixed
data. For character host variables, the CCSID specified must be an SBCS,
mixed CCSID, or UNICODE (UTF-8) CCSID. For graphic host variables, the
CCSID specified must be a DBCS or UNICODE (UTF-16) CCSID. The valid
range of values for the integer is 1 - 65533.

**Notes**

**Placement of statement:** The DECLARE VARIABLE statement can be specified
anywhere in an application program that SQL statements are valid with the
following exception. The DECLARE VARIABLE statement must occur before an
SQL statement that refers to a host variable specified in the DECLARE VARIABLE
statement.

**CCSID exceptions for EXECUTE IMMEDIATE or PREPARE:** When the host
variable appears in an SQL statement, the DB2 precompiler places the appropriate
numeric CCSID into the structures it generates for the SQL statement. This
placement of the CCSID occurs for any SQL statement other than the EXECUTE
IMMEDIATE or PREPARE statements. The placement of the CCSID also occurs for
a host-variable in an EXECUTE IMMEDIATE or PREPARE statement, but it does not
occur for a variable in a string-expression in an EXECUTE IMMEDIATE or
PREPARE statement.

If a PL/1 application program contains at least one DECLARE VARIABLE
statement, a string-expression in any EXECUTE IMMEDIATE or PREPARE statement
cannot be preceded by a colon. An expression that consists of just a variable name
preceded by a colon is interpreted as a host-variable.

**Specific host languages:** If a DECLARE VARIABLE statement is used in an
assembler source program, the ONEPASS SQL processing option must not be used.
If a DECLARE VARIABLE statement is used in a C, C++, or PL/1 source program,
the TWOPASS SQL processing option must be used. For those languages, or
COBOL, the host-variable definition can either precede or follow a DECLARE
VARIABLE statement that refers to that variable. If a DECLARE VARIABLE
statement is used in a FORTRAN source program, then the host-variable definition must precede the DECLARE VARIABLE statement.

Example

Example: Define the following host variables using PL/I data types: FRED as fixed length bit data, JEAN as fixed length UTF-8 (mixed) data, DAVE as varying length UTF-8 (mixed) data, PETE as fixed length graphic UTF-16 data, and AMBER as varying length graphic UTF-16 data.

Use the DECLARE VARIABLE statement to specify a data subtype or CCSID for these host variables: FRED as CCSID EBCDIC, JEAN as CCSID 1208 or CCSID UNICODE, DAVE as CCSID 1208 or CCSID UNICODE, PETE as CCSID 1200 or CCSID UNICODE, and AMBER as CCSID 1200 or CCSID UNICODE.

EXEC SQL BEGIN DECLARE SECTION;
DCL FRED CHAR(10);
  EXEC SQL DECLARE :FRED VARIABLE CCSID EBCDIC FOR BIT DATA;
DCL JEAN CHAR(30);
  EXEC SQL DECLARE :JEAN VARIABLE CCSID 1208;
DCL DAVE CHAR(9) VARYING;
  EXEC SQL DECLARE :DAVE VARIABLE CCSID UNICODE;
DCL PETE GRAPHIC(10);
  EXEC SQL DECLARE :PETE VARIABLE CCSID 1200;
DCL AMBER GRAPHIC(20) VARYING;
  EXEC SQL DECLARE :AMBER VARIABLE CCSID UNICODE;
EXEC SQL END DECLARE SECTION;
The DELETE statement deletes rows from a table or view or activates an instead of delete trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Deleting a row from a view deletes the row from the table on which the view is based if no instead of trigger is defined for the delete operation on this view. If such a trigger is defined, the trigger is activated instead of the delete operation.

There are two forms of this statement:
- The searched DELETE form is used to delete one or more rows, optionally determined by a search condition.
- The positioned DELETE form specifies that one or more rows corresponding to the current cursor position are to be deleted.

**Invocation**

This statement can be embedded in an application program or issued interactively. A positioned DELETE is embedded in an application program. Both the embedded and interactive forms are executable statements that can be dynamically prepared.

**Authorization**

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table, or a view, and whether the statement is a searched DELETE and SQL standard rules are in effect:

*When a table other than a catalog table is identified:* The privilege set must include at least one of the following:
  - The DELETE privilege on the table
  - Ownership of the table
  - DBADM authority on the database that contains the table
  - SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

*When a catalog table is identified:* The privilege set must include at least one of the following:
  - DBADM authority on the catalog database
  - SYSCTRL authority
  - SYSADM authority

*When a view is identified:* The privilege set must include at least one of the following:
  - The DELETE privilege on the view
  - SYSADM authority

If the search-condition in a searched DELETE contains a reference to a column of the table or view, or the expression in the assignment-clause contains a reference to a column of the table or view, the privilege set must include at least one of the following:
  - The SELECT privilege on the table or view
Ownership of the table or view
DBADM authority on the database that contains the table, if the target is a table
and that table that is not a catalog table
DATAACCESS
SYSADM authority

If the search-condition in a searched DELETE includes a subquery, or if the
assignment-clause includes a scalar-fullselect or a row-fullselect, see "Authorization" on
page 782 for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have DELETE
authority on the view (or might have DELETE authority without being able to
grant it to others). The nature of the view itself can preclude its use for DELETE.
For more information, see the description of authority in "CREATE VIEW" on page
1590.

If the statement is embedded in an application program, the privilege set is the
privileges that are held by the owner of the plan or package. If the statement is
dynamically prepared, the privilege set is determined by the DYNAMICRULES
behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on
page 873 (For more information on these behaviors, including a list of the
DYNAMICRULES bind option values that determine them, see "Authorization IDs
and dynamic SQL" on page 77.)

searched delete:

positioned delete:

Notes:
1 The same clause must not be specified more than one time.
assignment clause:
Notes:
1 The number of \textit{expressions} and \texttt{NULL} keywords must match the number of \textit{column-names}.
2 The number of columns in the select list must match the number of \textit{column-names}.

\textbf{Description}

\textbf{FROM} \textit{table-name} or \textit{view-name}

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the DB2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify:

\begin{itemize}
  \item An auxiliary table
  \item A catalog table for which deletes are not allowed
  \item A view of such a catalog table
  \item A read-only view (For a description of a read-only view, see \textit{CREATE VIEW} on page 1590.)
  \item A system-maintained materialized query table
  \item A table that is implicitly created for an XML column
  \item An archive-enabled table if the SYSIBMADM.GET_ARCHIVE global variable is set to Y, the ARCHIVESENSITIVE bind option is set to YES, and the operation is a positioned delete
\end{itemize}

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

\textit{period-clause}

Specifies that a period clause applies to the target of the delete operation. The same period name must not be specified more than one time. If the target of the delete operation is a view:

\begin{itemize}
  \item The FROM clause of the outer fullselect of the view definition must include a reference, directly or indirectly, to an application-period temporal table.
  \item An INSTEAD OF trigger must not be defined for that view.
\end{itemize}
FOR PORTION OF BUSINESS_TIME
Specifications that the delete only applies to row values for the portion of the BUSINESS_TIME period in the row that is specified by the period clause. BUSINESS_TIME must be a period that is defined on the table.

FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES.

FROM value1 TO value2
Specifies that the delete operation applies to rows for the period that is specified from value1 to value2. No rows are deleted if value1 is greater than or equal to value2, or if value1 or value2 is the null value.

For the period condition that is specified with FROM value1 TO value2, the period that is specified by period-name in a row of the target table of the delete covers one of the following ranges:

- If the value of the begin column is less than value1 and the value of the end column is greater than value1, the range overlaps the beginning of the specified period.
- If the value of the end column is greater than or equal to value2 and the value of the begin column is less than value2, the range overlaps the end of the specified period.
- If the value for the begin column for period-name in the row is greater than or equal to value1 and the value for the corresponding end column in the row is less than or equal to value2, the range is fully contained within the specified period.
- If the row overlaps the beginning of the specified period or the end of the specified period, but not both, the range is partially contained in the specified period.
- If the period in the row overlaps the beginning of the specified period and overlaps the end of the specified period, the range fully overlaps the specified period.
- If both columns of period-name are less than or equal to value1 or are greater than or equal to value2, the range is not contained in the period.

If the period period-name in a row is not contained in the specified period, the row is not deleted. Otherwise, the delete operation is applied based on the specification of the PORTION OF clause and how the values in the columns of period-name overlap the specified period as follows:

- If the period period-name in a row is fully contained within the specified period, the row is deleted.
- If the period period-name in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to value1, and new values are used for other generated columns.
- If the period period-name in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the begin column is set to value2, and new values are used for other generated columns.
• If the period period-name in a row fully overlaps the specified period:
  – The row is deleted.
  – A row is inserted using the original values from the row, except that
    the end column is set to value1, a column defined as DATA CHANGE
    OPERATION is set to 'I', and new values are used for other generated
    columns.
  – An additional row is inserted using the original values from the row,
    except that the begin column is set to value2, a column defined as
    DATA CHANGE OPERATION is set to 'I', and new values are used
    for other generated columns.

Any existing delete triggers are activated for the rows that are deleted, and
any existing insert triggers are activated for the rows that are implicitly
inserted.

value1, value2
  Specifies expressions that return a value of a built-in data type. The result
  of each expression must be comparable to the data type of the columns of
  the specified period. See the comparison rules described in "Assignment
  and comparison" on page 123. Each expression can contain any of the
  following supported operands:
  • A constant
  • A special register
  • A variable
  • An array element specification
  • A built-in scalar function whose arguments are supported operands
  • A CAST specification where the cast operand is a supported operand
  • An expression that uses arithmetic operators and operands

Each expression must not have a timestamp precision that is greater than
the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP
WITHOUT TIME ZONE, each expression must not return a value of a
timestamp with a time zone.

A period clause for a view must not contain a global variable or an
untyped parameter marker.

correlation-name
  Specifies an alternate name that can be used within the search-condition to
designate the table or view. (For an explanation of correlation names, see
"Correlation names" on page 216.)

include-column
  Specifies a set of columns that are included, along with the columns of
table-name or view-name, in the result table of the DELETE statement when it is
nested in the FROM clause of the outer fullselect that is used in a subselect,
SELECT statement, or in a SELECT INTO statement. The included columns are
appended to the end of the list of columns that is identified by table-name or
view-name. If no value is assigned to a column that is specified by an
include-column, a NULL value is returned for that column.

INCLUDE
  Introduces a list of columns that are to be included in the result table of
the DELETE statement. The included columns are only available if the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name
Specifies the name for a column of the result table of the DELETE statement that is not the same name as another included column nor a column in the table or view that is specified in table-name or view-name.

data-type
Specifies the data type of the included column. The included columns are nullable.

built-in-type
Specifies a built-in data type. See “CREATE TABLE” on page 1446 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

distinct-type
Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

SET
Introduces the assignment of values to columns.

assignment-clause
The assignment-clause introduces a list of one or more column-names and the values that are to be assigned to the columns. The column-names are the only columns that can be set using the assignment-clause.

column-name
Identifies an INCLUDE column.

Assignments to included columns are only processed when the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. The columns that are named in the INCLUDE clause are the only columns that can be set using the SET clause. The null value is returned for an included column that is not set by using an explicit SET clause.

expression
Indicates the new value of the column. The expression is any expression of the type described in “Expressions” on page 243. It must not include an aggregate function.

A column-name in an expression must identify a column of the table or view. For each row that is deleted, the value of the column in the expression is the value of the column in the row before the row is deleted.

NULL
Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

row-fullselect
Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding column-names. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column that is to be deleted is not nullable. An error also occurs if there is more than one row in the result.
If the fullselect refers to columns that are to be deleted, the value of such a
column in the fullselect is the value of the column in the row before the
row is deleted.

**WHERE**

Specifies the rows to be deleted. You can omit the clause, give a search
condition, or specify a cursor. For a created temporary table or a view of a
created temporary table, you must omit the clause. When the clause is omitted,
all the rows of the table or view are deleted.

**search-condition**

Is any search condition as described in Chapter 2, “Language elements,” on
page 55. Each *column-name* in the search condition, other than in a
subquery, must identify a column of the table or view.

The search condition is applied to each row of the table or view and the
deleted rows are those for which the result of the search condition is true.

If the search condition contains a subquery, the subquery can be thought of
as being executed each time the search condition is applied to a row, and
the results used in applying the search condition. In actuality, a subquery
with no correlated references is executed just once, whereas it is possible
that a subquery with a correlated reference must be executed once for each
row.

Let T2 denote the object table of a DELETE statement and let T1 denote a
table that is referred to in the FROM clause of a subquery of that
statement. T1 must not be a table that can be affected by the DELETE on
T2. Thus, the following rules apply:

- T1 must not be a dependent of T2 in a relationship with a delete rule of
  CASCADE or SET NULL, unless the result of the subquery is
  materialized before the DELETE action is executed.
- T1 must not be a dependent of T3 in a relationship with a delete rule of
  CASCADE or SET NULL if deletes of T2 cascade to T3.

**WHERE CURRENT OF cursor-name**

Identifies the cursor to be used in the delete operation. *cursor-name* must
identify a declared cursor as explained in the description of the DECLARE
CURSOR statement in “DECLARE CURSOR” on page 1598. If the DELETE
statement is embedded in a program, the DECLARE CURSOR statement must
include *select-statement* rather than *statement-name*.

The table or view named must also be named in the FROM clause of the
SELECT statement of the cursor, and the result table of the cursor must be
capable of being deleted. For an explanation of read-only result tables, see
Read-only cursors. Note that the object of the DELETE statement must not be
identified as the object of the subquery in the WHERE clause of the SELECT
statement of the cursor.

If the cursor is ambiguous and the plan or package was bound with
CURRENTDATA(NO), DB2 might return an error to the application if DELETE
WHERE CURRENT OF is attempted for any of the following:

- A cursor that is using block fetching
- A cursor that is using query parallelism
- A cursor that is positioned on a row that has been modified by this or
  another application process

When the DELETE statement is executed, the cursor must be open and
positioned on a row or rowset of the result table.
• If the cursor is positioned on a single row, that row is the one deleted, and after the deletion the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.

• If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted, and after the deletion the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

A positioned DELETE must not be specified for a cursor that references a view on which an instead of delete trigger is defined, even if the view is an updatable view.

**FOR ROW n OF ROWSET**

Specifies which row of the current rowset is to be deleted. The corresponding row of the rowset is deleted, and the cursor remains positioned on the current rowset. If the rowset consists of a single row, or all other rows in the rowset have already been deleted, then the cursor is positioned before the next rowset of the result table. If there is no next rowset, the cursor is positioned after the last rowset.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range of 1 to 32767. The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor.

If the specified row cannot be deleted, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as a delete hole (that is, a row in the result table whose corresponding row has deleted from the base table), an error is returned.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies a predicate of the SELECT statement), an error is returned.

It is possible for another application process to delete a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to delete such a row results in an error.

If the FOR ROW n OF ROWSET clause is not specified, the current position of cursor determines the rows that are affected by the statement:

• If the cursor is positioned on a single row, that row is the one deleted. After the row is deleted, the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.

• If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted. After the rows are deleted, the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

**isolation-clause**

Specifies the isolation level used when locating the rows to be deleted by the statement.
WITH
Introduces the isolation level, which may be one of the following:

RR  Repeatable read
RS  Read stability
CS  Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

SKIP LOCKED DATA
The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

For DELETE statements, SKIP LOCKED DATA can be specified only in the searched form of the DELETE statement. SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

QUERYNO  integer
Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:
• For simplifying the use of optimization hints for access path selection
• For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see DB2 Performance Monitoring and Tuning Guide.

Notes
Delete operation errors:
If an error occurs during the execution of any delete operation, no changes are made. If an error occurs during the execution of a positioned delete, the position of the cursor is unchanged. However, it is possible for an error to make the position of the cursor invalid, in which case the cursor is closed. It is also possible for a delete operation to cause a rollback, in which case the cursor is closed.

Position of cursor:
If an application process deletes a row on which any of its cursors are
positioned, those cursors are positioned before the next row of the result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a searched DELETE). In the presence of an SQL data change statements that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.

Locking:
Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful delete operation. Until the locks are released by a commit or rollback operation, the effect of the delete operation can only be perceived by the application process that performed the deletion and the locks can prevent other application processes from performing operations on the table. Locks are not acquired when rows are deleted from a declared temporary table unless all the rows are deleted (DELETE FROM T). When all the rows are deleted from a declared temporary table, a segmented table lock is acquired on the pages for the table and no other table in the table space is affected.

Triggers:
Delete operations can cause triggers to be activated. A trigger might cause other statements to be executed or might raise error conditions that are based on the deleted rows. If a DELETE statement on a view causes an INSTEAD OF trigger to be activated, referential integrity is checked against the updates that are performed in the trigger and not against the underlying tables of the view that cause the trigger to be activated.

Triggers defined on a table for which row or column access control is also enforced:
Row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control that is enforced for the triggering table is also ignored for any transition variables or transition tables that are referenced in the trigger body or that are passed as arguments to user-defined functions that are invoked in the trigger body. To ensure that no security concern exists for SQL statements in the trigger action (access to sensitive data in transition variables and transition tables, for example), the trigger must be secure. For information about securing a trigger, see "CREATE TRIGGER" on page 1544 and "ALTER TRIGGER" on page 1140.

Referential integrity:
If the identified table or the base table of the identified view is a parent, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION. In addition, the delete operation must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted and any rows that are dependents of the selected rows are also deleted.

- The nullable columns of foreign keys in any rows that are their dependents in a relationship governed by a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship governed by a delete rule of CASCADE are also deleted, and these rules apply, in turn, to those rows.
The only difference between NO ACTION and RESTRICT is when the referential constraint is enforced. RESTRICT (IBM SQL rules) enforces the rule immediately, and NO ACTION (SQL standard rules) enforces the rule at the end of the statement. This difference matters only in the case of a searched DELETE involving a self-referencing constraint that deletes more than one row. NO ACTION might allow the DELETE to be successful where RESTRICT (if it were allowed) would prevent it.

Check constraint:
A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL. If deleting a row in the parent table would cause a column in a dependent table to be set to null and there is a check constraint that specifies that the column must not be null, the row is not deleted.

Referential constraints defined on a table for which row or column access control is enforced:
Row and column access controls do not effect referential constraints.

Nesting user-defined functions or stored procedures:
A DELETE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as nesting of SQL statements. A user-defined function or stored procedure that is nested within the DELETE must not access the table from which you are deleting rows.

Indexes with VARBINARY columns:
If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

Number of rows deleted:
Except as noted below, a delete operation sets SQLERRD(3) in the SQLCA to the number of deleted rows. This number does not include any rows that were deleted as a result of a CASCADE delete rule or a trigger.

DELETE FROM T without a WHERE clause deletes all rows of T. If a table T is contained in a segmented table space and is not a parent table, this deletion will be performed without accessing T. The SQLERRD(3) field is set to -1. (For a complete description of the SQLCA, including exceptions to the above, see "SQL communication area (SQLCA)" on page 2134.

Rules for positioned DELETE with SENSITIVE STATIC scrollable cursor:
When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- **Delete attempt of delete holes or update holes.** If, with a positioned delete against a SENSITIVE STATIC scrollable cursor, an attempt is made to delete a row that has been identified as a delete hole (that is, a row in the result table whose corresponding row has been deleted from the base table), an error occurs.

  If an attempt is made to delete a row that has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies the predicate of the SELECT statement), an error occurs.

- **Delete operations.** Positioned delete operations with SENSITIVE STATIC scrollable cursors perform as follows:
1. The SELECT list items in the target row of the base table of the
cursor are compared with the values in the corresponding row of the
result table (that is, the result table must still agree with the base
table). If the values are not identical, the delete operation is rejected
and an error occurs. The operation can be attempted again after a
successful FETCH SENSITIVE has occurred for the target row.

2. The WHERE clause of the SELECT statement is re-evaluated to
determine whether the current values in the base table still satisfy
the search criteria. The values in the SELECT list are compared to
determine that these values have not changed. If the WHERE clause
evaluates as true, and the values in the SELECT list have not
changed, the delete operation is allowed to proceed. Otherwise, an
error occurs, the delete operation is rejected, and an update hole
appears in the cursor.

3. After the base table row is successfully deleted, the temporary result
table is updated and the row is marked as a delete hole.

- Rollback of delete holes. Delete holes are usually permanent. Once a delete
  hole is identified, it remains a delete hole until the cursor is closed.
  However, if a positioned delete using this cursor actually caused the
  creation of the hole (that is, this cursor was used to make the changes
  that resulted in the hole) and the delete was subsequently rolled back,
  then the row is no longer considered a delete hole.

- Result table. Any deletes, either positioned or searched, to rows of the
  base table on which a SENSITIVE STATIC scrollable cursor is defined
  are reflected in the result table if a positioned update or positioned
  delete is attempted with the scrollable cursor. A SENSITIVE STATIC
  scrollable cursor sees these deletes when a FETCH SENSITIVE is
  attempted.

If the FOR ROW n OF ROWSET clause is not specified, the entire rowset
fetched by the most recent FETCH statement that returned data for the
specified cursor is deleted.

Deleting rows from a table with multilevel security:
When you delete rows from a table with multilevel security, DB2 compares
the security label of the user (the primary authorization ID) to the security
label of the row. The delete proceeds according to the following rules:

- If the security label of the user and the security label of the row are
  equivalent, the row is deleted.

- If the security label of the user dominates the security label of the row,
  the user's write-down privilege determines the security the result of the
  DELETE statement:
  - If the user has write-down privilege or write-down control is not
    enabled, the row is deleted.
  - If the user does not have write-down privilege and write-down
    control is enabled, the row is not deleted.

- If the security label of the row dominates the security label of the user,
  the row is not deleted.

Deleting rows from a table for which row and column access control is
enforced:
When a DELETE statement is issued for a table for which row access
control is enforced, the rules specified in the row permissions affect
whether a row can be deleted. Typically those rules are based on the
authorization ID or role of the process.
A table for which row access control is enforced has at least one row permission, the default row permission that prevents all access to the table. When multiple row permissions are defined and enabled for a table, a row access control search condition is derived by using the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID or role of the DELETE statement. If the WHERE clause is specified in the DELETE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be deleted. If there is no WHERE clause, the accessible rows are the rows to be deleted.

If there are rows to be deleted, and there is a DELETE trigger for the table, the trigger is activated.

When a DELETE statement is issued for a table for which column access control is enforced, column masks do not affect the DELETE statement.

The preceding rules are not applicable to include-columns. include-columns are subject to the rules for the select list because they are not the columns of the object table of the DELETE statement.

**Other SQL statements in the same unit of work:**

The following statements cannot follow a DELETE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)

**Considerations for a system-period temporal table:**

If the DELETE statement has a search condition that contains a correlated subquery that references the history table (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows that are subsequently processed for the statement.

The mass delete operation is not used for a DELETE statement that does not contain a search condition if the table is defined as a system-period temporal table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target of the DELETE statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

**Considerations for a history table:**

When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. DB2 generates a value using the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures the uniqueness of the generated values for an end column in a history table across transactions. If a conflicting transaction is
updating the same row in the system-period temporal table and the row that is to be inserted into the associated history table will have a value for the end column that is greater than the value of the corresponding begin column, an error is returned.

**Considerations for an application-period temporal table:**

A DELETE statement that contains a FOR PORTION OF BUSINESS_TIME clause for an application-period temporal table indicates the two points in time between which the specified delete operations are effective.

Suppose that FOR PORTION OF BUSINESS_TIME is specified and the period value for a row is only partially contained in the period that is specified from value1 up to value2. (The period value for a row is specified by the values of the begin column and end column.) In this case, the row is deleted and one or two rows are automatically inserted to represent the portion of the row that is not deleted. For each row that is automatically inserted as a result of a delete operation on the table, new values are generated for each generated column in the application-period temporal table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, an automatic insert might violate a constraint or index. In this case, an error is returned.

When an application-period table is the target of a DELETE statement and the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, DB2 adds the following additional predicates to the statement:

```
bt_begin <= CURRENT TEMPORAL BUSINESS_TIME AND
bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

In the preceding code, bt_begin and bt_end are the begin and end columns of the BUSINESS_TIME period of the target table of the DELETE statement.

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value, the target of the DELETE statement must not be a view if both of the following conditions are true:

- The view is defined with the WITH CHECK option.
- The view definition includes a WHERE clause that contains one of the following syntax elements:
  - A subquery that directly or indirectly references an application-period temporal table.
  - An invocation of an SQL routine that has a package associated with it.
  - An invocation of an external routine with a data access indication other than NO SQL.

**Deleting rows from archive-enabled tables:**

If the target of the DELETE statement is an archive-enabled table, existing rows in the associated archive table are not affected.

When a row of an archive-enabled table is deleted, the effect on the associated archive table is determined by the setting of the SYSIBMADM.MOVE_TO_ARCHIVE global variable. If the global variable is set to Y, a copy of a deleted row is inserted into the associated archive table. Otherwise, a copy of a deleted row is not inserted into the associated archive table.
A data change statement cannot reference an archive-enabled table when a system-period temporal table or application-period temporal table is also referenced.

Syntax alternatives:
For compatibility with other SQL implementations, the FROM keyword that immediately follows the DELETE keyword can be omitted.

Examples

Assume that the statements in the examples are embedded in PL/I programs.

Example 1: From the table DSN8B10.EMP delete the row on which the cursor C1 is currently positioned.
EXEC SQL DELETE FROM DSN8B10.EMP WHERE CURRENT OF C1;

Example 2: From the table DSN8B10.EMP, delete all rows for departments E11 and D21.
EXEC SQL DELETE FROM DSN8B10.EMP
WHERE WORKDEPT = 'E11' OR WORKDEPT = 'D21';

Example 3: From employee table X, delete the employee who has the most absences.
EXEC SQL DELETE FROM EMP X
WHERE ABSENT = (SELECT MAX(Absent) FROM EMP Y
WHERE X.WORKDEPT = Y.WORKDEPT);

Example 4: Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete all 10 rows in the rowset.
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1;

Example 5: Assuming cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete the fourth row of the rowset.
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1 FOR ROW 4 OF ROWSET;

Example 6: Delete rows in table T1 if the value for column COL2 matches the cardinality of array INTA. The array INTA is specified as an argument for the CARDINALITY function in the DELETE statement.
CREATE TYPE INTARRAY AS INTEGER ARRAY[6];
DECLARE INTA AS INTARRAY;
SET INTA = ARRAY[1, 2, 3, 4, 5];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES('abc', 10);
DELETE FROM T1 WHERE COL2 = CARDINALITY(INTA);
DESCRIBE

The DESCRIBE statement obtains information about an object. You can obtain the following types of information with this statement, each of which is described separately.

- Cursors
  Gets information about the result set that is associated with the cursor. This information, such as column information, is put into a descriptor. See “DESCRIBE CURSOR” on page 1654.

- Input parameter markers of a prepared statement.
  Gets information about the input parameter markers in a prepared statement. This information is put into a descriptor. See “DESCRIBE INPUT” on page 1656.

- The output of a prepared statement
  Gets information about a prepared statement or information about the select list columns in a prepared SELECT statement. This information is put into a descriptor. See “DESCRIBE OUTPUT” on page 1659.

- Procedures
  Gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor. See “DESCRIBE PROCEDURE” on page 1666.

- Tables
  Gets information about a table or view. This information is put into a descriptor. See “DESCRIBE TABLE” on page 1669.
DESCRIBE CURSOR

The DESCRIBE CURSOR statement obtains information about the result set that is associated with the cursor. The information, such as column information, is put into a descriptor. Use DESCRIBE CURSOR for result set cursors from stored procedures. The cursor must be defined with the ALLOCATE CURSOR statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
DESCRIBE CURSOR cursor-name INTO descriptor-name host-variable
```

Description

cursor-name or host-variable

Identifies a cursor by the specified cursor-name or the cursor name contained in host-variable. The name must identify a cursor that has already been allocated in the source program.

A column of the result table of the cursor must not be an array.

If host-variable is used:

- It must be a character string variable that has a maximum length of 18 bytes.
- It must not be followed by an indicator variable.
- The cursor name must be left justified within the host variable and must not contain embedded blanks.
- If the length of the cursor name is less than the length of the host variable, it must be padded on the right with blanks.

INTO descriptor-name

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the columns in the result set associated with the named cursor.

The considerations for allocating and initializing the SQLDA are similar to those of a varying-list SELECT statement. For more information, see DB2 Application Programming and SQL Guide.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE CURSOR statement is executed, the contents of the SQLDA are the same as after a DESCRIBE for a SELECT statement, with the following exceptions:

- The first 5 bytes of the SQLDAID field are set to ‘SQLRS’.
• Bytes 6 to 8 of the SQLDAID field are reserved. If the cursor is declared
  WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set
to 1.

These exceptions do not apply to a REXX SQLDA, which does not include the
SQLDAID field.

Notes

Using cursors for result sets: Column names are included in the information that
DESCRIBE CURSOR obtains when the statement that generates the result set is
either:
• Dynamic
• Static and the value of field DESCRIBE FOR STATIC on installation panel
  DSNTIP4 was YES when the package or stored procedure was bound. If the
  value of the field was NO, the returned information includes only the data type
  and length of the columns.

Using host variables: If the DESCRIBE CURSOR statement contains host variables,
the contents of the host variables are assumed to be in the encoding scheme that
was specified in the ENCODING parameter when the package or plan that
contains the statement was bound.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Place information about the result set associated with cursor C1 into the
descriptor named by :sqlda1.

  EXEC SQL DESCRIBE CURSOR C1 INTO :sqlda1

Example 2: Place information about the result set associated with the cursor named
by :hv1 into the descriptor named by :sqlda2.

  EXEC SQL DESCRIBE CURSOR :hv1 INTO :sqlda2
DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the input parameter markers of a prepared statement.

For an explanation of prepared statements, see "PREPARE" on page 1846 and "DESCRIBE PROCEDURE" on page 1666.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

Syntax

```
DESCRIBE INPUT statement-name INTO descriptor-name
```

Description

**statement-name**

Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server. An input parameter marker must not refer to an array value.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in "SQL descriptor area (SQLDA)" on page 2144. See "Identifying an SQLDA in C or C++" on page 2164 for how to represent descriptor-name in C. The information returned in the SQLDA describes the parameter markers.

Before the DESCRIBE INPUT statement is executed, the user must set the SQLN field in the SQLDA and the SQLDA must be allocated. Considerations for initializing and allocating the SQLDA are similar to those for the DESCRIBE statement (see "DESCRIBE" on page 1653). An occurrence of an extended SQLVAR is needed for each parameter in addition to the required base SQLVAR only if the input data contains LOBs.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE INPUT statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. The SQLDA contents are similar to the contents returned for the DESCRIBE statement (see page "The SQLDA contents returned after DESCRIBE") with these exceptions:

- In the SQLDAID, DB2 sets the value of the seventh byte only to the space character or '2'. A value of '3' is never used. The value '2' indicates that two SQLVAR entries (an occurrence of both a base SQLVAR and an extended...
SQLVAR) are required for each parameter because the input data contains
LOBs. The seventh byte is a space character when either of the following
conditions is true:
- The input data does not contain LOBs. Only a base SQLVAR occurrence is
  needed for each parameter.
- Only a base SQLVAR occurrence is needed for each column of the result,
  and the SQLDA is not large enough to contain the returned information.
  • The SQLD field is set to the number of parameter markers being described.
  The value is 0 if the statement being described does not have input
  parameter markers.
  • The SQLNAME field is not used.
  • The SQLDATATYPE is set to a nullable, regardless of the usage of the
    parameter markers in the prepared statement.
  • The SQLDATATYPE-NAME is not used if an extended SQLVAR entry is
    present. DESCRIBE INPUT does not return information about distinct types.

For complete information on the contents of the fields, see “SQL descriptor
area (SQLDA)” on page 2144.

Notes

Preparing the SQLDA for OPEN or EXECUTE: This note is relevant if you are
applying DESCRIBE INPUT to a prepared statement and you intend to use the
SQLDA in an OPEN or EXECUTE statement. To prepare the SQLDA for that
purpose:
• Set SQLDATA to a valid address.
• If SQLTYPE is odd, set SQLIND to a valid address.

For the meaning of those fields in that context, see “SQL descriptor area (SQLDA)”
on page 2144.

Support for extended dynamic SQL in a distributed environment: Unlike the
DESCRIBE statement, which can be used in a distributed environment to describe
static SQL statements generated by extended dynamic SQL, you cannot describe
host variables in static SQL statements that are generated by extended dynamic
SQL. A DESCRIBE INPUT statement issued against such static SQL statements
always fails.

For information on how the DESCRIBE statement supports extended dynamic SQL,
see “Support for extended dynamic SQL in a distributed environment”

Using host variables: If the DESCRIBE INPUT statement contains host variables,
the contents of the host variables are assumed to be in the encoding scheme that
was specified in the ENCODING parameter when the package or plan that
contains the statement was bound.

Example

Execute a DESCRIBE INPUT statement with an SQLDA that has enough SQLVAR
occurrences to describe any number of input parameters a prepared statement
might have. Assume that five parameter markers at most will need to be described
and that the input data does not contain LOBs.

    /* STMT1_STR contains INSERT statement with VALUES clause */
    EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
    ... /* code to set SQLN to 5 and to allocate the SQLDA */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;

This example uses the first technique described in Allocating the SQLDA to allocate the SQLDA.
DESCRIBE OUTPUT

The DESCRIBE OUTPUT statement obtains information about a prepared statement.

For an explanation of prepared statements, see "PREPARE" on page 1846 and "DESCRIBE PROCEDURE" on page 1666.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

See "PREPARE" on page 1846 for the authorization required to create a prepared statement.

Syntax

```
DESCRIBE OUTPUT statement-name INTO descriptor-name
  NAMES USING LABELS ANY BOTH
```

Description

OUTPUT

When a `statement-name` is specified, optional keyword to indicate that the describe will return information about the select list columns in a the prepared SELECT statement.

`statement-name`

Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a statement that has been prepared by the application process at the current server. A column of the result table of the prepared statement must not be an array.

`INTO descriptor-name`

Identifies an SQL descriptor area (SQLDA), which is described in "SQL descriptor area (SQLDA)" on page 2144. See "Identifying an SQLDA in C or C++" on page 2164 for how to represent `descriptor-name` in C.

For languages other than REXX: Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

`SQLN` Indicates the number of SQLVAR occurrences provided in the SQLDA.
DB2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.

For REXX: The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable stem.SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with stem.n.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

**USING**

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

**NAMES**

Assigns the name of the column. This is the default.

**LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

**ANY**

Assigns the column label, and if the column has no label, the column name.

**BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to \(2n\) or \(3n\), where \(n\) is the number of columns in the object being described. For each of the columns, the first \(n\) occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third \(n\) occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

**Notes**

*Using PREPARE INTO clause:* Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.

*Allocating the SQLDA:* Before the DESCRIBE or PREPARE INTO statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Also, enough storage must be allocated to contain the number of occurrences that SQLN specifies. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must be at least equal to the number of columns. Furthermore, if USING BOTH is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two or three times the number of columns. See “Determining how many SQLVAR occurrences are needed” on page 2149 for more information.

*First technique:* Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. At the
extreme, the number of SQLVARs could equal three times the maximum number of columns allowed in a result table. After the SQLDA is allocated, the application can use the SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique: Repeat the following two steps for every processed select list:
1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero.
2. Allocate a new SQLDA with enough occurrences of SQLVAR. Use the values that are returned in SQLD and SQLCODE to determine the number of SQLVAR entries that are needed. The value of SQLD is the number of columns in the result table, which is either the required number of occurrences of SQLVAR or a fraction of the required number (see “Determining how many SQLVAR occurrences are needed” on page 2149 for details). If the SQLCODE is +236, +237, +238, or +239, the number of SQLVAR entries that is needed is two or three times the value in SQLD, depending on whether USING BOTH was specified. Set SQLN to reflect the number of SQLVAR entries that have been allocated.
3. Execute the DESCRIBE statement again, using the new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

Third technique: Allocate an SQLDA that is large enough to handle most (hopefully, all) select lists but is also reasonably small. If an execution of DESCRIBE fails because SQLDA is too small, allocate a larger SQLDA and execute the DESCRIBE statement again.

For the new larger SQLDA, use the values that are returned in SQLD and SQLCODE from the failing DESCRIBE statement to calculate the number of occurrences of SQLVAR that are needed, as described in technique two. Remember to check for SQLCODEs +236, +237, +238, and +239, which indicate whether extended SQLVAR entries are needed because the data includes LOBs or distinct types.

This third technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

The SQLDA contents returned on DESCRIBE: After a DESCRIBE statement is executed, the following list describes the contents of the SQLDA fields as they are set by DB2 or ignored. These descriptions do not necessarily apply to the uses of an SQLDA in other SQL statements (EXECUTE, OPEN, FETCH). For more on the other uses, see “SQL descriptor area (SQLDA)” on page 2144.

SQLDAID
DB2 sets the first 6 bytes to 'SQLDA ' (5 letters followed by the space character) and the eighth byte to a space character. The seventh byte is set to indicate the number of SQLVAR entries that are needed to describe each column of the result table as follows:

space The value of space occurs when:
• USING BOTH was not specified and the columns being described do not include LOBs or distinct types. Each column
only needs one SQLVAR entry. If the SQL standard option is yes, DB2 sets SQLCODE to warning code +236. Otherwise, SQLCODE is zero.

- USING BOTH was specified and the columns being described do not include LOBs or distinct types. Each column needs two SQLVAR entries. DB2 sets SQLD to two times the number of columns of the result table. The second set of SQLVARs is used for the labels.

2. Each column needs two SQLVAR entries. Two entries per column are required when:
   - USING BOTH was not specified and the columns being described include LOBs or distinct types or both. DB2 sets the second set of SQLVAR entries with information for the LOBs or distinct types being described.
   - USING BOTH was specified and the columns include LOBs but not distinct types. DB2 sets the second set of SQLVAR entries with information for the LOBs and labels for the columns being described.

3. Each column needs three SQLVAR entries. Three entries are required only when USING BOTH is specified and the columns being described include distinct types. The presence of LOB data does not matter. It is the distinct types and not the LOBs that cause the need for three SQLVAR entries per column when labels are also requested. DB2 sets the second set of SQLVAR entries with information for the distinct types (and LOBs, if any) and the third set of SQLVAR entries with the labels of the columns being described.

A REXX SQLDA does not contain this field.

**SQLDABC**

The length of the SQLDA in bytes. DB2 sets the value to SQLN×44+16.

A REXX SQLDA does not contain this field.

**SQLD**

If the prepared statement is a query, DB2 sets the value to the number of columns in the object being described (the value is actually twice the number of columns in the case where USING BOTH was specified and the result table does not include LOBs or distinct types). Otherwise, if the statement is not a query, DB2 sets the value to 0.

**SQLVAR**

An array of field description information for the column being described. There are two types of SQLVAR entries—the base SQLVAR and the extended SQLVAR.

If the value of SQLD is 0, or is greater than the value of SQLN, no values are assigned to any occurrences of SQLVAR. If the value of SQLN was set so that there are enough SQLVAR occurrences to describe the specified columns (columns with LOBs or distinct types and a request for labels increase the number of SQLVAR entries that are needed), the values are assigned to the first \( n \) occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column, the second occurrence of SQLVAR contains a description of the second column, and so on. This first set of SQLVAR entries are referred to as *base SQLVAR* entries. Each column always has a base SQLVAR entry.
If the DESCRIBE statement included the USING BOTH clause, or the columns being described include LOBs or distinct types, additional SQLVAR entries are needed. These additional SQLVAR entries are referred to as the extended SQLVAR entries. There can be up to two sets of extended SQLVAR entries for each column.

For REXX, the SQLVAR is a set of stem variables that begin with *stem.n*, instead of a structure. The REEX SQLDA uses only a base SQLVAR. The way in which DB2 assigns values to the SQLVAR variables is the same as for other languages. That is, the *stem.1* variables describe the first column in the result table, the *stem.2* variables describe the second column in the result table, and so on. If USING BOTH is specified, the *stem.n+1* variables also describe the first column in the result table, the *stem.n+2* variables also describe the second column in the result table, and so on.

The base SQLVAR:

- **SQLTYPE**
  A code that indicates the data type of the column and whether the column can contain null values. For the possible values of SQLTYPE, see Table 174 on page 2155.

- **SQLLEN**
  A length value depending on the data type of the result columns. SQLLEN is 0 for LOB and XML data types. For the other possible values of SQLLEN, see Table 174 on page 2155.
  In a REXX SQLDA, for DECIMAL or NUMERIC columns, DB2 sets the SQLPRECISION and SQLSCALE fields instead of the SQLLEN field.

- **SQLDATA**
  The CCSID of a string column. For possible values, see Table 175 on page 2158.
  In a REXX SQLDA, DB2 sets the SQLCCSID field instead of the SQLDATA field.

- **SQLIND**
  Reserved.

- **SQLNAME**
  The unqualified name or label of the column, depending on the value of USING (NAMES, LABELS, ANY, or BOTH). The field is a string of length 0 if the column does not have a name or label. For more details on unnamed columns, see the discussion of the names of result columns under "select-clause" on page 785. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains the statement.

The extended SQLVAR:

- **SQLLONGLEN**
  The length attribute of a BLOB, CLOB, or DBCLOB column.
  *
  Reserved.

- **SQLDATALEN**
  Not Used.
SQLDATATYPE-NAME
For a distinct type, the fully qualified distinct type name.
Otherwise, the value is the fully qualified name of the built-in data type.
For a label, the label for the column.
This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

The REXX SQLDA does not use the extended SQLVAR.

Performance considerations: Although DB2 does not change the value of SQLN, you might want to reset this value after the DESCRIBE statement is executed. If the contents of SQLDA from the DESCRIBE statement is used in a later FETCH statement, set SQLN to \( n \) (where \( n \) is the number of columns of the result table) before executing the FETCH statement. For details, see Preparing the SQLDA for data retrieval.

Preparing the SQLDA for data retrievals: This note is relevant if you are applying DESCRIBE to a prepared query and you intend to use the SQLDA in the FETCH statements you employ to retrieve the result table rows. To prepare the SQLDA for that task, you must set the SQLDATA field of SQLVAR. SQLIND must be set if SQLTYPE is odd, and SQLNAME must be set when overriding the CCSID. For the meaning of those fields in that context, see “SQL descriptor area (SQLDA)” on page 2144.

Also, SQLN and SQLDABC should be reset (if necessary) to \( n \) and \( n \times 44 + 16 \), where \( n \) is the number of columns in the result table. Doing so can improve performance when the rows of the result table are fetched.

Support for extended dynamic SQL in a distributed environment: In a distributed environment where DB2 for z/OS is the server and the requester supports extended dynamic SQL, such as DB2 Server for VSE & VM, a DESCRIBE statement that is executed against an SQL statement in the extended dynamic package appears to DB2 as a DESCRIBE statement against a static SQL statement in the DB2 package. A DESCRIBE statement cannot normally be issued against a static SQL statement. However, a DESCRIBE against a static SQL statement that is generated by extended dynamic SQL executes without error if the package has been rebound after field DESCRIBE FOR STATIC on installation panel DSNTIP4 has been set to YES.

YES indicates that DB2 generates an SQLDA for the DESCRIBE at bind time so that DESCRIBE requests for static SQL statements can be satisfied at execution time. For more information, see DB2 Installation Guide.

Avoiding double preparation when using REOPT(ALWAYS) or REOPT(ONCE): If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, DESCRIBE causes the statement to be prepared if it is not already prepared. If issued before an OPEN or an EXECUTE, the DESCRIBE causes the statement to be prepared without input variables. If the statement has input variables, the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid preparing statements twice, issue the DESCRIBE after the OPEN. For non-cursor statements, open and fetch processing are performed on the EXECUTE. So, if a DESCRIBE must be issued, the statement will be prepared twice.
The use of a prepared statement for an EXPLAIN statement can cause duplicate entries in the explain tables when the prepared statement specifies the REOPT(ALWAYS) bind option and is executed using the jcc driver.

**Errors occurring on DESCRIBE:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on DESCRIBE.

**Considerations for implicitly hidden columns:** A DESCRIBED OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

**Using host variables:** If the DESCRIBE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Considerations for array elements:** CCSID UNICODE is returned for a result column that corresponds to a reference to an array element with a datetime data type.

**Example**

In a PL/I program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA. This is the second technique described in Allocating the SQLDA.

```
EXEC SQL BEGIN DECLARE SECTION;
  DCL STMT1_STR CHAR(200) VARYING;
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
... /* code to prompt user for a query, then to generate */
  /* a select-statement in the STMT1_STR */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
... /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
... /* code to check that SQLD is greater than zero, to set */
  /* SQLN to SQLD, then to re-allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
... /* code to prepare for the use of the SQLDA */
EXEC SQL OPEN DYN_CURSOR;
... /* loop to fetch rows from result table */
EXEC SQL FETCH DYN_CURSOR USING DESCRIPTOR :SQLDA;
  .
  .
  .
```
DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
DESCRIBE PROCEDURE procedure-name INTO descriptor-name host-variable
```  

Description

*procedure-name* or *host-variable*

Identifies the stored procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one, two, or three-part name. The procedure name in the DESCRIBE PROCEDURE statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the DESCRIBE PROCEDURE statement.

If a host variable is used:

- It must be a character string variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the database server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

**INTO** *descriptor-name*

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the result sets returned by the stored procedure.

Considerations for allocating and initializing the SQLDA are similar to those for DESCRIBE TABLE.

The contents of the SQLDA after executing a DESCRIBE PROCEDURE statement are:
- The first 5 bytes of the SQLDAID field are set to 'SQLPR'.
  A REXX SQLDA does not contain SQLDAID.
- Bytes 6 to 8 of the SQLDAID field are reserved.
- The SQLD field is set to the total number of result sets. A value of 0 in the field indicates there are no result sets.
- There is one SQLVAR entry for each result set.
- The SQLDATA field of each SQLVAR entry is set to the result set locator value associated with the result set.
  For a REXX SQLDA, SQLLOCATOR is set to the result set locator value.
- The SQLIND field of each SQLVAR entry is set to the estimated number of rows in the result set.
  For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.
- The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

**Notes**

**SQLDA information:** A value of -1 in the SQLIND field indicates that an estimated number of rows in the result set is not provided. DB2 for z/OS always sets SQLIND to -1. For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.

DESCRIBE PROCEDURE does not return information about the parameters expected by the stored procedure.

**Assignment of locator values:** Locator values are assigned to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

**Using host variables:** If the DESCRIBE PROCEDURE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Examples**

The statements in the following examples are assumed to be in PL/I programs.

**Example 1:** Place information about the result sets returned by stored procedure P1 into the descriptor named by SQLDA1. Assume that the stored procedure is called with a one-part name from current server SITE2.
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL P1;
EXEC SQL DESCRIBE PROCEDURE P1 INTO :SQLDA1;

**Example 2:** Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSHEMA is used.

```sql
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL MYSHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE MYSHEMA.P1 INTO :SQLDA1;
```

**Example 3:** Place information about the result sets returned by the stored procedure identified by host variable HV1 into the descriptor named by SQLDA2. Assume that host variable HV1 contains the value SITE2.MYSHEMA.P1 and the stored procedure is called with a three-part name.

```sql
EXEC SQL CALL SITE2.MYSHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE :HV1 INTO :SQLDA2;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the DESCRIBE PROCEDURES statement.

```sql
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL SITE2.MYSHEMA.P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
   WITH PROCEDURE :HV1;
```
DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a designated table or view.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The privileges that are held by the authorization ID that owns the plan or package must include at least one of the following (if there is a plan, authorization checking is done only against the plan owner):

- Ownership of the table or view
- The SELECT, INSERT, UPDATE, DELETE, or REFERENCES privilege on the object
- The ALTER or INDEX privilege on the object (tables only)
- DBADM authority over the database that contains the object (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- System DBADM
- DATAACCESS authority
- EXPLAIN authority
- SQLADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

For an RRSAF application that does not have a plan and in which the requester and the server are DB2 for z/OS systems, authorization to execute the package is performed against the primary or secondary authorization ID of the process.

Syntax

```plaintext
DESCRIBE TABLE host-variable INTO descriptor-name
```

Description

**TABLE host-variable**

Identifies the table or view. The name must not identify an auxiliary table. When the DESCRIBE statement is executed, the host variable must contain a name which identifies a table or view that exists at the current server. This
variable must be a fixed-length or varying-length character string with a length attribute less than 256. The name must be followed by one or more blanks if the length of the name is less than the length of the variable. It cannot contain a period as the first character and it cannot contain embedded blanks. In addition, the quotation mark is the escape character regardless of the value of the string delimiter option. An indicator variable must not be specified for the host variable.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in “SQL descriptor area (SQLDA)” on page 2144. See “Identifying an SQLDA in C or C++” on page 2164 for how to represent descriptor-name in C.

*For languages other than REXX:* Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

**SQLN** Indicates the number of SQLVAR occurrences provided in the SQLDA. DB2 does not change this value. For techniques to determine the number of required occurrences, see [Allocating the SQLDA](#).

*For REXX:* The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable stem.SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with stem.n.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see [The SQLDA contents returned after DESCRIBE](#).

**USING**

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

**NAMES**

Assigns the name of the column. This is the default.

**LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

**ANY**

Assigns the column label, and if the column has no label, the column name.

**BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2×n or 3×n, where n is the number of columns in the object being described. For each of the columns, the first n occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third n occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

For a declared temporary table, the name of the column is assigned regardless of the value specified in the USING clause because declared temporary tables cannot have labels.
Notes

See ["DESCRIBE OUTPUT" on page 1659](#) for information about the following topics:

- Allocating the SQLDA
- The SQLDA contents that are returned on DESCRIBE
- Performance considerations for DESCRIBE
- Using host variables in DESCRIBE statements

*Considerations for implicitly hidden columns*: A DESCRIBE TABLE statement does return information about implicitly hidden columns in tables.
The DROP statement removes an object at the current server. Except for storage groups, any objects that are directly or indirectly dependent on that object are deleted. Whenever an object is deleted, its description is deleted from the catalog at the current server, and any packages that refer to the object are invalidated.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

To drop the following objects, the privilege set must include at least one of the listed authorities or privileges:

**Table, table space, or index:**

- Ownership of the object (for an index, the owner is the owner of the table or index)
- DBADM authority
- SYSADM or SYSCTRL authority
- System DBADM

If the table space is in a database that is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Database:**

- The DROP privilege on the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

**Storage group, or view:**

- Ownership of the object
- SYSADM or SYSCTRL authority
- System DBADM

**Alias for a table or view:**

- Ownership of the object
- SYSADM or SYSCTRL authority
- System DBADM

**Alias for a sequence:**

- Ownership of the object
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

**Package:**

- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

**Synonym:**
Ownership of the synonym

**Role or trusted context:**
- Ownership of the object
- SYSADM or SYSCTRL authority
- SECADM

If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

**Row permission or column mask:**
At least SECADM authority

**Distinct type, stored procedure, trigger, user-defined function, global variable, or sequence:**
- Ownership of the object
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process. If running in a trusted context with a role, the privilege set also includes those privileges that are held by the role that is associated with the primary authorization ID. However, the implicit schema match does not apply to the role when determining if DROPIN schema privilege is held.

---

38. Not applicable for stored procedures defined in releases of DB2 for z/OS prior to Version 6.
Syntax

alias-designator:

Notes:
1. If PUBLIC is specified, FOR SEQUENCE must also be specified.

parameter type:
Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

Data type:

Built-in-type:

Distinct-type-name:

Array-type-name:
Description

**alias-designator**

**PUBLIC**

Specifies that the alias to be dropped is a public alias. The *alias-name* must identify an alias that exists in the SYSPUBLIC schema.

If the PUBLIC keyword is specified, *alias-name* must identify a public alias that exists at the current server.

**ALIAS alias-name**

Identifies the alias to be dropped. The *alias-name* must identify an alias that exists at the current server.
Dropping an alias for a table or view has no effect on any view, materialized query table, or synonym that was defined using the alias. If the alias is referenced in the definition of a row permission or a column mask, it cannot be dropped.

Dropping an alias for a sequence has no effect on any view or materialized query table that was defined using the alias. If the alias is referenced in the definition of an inline SQL function, it cannot be dropped. When an alias for a sequence is dropped, all packages that refer to the sequence alias are invalidated.

If the alias is referenced in the definition of a row permission or a column mask, the alias cannot be dropped.

**FOR TABLE**
Specifies that the alias to be dropped is for a table or view. Dropping an alias for a table has no effect on any view, materialized query table, or synonym that was defined using the alias.

**FOR SEQUENCE**
Specifies that the alias to be dropped is for a sequence. Dropping an alias for a sequence has no effect on any view, or materialized query table that was defined using the alias.

**DATABASE database-name**
Identifies the database to drop. The name must identify a database that exists at the current server. DSNDB04 or DSNDB06 must not be specified. The privilege set must include SYSADM authority.

Whenever a database is dropped, all of its table spaces, tables, index spaces, and indexes are also dropped. Any pending changes to the definitions of the table spaces and indexes in the database are also dropped.

You can drop a database that contains a history table only if the database also contains the associated system-period temporal table. You can drop a database that contains a system-period temporal table when the associated history table is in another database. In this case, the action cascades to drop the history table in the other database.

You can drop a database that contains an archive table only if the database also contains the associated archive-enabled table. You can drop a database that contains an archive-enabled table when the associated archive table is contained in another database. In this case, the action cascades to drop the archive table in the other database.

**FUNCTION or SPECIFIC FUNCTION**
Identifies the function to drop. The function must exist at the current server, and it must have been defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name.

Functions that are implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

As indicated by the default keyword RESTRICT, the function is not dropped if any of the following dependencies exist:

• Another function is sourced on the function.
• A view uses the function.
• A trigger package uses the function.
• The definition of a materialized query table uses the function.
• The definition of a row permission or a column mask uses the function.

When a function is dropped, all privileges on the function are also dropped. Any packages that are dependent on the function dropped are made inoperative.

FUNCTION function-name
  Identifies the function by its name. The function-name must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

FUNCTION function-name (parameter-type,...)
  Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If function-name () is specified, the function identified must have zero parameters.

function-name
  Identifies the name of the function.

(parameter-type,...)
  Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

• Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
• If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

**SPECIFIC FUNCTION** `specific-name`

Identifies the function by its specific name. The `specific-name` must identify a specific function that exists at the current server.

**INDEX** `index-name`

Identifies the index to drop. The name must identify a user-defined index that exists at the current server but must not identify a populated index on an auxiliary table or an index that was implicitly created for a table that contains an XML column. (For details on dropping user-defined indexes on catalog tables, see "SQL statements allowed on the catalog" on page 2178.) A populated index on an auxiliary table can only be dropped by dropping the base table. The name must not identify an auxiliary table for an object that is involved in a clone relationship.

If the index that is dropped was created by specifying the ENDING AT clause to define partition boundaries, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

Whenever an index is directly or indirectly dropped, its index space is also dropped. The name of a dropped index space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the index is also dropped.

If the index is a unique index used to enforce a unique constraint (primary or unique key), the unique constraint must be dropped before the index can be dropped. In addition, if a unique constraint supports a referential constraint, the index cannot be dropped unless the referential constraint is dropped.

However, a unique index (for a unique key only) can be dropped without first dropping the unique key constraint if the unique key was created in a release of DB2 before Version 7 and if the unique key constraint has no associated referential constraints. For information about dropping constraints, see "ALTER TABLE" on page 1027.

If the table space is explicitly created and a unique index is dropped and that index was defined on a ROWID column that is defined as GENERATED BY DEFAULT, the table can still be used, but rows cannot be inserted into that table.

If the table space is implicitly created, the index cannot be dropped if it is defined on a ROWID column that is defined as GENERATED BY DEFAULT.
If an empty index on an auxiliary table is dropped, the base table is marked incomplete. If the base table space is implicitly created, the index on an auxiliary table cannot be dropped.

Drop index will result in the deletion of rows in the SYSCOLDIST and SYSCOLDISTATS catalog tables if no other indexes on the table have the same column group in their key sequence prefix.

**MASK** *mask-name*
Identifies the column mask to drop. The name must identify a column mask that exists at the current server.

**PACKAGE** *collection-id.package-name*
Identifies the package version to drop. The name plus the implicitly or explicitly specified *version-id* must identify a package version that exists at the current server. Omission of the *version-id* is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. A trigger package can only be dropped by dropping the associated trigger or subject table. A package that is associated with a native SQL procedure can only be dropped with an ALTER PROCEDURE statement with a DROP VERSION clause that specifies the particular version that is to be dropped, or with a DROP PROCEDURE statement if it is the only version that is defined for the procedure.

Specify this clause to drop a package that is created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

If a package has current, previous, and original copies, the DROP statement will drop all copies.

**VERSION** *version-id*

*version-id* is the version identifier that was assigned to the package's DBRM when the DBRM was created. If *version-id* is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:
• Is generated by the VERSION(AUTO) precompiler option
• Begins with a digit
• Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in *DB2 Application Programming and SQL Guide*.

**PERMISSION** *permission-name*
Identifies the row permission to drop. The name must identify a row permission that exists at the current server. The name must not identify the default row permission that was created implicitly by DB2.

**PROCEDURE** *procedure-name*
Identifies the stored procedure to drop. The name must identify a stored procedure that has been defined with the CREATE PROCEDURE statement at the current server.

All versions of the native SQL procedure are dropped; all privileges on the procedure are also dropped. In addition, any packages that are dependent on the procedure are marked invalid.

If the procedure is a native SQL procedure, use an ALTER PROCEDURE statement with the DROP VERSION clause to drop a specific version of a
procedure. Use a DROP PACKAGE statement to drop a package for a version of the procedure that is created using the BIND COPY command.

**ROLE role-name**

Identifies the role to drop. *role-name* must identify a role that exists at the current server.

When a role is dropped, all privileges and authorities that have been previously granted to that role are revoked. If the role that is dropped is the owner of statements in the dynamic statement cache, the cached statements are invalidated.

The role is not dropped if any REVOKE restrictions are encountered. REVOKE restrictions include the following:

- Restrictions that are encountered when dependent privileges are included when the privileges of a role are revoked.
- The role is the grantor of any privilege or authority that used ACCESSCTRL or SECADM authority to perform the grant.

If RESTRICT is specified, the role is not dropped is any of the following dependencies exist:

- The role is associated with any trusted context or any user in a trusted context.
- The role is associated with a currently running thread.
- The role is the owner of any of the following objects:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alias</td>
<td>Row permission</td>
</tr>
<tr>
<td>Array type</td>
<td>Sequence</td>
</tr>
<tr>
<td>Column mask</td>
<td>Storage group</td>
</tr>
<tr>
<td>Database</td>
<td>Stored procedure</td>
</tr>
<tr>
<td>Distinct type</td>
<td>Table</td>
</tr>
<tr>
<td>Index</td>
<td>Table space</td>
</tr>
<tr>
<td>JAR file</td>
<td>Trigger</td>
</tr>
<tr>
<td>Materialized query table</td>
<td>Trusted context</td>
</tr>
<tr>
<td>Package</td>
<td>User-defined function</td>
</tr>
<tr>
<td>Role</td>
<td>View</td>
</tr>
</tbody>
</table>

**SEQUENCE sequence-name**

Identifies the sequence to drop. The name must identify an existing sequence at the current server.

*sequence-name* must not be the name of an internal sequence object that is used by DB2 (including an implicitly generated sequence for a DB2_GENERATED_DOCID_FOR_XML column). Sequences that are generated by the system for identity columns or implicitly created databases cannot be dropped by using the DROP SEQUENCE statement. A sequence object for an identity column is implicitly dropped when the table that contains the identity column is dropped.

The default keyword RESTRICT indicates that the sequence is not dropped if any of the following dependencies exist:

- A trigger that uses the sequence in a NEXT VALUE or PREVIOUS VALUE expression exists.
- An inline SQL function that uses the sequences in a NEXT VALUE or PREVIOUS VALUE expression exists.
Whenever a sequence is dropped, all privileges on the sequence are also dropped, and the packages that refer to the sequence are invalidated. Dropping a sequence, even if the drop process is rolled back, results in the loss of the still-unassigned cache values for the sequence.

**STOGROUP** `stogroup-name`

Identifies the storage group to drop. The name must identify a storage group that exists at the current server but not a storage group that is used by any table space or index space.

For information on the effect of dropping the default storage group of a database, see [Dropping a default storage group](#).

**SYNONYM** `synonym`

Identifies the synonym to drop. In a static DROP SYNONYM statement, the name must identify a synonym that is owned by the owner of the plan or package. In a dynamic DROP SYNONYM statement, the name must identify a synonym that is owned by the SQL authorization ID. Thus, using interactive SQL, a user with SYSADM authority can drop any synonym by first setting CURRENT SQLID to the owner of the synonym.

Dropping a synonym has no effect on any view, materialized query table, or alias that was defined using the synonym, nor does it invalidate any packages that use such views, materialized query tables, or aliases.

If the synonym is referenced in the definition of a row permission or a column mask, it cannot be dropped.

**TABLE** `table-name` or `alias-name`

Identifies the table to drop. The name must identify a table that exists at the current server. It must not identify a catalog table, a table in a partitioned table space, a table that is implicitly created for an XML column, or a populated auxiliary table. A table in a partitioned table space can be dropped only by dropping the table space. A populated auxiliary table or a table that is implicitly created for an XML column can be dropped only by dropping the associated base table.

If `alias-name` is specified, the actual table is dropped as if `table-name` were specified. However, the alias is not dropped. It can be dropped by using the DROP ALIAS statement.

When a table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the table
- All referential constraints in which the table is a parent or dependent
- All synonyms, views, and indexes that are defined on the table
- All row permissions (including the default row permission)
- All column masks that are created for the table

If the table space for the table was implicitly created, it is also dropped. However, if the containing database was implicitly created, it is not dropped. Any pending changes to the definitions of the dropped table space and indexes are also dropped.

For more information, see [Dropping an implicitly created database](#).

When a table is directly or indirectly dropped, all materialized query tables that are defined on the table are also dropped. When a materialized query table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the materialized query table
• All synonyms, views, and indexes that are defined on the materialized query table

Any alias that is defined on the materialized query table is not dropped. Any packages that are dependent on the dropped materialized query table are marked invalid.

You cannot use DROP TABLE to drop a clone table. You must use the ALTER TABLE statement with the DROP CLONE clause to drop a clone table. If a base table that is involved in a clone relationship is dropped, the associated clone table is also dropped. You cannot drop an auxiliary table for an object that is involved in a clone relationship.

The table cannot be dropped if it is defined as a history table for a system-period temporal table.

The table cannot be dropped if it is referenced in the definition of a row permission or a column mask.

To drop a system-period temporal table, the privilege set must also contain the authorization that is required to drop the history table. The history table is dropped when a system-period temporal table is dropped.

If a table with LOB columns is dropped, the auxiliary tables that are associated with the table and the indexes on the auxiliary tables are also dropped. Any LOB table spaces that were implicitly created for the auxiliary tables are also dropped.

If a table with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

If an empty auxiliary table is dropped, the definition of the base table is marked incomplete. If the base table space is implicitly created, the auxiliary table cannot be dropped.

If the table has a security label column, the primary authorization ID of the DROP statement must have a valid security label, and the RACF SECLABEL class must be active.

If a table that uses hash organization is dropped, all catalog entries for the hash organization are cleaned up.

If an archive-enabled table is dropped, the archive table and any indexes that are defined on the archive table are also dropped. To drop an archive-enabled table, the privilege set must also contain the authorization that is required to drop the archive table. An archive table cannot be explicitly dropped by using the DROP statement.

TABLESPACE database-name.table-space-name

Identifies the table space to drop. The name must identify a table space that exists at the current server. The database name must not be DSNDB06. Omission of the database name is an implicit specification of DSNDB04. table-space-name must not identify a table space that is implicitly created for an XML column.

Whenever a table space is directly or indirectly dropped, all the tables in the table space are also dropped. The name of a dropped table space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the table space and its indexes are also dropped.

A LOB table space can be dropped only if it does not contain an auxiliary table. If the LOB table space is implicitly created, it cannot be dropped.
Whenever a base table space that contains tables with LOB columns is dropped, all the auxiliary tables and indexes on those auxiliary tables that are associated with the base table space are also dropped.

Whenever a base table space that contains tables with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

The table space cannot be dropped if it contains a history table or an archive table.

**TRIGGER** trigger-name

Identifies the trigger to drop. The name must identify a trigger that exists at the current server.

Whenever a trigger is directly or indirectly dropped, all privileges on the trigger are also dropped and the associated trigger package is freed. The name of that trigger package is the same as the trigger name and the collection ID is the schema name.

When an INSTEAD OF trigger is dropped, the associated privilege is revoked from anyone that possesses the privilege as a result of an implicit grant that occurred when the trigger is created.

Dropping triggers causes certain packages to be marked invalid. For example, if trigger-name specifies an INSTEAD OF trigger on a view V, another trigger might depend on trigger-name through an update to the view V, and that trigger package is invalidated.

If a trigger has current, previous, and original copies, the DROP statement will drop all copies.

**TRUSTED CONTEXT** context-name

Identifies the trusted context to drop. The context-name must identify a trusted context that exists at the current server. When a trusted context is dropped, all associations to attributes (IP addresses, job names) and associations to users of the trusted context are dropped. If the trusted context is dropped while trusted connections for the context are active, the connections remain active until they terminate or the next attempt at reuse is made.

**TYPE** type-name

Identifies the user-defined type to drop. The name must identify a user-defined type that exists at the current server. The default keyword RESTRICT indicates that the user-defined type is not dropped if any of the following dependencies exist:

- The definition of a column of a table uses the user-defined type.
- The definition of an input or result parameter of a user-defined function uses the user-defined type.
- The definition of a parameter of a stored procedure uses the user-defined type.
- The definition of an extended index uses a cast function that is implicitly generated for the user-defined type.
- The definition of an SQL variable in a procedure or function uses the user-defined type.
- The definition of a row permission or a column mask uses the user-defined type.
- A sequence exists for which the data type of the sequence is the user-defined type.
One of the following dependencies exists on one of the cast functions that are generated for the user-defined type:

- Another function is sourced from one of the cast functions
- A view uses one of the cast functions
- A trigger package uses one of the cast functions
- The definition of a materialized query table uses one of the cast functions

Whenever a user-defined type is dropped, all privileges on the distinct type are also dropped. In addition, the cast functions that were generated when the user-defined type was created and the privileges on those cast functions are also dropped.

**VARIABLE** variable-name

Identifies the global variable to drop. The name must identify a global variable that exists at the current server. The name must not identify a built-in global variable. The default keyword RESTRICT indicates that the global variable is not dropped if any of the following dependencies exist:

- The definition of a function, trigger, or view is dependent on the global variable

Packages that are dependent on the global variable are marked invalid when the global variable is dropped. If a statement that is in the dynamic statement cache depends on the global variable and the global variable is dropped, the statement in the dynamic statement cache will be invalidated if it is not in use.

**VIEW** view-name or alias-name

Identifies the view to drop. The name must identify a view that exists at the current server.

Whenever a view is directly or indirectly dropped, all privileges on the view and all synonyms and views that are defined on the view are also dropped. Whenever a view is directly or indirectly dropped, all materialized query tables defined on the view are also dropped.

If alias-name is specified, the actual view will be dropped as if view-name were specified. However, the alias is not dropped and can be dropped using the DROP ALIAS statement.

If the view is referenced in the definition of a row permission or a column mask, it cannot be dropped.

**Notes**

**Restrictions on DROP:**

DROP is subject to these restrictions:

- DROP DATABASE cannot be performed while a DB2 utility has control of any part of the database.
- DROP INDEX cannot be performed while a DB2 utility has control of the index or its associated table space.
- DROP INDEX cannot be performed if the index is a unique index that is defined on a ROWID column that is defined as GENERATED BY DEFAULT and there are pending changes to the definition of the table space or to any objects within the table space that are explicitly created.
- DROP INDEX cannot be performed if the index is an empty index on an auxiliary table that resides in an explicitly created LOB table space and there are pending changes to the definition of the base table space or to any objects within the base table space.
• DROP INDEX cannot be performed if the index is the hash overflow
index for a table that uses hash organization.
• DROP TABLE cannot be performed while a DB2 utility has control of the
  table space that contains the table.
• DROP TABLE cannot be performed if the table space was explicitly
  created and there are pending changes to the definition of the table
  space.
• DROP TABLE cannot be performed if the table is an empty auxiliary
  table and there are any pending changes to the definition of the base
  table space or to any objects within the base table space.
• DROP TABLESPACE cannot be performed while a DB2 utility has
  control of the table space.

In a data sharing environment, the following restrictions also apply:
• If any member has an active resource limit specification table (RLST)
  you cannot drop the database or table space that contains the table, the
  table itself, or any index on the table.
• If the member executing the drop cannot access the DB2-managed data
  sets, only the catalog and directory entries for those data sets are
  removed.

Objects that have certain dependencies cannot be dropped. For information
on these restrictions, see [Table 143 on page 1690].

Recreating objects:
After an index or table space is dropped, a commit must be performed
before the object can be re-created with the same name. If a table that was
created without an IN clause (thereby causing a table space to be implicitly
created) is dropped, a table cannot be re-created with the same name until
a commit is performed.

Dropping a parent table:
DROP is not DELETE and therefore does not involve delete rules.

Dropping a default storage group:
If you drop the default storage group of a database, the database no longer
has a legitimate default. You must then specify USING in any statement
that creates a table space or index in the database. You must do this until
you either:
• Create another storage group with the same name using the CREATE
  STOGROUP statement, or
• Designate another default storage group for the database using the
  ALTER DATABASE statement.

Dropping an implicitly created database:
When a table that resides in an implicitly created table space is dropped,
the implicitly created table space and related objects are dropped.
However, the implicitly created database is not dropped. This can result in
a large number of empty databases in a system. These databases might be
eventually reused for newly created implicit table spaces. These implicitly
created databases can be dropped using DROP DATABASE.

Dropping a table space or index:
To drop a table space or index, the size of the buffer pool associated with
the table space or index must not be zero.

Dropping a LOB table space:
If the base table space is explicitly created, both explicitly created LOB
table spaces and implicitly created LOB table spaces can be dropped if it does not contain any auxiliary tables. If the LOB table space is implicitly created, it will be dropped automatically when the auxiliary table is dropped. If the LOB table space is explicitly created, it is not dropped when the auxiliary table is dropped, and can be explicitly dropped later.

If the base table space is implicitly created, the LOB table space cannot be dropped. If the LOB table space is explicitly created, it can be dropped when the auxiliary table is dropped. The following table shows the relationship between the base table space, the LOB table space, and the use of DROP for the LOB table space and base table space:

<table>
<thead>
<tr>
<th>How base table was created</th>
<th>How LOB table space was created</th>
<th>Whether DROP can be used on LOB table space</th>
<th>State of LOB table space if base table space is dropped</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explicitly</td>
<td>Explicitly</td>
<td>Yes</td>
<td>LOB table space remains</td>
</tr>
<tr>
<td>Explicitly</td>
<td>Implicitly</td>
<td>Yes</td>
<td>LOB table space is dropped</td>
</tr>
<tr>
<td>Implicitly</td>
<td>Explicitly</td>
<td>Yes</td>
<td>LOB table space remains</td>
</tr>
<tr>
<td>Implicitly</td>
<td>Implicitly</td>
<td>No</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Dropping a database when data sets for DB2 objects have already been deleted:
When some of the data sets for DB2 objects that are associated with the database have already been deleted, DROP DATABASE will perform in the following manner:

**For DB2-managed objects:**
The DROP DATABASE statement will delete the underlying data sets if they exist. If the data sets do not exist, DROP DATABASE will delete only the catalog entries for those data sets.

**For user-managed objects:**
The DROP DATABASE statement will delete only the catalog entries for the data sets. The underlying data sets will need to be manually deleted after the DROP DATABASE statement is complete.

Dropping a table space in a work file database:
If one member of a data sharing group drops a table space in a work file database, or an entire work file database, that belongs to another member, DB2-managed data sets that the executing member cannot access are not dropped. However, the catalog and directory entries for those data sets are removed.

Dropping resource limit facility (governor) indexes, tables, and table spaces:
While the RLST is active, you cannot issue a DROP DATABASE, DROP INDEX, DROP TABLE, or DROP TABLESPACE statement for an object associated with an RLST that is active on any member of a data sharing group. See Resource limit facility implications for data sharing (DB2 Data Sharing Planning and Administration) for details.

Dropping a temporary table:
To drop a created temporary table or a declared temporary table, use the DROP TABLE statement.
Dropping a materialized query table:
To drop a materialized query table, use the DROP TABLE statement.

Dropping an alias:
Dropping a table or view does not drop its aliases. However, if you use the DROP TABLE statement and specify an alias for a table or view, the table or view will be dropped. To drop an alias, use the DROP ALIAS statement.

Dropping a table from an implicitly created table space:
If you drop a table from an implicitly created table space, the following related objects are also dropped:
• The enforcing primary and unique key indexes
• Any LOB table spaces, auxiliary tables, and auxiliary indexes
• The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

If any LOB columns are defined on the table, the LOB table space is dropped if it was implicitly created. You can use the DROP statement to drop a LOB table space only if one of the following conditions it true:
• The base table space is explicitly created
• The base table space is implicitly created but the LOB table space is explicitly created

You cannot use the DROP statement to drop a LOB table space if both the base table space and the LOB table space are implicitly created.

Dropping an index on an auxiliary table and an auxiliary table:
You can explicitly drop an empty index on an auxiliary table with the DROP INDEX statement, unless the base table space is implicitly created. An empty or populated index on an auxiliary table is implicitly dropped when:
• The auxiliary table is empty and it is explicitly dropped (empty indexes only).
• The associated base table for the auxiliary table is dropped.
• The base table space that contains the associated base table is dropped.

You can explicitly drop an empty auxiliary table with the DROP TABLE statement, unless the base table space is implicitly created. An empty or populated auxiliary table is implicitly dropped when:
• The associated base table for the auxiliary table is dropped.
• The base table space that contains the associated base table is dropped.

The following table shows which DROP statements implicitly or explicitly cause an auxiliary table and the index on that table to be dropped, as indicated by the 'D' in the column.

<table>
<thead>
<tr>
<th>Statement</th>
<th>Auxiliary table</th>
<th>Index on auxiliary table</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP TABLESPACE (base table space)</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>DROP TABLE (base table)</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>DROP TABLE (auxiliary table)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Table 142. Effect of various DROP statements on auxiliary tables and indexes that are in explicitly created table spaces (continued)

<table>
<thead>
<tr>
<th>Statement</th>
<th>Auxiliary table</th>
<th>Index on auxiliary table</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP INDEX (index on auxiliary table)</td>
<td>D</td>
<td>D</td>
</tr>
</tbody>
</table>

Note: D indicates that the table or index is dropped.

Dropping a migrated index or table space:
Here, “migration” means migrated by the Hierarchical Storage Manager (DFSMShsm). DB2 does not wait for any recall of the migrated data sets. Hence, recall is not a factor in the time it takes to execute the statement.

Dropping a trusted context:
The drop of a trusted context takes effect after the DROP TRUSTED CONTEXT statement is committed. If the DROP TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not dropped.

Avoiding DROP failure due to excessive locking
Dropping a table space, database, or index with the COPY YES attribute deletes all corresponding records in the SYSCOPY and SYSLGRNX catalog statistics tables. The DROP fails if the lock structure size cannot accommodate the number of locks obtained during DROP processing. DROP failure is more likely if the SYSCOPY, SYSLGRNX, or other catalog statistics tables contain many entries, especially if the object you are dropping was created long ago or contains many partitions. DROP failure is also more likely if objects are copied frequently while the MODIFY RECOVERY and MODIFY STATISTICS utilities are run relatively infrequently.

To avoid DROP failure, run the MODIFY RECOVERY and MODIFY STATISTICS utilities on objects before dropping them. You can Specify AGE(*) or DATE(*) to remove all recovery and statistics information regardless of past update, copy, or cleanup frequency. Be aware that running the MODIFY utility with AGE(*) or DATE(*) will leave objects unrecoverable after they are dropped unless you make a copy or other form of back-up first.

Also, ensure that your applications commit drops frequently, especially for databases containing multiple table spaces, and table spaces containing multiple tables. You can also increase the size of your lock structures to accommodate excessive locks.

Invalidation of packages and dynamic cached statements after dropping row permissions or column masks:
If row or column access control is currently enforced for the table, dropping the row permission or the column mask invalidates all packages and dynamic cached statements that reference the table. Otherwise no package or dynamic cached statement is invalidated.

Dependencies when dropping objects:
Whenever an object is directly or indirectly dropped, other objects that depend on the dropped object might also be dropped. (The catalog stores information about the dependencies of objects on each other.) The following semantics determine what happens to a dependent object when the object that it depends on (the underlying object) is dropped:
Cascade (D)
Dropping the underlying object causes the dependent object to be dropped. However, if the dependent object cannot be dropped because it has a restrict dependency on another object, the drop of the underlying object fails.

Restrict (D)
The underlying object cannot be dropped if a dependent object exists.

Inoperative (O)
Dropping the underlying object causes the dependent object to become inoperative.

Invalidation (V)
Dropping the underlying object causes the dependent object to become invalidated.

For objects that directly depend on others, the following table uses the letter abbreviations above to summarize what happens to a dependent object when its underlying object is specified in a DROP statement. Additional objects can be indirectly affected, too.

To determine the indirect effects of a DROP statement, assess what happens to the dependent object and whether the dependent object has objects that depend on it. For example, assume that view B is defined on table A and view C is defined on view B. In the following table, the 'D' in the VIEW column of the DROP TABLE row indicates that view B is dropped when table A is dropped. Next, because view C is dependent on view B, check the VIEW column for DROP VIEW. The 'D' in the column indicates that view C will be dropped, too.

The letters in the following table have the following meanings:
D Dependent object is dropped.
O Dependent object is made inoperative.
V Dependent object is invalidated.
R DROP statement fails.

</table>

Notes:
1. The PACKAGE column represents packages for user-defined functions, procedures, and triggers, as well as other packages. The PACKAGE column also applies for plans.
2. The index space associated with the index is dropped.
3. If a function is dependent on the user-defined type being dropped, the user-defined type cannot be dropped unless the function is one of the cast functions that was created for the user-defined type.
4. If the definition of a parameter of a stored procedure uses the user-defined type, the user-defined type cannot be dropped.
5. If other user-defined functions are sourced on the user-defined function being dropped, the function cannot be dropped.
6. An index on an auxiliary table cannot be explicitly dropped.
7. A trigger package cannot be explicitly dropped with DROP PACKAGE. A trigger package is implicitly dropped when the associated trigger or subject table is dropped.
8. A storage group cannot be dropped if it is used by any table space or index space.
9. An auxiliary table cannot be explicitly dropped with DROP TABLE. An auxiliary table is implicitly dropped when the associated base table is dropped.
10. If an implicit table space was created when the table was created, the table space is also dropped.
11. When a subject table is dropped, any associated triggers and related trigger packages are also dropped.
12. A LOB table space cannot be dropped until the base table with the LOB columns is dropped.
13. This restriction is only for SQL functions.
14. The index in this case must be an expression-based index.
15. When a subject view is dropped, any associated triggers and related trigger packages are also dropped.
16. Any packages that have a dependency on an INSTEAD OF trigger will be marked invalid.
17. A routine that is referenced by a non-inline SQL scalar function cannot be dropped.
18. A routine that is referenced by a native SQL procedure cannot be dropped.
19. Only dependent table functions are dropped.

Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:
• DATA TYPE or DISTINCT TYPE as a synonym for TYPE
• PROGRAM as a synonym for PACKAGE
• DROP ALIAS SYSPUBLIC.<name> can be specified as an alternative to
  DROP PUBLIC ALIAS SYSPUBLIC.<name>

Examples

Example 1: Drop table DSN8B10.DEPT.
  DROP TABLE DSN8B10.DEPT;

Example 2: Drop table space DSN8S11D in database DSN8D11A.
  DROP TABLESPACE DSN8D11A.DSN8S11D;

Example 3: Drop the view DSN8B10.VPROJRE1:
  DROP VIEW DSN8B10.VPROJRE1;

Example 4: Drop the package DSN8CC0 with the version identifier VERSZZZZ. The
package is in the collection DSN8CC61. Use the version identifier to distinguish
the package to be dropped from another package with the same name in the same
collection.
  DROP PACKAGE DSN8CC61.DSN8CC0 VERSION VERSZZZZ;

Example 5: Drop the package DSN8CC0 with the version identifier
"1994-07-14-09.56.30.196952". When a version identifier is generated by the
VERSION(AUTO) precompiler option, delimit the version identifier.
  DROP PACKAGE DSN8CC61.DSN8CC0 VERSION "1994-07-14-09.56.30.196952";

Example 6: Drop the distinct type DOCUMENT, if it is not currently in use:
  DROP TYPE DOCUMENT;

Example 7: Assume that you are SMITH and that ATOMIC_WEIGHT is the only
function with that name in schema CHEM. Drop ATOMIC_WEIGHT.
  DROP FUNCTION CHEM.ATOMIC_WEIGHT;

Example 8: Assume that you are SMITH and that you created the function CENTER
in schema SMITH. Drop CENTER, using the function signature to identify the
function instance to be dropped.
  DROP FUNCTION CENTER(INTEGER, FLOAT);

Example 9: Assume that you are SMITH and that you created another function
named CENTER, which you gave the specific name FOCUS97, in schema
JOHNSON. Drop CENTER, using the specific name to identify the function
instance to be dropped.
  DROP SPECIFIC FUNCTION JOHNSON.FOCUS97;

Example 10: Assume that you are SMITH and that stored procedure OSMOSIS is in
schema BIOLOGY. Drop OSMOSIS.
  DROP PROCEDURE BIOLOGY.OSMOSIS;

Example 11: Assume that you are SMITH and that trigger BONUS is in your
schema. Drop BONUS.
  DROP TRIGGER BONUS;

Example 12: Drop the role CTXROLE:
DROP ROLE CTXROLE;

Example 13: Drop the trusted context CTX1:
    DROP TRUSTED CONTEXT CTX1;

Example 14: Drop public alias PUBALIAS1:
    DROP PUBLIC ALIAS PUBALIAS1 FOR SEQUENCE;
The END DECLARE SECTION statement marks the end of an SQL declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
EXEC SQL BEGIN DECLARE SECTION;
-- host variable declarations
EXEC SQL END DECLARE SECTION;
```

Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement described in “BEGIN DECLARE SECTION” on page 1161.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) precompiler option is specified:

- A variable referred to in an SQL statement must be declared within an SQL declare section of the source program.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- SQL declare sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes

SQL declare sections are only required if the STDSQL(YES) option is specified or the host language is C. However, SQL declare sections can be specified for any host language so that the source program can conform to IBM SQL. If SQL declare sections are used, but not required, variables declared outside an SQL declare section should not have the same name as variables declared within an SQL declare section.

Example

```
EXEC SQL BEGIN DECLARE SECTION;
-- host variable declarations
EXEC SQL END DECLARE SECTION;
```
EXCHANGE

The EXCHANGE statement switches the content of a base table and its associated clone table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following privileges:

- The INSERT and DELETE privileges on both the base table and the clone table
- Ownership of both the base table and the clone table
- DBADM authority for the database
- SYSADM authority
- DATAACCESS authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax

```
EXCHANGE DATA BETWEEN TABLE table-name1 AND table-name2
```

Description

table-name1 and table-name2

Identifies the base table and the associated clone table for which the exchange of data will take place. Either table-name1 or table-name2 can identify the base table. The other table name must identify a clone table that is associated with the specified base table. The name of the base table and the name of the clone table remain unchanged after a data exchange.

Notes

Rules and restrictions: Data exchanges cannot be done for a subset of a table’s partitions. There must be a commit between consecutive data exchanges using the EXCHANGE statement.

Examples

Example: Exchange the data of the EMPLOYEE table and its clone table, EMPCLONE.

```
EXCHANGE DATA BETWEEN TABLE EMPCLONE AND EMPLOYEE;
```
EXECUTE

The EXECUTE statement executes a prepared SQL statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See “PREPARE” on page 1846 for the authorization required to create a prepared statement.

Syntax

```
EXECUTE statement-name

USING variable

USING DESCRIPTOR descriptor-name (1)

source-row-data
```

Notes:

1 This option can be specified only when `statement-name` refers to a dynamic INSERT or MERGE statement that is prepared with FOR MULTIPLE ROWS and is specified as part of the ATTRIBUTES clause on the PREPARE statement.

source-row-data:

```
USING host-variable-array

USING DESCRIPTOR descriptor-name (1)

FOR host-variable ROWS integer-constant
```

Notes:

1 The FOR n ROWS clause is required on the EXECUTE statement if it is not specified as part of the MERGE statement and a host variable array is specified. The FOR n ROWS clause is also required if MERGE is used with multiple rows of source data. For an INSERT statement, the FOR n ROWS clause can only be specified for a dynamic statement that contains only a single multiple-row INSERT statement.

Description

`statement-name`

Identifies the prepared statement to be executed. `statement-name` must identify a
statement that was previously prepared within the unit of work and the prepared statement must not be a select-statement.

**USING**

Introduces a list of variables whose values are substituted for the parameter markers (question marks) in the prepared statement. (For an explanation of parameter markers, see “PREPARE” on page 1846.) If the prepared statement includes parameter markers, you must include USING in the EXECUTE statement. USING is ignored if there are no parameter markers.

The nth value corresponds to the nth parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

For more on the substitution of values for parameter markers, see Parameter marker replacement.

**variable,...**

Identifies a variable or a host structure that is declared in the application program in accordance with the rules for declaring variables and host structures. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement.

**USING DESCRIPTOR descriptor-name**

Identifies an SQLDA that contains a valid description of the input host variables.

Before invoking the EXECUTE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences that are provided in the SQLDA
  - A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA
- SQLD to indicate the number of variables that are used in the SQLDA when processing the statement
- SQLVAR entries to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR entries. If an SQLVAR entry includes a LOB value or a distinct type based on a LOB, there must be additional SQLVAR entries for each parameter. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR entries, see “SQL descriptor area (SQLDA)” on page 2144.

SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The nth variable described by the SQLDA corresponds to the nth parameter marker in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 2164 for how to represent descriptor-name in C.

**source-row-data**

The prepared statement must be an INSERT or MERGE statement for which the FOR MULTIPLE ROWS clause is specified as part of the ATTRIBUTES clause on the PREPARE statement.
**USING** *host-variable-array* or *host-variable*

Introduces a list of host variables or host variable arrays whose values are substituted for the parameter markers (question marks) in the prepared INSERT or MERGE statement. The number of columns specified in the INSERT or MERGE statement must be less than or equal to the total number of host variables or host variable arrays that are specified.

*host-variable-array*

Identifies a host-variable array that must be defined in the application program in accordance with the rules for declaring a host variable array. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The nth variable supplies the value for the nth parameter marker in the prepared statement.

*host-variable*

Identifies a variable that must be described in the application program in accordance with the rules for declaring host variables.

**USING DESCRIPTOR** *descriptor-name*

Identifies an SQLDA that must contain a valid description of the host variable arrays or host variables that contain the values to insert.

Before invoking the EXECUTE statement for a dynamic INSERT or MERGE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR entries that are provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA.
- SQLD to indicate the number of variables, plus one, that are used in the SQLDA that provide values for columns that are the source of the INSERT or MERGE statement. SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN.
- SQLVAR entries to indicate the attributes of an element of the host variable array for the SQLVAR entries that correspond to values that are provided for the source columns of the INSERT or MERGE statement. Within each SQLVAR, the following fields are set:
  - SQLTYPE indicates the data type of the elements of the host variable array.
  - SQLDATA points to the corresponding host variable array.
  - SQLLEN and SQLLONGLEN indicate the length of a single element of the array.
- SQLNAME, the fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must contain a binary small integer (halfword) that contains the dimension of the host-variable array and, if specified, the corresponding indicator array.

The SQLDA must have enough storage to contain a SQLVAR entry for each target column for which values are provided, plus an additional SQLVAR entry for the number of rows. The DB2 system generates code to enter the required information for this extra SQLVAR entry. Each SQLVAR entry describes a host variable, host variable array, or buffer that contains the values for a column of the source table. The last SQLVAR entry contains the number of rows of data. For example, if the INSERT or MERGE statement is providing values for five columns of the target table, six SQLVAR entries must be provided. If any value is a LOB value, twice as many SQLVAR entries must be provided, and SQLN
must be set to the number of SQLVAR entries. Thus, if the INSERT or MERGE statement is providing values for five columns of the source table, and some of the values to insert are LOB values, 12 SQLVAR entries must be provided.

The SQLVAR entry for the number of rows must also contain a flag value. See "Field descriptions of an occurrence of a base SQLVAR" on page 2150 for more information.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays.

**FOR host-variable or integer-constant ROWS**

Specifies the number of rows of source data. The values for the insert or merge operation are specified in the USING clause.

*host-variable or integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. *k* must be in the range 0 to 32767.

FOR n ROWS cannot be specified on the EXECUTE statement if the statement being processed is a dynamic INSERT or MERGE statement that includes a FOR n ROWS clause.

### Notes

**Excessive processor time:**

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much processor time to finish. When this happens, an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

**Parameter marker replacement:**

Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in "Assignment and comparison" on page 123. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let *V* denote a host variable that corresponds to parameter marker *P*. The value of *V* is assigned to the target variable for *P* in accordance with the rules for assigning a value to a column:

- *V* must be compatible with the target.
- If *V* is a string, its length must not be greater than the length attribute of the target.
- If *V* is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of *V* are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, *V* must not be null.
When the prepared statement is executed, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks.

**Errors occurring on EXECUTE:**

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on EXECUTE.

**Considerations for executing data definition statements written in native SQL language:**

A data definition statement written in native SQL language can only be executed one time. To execute the data definition statement multiple times, issue the PREPARE statement prior to each use of the EXECUTE statement for the data definition statement.

**Examples**

**Example 1:** In this example, an INSERT statement with parameter markers is prepared and executed. S1 is a structure that corresponds to the format of DSN8B10.DEPT.

```sql
EXEC SQL PREPARE DEPT_INSERT FROM 'INSERT INTO DSN8B10.DEPT VALUES(?,?,?,?)';
-- Check for successful execution and read values into S1
EXEC SQL EXECUTE DEPT_INSERT USING :S1;
```

**Example 2:** Assume that the IWH.PROGPARM table has 9 columns. Prepare and execute a dynamic INSERT statement that inserts 5 rows of data into the IWH.PROGPARM table. The values to be inserted are provided in arrays, where all the values for a column are provided in an host-variable-array with the EXECUTE statement.

```sql
STMT = 'INSERT INTO IWH.PROGPARM (IWHID, UPDATE_BY,UPDATE_TS,NAME,
SHORT_DESCRIPTION, ORDERNO, PARMDATA,
PARMDATALONG, VWPROGKEY)
VALUES(?,?,?,?,?,?,?,?,?) ' ;
ATTRVAR = 'FOR MULTIPLE ROWS';
EXEC SQL PREPARE INS_STMT ATTRIBUTES :ATTRVAR FROM :STMT;
NROWS = 5;
EXEC SQL EXECUTE INS_STMT FOR :NROWS ROWS
```

In this example, each host variable in the USING clause represents an array of values for the corresponding column of the target of the INSERT statement.

**Example 3:** Using dynamically supplied values for an employee row, update the master EMPLOYEE table if the data is for an existing employee or insert a new row if the data is for a new employee.

```sql
hv_stmt = "MERGE INTO EMPLOYEE AS T
  USING (VALUES (CAST (? AS CHAR(6)), CAST (? AS VARCHAR(12)),
  CAST (? AS CHAR(1)), CAST (? AS VARCHAR(15)),
  CAST (? AS INTEGER)))
  AS S (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
  ON T.EMPNO = S.EMPNO
  WHEN MATCHED THEN UPDATE
    SET SALARY = S.SALARY
  WHEN NOT MATCHED THEN INSERT (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
    VALUES (S.EMPNO, S.FIRSTNAME, S.MI, S.LASTNAME, S.SALARY)
```
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

hv_attr = 'FOR MULTIPLE ROWS';
EXEC SQL
  PREPARE merge_stmt
    ATTRIBUTES :hv_attr FROM :hv_stmt;
hv_nrows = 5;
/* Initialize the hostvar array of hv_empno, hv_firstname... */
EXEC SQL
  EXECUTE merge_stmt
    USING :hv_empno, :hv_firstname, :hv_mi,
    :hv_lastname, :hv_salary
  FOR :hv_nrows ROWS;

Example 4: Suppose that the following array type, array variable, and table have
been defined.
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TYPE STRINGARRAY AS VARCHAR(10) ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);

Use as an array variable as an input value for an expression in an EXECUTE
statement.
CREATE PROCEDURE PROCESSPERSONS (OUT WITHO STRINGARRAY, INOUT INT0 INT)
BEGIN
  DECLARE INTA INTARRAY;
  DECLARE STMT CHAR(100);
  -- Initialize the array
  SET INTA = ARRAY[1,INTEGER(2),3+0,4,5,6] ;
  -- Use dynamic sql with an array parameter marker to
  -- provide a value for a dynamic INSERT statement
  SET STMT = 'INSERT INTO T1 VALUES('XYZ', CARDINALITY(CAST(? AS INTARRAY)))';
  PREPARE INS_STMT FROM STMT;
  EXECUTE INS_STMT USING INTA;
  -- INTA is an array variable used as input for the
  -- INSERT statement
... END
EXECUTE IMMEDIATE

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute an SQL statement that contains neither host variables nor parameter markers.

The EXECUTE IMMEDIATE statement:
• Prepares an executable form of an SQL statement from a string form of the statement
• Executes the SQL statement
• Destroys the executable form

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by EXECUTE IMMEDIATE. For example, see "INSERT" on page 1799 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

Syntax

```
EXECUTE IMMEDIATE host-variable
    string-expression
```

Description

host-variable

host-variable must be specified. It must identify a host variable that is described in the application program in accordance with the rules for declaring character or graphic string variables. If the source string is over 32KB in length, the host-variable must be a CLOB or DBCLOB variable. The maximum source length is 2MB although the host variable can be declared larger than 2MB. An indicator variable must not be specified. In Assembler, C, COBOL, and PL/I, the host variable must be a varying-length string variable. In C, it must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable and the value must not be null.

string-expression

string-expression is any PL/I expression that yields a string. string-expression cannot be preceded by a colon. Variables that are within string-expression that include operators or functions should not be preceded by a colon. When string-expression is specified, the precompiler-generated structures for string-expression use an EBCDIC CCSID and an informational message is returned.
Notes

Allowable SQL statements:

The value of the identified host variable or the specified string-expression is called the statement string.

The statement string must be one of the following SQL statements, and cannot be a select-statement:

<table>
<thead>
<tr>
<th>ALLOCATE CURSOR</th>
<th>REVOKE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER</td>
<td>ROLLBACK</td>
</tr>
<tr>
<td>ASSOCIATE LOCATORS</td>
<td>SAVEPOINT</td>
</tr>
<tr>
<td>COMMENT</td>
<td>SET CURRENT DEGREE</td>
</tr>
<tr>
<td>COMMIT</td>
<td>SET CURRENT DECFLOAT Rounding MODE</td>
</tr>
<tr>
<td>CREATE</td>
<td>SET CURRENT DEBUG MODE</td>
</tr>
<tr>
<td>DECLARE GLOBAL TEMPORARY TABLE</td>
<td>SET CURRENT LOCALE LC_CTYPE</td>
</tr>
<tr>
<td>FREE LOCATOR</td>
<td>SET CURRENT MAINTAINED TABLE TYPES</td>
</tr>
<tr>
<td>GRANT</td>
<td>FOR OPTIMIZATION</td>
</tr>
<tr>
<td>HOLD LOCATOR</td>
<td>SET CURRENT OPTIMIZATION HINT</td>
</tr>
<tr>
<td>INSERT</td>
<td>SET CURRENT PRECISION</td>
</tr>
<tr>
<td>LABEL</td>
<td>SET CURRENT QUERY ACCELERATION</td>
</tr>
<tr>
<td>LOCK TABLE</td>
<td>SET CURRENT REFRESH AGE</td>
</tr>
<tr>
<td>MERGE</td>
<td>SET CURRENT RULES</td>
</tr>
<tr>
<td>REFRESH TABLE</td>
<td>SET CURRENT ROUTINE VERSION</td>
</tr>
<tr>
<td>RELEASE SAVEPOINT</td>
<td>SET CURRENT S Q L D</td>
</tr>
<tr>
<td>RENAME</td>
<td>SET ENCRYPTION PASSWORD</td>
</tr>
<tr>
<td></td>
<td>SET PATH</td>
</tr>
<tr>
<td></td>
<td>SET SCHEMA</td>
</tr>
<tr>
<td></td>
<td>SIGNAL</td>
</tr>
<tr>
<td></td>
<td>TRUNCATE</td>
</tr>
<tr>
<td></td>
<td>UPDATE</td>
</tr>
</tbody>
</table>

The statement string must not:

• Begin with EXEC SQL
• End with END-EXEC or a semicolon
• Include references to variables
• Include parameter markers

Errors and error handling:

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is invalid, it is not executed and the error condition that prevents its execution is reported in the SQLCA. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the SQLCA.

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much CPU time to finish. When this happens an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

Effect of the CURRENT EXPLAIN MODE special register:

If the CURRENT EXPLAIN MODE special register is set to EXPLAIN, the statement is prepared for explain only and is not executable, unless the statement is a SET statement. Attempting to execute the prepared statement will return an error. See the "CURRENT EXPLAIN MODE" on page 180 special register for more information.
Performance considerations:

If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

Examples

Example 1: In this PL/I example, the EXECUTE IMMEDIATE statement is used to execute a DELETE statement in which the rows to be deleted are determined by a search-condition specified by the value of PREDs.

```sql
EXEC SQL EXECUTE IMMEDIATE 'DELETE FROM DSN8B10.DEPT
   WHERE' || PREDs;
```

Example 2: Use C to execute the SQL statement in the host variable Qstring.

```sql
EXEC SQL INCLUDE SQLCA;
void main ()
{
   EXEC SQL BEGIN DECLARE SECTION;
   char Qstring[100M =
   "INSERT INTO WORK_TABLE SELECT * FROM EMPPROJECT WHERE ACTNO >= 100";
   EXEC SQL END DECLARE SECTION;
   .
   .
   .
   EXEC SQL EXECUTE IMMEDIATE :Qstring;
   return;
}
```
EXPLAIN

The EXPLAIN statement obtains information about access path selection for an explainable statement. A statement is explainable if it is a SELECT, MERGE, or INSERT statement, or the searched form of an UPDATE or DELETE statement. The information that is obtained is placed in a set of supplied user tables that are called EXPLAIN tables.

PSP

The plan table contains information about the access path for the explained statement. The statement table can be populated with information about the estimated cost of executing the explainable statement. The function table can be populated with information about how DB2 resolves the user-defined functions that are referred to in the explainable statement. Other EXPLAIN tables can be populated with additional information about the execution of the explainable statement. For a complete list of EXPLAIN tables, see “EXPLAIN tables” on page 2538.

Using EXPLAIN in queries that references system-period temporal tables that are enabled for system data versioning, the result will show the system-period temporal tables and the history tables in EXPLAIN output if the query needs to reference both tables to satisfy the query.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization rules are those defined for the SQL statement specified in the EXPLAIN statement. For example, see the description of the DELETE statement for the authorization rules that apply when a DELETE statement is explained.

If the EXPLAIN statement is embedded in an application program, the authorization rules that apply are those defined for embedding the specified SQL statement in an application program. In addition, the owner of the plan or package must also have one of the following characteristics:
• Be the owner of a plan table named PLAN_TABLE
• Have an alias on a plan table named owner.PLAN_TABLE and have SELECT and INSERT privileges on the table

If the EXPLAIN statement is dynamically prepared, the authorization rules that apply are those defined for dynamically preparing the specified SQL statement. In addition, the SQL authorization ID of the process or the role this is associated with the process (if the EXPLAIN statement is running in a trusted context that specifies the ROLE AS OBJECT OWNER AND QUALIFIER clause) must also have one of the following characteristics:
• Be the owner of a plan table named PLAN_TABLE
• Have an alias on a plan table named owner.PLAN_TABLE and have SELECT and INSERT privileges on the table
To issue the EXPLAIN statement with the PLAN and ALL keywords, the privilege set that is defined below must include at least one of the following:

- EXPLAIN
- SQLADM
- System DBADM
- The authorization rules that are defined for the SQL statement specified in the EXPLAIN statement. For example, the authorization rules that apply when a DELETE statement is explained are the authorization rules for the DELETE statement.

The authorization rules are different if the STMTCACHE keyword is specified to have a cached statement explained. The privilege set must include at least one of the following:

- SQLADM authority
- SYSADM authority
- The authority that is required to share the cached statement.
- System DBADM authority

For the STMTCACHE ALL keyword, the privilege set must include at least one of the following:

- SQLADM authority
- System DBADM authority
- SYSADM authority to explain all statements in the dynamic statement cache

If the privilege set does not have the required authority, only those statements that have the same authorization ID as the privilege set are explained.

For the PACKAGE keyword, the privilege set must include at least one of the following:

- SQLADM authority
- SYSADM authority
- SYSOPR authority
- SYSCTRL authority

**Privilege set:** The privilege set comprises the union of authorities that are held by the authorization IDs of the process. If the process is running in a trusted context with a role, this role would be included as an authorization ID of the process.

**Syntax**

```sql
EXPLAIN
PLAN
SET QUERYNO=integer
ALL
STMTCACHE
ALL
STMID id-host-variable
INTEGER-constant
STMTOKEN token-host-variable
STRING-constant
PACKAGE package-scope-specification
```
Description

PLAN

Specifies that access path information is captured for the SQL statement. Under this option, DB2 uses the access path selection process to generate the access path information for the statement. One row is inserted into the PLAN_TABLE for each step used in executing `explainable-sql-statement`. The steps for enforcing referential constraints are not included.

If a statement table exists, one row that provides a cost estimate of processing the explainable statement is inserted into the statement table. If the explainable statement is a SELECT FROM `data-change-statement`, two rows are inserted into the statement table.

If a function table exists, one row is inserted into the function table for each user-defined function that is referred to by the explainable statement.

If additional EXPLAIN tables exist, rows are also inserted into those tables.

```
"EXPLAIN tables" on page 2538
"PLAN_TABLE" on page 2539
"DSN_STATEMNT_TABLE" on page 2643
"DSN_FUNCTION_TABLE" on page 2578
```

ALL

Has the same effect as PLAN.

SET `QUERYNO` = `integer`

Associates `integer` with `explainable-sql-statement`. The column `QUERYNO` is given the value `integer` in every row inserted into the plan table, statement table, or function table by the EXPLAIN statement. If `QUERYNO` is not specified, DB2 itself assigns a number. For an embedded EXPLAIN statement, the number is the statement number that was assigned by the precompiler and placed in the DBRM.

FOR `explainable-sql-statement`

Specifies the SQL statement to be explained. `explainable-sql-statement` can be any explainable SQL statement. If EXPLAIN is embedded in a program, the statement can contain references to host variables. If EXPLAIN is dynamically prepared, the statement can contain parameter markers. Host variables that appear in the statement must be defined in the statement's program.

The statement must refer to objects at the current server.
explainable-sql-statement must not contain a QUERYNO clause. To specify the value of the QUERYNO column in plan table for the statement being explained, use the SET QUERYNO = clause of the EXPLAIN statement.

explainable-sql-statement cannot be a statement-name or a host-variable. To use EXPLAIN to get information about dynamic SQL statements, you must prepare the entire EXPLAIN statement dynamically.

To obtain information about an explainable SQL statement that references a declared temporary table, the EXPLAIN statement must be executed in the same application process in which the table was declared. For static EXPLAIN statements, the information is not obtained at bind-time but at run time when the EXPLAIN statement is incrementally bound.

**STMTCACHE**

Specifies that access path information is captured in EXPLAIN tables for specified SQL statements in the dynamic statement cache. Under this option, no new access path selection processing occurs. The values that are captured to EXPLAIN tables are extracted from the existing access path that was selected when the dynamic SQL statement was prepared and entered the statement cache.

**ALL**

Specifies that access path information is captured for all cached statements. STMTCACHE ALL returns one row for each cached statement to the DSN_STATEMENT_CACHE_TABLE. These rows contain identifying information about the statements in the cache, as well as statistics that reflect the execution of the statements by all processes that have executed the statement. Records are not returned to other EXPLAIN tables when STMTCACHE ALL is specified.

**STMID id-host-variable or integer-constant**

Specifies that access path information is captured for the cached statement with the specified statement ID. The value contained in id-host-variable or specified by integer-constant identifies the statement ID. STMTCACHE STMID returns rows to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMNT_TABLE
- DSN_FUNCTION_TABLE
- DSN_STATEMENT_CACHE_TABLE

The statement ID is an integer that uniquely identifies a statement that has been cached in the dynamic statement cache. The statement ID of a cached statement can be retrieved through IFI monitor facilities from IFCID 0316 or 0124. Some diagnostic trace records, such as IFCIDs 0173, 0196, and 0337, also show the statement ID.

The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

**STMTOKEN id-host-variable or string-constant**

Specifies that access path information is captured for the cached statements with the specified statement token. The value contained in token-host-variable or specified by string-constant identifies the statement token. STMTCACHE STMTOKEN returns rows to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMNT_TABLE
• DSN_FUNCTION_TABLE
• DSN_STATEMENT_CACHE_TABLE

The statement token must be a character string that is no longer than 240 bytes. The application program that originally prepares and inserts a statement into the cache associates a statement token with the cached statement. The program can make this association with the RRSAF SET_ID function, or the sqleseti API if the program is connected remotely.

The STMTTOKEN column of each PLAN_TABLE record that is returned contains the statement token value. The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

Related information:
“DSN_STATEMENT_CACHE_TABLE” on page 2637

PACKAGE
Specifies that access path information is captured to EXPLAIN tables for SQL statements in the package that matches the specified scope. Under this option, no new access path selection processing occurs. The values that are captured to the EXPLAIN tables are extracted from the existing access paths that were selected when the package was bound. The explain information is added to the PLAN_TABLE that is owned by the current user. Other EXPLAIN tables are not populated.

Explain information is not captured for packages that are bound prior to DB2 Version 9.1 for z/OS.

COLLECTION collection-name
Specifies that only statements under the specified collection-name are to be explained. collection-name is a string constant or a host variable that represents the collection name.

PACKAGE package-name
Specifies that only statements under the specified package-name are to be explained. package-name is a string constant or a host variable that represents the package name.

VERSION version-name
Specifies that only statements under the specified version-name are to be explained. version-name is a string constant or a host variable that represents the version name.

COPY copy-id
Specifies that only statements under the specified copy-id are to be explained. copy-id must be one of the following values:
• CURRENT
• PREVIOUS
• ORIGINAL

If the COPYID clause is not specified, statements under all copies that exist for that package (CURRENT, PREVIOUS, and ORIGINAL) are explained.

The HINT_USED column in the PLAN_TABLE is populated with EXPLAIN PACKAGE:

COPY: copy-id. copy-id in the HINT_USED column will be one of the following values:
• “0” - the current copy
• “1” - the previous copy
• “2” - the original copy
Notes

Output from EXPLAIN:

DB2 inserts one or more rows of data into a plan table and other existing EXPLAIN tables. A plan table must exist before the operation that results in EXPLAIN output. For information about valid plan table formats see "PLAN_TABLE" on page 2539. You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

Unless you need the information that is provided by the additional EXPLAIN tables, it is not necessary to create those tables to use EXPLAIN. However, a statement cache table is required when the STMTCACHE ALL keyword is specified as part of an EXPLAIN statement.

Column access control or row permissions enforced for EXPLAIN tables:

Column access control and row permissions can be enforced for EXPLAIN tables. However, row permissions and column masks are not applied when DB2 inserts rows into those tables.

If the statement to be explained references tables for which row or column access control is activated, the following information from row permission and column mask definitions created for the tables might appear in the EXPLAIN tables:

- DSN_FUNCTION_TABLE - user-defined functions
- DSN_PREDICAT_TABLE - predicates (except predicates in CASE WHEN clauses)
- DSN_STRUCT_TABLE - query blocks
- PLAN_TABLE - access path of subqueries

In addition, the complete or partial definition text might appear in EXPLAIN tables like DSN_FUNCTION_TABLE, DSN_PREDICAT_TABLE, DSN_QUERY_TABLE, DSN_SORTKEY_TABLE, DSN_STATEMENT_CACHE_TABLE, and DSN_STATEMENT_RUNTIME_INFO.

Impact to the existing access paths when the table has enforced column access control or row permissions:

The predicates from the row permissions are considered in the access path selection. Therefore, they are shown in the EXPLAIN tables for the performance tuning purpose.

Considerations when using the EXPLAIN statement to explain the acceleration of rowset queries:

A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

You cannot use a static EXPLAIN statement to determine whether a rowset query is passed to an accelerator server, because you cannot specify the WITH ROWSET POSITIONING cursor attribute for a static EXPLAIN statement. Instead, you must use a dynamic EXPLAIN statement, where the WITH ROWSET POSITIONING clause is specified in the attribute string. You also can specify the WITH RETURN clause in the attribute string to see the ineligibility of result sets.
Also, the EXPLAIN statement cannot be used to determine that a rowset query cannot be passed to an accelerator server because the query is being run remotely or under an SQL PL routine. If the PREPARE of the EXPLAIN statement is run locally, DB2 determines if the rowset query can be accelerated as a local query offload. However, if the PREPARE of the EXPLAIN statement runs remotely, DB2 indicates that the rowset query cannot be accelerated. Instead, you can use the CURRENT EXPLAIN MODE special register to determine the behavior for eligible dynamic SQL statements during application execution. For more information, see “CURRENT EXPLAIN MODE” on page 180.

EXPLAIN tables:
Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods.

Instances of these tables might also be created and used by certain optimization tools. For information about the meanings of different values in plan table and other EXPLAIN tables, see .

For information about how to correlate information across EXPLAIN tables, see Correlating information across EXPLAIN tables (DB2 Performance).

EXPLAIN tables might contain names that begin with “DSN” that have been generated by DB2.

**Important:** Do not manually manipulate the data in EXPLAIN tables that are created by optimization tools.

- **Plan table**
  
  owner.PLAN_TABLE.

- **Function table**

  owner.DSN_FUNCTION_TABLE.

- **Statement table**

- **Filter table**

  owner.DSN_FILTER_TABLE.
Examples

Example 1: Determine the steps required to execute the query 'SELECT X.ACTNO...'.
Assume that no set of rows in the PLAN_TABLE has the value 13 for the
QUERYNO column.

```
EXPLAIN PLAN SET QUERYNO = 13
FOR SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
FROM DSN8B10.EMPPROJECT X, DSN8B10.EMP Y
WHERE X.EMPNO = Y.EMPNO
AND X.EMPTIME > 0.5
AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
ORDER BY X.ACTNO, X.PROJNO;
```

Example 2: Retrieve the information returned in Example 1. Assume that a
statement table exists, so also retrieve the estimated cost of processing the query.
Use the following query, which joins the plan table and the statement table.

```
SELECT * FROM PLAN_TABLE A, DSN_STATEMENT_TABLE B
WHERE A.QUERYNO = 13 and B.QUERYNO = 13
ORDER BY A.QBLOCKNO, A.PLANNO, A.MIXOPSEQ;
```

Example 3: Have the cached statement with statement ID 124 explained. Assume
that host variable SID contains 124.

```
EXPLAIN STMTCACHE STMID :SID;
```

Example 4: Have one row of data for each statement in the dynamic statement
cache written to the DSN_STATEMENT_CACHE_TABLE.

```
EXPLAIN STMTCACHE ALL;
```

Example 5: Assume that you want to use the plan table that was created by
ADMF001 and your authorization ID is SYSADM. If you have an alias on
ADMF001.PLAN_TABLE (CREATE ALIAS SYSADM.PLAN_TABLE FOR
ADMF001.PLAN_TABLE) and sufficient INSERT and SELECT privileges on the
table, the following EXPLAIN statement will execute and ADMF001.PLAN_TABLE
will be populated.

```
EXPLAIN PLAN SET QUERYNO = 101
FOR SELECT * FROM DSN8B10.EMP;
```
Example 6: Add explain information to the current user’s PLAN_TABLE for all static SQL statements in the current copy of the package 'COLLA.PACK52604':

```sql
EXPLAIN PACKAGE COLLECTION 'COLLA' PACKAGE 'PACK52604' COPY 'CURRENT';
```

## FETCH

The FETCH statement positions a cursor on a row of its result table. It can return zero, one, or multiple rows and assigns the values of the rows to variables if there is a target specification.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not supported in REXX, Fortran, or SQL Procedure applications. The FETCH statement with the WITH CONTINUE clause is not supported in REXX.

### Authorization

See “DECLARE CURSOR” on page 1598 for an explanation of the authorization required to use a cursor.

### Syntax

```
FETCH
   (1)
   INSENSITIVE
   (2)
   SENSITIVE
   WITH CONTINUE
   (3)
   fetch-orientation
   FROM
   /SM590000
   /SM590000
   cursor-name
   single-row-fetch
   multiple-row-fetch
   (4)
```

### Notes:

1. The default depends on the sensitivity of the cursor. If INSENSITIVE is specified on the DECLARE CURSOR, then the default is INSENSITIVE and if SENSITIVE is specified on the DECLARE CURSOR, then the default is SENSITIVE.
2. If INSENSITIVE or SENSITIVE is specified, single-row-fetch or multiple-row-fetch must be specified.
3. If WITH CONTINUE is specified, single-row-fetch must be specified.
4. If multiple-row-fetch is specified, a rowset-positioned fetch orientation must also be specified.

39. ASSEMBLER and other languages are supported, but this support is limited to statements that allow USING DESCRIPTOR. The precompiler does not recognize host-variable-arrays except in C/C++, COBOL, and PL/I.
fetch-orientation:

  (1) BEFORE
  (1) AFTER
  row-positioned (2)
  rowset-positioned (3)

row-positioned:

  NEXT
  PRIOR
  FIRST
  LAST
  CURRENT
  CONTINUE
  ABSOLUTE host-variable
  integer-constant
  RELATIVE host-variable
  integer-constant

rowset-positioned:

  NEXT ROWSET
  PRIOR ROWSET
  FIRST ROWSET
  LAST ROWSET
  CURRENT ROWSET
  ROWSET STARTING AT ABSOLUTE host-variable
  RELATIVE integer-constant

Notes:
1. If BEFORE or AFTER is specified, SENSITIVE, INSENSITIVE, single-row-fetch, or multiple-row-fetch must not be specified.
2. A row-positioned fetch orientation can be specified only if multiple-row-fetch is not specified.
3. If multiple-row-fetch is specified, a rowset-positioned fetch orientation must also be specified.

fetch-type
Notes:

1. For single-row-fetch, a host-variable-array can be specified instead of a host variable and the descriptor can describe host-variable-arrays. In either case, data is returned only for the first entry of the host-variable-array.

2. An array element must only be specified in an SQL PL context.

3. This clause must not be specified if a row-positioned fetch orientation or if no fetch orientation was specified.

4. This clause is optional. If this clause is not specified and either a rowset size has not been established yet or a row positioned FETCH statement was the last type of FETCH statement issued for this cursor, the rowset size is implicitly one. If the last FETCH statement issued for this cursor was a rowset positioned FETCH statement and this clause is not specified, the rowset size is the same size as the previous rowset positioned FETCH.

Description

**INSENSITIVE**

Returns the row from the result table as it is. If the row has been previously fetched with a FETCH SENSITIVE, it reflects changes made outside this cursor before the FETCH SENSITIVE statement was issued. Positioned updates and deletes are reflected with FETCH INSENSITIVE if the same cursor was used for the positioned update or delete.

INSENSITIVE can only be specified for cursors declared as INSENSITIVE or SENSITIVE STATIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to INSENSITIVE). Otherwise, if the cursor is declared as SENSITIVE DYNAMIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to...
SENSITIVE DYNAMIC), an error occurs and the FETCH statement has no effect. For an INSENSITIVE cursor, specifying INSENSITIVE is optional because it is the default.

**SENSITIVE**

Updates the fetched row in the result table from the corresponding row in the base table of the cursor's SELECT statement and returns the current values. Thus, it reflects changes made outside this cursor. SENSITIVE can only be specified for a sensitive cursor. Otherwise, if the cursor is insensitive, an error occurs and the FETCH statement has no effect. For a SENSITIVE cursor, specifying SENSITIVE is optional because it is the default.

When the cursor is declared as SENSITIVE STATIC and a FETCH SENSITIVE is requested, the following steps are taken:

1. DB2 retrieves the row of the database that corresponds to the row of the result table that is about to be fetched.
2. If the corresponding row has been deleted, a "delete hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole", and no data is fetched. (DB2 marks a row in the result table as a "delete hole" when the corresponding row in the database is deleted.)
3. If the corresponding row has not been deleted, the predicate of the underlying SELECT statement is re-evaluated. If the row no longer satisfies the predicate, an "update hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole," and no data is fetched. (DB2 marks a row in the result table as an "update hole" when an update to the corresponding row in the database causes the row to no longer qualify for the result table.)
4. If the corresponding row does not result in a delete or an update hole in the result table, the cursor is repositioned on the row of the result table and the data is fetched.

**WITH CONTINUE**

Specifies that the DB2 subsystem should prepare to allow subsequent FETCH CURRENT CONTINUE operations to access any truncated LOB or XML result column following an initial FETCH operation that provides output variables that are not large enough to hold the entire LOB or XML columns. When the WITH CONTINUE clause is specified, the DB2 subsystem takes the following actions that can differ from the case where the FETCH statement does not include the WITH CONTINUE clause:

- If truncation occurs when returning an XML or LOB column, the DB2 subsystem will remember the truncation position and will not discard the remaining data.
- If truncation occurs when returning an XML or LOB column, the DB2 subsystem returns the total length that would have been required to hold all of the data of the LOB or XML column. This will either be in the first four bytes of the LOB host variable structure or in the 4 byte area that is pointed to by the SQLDATALEN pointer in the SQLVAR entry of the SQLDA for that host variable. What is returned depends on the programming method that is used. See “SQL descriptor area (SQLDA)” on page 2144 for details about the SQLDA contents.
- If returning XML data, the result column will be fully materialized in the database before the data is returned.

If the CURRENT CONTINUE clause is specified, the WITH CONTINUE behavior is assumed.
AFTER
Positions the cursor after the last row of the result table. Values are not assigned to host variables. The number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for cursors with an effective sensitivity of INSENSITIVE or SENSITIVE STATIC.

BEFORE
Positions the cursor before the first row of the result table. Values are not assigned to host variables.

row-positioned
Positioning of the cursor with row-positioned fetch orientations NEXT, PRIOR, CURRENT and RELATIVE is done in relation to the current cursor position. Following a successful row-positioned FETCH statement, the cursor is positioned on a single row of data. If the cursor is enabled for rowsets, positioning is performed relative to the current row or the first row of the current rowset, and the cursor is positioned on a rowset consisting of a single row.

NEXT
Positions the cursor on the next row or rows of the result table relative to the current cursor position, and returns data if a target is specified. NEXT is the only row-positioned fetch operation that can be explicitly specified for cursors that are defined as NO SCROLL. NEXT is the default if no other cursor positioning is specified. If a specified row reflects a hole, a warning is issued and data values are not assigned to host variables for that row.

Table 144 lists situations for different cursor positions and the results when NEXT is used.

Table 144. Results when NEXT is used with different cursor positions

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH NEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row</td>
<td>Cursor is positioned on the first row and data is returned if requested.</td>
</tr>
<tr>
<td>On the last row or after the last row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
<tr>
<td>Before a hole</td>
<td>For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.</td>
</tr>
<tr>
<td>Unknown</td>
<td>An error occurs, values are not assigned to host variables, and the cursor position remains unknown.</td>
</tr>
</tbody>
</table>

Note:
1. This row is not applicable in the case of a forward-only cursor (that is when NO SCROLL was specified implicitly or explicitly).

PRIOR
Positions the cursor on the previous row or rows of the result table relative to the current cursor position, and returns data if a target is specified. If a specified row reflects a hole, a warning is issued, and data values are not assigned to host variables for that row.

Table 145 on page 1720 lists situations for different cursor positions and the results when PRIOR is used.
### Table 145. Results when PRIOR is used with different cursor positions

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH PRIOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row or on the first row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
<tr>
<td>After a hole</td>
<td>For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.</td>
</tr>
<tr>
<td>After the last row</td>
<td>Cursor is positioned on the last row.</td>
</tr>
<tr>
<td>Unknown</td>
<td>An error occurs, values are not assigned to host variables, and the cursor position remains unknown.</td>
</tr>
</tbody>
</table>

**FIRST**

Positions the cursor on the first row of the result table, and returns data if a target is specified. For a SENSITIVE STATIC cursor, if the first row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

**LAST**

Positions the cursor on the last row of the result table, and returns data if a target is specified. The number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for an insensitive or sensitive static cursor. For a SENSITIVE STATIC cursor, if the last row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

**CURRENT**

The cursor position is not changed, data is returned if a target is specified. If the cursor was positioned on a rowset of more than one row, the cursor position is on the first row of the rowset.

Table 146 lists situations in which errors occur with the CURRENT clause.

### Table 146. Situations in which errors occur with CURRENT

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH CURRENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row or after the last row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
<tr>
<td>On a hole</td>
<td>For a SENSITIVE STATIC, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.</td>
</tr>
</tbody>
</table>

If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row of data.
Table 146. Situations in which errors occur with CURRENT (continued)

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH CURRENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown</td>
<td>An error occurs, values are not assigned to host variables, and the cursor position remains unknown.</td>
</tr>
</tbody>
</table>

**CONTINUE**

The cursor positioning is not changed, and data is returned if a target is specified. The FETCH CURRENT CONTINUE statement retrieves remaining data for any LOB or XML column result values that were truncated on a previous FETCH or FETCH CURRENT CONTINUE statement. It assigns the remaining data for those truncated columns to the host variables that are referenced in the statement or pointed to by the descriptor. The data that is returned for previously-truncated result values begins at the point of truncation. This form of the CURRENT clause must only be used after a single-row FETCH WITH CONTINUE or FETCH CURRENT CONTINUE statement that has returned partial data for one or more LOB or XML columns. The cursor must be open and positioned on a row.

FETCH CURRENT CONTINUE must pass host variables entries for all columns in the SELECT list, even though the non-LOB columns or non-XML columns will not return any data.

**ABSOLUTE**

*host-variable* or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0). An *integer-constant* can be up to 31 digits, depending on the application language.

If *k*=0, the cursor is positioned before the first row of the result table. Otherwise, ABSOLUTE positions the cursor to row *k* of the result table if *k>*0, or to *k* rows from the bottom of the table if *k>*0. For example, "ABSOLUTE -1" is the same as "LAST".

Data is returned if the specified position is within the rows of the result table, and a target is specified.

If an absolute position is specified that is before the first row or after the last row of the result table, a warning occurs, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If row *k* of the result table is a hole, a warning occurs and values are not assigned to host variables.

FETCH ABSOLUTE 0 results in positioning before the first row and a warning is issued. FETCH BEFORE results in positioning before the first row and no warning is issued.

Table 147 lists some synonymous specifications.

**Note:** Assume: 0≤m≤n<n≤x Where, n is the number of rows in the result table.

### RELATIVE

The `host-variable` or `integer-constant` is assigned to an integral value k. If a `host-variable` is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are `DECIMAL(n,0)` or integer. The `DECIMAL` data type is limited to `DECIMAL(18,0)`.

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If n is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs.
- If n is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting at row n.
- If n is positive, and the cursor is positioned after the last row, a warning occurs.
- If n is negative, and the cursor is positioned before the first row, a warning occurs.
- If n is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting as row n from the end of the result table.

An `integer-constant` can be up to 31 digits, depending on the application language.

Data is returned if the specified position is within the rows of the result table, and a target is specified.

RELATIVE positions the cursor to the row in the result table that is either k rows after the current row if k>0, or ABS(k) rows before the current row if k<0. For example, "RELATIVE -1" is the same as "PRIOR". If k=0, the position of the cursor does not change (that is, "RELATIVE 0" is the same as "CURRENT").

If a relative position is specified that results in positioning before the first row or after the last row, a warning is issued, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If the cursor is positioned on a hole and RELATIVE 0 is specified or if the target row is a hole, a warning occurs and values are not assigned to host variables.
If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row data.

If the cursor position is unknown and RELATIVE 0 is specified, an error occurs.

Table 148 lists some synonymous specifications.

<table>
<thead>
<tr>
<th>Specification</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELATIVE +1</td>
<td>NEXT</td>
</tr>
<tr>
<td>RELATIVE -1</td>
<td>PRIOR</td>
</tr>
<tr>

<td>CURRENT</td>
</tr>
<tr>
<td>RELATIVE +r (with a warning)</td>
<td>AFTER (without a warning)</td>
</tr>
<tr>
<td>RELATIVE -r (with a warning)</td>
<td>BEFORE (without a warning)</td>
</tr>
</tbody>
</table>

Note: r has to be large enough to position the cursor beyond either end of the result table.

rowset-positioned

Positioning of the cursor with rowset-positioned fetch orientations NEXT ROWSET, PRIOR ROWSET, CURRENT ROWSET, and ROWSET STARTING AT RELATIVE is done in relation to the current cursor position. Following a successful rowset-positioned FETCH statement, the cursor is positioned on a rowset of data. The number of rows in the rowset is determined either explicitly or implicitly. The FOR n ROWS clause in the multiple-row-fetch clause is used to explicitly specify the size of the rowset. Positioning is performed relative to the current row or first row of the current rowset, and the cursor is positioned on all rows of the rowset.

A rowset-positioned fetch orientation must not be specified if the current cursor position is not defined to access rowsets. NEXT ROWSET is the only rowset-positioned fetch orientation that can be specified for cursors that are defined as NO SCROLL.

If a row of the rowset reflects a hole, a warning is returned, data values are not assigned to host variable arrays for that row (that is, the corresponding positions in the target host variable arrays are untouched), and -3 is returned in all provided indicator variables for that row. If a hole is detected, and at least one indicator variable is not provided, an error occurs.

NEXT ROWSET

Positions the cursor on the next rowset of the result table relative to the current cursor position, and returns data if a target is specified. The next rowset is logically obtained by fetching the row that follows the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned before the first row of the result table, the cursor is positioned on the first rowset.

If the cursor is positioned on the last row or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.
If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned. If a row of the rowset would be after the last row of the result table, values are not assigned to host-variable-arrays for that row and any subsequent requested rows of the rowset, and a warning is returned.

NEXT ROWSET is the only rowset positioned fetch orientation that can be explicitly be specified for cursors that are defined as NO SCROLL.

PRIOR ROWSET

Positions the cursor on the previous rowset of the result table relative to the current position, and returns data if a target is specified.

The prior rowset is logically obtained by fetching the row that precedes the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned after the last row of the result table, the cursor is positioned on the last rowset.

If the cursor is positioned before the first row or on the first row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.

If a row would be before the first row of the result table, the cursor is positioned on a partial rowset that consists of only those rows that are prior to the current position of the cursor starting with the first row of the result table, and a warning is returned. Values are not assigned to the host-variable-arrays for the rows in the rowset for which the warning is returned.

Although the rowset is logically obtained by fetching backwards from before the current rowset, the data is returned to the application starting with the first row of the rowset, to the end of the rowset.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned.
**FIRST ROWSET**

Positions the cursor on the first rowset of the result table, and returns data if a target is specified.

If a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR $n$ ROWS clause, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

**LAST ROWSET**

Positions the cursor on the last rowset of the result table and returns data if a target is specified. The last rowset is logically obtained by fetching the last row of the result table and fetching prior rows until the number of rows in the rowset is obtained or the first row of the result table is reached. Although the rowset is logically obtained by fetching backwards from the bottom of the result table, the data is returned to the application starting with the first row of the rowset, to the end of the rowset, which is also the end of the result table.

If a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR $n$ ROWS clause, the last rowset is the same as the first rowset, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

**CURRENT ROWSET**

If the FOR $n$ ROWS clause specifies a number different from the number of rows specified implicitly or explicitly in the FOR $n$ ROWS clause on the most recent FETCH statement for this cursor, the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset. If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs. If the FOR $n$ ROWS clause is not specified, it is possible that the FETCH statement will position the cursor on a partial rowset when the FETCH CURRENT ROWSET statement is processed. In this case, DB2 attempts to position the cursor on a full rowset starting with the first row of the current rowset. Otherwise, the position of the cursor on the current rowset is unchanged. Data is returned if a target is specified.
With isolation level UR or a sensitive dynamic scrollable cursor, it is
possible that different rows will be returned than the FETCH that
established the most recent rowset cursor position. This can occur while
refetching the first row of the rowset when it is determined to not be there
anymore. In this case, fetching continues moving forward to get the first
row of data for the rowset. This can also occur when changes have been
made to other rows in the current rowset such that they no longer exist or
have been logically moved within (or out of) the result table of the cursor.

If the cursor is not positioned because of a prior error, values are not
assigned to the host-variable-array, and an error occurs.

If the current rowset contains fewer rows than specified implicitly or
explicitly in the FOR \( n \) ROWS clause, values are not assigned to
host-variable-arrays after the last row, and a warning is returned.

**ROWSET STARTING AT ABSOLUTE or RELATIVE host-variable or
integer-constant**

Positions the cursor on the rowset beginning at the row of the result table
that is indicated by the ABSOLUTE or RELATIVE specification, and returns
data if a target is specified.

*host-variable* or *integer-constant* is assigned to an integral value \( k \). If
*host-variable* is specified, it must be an exact numeric type with scale zero,
and must not include an indicator variable. The possible data types for the
host variable are DECIMAL(\( n,0 \)) or integer, where the DECIMAL data type
is limited to DECIMAL(18,0). If a constant is specified, the value must be
an integer.

If a row of the result table would be after the last row or before the first
row of the result table, values are not assigned to host-variable-arrays for
that row and a warning is returned.

**ABSOLUTE**

If \( k = 0 \), an error occurs. If \( k > 0 \), the first row of the rowset is row \( k \). If
\( k < 0 \), the rowset is positioned on the ABS(\( k \)) rows from the bottom of
the result table. Assume that ABS(\( k \)) is equal to the number of rows for
the rowset and that there are enough row to return a complete rowset:

- FETCH ROWSET STARTING AT ABSOLUTE -\( k \) is the same as FETCH LAST ROWSET.
- FETCH ROWSET STARTING AT ABSOLUTE 1 is the same as FETCH FIRST ROWSET.

**RELATIVE**

If \( k = 0 \) and the FOR \( n \) ROWS clause does not specify a number
different from the number most recently specified implicitly or
explicitly for this cursor, then the position of the cursor does not
change (that is, "RELATIVE ROWSET 0" is the same as "CURRENT
ROWSET"). If \( k = 0 \) and the FOR \( n \) ROWS clause specifies a number
different from the number most recently specified implicitly or
explicitly for this cursor, then the cursor is repositioned on the
specified number of rows, starting with the first row of the current
rowset.

If the cursor is positioned before the first row, or after the last row of
the result table, the cursor position is determined as follows:

- If \( n \) is 0, the cursor position is unchanged, values are not assigned to
host variables, and a warning occurs. This is the same as FETCH
CURRENT ROWSET.
If \( n \) is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting a row \( n \).

If \( n \) is positive, and the cursor is positioned after the last row, a warning occurs.

If \( n \) is negative, and the cursor is positioned before the first row, a warning occurs.

If \( n \) is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting at row \( n \) from the bottom of the result table.

Otherwise, RELATIVE repositions the cursor so that the first row of the new rowset cursor position is on the row in the result table that is either \( k \) rows after the first row of the current rowset cursor position if \( k > 0 \), or \( \text{ABS}(k) \) rows before the first row of the current rowset cursor position if \( k < 0 \). Assume that \( \text{ABS}(k) \) is equal to the number of rows for the resulting rowset.

- FETCH ROWSET STARTING AT RELATIVE \(-k\) is the same as FETCH PRIOR ROWSET.
- FETCH ROWSET STARTING AT RELATIVE \(k\) is the same as FETCH NEXT ROWSET.
- FETCH ROWSET STARTING AT RELATIVE \(0\) is the same as FETCH CURRENT ROWSET.

When ROWSET STARTING AT RELATIVE \(-n\) is specified and there are not enough rows between the current position of the cursor and the beginning of the result table to return a complete rowset:

- A warning is returned.
- Values are not assigned to the host-variable-arrays.
- The cursor is positioned before the first row.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of \(-3\) is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned. If a row of the rowset is unknown, values are not assigned to host variable arrays for that row, and an error is returned. If a row of the rowset would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row, and a warning is returned.

**cursor-name**

Identifies the cursor to be used in the fetch operation. The cursor name must identify a declared cursor, as explained in the description of the DECLARE CURSOR statement in [DECLARE CURSOR](#) on page 1598, or an allocated cursor, as explained in [ALLOCATE CURSOR](#) on page 879. When the FETCH statement is executed, the cursor must be in the open state.

If a single-row-fetch or multiple-row-fetch clause is not specified, the cursor position is adjusted as specified, but no data is returned to the user.
**single-row-fetch**

When `single-row-fetch` is specified, SENSITIVE or INSENSITIVE can be specified though there is a default. The default depends on the sensitivity of the cursor. If the sensitivity of the cursor is INSENSITIVE, then the default is INSENSITIVE. If the effective sensitivity of the cursor is SENSITIVE DYNAMIC or SENSITIVE STATIC, then the default is SENSITIVE. The `single-row-fetch` or `multiple-row-fetch` clause must not be specified when the FETCH BEFORE or FETCH AFTER option is specified. They are required when FETCH BEFORE or FETCH AFTER is not specified. If an individual fetch operation causes the cursor to be positioned or to remain positioned on a row if there is a target specification, the values of the result table are assigned to host variables as specified by the single-fetch-clause.

**INTO** `target-variable` or `array-variable[array-index]`

Identifies one or more targets for the assignment of output values. The number of targets in the INTO clause must equal the number of values that are to be assigned. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. A target variable must not be specified more than once in the INTO clause. Each assignment to a target is made in sequence through the list according to the rules described in "Assignment and comparison" on page 123.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

**host-variable-name**

Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

**SQL-parameter-name**

Identifies the parameter that is the assignment target.

**SQL-variable-name**

Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

**array-variable [array-index]**

Specifies an array element that is the target of the assignment.

**array-variable**

Specifies and array variable.

**[array-index]**

An expression that specifies which element in the array is the target of the assignment.

For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

**array-index** must not be:
An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register

A nondeterministic function

A function that is defined with EXTERNAL ACTION

A function that is defined with MODIFIES SQL DATA

A sequence expression

### INTO DESCRIPTOR descriptor-name

Identifies an SQLDA that contains a valid description of the host output variables. Result values from the associated SELECT statement are returned to the application program in the output host variables.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
  - A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated in the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host variable or buffer into which a value in the result table is to be assigned. If LOBs are present in the results, there must be additional SQLVAR entries for each column of the result table. If the result table contains only base types and distinct types, multiple SQLVAR entries are not needed for each column. However, extra SQLVAR entries are needed for distinct types as well as for LOBs in DESCRIBE and PREPARE INTO statements. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see “SQL descriptor area (SQLDA)” on page 2144.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

See “Identifying an SQLDA in C or C++” on page 2164 for how to represent descriptor-name in C.

### multiple-row-fetch

Retrieves multiple rows of data from the result table of a query. The FOR n ROWS clause of the FETCH statement controls how many rows are returned on a single FETCH statement. The fetch orientation determines whether the resulting cursor position (for example, on a single row, rowset, before, or after the result table). Fetching stops when an error is returned, all requested rows are fetched, or the end of data condition is reached.

Fetching multiple rows of data can be done with scrollable or non-scrollable cursors. The operations used to define, open, and close a cursor used for fetching multiple rows of data are the same as for those used for single row FETCH statements.

If the BEFORE or AFTER option is specified, neither single-row-fetch or multiple-row-fetch can be specified.
FOR host-variable or integer-constant ROWS

host-variable or integer-constant is assigned to an integral value k. If a host variable is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. Furthermore, k must be in the range, 0<k<=32767.

This clause must not be specified if a row-positioned fetch-orientation clause was specified. This clause must also not be specified for a cursor that is defined without rowset access.

If a rowset fetch orientation is specified and this clause is not specified, the number of rows in the resulting rowset is determined as follows:

- If the most recent FETCH statement for this cursor was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that was most recently specified (implicitly or explicitly) for this cursor.
- When the most recent FETCH statement for this cursor was either FETCH BEFORE or FETCH AFTER and the most recent FETCH statement for this cursor prior to that was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that were most recently specified (implicitly or explicitly) for this cursor.
- Otherwise, the rowset consists of a single row.

For result set cursors, the number of rows for a rowset cursor position, established in the procedure that defined the rowset, is not inherited by the caller when the rowset is returned. Use the FOR n ROWS clause on the first rowset FETCH statement for the result set in the calling program to establish the number of rows for the cursor. Otherwise, the rowset consists of a single row.

The cursor is positioned on the row or rowset that is specified by the orientation clause (for example, NEXT ROWSET), and those rows are fetched if a target is specified. After the cursor is positioned on the first row being fetched, the next k-1 rows are fetched. Fetching moves forward from the cursor position in the result table and continues until the end of data condition is returned, k-1 rows have been fetched, or an assignment error is returned.

The resulting cursor position depends on the fetch orientation that is specified:

- For a row-positioned fetch orientation, the cursor is positioned at the last row successfully retrieved.
- For a rowset-positioned fetch orientation, the cursor is positioned on all the rows retrieved.

The values from each individual fetch are placed in data areas that are described in the INTO or USING clause. If a target specification is provided for a rowset-positioned FETCH, the host variable arrays must be specified as the target specification, and the arrays must be defined with a dimension of 1 or greater. The target specification must be defined as an array for a rowset-positioned FETCH even if the number of rows that is specified implicitly or explicitly is one. See Diagnostics information for rowset positioned FETCH statements.

INTO host-variable-array

Identifies for each column of the result table a host-variable-array to receive the data that is retrieved with this FETCH statement. If the number
of host-variable-arrays is less than the number of columns of the result
table, the SQLWARN3 field of the SQLCA is set to 'W'. No warning is
given if there are more host-variable-arrays than the number of columns in
the result table.

Each host-variable-array must be defined in the application program in
accordance with the rules for declaring an array. A host-variable-array is
used to return the values for a column of the result table. The number of
rows to be fetched must be less than or equal to the dimension of each of
the host-variable-arrays.

An optional indicator array can be specified for a host-variable-array. It
should be specified if the SQLTYPE of any SQLVAR occurrence indicates
that the column of the result table is nullable. Additionally, if an operation
may result in null values, such as an UPDATE operation that results in a
hole, is performed in the application, an indicator array should be
specified. Otherwise an error occurs if null values are encountered. The
indicators are returned as small integers.

**INTO DESCRIPTOR** descriptor-name

Identifies an SQLDA that must contain a valid description of zero or more
host-variable-arrays or buffers into which the values for a column of the
result table are to be returned.

Before the FETCH statement is processed, you must set the following fields
in the SQLDA:
- SQLN to indicate the number of SQLVAR occurrences provided in the
  SQLDA.
- SQLABC to indicate the number of bytes of storage allocated for the
  SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when
  processing the statement.
- SQLVAR occurrences to indicate the attributes of an element of the
  host-variable-array. Within each SQLVAR representing an array:
  - SQLTYPE indicates the data type of the elements of the
    host-variable-array.
  - SQLDATA field points to the first element of the host-variable-array.
  - The length fields (SQLLEN and SQLLONGLEN) are set to indicate
    the maximum length of a single element of the array.
  - SQLNAME - The length of SQLNAME must be set to 8, and the first
two bytes of the data portion of SQLNAME must be initialized to
  X'0000'. The fifth and sixth bytes must contain a flag field and the
  seventh and eighth bytes must be initialized to a binary small integer
  (half word) representation of the dimension of the host-variable-array,
  and the corresponding indicator array, if one is specified.

The SQLVAR entry for the number of rows must also contain a flag
value. The number of rows to be fetched must be less than or equal to
the dimension of each of the host variable arrays.

You set the SQLDATA and SQLIND pointers to the beginning of the
 corresponding arrays. The SQLDA must have enough storage to contain all
SQLVAR occurrences. Each SQLVAR occurrence describes a
host-variable-array or buffer into which the values for a column in the
result table are to be returned. If any column of the result table is a LOB,
two SQLVAR entries must be provided for each SQLVAR, and SQLN must
be set to two times the number of SQLVARS. SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

Notes

Assignment to targets:
The \( n \)th target identified by the INTO clause or described in the SQLDA corresponds to the \( n \)th column of the result table of the cursor. The data type of target must be compatible with its corresponding value. If the value is numeric, the target must have the capacity to represent the whole part of the value. For a datetime value, the target must be a character string variable of a minimum length as defined in "String representations of datetime values" on page 103. When the target is a host variable, if the value is null, an indicator variable must be specified.

Assignments are made in sequence through the list. Each assignment to a target is made according to the rules described in Chapter 2, “Language elements,” on page 55. If the number of targets is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to 'W'. There is no warning if there are more targets than the number of result columns. If the target is a host variable and the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the target and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned.

If more than one assignment is included in the same assignment statement, all expressions are evaluated before the assignments are performed. For example, a reference to a variable in an expression always uses the value of the variable prior to any assignment in the assignment statement.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to targets with other data types. For more information on using locators, see "Saving storage when manipulating LOBs by using LOB locators (DB2 Application programming and SQL)."

A timestamp without time zone value must not be assigned to a timestamp with time zone target.

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

Restrictions on using the WITH CONTINUE and CURRENT CONTINUE clauses:
When using the WITH CONTINUE clause, the DB2 system will only reserve truncated data for result set columns of the BLOB, CLOB, DBCLOB, or XML data type, and only when the output host variable data type is the appropriate LOB data type.

If an application uses FETCH WITH CONTINUE, and truncated data remains after the FETCH operation, the application cannot perform any
intervening operation on that cursor before performing the FETCH CURRENT CONTINUE. If intervening operations on that cursor are performed, the truncated data is lost.

FETCH CURRENT CONTINUE is not supported with multi-row fetch. Also, FETCH CURRENT CONTINUE is not supported for non-LOB and non-XML columns that have been truncated. If truncation occurs for these non-LOB and non-XML columns, the truncated data will be discarded as usual.

Result column evaluation considerations:
If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero, or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If the specified host variable is not large enough to contain the result, a warning is returned and W is assigned to SQLWARN1 in the SQLCA. The actual length of the result is returned in the indicator variable associated with the host-variable, if an indicator is provided. It is possible that a warning may not be returned on a FETCH operation. This occurs as a result of optimizations, such as the use of system temporary tables or blocking. It is also possible that the returned warning applies to a previously fetched row. When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, a warning or an error is returned.

Considerations when using the FETCH statement for a rowset cursor that was passed to an accelerator server for processing:
DB2 provides limited support for rowset queries that are passed to an accelerator server for processing. DB2 supports only high performance access to accelerated query data. The data is pre-fetched in rowsets and returned by using multiple-row-fetch statements, returning multiple rows of data in one FETCH statement. The following restrictions apply to FETCH statements that are executed against a rowset cursor that was accelerated:
- All FETCH requests must be rowset fetches.
- All FETCH requests must specify a FOR n ROWS clause.
- All FETCH requests must specify the same rowset size.
- All FETCH requests must specify target host variables. (The FETCH operation must have a target for positioning.)

Cursor positioning:
An open cursor has three possible positions:
- Before a row
- On a row or rowset
- After the last row
When a scrollable or non-scrollable cursor is opened, it is positioned before
the first row in the result table. If a cursor is on a row, that row is called
the current row of the cursor. If a cursor is on a rowset, the rows are called
the current rowset of the cursor.

A cursor referred to in an UPDATE or DELETE statement must be
positioned on a row or rowset. A cursor can only be on a row or rowset as
a result of a FETCH statement.

If the cursor was declared SENSITIVE STATIC SCROLL, a row may be a
hole, from which no values may be fetched, updated, or deleted. Holes do
not exist with sensitive dynamic cursors because there is no temporary
result table. For information about holes in the result table of a cursor, see
DB2 Application Programming and SQL Guide.

For scrollable cursors, the cursor position after an error varies depending
on the type of error:
• When an operation is attempted against an update or delete hole, or
  when an update or delete hole is detected, the cursor is positioned on
  the hole.
• When a FETCH operation is attempted past the end of file, the cursor is
  positioned after the last row.
• When a FETCH operation is attempted before the beginning of file, the
cursor is positioned before the first row.
• When an error causes the cursor position to be invalid such as when a
  single row positioned update or positioned delete error occurs that
causes a rollback, the cursor is closed.

Cursor position after exception condition:
If an error occurs during the execution of a fetch operation, the position of
the cursor and the result of any later fetch is unpredictable. It is possible
for an error to occur that makes the position of the cursor invalid, in which
case the cursor is closed.

If an individual fetch operation specifies a destination that is outside the
range of the cursor, a warning is issued (except for FETCH BEFORE or
FETCH AFTER), the cursor is positioned before or after the result table,
and values are not assigned to host variables.

Concurrency and scrollability:
The current row of a cursor cannot be updated or deleted by another
application process if it is locked. Unless it is already locked because it was
inserted or updated by the application process during the current unit of
work, the current row of a cursor is not locked if:
• The isolation level is UR, or
• The isolation level is CS, and
  – The result table of the cursor is read-only
  – The bind option CURRENTDATA(NO) is in effect

A dynamic scrollable cursor is useful when it is more important to the
application to see updated rows and newly inserted rows and there is no
need to see deleted rows. The isolation level of CS should be used for
maximum concurrency with dynamic scrollable cursors. Specifying an
isolation level of RR or RS severely restricts the update of the table, thus
defeating the purpose of a SENSITIVE DYNAMIC scrollable cursor. If the
application needs a constant result table, a SENSITIVE STATIC scrollable
cursor with an isolation level of CS should be used.
Sensitivity of SENSITIVE STATIC SCROLL cursors to database changes:
When SENSITIVE STATIC SCROLL has been declared, the following rules apply:

- For the result of an update operation to be visible within a cursor after "open," the update operation must be a positioned update executed against the cursor, or a FETCH SENSITIVE in a STATIC cursor must be executed against a row which has been updated by some other means (that is, a searched update, committed updates of others, or an update with another cursor in the same process).

- Another process can update the base table of the SELECT statement so that the current values no longer satisfy the WHERE clause. In this case, an "update hole" effectively exists during the time the values in the base table do not satisfy the WHERE clause, and the row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as an update hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, update holes are only identified during positioned update, positioned delete, and FETCH SENSITIVE operations. Each positioned update, positioned delete, and FETCH SENSITIVE operation does the necessary tests to determine if an update hole exists.

- For the result of a delete operation to be visible within a SENSITIVE STATIC SCROLL cursor, the delete operation must be a positioned delete executed against the cursor or a FETCH SENSITIVE in a STATIC cursor must be executed against a row that has been deleted by some other means (that is, a searched delete, committed deletes of others, or a delete with another cursor in the same process).

- Another process, or the even the same process, may delete a row in the base table of the SELECT statement so that a row of the cursor no longer has a corresponding row in the base table. In this case, a "delete hole" effectively exists, and that row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as a delete hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, delete holes are identified during positioned update, positioned delete, and FETCH SENSITIVE operations.

- Inserts into the base table or tables of SENSITIVE STATIC SCROLL cursors are not seen after the cursor is opened.

LOB locators:
When information is retrieved into LOB locators and it is not necessary to retain the locator across FETCH statements, it is a good practice to issue a FREE LOCATOR statement before issuing another FETCH statement because locator resources are limited.

Isolation level considerations:
The isolation level of the statement (specified implicitly or explicitly) can affect the result of a rowset-positioned FETCH statement. This is possible when changes are made to the tables underlying the cursor when isolation level UR is used with a dynamic scrollable cursor, or with other isolation levels when rows have been added by the application fetching from the cursor. These situations can occur with the following fetch orientations:

PRIOR ROWSET
With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is
possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**CURRENT ROWSET**

With a dynamic scrollable cursor, additional rows can be added between rows that form the rowset that was returned to the user. With isolation level RR, these rows can only be added by the application fetching from the cursor. For isolation levels other than RR, other applications can insert rows that can affect the results of a subsequent FETCH CURRENT ROWSET. To avoid this behavior, use a static scrollable cursor instead of a dynamic scrollable cursor.

**LAST ROWSET**

With a dynamic scrollable cursor and isolation level UR, the content of the last rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "last" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**ROWSET STARTING AT RELATIVE -n (where -n is a negative number)**

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**Row positioned and rowset positioned FETCH statement interaction:**

The following table demonstrates the interaction between row positioned and rowset positioned FETCH statements. The table is based on the following assumptions:

- TABLE T1 has 15 rows
- CURSOR CS1 is declared as follows:
  
  DECLARE CS1 SCROLL CURSOR WITH ROWSET POSITIONING FOR
  SELECT * FROM T1;
- An OPEN CURSOR statement has been successfully executed for CURSOR CS1 and the FETCH statements in the table are executed in the order that they appear in the table.

<tr>
<td>FETCH FIRST ROWSET</td>
<td>Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.</td>
</tr>
</tbody>
</table>

**Note:** Even though the previous FETCH statement returned only 3 rows because EOF was encountered, DB2 will remember that 5 rows were requested by the previous FETCH statement.

Considerations for using the FOR n ROWS clause with the FETCH FIRST n ROWS ONLY clause:
A clause specifying the number of rows that you want can be specified in the SELECT statement of a cursor, the FETCH statement for a cursor, or both. However, these clauses have different effects:

- In the SELECT statement, a FETCH FIRST n ROWS ONLY clause controls the maximum number of rows that can be accessed with the cursor. When a FETCH statement attempts to retrieve a row beyond the number specified in the FETCH FIRST n ROWS ONLY clause of the SELECT statement, an end-of-data condition occurs.
- In a FETCH statement, a FOR n ROWS clause controls the number of rows that are returned for a single FETCH statement.
Both of these clauses can be specified.

**Diagnostics information for rowset positioned FETCH statements:**

A single FETCH statement from a rowset cursor might encounter zero, one, or more conditions. If the current cursor position is not valid for the fetch orientation, a warning occurs and the statement terminates. If a warning or non-terminating error (such as a bind out error) occurs during the fetch of a row, processing continues. In this case, a summary message is returned for the FETCH statement, and additional information about each fetched row is available with the GET DIAGNOSTICS statement. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these FETCH statements. See “GET DIAGNOSTICS” on page 1744 for more information.

The SQLCA returns some information about errors and warnings that are found while fetching from a rowset cursor. Processing stops when the end of data is encountered, or when a terminating condition occurs. After each FETCH statement from a rowset cursor, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- **SQLCODE** contains the SQLCODE.
- **SQLSTATE** contains the SQLSTATE.
- **SQLERRD1** and **SQLERRD2** contain the number of rows of the result table if the cursor is positioned on the last row of the result table.
- **SQLERRD3** contains the actual number of rows returned. If SQLERRD3 is less than the number of rows requested, an error or end-of-data condition occurred.
- **SQLWARN** flags are set to represent all the warnings that were accumulated while processing the FETCH statement.

Consider the following examples, where 10 rows are fetched with a single FETCH statement.

**Example 1:** Assume that an error is detected on the 5th row. SQLERRD3 is set to 4 for the 4 returned rows, SQLSTATE is set to 22537, and SQLCODE is set to -354. This information is also available from the GET DIAGNOSTICS statement (the information that is returned is generated from connected server, which may differ across different servers). For example:

```sql
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 4 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22537, sqlcode = -354, and row_num = 5
```

**Example 2:** Assume that an end-of-data condition is detected on the 6th row and that the cursor does not have immediate sensitivity to updates. SQLERRD3 is set to 5 for the 5 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. This information is also available from the GET DIAGNOSTICS statement. For example:

```sql
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 5 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 6
```
**Example 3:** Assume that a bind error condition is detected on the 5th row, the condition is recorded, and processing continues. Also, assume that an end-of-data condition is detected on the 8th row. SQLERRD3 is set to 7 for the 7 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. Processing to complete the FETCH statement is performed, and the bind out error that occurred is noted. An additional SQLCODE is recorded for the bind out error. SQLCODE is set to –354, and SQLSTATE is set to 01668. Use the GET DIAGNOSTICS statement to determine what went on. For example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 7 and num_cond = 3 (3 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01668, sqlcode = -354, and row_num = 0
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 0
GET DIAGNOSTICS CONDITION 3 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -302, and row_num = 5
```

In some cases, DB2 returns a warning if indicator variables are provided, or an error if indicator variables are not provided. These errors can be thought of as data mapping errors that result in a warning if indicator variables are provided.

- If indicator variables are provided, DB2 returns all rows to the user, marking the errors in the indicator variables. The SQLCODE and SQLSTATE contain the warning from the last data mapping error. The GET DIAGNOSTICS statement can be used to retrieve information about the last data mapping error that occurred.

- If some or no indicator variables are provided, all rows are returned as above until the first data mapping error that does not have indicator variables is detected. The rows successfully fetched are returned and the SQLSTATE, SQLCODE, and SQLWARN flags are set, if necessary. (The SQLCODE may be 0 or a positive value).

It is possible, if a data mapping error occurs, for the positioning of the cursor to be successful. In this case, the cursor is positioned on the rowset that encountered the data mapping error.

Consider the following examples, which try to fetch 10 rows with a single FETCH statement.

**Example 1:** Assume that indicators have been provided for values returned for column 1, but not for column 2. The 5th row has a data mapping error (802) for column 1, and the 7th row has a data mapping error for column 2 (-802 is returned because an indicator was not provided for column 2). SQLERRD3 is set to 6 for the 6 returned rows, SQLSTATE and SQLCODE are set to the error from the 7th row fetched. The indicator variable for the 5th row column 1 indicates that a data mapping error was found. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 6 and num_cond = 2 (2 conditions)
```
The resulting cursor position is unknown.

**Example 2:** Assume that null indicators are provided, that rows 3 and 5 are holes, and that data exists for the other requested rows. SQLERRD3 is set to 10 to reflect that 10 fetches were completed and that information has been returned for the 10 requested rows. Eight rows actually contain data. For two rows, indicator variables are set to indicate no data was returned for those rows. SQLSTATE is set to 02502, SQLCODE is set to +222, and all null indicators for rows 3 and 5 are set to -3 to indicate that a hole was detected. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 10 and num_cond = 2 (2 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 3
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2 ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 5
```

If a null indicator was not provided for any variable in a row that was a hole, an error occurs.

**SQLCA usage summary:**
For multiple-row-fetch, the fields of the SQLCA are set as follows:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Action: Resulting Values Stored in the SQLCA Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Errors</td>
<td>Data</td>
</tr>
<tr>
<td>No</td>
<td>Return all requested rows</td>
</tr>
<tr>
<td>No</td>
<td>Return data for subset of requested rows, end of data</td>
</tr>
<tr>
<td>No</td>
<td>Return all requested rows</td>
</tr>
<tr>
<td>Yes</td>
<td>Return successfully fetched rows</td>
</tr>
<tr>
<td>Yes</td>
<td>Return successfully fetched rows</td>
</tr>
</tbody>
</table>
Providing indicator variables for error conditions:

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.)

If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned. Additionally, a -3 is returned in all indicators provided by the application when a hole was detected for the row on a rowset positioned FETCH, and values were not returned for the row. Processing of the statement terminates if a hole is detected and at least one indicator variable was not provided by the application.

Alternative syntax and synonyms:

USING DESCRIPTOR can be specified as a synonym for INTO DESCRIPTOR.

Example

Example 1: The FETCH statement fetches the results of the SELECT statement into the application program variables DNUM, DNAME, and MNUM. When no more rows remain to be fetched, the not found condition is returned.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8B10.DEPT
   WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
   EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```

Example 2: For an example of FETCH statements with a dynamic scrollable cursor, see Example 8.

Example 3: Fetch the last 5 rows of the result table C1 using cursor C1:
FETCH ROWSET STARTING AT ABSOLUTE -5
FROM C1 FOR 5 ROWS INTO DESCRIPTOR :MYDESCR;

Example 4: Fetch 6 rows starting at row 10 for cursor CURS1, and fetch the data into three host-variable-arrays:
FETCH ROWSET STARTING AT ABSOLUTE 10
FROM CURS1 FOR 6 ROWS
INTO :hav1, :hva2, :hva3;

Alternatively, a descriptor could have been specified in an INTO DESCRIPTOR clause where the information in the SQLDA reflects the data types of the host-variable-arrays:
FETCH ROWSET STARTING AT ABSOLUTE 10
FROM CURS1 FOR 6 ROWS
INTO DESCRIPTOR :MYDESCR;

Example 5: Suppose that the following array type, array variable, and table have been defined.
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);

Use an array variable as an output target for a FETCH statement. The array variable is specified in the INTO clause of the FETCH statement.
CREATE PROCEDURE PROCESSINTARRAY (OUT INTOUTARRAY INTARRAY)
BEGIN
  DECLARE INTA INTARRAY;
  DECLARE INTB INTARRAY;
  DECLARE INTV INTEGER DEFAULT 1;
  DECLARE STMT CHAR(100);
  DECLARE C2 CURSOR FOR S1;
  --
  -- Initialize the array
  --
  SET INTA = ARRAY[1,INTEGER(2),3+0,4,5,6] ;
  --
  -- Use dynamic SQL with an array parameter marker and a parameter marker
  -- containing the index to retrieve the value from the array parameter.
  -- The array is referenced in a predicate.
  --
  SET STMT = 'SELECT COL1 FROM T1 WHERE COL2 = CAST(? AS INTARRAY)[?];'
  PREPARE S1 FROM STMT;
  OPEN C2 USING INTA, INTV;
  FETCH C2 INTO INTB ; -- INTB is an array variable that is used
  -- as a target for the fetch statement.
  CLOSE C2;
  SET INTOUTARRAY=INTB;
END
FREE LOCATOR

The FREE LOCATOR statement removes the association between a LOB locator variable and its value.

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java.

Authorization

None required.

Syntax

FREE LOCATOR

host-variable

Description

host-variable, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The host-variable must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET host-variable statement, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been freed and others have not been freed.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. Free the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC.

EXEC SQL FREE LOCATOR :LOCRES, :LOCHIST, :LOCPIC
GET DIAGNOSTICS

The GET DIAGNOSTICS statement provides diagnostic information about the last SQL statement (other than a GET DIAGNOSTICS statement) that was executed. This diagnostic information is gathered as the previous SQL statement is executed. Some of the information available through the GET DIAGNOSTICS statement is also available in the SQLCA.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

```
Description

Diagnostic information is provided in three main areas: statement information, condition information, and combined information. After the execution of an SQL statement, information about the execution of the statement is provided as statement information, and at least one instance of condition information is provided. The number of instances of the condition information is indicated by the NUMBER item that is available in the statement information. Combined information contains a text representation of all the information gathered about the execution of the SQL statement.

The diagnostic information that is provided is specific to the server. If you are connected to a server other than DB2 for z/OS, see that product's documentation for the diagnostic information that is returned.

**CURRENT**

Specifies that information is to be returned from the first diagnostics area. It corresponds to the previous SQL statement that was executed that was not a GET DIAGNOSTICS or compound statement. **CURRENT** is the default.

**STACKED**

Specifies that information is to be returned from the stacked diagnostics area. The stacked diagnostics area is only available within a handler in a native SQL procedure and compiled SQL functions. The stacked diagnostics area corresponds to the previous SQL statement (that was not a GET DIAGNOSTICS or compound statement) that was executed before the handler was entered. If the GET DIAGNOSTICS statement is the first statement within a handler, the current diagnostics area and the stacked diagnostics area contain the same diagnostics information.

**statement-information**

Provides information about the last SQL statement executed.

**variable1**

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in Data types for GET DIAGNOSTICS items.

The variable is assigned the value of the specified statement information item. If the value is truncated when assigning it to the variable, a warning is displayed.
returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition. If a DIAGNOSTICS item is not set, the variable is set to a default value, based on its data type: 0 for an exact numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

DB2_GET_DIAGNOSTICS_DIAGNOSTICS
Contains textual information about errors or warnings that might have occurred in the execution of the GET DIAGNOSTICS statement. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

DB2_SQL_NESTING_LEVEL
Identifies the current level of nesting or recursion that is in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of a compiled SQL function, native SQL procedure, or trigger. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value of zero is returned.

statement-information-item-name:

DB2_LAST_ROW
For a multiple-row FETCH statement, contains a value of +100 if the last row currently in the table is in the set of rows that have been fetched. For cursors that are not sensitive to updates, there would be no need to do a subsequent FETCH, because the result would be an end-of-data indication. For cursors that are sensitive to updates, a subsequent FETCH may return more data if a row had been inserted before the FETCH was executed. For statements other than multiple-row FETCH statements, or for multiple-row FETCH statements that do not contain the last row, this variable contains the value 0.

An end of data warning might not occur and DB2_LAST_ROW might not contain +100 when the number of rows returned is equal to the number of rows requested and the last row of data returned is the last row of data.

DB2_NUMBER_PARAMETER_MARKERS
For a PREPARE statement, contains the number of parameter markers in the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_NUMBER_RESULT_SETS
For a CALL statement, contains the actual number of result sets returned by the procedure. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_NUMBER_ROWS
If the previous SQL statement was an OPEN or a FETCH that caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE DYNAMIC cursors, this value can be thought of as an approximation because rows that are inserted and deleted will affect the next retrieval of this value. If the previous SQL statement was a PREPARE statement, returns the estimated number of rows in the result table for the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

DB2_RETURN_STATUS
Identifies the status value returned from the stored procedure associated with the previously executed SQL statement, provided that the statement
was a CALL statement that invoked a procedure that returns a status. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_SQL_ATTR_CURSOR_HOLD**
For an ALLOCATE or OPEN statement, indicates whether a cursor can be held open across multiple units of work.
- N indicates that this cursor does not remain open across multiple units of work.
- Y indicates that this cursor remains open across multiple units of work.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_ROWSET**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be accessed using rowset positioning.
- N indicates that this cursor supports only row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_SCROLLABLE**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be scrolled forward and backward.
- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_SENSITIVITY**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor does or does not show updates to cursor rows made by other connections.
- I indicates insensitive.
- S indicates sensitive.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_TYPE**
For an ALLOCATE or OPEN statement, indicates the type of cursor, whether a cursor type is forward-only, static, or dynamic.
- F indicates a forward cursor.
- D indicates a dynamic cursor.
- S indicates a static cursor.
Otherwise, a blank is returned.

**MORE**
Indicates whether some of the warning and errors from the previous SQL statement were stored or discarded.
- N indicates that all the warnings and errors from the previous SQL statement are stored in the diagnostic area.
- Y indicates that some of the warnings and errors from the previous SQL statement were discarded because the amount of storage needed to record warnings and errors exceeded 65535 bytes.

**NUMBER**
Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL
statement returned an SQLSTATE of 00000 or no previous SQL statement has been executed, the number returned is one.

The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS item.

**ROW_COUNT**
Identifies the number of rows associated with the previous SQL statement that was executed.

If the previous SQL statement is a DELETE, INSERT, UPDATE, or MERGE statement, ROW_COUNT indicates the number of rows that are qualified to be deleted, inserted, or updated by that statement, excluding rows that are affected by triggers or referential integrity constraints. The count does not include rows that are inserted as a result of processing a FOR PORTION OF clause for in an SQL data change statement.

For the OPEN of a cursor for a SELECT with a data change statement, or a SELECT INTO statement, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled.

A value of -1 indicates a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria, or a truncate operation. If the delete was against a view, then neither the DELETE statement nor the nor the definition of the view included selection criteria.

For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.

If the previous SQL statement is a multiple-row FETCH, ROW_COUNT identifies the number of rows fetched.

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**condition-information**
Assigns the values of the specified condition information to the associated variables. The variable specified must be of the data type that is compatible with the data type of the specified diagnostic-ID or an error occurs. If the value of the condition is truncated when assigning it to the variable, an error occurs. If an indicator variable was provided, the length of the value is returned in the indicator variable.

If a DIAGNOSTICS item is not set, then the variable is set to a default value, based on the data type of the item. The specific value will be 0 for a numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

**variable2 or integer**
Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic, and so on. If the value is 1, the diagnostic information that is retrieved corresponds to the condition that is indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The variable specified must be an integer data type, or an error occurs. An indicator variable is not allowed when this is a host variable; an
error occurs. If a value is specified that is less than or equal to zero, or greater than the number of available diagnostics, an error occurs.

`variable3`

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in Data types for GET DIAGNOSTICS items for the indicated condition-information item.

`condition-information-item-name`

**CATALOG_NAME**

If the returned SQLSTATE is any one of the following values, the constraint that caused the error is a referential, check, or unique constraint. The location (RDB) name of the server that generated the condition is returned.

- Class 09 (Triggered Action Exception),
- Class 23 (Integrity Constraint Violation)
- Class 27 (Triggered Data Change Violation)
- 40002 (Transaction Rollback - Integrity Constraint Violation)
- 40004 (Transaction Rollback - Triggered Action Exception)

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned.

Otherwise, the empty string is returned.

The actual server name may be different than the server name specified, either implicitly or explicitly, on the CONNECT statement because of the use of aliases or synonyms.

**CONDITION_NUMBER**

Returns the number of the diagnostic returned.

**CURSOR_NAME**

If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

**DB2_ERROR_CODE1**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2_ERROR_CODE2**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2_ERROR_CODE3**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2_ERROR_CODE4**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2_INTERNAL_ERROR_POINTER**

For some errors, this is a negative value that is an internal error pointer. Otherwise, the value 0 is returned.

**DB2_LINE_NUMBER**

Returns the line number where an error is encountered in parsing a
dynamic statement. Also returns the line number where an error is
encountered in parsing, binding, or executing a CREATE or ALTER
statement for a native SQL procedure or compiled SQL function.
DB2_LINE_NUMBER also returns the line number when a CALL statement
invokes a native SQL procedure and the procedure returns with an error.
This information is not returned for an external SQL procedure.

This value will only be meaningful if the statement source contains new
line control characters.

DB2_MESSAGE_ID
Corresponds to the message that is contained in the MESSAGE_TEXT
diagnostic item (for example, DSNT102I or DSNU180I).

DB2_MODULE_DETECTING_ERROR
Returns an identifier indicating which module detected the error. For a
SIGNAL statement that is issued from a routine, the value ’ROUTINE’ is
returned. Otherwise, the string ’DSN ’ is returned.

DB2_ORDINAL_TOKEN_n
Returns the n
th token. n must be a value from 1 to 100. For example,
DB2_ORDINAL_TOKEN_1 would return the value of the first token,
DB2_ORDINAL_TOKEN_2 the second token, and so on. A numeric value
for a token is converted to characters before being returned. If there is no
value for the token, or if the server only returns an SQLCA, an empty
string is returned.

DB2_REASON_CODE
Contains the reason code for errors that have a reason code token in the
message text. Otherwise, the value zero is returned.

DB2_RETURNED_SQLCODE
Returns the SQLCODE for the specified diagnostic.

DB2_ROW_NUMBER
Returns the number of the row where the condition was encountered,
when such information is available and applicable. If SQLCODE +1– or
+20237 is returned, DB2_ROW_NUMBER returns a value of 0.

DB2_SQLERRD_SET
A value of Y indicates that the DB2_SQLERRD1 through DB2_SQLERRD
items might be set. These items are set only when communicating with a
server that returns the SQLCA SQL communications area and not the new
diagnostics area. Otherwise, a blank is returned.

DB2_SQLERRD1
Returns the value of sqlerrd(1) from the SQLCA that is returned by the
server. Otherwise, the value zero is returned.

DB2_SQLERRD2
Returns the value of sqlerrd(2) from the SQLCA that is returned by the
server. Otherwise, the value zero is returned.

DB2_SQLERRD3
Returns the value of sqlerrd(3) from the SQLCA that is returned by the
server. Otherwise, the value zero is returned.

DB2_SQLERRD4
Returns the value of sqlerrd(4) from the SQLCA that is returned by the
server. Otherwise, the value zero is returned.
**DB2_SQLERRD5**
Returns the value of sqlerrd(5) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2_SQLERRD6**
Returns the value of sqlerrd(6) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2_TOKEN_COUNT**
Returns the number of tokens available for the specified diagnostic ID.

**MESSAGE_TEXT**
Returns the message text that is associated with the SQLCODE. This is the short text, including substituted tokens. The message text does not contain the message number. When the SQLCODE is 0, the empty string is returned, even if the RETURNED_SQLSTATE value indicates a warning condition.

**RETURNED_SQLSTATE**
Returns the SQLSTATE for the specified diagnostic.

**SERVER_NAME**
If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION statement, returns the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executes is returned.

**connection-information-item-name**
Provides information about the last SQL statement executed if it was a CONNECT statement.

**DB2_AUTHENTICATION_TYPE**
Contains an authentication type value of:
- ‘S’ for a server authentication
- ‘C’ for client authentication
- ‘T’ for trusted server authentication
- Otherwise, or if the server only returns an SQLCA, a blank is returned

**DB2_AUTHORIZATION_ID**
Authorization ID used by connected server. Because of user ID translation and authorization exits, the local user ID may not be the authorized ID used by the server.

**DB2_CONNECTION_STATE**
Contains the connection state:
- -1 if the connection is unconnected
- 1 if the connection is connected

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_CONNECTION_STATUS**
Contains a value of:
- 1 if committable updates can be performed on the connection for this unit of work
- 2 if no committable updates can be performed on the connection for this unit of work

Otherwise, or if the server only returns an SQLCA, the value zero is returned.
**DB2_SERVER_CLASS_NAME**
For a CONNECT or SET CONNECTION statement, contains one of the following values:
- QAS for DB2 for i
- QDB2 forDB2 for z/OS
- QDB2/2 for DB2 for OS/2
- QDB2/6000 for DB2 for AIX®
- QDB2/6000 PE for DB2 for AIX Parallel Edition
- QDB2/AIX64 for DB2 for AIX 64-bit
- QDB2/HPUX for DB2 for HP-UX
- QDB2/HP64 for DB2 for HP-UX 64-bit
- QDB2/LINUX for DB2 for Linux, UNIX, and Windows
- QDB2/LINUX390 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXIA64 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC forDB2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC64 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXZ64 for DB2 for Linux, UNIX, and Windows
- QDB2/NT for DB2 for Linux, UNIX, and Windows
- QDB2/NT64 for DB2 for Linux, UNIX, and Windows
- QDB2/PTX for DB2 for NUMA-Q®
- QDB2/SCO for DB2 for SCO UnixWare
- QDB2/SGI for DB2 for Silicon Graphics
- QDB2/SNI for DB2 for Siemens Nixdorf
- QDB2/SUN for DB2 for SUN Solaris
- QDB2/SUN64 for DB2 for SUN Solaris 64-bit
- QDB2/Windows 95 for DB2 for Linux, UNIX, and Windows
- QSQLDS/VM for DB2 Server for VSE & VM
- QSQLDS/VSE for DB2 Server for VSE & VM
Otherwise, the empty string is returned.

**DB2_ENCRYPTION_TYPE**
The level of encryption for the connection:
- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.
- Otherwise, a blank is returned.

**DB2_PRODUCT_ID**
Returns a product signature. If the application server is an IBM relational database product, the form is pppvvermm.

**combined-information**
Provides a text representation of all the information gathered about the execution of the SQL statement.

**ALL**
Indicates that all diagnostic items that are set for the last SQL statement executed are to be combined into one string. The format of the string is a
semicolon separated list of all of the available diagnostic information in the form: \textit{item-name}[\textit{condition-number}]=\textit{value-converted-to-character}...; as shown in the following example:

\begin{verbatim}
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE+=100;
\end{verbatim}

\texttt{variable4}

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be VARCHAR. If the length of \texttt{variable4} is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned, and the \texttt{GET\_DIAGNOSTICS\_DIAGNOSTICS} item of the diagnostics area is updated with the details of this condition.

\texttt{STATEMENT}

Indicates that all statement-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. The format is the same as described for the ALL option.

\texttt{CONDITION}

Indicates that all condition-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If \texttt{variable5} or integer is supplied after CONDITION, the format is the same as described above for the ALL option. If \texttt{variable5} or integer is not supplied, the format includes a condition number entry at the beginning of the information for that condition in the form:

\begin{verbatim}
CONDITION\_NUMBER=x\textit{item-name}=\textit{value-converted-to-character};... where X is the number of the condition, as shown in the following example:
CONDITION\_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED\_SQLCODE=100;
CONDITION\_NUMBER=2;RETURNED\_SQLSTATE=01004;
\end{verbatim}

\texttt{CONNECTION}

Indicates that all connection-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If \texttt{variable5} or integer is supplied after CONNECTION, the format is the same as described for the ALL option. If \texttt{variable5} or integer is not supplied, then the format includes a condition number entry at the beginning of the information for that condition in the form:

\begin{verbatim}
CONNECTION\_NUMBER=x\textit{item-name}=\textit{value-converted-to-character};... where X is the number of the condition, as shown in the following example:
CONNECTION\_NUMBER=1;CONNECTION\_NAME=SVL1;DB2\_PRODUCT\_ID=DSN11015;
\end{verbatim}

\texttt{variable5 or integer}

Identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The variable specified must be an integer data type or an error occurs. An indicator variable is not allowed when this is a host variable; an error occurs. If a value is specified that is less than or equal to zero or greater than the number of available diagnostics, an error occurs.

**Notes**

**Effect of the statement in a native SQL routine:**

The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2\_GET\_DIAGNOSTICS\_DIAGNOSTICS.

If you want information about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error condition.
If you want information about a warning and a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first executable statement specified in that handler.

If you want information about a warning and a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

**Considerations for the SQLSTATE and SQLCODE SQL variables:**
The GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables.

**Data types for items:**
When a diagnostic item is assigned to a variable, SQL variable, or SQL parameter, the data type of the target must be compatible with the data type of the requested diagnostic item.

DRDA considerations

The GET DIAGNOSTICS statement is supported from a current DB2 for z/OS client, regardless of the level of the server (a DB2 for z/OS Version 7 or a DB2 for Windows Version 7, for example). When the application is connected to servers that do not support the Open Group Version 3 DRDA standard, the diagnostic information that is returned by the servers is available in the condition information.
Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RETURN_STATUS as a synonym for DB2_RETURN_STATUS
- EXCEPTION as a synonym for CONDITION

Examples

Example 1: In an application, use the GET DIAGNOSTICS statement to determine how many rows were updated.

```sql
long rcount;
EXEC SQL UPDATE T1 SET C1 = C1 + 1;
EXEC SQL GET DIAGNOSTICS :rcount = ROW_COUNT;
```

After execution of this code segment, `rcount` will contain the number of rows that were updated.

Example 2: In an application, use the GET DIAGNOSTICS statement to handle multiple SQL Errors.

```sql
long numerrors, counter;
char retsqlstate[5];
long hva[5];
EXEC SQL INSERT INTO T1 FOR 5 ROWS VALUES (:hva) NOT ATOMIC CONTINUE ON SQLEXCEPTION;
EXEC SQL GET DIAGNOSTICS :numerrors = NUMBER;
for ( i=1;i < numerrors;i++)
{
  EXEC SQL GET DIAGNOSTICS CONDITION :i :retsqlstate = RETURNED_SQLSTATE;
...
```

Execution of this code segment sets and prints `retsqlstate` with the SQLSTATE for each error that was encountered in the previous SQL statement.

Example 3: Retrieve information about a connection.

```sql
EXEC SQL GET DIAGNOSTICS CONDITION :HV_PRODUCT_ID = DB2_PRODUCT_ID;
```

Example 4: Use the GET DIAGNOSTICS statement to retrieve information that is similar to what is returned in the SQLCA:

```sql
EXEC SQL GET DIAGNOSTICS CONDITION 1
  :dasqrcode = DB2_RETURNED_SQLCODE,
  :datencode = DB2_TOKEN_COUNT,
  :datoken1 = DB2_ORDINAL_TOKEN_1,
  :datoken2 = DB2_ORDINAL_TOKEN_2,
  :datoken3 = DB2_ORDINAL_TOKEN_3,
  :datoken4 = DB2_ORDINAL_TOKEN_4,
  :datoken5 = DB2_ORDINAL_TOKEN_5,
  :dasqrcode1b = DB2_MESSAGE_ID,
  :damsgtext = MESSAGE_TEXT,
  :dasqlerrrp = DB2_MODULE_DETECTING_ERROR,
  :dasqlstate = RETURNED_SQLSTATE;
```

Example 5: Specify the STACKED keyword on a GET DIAGNOSTICS statement that is used within a handler to access information in the diagnostics area that caused the handler to be activated:

```sql
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER,
                           OUT divide_error VARCHAR(70))
BEGIN
  LANGUAGE SQL
```
DECLARE msg_text CHAR(70) DEFAULT '';
DECLARE divide_error CHAR(70) DEFAULT '';

DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    INSERT .....; -- insert row into a log table
    -- get diagnostic information for the INSERT statement
    GET CURRENT DIAGNOSTICS CONDITION 1 msg_text = MESSAGE_TEXT;
    -- get information about condition that activated the handler
    GET STACKED DIAGNOSTICS CONDITION 1 divide_error = MESSAGE_TEXT;
END;

SET divide_result = numerator/denominator;
END;

The first GET DIAGNOSTICS statement obtains diagnostic information about the
INSERT statement.

The second GET DIAGNOSTICS statement specifies the STACKED keyword. The
use of the STACKED keyword allows access the stacked diagnostics area which
contains the diagnostic information for the condition that caused the handler to be
activated. The information about the original condition is still accessible within the
handler even after another statement has been issued, such as the INSERT
statement in the example.

Example 6: The following application logs information whenever a routine is
invoked directly by an application rather than indirectly by another routine. The
application uses the GET DIAGNOSTICS statement that specifies
DB2_SQL_NESTING_LEVEL to obtain the current nesting level, and invokes the
LOG_INVOCATION procedure if the nesting level is 1:

CREATE PROCEDURE TEST
MODIFIES SQL DATA
LANGUAGE SQL
BEGIN
    DECLARE NESTING_LEVEL INT DEFAULT 0;
    GET DIAGNOSTICS NESTING_LEVEL = DB2_SQL_NESTING_LEVEL;
    -- If routine is invoked at nesting level 1,
    -- invoke a routine to log the invocation.
    IF (NESTING_LEVEL = 1) THEN
        CALL LOG_INVOCATION();
    END IF;
    -- Remainder of procedure logic
    -- ...
END
The DB2 GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Distinct type
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Distinct type, array type, or JAR file
- Variable
- Use

The applicable objects are always at the current server. The grants are recorded in the current server's catalog.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

If the authorization mechanism was not activated when the DB2 subsystem was installed, an error condition occurs.

**Authorization**

To grant a privilege P, the privilege set must include one of the following:

- The privilege P WITH GRANT OPTION
- Ownership of the object on which P is a privilege
- SECADM authority

**Note:** If installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM authority.

- ACCESSCTRL authority

The presence of ACCESSCTRL authority in the privilege set allows the granting of all authorities except:

- System DBADM
- CREATE_SECURE_OBJECT privilege
- DATAACCESS
- ACCESSCTRL

**Note:** If installation parameter SEPARATE SECURITY is NO, SYSCALL authority has implicit ACCESSCTRL authority that allows the granting of all privileges except:
- DBADM on databases
- DELETE, INSERT, SELECT, and UPDATE on user tables or views
- EXECUTE on plans, packages, functions, or stored procedures
- PACKADM on collections
- SYSADM authority
- USAGE on distinct types, JARs, and sequences
- READ, WRITE on global variables

To grant the CREATE_SECURE_OBJECT system privilege, the privileges that are
held by the authorization ID of the statement must include SECADM authority.

Except for views, the GRANT option for privileges on a table is also inherent in
DBADM authority for its database, provided DBADM authority was acquired with
the GRANT option. See [“CREATE VIEW” on page 1590] for a description of the
rules that apply to views.

If the statement is embedded in an application program, the privilege set is the
privileges that are held by the owner of the plan or package. The owner can be a
role. If the statement is dynamically prepared, the privilege set is the privileges
that are held by the SQL authorization ID of the process. However, if the process is
running in a trusted context that is defined with the ROLE AS OBJECT OWNER
CLAUSE, the privilege set is the privileges that are held by the role in effect.

**Syntax**

```
GRANT authorization-specification TO authorization-name
               ROLE role-name
               WITH GRANT OPTION
               PUBLIC
```

**Description**

*authorization-specification*

Specifies one or more privileges for the class of privilege. The same privilege
must not be specified more than once.

TO

Specifies to what authorization IDs the privileges are granted.

authorization-name,...

Lists one or more authorization IDs.

ROLE role-name

Lists one or more role names. Each name must identify a role that exists at
the current server.

The value of the CURRENT RULES special register determines whether
you can use the ID or role of the GRANT statement itself (to grant
privileges to yourself). When CURRENT RULES is:

- **DB2** You cannot use the ID or role of the GRANT statement.
- **STD** You can use the ID or role of the GRANT statement.
PUBLIC
Grants the privileges to all users at the current server, including database requesters using DRDA access.

CREATE_SECURE_OBJECT must not be granted to PUBLIC.

ACCESSCTRL, DATAACCESS and system DBADM authorities cannot be granted to PUBLIC.

WITH GRANT OPTION
Allows the named users to grant the privileges to others. Granting an administrative authority with this option allows the user to specifically grant any privilege belonging to that authority. If you omit WITH GRANT OPTION, the named users cannot grant the privileges to others unless they have that authority from some other source.

GRANT authority cannot be passed to PUBLIC. When WITH GRANT OPTION is used with PUBLIC, a warning is issued, and the named privileges are granted, but without GRANT authority.

If you grant the CREATE_SECURE_OBJECT system privilege, the WITH GRANT OPTION clause is ignored because the CREATE_SECURE_OBJECT system privilege cannot be granted to others.

GRANT ACCESSCTRL, DATAACCESS and system DBADM authorities cannot be passed to others. If WITH GRANT OPTION is used when granting these authorities, a warning is issued and the named authorities are granted, but without GRANT authority.

Notes
For more on DB2 privileges, read DB2 Administration Guide.

A grant is the granting of a specific privilege by a specific grantor to a specific grantee. The grantor for a given GRANT statement is the authorization ID for the privilege set; that is, the SQL authorization ID of the process or a role, or the authorization ID of the owner of the plan or package. Grant statements that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the grantor being the role that is in effect. If the statement is prepared dynamically, the grantor is the role that is associated with the ID that is running the statement. If the statement is embedded in an application program that was bound in a trusted context that was defined with the ROLE AS OBJECT OWNER clause the owner of the plan or package is a role which is the grantor. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the grantor is the authorization ID of the process.

The grantee, as recorded in the catalog, is an authorization ID or PUBLIC.

Duplicate grants from the same grantor are not recorded in the catalog. Otherwise, the result of executing a GRANT statement is recorded as one or more grants in the current server’s catalog.

If more than one privilege or authorization-name is specified after the TO keyword and one of the grants is in error, execution of the statement is stopped and no grants are made. The status of the privilege or privileges granted is recorded in the catalog for each authorization-name.

Different grantors can grant the same privilege to a single grantee. The grantee retains that privilege as long as one or more of those grants are recorded in the
catalog. Privileges that imply other privileges are also termed *authorities*. Grants are removed from the catalog by executing SQL REVOKE statements.

Whenever a grant is made for a database, distinct type, package, plan, schema, stored procedure, table, trigger, user-defined function, view, or USE privilege for an object that does not exist, an SQL return code is issued and the grant is not made.

The grantee, as recorded in the catalog for PUBLIC AT ALL LOCATIONS is PUBLIC*.
GRANT (collection privileges)

This form of the GRANT statement grants privileges on collections.

Syntax

```
GRANT [CREATE | PACKADM] ON COLLECTION collection-id,... TO authorization-name
```

- CREATE IN
  - Grants the privilege to use the BIND subcommand to create packages in the designated collections.
  - The word ON can be used instead of IN.

- PACKADM ON
  - Grants package administrator authority for the designated collections.
  - The word IN can be used instead of ON.

- COLLECTION collection-id,...
  - Identifies the collections on which the specified privilege is granted. The collections do not have to exist.

- COLLECTION *
  - Indicates that the specified privilege is granted on all collections including those that do not currently exist.

- TO
  - Refer to "GRANT" on page 1760 for a description of the TO clause.

- WITH GRANT OPTION
  - Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.

Examples

**Example 1:** Grant the privilege to create new packages in collections QAACLONE and DSN8CC61 to CLARK.

```
GRANT CREATE IN COLLECTION QAACLONE, DSN8CC61 TO CLARK;
```

**Example 2:** Grant the privileges to create new packages in collection DSN8CC91 to role ROLE1:

```
GRANT CREATE IN COLLECTION DSN8CC91 TO ROLE ROLE1;
```
GRANT (database privileges)

This form of the GRANT statement grants privileges on databases.

Syntax

```
GRANT
  DBADM
  DBCTRL
  DBMAINT
  CREATETAB
  CREATETS
  DISPLAYDB
  DROP
  IMAGCOPY
  LOAD
  RECOVERDB
  REORG
  REPAIR
  STARTDB
  STATS
  STOPDB
ON DATABASE database-name
TO authorization-name
  ROLE role-name
  PUBLIC
WITH GRANT OPTION
```

Description

Each keyword listed grants the privilege described, but only as it applies to or within the databases named in the statement.

DBADM
Grants the database administrator authority.

DBCTRL
Grants the database control authority.

DBMAINT
Grants the database maintenance authority.

CREATETAB
Grants the privilege to create new tables. To create tables in an implicitly created database, CREATETAB privileges are needed on the DSNDB04 database. For a work file database, PUBLIC implicitly has the CREATETAB privilege (without GRANT authority) to define declared temporary tables; this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

CREATETS
Grants the privilege to create new table spaces.

DISPLAYDB
Grants the privilege to issue the DISPLAY DATABASE command.
DROP
Grants the privilege to issue the DROP or ALTER DATABASE statements for
the designated databases.

IMAGCOPY
Grants the privilege to run the COPY, MERGECOPY, and QUIESCE utilities
against table spaces of the specified databases, and to run the MODIFY
RECOVERY utility.

LOAD
Grants the privilege to use the LOAD utility to load tables.

RECOVERDB
Grants the privilege to use the RECOVER and REPORT utilities to recover
table spaces and indexes.

REORG
Grants the privilege to use the REORG utility to reorganize table spaces and
indexes.

REPAIR
Grants the privilege to use the REPAIR and DIAGNOSE utilities.

STARTDB
Grants the privilege to issue the START DATABASE command.

STATS
Grants the privilege to use the RUNSTATS utility to update statistics, the
CHECK utility to test whether indexes are consistent with the data they index,
and the MODIFY STATISTICS utility to delete unwanted statistics history
records from the corresponding catalog tables.

STOPDB
Grants the privilege to issue the STOP DATABASE command.

ON DATABASE database-name,...
Identifies databases on which privileges are to be granted. For each named
database, the grantor must have all the specified privileges with the GRANT
option. Each name must identify a database that exists at the current server.
DSNDB01 must not be identified; however, a grant of a privilege on DSNDB06
implies the granting of the same privilege on DSNDB01 for utility operations
only.

Database privileges granted on DSNDB04 are applicable to all implicitly
created databases. This means that a user with the STOPDB privilege on
DSNDB04 can also stop database objects in any implicitly created database.
Similarly, having DBADM on DSNDB04 allows access to all tables in all
implicitly created databases. However, having a database privilege on
DSNDB04 does not allow granting of this privilege on an implicitly created
database to others.

TO
Refer to “GRANT” on page 1760 for a description of the TO clause.

WITH GRANT OPTION
Refer to “GRANT” on page 1760 for a description of the WITH GRANT
OPTION clause.

Examples

Example 1: Grant drop privileges on database DSN8D11A to user PEREZ.
GRANT DROP
  ON DATABASE DSN8D11A
  TO PEREZ;

Example 2: Grant repair privileges on database DSN8D11A to all local users.

GRANT REPAIR
  ON DATABASE DSN8D11A
  TO PUBLIC;

Example 3: Grant authority to create new tables and load tables in database
DSN8D11A to users WALKER, PIANKA, and FUJIMOTO, and give them grant
privileges.

GRANT CREATETAB,LOAD
  ON DATABASE DSN8D11A
  TO WALKER,PIANKA,FUJIMOTO
  WITH GRANT OPTION;

Example 4: Grant load privileges to database DSN9D91A to role ROLE1:

GRANT LOAD
  ON DATABASE DSN9D91A
  TO ROLE ROLE1;
GRANT (function or procedure privileges)

This form of the GRANT statement grants privileges on user-defined functions, cast functions that are generated for distinct types, array types, and stored procedures.

Syntax

```
GRANT EXECUTE ON /SM590000/SM590000 /
  FUNCTION function-name () ,
  parameter-type * ,
  SPECIFIC FUNCTION specific-name ,
  PROCEDURE procedure-name * ,
  TO authorization-name
  ROLE role-name
  PUBLIC
  WITH GRANT OPTION

Notes:
1   AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
```

data-type:
Description

EXECUTE
Grants the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.
FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the privilege is granted. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

FUNCTION function-name

Identifies the function by its name. The function-name must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An * can be specified for a qualified or unqualified function-name. An * (or schema-name.*) indicates that the privilege is granted on all the functions in the schema including those that do not currently exist. SYSADM authority is required if an * (or schema-name.*) is specified. Specifying an * does not affect any EXECUTE privileges that are already granted on a function.

FUNCTION function-name (parameter-type,...)

Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If function-name () is specified, the function identified must have zero parameters.

function-name

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION function-name.

(parameter-type,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

• Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For
example, DEC() will be considered a match for a parameter of a
function defined with a data type of DEC(7,2). Similarly,
DECFLOAT() will be considered a match for DECFLOAT(16) or
DECFLOAT(34). However, FLOAT cannot be specified with empty
parenthesis because its parameter value indicates a specific data type
(REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is
  specified, the value must exactly match the value that was specified
  (implicitly or explicitly) in the CREATE FUNCTION statement. If the
data type is FLOAT, the precision does not have to exactly match the
value that was specified because matching is based on the data type
(REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty
  parentheses are not specified, the default attributes of the data type
  are implied. The implicit length must exactly match the value that
  was specified (implicitly or explicitly) in the CREATE FUNCTION
  statement.

For data types with a subtype or encoding scheme attribute, specifying
the FOR subtype DATA clause or the CCSID clause is optional.
Omission of either clause indicates that DB2 ignores the attribute when
determining whether the data types match. If you specify either clause,
it must match the value that was implicitly or explicitly specified in the
CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this
parameter. If AS LOCATOR is specified, the data type must be a LOB
or a distinct type based on a LOB.

**SPECIFIC FUNCTION** *specific-name*

Identifies the function by its specific name. The *specific-name* must identify
a specific function that exists at the current server.

**PROCEDURE** *procedure-name*

Identifies a stored procedure that is defined at the current server. The name,
including the implicit or explicit schema name, must identify a stored
procedure that exists at the current server.

An * can be specified for a qualified or unqualified *procedure-name*. An * (or
*schema-name.*) indicates that the privilege is granted on all the stored
procedures in the schema including those that do not currently exist.
Specifying an * does not affect any EXECUTE privileges that are already
granted on a stored procedure.

**TO**

Refer to “GRANT” on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to “GRANT” on page 1760 for a description of the WITH GRANT
OPTION clause.

**Examples**

*Example 1:* Grant the EXECUTE privilege on function CALC_SALARY to user
JONES. Assume that there is only one function in the schema with function name
CALC_SALARY.

```
GRANT EXECUTE ON FUNCTION CALC_SALARY TO JONES;
```
Example 2: Grant the EXECUTE privilege on procedure VACATION_ACCR to all users at the current server.

   GRANT EXECUTE ON PROCEDURE VACATION_ACCR TO PUBLIC;

Example 3: Grant the EXECUTE privilege on function DEPT_TOTALS to the administrative assistant and give the assistant the ability to grant the EXECUTE privilege on this function to others. The function has the specific name DEPT85_TOT. Assume that the schema has more than one function that is named DEPT_TOTALS.

   GRANT EXECUTE ON SPECIFIC FUNCTION DEPT85_TOT TO ADMIN_A
       WITH GRANT OPTION;

Example 4: Grant the EXECUTE privilege on function NEW_DEPT_HIRES to HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW_DEPT_HIRES.

   GRANT EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
       TO HR;

You can also code the CHAR(10) data type as CHAR().

Example 5: Grant the EXECUTE privilege on function FIND_EMPDEPT to role ROLE1:

   GRANT EXECUTE ON FUNCTION FIND_EMPDEPT TO ROLE ROLE1;
GRANT (package privileges)

This form of the GRANT statement grants privileges on packages.

Syntax

```
GRANT ALL, BIND, COPY, EXECUTE ON PACKAGE collection-id.package-name
, collection-id.* TO authorization-name
[ ROLE role-name ] [ PUBLIC ]
```

Description

**BIND**

Grants the privilege to use the BIND and REBIND subcommands for the designated packages.

The BIND package privilege can also be used to allow a user to add a new version of an existing package. For details on the authorization required to create new packages and new versions of existing packages, see "Notes" on page 1774.

**COPY**

Grants the privilege to use the COPY option of the BIND subcommand for the designated packages.

**EXECUTE**

Grants the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

**ALL**

Grants all package privileges for which you have GRANT authority for the packages named in the ON clause.

**ON PACKAGE collection-id.package-name,...**

Identifies packages for which you are granting privileges. The granting of a package privilege applies to all versions of a package. The list can simultaneously contain items of the following two forms:

- `collection-id.package-name` explicitly identifies a single package. The name must identify a package that exists at the current server.
- `collection-id.*` applies to every package in the indicated collection. This includes packages that currently exist and future packages. The grant applies
to a collection at the current server, but the *collection-id* does not have to identify a collection that exists when the grant is made.

To grant a privilege in this form requires PACKADM with the WITH GRANT OPTION over the collection or all collections, SYSADM, or SYSCTRL authority. Because of this fact, WITH GRANT OPTION, if included in the statement, is ignored for grants of this form, but not for grants for specific packages.

**TO** Refer to “GRANT” on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
Refer to “GRANT” on page 1760 for a description of the WITH GRANT OPTION clause.

**Notes**

The authorization required to add a new package or a new version of an existing package depends on the value of field BIND NEW PACKAGE on installation panel DSNTIPP. The default value is BINDADD.

If the value of BIND NEW PACKAGE is BINDADD, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

If the value of BIND NEW PACKAGE is BIND, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- PACKADM authority for the collection or for all collections
- Users with the BIND package privilege can also add a new version of an existing package

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports specifying PROGRAM as a synonym for PACKAGE.

**Examples**

*Example 1:* Grant the privilege to copy all packages in collection DSN8CC61 to LEWIS.

```
GRANT COPY ON PACKAGE DSN8CC61.* TO LEWIS;
```

*Example 2:* You have the BIND privilege with GRANT authority over the package CLCT1_PKG1. You have the EXECUTE privilege with GRANT authority over the package CLCT2_PKG2. You have no other privileges with GRANT authority over any package in the collections CLCT1 AND CLCT2. Hence, the following statement, when executed by you, grants LEWIS the BIND privilege on CLCT1_PKG1 and the EXECUTE privilege on CLCT2_PKG2, and makes no other grant. The privileges granted include no GRANT authority.

```
GRANT ALL ON PACKAGE CLCT1_PKG1, CLCT2_PKG2 TO JONES;
```
Example 3: Grant the privileges to run all packages in collection DSN9CC13 to role ROLE1:

GRANT EXECUTE ON PACKAGE DSN9CC13.* TO ROLE ROLE1;
GRANT (plan privileges)

This form of the GRANT statement grants privileges on plans.

Syntax

```
GRANT BIND ON PLAN plan-name TO authorization-name

GRANT EXECUTE ON PLAN plan-name TO authorization-name

GRANT ON PLAN plan-name TO authorization-name

GRANT ON PLAN plan-name TO PUBLIC

GRANT ON PLAN plan-name TO ROLE role-name

WITH GRANT OPTION
```

Description

**BIND**

Grants the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans. (The authority to create new plans using BIND ADD is a system privilege.)

**EXECUTE**

Grants the privilege to run programs that use the identified plans.

**ON PLAN plan-name,**...

Identifies the application plans on which the privileges are granted. For each identified plan, you must have all specified privileges with the GRANT option.

**TO**

Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.

Examples

*Example 1:* Grant the privilege to bind plan DSN8IP11 to user JONES.

```
GRANT BIND ON PLAN DSN8IP11 TO JONES;
```

*Example 2:* Grant privileges to bind and execute plan DSN8CP11 to all users at the current server.

```
GRANT BIND,EXECUTE ON PLAN DSN8CP11 TO PUBLIC;
```

*Example 3:* Grant the privilege to execute plan DSN8CP11 to users ADAMSON and BROWN with grant option.

```
GRANT EXECUTE ON PLAN DSN8CP11 TO ADAMSON,BROWN WITH GRANT OPTION;
```

*Example 4:* Grant the privileges to bind the DSN91PLN plan to role ROLE1:

```
GRANT BIND ON PLAN DSN91PLN TO ROLE ROLE1;
```
GRANT (schema privileges)

This form of the GRANT statement grants privileges on schemas.

Syntax

```
GRANT
  ALTERIN
  CREATEIN
  DROPIN
ON SCHEMA
  schema-name
TO
  authorization-name
  ROLE role-name
  PUBLIC
WITH GRANT OPTION
```

Description

**ALTERIN**
Grants the privilege to alter stored procedures and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**CREATEIN**
Grants the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**DROPIN**
Grants the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**SCHEMA schema-name**
Identifies the schemas on which the privilege is granted. The schemas do not need to exist when the privilege is granted.

**SCHEMA * **
Indicates that the specified privilege is granted on all schemas including those that do not currently exist.

**TO**
Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.

Notes

**Grant on SYSPUBLIC:**
Privileges can be granted on the reserved schema SYSPUBLIC. Granting CREATEIN privilege allows the user to create a public alias and granting DROPIN privilege allows the user to drop any public alias.
Examples

Example 1: Grant the CREATEIN privilege on schema T_SCORES to user JONES.

    GRANT CREATEIN ON SCHEMA T_SCORES TO JONES;

Example 2: Grant the CREATEIN privilege on schema VAC to all users at the current server.

    GRANT CREATEIN ON SCHEMA VAC TO PUBLIC;

Example 3: Grant the ALTERIN privilege on schema DEPT to the administrative assistant and give the grantee the ability to grant ALTERIN privileges on this schema to others.

    GRANT ALTERIN ON SCHEMA DEPT TO ADMIN_A
    WITH GRANT OPTION;

Example 4: Grant the CREATEIN, ALTERIN, and DROPIN privileges on schemas NEW_HIRE, PROMO, and RESIGN to HR (Human Resources).

    GRANT CREATEIN, ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN TO HR;

Example 5: Grant the ALTERIN privileges on the EMPLOYEE schema to role ROLE1:

    GRANT ALTERIN ON SCHEMA EMPLOYEE TO ROLE ROLE1;
**GRANT (sequence privileges)**

This form of the GRANT statement grants privileges on a user-defined sequence.

**Syntax**

```
GRANT ALTER ON SEQUENCE sequence-name (1)
    USAGE
    TO authorization-name
    ROLE role-name
    PUBLIC
    WITH GRANT OPTION
```

**Notes:**

1. The keyword SELECT is an alternative keyword for USAGE.

**Description**

**ALTER**

Grants the privilege to alter a sequence or record a comment on a sequence.

**USAGE**

Grants the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

**SEQUENCE sequence-name**

Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. *sequence-name* must not be the name of an internal sequence object that is used by DB2.

**TO**

Refer to “GRANT” on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to “GRANT” on page 1760 for a description of the WITH GRANT OPTION clause.

**Examples**

*Example 1:* Grant USAGE privilege on sequence MYNUM to user JONES.

```
GRANT USAGE
    ON SEQUENCE MYNUM
    TO JONES;
```

*Example 2:* Grant USAGE privileges on sequence ORDER_SEQ to role ROLE1:

```
GRANT USAGE ON SEQUENCE ORDER_SEQ TO ROLE ROLE1;
```
GRANT (system privileges)

This form of the GRANT statement grants system privileges.

Syntax

```sql
GRANT ACCESSCTRL
  (1) WITH ACCESSCTRL
  WITH DATAACCESS
  (2)
  TO authorization-name
    ROLE role-name
    PUBLIC
    WITH GRANT OPTION
ON SYSTEM
```

Notes:
1. The ACCESSCTRL and DATAACCESS clauses can be specified in any order.
2. The WITH GRANT OPTION can be specified but is ignored for DBADM, DATAACCESS, and ACCESSCTRL.

Description

**ACCESSCTRL**

Grants the ACCESSCTRL authority. ACCESSCTRL allows the user to grant all authorities and privileges, except system DBADM, DATAACCESS, ACCESSCTRL, and privileges on security related objects.
A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

ACCESSCTRL cannot be granted to PUBLIC.

**ARCHIVE**
Grants the privilege to use the ARCHIVE LOG and SET LOG commands.

**BINDADD**
Grants the privilege to create plans and packages by using the BIND subcommand with the ADD option.

**BINDAGENT**
Grants the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A warning is issued if WITH GRANT OPTION is specified when granting this privilege.

**BSDS**
Grants the privilege to issue the RECOVER BSDS command.

**CREATEALIAS**
Grants the privilege to use the CREATE ALIAS statement.

**CREATEDBA**
Grants the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

**CREATEDBC**
Grants the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

**CREATESG**
Grants the privilege to create new storage groups.

**CREATETMTAB**
Grants the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

**CREATE_SECURE_OBJECT**
Grants the privilege to create a secure object.

**DATAACCESS**
Grants the DATAACCESS authority. DATAACCESS allows the user to access data in all user tables, views, and materialized query tables in a DB2 subsystem and allows the user to execute plans, packages, functions, and procedures.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DATAACCESS cannot be granted to PUBLIC.

**DBADM**
Grants the DBADM authority. DBADM allows the user to manage all objects in the DB2 subsystem, except security objects.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DBADM cannot be granted to PUBLIC.
WITH ACCESSCTRL
Specifies that the ACCESSCTRL authority is granted along with the system
DBADM authority. ACCESSCTRL allows system DBADM to grant all
authorities and privileges, except system DBADM, DATAACCESS,
ACCESSCTRL authorities and privileges on security related objects.
ACCESSCTRL can be used to REVOKE privileges using the BY clause.

WITH ACCESSCTRL is the default.

WITHOUT ACCESSCTRL
Specifies that system DBADM authority is not granted the ACCESSCTRL
authority.

WITH DATAACCESS
Specifies that the DATAACCESS authority is granted along with the
system DBADM authority. DATAACCESS allows the system DBADM to
access data in all user tables, views, and materialized query tables in a DB2
subsystem and allows the user to execute plans, packages, functions, and
procedures.

WITH DATAACCESS is the default.

WITHOUT DATAACCESS
Specifies that system DBADM authority is not granted the DATAACCESS
authority.

DISPLAY
Grants the privilege to use the following commands:
- The DISPLAY ARCHIVE command for archive log information
- The DISPLAY BUFFERPOOL command for the status of buffer pools
- The DISPLAY DATABASE command for the status of all databases
- The DISPLAY LOCATION command for statistics about threads with a
distributed relationship
- The DISPLAY LOG command for log information, including the status of the
  offload task
- The DISPLAY THREAD command for information on active threads within
  DB2
- The DISPLAY TRACE command for a list of active traces

DEBUGSESSION
Grants the privilege to attach a debug client to the current application process
connection, which enables client application debugging of native SQL or Java
procedures that are executed within the session.

EXPLAIN
Grants the privilege to issue the following without requiring the privileges
needed to execute the statement:
- EXPLAIN statement with the options:
  - PLAN
  - ALL
- PREPARE statement
- DESCRIBE TABLE statement
- Explain dynamic SQL statements that execute under the special register
  CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE =
  EXPLAIN
- BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)
EXPLAIN(ONLY) allows to explain the statements.
SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements that are being bound.

**MONITOR1**
Grants the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

**MONITOR2**
Grants the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. Users with MONITOR2 privileges have MONITOR1 privileges.

**RECOVER**
Grants the privilege to issue the RECOVER INDOUBT command.

**SQLADM**
Grants the authority to perform the following actions without requiring any additional privileges:
- DESCRIBE TABLE statement
- EXPLAIN statement with the following options:
  - PLAN
  - ALL
  - STMTCACHE ALL
  - STMTID
  - STMTTOKEN
  - MONITORED STMTS
- PREPARE statement
- Explain dynamic SQL statements that execute under the special register CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE = EXPLAIN
- BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)
  EXPLAIN(ONLY) allows to explain the statements.
  SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements that are being bound.
- START command
- STOP command
- DISPLAY PROFILE command
- Execute the RUNSTATS utility and the MODIFY STATISTICS utility in any database.
- MONITOR2 privilege to obtain IFC data classified as containing potentially sensitive data, such as SQL statement text and audit data, as well as IFC data classified as serviceability data, statistics, accounting, and other performance data.

**STOPALL**
Grants the privilege to issue the STOP DB2 command.

**STOSPACE**
Grants the privilege to use the STOSPACE utility.

**SYSADM**
Grants all DB2 privileges except for a few reserved for installation SYSADM authority. The privileges the user possesses are all grantable, including the
SYSADM authority itself. The privileges the user lacks restrict what the user can do with the directory and the catalog. Using WITH GRANT OPTION when granting SYSADM is redundant but valid. For more on SYSADM and installation SYSADM authority, see *DB2 Administration Guide*.

**SYSCTRL**
Grants the system control authority, which allows the user to have most of the privileges of a system administrator but excludes the privileges to read or change user data. Using WITH GRANT OPTION when granting SYSCTRL is redundant but valid. For more information on SYSCTRL authority, see *DB2 Administration Guide*.

**SYSOPR**
Grants the privilege to have system operator authority.

**TRACE**
Grants the privilege to issue the MODIFY TRACE, START TRACE, and STOP TRACE commands.

**TO** Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
If you grant the SYSADM or SYSCTRL system privilege, WITH GRANT OPTION is valid but unnecessary. It is unnecessary because whoever is granted SYSADM or SYSCTRL has that authority and all the privileges it implies, with the GRANT option.

**Examples**

*Example 1:* Grant DISPLAY privileges to user LUTZ.

```
GRANT DISPLAY
TO LUTZ;
```

*Example 2:* Grant BSDS and RECOVER privileges to users PARKER and SETRIGHT, with the WITH GRANT OPTION.

```
GRANT BSDS,RECOVER
TO PARKER,SETRIGHT
WITH GRANT OPTION;
```

*Example 3:* Grant TRACE privileges to all local users.

```
GRANT TRACE
TO PUBLIC;
```

*Example 4:* Grant ARCHIVE privileges to role ROLE1:

```
GRANT ARCHIVE TO ROLE ROLE1;
```

*Example 5:* SECADM Linda grants the privilege to Steve to create a secure object:

```
GRANT CREATE_SECURE_OBJECT
TO STEVE;
```

*Example 6:* Grant system DBADM with ACCESSCTRL and with DATAACCESS to role, ADMINROLE and authid, SALLY. Since GRANT system DBADM also grants ACCESSCTRL and DATAACCESS by default, WITH ACCESSCTRL and WITH DATAACCESS clauses need not be specified explicitly.

```
GRANT DBADM ON SYSTEM
TO ROLE ADMINROLE;
GRANT DBADM, ACCESSCTRL, DATAACCESS
ON SYSTEM
TO SALLY;
```
Example 7: Grant system DBADM without ACCESSCTRL and without DATAACCESS to John. The WITHOUT ACCESSCTRL and WITHOUT DATAACCESS clauses need to be specified explicitly.

```
GRANT DBADM WITHOUT ACCESSCTRL
   WITHOUT DATAACCESS
ON SYSTEM
TO JOHN;
```

GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables and views.

Syntax

```
GRANT

PRIVILEGES

ALL,

ALTER

DELETE

INDEX

INSERT

REFERENCES,

(column-name)

SELECT

TRIGGER

UPDATE,

(column-name)

ON

table-name

view-name

TO

authorization-name

ROLE role-name

PUBLIC

WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants all table or view privileges for which you have GRANT authority, for
the tables and views named in the ON clause.

If you do not use ALL, you must use one or more of the keywords in the
following list. For each keyword that you use, you must have GRANT
authority for that privilege on every table or view identified in the ON clause.

**ALTER**

Grants the privilege to alter the specified table or create a trigger on the
specified table. ALTER cannot be used if the statement identifies an auxiliary
table or a view.

**DELETE**

Grants the privilege to delete rows in the specified table or view. DELETE
cannot be granted on an auxiliary table.

**INDEX**

Grants the privilege to create an index on the specified table. INDEX cannot be
granted on a view.
**INSERT**
Grants the privilege to insert rows into the specified table or view. INSERT cannot be granted on an auxiliary table.

**REFERENCES**
Grants the privilege to add a referential constraint in which the specified table is a parent. If a list of column names is not specified or if REFERENCES is granted via the specification of ALL PRIVILEGES, the grantee can define referential constraints using all columns of the table as a parent key, even those added later via the ALTER TABLE statement. This privilege cannot be granted on a view or auxiliary table.

**REFERENCES(column-name,...)**
Grants the privilege to add or drop a referential constraint in which the specified table is a parent using only those columns that are specified in the column list as a parent key. Each column-name must be an unqualified name that identifies a column of the table identified in the ON clause. This privilege cannot be granted on a view or auxiliary table.

**SELECT**
Grants the privilege to create a view or read data from the specified table or view. SELECT cannot be granted on an auxiliary table.

**TRIGGER**
Grants the privilege to create a trigger on the specified table. TRIGGER cannot be granted on an auxiliary table or a view.

**UPDATE**
Grants the privilege to update rows in the specified table or view. UPDATE cannot be granted on an auxiliary table.

**UPDATE(column-name,...)**
Grants the privilege to update only the columns named. Each column-name must be the unqualified name of a column of every table or view identified in the ON clause. Each column-name must not identify a column of an auxiliary table.

**ON table-name or view-name**
Specifies the tables or views on which you are granting the privileges. The list can be a list of table names or view names, or a combination of the two. A declared temporary table and a table that is implicitly created for an XML column must not be identified.

If you use GRANT ALL, then for each named table or view, the privilege set (described in “Authorization” on page 1760 in “GRANT” on page 1760) must include at least one privilege with the GRANT option.

**TO**
Refer to “GRANT” on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
Refer to “GRANT” on page 1760 for a description of the WITH GRANT OPTION clause.

**Notes**

The REFERENCES privilege does not replace the ALTER privilege. It was added to conform to the SQL standard. To define a foreign key that references a parent table, you must have either the REFERENCES or the ALTER privilege, or both.
For a created temporary table, only ALL or ALL PRIVILEGES can be granted. Specific table privileges cannot be granted. In addition, only the ALTER, DELETE, INSERT, and SELECT privileges apply to a created temporary table.

For a view of a created temporary table, either ALL or the specific UPDATE, DELETE, INSERT and SELECT privileges can be granted. When ALL is specified only the UPDATE, DELETE, INSERT, and SELECT privileges apply to a view on created temporary table. However, the UPDATE operation of the view is not allowed.

To grant table privileges on a created temporary table, the privilege set must include one of the following:
- SYSADM
- DBADM on DSNDB06
- Ownership of the created temporary table

To grant table privileges on a view of a created temporary table, the privilege set must include one of the following:
- SYSADM
- ownership of the created temporary table

For a declared temporary table, no privileges can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the DB2 catalog, and they cannot be revoked.

For an auxiliary table, only the INDEX privilege can be granted. DELETE, INSERT, SELECT, and UPDATE privileges on the base table that is associated with the auxiliary table extend to the auxiliary table.
- ALTER
- INDEX
- REFERENCES
- TRIGGER

Examples

Example 1: Grant SELECT privileges on table DSN8B10.EMP to user PULASKI.
   GRANT SELECT ON DSN8B10.EMP TO PULASKI;

Example 2: Grant UPDATE privileges on columns EMPNO and WORKDEPT in table DSN8B10.EMP to all users at the current server.
   GRANT UPDATE (EMPNO, WORKDEPT) ON TABLE DSN8B10.EMP TO PUBLIC;

Example 3: Grant all privileges on table DSN8B10.EMP to users KWAN and THOMPSON, with the WITH GRANT OPTION.
   GRANT ALL ON TABLE DSN8B10.EMP TO KWAN, THOMPSON WITH GRANT OPTION;

Example 4: Grant the SELECT and UPDATE privileges on the table DSN8B10.DEPT to every user in the network.
   GRANT SELECT, UPDATE ON TABLE DSN8B10.DEPT TO PUBLIC;
Even with this grant, it is possible that some network users do not have access to
the table at all, or to any other object at the subsystem where the table exists.
Controlling access to the subsystem involves the communications databases at the
subsystems in the network. The tables for the communication databases are
described in "DB2 catalog tables" on page 2167. Controlling access is described in
DB2 Administration Guide.

Example 5: Grant ALTER privileges on table DSN9910.EMP to role ROLE1:

  GRANT ALTER ON TABLE DSN9910.EMP TO ROLE ROLE1;
GRANT (type or JAR file privileges)

This form of the GRANT statement grants the privilege to use distinct types, array types, or JAR files.

Syntax

```
GRANT USAGE ON TYPE type-name, JAR jar-name, TO authorization-name
  [ROLE role-name | PUBLIC]
  WITH GRANT OPTION
```

Description

**USAGE**

Grants the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

**TYPE type-name**

Identifies the user-defined type. The name, including the implicit or explicit schema name, must identify a unique user-defined type that exists at the current server.

**JAR jar-name**

Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

**TO**

Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.

Notes

*Alternative syntax and synonyms: To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.*

Examples

*Example 1:* Grant the USAGE privilege on distinct type SHOE_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE_SIZE.

```
GRANT USAGE ON TYPE SHOE_SIZE TO JONES;
```

*Example 2:* Grant the USAGE privilege on distinct type US_DOLLAR to all users at the current server.

```
GRANT USAGE ON TYPE US_DOLLAR TO JONES;
```
GRANT USAGE ON TYPE US_DOLLAR TO PUBLIC;

Example 3: Grant the USAGE privilege on distinct type CANADIAN_DOLLAR to the administrative assistant (ADMIN_A), and give this user the ability to grant the USAGE privilege on the distinct type to others. The administrative assistant cannot grant the privilege to execute the cast functions that are associated with the distinct type CANADIAN_DOLLAR because WITH GRANT OPTION does not give the administrative assistant the EXECUTE authority on these cast functions.

    GRANT USAGE ON TYPE CANADIAN_DOLLAR TO ADMIN_A
    WITH GRANT OPTION;

Example 4: Grant the USAGE privilege on the distinct type MILES to role ROLE1 at the current server:

    GRANT USAGE ON TYPE MILES
    TO ROLE ROLE1;
GRANT (variable privileges)

This form of the GRANT statement grants privileges on global variables.

Syntax

```
GRANT PRIVILEGES
    ON VARIABLE variable-name
    TO authorization-name
    WITH GRANT OPTION
```

Description

**ALL PRIVILEGES**
Grants both READ and WRITE privileges on the specified global variable.

**READ**
Grants the privilege to access the content of the specified global variable.

**WRITE**
Grants the privilege to modify the content of the specified global variable.

**ON VARIABLE variable-name**
Identifies the global variable for which you are granting privileges.
`variable-name`, including an implicit or explicit qualifier, must identify a global variable that exists at the current server.

**TO**
Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.

Examples

Example 1: Grant the read privilege on the ACCOUNTNO variable on the current server to user Jones:

```
GRANT READ ON VARIABLE ACCOUNTNO TO JONES;
```
GRANT (use privileges)

This form of the GRANT statement grants authority to use particular buffer pools, storage groups, or table spaces.

Syntax

```
GRANT USE OF

BUFFERPOOL bpname
ALL BUFFERPOOLS
STOGROUP stogroup-name
TABLESPACE database-name.table-space-name

TO authorization-name
ROLE role-name
PUBLIC
WITH GRANT OPTION
```

Description

**BUFFERPOOL bpname,**...
Grants the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See "Naming conventions" on page 59 for more details about `bpname`.

**ALL BUFFERPOOLS**
Grants the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**STOGROUP stogroup-name,**...
Grants the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**TABLESPACE database-name.table-space-name,**...
Grants the privilege to refer to any of the identified table spaces in a CREATE TABLE statement. The default for `database-name` is DSNDB04.

You cannot grant the privilege for table spaces that are for declared temporary tables (table spaces in a work file database). For these table spaces, PUBLIC implicitly has the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**TO**
Refer to "GRANT" on page 1760 for a description of the TO clause.

**WITH GRANT OPTION**
Refer to "GRANT" on page 1760 for a description of the WITH GRANT OPTION clause.
Notes

You can grant privileges for only one type of object with each statement. Thus, you can grant the use of several table spaces with one statement, but not the use of a table space and a storage group. For each object you identify, you must have the USE privilege with GRANT authority.

Examples

Example 1: Grant authority to use buffer pools BP1 and BP2 to user MARINO.

```
GRANT USE OF BUFFERPOOL BP1,BP2
  TO MARINO;
```

Example 2: Grant to all local users the authority to use table space DSN8S11D in database DSN8D11A.

```
GRANT USE OF TABLESPACE
  DSN8D11A.DSN8S11D
  TO PUBLIC;
```

Example 3: Grant authority to use storage group SG1 to role ROLE1:

```
GRANT USE OF STOGROUP SG1
  TO ROLE ROLE1;
```
HOLD LOCATOR

The HOLD LOCATOR statement allows a LOB locator variable to retain its association with a value beyond a unit of work.

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement.

Authorization

None required.

Syntax

```
HOLD LOCATOR
```

Description

*host-variable*, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been held and others have not been held.

Notes

A host-variable LOB locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement is executed.
- The SQL session is terminated.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the
values represented by the columns. Give the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC the hold property.

```
EXEC SQL HOLD LOCATOR :LOCRES, :LOCHIST, :LOCPIC
```
**INCLUDE**

The INCLUDE statement inserts application code, including declarations and statements, into a source program.

**Invocation**

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

**Authorization**

None required.

**Syntax**

```
INCLUDE SQLCA
SQLDA member-name
```

**Description**

**SQLCA**

Indicates that the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified more than once in the same application program. In COBOL, INCLUDE SQLCA must be specified in the Working-Storage Section or the Linkage Section. INCLUDE SQLCA must not be specified if the program is prepared (either with the DB2 precompiler or coprocessor) with the STDSQL(YES) SQL processing option.

For a description of the SQLCA, see “SQL communication area (SQLCA)” on page 2134.

**SQLDA**

Indicates that the description of an SQL descriptor area (SQLDA) is to be included. It must not be specified in a Fortran. For a description of the SQLDA, see “SQL descriptor area (SQLDA)” on page 2144.

**member-name**

Names a member of the partitioned data set to be the library input when your application program is prepared (either with the DB2 precompiler or coprocessor). It must be an SQL identifier.

The member can contain any host language source statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE member-name must not be specified in other than the Data Division or the Procedure Division.

**Notes**

When your application program is prepared (either with the DB2 precompiler or coprocessor), the INCLUDE statement is replaced by source statements. Thus, the INCLUDE statement must be specified at a point in your application program where the resulting source statements are acceptable to the compiler.
The INCLUDE statement cannot refer to source statements that themselves contain INCLUDE statements.

The declarations that are generated by DCLGEN can be used in an application program by specifying the same member in the INCLUDE statement as in the DCLGEN LIBRARY parameter.

Example

Include an SQL communications area in a PL/I program.

EXEC SQL INCLUDE SQLCA;
The INSERT statement inserts rows into a table or view or activates the INSTEAD OF INSERT trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Inserting a row into a view inserts the row into the table on which the view is based if no INSTEAD OF INSERT trigger is defined on the specified view. If an INSTEAD OF INSERT trigger is defined, the trigger is activated instead of the INSERT statement.

There are three forms of this statement:
- The INSERT via VALUES form is used to insert a single row into the table or view using the values provided or referenced.
- The INSERT via SELECT form is used to insert one or more rows into the table or view using values from other tables, or views, or both.
- The INSERT via FOR n ROWS form is used to insert multiple rows into the table or view using values provided or referenced. Although not required, the values can come from host-variable arrays. This form of INSERT is supported in SQL procedure applications. However, since host-variable arrays are not supported in SQL procedure applications, the support is limited to insertion of scalar values.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which inserts are allowed, or a view:

When a user-defined table is identified: The privilege set must include at least one of the following:
- The INSERT privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:
- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority
- DATAACCESS authority

When a view is identified: The privilege set must include at least one of the following:
- The INSERT privilege on the view
- SYSADM authority
- **DATAACCESS authority**

The owner of a view, unlike the owner of a table, might not have INSERT authority on the view (or can have INSERT authority without being able to grant it to others). The nature of the view itself can preclude its use for INSERT. For more information, see the discussion of authority in [CREATE VIEW](#) on page 1590.

If the INSERT statement is embedded in a SELECT statement, the privilege set must include the SELECT privilege on the table or view.

If a fullselect is specified, the privilege set must include authority to execute the fullselect. For more information about the authorization rules, see [“Authorization”](#) on page 782.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on page 873. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see [“Authorization IDs and dynamic SQL”](#) on page 77.)

**Syntax**

```
INSERT INTO table-name
  
  view-name

  INCLUDE (column-name)

VALUES (expression

  DEFAULT NULL

  (expression

  DEFAULT NULL

  fullselect

  isolation-clause

  QUERYNO integer

  WITH common-table-expression

  multiple-row-insert

OVERRIDDING USER VALUE
```

**include-column:**

```
INCLUDE (column-name data-type)
```

**data-type:**
built-in-type:

```
SMALLINT
  INTEGER
  INT
  BIGINT

DECIMAL
  DEC
  NUMERIC

FLOAT
  (integer)

REAL
  PRECISION

DOUBLE
  PRECISION

DECIMAL
  (integer)

DATE
  TIME
  TIMESTAMP

BINARY
  VARGRAPHIC

CHARACTER
  CHAR
  VARCHAR
  VARYING

GRAPHIC
  VARGRAPHIC

isolation-clause:

WITH RR
  RS
  CS
```
multiple-row-insert:

![Diagram of multiple-row-insert syntax]

Notes:
1. The FOR \( n \) ROWS clause must be specified for a static multiple-row-insert. However, this clause is optional for a dynamic INSERT statement. For a dynamic statement, the FOR \( n \) ROWS clause is specified on the EXECUTE statement.
2. The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clauses can be specified for a static multiple-row-insert. However, this clause must not be specified for a dynamic INSERT statement. For a dynamic statement, the ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is specified as an attribute on the PREPARE statement.

Description

**INTO table-name or view-name**

Identifies the object of the INSERT statement. The name must identify a table or view that exists at the current server. The name must not identify:
- An auxiliary table
- A catalog table
- A read-only view unless an instead of trigger is defined for the insert operation on the view. (For a description of a read-only view, see "CREATE VIEW" on page 1590.)
- A view column that is derived from a constant, expression, or scalar function
- A view column that is derived from the base table column as some other column of the view
- A materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

**column-name,**

Specifies the columns for which insert values are provided. Each name must identify a column of the table or view. The columns can be identified in any order, but the same column must not be identified more than one time. A view column that cannot accept insert values must not be identified. If the object of
the INSERT statement is a view with columns that cannot accept insert values, a list of column names must be specified, and the list must not identify these columns. If a qualifier is specified, it must be valid (that is, the table name must be the table or view name specified after the INTO keyword, and if a qualifier is specified for the table name, it must match the default qualifier).

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

The effect of a rebind on INSERT statements that do not include a column list is that the implicit list of names is re-established. Therefore, the number of columns into which data is inserted can change and cause an error.

**include-column**

Specifies a set of columns that are included, along with the columns of `table-name` or `view-name`, in the result table of the INSERT statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by `table-name` or `view-name`.

**INCLUDE**

Introduces a list of columns that is to be included in the result table of the INSERT statement. The included columns are only available if the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

**column-name**

Specifies the name for a column of the result table of the INSERT statement that is not the same name as another included column nor a column in the table or view that is specified in `table-name` or `view-name`.

**data-type**

Specifies the data type of the included column. The included columns are nullable.

**built-in-type**

Specifies a built-in data type. See the "CREATE TABLE" on page 1446 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

**distinct-type**

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**OVERRIDING USER VALUE**

Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.

If OVERRIDING USER VALUE is specified, the implicit or explicit list of column must include a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT. For example, a ROWID column, an identity column, or a row change timestamp column.
VALUES
Specifies one new row in the form of a list of values. The number of values in
the VALUES clause must be equal to the number of names in the column list
and the columns that are identified in the INCLUDE clause. The first value is
inserted in the first column in the list, the second value in the second column,
and so on. If more than one value is specified, the list of values must be
enclosed in parentheses. Assignments to included columns are only processed
when the INSERT statement is nested in the FROM clause in a SELECT
statement or a SELECT INTO statement.

expression
Any expression of the type described in "Expressions" on page 243. The
expression must not include a column name. If expression is a host variable,
the host variable can identify a structure. Any host variable or structure
that is specified must be described in the application program according to
the rules for declaring host structures and variables.

If expression is a host variable, it can include an indicator variable or an
indicator array (in the case of a host structure). When extended indicator
variables are enabled, an expression must not be more complex than a
reference to a single host variable if the indicator is set to an extended
indicator value of default (-5) or unassigned (-7). In addition:

- A CAST specification can be used if either of the following is true:
  - The target column is defined as nullable.
  - The target column is defined as NOT NULL with a non-null default,
    the source of the CAST specification is a single host variable, and the
data attributes (data type, length, precision, and scale) of the host
variable are the same as the result of the cast specification.
- A scalar fullselect can be used if either of the following is true for each
  expression in the select list of the fullselect:
  - The target column that corresponds to the expression is defined as
    nullable.
  - The expression is not more complex than a reference to a single host
    variable for which the indicator is set to an extended indicator value
    of default (-5) or unassigned (-7), or the expression is a CAST
    specification which would have been valid as a stand-alone
    expression.

DEFAULT
The default value that is assigned to the column. If the column is a
ROWID column, an identity column, a row-begin column, a row-end column,
or a transaction-start-ID column, DB2 will generate a value for the column.
You can specify DEFAULT only for columns that have an assigned default
value, ROWID columns, and identity columns.

For information on default values of data types, see the description of the
DEFAULT clause for "CREATE TABLE" on page 1446.

NULL
Specifies the null value as the value of the column. Specify NULL only for
nullable columns.

If the implicit or explicit list of columns includes a ROWID, an identity
column, or a row change timestamp column that was defined as GENERATED
ALWAYS, you must specify DEFAULT unless you specify the OVERRIDING
USER VALUE clause to indicate that any user-specified value will be ignored
and a unique system-generated value will be inserted.
For a ROWID or identity column that is defined as GENERATED BY DEFAULT, you can specify a value. However, a value can be inserted into ROWID column defined BY DEFAULT only if a single-column unique index is defined on the ROWID column and the specified value is a valid row ID value that was previously generated by DB2. When a value is inserted into an identity column defined BY DEFAULT, DB2 does not verify that the specified value is a unique value for the column unless the identity column has a single-column unique index.

Although an implicitly hidden DOCID column for XML values is defined as GENERATED ALWAYS, you can include the DOCID column in the explicit list of columns and specify a value for it. However, DB2 will ignore the value.

**WITH common-table-expression**

Specifies a common table expression. For an explanation of common table expression, see “common-table-expression” on page 852.

**fullselect**

Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLCODE is set to +100, and SQLSTATE is set to '02000'.

The base object of the INSERT statement and the base object of the fullselect or any subquery of the fullselect can be the same table. In this case, the fullselect is evaluated completely before any rows are inserted.

For an explanation of fullselect, see “fullselect” on page 843.

The number of columns in the result table must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on. Any values that are produced for a generated column must conform to the rules that are described for those columns under the VALUES clause. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

If the expression that specifies the value of a result column is a variable, the host variable can include an indicator variable. When extended indicator variables are enabled, the target column that corresponds to an expression in the select list of the fullselect that involves a host variable with an extended indicator value of default (-5) or unassigned (-7), must be defined as nullable and either of the following expressions:

- The expression must not be more complex than a reference to a single host variable.
- The expression must be a CAST specification with the following characteristics:
  - The source of the CAST specification must be a single host variable.
  - The data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

If the object table is self-referencing, the fullselect must not return more than one row.

**isolation-clause**

Specifies the isolation level that is used when the fullselect is executed.

**WITH**

Introduces the isolation level, which can be one of the following values:

- **RR** Repeatable read
The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**QUERYNO integer**

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information about using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information about accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

**multiple-row-insert**

**VALUES**

Specifies the items for the rows to be inserted. The number of items in the VALUES clause must equal the number of names in the implicit or explicit column list. The first item in the list provides the value (or values) for the first column in the list. The second item in the list provides the value (or values) for the second column, and so on.

**expression**

Any expression of the type described in [“Expressions” on page 243](#). The expression must not include a column name. For each row that is inserted, the corresponding column is assigned the value of the expression.

**host-variable-array**

Each host-variable array must be defined in the application program in accordance with the rules for declaring an array. A host-variable array contains the data for a column of table that is a target of the INSERT. The number of rows to be inserted must be less than or equal to the dimension of each of the host-variable arrays.

An optional indicator array can be specified for each host-variable array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the SQLVAR is nullable. The indicators must be small integers. The indicator array must be large enough to contain an indicator for each row of input data.
If extended indicator variables are enabled, the extended indicator variable values of DEFAULT or UNASSIGNED can be used inside the indicator array.

**DEFAULT**
Specifies that the default value is assigned to the column. For each row inserted, the corresponding column is assigned its default value. DEFAULT can be specified only for columns that have a default value. For information on default values of data types, see the description of the DEFAULT clause for “CREATE TABLE” on page 1446.

**NULL**
Specifies the null value as the value of the column in each row inserted. For each row inserted, the corresponding column is assigned the NULL value. Specify NULL only for nullable columns.

**FOR host-variable or integer-constant ROWS**
Specifies the number of rows to be inserted. For a dynamic INSERT statement, this clause can be specified on the EXECUTE statement. For more information, see the EXECUTE statement. However, this clause is required when a dynamic SELECT statement contains more than one multiple-row INSERT statement.

`host-variable or integer-constant` is assigned to an integral value $k$. If `host-variable` is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. Furthermore, $k$ must be in the range, $0<k<=32767$. $k$ rows are inserted into the target table from the specified source data.

If a parameter marker is specified in this clause, a value must be provided with the USING clause of the associated EXECUTE or OPEN statement.

**ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION**
Specifies whether all of the rows should be inserted as an atomic operation or not.

**ATOMIC**
Specifies that if the insert for any row fails, all changes made to the database by any of the inserts, including changes made by successful inserts, are undone. This is the default.

**NOT ATOMIC CONTINUE ON SQLEXCEPTION**
Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert to complete), including any triggers that might have been executed as a result of the INSERT statement.

This clause is only valid for a static INSERT statement. This clause must also not be specified if the INSERT statement is contained within a SELECT statement. For a dynamic INSERT statement, specify the clause on the PREPARE statement. For more information, see “PREPARE” on page 1846.

**Notes**

**Insert rules:**
Insert values must satisfy the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted and the position of the cursors are not changed.
• **Default values.** The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.

• **Length.** If the insert value of a column is a number, the column must be a numeric column with the capacity to represent the integral part of the number. If the insert value of a column is a string, the column must be either a string column with a length attribute at least as great as the length of the string, or a datetime column if the string represents a date, time, or timestamp.

• **Assignment.** Insert values are assigned to columns in accordance with the assignment rules described in Chapter 2, “Language elements,” on page 55.

• **Uniqueness constraints.** If the identified table or the base table of the identified view has one or more unique indexes, each row inserted into the table must conform to the constraints imposed by those indexes.

• **Referential constraints.** Each nonnull insert value of a foreign key must be equal to some value of the parent key of the parent table in the relationship.

• **Check constraints.** The identified table or the base table of the identified view might have one or more check constraints. Each row inserted must conform to the conditions imposed by those constraints. Thus, each check condition must be true or unknown.

• **Field and validation procedures.** If the identified table or the base table of the identified view has a field or validation procedure, each row inserted must conform to the constraints imposed by that procedure.

• **Indexes with VARBINARY columns.** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

• **Views and the WITH CHECK OPTION.** For views defined with WITH CHECK OPTION, each row you insert into the view must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the inserted rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see **CREATE VIEW** on page 1590.

For views that are not defined with WITH CHECK OPTION, you can insert rows that do not conform to the definition of the view. Those rows cannot appear in the view but are inserted into the base table of the view.

• **Omitting the column list.** When you omit the column list, you must specify a value for every column that was present in the table when the INSERT statement was bound or (for dynamic execution) prepared.

• **Triggers.** An INSERT statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If an INSERT statement for a view activates an INSTEAD OF trigger, the validity, referential integrity, and check constraints are checked against the data changes that are
performed in the trigger, and not against the definition of the view that activates the trigger or the definition of the underlying tables or views.

When triggers are processed for an INSERT statement that inserts multiple rows depends on the atomicity option that is in effect for the INSERT statement:

- **ATOMIC**. The inserts are processed as a single statement. Any statement level triggers are activated one time for the statement, and the transition tables will include all of the rows that were inserted.

- **NOT ATOMIC CONTINUE ON SQLEXCEPTION**. The inserts are processed separately. Any statement level triggers are processed for each row that is inserted, and the transition table includes the individual row that is inserted. When errors are encountered with this option in effect, processing continues, and some of the specified rows will not be inserted. In this case, if an insert trigger is defined on the underlying base table, the statement level triggers will only be activated for rows that were successfully inserted.

Regardless of the failure of any particular source row, the INSERT statement will not undo any changes that are made to the database by the statement. Insert will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

**Inserting XML documents:**

When XML documents are inserted into a table that contains an XML index, the XML values that are inserted into the index are cast to the data type that is specified on the CREATE INDEX statement. If the XML value cannot be cast to the specified data type, the XML value is ignored for the XML index but the document is still inserted into the table. If the data type that is specified for casting is DECIMAL, values can be rounded when they are inserted into the index. If the index is unique, the rounding that happens during the cast can result in duplicate values.

**Number of rows inserted:**

Normally, after an INSERT statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows inserted. The value in SQLERRD(3) does not include the number of rows that were inserted as the result of a trigger.

For a complete description of the SQLCA, including exceptions to the above statement, see “SQL communication area (SQLCA)” on page 2134.

**Nesting user-defined functions or stored procedures:**

An INSERT statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as nesting of SQL statements. A user-defined function or stored procedure that is nested within the INSERT must not access the table into which you are inserting values.

**Locking:**

Unless appropriate locks already exist, one or more exclusive locks are acquired at the execution of a successful insert operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the inserted row. If LOBs are not inserted into the row, application processes that are running with uncommitted read can also access the inserted row. The locks can also prevent other
application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

**Inserting rows into a table with multilevel security:**
When you insert rows into a table with multilevel security, DB2 determines the value for the security label column of the row according to the following rules:

- If the user (the primary authorization ID) has write-down privilege or write-down control is not enabled, the user can set the security label for the row to any valid security label. The value that is specified must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL. If the user does not specify a value for the security label or specifies DEFAULT, the security label of the row becomes the same as the security label of the user.

- If the user does not have write-down privilege and write-down control is enabled, the security label of the row becomes the same as the security label of the user.

**Inserting rows into a table for which row or column access control is enforced:**
When an INSERT statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be inserted. Typically those rules are based on the authorization ID or role of the process. The following rules describe how the enabled row permissions and column masks are used during INSERT:

- A row to be inserted must not be effected by enabled column masks whose columns are referenced while deriving the source values for the row.

When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table is also column access control activated, the column mask that is applied to derive the new values must ensure that the evaluation of the access control rules defined in the column mask resolves the column to itself, not to a constant or to an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert and an error is returned at run time.

If the OVERRIDING USER VALUE clause is specified, the corresponding values in the new row are ignored, and the above rule for column masks is not applicable to those values.

- If the row can be inserted, and there is a BEFORE INSERT trigger for the table, the trigger is activated.

Within the trigger actions, the new values for insert can be modified in the transition variables. When the values return from the trigger, the final values for the new values are the ones for insert.

- A row to be inserted must conform to the enabled row permissions.

When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. A row that conforms to the enabled row permissions is a row that if the row is inserted it can be retrieved back using the row access control search condition.

Column masks are not applicable in this process.
• If the rows can be inserted, and there is an AFTER INSERT trigger for the table, the trigger is activated.

The preceding rules are not applicable to the include-columns. The include-columns are subject to the rules for the select list because they are not the columns of the object table of the INSERT statement.

Extended indicator variable usage:
When extended indicator variables are enabled, negative indicator values that are outside the range of -1 through -7 must not be specified, and the default and unassigned extended indicator values must not be specified in contexts in which they are not supported.

Extended indicator variables:
In an INSERT statement, a value of unassigned has the effect of setting the column to its default value.

Extended indicator variables and insert triggers:
The activation of insert triggers is not affected by the use of extended indicator variables. If all columns in the implicit or explicit column list have been assigned an extended indicator value of unassigned or default, an insert where all columns have their respective default values is attempted, and, if successful, the insert trigger is activated.

Table space data compression during an insert operation:
If the table space is defined with the COMPRESS YES option, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a DB2-determined amount of data has been inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed using the compression dictionary.

Generated columns:
A generated column that is defined as GENERATED ALWAYS should not be specified in the column-list unless the corresponding entry in the VALUES list is DEFAULT or an extended indicator that specifies that a default value is to be assigned. Specify the OVERRIDING USER VALUE clause to indicate that any user-specified value should be ignored and DB2 should assign the default value when a row is inserted.

Inserting rows into system-period temporal tables:
When a row for a system-period temporal table is inserted, DB2 assigns values to the following columns as indicated:
• A row-begin column is assigned a value that is generated by reading the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or a transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures the uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted within a single SQL transaction, the values for the row-begin column are the same for all of the rows and are unique from the values that are generated for the column by another transaction.
• A row-end column is assigned the a value for the data type of the column.
• A transaction-start-ID column is assigned a unique value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated by reading the time-of-day clock during execution of the first data change
statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column by another transaction.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target of the INSERT statement cannot be a system-period temporal table. This restriction applies regardless of whether the system-period temporal table is directly or indirectly referenced.

**Inserting rows into application-period temporal tables:**
When a row is inserted into an application-period temporal table, an error is returned if the period that is defined by the begin column and end column of the application period overlap with the period that is defined by the begin column and end column of the application period for another row in the table.

**Inserting rows into archive-enabled tables:**
You cannot insert rows into an archive-enabled table if the value of the SYSIBMADM.MOVE_TO_ARCHIVE global variable is Y. Otherwise, if this global variable is not set to Y, you can specify an archive-enabled table as the target of the INSERT statement. In this case, the content of the associated archive table is not affected.

A data change statement must not reference an archive-enabled table when a system-period temporal table or application-period temporal table is also referenced.

**INSERT without a column list:**
An INSERT statement without a column list does not include implicitly hidden columns, so columns that are defined as implicitly hidden must have a defined default value.

**Inserting a row into catalog table SYSIBM.SYSSTRINGS:**
If the object table is SYSIBM.SYSSTRINGS, only certain values can be specified, as described in Specifying conversion procedures (DB2 Administration Guide).

**Datetime representation when using datetime registers:**
As explained in Datetime special registers, when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are inserted. When ATOMIC is in effect for the INSERT statement, the special registers are evaluated one time for the processing of the statement. If NOT ATOMIC is in effect, the special registers are evaluated as each row of source data is processed.

**Non-atomic processing of an INSERT statement:**
When NOT ATOMIC is specified the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the INSERT statement are evaluated as each row of source data is processed, Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the execution of an insert of a row, processing continues. The row that was being inserted at the time of the error is not inserted. Execution continues with the next row to be inserted,
and any other changes made during the execution of the multiple-row INSERT statement are not backed out. However, the insert of an individual row is an atomic action.

**Diagnostics information for a multiple-row INSERT statement:**
A single multiple-row INSERT statement might encounter multiple conditions. These conditions can be errors or warnings. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these INSERT statements. See "GET DIAGNOSTICS" on page 1744 for more information.

If a warning occurs during the execution of an insert of a row, processing continues.

When multiple errors or warnings occur with a non-atomic INSERT statement, diagnostic information for each row is available using the GET DIAGNOSTICS statement. The SQLSTATE and SQLCODE reflect a summary of what happened during the INSERT statement:

- **SQLSTATE 01659, SQLCODE +252.** All rows were inserted, but one or more warnings occurred.
- **SQLSTATE 22529, SQLCODE -253.** At least one row was successfully inserted, but one or more errors occurred. Some warnings might also have occurred.
- **SQLSTATE 22530, SQLCODE -254.** No row was inserted. One or more errors occurred while trying to insert multiple rows of data.
- **SQLSTATE 429BI, SQLCODE -20252.** More errors occurred that DB2 is capable of recording. Statement processing is terminated.

When ATOMIC is in effect, if an insert value violates any constraints or if any other error occurs during the execution of an insert of a row, all changes made during the execution of the multiple-row INSERT statement are backed out. The SQLCA reflects the last warning encountered.

After an INSERT statement that inserts multiple rows of data, both atomic and non-atomic, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD3 contains the number of rows actually inserted. SQLERRD3 is the number of rows inserted, if this is less than the number of rows requested, then an error occurred.
- SQLWARN flags are set if they were set during any single insert operation.

The SQLCA is used to return information on errors and warnings found during a multiple-row insert. If indicator arrays are provided, the indicator variable values are used to determine if the value from the host-variable array, or NULL, will be used. The SQLSTATE contains the warning from the last data mapping error.

**Specifying the number of rows for a dynamic multiple-row INSERT statement:**
Be aware of these considerations when specifying the number of rows to be inserted with a dynamic multiple-row INSERT statement that uses host-variable arrays:

- The FOR n ROWS clause can be specified as part of an INSERT statement or as part of an EXECUTE statement, but not both.
In the INSERT statement, you can specify a numeric constant in the FOR n ROWS clause to indicate the number of rows to be inserted or specify a parameter marker to indicate that the number of rows will be specified with the associated EXECUTE or OPEN statement. A multiple-row INSERT statement that is contained within a SELECT statement must include a FOR n ROWS clause.

In an EXECUTE statement, when a dynamic INSERT statement is not contained within a SELECT statement, the number of rows can be specified with either the FOR n ROWS clause or the USING clause of the EXECUTE statement:

- If the INSERT statement did not contain a FOR n ROWS clause, a value for the number of rows to be inserted can be specified in the FOR n ROWS clause of the EXECUTE statement with a numeric constant or host variable.
- If a parameter marker was specified as part of a FOR n ROWS clause in the INSERT statement, a value for the number of rows must be specified with the USING clause of the EXECUTE statement.

In an OPEN statement, when a dynamic SELECT statement contains one or more INSERT statements that have FOR n ROWS clauses with parameter markers, the values for the number of rows to be inserted (that is, the values for the parameter markers) must be specified with the USING clause of the OPEN statement.

**DRDA considerations for a multiple-row INSERT statement:**

DB2 for z/OS limits the size of user data and control information to 10M (except for LOBs, which are processed in a different data stream) for a single multiple-row INSERT statement using host-variable arrays.

Multiple-row insert and fetch statements are supported by any requester or server that supports the DRDA Version 3 protocols. If an attempt is made to issue a multiple-row INSERT or FETCH statement on a server that does not support DRDA Version 3 protocols, an error occurs.

When a multiple-row INSERT statement is executed at a DB2 for z/OS requester, the number of rows being inserted at the requester might not be known in some cases. These cases include:

- The FOR n ROWS clause contains a constant value for n for either a static or dynamic INSERT statement.
- Host variables are specified on the USING clause of an EXECUTE statement for a dynamic INSERT statement.

In either case, if the number of rows that is being inserted is not known, the requester might flow more data than is required to the server. The number of rows that is actually inserted will be correct because the server knows the correct number of rows to insert. However, performance can be adversely affected. Consider the following scenario:

```sql
... long serial_num [10];
struct {
  short len;
  char data [18];
} name [20]
...
EXEC SQL INSERT INTO T1 VALUES (:serial_num, :name) FOR 5 ROWS
```

At the requester, when this statement is executed, the number of rows being inserted, 5, is not known. As a result, the requester will flow 10
values for serial_num and 10 values for name to the server (because the maximum number of rows that can be inserted without error is 10, which is the size of the smallest host-variable array).

Use the following programming techniques to avoid or minimize problems:

- Avoid using constant values for \( n \) in the FOR \( n \) ROWS clause of INSERT statements. For static INSERT statements, this technique ensures that the value for \( n \) will be known at the requester.
- For dynamic INSERT statements, use the USING DESCRIPTOR clause instead of the USING host-variables clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for \( n \) must be indicated in the DESCRIPTOR.
- If neither of the above methods can be used:
  - Declare your host-variable arrays as small as possible, or indicate that the size of your host-variable arrays are the size of \( n \) in your descriptor. This avoids sending large numbers of host-variable-array entries that will not be used to the server.
  - Ensure that varying length string arrays are initialized to a length of 0 (zero). This minimizes the amount of data that is sent to the server.
  - Ensure that decimal host-variable arrays are initialized to valid values. This avoids a negative SQLCODE from being returned if the requester encounters invalid decimal data.

Other SQL statements in the same unit of work:
The following statements cannot follow an INSERT statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)

Examples

**Example 1:** Insert values into sample table DSN8B10.EMP.

```sql
INSERT INTO DSN8B10.EMP
VALUES ('000205','MARY','T','SMITH','D11','2866','1981-08-10','ANALYST',16,'F','1956-05-22',16345,500,2300);
```

**Example 2:** Assume that SMITH.TEMPEMPL is a created temporary table. Populate the table with data from sample table DSN8B10.EMP.

```sql
INSERT INTO SMITH.TEMPEMPL
SELECT * FROM DSN8B10.EMP;
```

**Example 3:** Assume that SESSION.TEMPEMPL is a declared temporary table. Populate the table with data from department D11 in sample table DSN8B10.EMP.

```sql
INSERT INTO SESSION.TEMPEMPL
SELECT * FROM DSN8B10.EMP
WHERE WORKDEPT='D11';
```

**Example 4:** Insert a row into sample table DSN8B10.EMP_PHOTO_RESUME. Set the value for column EMPNO to the value in host variable HV_ENUM. Let the
value for column EMP_ROWID be generated because it was defined with a row ID
data type and with clause GENERATED ALWAYS.

```sql
INSERT INTO DSN8B10.EMP_PHOTO_RESUME(EMPNO, EMP_ROWID)
VALUES (:HV_ENUM, DEFAULT);
```

You can only insert user-specified values into ROWID columns that are defined as
GENERATED BY DEFAULT and not as GENERATED ALWAYS. Therefore, in the
above example, if you were to try to insert a value into EMP_ROWID instead of
specifying DEFAULT, the statement would fail unless you also specify
OVERRIDING USER VALUE. For columns that are defined as GENERATED
ALWAYS, the OVERRIDING USER VALUE clause causes DB2 to ignore any
user-specified value and generate a value instead.

For example, assume that you want to copy the rows in
DSN8B10.EMP_PHOTO_RESUME to another table that has a similar definition
(both tables have a ROWID columns defined as GENERATED ALWAYS). For the
following INSERT statement, the OVERRIDING USER VALUE clause causes DB2
to ignore the EMP_ROWID column values from DSN8B10.EMP_PHOTO_RESUME
and generate values for the corresponding ROWID column in
B.EMP_PHOTO_RESUME.

```sql
INSERT INTO B.EMP_PHOTO_RESUME
OVERRIDING USER VALUE
SELECT * FROM DSN8B10.EMP_PHOTO_RESUME;
```

**Example 5:** Assume that the T1 table has one column. Insert a variable (:hv) number
of rows of data into the T1 table. The values to be inserted are provided in a
host-variable array (:hva).

```sql
EXEC SQL INSERT INTO T1 FOR :hv ROWS VALUES (:hva:hvind) ATOMIC;
```

In this example, :hva represents the host-variable array and :hvind represents the
array of indicator variables.

**Example 6:** Assume that the T2 table has 2 columns, C1 is a SMALL INTEGER
column, and C2 is an INTEGER column. Insert 10 rows of data into the T2 table.
The values to be inserted are provided in host-variable arrays :hva1 (an array of
INTEGERS) and :hva2 (an array of DECIMAL(15,0) values). The data values for
:hva1 and :hva2 are represented in Table 151:

Table 151. Data values for :hva1 and :hva2

<table>
<thead>
<tr>
<th>Array entry</th>
<th>:hva1</th>
<th>:hva2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>32768</td>
</tr>
<tr>
<td>2</td>
<td>-12</td>
<td>90000</td>
</tr>
<tr>
<td>3</td>
<td>79</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>32768</td>
<td>19</td>
</tr>
<tr>
<td>5</td>
<td>8</td>
<td>36</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>24</td>
</tr>
<tr>
<td>7</td>
<td>400</td>
<td>36</td>
</tr>
<tr>
<td>8</td>
<td>73</td>
<td>40000000000</td>
</tr>
<tr>
<td>9</td>
<td>-200</td>
<td>20000000000</td>
</tr>
<tr>
<td>10</td>
<td>35</td>
<td>88</td>
</tr>
</tbody>
</table>
EXEC SQL INSERT INTO T2 (C1, C2) 
   FOR 10 ROWS VALUES (:hva1:hvind1, :hva2:hvind2) 
   NOT ATOMIC CONTINUE ON SQLEXCEPTION;

After execution of the INSERT statement, the following information will be in the SQLCA:
SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 8

Although an attempt was made to insert 10 rows, only 8 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;

The result of this statement is num_rows = 8 and num_cond = 2 (2 conditions).
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE, 
   :sqlcode = DB2_RETURNED_SQLCODE, 
   :row_num = DB2_ROW_NUMBER;

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE, 
   :sqlcode = DB2_RETURNED_SQLCODE, 
   :row_num = DB2_ROW_NUMBER;

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

Example 7: Assume the above table T2 with two columns. C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 8 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values.) The data values for :hva1 and :hva2 are represented in Table 151 on page 1816.
EXEC SQL INSERT INTO T2 (C1, C2) 
   FOR 8 ROWS VALUES (:hva1:hvind1, :hva2:hvind2) 
   NOT ATOMIC CONTINUE ON SQLEXCEPTION;

After execution of the INSERT statement, the following information will be in the SQLCA:
SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 6

Although an attempt was made to insert 8 rows, only 6 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;

The result of this statement is num_rows = 68 and num_cond = 2 (2 conditions).
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE, 
   :sqlcode = DB2_RETURNED_SQLCODE, 
   :row_num = DB2_ROW_NUMBER;

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE,
:row_num = DB2_ROW_NUMBER;

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

Example 8: Assume that table T1 has two columns. Insert a variable number (:hvn) or rows into T1. The values to be inserted are in host-variable arrays :hva and :hvb. In this example, the INSERT statement is contained within the SELECT statement of cursor CS1. The SELECT statement makes use of two other input host variables (:hv1 and :hv2) in the WHERE clause. Either a static or dynamic INSERT statement can be used.

-- Static INSERT statement:
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR
  SELECT *
  FROM FINAL TABLE
  (INSERT INTO T1 VALUES (:hva, :hvb) FOR :hvn ROWS)
  WHERE C1 > :hv1 AND C2 < :hv2;
OPEN CS1;

-- Dynamic INSERT statement:
PREPARE INSSTMT FROM
  'SELECT *
  FROM FINAL TABLE
  (INSERT INTO T1 VALUES (?,?) FOR ? ROWS)
  WHERE C1 > ? AND C2 < ?';
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR :INSSTMT;
OPEN CS1 USING :hva, :hvb, :hvn, :hv1, :hv2; (or OPEN CS1 USING DESCRIPTOR ...)

If the host-variable arrays for the multiple-row INSERT statement were to be specified using a descriptor, that descriptor (SQLDA) would have to describe all input host variables in the statement, and the order of the entries in the SQLDA should be the same as the order of the order of the host variables, host-variable arrays, and values for the FOR n ROWS clauses in the statement. For example, given the statement above, the SQLVAR entries in the descriptor must be assigned in the following order: :hvn, :hva, :hvb, :hv1, :hv2. In addition, the SQLVAR entries for host-variable arrays must be tagged in the SQLDA as column arrays (by specifying a special value in part of the SQLNAME field for a host variable), and the SQLVAR entry for the number of rows value must be tagged in the SQLDA (by specifying another special value in part of the SQLNAME field for the host variable).

Example 9: Insert a row into table T1. The row contains the value 'xyz' for column COL1, and the cardinality of array INTA for column COL2.

CREATE TYPE INTARRAY AS INTEGER ARRAY [6];
DECLARE INTA AS INTARRAY;
SET INTA = ARRAY [ 1, 2, 3, 4, 5 ];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES ('xyz', CARDINALITY(INTA));

Example 10: Insert the values from arrays CHARA and INTA into table T1. For a row of T1, a value of the CHARA array is used for column COL1, and the value of the INTA array with the same array index is used for column COL2.

CREATE TYPE INTARRAY AS INTEGER ARRAY[10];
CREATE TYPE CHARARRAY AS CHAR(7) ARRAY[10];
DECLARE INTA AS INTARRAY;
DECLARE CHARA AS CHARARRAY;
SET INTA = ARRAY [1, 2, 3, 4, 5];
SET CHARA = ARRAY ['a', 'b', 'c', 'd'];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
Example 11: Insert three rows of data into table T1. For each inserted row, assign the value of the tenth element in the INTA array variable to the COL1 column.

```
CREATE TYPE INTARRAY AS INTEGER ARRAY[10];
DECLARE INTA AS INTARRAY;
CREATE VARIABLE VAR1 AS INTEGER;
CREATE VARIABLE VAR2 AS INTEGER;
SET INTA = ARRAY[10, 20, 30, 40, 50, 60, 70, 80, 90, 100];
CREATE TABLE T1 (COL1 INT, COL2 CHAR(10));
SET VAR1 = 10;
SET VAR2 = 3;
-- Perform a multiple row insert (specifying a FOR n ROWS clause).
-- The value to be inserted is specified by a reference to an array element.
INSERT INTO T1 (COL1) VALUES(INTA[VAR1]) FOR VAR2 ROWS;
```

The result of these operations is that a value of 100 is assigned to column COL1 for three rows.
The LABEL statement adds or replaces labels in the descriptions of tables, views, aliases, or columns in the catalog at the current server.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privilege set that is defined below must include at least one of the following:

- Ownership of the table, view, or alias
- DBADM authority for its database (tables only)
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSND804.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on page 873. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 77.)

**Syntax**

```
LABEL ON
  TABLE table-name IS string-constant
  view-name

  ALIAS alias-name

  COLUMN table-name.column-name IS string-constant
  view-name.column-name

  table-name (column-name IS string-constant)
  view-name
```

**Description**

**TABLE table-name or view-name**

Identifies the table or view to which the label applies. The name must identify a table or view that exists at the current server. `table-name` must not identify a declared temporary table. The label is placed into the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

**ALIAS alias-name**

Identifies the alias to which the label applies. The name must identify an alias
for a table or view that exists at the current server. The label is placed in the
LABEL column of the SYSIBM.SYSTABLES catalog table for the row that
describes the alias.

**COLUMN** `table-name.column-name` or `view-name.column-name`

Identifies the column to which the label applies. The name must identify a
column of a table or view that exists at the current server. The name must not
identify a column of a declared temporary table. The label is placed in the
LABEL column of the SYSIBM.SYSCOLUMNS catalog table in the row that
describes the column.

**Do not use TABLE or COLUMN to define a label for more than one column in a table or view.** Give the table or view name and then, in parentheses, a list
in the form:

```
column-name IS string-constant,
column-name IS string-constant,...
```

See Example 2 below.

The column names must not be qualified, each name must identify a column
of the specified table or view, and that table or view must exist at the current
server.

**IS** Introduces the label you want to provide.

**string-constant**

Can be any SQL character string constant of up to 30 bytes in length.

**Examples**

**Example 1:** Enter a label on the DEPTNO column of table DSN8B10.DEPT.

```
LABEL ON COLUMN DSN8B10.DEPT.DEPTNO
   IS 'DEPARTMENT NUMBER';
```

**Example 2:** Enter labels on two columns in table DSN8B10.DEPT.

```
LABEL ON DSN8B10.DEPT
   (MGRNO IS 'EMPLOYEE NUMBER FOR THE MANAGER',
    ADMRDEPT IS 'ADMINISTERING DEPARTMENT');
```
LOCK TABLE

The LOCK TABLE statement requests a lock on a table or table space at the current server. The lock is not acquired if the process already holds an appropriate lock.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:
- The SELECT privilege on the identified table (the SELECT privilege does not apply to the auxiliary table)
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on page 873. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 77.)

Syntax

```sql
LOCK TABLE table-name [PARTITION integer] IN SHARE MODE EXCLUSIVE
```

Description

table-name
Identifies the table to be locked. The name must identify a table that exists at the current server. It must not identify a view, a temporary table (created or declared), or a catalog table. The lock might or might not apply exclusively to the table. The effect of locking an auxiliary table is to lock the LOB table space that contains the auxiliary table.

PARTITION integer
Identifies the partition of a partitioned table space to lock. The table identified by table-name must belong to a partitioned table space. The value specified for integer must be an integer that is no greater than the number of partitions in the table space.
IN SHARE MODE
For a lock on a table that is not an auxiliary table, requests the acquisition of a lock that prevents other processes from executing anything but read-only operations on the table. For a lock on a LOB table space, IN SHARE mode requests a lock that prevents storage from being reallocated. When a LOB table space is locked, other processes can delete LOBs or update them to a null value, but they cannot insert LOBs with a nonnull value. The type of lock that the process holds after execution of the statement depends on what lock, if any, the process already holds.

IN EXCLUSIVE MODE
Requests the acquisition of an exclusive lock for the application process. Until the lock is released, it prevents concurrent processes from executing any operations on the table. However, unless the lock is on a LOB table space, concurrent processes that are running at an isolation level of uncommitted read (UR) can execute read-only operations on the table.

Notes
Releasing locks:
If LOCK TABLE is a static SQL statement, the RELEASE option of bind determines when DB2 releases a lock. For RELEASE(COMMIT), DB2 releases the lock at the next commit point. For RELEASE(DEALLOCATE), DB2 releases the lock when the plan is deallocated (the application ends).

If LOCK TABLE is a dynamic SQL statement, DB2 uses RELEASE(COMMIT) and releases the lock at the next commit point, unless the table or table space is referenced by cached dynamic statements. Caching allows DB2 to keep prepared statements in memory past commit points. In this case, DB2 holds the lock until deallocation or until the commit after the prepared statements are freed from memory. Under some conditions, if a lock is held past a commit point, DB2 demotes the lock state of a segmented table or a nonsegmented table space to an intent lock at the commit point.

When you issue the MODIFY DDF PKGREL(BNDOPT) or MODIFY DDF PKGREL command, the use of processor resources for package allocation and deallocation are minimized for packages that use database access threads and are bound with RELEASE(DEALLOCATE). When the MODIFY DDF PKGREL(BNDOPT) command has been issued, DB2 honors the RELEASE bind option even for dynamic SQL statements.

Syntax alternatives and synonyms:
For compatibility with previous releases of DB2, PART can be specified as a synonym for PARTITION.

Example
Obtain a lock on the sample table named DSN8B10.EMP, which resides in a partitioned table space. The lock obtained applies to every partition and prevents other application programs from either reading or updating the table.

    LOCK TABLE DSN8B10.EMP IN EXCLUSIVE MODE;

Related tasks:
Controlling concurrent access to tables (DB2 Performance)

Programming for concurrency (DB2 Performance)

Related reference:

- ISOLATION bind option (DB2 Commands)
- RELEASE bind option (DB2 Commands)
- DYNAMICRULES bind option (DB2 Commands)
The MERGE statement updates a target (a table or view, or the underlying tables or views of a fullselect) using the specified input data. Rows in the target that match the input data are updated as specified, and rows that do not exist in the target are inserted. Updating or inserting a row into a view updates or inserts the row into the tables on which the view is based, if no INSTEAD OF trigger is defined on this view.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges that are held by the privilege set that is defined below must include at least one of the following privileges:

- SYSADM authority
- Ownership of the table
- DATAACCESS authority
- If the search condition contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view
- If the insert operation is specified, the INSERT privilege for the table or view
- If the update operation is specified, at least one of the following privileges is required:
  - the UPDATE privilege for the table or view
  - the UPDATE privilege on each column that is updated
  - If the right side of the assignment clause contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the insert operation or assignment clause includes a subquery, the privileges that are held by the privilege set must also include at least one of the following privileges:

- SYSADM authority
- The SELECT privilege on every table or view that is identified in the subquery
- Ownership of the tables or views that are identified in the subquery
- DATAACCESS authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 97 on page 873. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 77.)
Syntax

```
MERGE INTO table-name
   view-name AS correlation-name
   include-columns
USING source-table
   ON search-condition
WHEN matching-condition THEN modification-operation
   NOT ATOMIC CONTINUE ON SQLEXCEPTION
   QUERYNO integer
```

**include-columns:**

```
INCLUDE(column-name data-type)
```

**data-type:**

```
built-in-type
   distinct-type
```

**built-in-type:**
Notes:

1. The NOT ATOMIC clause must be specified when `values-multiple-row` is specified.

values-single-row:
values-multiple-row:

```
expression

( expression )
```

Notes:

1. For a static MERGE statement, if FOR n ROWS is not specified, `values-multiple-row` is treated as `values-single-row`. For a dynamic MERGE statement, FOR n ROWS does not need to be specified in the MERGE statement. It can be specified in the EXECUTE statement, but cannot be specified in both the MERGE and EXECUTE statements.

matching-condition:

```
NOT MATCHED
```

modification-operation:

```
UPDATE SET assignment-clause
```

assignment-clause:
Notes:
1 The number of expressions, DEFAULT, and NULL keywords must match the number of column-names.

Description

**INTO table-name or view-name**

Identifies the target of the insert or update operations of the MERGE statement. The name must identify a table or view that exists at the current server. The name must not identify:

- A catalog table
- A created global temporary table
- A read-only view
- A system-maintained materialized query table
- A table that is implicitly created for an XML column

If a view is specified as the target of the MERGE statement, the view must not be defined with any INSTEAD OF triggers.

**AS correlation-name**

*correlation-name* provides an alternate name that can be used when referencing columns of the intermediate result table. If *no correlation-name* is specified, the name of the intermediate result table is the name of the target table or view of the MERGE statement. Otherwise, the name is the *correlation-name*.

**include-column**

Specifies a set of columns that are included, along with the columns of the specified table or view, in the result table of the MERGE statement when it is nested in the FROM clause of the outer fullselect that is used in a SELECT statement, or in a SELECT INTO statement. The included columns are
appended to the end of the list of columns that are identified by table-name or view-name. If a value is not specified for an included column, a null value is returned for that column.

**INCLUDE**
Introduces a list of columns that is to be included in the result table of the MERGE statement. The included columns are only available if the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. INCLUDE can only be specified when the MERGE statement is nested in the FROM clause of a SELECT statement.

column-name
Specifies the name for a column of the result table of the MERGE statement that is not the same name as another included column or a column in the table or view that is specified in table-name or view-name.

data-type
Specifies the data type of the included column. The included columns are nullable.

Columns with the following data types can not be used as INCLUDE columns:
- LONG VARCHAR,
- LONG VARGRAPHIC,
- XML
- LOBs
- distinct types that are based on any of the listed data types.

**built-in-type**
Specifies a built-in data type. See "CREATE TABLE" on page 1446 for a description of each built-in type.

The CCSID 1208 and CCSID 1200 clauses must not be specified for an INCLUDE column.

**distinct-type**
Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**USING VALUES values-single-row or values-multiple-row**
Specifies the values for the row data to merge into the target table or view. values-single-row specifies a single row of source data. values-multiple-row specifies multiple rows of source data.

equation
Specifies an expression of the type that is described in "Expressions" on page 243. The expression must not include a column name. The expression must not reference a NEXT VALUE or PREVIOUS VALUE expression. If the expression is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

If the expression is a host variable, or if a host variable is being explicitly cast, the host variable can include an indicator variable or an indicator array (in the case of a host structure). Either indicator variables or indicator arrays can be enabled for extended indicator variables.
To provide a null value, specify the NULL keyword on a CAST specification.

**host-variable-array**

Specifies a host variable array. Each host variable array must be defined in the application program in accordance with the rules for declaring an array. A host variable array contains the data to merge into a target column. The number of rows must be less than or equal to the dimension of each of the host variable arrays. An optional indicator array can be specified for each host variable array. An indicator array should be specified if the SQLTYPE of any SQLVAR occurrence indicates that a column is nullable. The indicator array can be enabled for extended indicator variables. The dimension of the indicator array must be large enough to contain an indicator for each row of input data.

A host structure is not supported in **host-variable-array**.

**host-variable-array** is supported in C/C++, COBOL, and PL/I.

**FOR host-variable or integer-constant ROWS**

Specifies the number of rows to merge. For a dynamic MERGE statement, this clause can be specified on the EXECUTE statement. **host-variable or integer-constant** is assigned to a value $k$. If **host-variable** is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. $k$ must be in the range of 1 to 32767. $k$ rows are merged into the target from the specified source data.

If a parameter marker is specified in FOR $n$ ROWS, a value must be provided with the USING clause of the associated EXECUTE statement.

**AS correlation-name**

Specifies a correlation name for the **source-table**.

**column-name**

Specifies a column name to associate the input data to the SET **assignment-clause** for an update operation or the VALUES clause for an insert operation.

**ON search-condition**

Specifies join conditions between the **source-table** and the target table or view.

Each **column-name** in the search condition must name a column of the target table, view, or **source-table**. A subquery is not allowed in the **search-condition**. If a **column-name** exists in both the target and the **source-table**, the column name must be qualified.

For each row of the **source-table**, the **search-condition** is applied to each row of the target. If the **search-condition** is evaluated as true and the target is not empty, the specified WHEN MATCHED clause is used. Otherwise, the specified WHEN NOT MATCHED clause is used.

**WHEN MATCHED or WHEN NOT MATCHED**

Specifies the condition under which the **modification-operation** is run.

**WHEN MATCHED**

Specifies the operation to perform on the rows where the ON **search-condition** is true and the target is not empty. Only UPDATE can be specified after the THEN clause. WHEN MATCHED must not be specified more than one time.

**WHEN NOT MATCHED**

Specifies the operation to perform on the rows where the ON
search-condition is false or unknown, or the target is empty. Only INSERT can be specified after the THEN clause. WHEN NOT MATCHED must not be specified more than one time.

**THEN update-operation or THEN insert-operation**

Specifies the operation to run when the matching-condition evaluates to true.

**UPDATE SET**

Specifies the update operation to run when the matching-condition evaluates to true.

When extended indicator variables are enabled, a column of the source table must not be referenced multiple times in a single modification-operation. Extended indicator variables are enabled when EXTENDEDINDICATOR(YES) is used, or when the WITH EXTENDED INDICATORS prepare attribute has been specified for the MERGE statement.

The rows that are updated from a source-row are subject to more updates by subsequent source-rows in the same statement. The update is cumulative.

An update-operation in a MERGE statement will not rest the AREO* status on a table.

**assignment-clause**

Specifies a list of column updates.

**column-name**

Identifies a column to update. column-name must identify a column of the specified table or view, and that column must be updatable. The column must not be a generated column, or a column of a view that is derived from a scalar function, a constant, or a expression. column-name can also identify an included column. The same column-name must not be specified more than one time.

Assignments to included columns are only processed when the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a column-name that is not an included column. A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

**expression**

Specifies the new value of the column. The expression is any expression of the type that is described in "Expressions" on page 243. The expression must not include an aggregate function.

An expression can contain references to columns of source-table or target. A column name is first checked as a column of the target, and then checked as a column of the source table. For each row that is updated, the value of a target column in an expression is the value of the column in the row before the row is updated. expression cannot contain references to an included column.

If expression is a reference to a single column of the source-table, the source-table column value might have been specified with an extended indicator variable value. The effects of such indicator variables apply to the corresponding target columns of the assignment-clause.

When extended indicator variables are enabled, an expression must not be more complex than a reference to a single column of the source
table, or a single host variable if the indicator is set to an extended
indicator value of default (-5) or unassigned (-7). In addition, a CAST
specification can be used if either:

- The target column is defined as nullable.
- the target column is defined as NOT NULL with a non-null default,
  the source of the CAST specification is a single host variable, and the
data attributes (data type, length, precision, and scale) of the host
variable are the same as the result of the cast specification.

**DEFAULT**
Specifies the default value for the column. The value that is assigned
depends on how the column is defined.

A ROWID column must not be set to the DEFAULT keyword.

An identity column or a row change timestamp column that is defined
as GENERATED ALWAYS can be set only to the DEFAULT keyword.

If the column is defined using the NOT NULL clause and the
GENERATED clause is not used, or the WITH DEFAULT clause is not
used, the DEFAULT keyword cannot be specified for that column.

**NULL**
Specifies the null value as the new value of the column. Specify NULL
only for nullable columns.

**insert-operation**
Specifies the insert operation to run for the rows where the
matching-condition evaluates to true.

The rows that are inserted from a source-row are immediately subject for
update by subsequent source-rows in the same statement.

**INSERT**
Specifies a list of column names and row value expressions to use of
the insert operation.

The number of values for the row in the row-value expression must be
equal to the number of names in the insert column list. The first value
is inserted into the first column in the list, the second value into the
second column, and so on.

**column-name**
Specifies the columns for which the insert values are provided.
Each name must identify a column of the table or view.

If an included column is not specified in the list of column names,
the value of the included column is set to null. The column list
cannot contain only included columns.

The same column must not be specified more than one time. A
view column that cannot accept insert values must not be
specified. A view column that cannot accept insert values must not
be specified.

If the object of the operation is a view that contains columns that
cannot accept insert values, a list of column names must be
specified and the list must not specify these columns.

Omission of the column list is an implicit specification of a list in
which every column of the table (that is not defined as implicitly
hidden) or view is identified in left-to-right order. This list is
established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

VALUES
Introduces one or more rows of values to insert.

expression
Specifies an expression of the type that does not include a column name of the target. If expression is a host variable, the host variable can include an indicator variable, or in the case of a host structure, an indicator array. When extended indicator variables are enabled, an expression must not be more complex than a reference to a single host variable if the indicator is set to an extended indicator value of default (-5) or unassigned (-7).

In addition, a CAST specification can be used if either:
- The target column is defined as nullable.
- the target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

DEFAULT
Specifies to assign the default value to the column. DEFAULT must only be specified for columns that have a default value. If the column is specified in the INCLUDE column list, the column value is set to null.

DEFAULT must be specified for a column that is defined as GENERATED ALWAYS. A valid value can be specified for a column that is defined as GENERATED BY DEFAULT.

NULL
Specifies the null value as the value of the column. Specify NULL only for nullable columns.

NOT ATOMIC CONTINUE ON SQLEXCEPTION
The rows of input data are processed separately. Any statement level triggers are processed for each row of source data that is processed, and the transition table includes the individual row that was processed. When errors are encountered and this option is in effect, processing continues, and some of the specified rows will not be processed. In this case, if an appropriate trigger is defined on the underlying base table, the statement level trigger will only be activated for rows that were successfully processed.

Regardless of the failure of any particular source row, the MERGE statement will not undo any changes that are made to the database by the statement. Merge will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial merge to complete), including any triggers that might have been activated as a result of the MERGE statement.

QUERYNO integer
Specifies the number for this SQL statement that is used in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan.
table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If QUERYNO is not specified, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, the statement number might change.

Notes

SQLCA and GET DIAGNOSTICS considerations:
The GET DIAGNOSTICS statement can be used immediately after the MERGE statement to check which input rows fail during the merge operation. The GET DIAGNOSTICS statement information item, NUMBER, indicates the number of conditions that are raised. The GET DIAGNOSTICS condition information item, DB2_ROW_NUMBER, indicates the input source rows that cause an error.

Trigger considerations:
A MERGE statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions depending on the source data values. A before-update or before-insert trigger processes immediately before the update or insert operation.

If a source row results in an insert, any after-insert triggers are activated after the insert operation completes.

If a source row results in updates, any after-update triggers are activated after all of the update operations complete.

Indexes with VARBINARY columns:
Suppose that the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type. In that case, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

Considerations for a MERGE without a column list in insert-operation:
A MERGE statement without a specified column list as part of insert-operation does not include implicitly hidden columns. Therefore, such columns must have a defined default value.

Considerations for non-atomic processing of a MERGE statement:
When NOT ATOMIC is specified, the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the MERGE statement are evaluated as each row of source data is processed. Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the operation for a row of source data, processing continues. The row that was being processed at the time of the error is not inserted or updated. Execution continues with the next row to be processed, and any other changes that are made during the execution of the multiple-row MERGE statement are not backed out. However, the processing of an individual row is an atomic action.
**DRDA considerations:**

DB2 Connect™ Version 9.1 and subsequent releases support the MERGE statement. The support is for CLI only, with no embedded static SQL support.

When you run a MERGE statement at a DB2 for z/OS requester, cases might exist where the requestor does not know the number of rows in the source table. This situation includes the following cases:

- For static or dynamic MERGE statements, of the FOR n ROWS clause contains a constant value for n.
- For dynamic MERGE statements, of host variables are specified on the USING clause of an EXECUTE statement.

For both of these cases, if the number of rows in the source table is not known, the requester might send more data than is required to the server. The number of rows that are processed is correct because the server knows the correct numbers of rows to process. However, performance might be adversely affected. Consider the following example:

```sql
...long serial num [10];
struct { short len;
  char data [18];
} name[20]...
EXEC SQL
MERGE INTO T1
USING (VALUES (:serial_num, :name))
FOR 5 ROWS...
```

When this statement is run at the requester, the number of rows to merge (five) is not known. As a result, the requester sends 10 values for serial-name and name to the server because 10 is the size of the smallest host variable array and is, therefore, the maximum number of rows that can merge without causing an error.

Do the following to help minimize performance problems:

- Avoid using numeric constants in the FOR n ROWS clause of the MERGE statement. For static MERGE statements, avoiding numeric constants ensures that the values for n are known at the requester.
- For dynamic MERGE statements, use the USING DESCRIPTOR clause instead of the USING host-variable clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for n must be indicated in the descriptor.
- If either of the previous methods cannot be used, perform the following actions:
  - Make your host variable arrays as small as possible, or declare that the size of your host variable arrays are the size of n in the descriptor. This action avoids sending many unused host variable array entries to the server.
  - Ensure that varying length string arrays are initialized to a length of 0 (zero). Doing so minimizes the amount of data that is sent to the server.
  - Ensure that decimal host variable arrays are initialized to valid values. Doing so causes the requester to avoid sending a negative SQLCODE if the requester encounters invalid decimal data.

**Extended indicator variable usage:**

When extended indicator variables are enabled, negative indicator values
outside the range of -1 through -7 must not be specified. Also, the default and unassigned extended indicator values must not be used in contexts in which they are not supported.

**Extended indicator variables in the assignment-clause:**
Assigning the extended indicator a value of unassigned leaves the target column set to its current value, as if it had not been specified in the statement. Assigning the extended indicator a value of default assigns the default value to the column.

The assignment-clause must not assign all target columns to an extended indicator value of unassigned.

**Extended indicator variables in the insert-operation:**
In insert-operation, a value of unassigned sets the column to its default value.

**Extended indicator variables and update triggers:**
If a target column is assigned an extended indicator value of unassigned, that column is not considered to have been updated. That column is treated as if it had not been specified in the `OF column-name` list of any update trigger that is defined on the target table.

**Extended indicator variables and insert triggers:**
The activation of insert triggers is not affected by the use of extended indicator variables. Suppose that all columns in the implicit or explicit column list are assigned an extended indicator value of unassigned or default. Then, assume that an insert operation where all columns are assigned to the respective default values is attempted. If that operation is successful, the insert trigger is activated.

**Table space data compression during an insert operation:**
If the table space is defined with the COMPRESS YES option, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a amount of data that is determined by DB2 is inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed by using the compression dictionary.

**System-period temporal tables:**
When a MERGE statement is processed for a system-period temporal table, the rows are affected in the same way as if the specific data change operation was invoked.

**Archive-enabled tables:**
Consider the case when the target of a MERGE statement is an archive-enabled table, and the merge operation includes an insert or update operation. In this case, the involved rows are affected in the same way as if the insert or update operation was directly invoked on the table.

**Related information:**
- **"INSERT" on page 1799**
- **"UPDATE" on page 1998**

**Tables with enforced row and column access controls:**
For information about how enabled row permissions and column masks affect the update and insert operations in the MERGE statement, see the INSERT and UPDATE statement information.
**Examples**

*Example 1:* Update the descriptions for activities that exist in the `RECORDS` table. Otherwise, insert the activity and its description into the `RECORDS` table.

```sql
MERGE INTO RECORDS AR
USING (VALUES (:hv_activity, :hv_description)
    FOR :hv_nrows ROWS)
AS AC (ACTIVITY, DESCRIPTION)
ON (AR.ACTIVITY = AC.ACTIVITY)
WHEN MATCHED THEN UPDATE SET DESCRIPTION = AC.DESCRIPTION
WHEN NOT MATCHED THEN INSERT (ACTIVITY, DESCRIPTION)
VALUES (AC.ACTIVITY, AC.DESCRIPTION)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

*Example 2:* Use the transaction data to merge rows into the `ACCOUNT` table. Update the balance from the transaction data against an account ID and insert new accounts from the transaction data where the accounts do not already exist.

```sql
MERGE INTO ACCOUNT AS A
USING (VALUES (:hv_id, :hv_amount)
    FOR 3 ROWS)
AS T (ID, AMOUNT)
ON (A.ID = T.ID)
WHEN MATCHED THEN UPDATE SET BALANCE = A.BALANCE + T.AMOUNT
WHEN NOT MATCHED THEN INSERT (ID, BALANCE)
VALUES (T.ID, T.AMOUNT)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

*Example 3:* Update the list of activities that are organized by group A in the `RECORDS` table. Update the activities information (description and date when last modified) in the `RECORDS` table if the activities exist in the `RECORDS` table and are also organized by group A. Insert new activities into the `RECORDS` table.

```sql
-- hv_nrows = 3
-- hv_activity(1) = 'D'; hv_description(1) = 'Dance'; hv_date(1) = '03/01/07'
-- hv_activity(2) = 'S'; hv_description(2) = 'Singing'; hv_date(2) = '03/17/07'
-- hv_activity(3) = 'T'; hv_description(3) = 'Tai-chi'; hv_date(3) = '05/01/07'
-- hv_group = 'A';
-- note that hv_group is not an array. All 3 values contain the same values
MERGE INTO RECORDS AR
USING (VALUES (:hv_activity, :hv_description, :hv_date, :hv_group)
    FOR :hv_nrows ROWS)
AS AC (ACTIVITY, DESCRIPTION, DATE, GROUP)
ON AR.ACTIVITY = AC.ACTIVITY AND AR.GROUP = AC.GROUP
WHEN MATCHED
THEN UPDATE SET (DESCRIPTION, DATE, LAST_MODIFIED)
    = (AC.DESCRIPTION, AC.DATE, CURRENT TIMESTAMP)
WHEN NOT MATCHED
THEN INSERT (GROUP, ACTIVITY, DESCRIPTION, DATE, LAST_MODIFIED)
    VALUES (AC.GROUP, AC.ACTIVITY, AC.DESCRIPTION, AC.DATE, CURRENT_TIMESTAMP)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

*Example 4:* Use two arrays, `CHARA` and `INTA`, as input to a `MERGE` statement. Column COL2 is set to the cardinality of `CHARA` for matching rows, and COL2 is set to the cardinality of `INTA` for non-matching rows.

```sql
CREATE TYPE INTARRAY AS INTEGER ARRAY[6];
CREATE TYPE CHARARRAY AS CHAR(20) ARRAY[7];
DECLARE INTA AS INTARRAY;
DECLARE CHARA AS CHARARRAY;
```
CREATE VARIABLE SI INT;
SET CHARA = ARRAY ['a', 'b', 'c'];
SET INTA = ARRAY [1, 2, 3, 4, 5];
CREATE TABLE T1 (COL1 CHAR(7), COL2 INT);
INSERT INTO T1 VALUES ('abc', 10);
MERGE INTO T1 AS A
USING TABLE (VALUES ('rsk', 3)) AS T (ID, AMOUNT)
ON A.COL1 = T.ID
WHEN MATCHED
  THEN UPDATE SET COL2 = CARDINALITY(CHARA)
WHEN NOT MATCHED
  THEN INSERT (COL1, COL2 ) VALUES (T.ID, CARDINALITY(INTA));
The OPEN statement opens a cursor so that it can be used to process rows from its result table.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

See “DECLARE CURSOR” on page 1598 for the authorization required to use a cursor.

**Syntax**

```
OPEN cursor-name
USING variable
USING DESCRIPTOR descriptor-name
```

**Description**

`cursor-name`

Identifies the cursor to be opened. The `cursor-name` must identify a declared cursor as explained in “DECLARE CURSOR” on page 1598. When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement of the cursor is either one of the following types of SELECT statements:

- The `select-statement` that is specified in the DECLARE CURSOR statement
- The prepared `select-statement` that is identified by the `statement-name` that is specified in the DECLARE CURSOR statement.

If the statement has not been successfully prepared, or is not a `select-statement`, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers or PREVIOUS
VALUE expressions that are specified in the SELECT statement, and the current values of any host variables that are specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement, and a temporary copy of a result table can be created to hold those rows. They can be derived during the execution of later FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table.

If the table is empty, the position of the cursor is effectively “after the last row.” The DB2 system does not indicate an empty table when the OPEN statement is executed. A subsequent fetch for the cursor might return the SQLSTATE warning of '02000'.

**USING**

Introduces a list of variables whose values are substituted for the parameter markers (question marks) or host variables in the statement of the cursor, depending on the declaration of the cursor:

- If the DECLARE CURSOR statement included `statement-name`, the statement was prepared with a PREPARE statement. The variables specified in the USING clause of the OPEN statement replace any parameter markers in the prepared statement. This reflects the typical use of the USING clause of the OPEN statement. For an explanation of parameter marker replacement, see "PREPARE" on page 1846.

If the prepared statement includes parameter markers, you must use USING. If the prepared statement does not include parameter markers, USING is ignored.

- If the DECLARE CURSOR statement included `select-statement` and the SELECT statement included variables, the USING clause of the OPEN statement can be used to specify variables that are to override the values that were specified when the cursor was defined. In this case, the OPEN statement is executed as if each variable in the SELECT statement were a parameter marker except that the attributes of the target variable are the same as the variables in the SELECT statement. The effect is to override the values of the variables in the SELECT statement of the cursor with the values of the variables specified in the USING clause. The overriding value is always the value of the main variable because indicator variables are ignored in this context without warning.

The nth variable corresponds to the nth parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

(variable)

Identifies a variable or a host structure that is declared in the application program in accordance with the rules for declaring variables and host structures. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement.

(array-variable) [array-index]

Identifies an array element. An array element must only be specified if the OPEN statement is issued in SQL PL.

(array-variable)

Specifies an array variable.

[array-index]

An expression that specifies which element in the array to use.
For an ordinary array, the array index expression must be castable to INTEGER, and must not be the null value. The index value must be between 1 and the maximum cardinality that is defined for the array.

For an associative array, the array index expression must be castable to the index data type of the associative array, and must not be the null value.

array-index must not be:

- An expression that references the CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special register
- A nondeterministic function
- A function that is defined with EXTERNAL ACTION
- A function that is defined with MODIFIES SQL DATA
- A sequence expression

**DESCRIPTOR descriptor-name**

Identifies an SQLDA that contains a valid description of the input host variables.

Before the OPEN statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
  
  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the result table, there must be additional SQLVAR entries for each input host variable. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see “SQL descriptor area (SQLDA)” on page 2144.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 2164 for how to represent descriptor-name in C.

**Notes**

**Errors occurring on OPEN:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive “delayed” errors. For example, an OPEN statement might receive an SQLCODE that normally occurs during PREPARE processing. Or a FETCH statement might receive an SQLCODE that normally occurs at OPEN time.

**Closed state of cursors:** All cursors in an application process are in the closed state when:

- The application process is started.
A new unit of work is started for the application process unless the WITH HOLD option has been used in the DECLARE CURSOR statement.

The application was precompiled with the CONNECT(1) option (which implicitly closes any open cursors).

A cursor can also be in the closed state because:
- A CLOSE statement was executed.
- An error was detected that made the position of the cursor unpredictable.

To retrieve rows from the result table of a cursor, you must execute a FETCH statement when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

**Effect of a temporary copy of a result table:** DB2 can process a cursor in two different ways:
- It can create a temporary copy of the result table during the execution of the OPEN statement. You can specify INSENSITIVE SCROLL on the cursor to force the use of a temporary copy of the result table.
- It can derive the result table rows as they are needed during the execution of later FETCH statements.

If the result table is not read-only, DB2 uses the latter method. If the result table is read-only, either method could be used. The results produced by these two methods could differ in the following respects:

**When a temporary copy of the result table is used:** An error can occur that would otherwise not occur until some later FETCH statement. Insert operations that are executed while the cursor is open cannot affect the result table once all the rows have been materialized in the temporary copy of the result table. For a scrollable insensitive cursor, update and delete operations that are executed while the cursor is open cannot affect the result table. For a scrollable sensitive static cursor, update and delete operations can affect the result table if the rows are subsequently fetched with sensitive FETCH statements.

**When a temporary copy of the result table is not used:** Insert, update, and delete operations that are executed while the cursor is open can affect the result table. The effect of such operations is not always predictable.

For example, if cursor C is positioned on a row of its result table defined as SELECT * FROM T, and you insert a row into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A later FETCH C might or might not retrieve the new row of T. To avoid these changes, you can specify INSENSITIVE SCROLL for the cursor to force the use of a temporary copy of the result table.

**Parameter marker replacement:** Before the OPEN statement is executed, each parameter marker in the query is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in “Assignment and comparison” on page 123. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see “Parameter markers.”
Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

- V must be compatible with the target.
- If V is a string, its length (excluding trailing blanks) must not be greater than the length attribute of the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, V must not be null.

When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by the value of its corresponding host variable. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks. For more on the process of replacement, see Parameter marker replacement.

**Considerations for scrollable cursors:** Following an OPEN cursor statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see “GET DIAGNOSTICS” on page 1744):

- DB2_SQL_ATTR_CURSOR_HOLD. Whether the cursor was defined with the WITH HOLD attribute.
- DB2_SQL_ATTR_CURSOR_SCROLLABLE. Scrollability of the cursor.
- DB2_SQL_ATTR_CURSOR_SENSITIVITY. Effective sensitivity of the cursor.
  The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.
- DB2_SQL_ATTR_CURSOR_ROWSET. Whether the cursor can be used to access rowsets.
- DB2_SQL_ATTR_CURSOR_TYPE. Whether a cursor type is forward-only, static, or dynamic.
  - The scrollability of the cursor is in SQLWARN1.
  - The sensitivity of the cursor is in SQLWARN4.
  - The effective capability of the cursor is in SQLWARN5.

**Number of rows inserted:** SQL data change statements and routines that modify SQL data embedded in the cursor definition are completely executed, and the result table is stored in a temporary table when the cursor opens. If statement execution is successful, the SQLERRD(3) field contains the sum of the number of rows that qualified for insert, update, and delete operations. If an error occurs during execution of an OPEN statement that involves a cursor that contains a data change statement within a fullselect, the results of that data change statement are rolled back.

**Materialization of the rows of the result table and NEXT VALUE expressions:** If the rows of the result table of a cursor are materialized when the cursor is opened and the SELECT statement of the cursor contains NEXT VALUE expressions, the expressions are processed when the cursor is opened. Otherwise, the NEXT VALUE expressions are evaluated as the rows of the result table are retrieved.
Opening the same cursor multiple times: A cursor in an SQL procedure that is declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the existing open cursor becomes a result set cursor and is no longer accessible by its cursor name. A new cursor is opened and becomes accessible by the cursor name. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. Cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.

Examples

Example 1: Execute an OPEN statement, which places the cursor at the beginning of the rows to be fetched.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8B10.DEPT
    WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
    EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```

Example 2: Suppose that the following array type, array variable, and table have been defined.

```sql
CREATE TYPE INTARRAY AS INTEGER ARRAY[100];
CREATE TYPE STRINGARRAY AS VARCHAR(10) ARRAY[100];
CREATE TABLE T1 (COL1 CHAR(10), COL2 INT);
```

Use an array variable as input for a dynamic SQL statement. The dynamic statement references an array element in the array variable. The dynamic statement contains two parameter markers, one for the array variable and one for the index of the array element. The OPEN statement provides two input values in the USING clause: the array variable, and a variable that contains the index for the array element.

```sql
CREATE PROCEDURE PROCESSPERSONS (OUT WITHO STRINGARRAY, INOUT INT0 INT)
BEGIN
    DECLARE INTA INTARRAY;
    DECLARE INTB INTARRAY;
    DECLARE INTV INTEGER;
    DECLARE STMT CHAR(100);
    DECLARE C2 CURSOR FOR S1;
    --
    -- Initialize the array
    --
    - SET INTA = ARRAY[1, INTEGER(2), 3+0, 4, 5, 6] ;
    --
    -- Use dynamic SQL with an array parameter marker and a parameter marker
    -- containing the index to retrieve the value from the array parameter.
    -- The array is referenced in a predicate.
    --
    - SET STMT = 'SELECT COL1 FROM T1 WHERE COL2 = CAST(? AS INTARRAY)[?]';
    PREPARE S1 FROM STMT;
    OPEN C2 USING INTA, INTV; -- Input: INTA is an array, and INTV is the
    -- index for the array element
    FETCH C2 INTO INTB ; -- Output: INTB is an array variable
    ...
    CLOSE C2;
    ...
END
```
**PREPARE**

The PREPARE statement creates an executable SQL statement from a string form of the statement. The character-string form is called a *statement string*. The executable form is called a *prepared statement*.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by the PREPARE statement. For example, see Chapter 5, "Queries," on page 781 for the authorization rules that apply when a SELECT statement is prepared.

The statement that is prepared using only the EXPLAIN privilege cannot be executed, and only the descriptive information can be obtained for that statement.

**Syntax**

```
PREPARE statement-name INTO descriptor-name
USING NAMES
ANY BOTH
FROM variable
ATTRIBUTES attr-host-variable
FROM string-expression
```

Notes:

1. `attr-host-variable` must be a string host variable and the content must conform to the rules for attribute-string. The ATTRIBUTES clause can only be specified before `variable`.

2. `string-expression` is only supported for PLI.

attribute-string
Notes:

1. The same clause must not be specified more than one time. If the options are not specified, their defaults are whatever was specified for the corresponding option in an associated statement.

2. The FOR SINGLE ROW or FOR MULTIPLE ROWS clause must only be specified for an INSERT or a MERGE statement.

3. The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause must only be specified for an INSERT statement.

holdability:

- WITHOUT HOLD
- WITH HOLD

returnability:
Description

statement-name
Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed. The name must not identify a prepared statement that is the SELECT statement of an open cursor.

INTO
If you use INTO, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the descriptor name. Thus, the PREPARE statement:

EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;

is equivalent to:

EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 INTO :SQLDA;

descrictor-name
Identifies the SQLDA. For languages other than REXX, SQLN must be set to indicate the number of SQLVAR occurrences. See "DESCRIBE" on page 1653 and "SQL descriptor area (SQLDA)" on page 2144 for information about how to determine the number of SQLVAR occurrences to use and for an explanation of the information that is placed in the SQLDA.

See "Identifying an SQLDA in C or C++" on page 2164 for how to represent descriptor-name in C.

USING
Indicates what value to assign to each SQLNAME variable in the SQLDA when INTO is used. If the requested value does not exist, SQLNAME is set to length 0.

NAMES
Assigns the name of the column. This is the default.
**LABELS**
Assigns the label of the column. (Column labels are defined by the LABEL statement.)

**ANY**
Assigns the column label, and, if the column has no label, the column name.

**BOTH**
Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to $2 \times n$ or $3 \times n$, where $n$ is the number of columns in the object being described. For each of the columns, the first $n$ occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third $n$ occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

A REXX SQLDA does not include the SQLN field, so you do not need to set SQLN for REXX programs.

**ATTRIBUTES** attr-host-variable
Specifies the attributes that are in effect if a corresponding attribute has not been specified as part of the associated statement. If attributes are specified as part of the associated statement, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE of a SELECT statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

attr-host-variable must identify a host variable that is described in the program in accordance with the rules for declaring string variables. attr-host-variable must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed 32758 bytes. Leading and trailing blanks are removed from the value of the host variable. The host variable must contain a valid attribute-string.

An indicator variable can be used to indicate whether or not attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not.

The options that can be specified as part of the attribute-string are as follows:

**ASENSITIVE, INSENSITIVE, SENSITIVE STATIC, or SENSITIVE DYNAMIC**
Specifies the sensitivity of the cursor to inserts, updates, or deletes that made to the rows underlying the result table. The sensitivity of the cursor determines whether DB2 can materialize the rows of the result into a temporary table. The default is ASENSITIVE.

**ASENSITIVE**
Specifies that the cursor should be as sensitive as possible. A cursor that defined as ASENSITIVE will be either insensitive or sensitive.

---

40. The scrollability and sensitivity of the cursor are independent and do not have to be specified together. Thus, the cursor might be defined as SCROLL INSENSITIVE, but the PREPARE statement might specify SENSITIVE STATIC as an override for the sensitivity.
dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see “OPEN” on page 1840.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

**INSENSITIVE**

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

**SENSITIVE**

Specifies that the cursor has sensitivity to changes made to the database after the result table is materialized. The cursor is always sensitive to positioned updates and deletes that are made using the same cursor. However, the *select-statement* of the cursor must not contain an SQL data change statement if the cursor is defined as either SENSITIVE DYNAMIC or SENSITIVE STATIC. When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

In addition, the cursor has sensitivity to changes made to values outside the cursor (that is, by other cursors or committed changes by other application processes). If DB2 can not make changes made outside the cursor visible to the cursor, an error is issued at OPEN CURSOR. Whether the cursor is sensitive to changes made outside this cursor depends on whether DYNAMIC or STATIC is in effect for the cursor and whether SENSITIVE or INSENSITIVE FETCH statements are used.

Whether the cursor is sensitive to newly inserted rows depends on whether DYNAMIC or STATIC is in effect for the cursor. The default is DYNAMIC.

**DYNAMIC**

Specifies that the result table of the cursor is dynamic in that the size of the result table can change after the cursor is opened as rows are inserted into or deleted from the underlying table, and the order of the rows can change. Inserts, deletes, and updates that are made by the same application process are immediately visible. Inserts, deletes, and updates that are made by other application processes are visible after they are committed.

All FETCH statements for sensitive dynamic cursors are sensitive to changes made by this cursor, changes made by other cursors in the same application process, and committed changes made by other application processes.
If a SENSITIVE DYNAMIC cursor is not possible, an error is returned. The FETCH FIRST $n$ ROWS ONLY clause must not be specified for the outermost fullselect for a sensitive dynamic cursor.

**STATIC**

Specifies that the order of the rows and size of the result table is static. The size of the result table does not grow after the cursor is opened and the rows are materialized. The order of the rows is established as the result table is materialized. Rows that are inserted into the underlying table are not added to the result table of the cursor regardless of how the rows were inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized.

Whether the changes that are made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor. For more information, see [Considerations for FETCH statements used with a sensitive static cursor](#).

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of select-statement or statement-name of a SENSITIVE STATIC cursor can cause misleading results. This occurs because DB2 constructs a temporary result table and retrieves rows from this table for INSENSITIVE FETCH statements. When DB2 processes a SENSITIVE FETCH statement, rows are fetched from the underlying table and predicates are re-evaluated if they contain non-correlated subqueries. Using a function that is not deterministic can yield a different result for the re-evaluated query causing the row to no longer be considered a match.

If SENSITIVE STATIC is specified and a sensitive static cursor is not possible, then an error is returned.

If ASENSITIVE, INSENSITIVE, SENSITIVE DYNAMIC, or SENSITIVE STATIC is specified as part of the ATTRIBUTES clause, SCROLL must be specified.

**SCROLL or NO SCROLL**

Specifies whether the cursor is scrollable.

**SCROLL**

Specifies that the cursor is scrollable.

**NO SCROLL**

Specifies that the cursor is not scrollable.

**WITHOUT RETURN or WITH RETURN**

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If statement-name is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is **WITHOUT RETURN**.

**WITHOUT RETURN**

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

**WITH RETURN**

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is
relevant only if the PREPARE statement is contained within the source
code for a procedure. In other cases, the precompiler might accept the
clause, but it has no effect.

When a cursor that is declared using the WITH RETURN TO CALLER
clause remains open at the end of a program or routine, that cursor
defines a result set from the program or routine. Use the CLOSE
statement to close a cursor that is not intended to be a result set from
the program or routine. Although DB2 will automatically close any
cursors that are not declared using a WITH RETURN clause, the
use of the CLOSE statement is recommended to increase the portability
of applications.

For non-scrollable cursors, the result set consists of all rows from the
current cursor position to the end of the result table. For scrollable
cursors, the result set consists of all rows of the result table.

**TO CALLER**

Specifies that the cursor can return a result set to the caller of the
procedure. The caller is the program or routine that executed the
SQL CALL statement that invokes the procedure that contains the
PREPARE statement. For example, if the caller is a procedure, the
result set is returned to the procedure. If the caller is a client
application, the result set is returned to the client application.

If the statement is contained within the source code for a
procedure, WITH RETURN TO CALLER specifies that the cursor
is used as a result set cursor. A result set cursor is used when
the result table of a cursor is to be returned from a procedure.
Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used
as a result set cursor.

**TO CLIENT**

Specifies that the cursor can return a result set to the client
application. This cursor is invisible to any intermediate nested
procedures. If a function or trigger calls the procedure (either
directly or indirectly), the result set cannot be returned to the client
and the cursor will be closed after the procedure finishes.

**rowset-positioning**

Specifies whether rows of data can be accessed as a rowset on a single
FETCH statement for this cursor.

**WITHOUT ROWSET POSITIONING**

Specifies that the cursor can only be used with row positioned FETCH
statements.

**WITH ROWSET POSITIONING**

Specifies that this cursor can be used with rowset positioned or row
positioned FETCH statements

**fetch-first-clause**

Limits the number of rows that can be fetched. It improves the
performance of queries with potentially large result sets when only a
limited number of rows are needed. If the clause is specified, the number
of rows retrieved will not exceed \( n \), where \( n \) is the value of the integer. An
attempt to fetch \( n+1 \) rows is handled the same way as normal end of date.
The value of integer must be positive and non-zero. The default is 1.
If the OPTIMIZE FOR clause is not specified, a default of OPTIMIZE FOR integer ROWS is assumed. If both the FETCH FIRST and OPTIMIZE FOR clauses are specified, the lower of the integer values from these clauses is used to influence optimization and the communications buffer size.

The FETCH FIRST clause must not be specified for the outermost fullselect for a sensitive dynamic cursor.

**read-only-clause**
Declares that the result table is read-only and therefore the cursor cannot be referred to in positioned UPDATE and DELETE statements.

**update-clause**
Identifies the columns that can updated in a later positioned UPDATE statement. Each column must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only. The clause must also not be specified if a created temporary table is referenced in the first FROM clause of the select-statement.

If the clause is specified without a list of columns, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

**optimize-clause**
Requests special optimization of the select-statement. If the clause is omitted, optimization is based on the assumption that all rows of the result table will be retrieved. If the clause is specified, optimization is based on the assumption that the number of rows retrieved will not exceed $n$, where $n$ is the value of the integer. The clause does not limit the number of rows that can be fetched or affect the result in any way other than performance.

**isolation-clause**
Specifies the isolation level at which the select statement is executed. See “isolation-clause” on page 858.

**concurrent-access-resolution**
Specifies the type concurrent access resolution to use for the select statement. Each clause in concurrent-access-resolution can only be specified one time. Only one of the clauses can be specified for each PREPARE statement. If none of the clauses is specified, the locking semantic depends on other attributes of the statement.

**SKIP LOCKED DATA**
Specifies to skip data on which incompatible locks are held by other transactions. See “SKIP LOCKED DATA” on page 861.

**USE CURRENTLY COMMITTED**
Specifies that DB2 can use the currently committed version of the data when the data is in the process of being updated. USE CURRENTLY COMMITTED only applies in the following cases:
- The table that is being accessed is defined in a universal table space
- The access is for a select-statement with an isolation level of cursor stability (CS) or read stability (RS) specified in the isolation-clause:
  - When a read transaction accesses a record that is locked by an insert transaction, both ISOLATION(CS) and ISOLATION(RS) are applicable.
- When a read transaction accesses a record that is locked by a delete transaction only ISOLATION(CS) is applicable and only when CURRENTDATA(NO) is in effect.

USE CURRENTLY COMMITTED is ignored if used in any other context.

When this clause is specified, the setting of the subsystem parameter EVALUNC applies. If the row qualifies, this clause determines if the row is accessed or skipped.

When this clause is specified and the subsystem parameter SKIPUNC is in effect, PREPARE uses the specification of this clause. See the Notes section for more information.

When this clause is specified and XML data that does not support multiple XML versions is being selected, DB2 cannot determine whether the data has been committed. In this case, DB2 uses WAIT FOR OUTCOME behavior when accessing the data.

WAIT FOR OUTCOME
Specifies that DB2 waits for the commit or rollback when encountering data that is in the process of being updated or deleted. Rows that are in the process of being inserted are not skipped.

FOR MULTIPLE ROWS or FOR SINGLE ROW
Specifies if a variable number of rows will be provided for a dynamic INSERT or MERGE statement.

FOR MULTIPLE ROWS
Specifies that multiple rows can be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR MULTIPLE ROWS must only be specified for an INSERT or a MERGE statement.

FOR SINGLE ROW
Specifies that multiple rows must not be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR SINGLE ROW must only be specified for an INSERT or a MERGE statement.

ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies if all rows are inserted as an atomic operation. This clause can only be specified for dynamic INSERT statements.

ATOMIC
Specifies that if the insert for any row fails, all changes that are made to the database by any of the inserts, including changes that are made by successful inserts, are undone. This is the default.

NOT ATOMIC CONTINUE ON SQLEXCEPTION
Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes that are made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

This clause must not be specified if the INSERT statement is contained within a SELECT statement.
For preparing the MERGE statement, atomicity is specified only on the
MERGE statement itself.

**WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS**

Specifies whether the values that are provided for indicator variables
during the execution of the statement follow standard SQL semantics for
indicating NULL values, or if the values can use extended indicator
variables to indicate a DEFAULT or UNASSIGNED value. WITHOUT
EXTENDED INDICATORS is the default.

**CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS**

Specifies whether a dynamic SQL statement that specifies literal constants
will be cached as a separate unique statement entry in the dynamic
statement cache instead of sharing an existing statement in the cache.
Dynamic SQL statements are eligible to share an existing statement in the
cache if the new statement meets all of the conditions for sharing a cached
version of the same dynamic statement except that the new statement
specifies one or more literal constants that are different than the cached
statement.

**CONCENTRATE STATEMENTS OFF**

Specifies that the dynamic SQL statement that specifies literal constants
will be cached as a unique statement entry if it specifies one or more
constants that are different than the cached version of the same
dynamic statement. **CONCENTRATE STATEMENTS OFF** is the
default dynamic statement caching behavior.

**CONCENTRATE STATEMENTS WITH LITERALS**

Specifies that the dynamic SQL statement that specifies literal constants
will share a cached version of the same dynamic statement that is also
prepared using the **CONCENTRATE STATEMENTS WITH LITERALS** option if the new dynamic statement meets all of the
conditions for sharing the cached statement and the constants that are
specified can be reused in place of the constants in the cached
statement.

**FROM**

Specifies the statement string. The statement string is the value of the specified
**string-expression** or the identified **variable**.

**variable**

Must identify a variable that is described in the application program in
accordance with the rules for declaring string variables. If the source string
is over 32KB in length, the **variable** must be a CLOB or DBCLOB variable.
The maximum source string length is 2MB although the variable can be
declared larger than 2MB. An indicator variable must not be specified with
a host variable. In PL/I, COBOL and Assembler language, the host variable
must be a varying-length string variable. In C, a host variable must not be
a NUL-terminated string. In SQL PL, an SQL variable is used in place of a
host variable, and the value must not be null.

**string-expression**

**string-expression** is any PL/I expression that yields a string. **string-expression**
cannot be preceded by a colon. Variables that are within **string-expression**
that include operators or functions should not be preceded by a colon.
When **string-expression** is specified, the precompiler-generated structures for
**string-expression** use an EBCDIC CCSID and an informational message is
returned.
Notes

**Rules for statement strings:** The value of the specified statement-name is called the statement string. The statement string must be one of the following SQL statements:

<table>
<thead>
<tr>
<th>Statement Name</th>
<th>Statement Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE CURSOR</td>
<td>RELEASE SAVEPOINT</td>
</tr>
<tr>
<td>ALTER</td>
<td>RENAME</td>

<td>SIGNAL</td>
</tr>
<tr>
<td>SET CURRENT PRECISION</td>
<td>TRUNCATE</td>
</tr>
<tr>
<td>SET CURRENT ROUTINE VERSION</td>
<td>UPDATE</td>
</tr>
</tbody>
</table>

The statement string must not:
- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables

**Parameter markers:** Although a statement string cannot include references to variables, other than global variables, it can include parameter markers. The parameter markers are replaced by the values of variables when the prepared statement is executed. A parameter marker is a question mark (?) that appears where a variable could appear if the statement string were a static SQL statement. For an explanation of how parameter markers are replaced by values, see the EXECUTE statement, OPEN on page 1840, and Dynamically executing a data change statement (DB2 Application programming and SQL).

The two types of parameter markers are typed and untyped:

**Typed parameter marker**
- A parameter marker that is specified with its target data type. A typed parameter marker has the general form:
  - `CAST(? AS data-type)`

This invocation of a CAST specification is a “promise” that the data type of the parameter at run time will be of the data type that is specified or some data type that is assignable to the specified data type. For example, in the...
following UPDATE statement, the value of the argument of the
TRANSLATE function will be provided at run time:

```
UPDATE EMPLOYEE
  SET LASTNAME = TRANSLATE(CAST(? AS VARCHAR(12)))
WHERE EMPNO = ?
```

The data type of the value that is provided for the TRANSLATE function
will either be VARCHAR(12), or some data type that can be converted to
VARCHAR(12). For more information, refer to “Assignment and
comparison” on page 123.

**Untyped parameter marker**

A parameter marker that is specified without its target data type. An
untyped parameter marker has the form of a single question mark. The
context in which the parameter marker appears determines its data type.
For example, in the above UPDATE statement, the data type of the
untyped parameter marker in the predicate is the same as the data type of
the EMPNO column.

Typed parameter markers can be used in dynamic SQL statements wherever a host
variable is supported and the data type is based on the promise made in the CAST
specification.

Untyped parameters markers can be used in dynamic SQL statements in selected
locations where host variables are supported. Table 152, Table 153 on page 1859,
Table 154 on page 1860, and Table 155 on page 1861 show these locations and the
resulting data type of the parameter. The tables group the locations into
expressions, predicates, functions, and other statements to help show where
untyped parameter markers are allowed.

Table 152. Untyped parameter marker usage in expressions (including select list, CASE, and
VALUES)

<table>

### Table 155. Untyped parameter marker usage in statements

<table>
<thead>
<tr>
<th>Location of untyped parameter marker</th>
<th>Data type (or error if not supported)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR $n$ ROWS clause of an INSERT or MERGE statement</td>
<td>Integer</td>
</tr>
<tr>
<td>The value on the right side of a SET clause in an UPDATE statement or the UPDATE clause of the MERGE statement</td>
<td>The data type of the column of the source-table, or if the column is defined as a distinct type, the source data type of the distinct type. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type.</td>
</tr>
<tr>
<td>$value$, $value1$, or $value2$ in a period specification for a table, or period clause for a data change statement if the target of the statement is a table</td>
<td>The data type of the columns of the period referenced in the period specification or period clause</td>
</tr>
<tr>
<td>$value$, $value1$, or $value2$ in a period specification for a view</td>
<td>Error</td>
</tr>
</tbody>
</table>
Considerations for FETCH statements used with a sensitive static cursor: Whether changes made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor:

- A SENSITIVE FETCH is sensitive to all updates and deletes that are made by this cursor (including changes made by triggers) and committed updates and deletes by all other application processes because every fetched row is retrieved from the underlying base table and not a temporary table. This is the default type of FETCH statement for a SENSITIVE cursor. Changes that are made to the underlying data using this cursor result in an automatic refresh of the row. The changes that are made using this type of cursor can result in holes in the result table of the cursor. In addition, re-fetching rows (fetching rows that have already been retrieved) can result in holes in the result table. If a sensitive FETCH is issued to re-fetch a row and the row no longer qualifies for the search condition of the query, it results in a "delete hole" or an "update hole". In this case, no data is returned, and the cursor is left positioned on the hole.

- An INSENSITIVE FETCH is not sensitive to updates and deletes that are made outside this cursor; however, it is sensitive to all updates and deletes that are made by this cursor. Changes that made with triggers are not visible with an INSENSITIVE FETCH until the content of the rows are updated in the result table with a SENSITIVE FETCH statement. If an application does not want to be sensitive to changes that are made outside this cursor (that is, the application does not want to see changes made either with another cursor or by another application process), INSENSITIVE can be explicitly specified as part of the FETCH statement for a SENSITIVE STATIC cursor. This type of FETCH is useful for refreshing data in user data buffers. For more information, see **INSENSITIVE**.

Error checking: When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is invalid, a prepared statement is not created and the error condition that prevents its creation is reported in the SQLCA.

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive “delayed” errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

Reference and execution rules: Prepared statements can be referred to in the following kinds of statements, with the following restrictions shown:

In... The prepared statement...

**DESCRIBE**
- has no restrictions

**DECLARE CURSOR**
- must be SELECT when the cursor is opened

**EXECUTE**
- must not be SELECT
