**Administration Guide**

**Note**

Before using this information and the product it supports, be sure to read the general information under “Notices” on page 1437.

**Eleventh Edition, Softcopy Only (October 2009)**

This edition applies to Version 8 of IBM DB2 Universal Database for z/OS (DB2 UDB for z/OS), product number 5625-DB2, and to any subsequent releases until otherwise indicated in new editions. Make sure you are using the correct edition for the level of the product.

This softcopy version is based on the printed edition of the book and includes the changes indicated in the printed version by vertical bars. Additional changes made to this softcopy version of the book since the hardcopy book was published are indicated by the hash (#) symbol in the left-hand margin. Editorial changes that have no technical significance are not noted.

This and other books in the DB2 UDB for z/OS library are periodically updated with technical changes. These updates are made available to licensees of the product on CD-ROM and on the Web (currently at [www.ibm.com/software/data/db2/zos/library.html](http://www.ibm.com/software/data/db2/zos/library.html)). Check these resources to ensure that you are using the most current information.

## **Part 1. Introduction** . . . . . **1**

### **Chapter 1. System planning concepts** . . . . . **3**

The structure of DB2. . . . .	3
Data structures . . . . .	3
System structures. . . . .	7
More information about data structures . . . . .	10
Control and maintenance of DB2 . . . . .	11
Commands . . . . .	11
Utilities. . . . .	11
High availability. . . . .	12
More information about control and maintenance of DB2 . . . . .	13
The DB2 environment . . . . .	13
Address spaces . . . . .	13
DB2 lock manager . . . . .	14
DB2 attachment facilities . . . . .	14
DB2 and distributed data. . . . .	18
DB2 and z/OS . . . . .	19
DB2 and the Parallel Sysplex . . . . .	19
DB2 and the Security Server for z/OS . . . . .	19
DB2 and DFSMS. . . . .	20
More information about the z/OS environment . . . . .	20

---

## **Part 2. Designing a database: advanced topics** . . . . . **23**

### **Chapter 2. Introduction to designing a database: advanced topics** . . . . . **25**

### **Chapter 3. Creating storage groups and managing DB2 data sets** . . . . . **27**

Managing data sets with DB2 storage groups . . . . .	27
Creating DB2 storage groups . . . . .	29
Using SMS to manage DB2 storage groups . . . . .	30
Deferring allocation of DB2-managed data sets . . . . .	30
Extending DB2-managed data sets. . . . .	31
Managing DB2 data sets with DFSMSHsm . . . . .	35
Migrating to DFSMSHsm . . . . .	35
Recalling archive logs . . . . .	36
Using DFSMSHsm with the RECOVER utility . . . . .	36
Using DFSMSHsm with the BACKUP SYSTEM utility . . . . .	37
Managing your own data sets . . . . .	37
Requirements for your own data sets. . . . .	38
Using the DEFINE CLUSTER command. . . . .	40
Extending user-managed data sets. . . . .	41
Defining index space storage . . . . .	41
Creating EA-enabled table spaces and index spaces . . . . .	42

<b>Chapter 4. Implementing your database design</b>	<b>43</b>
Implementing databases	43
Implementing table spaces	44
Creating a table space explicitly	44
Creating a table space implicitly	45
Choosing a page size	45
Choosing a page size for LOBs	46
Implementing tables	48
Distinctions between DB2 base tables and temporary tables	48
Implementing table-controlled partitioning	51
Implementing indexes	54
Types of indexes	54
Using the NOT PADDED clause for indexes with varying-length columns	57
Using indexes to avoid sorts	58
Using schemas	58
Creating a schema	58
Authorization to process schema definitions	59
Processing schema definitions	59
 <b>Chapter 5. Loading data into DB2 tables</b>	 <b>61</b>
Loading tables with the LOAD utility	61
Making corrections after LOAD	63
Loading data using the SQL INSERT statement	63
Inserting a single row	64
Inserting multiple rows	64
Special considerations when using INSERT statement to load tables	64
Loading data from DL/I	65
 <b>Chapter 6. Altering your database design</b>	 <b>67</b>
Altering DB2 storage groups	67
Letting SMS manage your DB2 storage groups	67
Adding or removing volumes from a DB2 storage group	67
Altering DB2 databases	68
Altering table spaces	69
Changing the space allocation for user-managed data sets	69
Dropping, re-creating, or converting a table space	69
Altering tables	71
Adding a new column to a table	71
Altering the data type of a column	73
Altering a table for referential integrity	77
Adding or dropping table check constraints	80
Adding a partition	80
Altering partitions	82
Registering or changing materialized query tables	85
Altering the assignment of a validation routine	86
Altering a table for capture of changed data	87
Changing an edit procedure or a field procedure	87
Altering the subtype of a string column	88
Altering the attributes of an identity column	88
Changing data types by dropping and re-creating the table	88
Moving a table to a table space of a different page size	91
Altering indexes	92
Adding a new column to an index	92
Altering how varying-length index columns are stored	93
Altering the clustering index	93
Rebalancing data in partitioned table spaces	93
Dropping and redefining an index	94
Index versions	94
Altering views	96
Altering stored procedures	96

	Altering user-defined functions . . . . .	96
	Moving from index-controlled to table-controlled partitioning . . . . .	97
	Changing the high-level qualifier for DB2 data sets . . . . .	98
	Defining a new integrated catalog alias . . . . .	99
	Changing the qualifier for system data sets . . . . .	99
	Changing qualifiers for other databases and user data sets . . . . .	102
	Moving DB2 data . . . . .	105
	Tools for moving DB2 data . . . . .	106
	Moving a DB2 data set . . . . .	108
	Copying a relational database . . . . .	109
	Copying an entire DB2 subsystem . . . . .	109
	<b>Chapter 7. Estimating disk storage for user data . . . . .</b>	<b>111</b>
	Factors that affect storage . . . . .	111
	Calculating the space required for a table . . . . .	113
	Calculating record lengths and pages . . . . .	113
	Saving space with data compression . . . . .	114
	Estimating storage for LOBs . . . . .	114
	Estimating storage when using the LOAD utility . . . . .	115
	Calculating the space required for a dictionary . . . . .	116
	Disk requirements . . . . .	116
	Virtual storage requirements . . . . .	117
	Calculating the space required for an index . . . . .	117
	Levels of index pages . . . . .	117
	Estimating storage from number of index pages . . . . .	118
	<hr/>	
	<b>Part 3. Security and auditing . . . . .</b>	<b>123</b>
	<b>Chapter 8. Introduction to security and auditing in DB2 . . . . .</b>	<b>127</b>
	Reading strategies for security . . . . .	127
	If you are new to DB2 . . . . .	127
	If you have used DB2 before . . . . .	128
	Reading strategies for auditing . . . . .	128
	Controlling data access . . . . .	128
#	Access control within DB2 . . . . .	129
	Controlling access to a DB2 subsystem . . . . .	131
	Data set protection . . . . .	132
	<b>Chapter 9. Controlling access to DB2 objects . . . . .</b>	<b>133</b>
	Explicit privileges and authorities . . . . .	133
	Authorization IDs . . . . .	134
	Granting explicit privileges . . . . .	134
	Administrative authorities . . . . .	138
	Field-level access control by views . . . . .	143
	Authority over the catalog and directory . . . . .	144
	Implicit privileges of ownership . . . . .	145
	Establishing ownership of objects with unqualified names . . . . .	145
	Establishing ownership of objects with qualified names . . . . .	146
	Privileges by type of object . . . . .	146
	Granting implicit privileges . . . . .	147
	Changing ownership . . . . .	147
	Privileges exercised through a plan or a package . . . . .	148
	Establishing or changing ownership of a plan or a package . . . . .	148
	Qualifying unqualified names . . . . .	149
#	Authorization to execute . . . . .	149
	Controls in the program . . . . .	153
	Privileges required for remote packages . . . . .	154
	Access control for user-defined functions and stored procedures . . . . .	154
	Additional authorization for stored procedures . . . . .	156
	Controlling access to catalog tables for stored procedures . . . . .	156

#	Example of roles and authorizations for a routine . . . . .	157
	Which IDs can exercise which privileges . . . . .	161
	Authorization for dynamic SQL statements . . . . .	164
	Composite privileges . . . . .	171
	Multiple actions in one statement. . . . .	171
	Matching job titles with privileges . . . . .	171
	Examples of granting and revoking privileges . . . . .	173
#	Examples using the GRANT statement . . . . .	174
	Examples with secondary IDs . . . . .	176
#	Examples using the REVOKE statement . . . . .	180
	Finding catalog information about privileges . . . . .	187
	Retrieving information in the catalog . . . . .	187
#	Creating views of the DB2 catalog tables . . . . .	191
	Multilevel security. . . . .	192
	Introduction to multilevel security . . . . .	192
	Implementing multilevel security with DB2 . . . . .	195
	Working with data in a multilevel-secure environment . . . . .	199
	Implementing multilevel security in a distributed environment. . . . .	206
	Data encryption through built-in functions . . . . .	207
	Defining columns for encrypted data . . . . .	208
	Defining encryption at the column level . . . . .	208
	Defining encryption at the value level . . . . .	210
	Ensuring accurate predicate evaluation for encrypted data . . . . .	211
	Encrypting non-character values . . . . .	211
#	Performance recommendations for data encryption. . . . .	212

## **Chapter 10. Controlling access through a closed application . . . . . 215**

	Registration tables. . . . .	216
	Columns of the ART . . . . .	216
	Columns of the ORT . . . . .	217
	Controlling data definition . . . . .	218
	Installing data definition control support . . . . .	219
	Controlling data definition by application name. . . . .	220
	Controlling data definition by application name with exceptions . . . . .	221
	Controlling data definition by object name . . . . .	222
	Controlling data definition by object name with exceptions . . . . .	224
	Registering sets of objects . . . . .	225
	Managing the registration tables and their indexes . . . . .	226
	Creating the tables and indexes . . . . .	226
	Adding columns . . . . .	228
	Updating the tables . . . . .	228
	Stopping data definition control . . . . .	228

## **Chapter 11. Controlling access to a DB2 subsystem . . . . . 231**

	Controlling local requests . . . . .	232
	Processing connections . . . . .	232
	Steps in processing connections . . . . .	233
	Supplying secondary IDs for connection requests . . . . .	234
	Required CICS specifications . . . . .	235
	Processing sign-ons . . . . .	236
	Steps in processing sign-ons . . . . .	236
	Supplying secondary IDs for sign-on requests . . . . .	237
	Controlling requests from remote applications . . . . .	238
	Overview of security mechanisms for DRDA and SNA . . . . .	238
	The communications database for the server . . . . .	240
	Controlling inbound connections that use SNA protocols . . . . .	242
	Controlling inbound connections that use TCP/IP protocols . . . . .	249
	Planning to send remote requests. . . . .	252
	The communications database for the requester . . . . .	253
	What IDs you send . . . . .	257

Translating outbound IDs . . . . .	260
Sending passwords . . . . .	262
Establishing RACF protection for DB2 . . . . .	264
Defining DB2 resources to RACF . . . . .	265
Permitting RACF access . . . . .	267
Issuing DB2 commands . . . . .	274
Establishing RACF protection for stored procedures . . . . .	274
Establishing RACF protection for TCP/IP . . . . .	278
Establishing Kerberos authentication through RACF . . . . .	278
Other methods of controlling access . . . . .	279
<b># Chapter 12. Protecting data sets through RACF . . . . .</b>	<b>281</b>
# Adding groups to control DB2 data sets . . . . .	281
# Creating generic profiles for data sets . . . . .	281
# Permitting DB2 authorization IDs to use the profiles . . . . .	283
# Allowing DB2 authorization IDs to create data sets . . . . .	283
<b>Chapter 13. Auditing . . . . .</b>	<b>285</b>
Using the audit trace . . . . .	285
Starting the audit trace . . . . .	286
Stopping the audit trace . . . . .	286
Audit class descriptions . . . . .	287
Limitations of the audit trace . . . . .	287
Auditing in a distributed data environment . . . . .	288
Auditing a specific table . . . . .	288
The role of authorization IDs in auditing . . . . .	289
Auditing specific IDs . . . . .	290
Determining which IDs hold privileges and authorities . . . . .	290
Using audit records . . . . .	290
The contents of audit records . . . . .	291
Formatting audit records . . . . .	291
Suggested audit trace reports . . . . .	291
Using other sources of audit information . . . . .	292
Determining which security measures are enabled . . . . .	292
Ensuring data accuracy and consistency . . . . .	293
Ensuring that the required data is present . . . . .	293
Ensuring that data is unique . . . . .	293
Ensuring that data fits a pattern or value range . . . . .	293
Ensuring that data is consistent . . . . .	294
Ensuring that changes are tracked . . . . .	295
Ensuring that concurrent users access consistent data . . . . .	295
Checking for lost and incomplete transactions . . . . .	296
Determining whether data is consistent . . . . .	296
# Automatically checking the consistency of data . . . . .	297
# Submitting SQL queries to check data consistency . . . . .	297
# Checking data consistency with the CHECK utility . . . . .	297
# Checking data consistency with the DISPLAY DATABASE command . . . . .	298
# Checking data consistency with the REPORT utility . . . . .	298
# Checking data consistency with the operation log . . . . .	298
Using internal integrity reports to check data consistency . . . . .	298
<b>Chapter 14. A sample security plan for employee data . . . . .</b>	<b>301</b>
Securing manager access . . . . .	301
Granting the SELECT privilege to managers . . . . .	302
Securing distributed access . . . . .	303
Auditing manager use . . . . .	304
Securing payroll operations access . . . . .	305
Securing compensation updates . . . . .	305
Additional controls for compensation updates . . . . .	306
Granting privileges to payroll operations and payroll management . . . . .	307

Auditing payroll operations and payroll management . . . . .	307
Securing administrator, owner, and other access . . . . .	308
Securing access by IDs with database administrator authority . . . . .	308
Securing access by IDs with system administrator authority . . . . .	308
Securing access by owners with implicit privileges on objects . . . . .	309
Securing access by other users. . . . .	310

---

**Part 4. Operation and recovery . . . . . 311**

**Chapter 15. Basic operation . . . . . 317**

Entering commands . . . . .	317
DB2 operator commands . . . . .	318
Authorities for DB2 commands . . . . .	323
Starting and stopping DB2 . . . . .	324
Starting DB2. . . . .	324
Stopping DB2 . . . . .	326
Submitting work . . . . .	327
Using DB2I (DB2 Interactive) . . . . .	327
Running TSO application programs . . . . .	327
Running IMS application programs . . . . .	328
Running CICS application programs. . . . .	329
Running batch application programs . . . . .	330
Running application programs using CAF. . . . .	330
Running application programs using RRSAP . . . . .	331
Receiving messages . . . . .	331
Receiving unsolicited DB2 messages. . . . .	332
Determining operational control . . . . .	332

**Chapter 16. Scheduling administrative tasks . . . . . 335**

Interacting with the administrative task scheduler . . . . .	335
Adding a task . . . . .	335
Listing scheduled tasks . . . . .	347
Listing the last execution status of scheduled tasks . . . . .	347
Removing a scheduled task. . . . .	348
Manually starting the administrative task scheduler . . . . .	351
Manually stopping the administrative task scheduler . . . . .	351
Synchronization between administrative task schedulers in a data sharing environment . . . . .	351
Troubleshooting the administrative task scheduler . . . . .	352
Architecture of the administrative task scheduler . . . . .	355
The lifecycle of the administrative task scheduler . . . . .	356
Scheduler task lists . . . . .	357
Architecture of the administrative task scheduler in a data sharing environment . . . . .	358
Security guidelines for the administrative task scheduler . . . . .	359
User roles in the administrative task scheduler . . . . .	360
Protection of the interface of the administrative task scheduler . . . . .	361
Protection of the resources of the administrative task scheduler . . . . .	361
Secure execution of tasks in the administrative task scheduler . . . . .	361
Execution of scheduled tasks in the administrative task scheduler . . . . .	362
Multi-threading in the administrative task scheduler . . . . .	363
Scheduled execution of a stored procedure . . . . .	364
How the administrative task scheduler works with Unicode. . . . .	364
Scheduled execution of a JCL job . . . . .	365
Execution of scheduled tasks in a data sharing environment. . . . .	365

**Chapter 17. Monitoring and controlling DB2 and its connections . . . . . 367**

Controlling DB2 databases and buffer pools . . . . .	367
Starting databases . . . . .	368
Monitoring databases. . . . .	369
Stopping databases . . . . .	375
Altering buffer pools . . . . .	376

Monitoring buffer pools . . . . .	377
Controlling user-defined functions . . . . .	377
Starting user-defined functions . . . . .	377
Monitoring user-defined functions . . . . .	378
Stopping user-defined functions . . . . .	378
Controlling DB2 utilities. . . . .	379
Starting online utilities . . . . .	379
Monitoring online utilities . . . . .	379
Stand-alone utilities . . . . .	380
Controlling the IRLM. . . . .	380
Starting the IRLM . . . . .	381
Modifying the IRLM . . . . .	381
Monitoring the IRLM connection . . . . .	382
Stopping the IRLM . . . . .	382
Monitoring threads . . . . .	383
Controlling TSO connections . . . . .	384
Connecting to DB2 from TSO . . . . .	385
Monitoring TSO and CAF connections . . . . .	385
Disconnecting from DB2 while under TSO. . . . .	387
Controlling CICS connections . . . . .	387
Connecting from CICS . . . . .	388
Controlling CICS connections . . . . .	389
Disconnecting from CICS . . . . .	391
Controlling IMS connections . . . . .	392
Connecting to the IMS control region . . . . .	392
Controlling IMS dependent region connections . . . . .	397
Disconnecting from IMS. . . . .	400
Controlling RRS connections . . . . .	401
Connecting to RRS using RRSAF . . . . .	401
Monitoring RRSAF connections . . . . .	403
Controlling connections to remote systems . . . . .	404
Starting the DDF . . . . .	405
Suspending and resuming DDF server activity . . . . .	405
Monitoring connections to other systems . . . . .	406
Monitoring and controlling stored procedures . . . . .	417
Using NetView to monitor errors. . . . .	420
Stopping the DDF . . . . .	421
Controlling traces . . . . .	422
Controlling the DB2 trace . . . . .	423
Diagnostic traces for attachment facilities . . . . .	424
Diagnostic trace for the IRLM . . . . .	424
Controlling the resource limit facility (governor). . . . .	425
Changing subsystem parameter values . . . . .	425
<b>Chapter 18. Managing the log and the bootstrap data set . . . . .</b>	<b>427</b>
How database changes are made . . . . .	427
Units of recovery . . . . .	427
Rolling back work. . . . .	428
Establishing the logging environment . . . . .	429
Creation of log records . . . . .	429
Retrieval of log records . . . . .	429
Writing the active log. . . . .	430
Writing the archive log (offloading) . . . . .	430
Controlling the log . . . . .	435
Archiving the log . . . . .	435
Dynamically changing the checkpoint frequency. . . . .	437
Monitoring the system checkpoint . . . . .	438
Setting limits for archive log tape units. . . . .	438
Displaying log information . . . . .	438
Resetting the log RBA . . . . .	438
Log RBA range. . . . .	439

Resetting the log RBA value in a data sharing environment . . . . .	439
Resetting the log RBA value in a non-data sharing environment . . . . .	440
Managing the bootstrap data set (BSDS) . . . . .	441
BSDS copies with archive log data sets . . . . .	442
Changing the BSDS log inventory . . . . .	442
Discarding archive log records. . . . .	443
Deleting archive logs automatically . . . . .	443
Locating archive log data sets . . . . .	444
<b>Chapter 19. Restarting DB2 after termination . . . . .</b>	<b>447</b>
Termination . . . . .	447
Normal termination . . . . .	447
Abends . . . . .	448
Normal restart and recovery . . . . .	448
Phase 1: Log initialization . . . . .	449
Phase 2: Current status rebuild . . . . .	450
Phase 3: Forward log recovery. . . . .	451
Phase 4: Backward log recovery . . . . .	452
Restarting automatically. . . . .	453
Deferring restart processing . . . . .	454
Restarting with conditions . . . . .	455
Resolving postponed units of recovery . . . . .	456
Choosing recovery operations for conditional restart . . . . .	457
Conditional restart records . . . . .	458
<b>Chapter 20. Maintaining consistency across multiple systems . . . . .</b>	<b>459</b>
Multiple system consistency . . . . .	459
The two-phase commit process . . . . .	459
Illustration of two-phase commit . . . . .	460
Maintaining consistency after termination or failure . . . . .	461
Termination for multiple systems. . . . .	462
Normal restart and recovery for multiple systems . . . . .	462
Restarting multiple systems with conditions . . . . .	463
Resolving indoubt units of recovery . . . . .	463
Resolution of IMS indoubt units of recovery . . . . .	464
Resolution of CICS indoubt units of recovery. . . . .	465
Resolution of WebSphere Application Server indoubt units of recovery . . . . .	465
Resolution of remote DBMS indoubt units of recovery. . . . .	467
Resolution of RRS indoubt units of recovery . . . . .	470
Consistency across more than two systems . . . . .	471
Commit coordinator and multiple participants . . . . .	471
Illustration of multi-site update . . . . .	472
<b>Chapter 21. Backing up and recovering databases . . . . .</b>	<b>475</b>
Planning for backup and recovery . . . . .	475
Considerations for recovering distributed data . . . . .	476
Extended recovery facility (XRF) toleration . . . . .	476
Considerations for recovering indexes . . . . .	477
Preparing for recovery . . . . .	477
Events that occur during recovery . . . . .	478
Maximizing data availability during backup and recovery . . . . .	481
How to find recovery information . . . . .	484
Preparing to recover to a prior point of consistency . . . . .	485
Preparing to recover the entire DB2 subsystem to a prior point-in-time . . . . .	486
Preparing for disaster recovery . . . . .	487
Ensuring more effective recovery from inconsistency . . . . .	490
Running the RECOVER utility in parallel . . . . .	492
Using fast log apply during RECOVER. . . . .	493
Reading the log without RECOVER . . . . .	493
Copying page sets and data sets . . . . .	493

Backing up with DFSMS . . . . .	495
Backing up with RVA storage control or Enterprise Storage Server. . . . .	495
Recovering page sets and data sets . . . . .	495
Recovering the work file database . . . . .	497
Problems with the user-defined work file data set . . . . .	497
Problems with DB2-managed work file data sets . . . . .	497
Recovering error ranges for a work file table space . . . . .	497
Recovering the catalog and directory . . . . .	498
Recovering data to a prior point of consistency . . . . .	499
Considerations for recovering to a prior point of consistency . . . . .	499
Using RECOVER to restore data to a previous point-in-time. . . . .	504
Recovery of dropped objects . . . . .	509
Discarding SYSCOPY and SYSLGRNX records . . . . .	514
System-level point-in-time recovery . . . . .	515
<b>Chapter 22. Recovery scenarios . . . . .</b>	<b>521</b>
IRLM failure recovery . . . . .	521
z/OS or power failure recovery . . . . .	522
Disk failure recovery . . . . .	522
Application error recovery . . . . .	524
IMS-related failure recovery . . . . .	525
IMS control region (CTL) failure recovery . . . . .	526
Resolution of indoubt units of recovery. . . . .	526
IMS application failure recovery . . . . .	528
CICS-related failure recovery . . . . .	529
CICS application failure recovery. . . . .	529
Recovery when CICS is not operational . . . . .	529
Recovery when CICS cannot connect to DB2 . . . . .	530
Manually recovering CICS indoubt units of recovery . . . . .	531
CICS attachment facility failure recovery . . . . .	534
Subsystem termination recovery . . . . .	534
Resource failure recovery . . . . .	535
Active log failure recovery . . . . .	535
Archive log failure recovery . . . . .	539
Temporary resource failure recovery. . . . .	541
BSDS failure recovery . . . . .	542
Recovering the BSDS from a backup copy. . . . .	543
DB2 database failures. . . . .	546
# Recovering a DB2 subsystem to a prior point in time . . . . .	547
Recovery from down-level page sets. . . . .	548
Procedure for recovering invalid LOBs . . . . .	550
Table space input/output error recovery . . . . .	550
DB2 catalog or directory input/output errors. . . . .	551
Integrated catalog facility failure recovery. . . . .	552
Recovery when the VSAM volume data set (VVDS) is destroyed . . . . .	552
Out of disk space or extent limit recovery . . . . .	554
Violation of referential constraint recovery. . . . .	558
Distributed data facility failure recovery . . . . .	558
Conversation failure recovery . . . . .	559
Communications database failure recovery . . . . .	559
Database access thread failure recovery. . . . .	560
VTAM failure recovery . . . . .	561
TCP/IP failure recovery . . . . .	561
Remote logical unit failure recovery . . . . .	561
Indefinite wait condition recovery . . . . .	562
Security failure recovery for database access threads . . . . .	562
Remote site recovery from a disaster at the local site . . . . .	563
Restoring data from image copies and archive logs . . . . .	563
Using a tracker site for disaster recovery . . . . .	574
Using data mirroring. . . . .	582
Resolving indoubt threads . . . . .	588

Description of the recovery environment . . . . .	589
Communication failure recovery . . . . .	590
Making a heuristic decision . . . . .	591
Recovery from an IMS outage that results in an IMS cold start . . . . .	592
Recovery from a DB2 outage at a requester that results in a DB2 cold start . . . . .	593
Recovery from a DB2 outage at a server that results in a DB2 cold start . . . . .	596
Correcting a heuristic decision. . . . .	596
<b>Chapter 23. Recovery from BSDS or log failure during restart . . . . .</b>	<b>597</b>
Log initialization or current status rebuild failure recovery . . . . .	599
Description of failure during log initialization . . . . .	600
Description of failure during current status rebuild. . . . .	601
Restart by truncating the log . . . . .	601
Failure during forward log recovery. . . . .	608
Understanding forward log recovery failure . . . . .	609
Starting DB2 by limiting restart processing . . . . .	609
Failure during backward log recovery . . . . .	613
Understanding backward log recovery failure . . . . .	614
Bypassing backout before restarting . . . . .	614
Failure during a log RBA read request . . . . .	615
Unresolvable BSDS or log data set problem during restart . . . . .	616
Preparing for recovery or restart . . . . .	617
Performing fall back to a prior shutdown point . . . . .	617
Failure resulting from total or excessive loss of log data . . . . .	619
Total loss of the log . . . . .	619
Excessive loss of data in the active log . . . . .	620
Resolving inconsistencies resulting from a conditional restart . . . . .	622
Inconsistencies in a distributed environment . . . . .	622
Procedures for resolving inconsistencies . . . . .	622
Method 1. Recover to a prior point of consistency . . . . .	623
Method 2. Re-create the table space . . . . .	624
Method 3. Use the REPAIR utility on the data . . . . .	624
<b>Part 5. Performance monitoring and tuning . . . . .</b>	<b>627</b>
<b>Chapter 24. Planning your performance strategy . . . . .</b>	<b>633</b>
Managing performance in general . . . . .	633
Setting reasonable performance objectives . . . . .	634
Defining the workload . . . . .	634
Initial performance planning . . . . .	635
Post-development review . . . . .	637
Planning for performance monitoring . . . . .	637
Continuous performance monitoring . . . . .	638
Periodic performance monitoring. . . . .	639
Detailed performance monitoring. . . . .	639
Exception performance monitoring . . . . .	640
A performance monitoring strategy . . . . .	640
Reviewing performance data . . . . .	640
Typical review questions . . . . .	641
Are your performance objectives reasonable?. . . . .	642
<b>Chapter 25. Analyzing performance data. . . . .</b>	<b>645</b>
Investigating the problem overall. . . . .	645
Looking at the entire system . . . . .	645
Beginning to look at DB2 . . . . .	645
Reading accounting reports from OMEGAMON. . . . .	646
The accounting report (short format) . . . . .	646
The accounting report (long format). . . . .	647
A general approach to problem analysis in DB2 . . . . .	652

<b>Chapter 26. Improving response time and throughput . . . . .</b>	<b>657</b>
Reducing I/O operations . . . . .	657
Using RUNSTATS to keep access path statistics current . . . . .	657
Reserving free space in table spaces and indexes . . . . .	658
Making buffer pools large enough for the workload . . . . .	660
Reducing the time needed to perform I/O operations . . . . .	660
Distributing data sets efficiently . . . . .	660
Creating additional work file table spaces . . . . .	663
Managing space for I/O performance . . . . .	664
Reducing processor resource consumption. . . . .	665
Reusing threads for your high-volume transactions. . . . .	666
Minimizing the use of DB2 traces . . . . .	666
Using fixed-length records . . . . .	667
Response time reporting. . . . .	667
<b>Chapter 27. Tuning DB2 buffer, EDM, RID, and sort pools . . . . .</b>	<b>671</b>
Tuning database buffer pools . . . . .	671
Terminology: Types of buffer pool pages . . . . .	672
Read operations . . . . .	672
Write operations . . . . .	672
Assigning a table space or index to a buffer pool . . . . .	673
Buffer pool thresholds . . . . .	673
Determining size and number of buffer pools . . . . .	677
Choosing a page-stealing algorithm . . . . .	680
Long-term page fix option for buffer pools . . . . .	681
Monitoring and tuning buffer pools using online commands . . . . .	681
Using OMEGAMON to monitor buffer pool statistics . . . . .	683
Tuning EDM storage . . . . .	685
EDM storage space handling . . . . .	686
Tips for managing EDM storage . . . . .	688
Increasing RID pool size. . . . .	689
Controlling sort pool size and sort processing . . . . .	690
Estimating the maximum size of the sort pool . . . . .	690
How sort work files are allocated. . . . .	690
Improving the performance of sort processing . . . . .	691
<b>Chapter 28. Improving resource utilization . . . . .</b>	<b>693</b>
Managing the opening and closing of data sets . . . . .	693
Determining the maximum number of open data sets . . . . .	693
Understanding the CLOSE YES and CLOSE NO options . . . . .	696
Switching to read-only for infrequently updated and infrequently accessed page sets . . . . .	697
Planning the placement of DB2 data sets . . . . .	698
Estimating concurrent I/O requests . . . . .	698
Crucial DB2 data sets. . . . .	698
Changing catalog and directory size and location . . . . .	699
Monitoring I/O activity of data sets. . . . .	699
Work file data sets. . . . .	699
DB2 logging. . . . .	700
Logging performance issues and recommendations. . . . .	700
Log capacity. . . . .	703
Controlling the amount of log data . . . . .	705
Improving disk utilization: space and device utilization . . . . .	707
Allocating and extending data sets . . . . .	707
Compressing your data . . . . .	708
Evaluating your indexes. . . . .	711
Improving real storage utilization . . . . .	712
Performance and storage . . . . .	714
Real storage . . . . .	714
Storage devices. . . . .	715
z/OS performance options for DB2 . . . . .	717

	Determining z/OS workload management velocity goals . . . . .	717
	How DB2 assigns I/O priorities . . . . .	718
#	IBM System z9 Integrated Information Processor usage monitoring . . . . .	719
	Controlling resource usage . . . . .	720
	Prioritizing resources . . . . .	721
	Limiting resources for each job . . . . .	721
	Limiting resources for TSO sessions . . . . .	721
	Limiting resources for IMS and CICS . . . . .	722
	Limiting resources for a stored procedure . . . . .	722
	Resource limit facility (governor) . . . . .	722
	Using resource limit tables (RLSTs) . . . . .	723
	Governing dynamic queries . . . . .	728
	Restricting bind operations . . . . .	733
	Restricting parallelism modes . . . . .	733
	<b>Chapter 29. Managing DB2 threads . . . . .</b>	<b>735</b>
	Setting thread limits . . . . .	735
	Allied thread allocation . . . . .	736
	Step 1: Thread creation . . . . .	736
	Step 2: Resource allocation . . . . .	737
	Step 3: SQL statement execution . . . . .	737
	Step 4: Commit and thread termination. . . . .	738
	Variations on thread management . . . . .	739
	Providing for thread reuse . . . . .	739
	Database access threads . . . . .	741
	Using allied threads and database access threads . . . . .	741
	Setting thread limits for database access threads. . . . .	741
	Using threads in INACTIVE MODE for DRDA-only connections . . . . .	742
	Using threads with private-protocol connections. . . . .	744
	Reusing threads for remote connections . . . . .	745
	Using z/OS workload management to set performance objectives . . . . .	745
	CICS design options . . . . .	748
	IMS design options . . . . .	748
	TSO design options . . . . .	749
	DB2 QMF design options . . . . .	750
	<b>Chapter 30. Tuning your queries . . . . .</b>	<b>751</b>
	General tips and questions . . . . .	751
	Is the query coded as simply as possible? . . . . .	751
	Are all predicates coded correctly? . . . . .	751
	Are there subqueries in your query?. . . . .	752
	Does your query involve aggregate functions? . . . . .	753
	Do you have an input variable in the predicate of an SQL query? . . . . .	754
	Do you have a problem with column correlation? . . . . .	754
	Can your query be written to use a noncolumn expression? . . . . .	754
	Can materialized query tables help your query performance? . . . . .	754
	Does the query contain encrypted data? . . . . .	755
	Writing efficient predicates . . . . .	755
	Properties of predicates . . . . .	755
	Predicates in the ON clause . . . . .	758
	General rules about predicate evaluation . . . . .	759
	Order of evaluating predicates. . . . .	759
	Summary of predicate processing. . . . .	760
	Examples of predicate properties . . . . .	765
	Predicate filter factors . . . . .	766
	Column correlation . . . . .	772
	DB2 predicate manipulation . . . . .	775
	Predicates with encrypted data . . . . .	779
	Using host variables efficiently . . . . .	779
	Changing the access path at run time . . . . .	779

Rewriting queries to influence access path selection . . . . .	782
Writing efficient subqueries. . . . .	785
Correlated subqueries . . . . .	785
Noncorrelated subqueries . . . . .	786
Conditions for DB2 to transform a subquery into a join . . . . .	788
Subquery tuning . . . . .	790
Using scrollable cursors efficiently . . . . .	790
Writing efficient queries on tables with data-partitioned secondary indexes. . . . .	792
Special techniques to influence access path selection . . . . .	794
Obtaining information about access paths . . . . .	794
Fetching a limited number of rows: FETCH FIRST <i>n</i> ROWS ONLY . . . . .	795
Minimizing overhead for retrieving few rows: OPTIMIZE FOR <i>n</i> ROWS . . . . .	795
Favoring index access . . . . .	798
Using a subsystem parameter to control outer join processing . . . . .	798
Using the CARDINALITY clause to improve the performance of queries with user-defined table function references . . . . .	798
Reducing the number of matching columns . . . . .	799
Creating indexes for efficient star-join processing . . . . .	801
Rearranging the order of tables in a FROM clause . . . . .	803
Updating catalog statistics . . . . .	804
Using a subsystem parameter . . . . .	805
Giving optimization hints to DB2. . . . .	806
<b>Chapter 31. Improving concurrency . . . . .</b>	<b>813</b>
Definitions of concurrency and locks . . . . .	814
Effects of DB2 locks . . . . .	814
Suspension . . . . .	814
Timeout . . . . .	815
Deadlock . . . . .	815
Basic recommendations to promote concurrency. . . . .	816
Recommendations for system and subsystem options . . . . .	816
Recommendations for database design . . . . .	817
Recommendations for application design . . . . .	818
Aspects of transaction locks . . . . .	821
The size of a lock . . . . .	821
The duration of a lock . . . . .	824
The mode of a lock . . . . .	825
The object of a lock . . . . .	827
DB2 choices of lock types . . . . .	830
Options for tuning locks. . . . .	836
IRLM startup procedure options . . . . .	836
Installation options for wait times . . . . .	837
Other options that affect locking . . . . .	841
Bind options. . . . .	847
Isolation overriding with SQL statements . . . . .	862
The LOCK TABLE statement . . . . .	863
LOB locks . . . . .	864
Relationship between transaction locks and LOB locks . . . . .	864
Hierarchy of LOB locks . . . . .	865
LOB and LOB table space lock modes . . . . .	866
LOB lock and LOB table space lock duration . . . . .	866
Instances when LOB table space locks are not taken . . . . .	867
Control of the number of LOB locks. . . . .	867
The LOCK TABLE statement for LOBs . . . . .	868
LOCKSIZE clause for LOB table spaces. . . . .	868
Claims and drains for concurrency control . . . . .	869
Objects that are subject to takeover . . . . .	869
Claims . . . . .	869
Drains. . . . .	870
Usage of drain locks . . . . .	870
Utility locks on the catalog and directory . . . . .	871

Compatibility of utilities . . . . .	871
Concurrency during REORG . . . . .	872
Utility operations with nonpartitioned indexes . . . . .	873
Monitoring of DB2 locking . . . . .	873
Using EXPLAIN to tell which locks DB2 chooses . . . . .	874
Using the statistics and accounting traces to monitor locking . . . . .	875
Scenario for analyzing concurrency . . . . .	876
Deadlock detection scenarios . . . . .	881
Scenario 1: Two-way deadlock with two resources . . . . .	881
Scenario 2: Three-way deadlock with three resources . . . . .	883
<b>Chapter 32. Using materialized query tables . . . . .</b>	<b>885</b>
Introduction to materialized query tables and automatic query rewrite . . . . .	885
Example of automatic query rewrite using a materialized query table . . . . .	886
Steps for using automatic query rewrite . . . . .	886
Defining a materialized query table . . . . .	887
Creating a new materialized query table . . . . .	887
Registering an existing table as a materialized query table . . . . .	888
Altering a materialized query table . . . . .	890
Populating and maintaining materialized query tables . . . . .	890
Using the REFRESH TABLE statement . . . . .	891
Using INSERT, UPDATE, DELETE, and LOAD for materialized query tables . . . . .	891
Collecting statistics on materialized query tables . . . . .	892
Using multilevel security with materialized query tables . . . . .	892
Creating a materialized query table . . . . .	892
Altering a source table . . . . .	893
Refreshing a materialized query table . . . . .	893
Exploiting automatic query rewrite . . . . .	893
Making materialized query tables eligible . . . . .	893
Query requirements and the rewrite process . . . . .	895
Recommendations for materialized query table and base table design . . . . .	901
Materialized query table examples shipped with DB2 . . . . .	902
<b>Chapter 33. Maintaining statistics in the catalog . . . . .</b>	<b>903</b>
Statistics used for access path selection . . . . .	903
Filter factors and catalog statistics . . . . .	910
Statistics for partitioned table spaces . . . . .	912
Setting default statistics for created temporary tables . . . . .	912
History statistics . . . . .	913
Gathering monitor statistics and update statistics . . . . .	916
Updating the catalog . . . . .	917
Correlations in the catalog . . . . .	917
Recommendation for COLCARDF and FIRSTKEYCARDF . . . . .	918
Recommendation for HIGH2KEY and LOW2KEY . . . . .	919
Statistics for distributions . . . . .	919
Recommendation for using the TIMESTAMP column . . . . .	919
Querying the catalog for statistics . . . . .	920
Improving index and table space access . . . . .	920
How clustering affects access path selection . . . . .	921
What other statistics provide index costs . . . . .	923
When to reorganize indexes and table spaces . . . . .	924
Whether to rebind after gathering statistics . . . . .	927
Modeling your production system . . . . .	927
<b>Chapter 34. Using EXPLAIN to improve SQL performance . . . . .</b>	<b>931</b>
Obtaining PLAN_TABLE information from EXPLAIN . . . . .	932
Creating PLAN_TABLE . . . . .	933
Populating and maintaining a plan table . . . . .	940
Reordering rows from a plan table . . . . .	943
Asking questions about data access . . . . .	943

Is access through an index? (ACCESSTYPE is I, I1, N or MX)	944
Is access through more than one index? (ACCESSTYPE=M)	944
How many columns of the index are used in matching? (MATCHCOLS=n)	945
Is the query satisfied using only the index? (INDEXONLY=Y)	946
Is direct row access possible? (PRIMARY_ACCESSTYPE = D)	946
Is a view or nested table expression materialized?	948
Was a scan limited to certain partitions? (PAGE_RANGE=Y)	948
What kind of prefetching is expected? (PREFETCH = L, S, D, or blank)	949
Is data accessed or processed in parallel? (PARALLELISM_MODE is I, C, or X)	949
Are sorts performed?	949
Is a subquery transformed into a join?	950
When are aggregate functions evaluated? (COLUMN_FN_EVAL)	950
How many index screening columns are used?	950
Is a complex trigger WHEN clause used? (QBLOCKTYPE=TRIGGR)	950
Interpreting access to a single table	951
Table space scans (ACCESSTYPE=R PREFETCH=S)	951
Overview of index access	952
Index access paths.	954
UPDATE using an index	958
Interpreting access to two or more tables (join)	959
Definitions and examples of join operations	959
Nested loop join (METHOD=1)	961
Merge scan join (METHOD=2)	963
Hybrid join (METHOD=4)	965
Star join (JOIN_TYPE='S')	967
Interpreting data prefetch	973
Sequential prefetch (PREFETCH=S)	973
Dynamic prefetch (PREFETCH=D)	974
List prefetch (PREFETCH=L)	974
Sequential detection at execution time	976
Determining sort activity	977
Sorts of data.	977
Sorts of RIDs	978
The effect of sorts on OPEN CURSOR	978
Processing for views and nested table expressions	979
Merge	979
Materialization	980
Using EXPLAIN to determine when materialization occurs	982
Using EXPLAIN to determine UNION activity and query rewrite	983
Performance of merge versus materialization	985
Estimating a statement's cost	985
Creating a statement table	986
Populating and maintaining a statement table	988
Retrieving rows from a statement table.	988
The implications of cost categories	989
<b>Chapter 35. Parallel operations and query performance</b>	<b>991</b>
Comparing the methods of parallelism	992
Partitioning for optimal parallel performance.	994
Determining if a query is I/O- or processor-intensive	995
Determining the number of partitions	995
Working with a table space that is already partitioned.	996
Making the partitions the same size	996
Working with partitioned indexes	997
Enabling parallel processing	997
Restrictions for parallelism	998
Interpreting EXPLAIN output	999
A method for examining PLAN_TABLE columns for parallelism	999
PLAN_TABLE examples showing parallelism.	999
Monitoring parallel operations	1001
Using DISPLAY BUFFERPOOL	1002

Using DISPLAY THREAD . . . . .	1002
Using DB2 trace . . . . .	1002
Tuning parallel processing. . . . .	1004
Disabling query parallelism . . . . .	1005

**Chapter 36. Tuning and monitoring in a distributed environment. . . . . 1007**

Remote access types: DRDA and private protocol . . . . .	1007
Characteristics of DRDA . . . . .	1007
Characteristics of DB2 private protocol . . . . .	1007
Tuning distributed applications . . . . .	1008
Application and requesting systems . . . . .	1008
Serving system . . . . .	1016
Monitoring DB2 in a distributed environment . . . . .	1017
The DISPLAY command . . . . .	1017
Tracing distributed events. . . . .	1017
Reporting server-elapsed time . . . . .	1021
Monitoring distributed processing with RMF . . . . .	1021
Duration of an enclave . . . . .	1021
RMF records for enclaves . . . . .	1022

**Chapter 37. Monitoring and tuning stored procedures and user-defined functions 1023**

Controlling address space storage . . . . .	1023
Assigning procedures and functions to WLM application environments . . . . .	1024
Providing DB2 cost information for accessing user-defined table functions . . . . .	1025
Monitoring stored procedures with the accounting trace. . . . .	1026
Accounting for nested activities . . . . .	1028
Comparing the types of stored procedure address spaces . . . . .	1029

---

**Part 6. Appendixes . . . . . 1033**

**Appendix A. DB2 sample tables . . . . . 1035**

Activity table (DSN8810.ACT) . . . . .	1035
Department table (DSN8810.DEPT). . . . .	1036
Employee table (DSN8810.EMP). . . . .	1038
Employee photo and resume table (DSN8810.EMP_PHOTO_RESUME). . . . .	1041
Project table (DSN8810.PROJ) . . . . .	1042
Project activity table (DSN8810.PROJACT) . . . . .	1043
Employee to project activity table (DSN8810.EMPPROJACT) . . . . .	1044
Unicode sample table (DSN8810.DEMO_UNICODE) . . . . .	1045
Relationships among the sample tables . . . . .	1046
Views on the sample tables . . . . .	1046
Storage of sample application tables . . . . .	1051
Storage group . . . . .	1052
Databases . . . . .	1052
Table spaces . . . . .	1052

**Appendix B. Writing exit routines . . . . . 1055**

Connection routines and sign-on routines . . . . .	1055
Specifying connection and sign-on routines . . . . .	1056
Sample connection and sign-on routines . . . . .	1056
When connection and sign-on routines are taken . . . . .	1057
EXPL for connection and sign-on routines . . . . .	1057
Exit parameter list for connection and sign-on routines . . . . .	1058
Authorization ID parameter list for connection and sign-on routines . . . . .	1058
Input values for connection routines . . . . .	1059
Input values for sign-on routines . . . . .	1060
Expected output for connection and sign-on routines. . . . .	1060
Processing in the sample connection and sign-on routines . . . . .	1061
Performance considerations for connection and sign-on routines . . . . .	1062

Debugging connection and sign-on routines . . . . .	1063
Session variables in connection and sign-on routines . . . . .	1064
Access control authorization exit routine . . . . .	1065
Specifying the access control authorization routine . . . . .	1066
The default access control authorization routine . . . . .	1067
When the access control authorization routine is taken . . . . .	1067
Considerations for the access control authorization routine . . . . .	1067
Parameter list for the access control authorization routine . . . . .	1070
Expected output for the access control authorization routine . . . . .	1078
Debugging the access control authorization routine . . . . .	1080
Determining whether the access control authorization routine is active . . . . .	1080
Edit routines . . . . .	1081
Specifying the edit routine routine . . . . .	1082
When the edit routine is taken . . . . .	1082
Parameter lists for the edit routine . . . . .	1082
Processing requirements for edit routines. . . . .	1083
Incomplete rows and edit routines . . . . .	1083
Expected output for edit routines . . . . .	1084
Validation routines . . . . .	1084
Specifying the validation routine . . . . .	1085
When the validation routine is taken . . . . .	1085
Parameter lists for the validation routine . . . . .	1085
Processing requirements for validation routines . . . . .	1086
Incomplete rows and validation routines . . . . .	1086
Expected output for validation routines . . . . .	1086
Date and time routines . . . . .	1087
Specifying the date and time routine . . . . .	1088
When date and time routines are taken . . . . .	1088
Parameter lists for date and time routines . . . . .	1089
Expected output for date and time routines . . . . .	1089
Conversion procedures . . . . .	1090
Specifying a conversion procedure . . . . .	1090
When conversion procedures are taken . . . . .	1091
Parameter lists for conversion procedures . . . . .	1091
Expected output for conversion procedures . . . . .	1092
Field procedures . . . . .	1093
Field definition for field procedures . . . . .	1094
Specifying the field procedure . . . . .	1094
When field procedures are taken . . . . .	1095
Control blocks for execution of field procedures . . . . .	1096
Field-definition (function code 8) . . . . .	1099
Field-encoding (function code 0). . . . .	1102
Field-decoding (function code 4). . . . .	1103
Log capture routines . . . . .	1105
Specifying the log capture routine . . . . .	1105
When log capture routines are taken . . . . .	1106
Parameter lists for log capture routines . . . . .	1106
Routines for dynamic plan selection in CICS . . . . .	1107
Routine for CICS transaction invocation stored procedure . . . . .	1108
General considerations for writing exit routines . . . . .	1108
Coding rules for exit routines . . . . .	1108
Modifying exit routines. . . . .	1109
Execution environment for exit routines . . . . .	1109
Registers at invocation for exit routines . . . . .	1109
Parameter lists for exit routines . . . . .	1110
Row formats for edit and validation routines . . . . .	1110
Column boundaries for edit and validation routines . . . . .	1111
Null values for edit procedures, field procedures, and validation routines . . . . .	1111
Fixed-length rows for edit and validation routines . . . . .	1111
Varying-length rows for edit and validation routines . . . . .	1111
Varying-length rows with nulls for edit and validation routines . . . . .	1112

Dates, times, and timestamps for edit and validation routines . . . . .	1112
Parameter list for row format descriptions . . . . .	1112
DB2 codes for numeric data in edit and validation routines. . . . .	1114
I RACF access control module . . . . .	1114

**Appendix C. Reading log records . . . . . 1115**

Contents of the log . . . . .	1115
Unit of recovery log records . . . . .	1116
Checkpoint log records . . . . .	1119
Database page set control records . . . . .	1120
Other exception information . . . . .	1120
The physical structure of the log . . . . .	1120
Physical and logical log records . . . . .	1120
The log record header . . . . .	1121
The log control interval definition (LCID) . . . . .	1122
Log record type codes . . . . .	1124
Log record subtype codes . . . . .	1124
Interpreting data change log records . . . . .	1125
Reading log records with IFI . . . . .	1126
Reading log records into a buffer . . . . .	1126
Reading specific log records (IFCID 0129) . . . . .	1126
Reading complete log data (IFCID 0306) . . . . .	1127
Reading log records with OPEN, GET, and CLOSE . . . . .	1130
Data sharing members that participate in a read . . . . .	1132
Registers and return codes . . . . .	1133
Stand-alone log OPEN request . . . . .	1133
Stand-alone log GET request . . . . .	1135
Stand-alone log CLOSE request . . . . .	1136
Sample application that uses stand-alone log services . . . . .	1137
Reading log records with the log capture exit routine. . . . .	1138

**Appendix D. Interpreting DB2 trace output . . . . . 1139**

The sections of the trace output . . . . .	1139
SMF writer header section. . . . .	1140
GTF writer header section. . . . .	1141
Self-defining section. . . . .	1147
Product section . . . . .	1149
Trace field descriptions . . . . .	1155

**Appendix E. Programming for the Instrumentation Facility Interface (IFI) . . . . . 1157**

Submitting DB2 commands through IFI . . . . .	1157
Obtaining trace data through IFI . . . . .	1158
Passing data to DB2 through IFI. . . . .	1158
IFI functions . . . . .	1158
Invoking IFI from your program . . . . .	1159
Using IFI from stored procedures . . . . .	1160
COMMAND: Syntax and usage with IFI . . . . .	1160
Authorization for DB2 commands through IFI . . . . .	1160
Syntax for DB2 commands through IFI . . . . .	1160
Example of DB2 command through IFI . . . . .	1162
READS: Syntax and usage with IFI. . . . .	1162
Authorization for READS requests through IFI . . . . .	1163
Syntax for READS requests through IFI . . . . .	1163
Which qualifications are used for READS requests issued through IFI? . . . . .	1171
Usage notes for READS requests through IFI . . . . .	1172
Synchronous data and READS requests through IFI . . . . .	1172
Using READS calls to monitor the dynamic statement cache . . . . .	1174
Controlling collection of dynamic statement cache statistics with IFCID 0318 . . . . .	1175
READA: Syntax and usage with IFI . . . . .	1176
Authorization for READA requests through IFI. . . . .	1176

Syntax for READA requests through IFI . . . . .	1176
Usage notes for READA requests through IFI . . . . .	1176
Asynchronous data and READA requests through IFI . . . . .	1177
Example of READA requests through IFI . . . . .	1178
WRITE: Syntax and usage with IFI . . . . .	1178
Authorization for WRITE requests through IFI . . . . .	1178
Syntax for WRITE requests through IFI . . . . .	1178
Usage notes for WRITE requests through IFI . . . . .	1179
Common communication areas for IFI calls . . . . .	1179
Instrument facility communications area (IFCA) . . . . .	1179
Return area . . . . .	1183
IFCID area . . . . .	1184
Output area . . . . .	1184
Using IFI in a data sharing group . . . . .	1184
Interpreting records returned by IFI . . . . .	1186
Trace data record format . . . . .	1186
Command record format . . . . .	1187
Data integrity and IFI . . . . .	1188
Auditing data and IFI . . . . .	1188
Locking considerations for IFI . . . . .	1188
Recovery considerations for IFI . . . . .	1189
Errors and IFI . . . . .	1189

**Appendix F. Using tools to monitor performance. . . . . 1191**

Using z/OS, CICS, and IMS tools . . . . .	1193
Monitoring system resources . . . . .	1194
Monitoring transaction manager throughput. . . . .	1195
DB2 trace . . . . .	1195
Types of traces . . . . .	1196
Effect on DB2 performance . . . . .	1199
Recording SMF trace data . . . . .	1199
Activating SMF . . . . .	1200
Allocating additional SMF buffers . . . . .	1200
Reporting data in SMF . . . . .	1201
Recording GTF trace data . . . . .	1201
OMEGAMON. . . . .	1202
Tivoli Decision Support for OS/390 . . . . .	1203
Monitoring application plans and packages . . . . .	1203

**Appendix G. EXPLAIN tables that are used by optimization tools . . . . . 1205**

DSN_PREDICAT_TABLE . . . . .	1205
DSN_STRUCT_TABLE . . . . .	1209
DSN_PGROUPE_TABLE . . . . .	1211
DSN_PTASK_TABLE . . . . .	1214
DSN_FILTER_TABLE . . . . .	1216
DSN_DETCOST_TABLE . . . . .	1218
DSN_SORT_TABLE . . . . .	1224
DSN_SORTKEY_TABLE . . . . .	1226
DSN_PGRANGE_TABLE . . . . .	1228
DSN_VIEWREF_TABLE . . . . .	1229
DSN_QUERY_TABLE . . . . .	1231

**Appendix H. Profile tables that are used by optimization tools. . . . . 1233**

SYSIBM.DSN_VIRTUAL_INDEXES. . . . .	1233
-------------------------------------	------

**Appendix I. Real-time statistics tables . . . . . 1235**

Setting up your system for real-time statistics . . . . .	1235
Creating and altering the real-time statistics objects . . . . .	1236
Setting the interval for writing real-time statistics . . . . .	1237
Starting the real-time statistics database . . . . .	1237

Establishing base values for real-time statistics . . . . .	1237
Contents of the real-time statistics tables . . . . .	1237
Operating with real-time statistics . . . . .	1249
When DB2 externalizes real-time statistics . . . . .	1250
How DB2 utilities affect the real-time statistics . . . . .	1250
How non-DB2 utilities affect real-time statistics. . . . .	1257
Real-time statistics on objects in work file databases and the TEMP database. . . . .	1258
I Real-time statistics for DEFINE NO objects . . . . .	1258
Real-time statistics on read-only or nonmodified objects. . . . .	1258
How dropping objects affects real-time statistics . . . . .	1258
How SQL operations affect real-time statistics counters . . . . .	1258
Real-time statistics in data sharing . . . . .	1259
Improving concurrency with real-time statistics . . . . .	1260
Recovering the real-time statistics tables . . . . .	1260
Statistics accuracy . . . . .	1260
<b>Appendix J. DB2-supplied stored procedures . . . . .</b>	<b>1261</b>
The DB2 real-time statistics stored procedure . . . . .	1263
Environment for DSNACCOR . . . . .	1264
Authorization required for DSNACCOR . . . . .	1264
DSNACCOR syntax diagram. . . . .	1265
DSNACCOR option descriptions . . . . .	1265
DSNACCOR formulas for recommending actions . . . . .	1273
Using an exception table . . . . .	1276
Example of DSNACCOR invocation . . . . .	1277
DSNACCOR output. . . . .	1281
WLM environment refresh stored procedure (WLM_REFRESH) . . . . .	1285
Environment for WLM_REFRESH . . . . .	1285
Authorization required for WLM_REFRESH. . . . .	1285
WLM_REFRESH syntax diagram . . . . .	1286
WLM_REFRESH option descriptions . . . . .	1286
Example of WLM_REFRESH invocation . . . . .	1287
The CICS transaction invocation stored procedure (DSNACICS) . . . . .	1287
Environment for DSNACICS . . . . .	1288
Authorization required for DSNACICS . . . . .	1288
DSNACICS syntax diagram . . . . .	1288
DSNACICS option descriptions . . . . .	1288
DSNACICX user exit routine. . . . .	1290
Example of DSNACICS invocation . . . . .	1292
DSNACICS output . . . . .	1294
DSNACICS restrictions. . . . .	1294
DSNACICS debugging . . . . .	1294
# The SYSIBM.USERNAMES encryption stored procedure. . . . .	1295
# Environment for DSNLEUSR. . . . .	1295
# Authorization required for DSNLEUSR . . . . .	1295
# DSNLEUSR syntax diagram . . . . .	1295
# DSNLEUSR option descriptions . . . . .	1295

## About this book

This two-volume book provides guidance information that you can use to perform a variety of administrative tasks with DB2® Universal Database™ for z/OS® (DB2®).

This information assumes that your DB2 subsystem is running in Version 8 new-function mode. New functions are available only in new-function mode, unless explicitly stated otherwise in the product documentation. A few general exceptions exist for utilities and for optimization. In most cases, new functions are not supported in compatibility mode unless noted. For utilities and optimization, new functions are available in compatibility mode unless noted. The new functions that are available in compatibility mode and enabling-new-function mode are almost identical, but some new functions are supported to provide easier migration. Exceptions to these general statements are noted in the information.

### Important

In this version of DB2 UDB for z/OS, the DB2 Utilities Suite is available as an optional product. You must separately order and purchase a license to such utilities, and discussion of those utility functions in this publication is not intended to otherwise imply that you have a license to them. See Part 1 of *DB2 Utility Guide and Reference* for packaging details.

The DB2 Utilities Suite is designed to work with the DFSORT program, which you are licensed to use in support of the DB2 utilities even if you do not otherwise license DFSORT for general use. If your primary sort product is not DFSORT, consider the following informational APARs mandatory reading:

- II14047/II14213: USE OF DFSORT BY DB2 UTILITIES
- II13495: HOW DFSORT TAKES ADVANTAGE OF 64-BIT REAL ARCHITECTURE

These informational APARs are periodically updated.

---

## Who should read this book

This book is primarily intended for system and database administrators. It assumes that the user is familiar with:

- The basic concepts and facilities of DB2
- Time Sharing Option (TSO) and Interactive System Productivity Facility (ISPF)
- The basic concepts of Structured Query Language (SQL)
- The basic concepts of Customer Information Control System (CICS®)
- The basic concepts of Information Management System (IMS™)
- How to define and allocate z/OS data sets using job control language (JCL).

Certain tasks require additional skills, such as knowledge of Transmission Control Protocol/Internet Protocol (TCP/IP) or Virtual Telecommunications Access Method (VTAM®) to set up communication between DB2 subsystems, or knowledge of the IBM® System Modification Program (SMP/E) to install IBM licensed programs.

---

## Terminology and citations

In this information, DB2 Universal Database for z/OS is referred to as "DB2 UDB for z/OS." In cases where the context makes the meaning clear, DB2 UDB for z/OS is referred to as "DB2." When this information refers to titles of books in this library, a short title is used. (For example, "See *DB2 SQL Reference*" is a citation to *IBM DB2 Universal Database for z/OS SQL Reference*.)

When referring to a DB2 product other than DB2 UDB for z/OS, this information uses the product's full name to avoid ambiguity.

The following terms are used as indicated:

**DB2** Represents either the DB2 licensed program or a particular DB2 subsystem.

### OMEGAMON

Refers to any of the following products:

- IBM Tivoli OMEGAMON XE for DB2 Performance Expert on z/OS
- IBM Tivoli OMEGAMON XE for DB2 Performance Monitor on z/OS
- IBM DB2 Performance Expert for Multiplatforms and Workgroups
- IBM DB2 Buffer Pool Analyzer for z/OS

### C, C++, and C language

Represent the C or C++ programming language.

**CICS** Represents CICS Transaction Server for z/OS or CICS Transaction Server for OS/390®.

**IMS** Represents the IMS Database Manager or IMS Transaction Manager.

**MVS™** Represents the MVS element of the z/OS operating system, which is equivalent to the Base Control Program (BCP) component of the z/OS operating system.

### RACF®

Represents the functions that are provided by the RACF component of the z/OS Security Server.

---

## How to read the syntax diagrams

The following rules apply to the syntax diagrams that are used in this book:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

The ►— symbol indicates the beginning of a statement.

The —► symbol indicates that the statement syntax is continued on the next line.

The ►— symbol indicates that a statement is continued from the previous line.

The —►◄ symbol indicates the end of a statement.

- Required items appear on the horizontal line (the main path).

►—*required\_item*—►◄

- Optional items appear below the main path.

►—*required\_item*—    *optional\_item*    —►◄

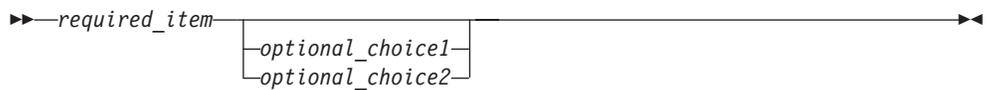

If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.

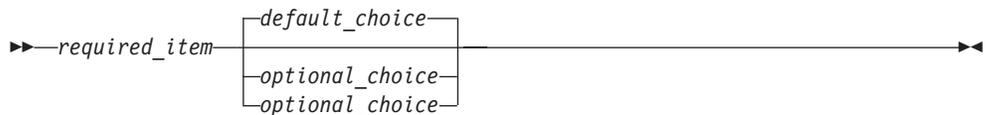

- If you can choose from two or more items, they appear vertically, in a stack. If you *must* choose one of the items, one item of the stack appears on the main path.

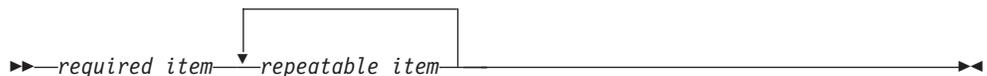

If choosing one of the items is optional, the entire stack appears below the main path.

If one of the items is the default, it appears above the main path and the remaining choices are shown below.

- An arrow returning to the left, above the main line, indicates an item that can be repeated.

If the repeat arrow contains a comma, you must separate repeated items with a comma.

A repeat arrow above a stack indicates that you can repeat the items in the stack.

- Keywords appear in uppercase (for example, FROM). They must be spelled exactly as shown. Variables appear in all lowercase letters (for example, *column-name*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

---

## Accessibility

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products. The major accessibility features in z/OS products, including DB2 UDB for z/OS, enable users to:

- Use assistive technologies such as screen reader and screen magnifier software
- Operate specific or equivalent features by using only a keyboard
- Customize display attributes such as color, contrast, and font size

Assistive technology products, such as screen readers, function with the DB2 UDB for z/OS user interfaces. Consult the documentation for the assistive technology products for specific information when you use assistive technology to access these interfaces.

Online documentation for Version 8 of DB2 UDB for z/OS is available in the Information management software for z/OS solutions information center, which is an accessible format when used with assistive technologies such as screen reader or screen magnifier software. The Information management software for z/OS solutions information center is available at the following Web site:  
<http://publib.boulder.ibm.com/infocenter/dzichelp>

---

## How to send your comments

Your feedback helps IBM to provide quality information. Please send any comments that you have about this book or other DB2 UDB for z/OS documentation. You can use the following methods to provide comments:

- Send your comments by e-mail to [db2zinfo@us.ibm.com](mailto:db2zinfo@us.ibm.com) and include the name of the product, the version number of the product, and the number of the book. If you are commenting on specific text, please list the location of the text (for example, a chapter and section title or a help topic title).
- You can send comments from the Web. Visit the DB2 for z/OS - Technical Resources Web site at:

<http://www.ibm.com/support/docview.wss?&uid=swg27011656>

This Web site has an online reader comment form that you can use to send comments.

- You can also send comments by using the feedback link at the footer of each page in the Information Management Software for z/OS Solutions Information Center at <http://publib.boulder.ibm.com/infocenter/db2zhlp>.

---

## Summary of changes to this book

This section summarizes the major changes to this book for Version 8.

Part 2, “Designing a database: advanced topics” has changed as follows:

- Chapter 3, “Creating storage groups and managing DB2 data sets,” on page 27 describes how to define data sets for partitioned table spaces and partitioned indexes (when you manage your own DB2 data sets with VSAM Access Method Services)
- Chapter 4, “Implementing your database design,” on page 43 describes:
  - Table-controlled partitioning, which uses the PARTITION BY clause of the CREATE TABLE statement
  - New definitions for clustering, partitioning, and secondary indexes
  - The NOT PADDED option of the CREATE INDEX statement, which allows DB2 to use index-only access for varying-length columns within the index key
  - How DB2 can use the same index to avoid sorts with either a forward index-scan or a backward index-scan (for queries with an ORDER BY clause)
- Chapter 6, “Altering your database design,” on page 67 describes how to use the ALTER TABLE and ALTER INDEX statements.

Part 3, “Security and auditing” has changed as follows:

- “Multilevel security” on page 192 describes a new security policy that prevents unauthorized users from accessing information at a higher classification than their authorization and prevents users from declassifying information.
- “Data encryption through built-in functions” on page 207 describes built-in functions that you can use to encrypt and decrypt sensitive data.
- Chapter 11, “Controlling access to a DB2 subsystem,” on page 231 includes information about enhanced options for data security in TCP/IP networks.

Part 4, “Operation and recovery” has changed as follows:

- “Monitoring databases” on page 369 describes the OVERVIEW option for DISPLAY DATABASE command, which you can use to display all of the objects in a database.
- “Resolution of WebSphere Application Server indoubt units of recovery” on page 465 explains how indoubt units of recovery are resolved for WebSphere® Application Server.
- “Considerations for recovering indexes” on page 477 describes how indexes on altered tables and indexes on tables in partitioned table spaces can restrict recovery.
- “System-level point-in-time recovery” on page 515 details how the system-level point-in-time (PIT) recovery capability of DB2 provides improved usability, more flexibility, and faster recovery times.
- Chapter 22, “Recovery scenarios,” on page 521 explains that with the introduction of table-based partitioning in Version 8 of DB2, you can redefine a table-based partition and an index-based partition when an out of disk space condition occurs or an extent limit is reached.

Part 5, “Performance monitoring and tuning” has changed as follows:

- “Allocating buffer pool storage” on page 679 provides recommendations on allocating buffer pool storage.
- “Long-term page fix option for buffer pools” on page 681 describes how to use the PGFIX keyword with the ALTER BUFFERPOOL command to fix a buffer pool in real storage for an extended period of time.
- “Evaluating your indexes” on page 711 provides information about evaluating the effectiveness of your indexes, avoiding unnecessary indexes, and using nonpadded indexes.
- “Database access threads” on page 741 introduces new terminology for database access threads. Type 1 inactive threads become inactive database access threads and type 2 inactive threads become inactive connections. Additionally, pooling behaviors are discussed.
- Chapter 30, “Tuning your queries ,” on page 751 includes discussion of the predicates IS DISTINCT FROM and IS NOT DISTINCT FROM.
- “Changing the access path at run time” on page 779 describes the bind options REOPT(ONCE) and REOPT(ALWAYS).
- “Favoring index access” on page 798 introduces the VOLATILE keyword and explains how to use it to minimize contention among certain applications.
- Chapter 32, “Using materialized query tables,” on page 885 describes how to use materialized query tables to improve the performance of queries that require expensive join and aggregation operations, such as some queries that are used in data warehousing applications.
- “Dedicated virtual memory pool for star join operations” on page 971 explains the advantages of a dedicated virtual memory pool for star join operations and demonstrates how to determine the size of the virtual memory pool.

Appendix B, “Writing exit routines” has changed as follows:

- “Session variables in connection and sign-on routines” on page 1064 explains how session variables work in connection and sign-on routines.
- “Creating materialized query tables” on page 1070 discusses the authorization issues involved with creating a materialized query table.
- “RACF access control module” on page 1114 describes the RACF access control module.

Appendix D, “Interpreting DB2 trace output” has changed as follows:

- “Self-defining section” on page 1147 describes the self-defining section for variable-length data items.

## Chapter 1. System planning concepts

This chapter introduces the DB2 UDB for z/OS system and explains the concepts that relate to system and database administration. It consists of the following sections:

- “The structure of DB2” describes the elements you deal with when using DB2.
- “Control and maintenance of DB2” on page 11 briefly describes commands and utility jobs.
- “The DB2 environment” on page 13 describes the main DB2 components and explains how DB2 operates with certain related IBM products.

Each section concludes with a list of citations to more detailed information about the topics that the sections introduce.

If you are new to using DB2 UDB for z/OS, begin with *The Official Introduction to DB2 UDB for z/OS* for extensive conceptual information.

General information about DB2 UDB for z/OS is available from the DB2 UDB for z/OS World Wide Web page:

<http://www.software.ibm.com/data/db2/os390/>

---

### The structure of DB2

The elements that DB2 manages can be divided into two broad categories:

- Data structures, which are accessed under the user’s direction and by which the user’s data (and some system data) is organized.
- System structures, which are controlled and accessed by DB2.

#### Data structures

DB2 data structures described in this section include:

- “Databases” on page 5
- “Storage groups” on page 5
- “Table spaces” on page 5
- “Tables” on page 6
- “Indexes” on page 6
- “Views” on page 7

The brief descriptions here show how the structures fit into an overall view of DB2.

Figure 1 on page 4 shows how some DB2 structures contain others. To some extent, the notion of “containment” provides a hierarchy of structures. This section introduces those structures from the most to the least inclusive.

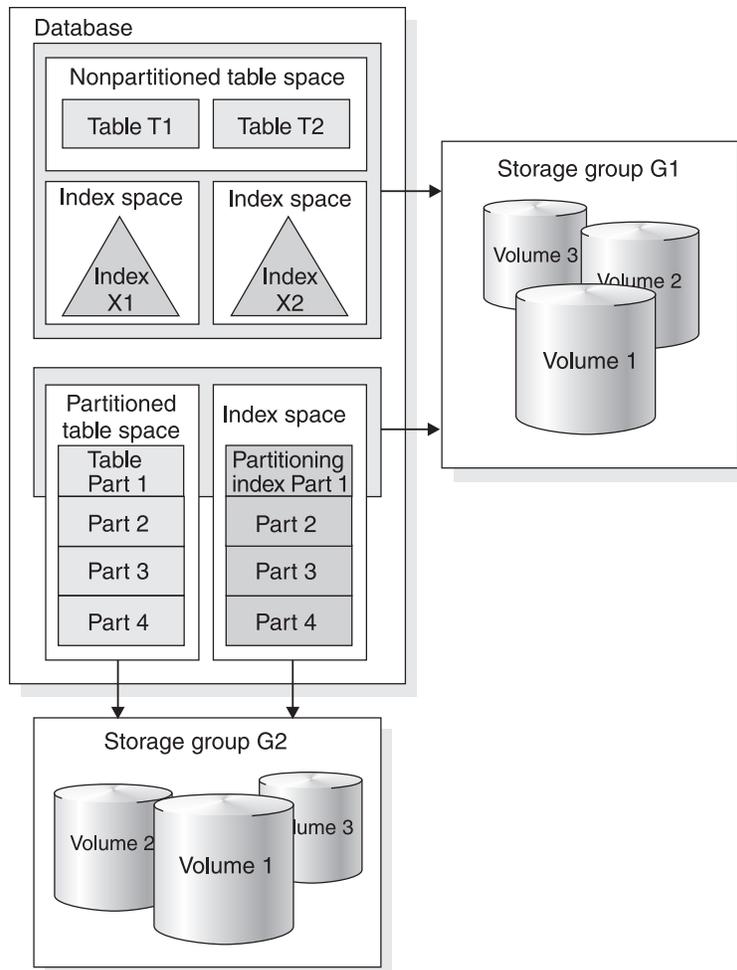

Figure 1. A hierarchy of DB2 structures

The DB2 objects that Figure 1 introduces are:

**Databases**

A set of DB2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside.

**Storage groups**

A set of volumes on disks that hold the data sets in which tables and indexes are actually stored.

**Table spaces**

A set of volumes on disks that hold the data sets in which tables and indexes are actually stored.

**Tables** All data in a DB2 database is presented in *tables*—collections of rows all having the same columns. A table that holds persistent user data is a *base table*. A table that stores data temporarily is a *temporary table*.

**Indexes**

An *index* is an ordered set of pointers to the data in a DB2 table. The index is stored separately from the table.

**Views** A *view* is an alternate way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

## Databases

A single database can contain all the data associated with one application or with a group of related applications. Collecting that data into one database allows you to start or stop access to all the data in one operation and grant authorization for access to all the data as a single unit. Assuming that you are authorized to do so, you can access data stored in different databases.

If you create a table space or a table and do not specify a database, the table or table space is created in the default database, DSNDB04. DSNDB04 is defined for you at installation time. All users have the authority to create table spaces or tables in database DSNDB04. The system administrator can revoke those privileges and grant them only to particular users as necessary.

When you migrate to Version 8, DB2 adopts the default database and default storage group you used in Version 7. You have the same authority for Version 8 as you did in Version 7.

## Storage groups

The description of a storage group names the group and identifies its volumes and the VSAM (virtual storage access method) catalog that records the data sets. The default storage group, SYSDEFLT, is created when you install DB2.

All volumes of a given storage group must have the same device type. But, as Figure 1 on page 4 suggests, parts of a single database can be stored in different storage groups.

## Table spaces

A table space can consist of a number of VSAM data sets. Data sets are VSAM linear data sets (LDSs). Table spaces are divided into equal-sized units, called *pages*, which are written to or read from disk in one operation. You can specify page sizes for the data; the default page size is 4 KB.

When you create a table space, you can specify the database to which the table space belongs and the storage group it uses. If you do not specify the database and storage group, DB2 assigns the table space to the default database and the default storage group.

You also determine what kind of table spaces is created.

### Partitioned

Divides the available space into separate units of storage called *partitions*. Each partition contains one data set of one table. You assign the number of partitions (from 1 to 4096) and you can assign partitions independently to different storage groups.

### Segmented

Divides the available space into groups of pages called *segments*. Each segment is the same size. A segment contains rows from only one table.

### Large object (LOB)

Holds large object data such as graphics, video, or very large text strings. A LOB table space is always associated with the table space that contains the logical LOB column values. The table space that contains the table with the LOB columns is called, in this context, the *base table space*.

### Simple

Can contain more than one table. The rows of different tables are not kept separate (unlike segmented table spaces).

## Tables

When you create a table in DB2, you define an ordered set of columns.

**Sample tables:** The examples in this book are based on the set of tables described in Appendix A, “DB2 sample tables,” on page 1035. The sample tables are part of the DB2 licensed program and represent data related to the activities of an imaginary computer services company, the Spiffy Computer Services Company. Table 1 shows an example of a DB2 sample table.

Table 1. Example of a DB2 sample table (Department table)

DEPTNO	DEPTNAME	MGRNO	ADMRDEPT
A00	SPIFFY COMPUTER SERVICE DIV.	000010	A00
B01	PLANNING	000020	A00
C01	INFORMATION CENTER	000030	A00
D01	DEVELOPMENT CENTER		A00
E01	SUPPORT SERVICES	000050	A00
D11	MANUFACTURING SYSTEMS	000060	D01
D21	ADMINISTRATION SYSTEMS	000070	D01
E11	OPERATIONS	000090	E01
E21	SOFTWARE SUPPORT	000100	E01

The department table contains:

- **Columns:** The ordered set of columns are DEPTNO, DEPTNAME, MGRNO, and ADMRDEPT. All the data in a given column must be of the same data type.
- **Row:** Each row contains data for a single department.
- **Value:** At the intersection of a column and row is a *value*. For example, PLANNING is the value of the DEPTNAME column in the row for department B01.
- **Referential constraints:** You can assign a *primary key* and *foreign keys* to tables. DB2 can automatically enforce the integrity of references from a foreign key to a primary key by guarding against insertions, updates, or deletions that violate the integrity.
  - **Primary key:** A column or set of columns whose values uniquely identify each row, for example, DEPTNO.
  - **Foreign key:** Columns of other tables, whose values must be equal to values of the primary key of the first table (in this case, the department table). In the sample employee table, the column that shows what department an employee works in is a foreign key; its values must be values of the department number column in the department table.

## Indexes

Each index is based on the values of data in one or more columns of a table. After you create an index, DB2 maintains the index, but you can perform necessary maintenance such as reorganizing it or recovering the index.

Indexes take up physical storage in *index spaces*. Each index occupies its own index space.

The main purposes of indexes are:

- To improve performance. Access to data is often faster with an index than without.
- To ensure that a row is unique. For example, a unique index on the employee table ensures that no two employees have the same employee number.

Except for changes in performance, users of the table are unaware that an index is in use. DB2 decides whether to use the index to access the table. There are ways to influence how indexes affect performance when you calculate the storage size of an index and determine what type of index to use. An index can be partitioning, nonpartitioning, or clustered. For example, you can apportion data by last names, maybe using one partition for each letter of the alphabet. Your choice of a partitioning scheme is based on how an application accesses data, how much data you have, and how large you expect the total amount of data to grow.

## Views

Views allow you to shield some table data from end users. A view can be based on other views or on a combination of views and tables.

When you define a view, DB2 stores the definition of the view in the DB2 catalog. However, DB2 does not store any data for the view itself, because the data already exists in the base table or tables.

## System structures

DB2 system structures described in this section include:

“DB2 catalog”

“DB2 directory” on page 8

“Active and archive logs” on page 8

“Bootstrap data set (BSDS)” on page 9

“Buffer pools” on page 9

“Data definition control support database” on page 9

“Resource limit facility database” on page 10

“Work file database” on page 10

“TEMP database” on page 10

In addition, Parallel Sysplex® data sharing uses shared system structures.

## DB2 catalog

The DB2 catalog consists of tables of data about everything defined to the DB2 system, including table spaces, indexes, tables, copies of table spaces and indexes, storage groups, and so forth. The system database DSNDB06 contains the DB2 catalog.

When you create, alter, or drop any structure, DB2 inserts, updates, or deletes rows of the catalog that describe the structure and tell how the structure relates to other structures. For example, SYSIBM.SYSTABLES is one catalog table that records information when a table is created. DB2 inserts a row into SYSIBM.SYSTABLES that includes the table name, its owner, its creator, and the name of its table space and its database.

Because the catalog consists of DB2 tables in a DB2 database, authorized users can use SQL statements to retrieve information from it.

The *communications database* (CDB) is part of the DB2 catalog. The CDB consists of a set of tables that establish conversations with remote database management systems (DBMSs). The distributed data facility (DDF) uses the CDB to send and receive distributed data requests.

## DB2 directory

The DB2 directory contains information that DB2 uses during normal operation. You cannot access the directory using SQL, although much of the same information is contained in the DB2 catalog, for which you can submit queries. The structures in the directory are not described in the DB2 catalog.

The directory consists of a set of DB2 tables stored in five table spaces in system database DSNDB01. Each of the table spaces listed in Table 2 is contained in a VSAM linear data set.

Table 2. Directory table spaces

Table space name	Description
SCT02 Skeleton cursor (SKCT)	Contains the internal form of SQL statements contained in an application. When you bind a plan, DB2 creates a skeleton cursor table in SCT02.
SPT01 Skeleton package	Similar to SCT02 except that the skeleton package table is created when you bind a package.
SYSLGRNX Log range	Tracks the opening and closing of table spaces, indexes, or partitions. By tracking this information and associating it with relative byte addresses (RBAs) as contained in the DB2 log, DB2 can reduce recovery time by reducing the amount of log that must be scanned for a particular table space, index, or partition.
SYSUTILX System utilities	Contains a row for every utility job that is running. The row stays until the utility is finished. If the utility terminates without completing, DB2 uses the information in the row when you restart the utility.
DBD01 Database descriptor (DBD)	Contains internal information, called <i>database descriptors</i> (DBDs), about the databases that exist within DB2.  Each database has exactly one corresponding DBD that describes the database, table spaces, tables, table check constraints, indexes, and referential relationships. A DBD also contains other information about accessing tables in the database. DB2 creates and updates DBDs whenever their corresponding databases are created or updated.

## Active and archive logs

DB2 records all data changes and significant events in a log as they occur. In the case of failure, DB2 uses this data to recover.

DB2 writes each log record to a disk data set called the *active log*. When the active log is full, DB2 copies the contents of the active log to a disk or magnetic tape data set called the *archive log*.

You can choose either single logging or dual logging.

#  
#  
#  
#  
|

- A single active log contains as many as 31 or 93 active log data sets, depending on the format of the BSDS. If the BSDS has been installed with support for the larger BSDS or converted to support it, then the maximum number of active log data sets is 93. Otherwise, the maximum number is 31.
- With dual logging, the active log has twice the capacity for active log data sets, because two identical copies of the log records are kept.

Each active log data set is a single-volume, single-extent VSAM LDS.

### **Bootstrap data set (BSDS)**

The *bootstrap data set* (BSDS) is a VSAM key-sequenced data set (KSDS) that contains information critical to DB2. Specifically, the BSDS contains:

- An inventory of all active and archive log data sets known to DB2. DB2 uses this information to track the active and archive log data sets. DB2 also uses this information to locate log records to satisfy log read requests during normal DB2 system activity and during restart and recovery processing.
- A wrap-around inventory of all recent DB2 checkpoint activity. DB2 uses this information during restart processing.
- The distributed data facility (DDF) communication record, which contains information necessary to use DB2 as a distributed server or requester.
- Information about buffer pools.

Because the BSDS is essential to recovery in the event of subsystem failure, during installation DB2 automatically creates two copies of the BSDS and, if space permits, places them on separate volumes.

### **Buffer pools**

*Buffer pools* are areas of virtual storage in which DB2 temporarily stores pages of table spaces or indexes. When an application program accesses a row of a table, DB2 retrieves the page containing that row and places the page in a buffer. If the needed data is already in a buffer, the application program does not have to wait for it to be retrieved from disk, significantly reducing the cost of retrieving the page.

Buffer pools require monitoring and tuning. The size of buffer pools is critical to the performance characteristics of an application or group of applications that access data in those buffer pools.

When you use Parallel Sysplex data sharing, buffer pools map to structures called *group buffer pools*. These structures reside in a special PR/SM<sup>™</sup> LPAR logical partition called a *coupling facility*, which enables several DB2s to share information and control the coherency of data.

|  
|  
|

Buffer pools reside in DB2's DBM1 primary address space. This option offers the best performance. In Version 8, the maximum size of a buffer pool increases to 1 TB.

### **Data definition control support database**

The *data definition control support database* is automatically created during installation. This database is a user-maintained collection of tables used by data definition control support to restrict the submission of specific DB2 DDL (data definition language) statements to selected application identifiers (plans or collections of packages). After this database is created, you must populate the tables to use of this facility. The system name for this database is DSNRGFDB.

## Resource limit facility database

The *resource limit facility database* (DSNRLST) is a facility that lets you control the amount of processor resources used by dynamic SELECT statements. For example, you might choose to disable bind operations during critical times of day to avoid contention with the DB2 catalog.

You can establish a single limit for all users, different limits for individual users, or both. You can choose to have these limits applied before the statement is executed (this is called *predictive* governing), or while a statement is running (sometimes called *reactive* governing). You can even use both modes of governing. You define these limits in one or more resource limit specification tables (RLST).

## Work file database

The *work file database* is used as storage for processing SQL statements that require working space, such as that required for a sort. DB2 creates a work file database for you at installation time, and you can create additional work file table spaces at any time using CREATE TABLESPACE statements.

In a non-data-sharing environment, the work file database is called DSNDB07. In a data sharing environment, each DB2 member in the data sharing group has its own work file database.

## TEMP database

The TEMP database is for declared temporary tables only. DB2 stores all declared temporary tables in this database. You can create one TEMP database for each DB2 subsystem or data sharing member.

## More information about data structures

Table 3 lists additional information sources about topics that this section introduces.

## Control and maintenance of DB2

You use commands and utilities to perform the tasks required to control and maintain DB2:

- Commands can be entered at a terminal, a z/OS console, or through an APF-authorized program or application that uses the instrumentation facility interface (IFI)
- Utility jobs run as standard batch jobs

### Commands

The commands are divided into the following categories:

- DSN command and subcommands
- DB2 commands
- IMS commands
- CICS attachment facility commands
- IRLM commands
- TSO CLIST commands

To enter a DB2 command from an authorized z/OS console, you use a subsystem command prefix (composed of 1 to 8 characters) at the beginning of the command. The default subsystem command prefix is *-DSN1*, which you can change when you install or migrate DB2.

**Example:** The following command starts the DB2 subsystem that is associated with the command prefix *-DSN1*:

```
-DSN1 START DB2
```

### Utilities

You use utilities to perform many of the tasks required to maintain DB2 data. Those tasks include loading a table, copying a table space, or recovering a database to a previous point in time.

The utilities run as batch jobs. *DB2 interactive* (DB2I) provides a simple way to prepare the job control language (JCL) for those jobs and to perform many other operations by entering values on panels. DB2I runs under TSO using ISPF services. A utility control statement tells a particular utility what task to perform.

## High availability

It is not necessary to start or stop DB2 often. DB2 continually adds function to improve availability, especially in the following areas:

- “Daily operations and tuning”
- “Backup and recovery”
- “Restart” on page 13

### Daily operations and tuning

Some of the high availability features related to normal DB2 operations include:

- You can bind application plans and packages online. Packages let you change and rebind smaller units. Using package *versions* permits binding while the applications continue to run.
- You can define and change databases and authorizations online.
- You can change buffer pool sizes online.
- You can use utilities to reorganize indexes, table spaces, or partitions of indexes or table spaces.
- DB2’s data sharing function lets several DB2 subsystems process applications on shared data. While the different subsystems share data, they appear as a single DB2 to end users. Applications can be rerouted to avoid outages if one of the subsystems must be taken down for maintenance.

### Backup and recovery

Unplanned outages are difficult to avoid entirely. However, a good backup strategy can reduce the elapsed time of an unplanned outage. To reduce the probability and duration of unplanned outages, you should periodically back up and reorganize your data.

A lot of factors affect the availability of the databases. Here are some key points to be aware of:

- You should limit your use of, and understand the options of, utilities such as COPY and REORG.
  - You can recover online such structures as table spaces, partitions, data sets, a range of pages, a single page, and indexes.
  - You can recover table spaces and indexes at the same time to reduce recovery time.
  - With some options on the COPY utility, you can read and update a table space while copying it.
- I/O errors have the following affects:
  - I/O errors on a range of data do not affect availability to the rest of the data.
  - If an I/O error occurs when DB2 is writing to the log, DB2 continues to operate.
  - If an I/O error is on the active log, DB2 moves to the next data set. If the error is on the archive log, DB2 dynamically allocates another data set.
- Documented disaster recovery methods are crucial in the case of disasters that might cause a complete shutdown of your local DB2 system.
- If DB2 is forced to a single mode of operations for the bootstrap data set or logs, you can usually restore dual operation while DB2 continues to run.

## Restart

A key to the perception of high availability is getting the DB2 subsystem back up and running quickly after an unplanned outage.

- Some restart processing can occur concurrently with new work. Also, you can choose to postpone some processing.
- During a restart, DB2 applies data changes from the log. This technique ensures that data changes are not lost, even if some data was not written at the time of the failure. Some of the process of applying log changes can run in parallel
- You can register DB2 to the Automatic Restart Manager of z/OS. This facility automatically restarts DB2 should it go down as a result of a failure.

## More information about control and maintenance of DB2

Table 4 lists additional information sources about topics that this section introduces.

Recovery	<ul style="list-style-type: none"><li>• "Recovering page sets and data sets" on page 495</li><li>• <i>DB2 Utility Guide and Reference</i></li></ul>

---

## The DB2 environment

This section provides an overview of DB2 components and environments that work together in the z/OS environment. DB2 operates as a formal subsystem of z/OS. DB2 utilities run in the batch environment, and applications that access DB2 resources can run in the batch, TSO, IMS, or CICS environments. IBM provides attachment facilities to connect DB2 to each of these environments.

## Address spaces

DB2 uses several different address spaces for the following purposes:

### Database services

*ssnm*DBM1 manipulates most of the structures in user-created databases. In Version 8, storage areas such as buffer pools reside above the 2GB bar in the *ssnm*DBM1 address space. With 64-bit virtual addressing to access these storage areas, buffer pools to scale to extremely large sizes.

### System services

*ssnm*MSTR performs a variety of system-related functions.

### Distributed data facility

*ssnm*DIST provides support for remote requests.

### IRLM (Internal resource lock manager)

IRLMPROC controls DB2 locking.

### DB2-established

*ssnm*SPAS, for stored procedures, provides an isolated execution environment for user-written SQL programs at a DB2 server.

### **WLM-established**

Zero to many address spaces for stored procedures and user-defined functions. WLM-established address spaces are handled in order of priority and isolated from other stored procedures or user-defined functions running in other address spaces

### **User address spaces**

At least one, possibly several, of the following types of user address spaces:

- TSO
- Batch
- CICS
- IMS dependent region
- IMS control region

## **DB2 lock manager**

DB2's internal resource lock manager (IRLM) is both a separate subsystem and an integral component of DB2. IRLM is shipped with DB2, and each DB2 subsystem must have its own instance of IRLM.

**Recommendation:** Always run with the latest level of IRLM.

You cannot share IRLM between DB2s or between DB2 and IMS. (IRLM is also shipped with IMS.) If you are running a DB2 data sharing group, there is a corresponding IRLM group.

### **What IRLM does**

IRLM works with DB2 to serialize access to your data. DB2 requests locks from IRLM to ensure data integrity when applications, utilities, commands, and so forth, are all attempting to access the same data.

### **Administering IRLM**

IRLM requires some control and monitoring. The external interfaces to the IRLM include:

- Installation

Install IRLM when you install DB2. Consider that locks take up storage, and adequate storage for IRLM is crucial to the performance of your system.

Another important performance item is to make the priority of the IRLM address space above all the DB2 address spaces.

- Commands

Some z/OS commands specifically for IRLM let you modify parameters, display information about the status of the IRLM and its storage use, and start and stop IRLM.

- Tracing

DB2's trace facility gives you the ability to trace lock interactions.

You can use z/OS trace commands or IRLMPROC options to control diagnostic traces for IRLM. You normally use these traces under the direction of IBM Service.

## **DB2 attachment facilities**

This section describes the attachment facilities that you can use in the z/OS environment to begin a DB2 session. You can also begin DB2 sessions from other environments on clients such as Windows® or UNIX® by using interfaces that include ODBC, JDBC, and SQLJ.

An *attachment facility* provides the interface between DB2 and another environment. Figure 2 shows the z/OS attachment facilities with interfaces to DB2.

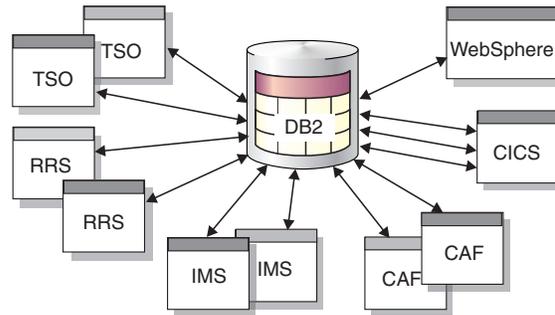

Figure 2. Attaching to DB2

The z/OS environments include:

- WebSphere
- CICS (Customer Information Control System)
- IMS (Information Management System)
- TSO (Time Sharing Option)
- Batch

The z/OS attachment facilities include:

- CICS
- IMS
- TSO
- CAF (call attachment facility)
- RRS (Resource Recovery Services)

In the TSO and batch environments, you can use the TSO, CAF, and RRS attachment facilities to access DB2.

## WebSphere

WebSphere products that are integrated with DB2 include WebSphere Application Server, WebSphere Studio, and Transaction Servers & Tools. In the WebSphere environment, you can use the RRS attachment facility.

## CICS

The *Customer Information Control System* (CICS) attachment facility provided with the CICS transaction server lets you access DB2 from CICS. After you start DB2, you can operate DB2 from a CICS terminal. You can start and stop CICS and DB2 independently, and you can establish or terminate the connection between them at any time. You also have the option of allowing CICS to connect to DB2 automatically.

The CICS attachment facility also provides CICS applications with access to DB2 data while operating in the CICS environment. CICS applications, therefore, can access both DB2 data and CICS data. In case of system failure, CICS coordinates recovery of both DB2 and CICS data.

**CICS operations:** The CICS attachment facility uses standard CICS command-level services where needed.

### Examples:

```
EXEC CICS WAIT
EXEC CICS ABEND
```

A portion of the CICS attachment facility executes under the control of the transaction issuing the SQL requests. Therefore these calls for CICS services appear to be issued by the application transaction.

With proper planning, you can include DB2 in a CICS XRF recovery scenario.

**Application programming with CICS:** Programmers writing CICS command-level programs can use the same data communication coding techniques to write the data communication portions of application programs that access DB2 data. Only the database portion of the programming changes. For the database portions, programmers use SQL statements to retrieve or modify data in DB2 tables.

To a CICS terminal user, application programs that access both CICS and DB2 data appear identical to application programs that access only CICS data.

DB2 supports this cross-product programming by coordinating recovery resources with those of CICS. CICS applications can therefore access CICS-controlled resources as well as DB2 databases.

Function shipping of SQL requests is not supported. In a CICS multi-region operation (MRO) environment, each CICS address space can have its own attachment to the DB2 subsystem. A single CICS region can be connected to only one DB2 subsystem at a time.

**System administration and operation with CICS:** An authorized CICS terminal operator can issue DB2 commands to control and monitor both the attachment facility and DB2 itself. Authorized terminal operators can also start and stop DB2 databases.

Even though you perform DB2 functions through CICS, you need to have the TSO attachment facility and ISPF to take advantage of the online functions supplied with DB2 to install and customize your system. You also need the TSO attachment to bind application plans and packages.

## IMS

The *Information Management System* (IMS) attachment facility allows you to access DB2 from IMS. The IMS attachment facility receives and interprets requests for access to DB2 databases using exits provided by IMS subsystems. Usually, IMS connects to DB2 automatically with no operator intervention.

In addition to Data Language I (DL/I) and Fast Path calls, IMS applications can make calls to DB2 using embedded SQL statements. In case of system failure, IMS coordinates recovery of both DB2 and IMS data.

With proper planning, you can include DB2 in an IMS XRF recovery scenario.

**Application programming with IMS:** With the IMS attachment facility, DB2 provides database services for IMS dependent regions. DL/I batch support allows users to access both IMS data (DL/I) and DB2 data in the IMS batch environment, which includes:

- Access to DB2 and DL/I data from application programs.
- Coordinated recovery through a two-phase commit process.
- Use of the IMS extended restart (XRST) and symbolic checkpoint (CHKP) calls by application programs to coordinate recovery with IMS, DB2, and generalized sequential access method (GSAM) files.

IMS programmers writing the data communication portion of application programs do not need to alter their coding technique to write the data communication portion when accessing DB2; only the database portions of the application programs change. For the database portions, programmers code SQL statements to retrieve or modify data in DB2 tables.

To an IMS terminal user, IMS application programs that access DB2 appear identical to IMS.

DB2 supports this cross-product programming by coordinating database recovery services with those of IMS. Any IMS program uses the same synchronization and rollback calls in application programs that access DB2 data as they use in IMS DB/DC application programs that access DL/I data.

Another aid for cross-product programming is the DataPropagator™ NonRelational (DPropNR) licensed program. DPropNR allows automatic updates to DB2 tables when corresponding information in an IMS database is updated, and it allows automatic updates to an IMS database when a DB2 table is updated.

**System administration and operation with IMS:** An authorized IMS terminal operator can issue DB2 commands to control and monitor DB2. The terminal operator can also start and stop DB2 databases.

Even though you perform DB2 functions through IMS, you need the TSO attachment facility and ISPF to take advantage of the online functions supplied with DB2 to install and customize your system. You also need the TSO attachment facility to bind application plans and packages.

## TSO

The *Time Sharing Option* (TSO) attachment facility is required for binding application plans and packages and for executing several online functions that are provided with DB2.

Using the TSO attachment facility, you can access DB2 by running in either foreground or batch. You gain foreground access through a TSO terminal; you gain batch access by invoking the TSO terminal monitor program (TMP) from a batch job.

The following two command processors are available:

- DSN command processor — Runs as a TSO command processor and uses the TSO attachment facility.
- DB2 Interactive (DB2I) — Consists of Interactive System Productivity Facility (ISPF) panels. ISPF has an interactive connection to DB2, which invokes the DSN command processor. Using DB2I panels, you can perform most DB2 tasks interactively, such as running SQL statements, commands, and utilities.

Whether you access DB2 in foreground or batch, attaching through the TSO attachment facility and the DSN command processor makes access easier. DB2 subcommands that execute under DSN are subject to the command size limitations as defined by TSO. TSO allows authorized DB2 users or jobs to create, modify, and maintain databases and application programs. You invoke the DSN processor from the foreground by issuing a command at a TSO terminal. From batch, first invoke TMP from within a batch job, and then pass commands to TMP in the SYSTSIN data set.

After DSN is running, you can issue DB2 commands or DSN subcommands. You cannot issue a -START DB2 command from within DSN. If DB2 is not running, DSN cannot establish a connection to it; a connection is required so that DSN can transfer commands to DB2 for processing.

## CAF

Most TSO applications must use the TSO attachment facility, which invokes the DSN command processor. Together, DSN and TSO provide services such as automatic connection to DB2, attention key support, and translation of return codes into error messages. However, when using DSN services, your application must run under the control of DSN.

The *call attachment facility* (CAF) provides an alternative connection for TSO and batch applications needing tight control over the session environment. Applications using CAF can *explicitly* control the state of their connections to DB2 by using connection functions that CAF supplies.

## RRS

z/OS Resource Recovery Services is a newer implementation of CAF with additional capabilities. RRS is a feature of z/OS that coordinates commit processing of recoverable resources in a z/OS system. DB2 supports use of these services for DB2 applications that use the RRS attachment facility provided with DB2. Use the RRS attachment to access resources such as SQL tables, DL/I databases, MQSeries® messages, and recoverable VSAM files within a single transaction scope.

The RRS attachment is required for stored procedures that run in a WLM-established address space.

## DB2 and distributed data

In a distributed data environment, DB2 applications can access data at many different DB2 sites and at remote relational database systems.

**Example:** Assume a company needs to satisfy customer requests at hundreds of locations and the company representatives who answer those requests work at locations that span a wide geographic area. You can document requests on workstations that have DB2® Connect™ Personal Edition. This information is uploaded to DB2 UDB for z/OS. The representatives can then use Java™ applications to access the customer request information in DB2 from their local offices.

The company's distributed environment relies on the distributed data facility (DDF), which is part of DB2 UDB for z/OS. DB2 applications can use DDF to access data at other DB2 sites and at remote relational database systems that support *Distributed Relational Database Architecture*™ (DRDA®). DRDA is a standard for distributed connectivity. All IBM DB2 servers support this DRDA standard.

DDF also enables applications that run in a remote environment that supports DRDA. These applications can use DDF to access data in DB2 servers. Examples of application requesters include IBM DB2 Connect and other DRDA-compliant client products.

With DDF, you can have up to 150 000 distributed *threads* connect to a DB2 server at the same time. A thread is a DB2 structure that describes an application's connection and traces its progress.

Use *stored procedures* to reduce processor and elapsed time costs of distributed access. A stored procedure is user-written SQL program that a requester can invoke at the server. By encapsulating the SQL, many fewer messages flow across the wire.

Local DB2 applications can use stored procedures as well to take advantage of the ability to encapsulate SQL that is shared among different applications.

The decision to access distributed data has implications for many DB2 activities: application programming, data recovery, authorization, and so on.

## DB2 and z/OS

z/OS is the next generation of the OS/390 operating system. z/OS and the IBM zSeries® 800, 900, 990, or the equivalent, offer architecture that provides qualities of service that are critical for e-business. The z/OS operating system is based on 64-bit z/Architecture®. The operating system is highly secure, scalable, and high performing. With these characteristics, z/OS provides a strong base for Internet and Java-enabled applications and a comprehensive and diverse environment for running your applications.

## DB2 and the Parallel Sysplex

The Parallel Sysplex is a key example of the synergy of DB2 and zSeries. DB2 takes advantage of the zSeries Parallel Sysplex, with its superior processing capabilities. By allowing two or more processors to share the same data, you can maximize performance while minimizing cost; improve system availability and concurrency; expand system capacity; and configure your system environment more flexibly. With data sharing, applications running on more than one DB2 subsystem can read from and write to the same set of data concurrently.

Sharing DB2s must belong to a DB2 data sharing *group*. A data sharing group is a collection of one or more DB2 subsystems accessing shared DB2 data. Each DB2 subsystem belonging to a particular data sharing group is a *member* of that group. All members of a group use the same shared DB2 catalog and directory.

With data sharing, you can grow your system incrementally by adding additional central processor complexes and DB2s to the data sharing group. You don't have to move part of the workload onto another system, alleviating the need to manage copies of the data or to use distributed processing to access the data.

You can configure your environment flexibly. For example, you can tailor each z/OS image to meet the requirements for the user set on that image. For processing that occurs during peak workload periods, you can bring up a dormant DB2 to help process the work.

## DB2 and the Security Server for z/OS

You can use the Resource Access Control Facility (RACF) component of the SecureWay™ Security Server for z/OS, or an equivalent product, to control access to your z/OS system. When users begin sessions with TSO, IMS, or CICS, their identities are checked to prevent unauthorized access to the system.

**Recommendation:** Use the Security Server check the security of DB2 users and to protect DB2 resources. The Security Server provides effective protection for DB2 data by permitting only DB2-mediated access to DB2 data sets.

Much authorization to DB2 objects can be controlled directly from the Security Server. An *exit routine* (a program that runs as an extension of DB2) that is shipped with the z/OS Security Server lets you centralize access control.

## DB2 and DFSMS

The DFSMSdftp™ *storage management subsystem* (SMS) can be used to manage DB2 disk data sets. The purpose of SMS is to automate as much as possible the management of physical storage by centralizing control, automating tasks, and providing interactive controls for system administrators. SMS can reduce users' needs to be concerned about physical details of performance, space, and device management.

Consult with your site's storage administrator about using SMS for DB2 private data, image copies, and archive logs. For data that is especially performance-sensitive, there might need to be more manual control over data set placement.

Table spaces or indexes with data sets larger than 4 gigabytes require SMS-managed data sets.

Extended partitioned data sets (PDSE), a feature of DFSMSdftp, are useful for managing stored procedures that run in a stored procedures address space. PDSE enables extent information for the load libraries to be dynamically updated, reducing the need to start and stop the stored procedures address space.

## More information about the z/OS environment

## Chapter 3. Creating storage groups and managing DB2 data sets

A *DB2 storage group* is a named set of disk volumes, in which DB2:

- Allocates storage for table spaces and indexes
- Defines the necessary VSAM data sets
- Extends and deletes VSAM data sets
- Alters VSAM data sets

DB2 can manage the auxiliary storage requirements of a database by using DB2 storage groups. Data sets in these DB2 storage groups are called *DB2-managed data sets*.

**Note:** These DB2 storage groups are not the same as storage groups that are defined by the DFSMS<sup>SM</sup> storage management subsystem (DFSMSsms).

You have several options for managing DB2 data sets:

- Let DB2 manage the data sets. This option means less work for DB2 database administrators. See “Managing data sets with DB2 storage groups” for more information.
- Let SMS manage some or all of the data sets, either when you use DB2 storage groups or when you use data sets that you have defined yourself. This option offers a reduced workload for DB2 database administrators and storage administrators. See “Managing DB2 data sets with DFSMSHsm” on page 35 for complete information.
- Define and manage your own data sets using VSAM Access Method Services. This option gives you the most control over the physical storage of tables and indexes. See “Managing your own data sets” on page 37 for detailed information.

**Recommendation:** Use DB2 storage groups whenever you can, either specifically or by default.

This chapter also includes the following additional topics:

- “Defining index space storage” on page 41
- “Creating EA-enabled table spaces and index spaces” on page 42

---

### Managing data sets with DB2 storage groups

This section describes how to create DB2 storage groups, how DB2 manages the data sets in your DB2 storage groups, and what you should consider when using storage groups :

- “Creating DB2 storage groups” on page 29
- “Using SMS to manage DB2 storage groups” on page 30
- “Deferring allocation of DB2-managed data sets” on page 30
- “Extending DB2-managed data sets” on page 31

Here are some of the things that DB2 does for you in managing your auxiliary storage requirements:

- When a table space is created, DB2 defines the necessary VSAM data sets using VSAM Access Method Services. After the data sets are created, you can process

them with access method service commands that support VSAM control-interval (CI) processing (for example, IMPORT and EXPORT).

**Exception:** You can defer the allocation of data sets for table spaces and index spaces by specifying the DEFINE NO clause on the associated statement (CREATE TABLESPACE and CREATE INDEX), which also must specify the USING STOGROUP clause. For more information about deferring data set allocation, see either “Deferring allocation of DB2-managed data sets” on page 30 or Chapter 5 of *DB2 SQL Reference*.

- When a table space is dropped, DB2 automatically deletes the associated data sets.
- When a data set in a segmented or simple table space reaches its maximum size of 2 GB, DB2 might automatically create a new data set. The primary data set allocation is obtained for each new data set.
- When needed, DB2 can extend individual data sets. For more information, see “Extending DB2-managed data sets” on page 31.
- When you create or reorganize a table space that has associated data sets, DB2 deletes and then redefines them, reclaiming fragmented space. However, when you run REORG with the REUSE option and SHRLEVEL NONE, REORG resets and reuses DB2-managed data sets without deleting and redefining them. If the size of your table space is not changing, using the REUSE parameter could be more efficient.

**Exception:** When reorganizing a LOB table space, DB2 does not delete and redefine the first data set that was allocated for the table space. If the REORG results in empty data sets beyond the first data set, DB2 deletes those empty data sets.

- When you want to move data sets to a new volume, you can alter the volumes list in your storage group. DB2 automatically relocates your data sets during the utility operations that build or rebuild a data set (LOAD REPLACE, REORG, REBUILD, and RECOVER). Note that if you use the REUSE option, DB2 does not delete and redefine the data sets and therefore does not move them.

For a LOB table space, you can alter the volumes list in your storage group, and DB2 automatically relocates your data sets during the utility operations that build or rebuild a data set (LOAD REPLACE and RECOVER).

To move user-defined data sets, you must delete and redefine the data sets in another location. For information about defining your own data sets, see “Managing your own data sets” on page 37.

| **Control interval sizing:** A *control interval* is a fixed-length area or disk in which  
| VSAM stores records and creates distributed free space. It is the unit of  
| information that VSAM transmits to or from disk.

| DB2 page sets are defined as VSAM linear data sets. Prior to Version 8, DB2  
| defined all data sets with VSAM control intervals that were 4 KB in size. Beginning  
| in Version 8, DB2 can define data sets with variable VSAM control intervals. One  
| of the biggest benefits of this change is an improvement in query processing  
| performance.

| The VARY DS CONTROL INTERVAL parameter on installation panel DSNTIP7  
| allows you to control whether DB2-managed data sets have variable VSAM control  
| intervals:

- A value of YES indicates that a DB2-managed data set is created with a VSAM control interval that corresponds to the size of the buffer pool that is used for the table space. This is the default value.

- A value of NO indicates that a DB2–managed data set is created with a fixed VSAM control interval of 4 KB, regardless of the size of the buffer pool that is used for the table space.

Table 7 shows the default and compatible control interval sizes for each table space page size. For example, a table space with pages 16 KB in size can have a VSAM control interval of 4 KB or 16 KB. Control interval sizing has no impact on indexes; index pages are always 4 KB in size.

*Table 7. Default and compatible control interval sizes*

Table space page size	Default control interval size	Compatible control interval sizes
4 KB	4 KB	4 KB
8 KB	8 KB	4 KB, 8 KB
16 KB	16 KB	4 KB, 16 KB
32 KB	32 KB	4 KB, 32 KB

## Creating DB2 storage groups

To create a DB2 storage group, use the SQL statement `CREATE STOGROUP`. For detailed information about `CREATE STOGROUP`, see Chapter 5 of *DB2 SQL Reference*.

DB2 storage group names are unqualified identifiers of up to 128 characters. A DB2 storage group name cannot be the same as any other storage group name in the DB2 catalog.

After you define a storage group, DB2 stores information about it in the DB2 catalog. (This catalog is not the same as the integrated catalog facility catalog that describes DB2 VSAM data sets). The catalog table `SYSIBM.SYSSTOGROUP` has a row for each storage group, and `SYSIBM.SYSVOLUMES` has a row for each volume. With the proper authorization, you can retrieve the catalog information about DB2 storage groups by using SQL statements. See Appendix F of *DB2 SQL Reference* for more information about using SQL statements to retrieve catalog information about DB2 storage groups.

When you create table spaces and indexes, you name the storage group from which space is to be allocated. You can also assign an entire database to a storage group. Try to assign frequently accessed objects (indexes, for example) to fast devices, and assign seldom-used tables to slower devices. This approach to choosing storage groups improves performance.

A *default storage group*, `SYSDEFLT`, is defined when DB2 is installed. If you are authorized and do not take specific steps to manage your own storage, you can still define tables, indexes, table spaces, and databases; DB2 uses `SYSDEFLT` to allocate the necessary auxiliary storage. Information about `SYSDEFLT`, as with any other storage group, is kept in the catalog tables `SYSIBM.SYSSTOGROUP` and `SYSIBM.SYSVOLUMES`.

For both user-managed and DB2-managed data sets, you need at least one integrated catalog facility (ICF) catalog—either user or master—that is created with the ICF. You must identify the catalog of the ICF when you create a storage group or when you create a table space that does not use storage groups.

## Using SMS to manage DB2 storage groups

When defining DB2 storage groups, use the VOLUMES('\*') attribute on the CREATE STOGROUP statement to let SMS control the selection of volumes during allocation. See “Managing DB2 data sets with DFSMSHsm” on page 35 for more information.

If you use DB2 to allocate data to specific volumes, you must assign an SMS storage class with guaranteed space, and you must manage free space for each volume to prevent failures during the initial allocation and extension. Using guaranteed space reduces the benefits of SMS allocation, requires more time for space management, and can result in more space shortages. You should only use guaranteed space when space needs are relatively small and do not change.

**Recommendation:** Let SMS manage your DB2 storage groups; to do this, use asterisks (nonspecific volume IDs) in the VOLUMES clause.

## Deferring allocation of DB2-managed data sets

When you execute a CREATE TABLESPACE statement with the USING STOGROUP clause, DB2 generally defines the necessary VSAM data sets for the table space. In some cases, however, you might want to define a table space without immediately allocating the associated data sets.

For example, you might be installing a software program that requires that many table spaces be created, but your company might not need to use some of those table spaces; you might prefer not to allocate data sets for the table spaces you will not be using.

# To defer the physical allocation of DB2-managed data sets, use the DEFINE NO  
# clause of the CREATE TABLESPACE statement. When you specify the DEFINE NO  
# clause, the table space is created, but DB2 does not allocate (that is, define) the  
# associated data sets until a row is inserted or loaded into a table in that table  
# space. The DB2 catalog table SYSIBM.SYSTABLEPART contains a record of the  
# created table space and an indication that the data sets are not yet allocated.

The DEFINE NO clause is not allowed for LOB table spaces, for table spaces in a work file database or a TEMP database, or for user-defined data sets. (In the case of user-defined data sets, the table space is created with the USING VCAT clause of the CREATE TABLESPACE statement).

Using the DEFINE NO clause is recommended when:

- Performance of the CREATE TABLESPACE statement is important.
- Disk resource is constrained.

Do not use the DEFINE NO clause on a table space if you plan to use a tool outside of DB2 to propagate data into a data set in the table space. When you use DEFINE NO, the DB2 catalog indicates that the data sets have not yet been allocated for that table space. Then, if data is propagated from a tool outside of DB2 into a data set in the table space, the DB2 catalog information does not reflect the fact that the data set has been allocated. The resulting inconsistency causes DB2 to deny application programs access to the data until the inconsistency is resolved.

## Extending DB2-managed data sets

When a data set is created, DB2 allocates a primary allocation space on a volume that has space available and that is specified in the DB2 storage group. Any extension to a data set always gets a secondary allocation space.

If new extensions reach the end of the volume, DB2 accesses all candidate volumes from the DB2 storage group and issues the Access Method Services command ALTER ADDVOLUMES to add these volumes to the integrated catalog facility (ICF) catalog as candidate volumes for the data set. DB2 then makes a request to allocate a secondary extent on any one of the candidate volumes that has space available. After the allocation is successful, DB2 issues the command ALTER REMOVEVOLUMES to remove all candidate volumes from the ICF catalog for the data set.

DB2 extends data sets when either of the following conditions occurs:

- The requested space exceeds the remaining space in the data set.
- 10% of the secondary allocation space (but not over 10 allocation units, based on either tracks or cylinders) exceeds the remaining space.

If DB2 fails to extend a data set with a secondary allocation space because of insufficient available space on any single candidate volume of a DB2 storage group, DB2 tries again to extend with the requested space if the requested space is smaller than the secondary allocation space. Typically, DB2 requests only one additional page. In this case, a small amount of two units (tracks or cylinders, as determined by dfsMS based on the SECQTY value) is allocated. To monitor data set extension activity, use IFCID 258 in statistics class 3.

**Extending nonpartitioned spaces:** For a nonpartitioned table space or a nonpartitioned index space, DB2 defines the first piece of the page set starting with a primary allocation space, and extends that piece by using secondary allocation spaces. When the end of the first piece is reached, DB2 defines a new piece (which is a new data set) and extends that new piece starting with a primary allocation space.

**Exception:** In the case where the OPTIMIZE EXTENT SIZING parameter (MGEXTSZ) on installation panel DSNTIP7 is set to YES and the SECQTY value for the table space or index space is greater than zero, the primary space allocation of each subsequent data set is the larger of the SECQTY setting and the value that is derived from a sliding scale algorithm. See “Secondary space allocation” on page 32 for information about the sliding scale algorithm.

**Extending partitioned spaces:** For a partitioned table space or a partitioned index space, each partition is a data set. Therefore, DB2 defines each partition with the primary allocation space and extends each partition’s data set by using a secondary allocation space, as needed.

**When data extension fails:** If a data set uses all possible extents, DB2 cannot extend that data set. For a partitioned page set, the extension fails only for the particular partition that DB2 is trying to extend. For nonpartitioned page sets, DB2 cannot extend to a new data set piece, which means that the extension for the entire page set fails.

To avoid extension failures, allow DB2 to use the default value for primary space allocation and to use a sliding scale algorithm for secondary extent allocations. These concepts are discussed in the topics that follow.

## Primary space allocation

By default, DB2 uses the following values for primary space allocation of DB2-managed data sets:

- 1 cylinder (720 KB) for non-LOB table spaces
- 10 cylinders for LOB table spaces
- 1 cylinder for indexes

To indicate that you want DB2 to use the default values for primary space allocation of table spaces and indexes, specify a value of 0 for the following parameters on installation panel DSNTIP7, as shown in Table 8.

Table 8. DSNTIP7 parameter values for managing space allocations

Installation panel DSNTIP7 parameter	Recommended value
TABLE SPACE ALLOCATION	0
INDEX SPACE ALLOCATION	0

Thereafter:

- On CREATE TABLESPACE and CREATE INDEX statements, do not specify a value for the PRIQTY option.
- On ALTER TABLESPACE and ALTER INDEX statements, specify a value of -1 for the PRIQTY option.

Primary space allocation quantities do not exceed DSSIZE or PIECESIZE clause values.

**Exception:** If the OPTIMIZE EXTENT SIZING parameter (MGEXTSZ) on installation panel DSNTIP7 is set to YES and the table space or index space has a SECQTY setting of greater than zero, the primary space allocation of each subsequent data set is the larger of the SECQTY setting and the value that is derived from a sliding scale algorithm. See “Secondary space allocation” for information about the sliding scale algorithm.

For those situations in which the default primary quantity value is not large enough, you can specify a larger value for the PRIQTY option when creating or altering table spaces and indexes. DB2 always uses a PRIQTY value if one is explicitly specified.

If you want to prevent DB2 from using the default value for primary space allocation of table spaces and indexes, specify a non-zero value for the TABLE SPACE ALLOCATION and INDEX SPACE ALLOCATION parameters on installation panel DSNTIP7.

## Secondary space allocation

DB2 can calculate the amount of space to allocate to secondary extents by using a sliding scale algorithm. The first 127 extents are allocated in increasing size, and the remaining extents are allocated based on the initial size of the data set:

- For 32 GB and 64 GB data sets, each extent is allocated with a size of 559 cylinders.
- For data sets that range in size from less than 1 GB to 16 GB, each extent is allocated with a size of 127 cylinders.

This approach has several advantages:

- It minimizes the potential for wasted space by increasing the size of secondary extents slowly at first.

- It prevents very large allocations for the remaining extents, which would likely cause fragmentation.
- It does not require users to specify SECQTY values when creating and altering table spaces and index spaces.
- It is theoretically possible to reach maximum data set size without running out of secondary extents.

In the case of severe DASD fragmentation, it can take up to 5 extents to satisfy a logical extent request. In this situation, the data set does not reach the theoretical data set size.

If you installed DB2 on the operating system z/OS Version 1 Release 7, or later, then you can modify the Extent Constraint Removal option. By setting the Extent Constraint Removal option to YES in the SMS data class, the maximum number of extents can be up to 7257. However, the limits of 123 extents per volume and a maximum volume count of 59 per data set remain valid. For more information, see "Using VSAM extent constraint removal" in the z/OS V1R7 guide "DFSMS: Using the New Functions" (order number SC26-7473-02).

Maximum allocation is shown in Table 9. This table assumes that the initial extent that is allocated is one cylinder in size.

*Table 9. Maximum allocation of secondary extents*

Maximum data set size, in GB	Maximum allocation, in cylinders	Extents required to reach full size
1	127	54
2	127	75
4	127	107
8	127	154
16	127	246
32	559	172
64	559	255

DB2 uses a sliding scale for secondary extent allocations of table spaces and indexes when:

- You do not specify a value for the SECQTY option of a CREATE TABLESPACE or CREATE INDEX statement
- You specify a value of -1 for the SECQTY option of an ALTER TABLESPACE or ALTER INDEX statement.

Otherwise, DB2 always uses a SECQTY value for secondary extent allocations, if one is explicitly specified.

**Exception:** For those situations in which the calculated secondary quantity value is not large enough, you can specify a larger value for the SECQTY option when creating or altering table spaces and indexes. However, in the case where the OPTIMIZE EXTENT SIZING parameter is set to YES and you specify a value for the SECQTY option, DB2 uses the value of the SECQTY option to allocate a secondary extent only if the value of the option is larger than the value that is derived from the sliding scale algorithm. The calculation that DB2 uses to make this determination is:

$$\text{Actual secondary extent size} = \max ( \min ( \text{ss\_extent}, \text{MaxAlloc} ), \text{SECQTY} )$$

In this calculation, *ss\_extent* represents the value that is derived from the sliding scale algorithm, and *MaxAlloc* is either 127 or 559 cylinders, depending on the maximum potential data set size. This approach allows you to reach the maximum page set size faster. Otherwise, DB2 uses the value that is derived from the sliding scale algorithm.

If you do not provide a value for the secondary space allocation quantity, DB2 calculates a secondary space allocation value equal to 10% of the primary space allocation value and subject to the following conditions:

- The value cannot be less than 127 cylinders for data sets that range in initial size from less than 1 GB to 16 GB, and cannot be less than 559 cylinders for 32 GB and 64 GB data sets.
- The value cannot be more than the value that is derived from the sliding scale algorithm.

The calculation that DB2 uses for the secondary space allocation value is:

$$\text{Actual secondary extent size} = \max ( 0.1 \times \text{PRIQTY}, \min ( \text{ss\_extent}, \text{MaxAlloc} ) )$$

In this calculation, *ss\_extent* represents the value that is derived from the sliding scale algorithm, and *MaxAlloc* is either 127 or 559 cylinders, depending on the maximum potential data set size.

Secondary space allocation quantities do not exceed DSSIZE or PIECESIZE clause values.

If you do not want DB2 to extend a data set, you can specify a value of 0 for the SECQTY option. Specifying 0 is a useful way to prevent DSNDB07 work files from growing out of proportion.

If you want to prevent DB2 from using the sliding scale for secondary extent allocations of table spaces and indexes, specify a value of NO for the OPTIMIZE EXTENT SIZING parameter on installation panel DSNTIP7.

### Example of primary and secondary space allocation

Table 10 shows how primary and secondary quantities are affected by a CREATE statement and two subsequent ALTER statements. This example assumes a maximum data set size of less than 32 GB, and the following parameter values on installation panel DSNTIP7:

```
TABLE SPACE ALLOCATION = 0
INDEX SPACE ALLOCATION = 0
OPTIMIZE EXTENT SIZING = YES
```

Table 10. Example of specified and actual space allocations

Action	Specified PRIQTY	Actual primary quantity allocated	Specified SECQTY	Actual secondary quantity allocated
CREATE TABLESPACE	100 KB	100 KB	1000 KB	2 cylinders
ALTER TABLESPACE	-1	1 cylinder	2000 KB	3 cylinders
ALTER TABLESPACE		1 cylinder	-1	1 cylinder

---

## Managing DB2 data sets with DFSMSHsm

This section describes how you can use the Hierarchical Storage Management functional component (DFSMSHsm) of DFSMS to manage space and data availability among the storage devices in your system:

- “Migrating to DFSMSHsm”
- “Recalling archive logs” on page 36
- “Using DFSMSHsm with the RECOVER utility” on page 36
- “Using DFSMSHsm with the BACKUP SYSTEM utility” on page 37

You can use DFSMSHsm to move data sets that have not been recently used to slower, less expensive storage devices. Moving the data sets helps to ensure that disk space is managed efficiently. For more information about using DFSMSHsm to manage DB2 data sets, see *MVS Storage Management Library: Storage Management Subsystem Migration Planning Guide* and *z/OS DFSMSHsm Managing Your Own Data*.

### Migrating to DFSMSHsm

If you decide to use DFSMSHsm for your DB2 data sets, you should develop a migration plan with your system administrator. With user-managed data sets, you can specify DFSMSHsm classes on the Access Method Services DEFINE command. With DB2 storage groups, you need to develop automatic class selection routines.

---

#### General-use Programming Interface

---

To allow DFSMSHsm to manage your DB2 storage groups, you can use one or more asterisks as volume IDs in your CREATE STOGROUP or ALTER STOGROUP statement, as shown here:

```
CREATE STOGROUP G202
VOLUMES ('*')
VCAT DB2SMST;
```

---

#### End of General-use Programming Interface

---

This example causes all database data set allocations and definitions to use nonspecific selection through DFSMSHsm filtering services.

When you use DFSMSHsm and DB2 storage groups, you can use the system parameters SMSDCFL and SMSDCIX to assign table spaces and indexes to different DFSMSHsm data classes.

- SMSDCFL specifies a DFSMSHsm data class for table spaces. If you assign a value to SMSDCFL, DB2 specifies that value when it uses Access Method Services to define a data set for a table space.
- SMSDCIX specifies a DFSMSHsm data class for indexes. If you assign a value to SMSDCIX, DB2 specifies that value when it uses Access Method Services to define a data set for an index.

Before you set the data class system parameters, you need to do two things:

- Define the data classes for your table space data sets and index data sets.
- Code the SMS automatic class selection (ACS) routines to assign indexes to one SMS storage class and to assign table spaces to a different SMS storage class.

For more information about creating data classes, see *z/OS DFSMS: Implementing System-Managed Storage*.

## Recalling archive logs

DFSMSHsm can automatically migrate and recall archive log and image copy data sets. If DB2 needs an archive log data set or an image copy data set that DFSMSHsm has migrated, a recall begins automatically and DB2 waits for the recall to complete before continuing.

For processes that read more than one archive log data set, such as the RECOVER utility, DB2 anticipates a DFSMSHsm recall of migrated archive log data sets. When a DB2 process finishes reading one data set, it can continue with the next data set without delay, because the data set might already have been recalled by DFSMSHsm.

If you accept the default value YES for the RECALL DATABASE parameter on the Operator Functions panel (DSNTIPO), DB2 also recalls migrated table spaces and index spaces. At data set open time, DB2 waits for DFSMSHsm to perform the recall. You can specify the amount of time DB2 waits while the recall is being performed with the RECALL DELAY parameter, which is also on panel DSNTIPO. If RECALL DELAY is set to zero, DB2 does not wait, and the recall is performed asynchronously.

You can use System Managed Storage (SMS) to archive DB2 subsystem data sets, including the DB2 catalog, DB2 directory, active logs, and work file databases (DSNDB07 in a non-data-sharing environment). However, before starting DB2, you should recall these data sets by using DFSMSHsm. Alternatively, you can avoid migrating these data sets by assigning them to a management class that prevents migration. Considerations for using DFSMSHsm for archive log data sets are discussed in “Archive log data sets” on page 433.

If a volume has a STOGROUP specified, you must recall that volume only to volumes of the same device type as others in the STOGROUP.

In addition, you must coordinate the DFSMSHsm automatic purge period, the DB2 log retention period, and MODIFY utility usage. Otherwise, the image copies or logs that you might need during a recovery could already have been deleted.

## Using DFSMSHsm with the RECOVER utility

The RECOVER utility can execute the DFSMSdss™ RESTORE command, which generally uses extensions larger than the data set’s primary and secondary space allocation values. RECOVER executes this command if the point of recovery is defined by an image copy that was taken by using the CONCURRENT option of the COPY utility.

The DFSMSdss RESTORE command extends a data set differently than DB2, so you must alter the page set to contain extents defined by DB2. To do this, use ALTER TABLESPACE to enlarge the primary and secondary space allocation values for DB2-managed data sets. After you use ALTER TABLESPACE, the new values take effect only when you use REORG or LOAD REPLACE. Using RECOVER again does not resolve the extent definition.

For user-defined data sets, define the data sets with larger primary and secondary space allocation values (see “Managing your own data sets” on page 37).

## Using DFSMSshm with the BACKUP SYSTEM utility

If you plan to use the DB2 BACKUP SYSTEM online utility to take volume-level copies of the data and logs of a non-data-sharing DB2 subsystem or a DB2 data sharing group, all of the DB2 data sets must reside on volumes that are managed by DFSMSshm.

The BACKUP SYSTEM utility uses copy pools, which are new constructs in z/OS DFSMSshm Version 1 Release 5. A *copy pool* is a named set of storage groups that can be backed up and restored as a unit; DFSMSshm processes the storage groups collectively for fast replication. Each DB2 subsystem has up to two copy pools, one for databases and one for logs.

Copy pools are also referred to as source storage groups. Each source storage group contains the name of an associated copy-pool backup storage group, which contains eligible volumes for the backups. The storage administrator must define both the source and target storage groups, and use the following DB2 naming convention:

DSN\$locn-name\$cp-type

The variables that are used in this naming convention are described in Table 11:

*Table 11. Naming convention variables*

Variable	Meaning
DSN	The unique DB2 product identifier
\$	A delimiter. You must use the dollar sign (\$) character.
locn-name	The DB2 location name
cp-type	The copy pool type. Use DB for database and LG for log

For detailed instructions on how to create storage groups, see the *z/OS DFSMSdss Storage Administration Reference*.

The DB2 BACKUP SYSTEM and RESTORE SYSTEM utilities invoke DFSMSshm to back up and restore the copy pools. DFSMSshm interacts with DFSMSsms to determine the volumes that belong to a given copy pool so that the volume-level backup and restore functions can be invoked.

For information about the BACKUP SYSTEM and RESTORE SYSTEM utilities, see the *DB2 Utility Guide and Reference*. For information about recovery procedures that use these utilities, see “System-level point-in-time recovery” on page 515.

---

## Managing your own data sets

This section describes how to manage your own data sets by using VSAM Access Method Services and what you should consider:

- “Requirements for your own data sets” on page 38
- “Using the DEFINE CLUSTER command” on page 40
- “Extending user-managed data sets” on page 41

You might choose to manage your own VSAM data sets for reasons such as these:

- You have a large linear table space on several data sets. If you manage your own data sets, you can better control the placement of individual data sets on the volumes (although you can keep a similar type of control by using single-volume DB2 storage groups).
- You want to prevent deleting a data set within a specified time period, by using the TO and FOR options of the Access Method Services DEFINE and ALTER commands. You can create and manage the data set yourself, or you can create the data set with DB2 and use the ALTER command of Access Method Services to change the TO and FOR options.
- You are concerned about recovering dropped table spaces. Your own data set is not automatically deleted when a table space is dropped, making it easier to reclaim the data.

To define the required data sets, use DEFINE CLUSTER; to add secondary volumes to expanding data sets, use ALTER ADDVOLUMES; and to delete data sets, use DELETE CLUSTER.

You must define a data set for each of these items:

- A simple or segmented table space
- A partition of a partitioned table space
- A partition of a partitioned index

Furthermore, as table spaces and index spaces expand, you might need to provide additional data sets. To take advantage of parallel I/O streams when doing certain read-only queries, consider spreading large table spaces over different disk volumes that are attached on separate channel paths.

## Requirements for your own data sets

DB2 checks whether you have defined your data sets correctly. If you plan to define and manage VSAM data sets yourself, you must perform these steps:

1. Define the data sets **before** you issue the CREATE TABLESPACE, the CREATE INDEX statement, or the ALTER TABLE ADD PARTITION statement.

If you create a partitioned table space, you must create a separate data set for each partition, or you must allocate space for each partition by using the PARTITION option of the Numparts clause in the CREATE TABLESPACE statement.

If you create a partitioned secondary index, you must create a separate data set for each partition. Alternatively, for DB2 to manage your data sets, you must allocate space for each partition by using the PARTITIONED option of the CREATE INDEX statement. For information about the performance of partitioned secondary indexes, see “Recommendations for database design” on page 817.

If you create a partitioning index that is partitioned, you must create a separate data set for each partition. Alternatively, for DB2 to manage your data sets, you must allocate space for each partition by using the PARTITIONED option or the PARTITION ENDING AT clause of the CREATE INDEX statement in the case of index-controlled partitioning.

2. Give each data set a name with this format:

```
catname.DSNDBX.dbname.psname.y0001.znnn
```

*catname*

Integrated catalog name or alias (up to eight characters). Use the same name or alias here as in the USING VCAT clause of the CREATE TABLESPACE and CREATE INDEX statements.

*x* C (for VSAM clusters) or D (for VSAM data components).

*dbname*

DB2 database name. If the data set is for a table space, *dbname* must be the name given in the CREATE TABLESPACE statement. If the data set is for an index, *dbname* must be the name of the database containing the base table. If you are using the default database, *dbname* must be DSNDB04.

*psname*

Table space name or index name. This name must be unique within the database.

You use this name on the CREATE TABLESPACE or CREATE INDEX statement. (You can use a name longer than eight characters on the CREATE INDEX statement, but the first eight characters of that name must be the same as in the data set's *psname*.)

*y0001* Instance qualifier for the data set.

Define one data set for the table space or index with a value of I for *y* if one of the following conditions is true:

- You plan to run REORG with SHRLEVEL CHANGE or SHRLEVEL REFERENCE without the FASTSWITCH YES option.
- You *do not* plan to run REORG with SHRLEVEL CHANGE or SHRLEVEL REFERENCE.

Define two data sets if you plan to run REORG, using the FASTSWITCH YES option, with SHRLEVEL CHANGE or SHRLEVEL REFERENCE. Define one data set with a value of I for *y*, and one with a value of J for *y*.

For more information about defining data sets for REORG, see Part 2 of *DB2 Utility Guide and Reference*.

| *znnn*

Data set number. The first digit *z* of the data set number is represented by the letter A, B, C, D, or E, which corresponds to the value 0, 1, 2, 3, or 4 as the first digit of the partition number.

|  
| For partitioned table spaces, if the partition number is less than 1000, the data set number is *Annn* in the data set name (for example, A999 represents partition 999). For partitions 1000 to 1999, the data set number is *Bnnn* (for example, B000 represents partition 1000). For partitions 2000 to 2999, the data set number is *Cnnn*. For partitions 3000 to 3999, the data set number is *Dnnn*. For partitions 4000 up to a maximum of 4096, the data set number is *Ennn*.

| The naming convention for data sets that you define for a partitioned index is the same as the naming convention for other partitioned objects.

| For simple or segmented table spaces, the number is 001 (preceded by A) for the first data set. When little space is available, DB2 issues a warning message. If the size of the data set for a simple or a segmented table space approaches the maximum limit, define another data set with the same name as the first data set and the number 002. The next data set will be 003, and so on.

| You can reach the VSAM extent limit for a data set before you reach the size limit for a partitioned or a nonpartitioned table space. If this happens, DB2 does not extend the data set.

3. Use the DEFINE CLUSTER command to define the size of the primary and secondary extents of the VSAM cluster. If you specify zero for the secondary extent size, data set extension does not occur.
4. Define the data sets as LINEAR. Do not use RECORDSIZE or CONTROLINTERVALSIZE; these attributes are invalid.
5. Use the REUSE option. You must define the data set as REUSE before running the DSN1COPY utility.
6. Use SHAREOPTIONS(3,3).

The DEFINE CLUSTER command has many optional parameters that do not apply when DB2 uses the data set. If you use the parameters SPANNED, EXCEPTIONEXIT, SPEED, BUFFERSPACE, or WRITECHECK, VSAM applies them to your data set, but DB2 ignores them when it accesses the data set.

The value of the OWNER parameter for clusters that are defined for storage groups is the first SYSADM authorization ID specified at installation.

When you drop indexes or table spaces for which you defined the data sets, you must delete the data sets unless you want to reuse them. To reuse a data set, first commit, and then create a new table space or index with the same name. When DB2 uses the new object, it overwrites the old information with new information, which destroys the old data.

Likewise, if you delete data sets, you must drop the corresponding table spaces and indexes; DB2 does not drop these objects automatically.

## Using the DEFINE CLUSTER command

Figure 3 shows an example of the DEFINE CLUSTER command, which defines a VSAM data set for the SYSUSER table space in database DSNDB06. Assume that an integrated catalog facility catalog named DSNCAT is already defined.

---

```

DEFINE CLUSTER -
  (NAME(DSNCAT.DSNDBC.DSNDB06.SYSUSER.I0001.A001) -
  LINEAR -
  REUSE -
  VOLUMES(DSNV01) -
  RECORDS(100 100) -
  SHAREOPTIONS(3 3) ) -
  DATA -
  (NAME(DSNCAT.DSNDBD.DSNDB06.SYSUSER.I0001.A001) -
  CATALOG(DSNCAT)

```

---

*Figure 3. Defining a VSAM data set for the SYSUSER table space*

For user-managed data sets, you must pre-allocate shadow data sets prior to running REORG with SHRLEVEL CHANGE, REORG with SHRLEVEL REFERENCE, or CHECK INDEX with SHRLEVEL CHANGE against the table space. You can specify the MODEL option for the DEFINE CLUSTER command so that the shadow is created like the original data set, as shown in Figure 4 on page 41.

---

```

DEFINE CLUSTER -
  (NAME('DSNCAT.DSNDBC.DSNDB06.SYSUSER.x0001.A001') -
  MODEL('DSNCAT.DSNDBC.DSNDB06.SYSUSER.y0001.A001')) -
DATA -
  (NAME('DSNCAT.DSNDBD.DSNDB06.SYSUSER.x0001.A001') -
  MODEL('DSNCAT.DSNDBD.DSNDB06.SYSUSER.y0001.A001')) -

```

---

Figure 4. Defining shadow data sets

In Figure 4, the instance qualifiers *x* and *y* are distinct and are equal to either **I** or **J**. You must determine the correct instance qualifier to use for a shadow data set by querying the DB2 catalog for the database and table space.

For more information about defining data sets for REORG, see Chapter 2 of *DB2 Utility Guide and Reference*. For more information about defining and managing VSAM data sets, see *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

## Extending user-managed data sets

A user-managed data set is allocated by using only volumes defined for that data set in the ICF catalog. Before the current volume runs out of space, you must issue the Access Method Services commands ALTER ADDVOLUMES or ALTER REMOVEVOLUMES for candidate volumes.

---

## Defining index space storage

Generally, the CREATE INDEX statement creates an index space in the same DB2 database that contains the table on which the index is defined. This is true even if you defer building the index.

### Exceptions:

- If you specify the USING VCAT clause, you create and manage the data sets yourself.
- If you specify the DEFINE NO clause on a CREATE INDEX statement that uses the USING STOGROUP clause, DB2 defers the allocation of the data sets for the index space.

When you use CREATE INDEX, always specify a USING clause. When you specify USING, you declare whether you want DB2-managed or user-managed data sets. For DB2-managed data sets, you specify the primary and secondary space allocation parameters on the CREATE INDEX statement. If you do not specify USING, DB2 assigns the index data sets to the default storage groups using default space attributes. For information about how space allocation can affect the performance of mass inserts, see “Formatting early and speed up formatting” on page 664.

You can specify the USING clause to allocate space for the entire index, or if the index is a partitioned index, you can allocate space for each partition. Information about space allocation for the index is kept in the SYSIBM.SYSINDEXPART table of the DB2 catalog. Other information about the index is in SYSIBM.SYSINDEXES. For more information about determining the space required for an index, see “Calculating the space required for an index” on page 117. For more information about CREATE INDEX clauses, see Chapter 5 of *DB2 SQL Reference*.

---

## Creating EA-enabled table spaces and index spaces

DFSMS has an extended-addressability function, which is necessary to create data sets that are larger than 4 GB. Therefore, the term for page sets that are enabled for extended addressability is *EA-enabled*. You must use EA-enabled table spaces or index spaces if you specify a DSSIZE that is larger than 4 GB in the CREATE TABLESPACE statement.

To create EA-enabled page sets, you must:

1. Use SMS to manage the data sets that are associated with the EA-enabled page sets.
2. Associate the data sets with a *data class* (an SMS construct) that specifies the extended format and extended addressability options.

To make this association between data sets and the data class, use an automatic class selection (ACS) routine to assign the DB2 data sets to the relevant SMS data class. The ACS routine does the assignment based on the data set name. No performance penalty occurs for having non-EA-enabled DB2 page sets assigned to this data class, too, if you would rather not have two separate data classes for DB2.

For user-managed data sets, you can use ACS routines or specify the appropriate data class on the DEFINE CLUSTER command when you create the data set.

3. Create the partitioned or LOB table space with a DSSIZE of 8 GB or greater. The partitioning index for the partitioned table space takes on the EA-enabled attribute from its associated table space. See *DB2 SQL Reference* for more information about the correct syntax.

After a page set is created, you cannot use the ALTER TABLESPACE statement to change the DSSIZE. You must drop and re-create the table space.

Also, you cannot change the data sets of the page set to turn off the extended addressability or extended format attributes. If someone modifies the data class to turn off the extended addressability or extended format attributes, DB2 issues an error message the next time that it opens the page set.

---

## Chapter 4. Implementing your database design

The information in this chapter is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

This chapter provides information about topics related to implementing a database.

Table 12 shows where you can find more information about topics that are related to implementing a database design.

*Table 12. More information about implementing a database design*

- “Using schemas” on page 58

---

### Implementing databases

In DB2 UDB for z/OS, a database is a logical collection of table spaces and index spaces. Consider the following factors when deciding whether to define a new database for a new set of objects:

- You can start and stop an entire database as a unit; you can display the statuses of all its objects by using a single command that names only the database. Therefore, place a set of tables that are used together into the same database. (The same database holds all indexes on those tables.)
- Some operations lock an entire database. For example, some phases of the LOAD utility prevent some SQL statements (CREATE, ALTER, and DROP) from using the same database concurrently. Therefore, placing many unrelated tables in a single database is often inconvenient.

When one user is executing a CREATE, ALTER, or DROP statement for a table, no other user can access the database that contains that table. QMF™ users, especially, might do a great deal of data definition; the QMF operations SAVE DATA and ERASE *data-object* are accomplished by creating and dropping DB2 tables. For maximum concurrency, create a separate database for each QMF user.

- The internal database descriptors (DBDs) might become inconveniently large; Part 2 of *DB2 Installation Guide* contains some calculations showing how the size depends on the number of columns in a table. DBDs grow as new objects are defined, but they do not immediately shrink when objects are dropped—the DBD space for a dropped object is not reclaimed until the MODIFY RECOVERY utility is used to delete records of obsolete copies from SYSIBM.SYSCOPY. DBDs occupy storage and are the objects of occasional input and output operations. Therefore, limiting the size of DBDs is another reason to define new databases. The MODIFY utility is described in Part 2 of *DB2 Utility Guide and Reference*.

If you use declared temporary tables, you must define a database that is defined AS TEMP (the TEMP database). DB2 stores all declared temporary tables in the TEMP database. The majority of the factors described in this section do not apply to the TEMP database. For details about declared temporary tables, see “Distinctions between DB2 base tables and temporary tables” on page 48.

---

## Implementing table spaces

Table spaces are the physical spaces that hold tables. A table space can have one or more tables. Simple and segmented table spaces hold a maximum of 64 GB of data and might use one or more VSAM data sets. Partitioned table spaces that are created with the DSSIZE or LARGE option, and LOB table spaces can be larger. When you create a partitioned table space, DB2 puts the last partition of the table space into a REORG-pending (REORP) state.

Table spaces are divided into units called pages that are 4 KB, 8 KB, 16 KB, or 32 KB in size. As a general rule, you should have no more than 50 to 100 table spaces in one DB2 database. Following this guideline helps to minimize maintenance, increase concurrency, and decrease log volume. If you are using declared temporary tables, you must create at least one table space in your TEMP database with pages that are 8 KB in size.

You need to create additional table spaces if your database contains LOB data. For more information about creating table spaces for LOB data, see Chapter 5 of *DB2 SQL Reference*.

Data in most table spaces can be compressed, which can allow you to store more data on each data page. For more information, see “Compressing your data” on page 708.

### Creating a table space explicitly

Use the CREATE TABLESPACE statement to create a table space explicitly. The statement allows you to specify the attributes of the table space.

Generally, when you use the CREATE TABLESPACE statement with the USING STOGROUP clause, DB2 allocates data sets for the table space. However, if you also specify the DEFINE NO clause, you can defer the allocation of data sets until data is inserted or loaded into a table in the table space. For more information about deferring data set allocation, see “Deferring allocation of DB2-managed data sets” on page 30.

You can create simple, segmented, partitioned, and LOB table spaces. For detailed information about CREATE TABLESPACE, see Chapter 5 of *DB2 SQL Reference*.

## Creating a table space implicitly

As with DB2 storage groups and databases, you do not need to create a table space before you create a table unless you are defining a declared temporary table or managing all your own data sets. When you use CREATE TABLE, DB2 generates a table space for you. However, DB2 generates a table space only if you use CREATE TABLE without specifying an existing table space name. If the table contains a LOB column and SQLRULES are STD, DB2 also creates the LOB table space, the auxiliary table, and auxiliary index. If you do not specify a database name in the CREATE TABLE statement, DB2 uses the default database, DSNDB04, and the default DB2 storage group, SYSDEFLT.

If you create a table space implicitly, DB2 uses defaults for the space allocation attributes. The default values of PRIQTY and SECQTY specify the space allocation for the table space. If the value of the TSQTY subsystem parameter is nonzero, it determines the default values for PRIQTY and SECQTY. If the value of TSQTY is zero, the default values for PRIQTY and SECQTY are determined as described in the CREATE TABLESPACE statement in Chapter 5 of *DB2 SQL Reference*.

When you do not specify a table space name in a CREATE TABLE statement (and the table space is created implicitly), DB2 derives the table space name from the name of your table according to these rules:

- The table space name is the same as the table name if these conditions apply:
  - No other table space or index space in the database already has that name.
  - The table name has no more than eight characters.
  - The characters are all alphanumeric, and the first character is not a digit.
- If some other table space in the database already has the same name as the table, DB2 assigns a name of the form *xxxxnyyy*, where *xxxx* is the first four characters of the table name, and *nyyy* is a single digit and three letters that guarantees uniqueness.

DB2 stores this name in the DB2 catalog in the SYSIBM.SYSTABLESPACE table along with all your other table space names. The rules for LOB table spaces are explained in Chapter 5 of *DB2 SQL Reference*.

## Choosing a page size

DB2 provides many options for data page sizes. The size of the data page is determined by the buffer pool in which you define the table space. For example, a table space that is defined in a 4-KB buffer pool has 4-KB page sizes, and one that is defined in an 8-KB buffer pool has 8-KB page sizes. (Indexes must be defined in a 4-KB buffer pool.)

Data in table spaces is stored and allocated in 4-KB record segments. Thus, an 8-KB page size means two 4-KB records, and a 32-KB page size means eight 4-KB records. A good starting point is to use the default of 4-KB page sizes when access to the data is random and only a few rows per page are needed. If row sizes are very small, using the 4-KB page size is recommended.

However, there are situations in which larger page sizes are needed or recommended:

- **When the size of individual rows is greater than 4 KB.** In this case, you must use a larger page size. When considering the size of work file table spaces,

remember that some SQL operations, such as joins, can create a result row that does not fit in a 4-KB page. Therefore, having at least one work file that has 32-KB pages is recommended. (Work files cannot use 8-KB or 16-KB pages.)

- **When you can achieve higher density on disk by choosing a larger page size.** For example, only one 2100-byte record can be stored in a 4-KB page, which wastes almost half of the space. However, storing the record in a 32-KB page can significantly reduce this waste. The downside with this approach is the potential of incurring higher buffer pool storage costs or higher I/O costs—if you only touch a small number of rows, you are bringing a bigger chunk of data from disk into the buffer pool.

Using 8-KB or 16-KB page sizes can let you store more data on your disk with less impact on I/O and buffer pool storage costs. If you use a larger page size and access is random, you might need to go back and increase the size of the buffer pool to achieve the same read-hit ratio you do with the smaller page size.

- **When a larger page size can reduce data sharing overhead.** One way to reduce the cost of data sharing is to reduce the number of times the coupling facility must be accessed. Particularly for sequential processing, larger page sizes can reduce this number. More data can be returned on each access of the coupling facility, and fewer locks must be taken on the larger page size, further reducing coupling facility interactions.

If data is returned from the coupling facility, each access that returns more data is more costly than those that return smaller amounts of data, but, because the total number of accesses is reduced, coupling facility overhead is reduced.

For random processing, using an 8-KB or 16-KB page size instead of a 32-KB page size might improve the read-hit ratio to the buffer pool and reduce I/O resource consumption.

| The maximum number of partitions for a table space depends on the page size and  
| on the DSSIZE. The size of the table space depends on how many partitions are in  
| the table space and on the DSSIZE. For specific information about the maximum  
| number of partitions and the total size of the table space, given the page size and  
| the DSSIZE, see the CREATE TABLESPACE statement in Chapter 5 of *DB2 SQL  
| Reference*.

## Choosing a page size for LOBs

Choosing a page size for LOBs (in the LOB table space) is a tradeoff between minimizing the number of getpages (maximizing performance) and not wasting space. With LOB table spaces, no more than one LOB value is ever stored in a given page in a LOB table space. Space that is not used by the LOB value in the last page that is occupied by the LOB remains unused. DB2 also uses additional space for control information. The smaller the LOB, the greater the proportion of space for this “non-data” is used.

For example, if you have a 17-KB LOB, the 4-KB page size is the most efficient for storage. A 17-KB LOB requires five 4-KB pages for a total of 20 KB of storage space. Pages that are 8 KB, 16 KB, and 32 KB in size waste more space, because they require 24 KB, 32 KB, and 32 KB, respectively, for the LOB.

Table 13 on page 47 shows that the number of data pages is lower for larger page sizes, but larger page sizes might have more unused space.

Table 13. Relationship between LOB size and data pages based on page size

LOB size	Page size	LOB data pages	% Non-LOB data or unused space
262 144 bytes	4 KB	64	1.6
	8 KB	32	3.0
	16 KB	16	5.6
	32 KB	8	11.1
4 MB	4 KB	1029	0.78
	8 KB	513	0.39
	16 KB	256	0.39
	32 KB	128	0.78
33 MB	4 KB	8234	0.76
	8 KB	4106	0.39
	16 KB	2050	0.19
	32 KB	1024	0.10

**Choosing a page size based on average LOB size:** If you know that all of your LOBs are not the same size, you can still make an estimate of what page size to choose. To estimate the average size of a LOB, you need to add a percentage to account for unused space and control information. To estimate the average size of a LOB value, use the following formula:

$$\text{LOB size} = (\text{average LOB length}) \times 1.05$$

Table 14 contains some suggested page sizes for LOBs with the intent to reduce the amount of I/O (getpages).

Table 14. Suggested page sizes based on average LOB length

Average LOB size (n)	Suggested page size
$n \leq 4 \text{ KB}$	4 KB
$4 \text{ KB} < n \leq 8 \text{ KB}$	8 KB
$8 \text{ KB} < n \leq 16 \text{ KB}$	16 KB
$16 \text{ KB} < n$	32 KB

The estimates in Table 14 mean that a LOB value of 17 KB can mean 15 KB of unused space. Again, you must analyze your data to determine what is best.

**General guidelines for LOBs of same size:** If your LOBs are all the same size, you can fairly easily choose a page size that uses space efficiently without sacrificing performance. For LOBs that are all the same size, consider the alternative in Table 15 to maximize your space savings.

Table 15. Suggested page sizes when LOBs are the same size

LOB size (y)	Suggested page size
$y \leq 4 \text{ KB}$	4 KB
$4 \text{ KB} < y \leq 8 \text{ KB}$	8 KB
$8 \text{ KB} < y \leq 12 \text{ KB}$	4 KB
$12 \text{ KB} < y \leq 16 \text{ KB}$	16 KB

Table 15. Suggested page sizes when LOBs are the same size (continued)

LOB size (y)	Suggested page size
16 KB < y ≤ 24 KB	8 KB
24 KB < y ≤ 32 KB	32 KB
32 KB < y ≤ 48 KB	16 KB
48 KB < y	32 KB

---

## Implementing tables

This section discusses the following topics:

- “Distinctions between DB2 base tables and temporary tables”
- “Implementing table-controlled partitioning” on page 51

### Distinctions between DB2 base tables and temporary tables

Table 16 on page 49 summarizes important distinctions between base tables and the two types of temporary tables. Additional examples of implementing temporary tables and information about restrictions and extensions of temporary tables can be found in Part 1 of *DB2 Application Programming and SQL Guide* and in Chapter 5 of *DB2 SQL Reference*. For information about temporary tables and their impact on DB2 resources, see “Work file data sets” on page 699.

Table 16. Important distinctions between DB2 base tables and DB2 temporary tables (continued)

Area of distinction	Base tables	Created temporary tables	Declared temporary tables
References to the table in application processes	<p>References to the table name in multiple application processes refer to the same single persistent table description and same instance at the current server.</p> <p>If the table name being referenced is not qualified, DB2 implicitly qualifies the name using the standard DB2 qualification rules applied to the SQL statements. The name can be a two-part or three-part name.</p>	<p>References to the table name in multiple application processes refer to the same single persistent table description but to a distinct instance of the table for each application process at the current server.</p> <p>If the table name being referenced is not qualified, DB2 implicitly qualifies the name using the standard DB2 qualification rules applied to the SQL statements. The name can be a two-part or three-part name.</p>	<p>References to that table name in multiple application processes refer to a distinct description and instance of the table for each application process at the current server.</p> <p>References to the table name in an SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) must include SESSION as the qualifier (the first part in a two-part table name or the second part in a three-part name). If the table name is not qualified with SESSION, DB2 assumes the reference is to a base table.</p>
Table privileges and authorization	<p>The owner implicitly has all table privileges on the table and the authority to drop the table. The owner's table privileges can be granted and revoked, either individually or with the ALL clause.</p> <p>Another authorization ID can access the table only if it has been granted appropriate privileges for the table.</p>	<p>The owner implicitly has all table privileges on the table and the authority to drop the table. The owner's table privileges can be granted and revoked, but only with the ALL clause; individual table privileges cannot be granted or revoked.</p> <p>Another authorization ID can access the table only if it has been granted ALL privileges for the table.</p>	<p>PUBLIC implicitly has all table privileges on the table without GRANT authority and has the authority to drop the table. These table privileges cannot be granted or revoked.</p> <p>Any authorization ID can access the table without a grant of any privileges for the table.</p>
Indexes and other SQL statement support	<p>Indexes and SQL statements that modify data (INSERT, UPDATE, DELETE, and so on) are supported.</p>	<p>Indexes, UPDATE (searched or positioned), and DELETE (positioned only) are not supported.</p>	<p>Indexes and SQL statements that modify data (INSERT, UPDATE, DELETE, and so on) are supported</p>
Locking, logging, and recovery	<p>Locking, logging, and recovery do apply.</p>	<p>Locking, logging, and recovery do not apply. Work files are used as the space for the table.</p>	<p>Some locking, logging, and limited recovery do apply. No row or table locks are acquired. Share-level locks on the table space and DBD are acquired. A segmented table lock is acquired when all the rows are deleted from the table or the table is dropped. Undo recovery (rolling back changes to a savepoint or the most recent commit point) is supported, but redo recovery (forward log recovery) is not supported.</p>

Table 16. Important distinctions between DB2 base tables and DB2 temporary tables (continued)

Area of distinction	Base tables	Created temporary tables	Declared temporary tables
Table space and database operations	Table space and database operations do apply.	Table space and database operations do not apply.	Table space and database operations do apply.
Table space requirements and table size limitations	<p>The table can be stored in simple table spaces in default database DSNDB04 or user-defined table spaces (simple, segmented, or partitioned) in user-defined databases.</p> <p>The table cannot span table spaces. Therefore, the size of the table is limited by the table space size (as determined by the primary and secondary space allocation values specified for the table space's data sets) and the shared usage of the table space among multiple users. When the table space is full, an error occurs for the SQL operation.</p>	<p>The table is stored in table spaces in the work file database.</p> <p>The table can span work file table spaces. Therefore, the size of the table is limited by the number of available work file table spaces, the size of each table space, and the number of data set extents that are allowed for the table spaces. Unlike the other types of tables, created temporary tables do not reach size limitations as easily.</p>	<p>The table is stored in segmented table spaces in the TEMP database (a database that is defined AS TEMP).</p> <p>The table cannot span table spaces. Therefore, the size of the table is limited by the table space size (as determined by the primary and secondary space allocation values specified for the table space's data sets) and the shared usage of the table space among multiple users. When the table space is full, an error occurs for the SQL operation.</p>

## Implementing table-controlled partitioning

Before DB2 Version 8, when you defined a partitioning index on a table in a partitioned table space, you specified the partitioning key and the limit key values in the PART VALUES clause of the CREATE INDEX statement. This type of partitioning is called *index-controlled partitioning*.

In DB2 Version 8, the partitioning index is no longer required. You can now specify the partitioning key and the limit key values for a table in a partitioned table space by using the PARTITION BY clause and the PARTITION ENDING AT clause of the CREATE TABLE statement. This type of partitioning is called *table-controlled partitioning*.

**Example:** Assume that you need to create a large transaction table that includes the date of the transaction in a column named POSTED. You want the transactions for each month in a separate partition. To create the table, issue the following statement:

```
CREATE TABLE TRANS
  (ACCTID ...,
   STATE ...,
   POSTED ...,
   ... , ...)
PARTITION BY (POSTED)
(PARTITION 1 ENDING AT ('01/31/2003'),
 PARTITION 2 ENDING AT ('02/28/2003'),
 ...
 PARTITION 13 ENDING AT ('01/31/2004'));
```

**Restriction:** If you use table-controlled partitioning, you cannot specify the partitioning key and the limit key values by using the PART VALUES clause of the

CREATE INDEX statement. (Note that in Version 8, the preferred syntax changed from PART VALUES to PARTITION ENDING AT.)

**Recommendation:** Use table-controlled partitioning instead of index-controlled partitioning. Table-controlled partitioning is a replacement for index-controlled partitioning. Table 17 lists the differences between the two partitioning methods.

*Table 17. Differences between table-controlled and index-controlled partitioning*

<b>Table-controlled partitioning</b>	<b>Index-controlled partitioning</b>
A partitioning index is not required; clustering index is not required.	A partitioning index is required; clustering index is required.
Multiple partitioned indexes can be created in a table space.	Only one partitioned index can be created in a table space.
A table space partition is identified by both a physical partition number and a logical partition number.	A table space partition is identified by a physical partition number.
The high-limit key is always enforced.	The high-limit key is not enforced if the table space is non-large.

See “Moving from index-controlled to table-controlled partitioning” on page 97 for detailed information about converting to table-controlled partitioning.

### **Automatic conversion**

DB2 automatically converts an index-controlled partitioned table space to a table-controlled partitioned table space if you perform any of the following operations:

- Use CREATE INDEX with the PARTITIONED clause to create a partitioned index on an index-controlled partitioned table space.
- Use CREATE INDEX with a PART VALUES clause and without a CLUSTER clause to create a partitioning index.  
DB2 stores the specified high limit key value instead of the default high limit key value.
- Use ALTER INDEX with the NOT CLUSTER clause on a partitioning index that is on an index-controlled partitioned table space.
- Use DROP INDEX to drop a partitioning index on an index-controlled partitioned table space.
- Use ALTER TABLE to add a new partition, change a partition boundary, or rotate a partition from first to last on an index-controlled partitioned table space.  
In these cases, DB2 automatically converts to table-controlled partitioning but does not automatically drop any indexes. DB2 assumes that any existing indexes are useful.

After the conversion to table-controlled partitioning, DB2 changes the existing high-limit key value for non-large table spaces to the highest value for the key. Beginning in Version 8, DB2 enforces the high-limit key value. By default, DB2 does not put the last partition of the table space into a REORG-pending (REORP) state. Exceptions to this rule are:

- When adding a new partition, DB2 stores the original high-limit key value instead of the default high-limit key value. If this value was not previously enforced, DB2 puts the last partition into a REORP state.

- When rotating a new partition, DB2 stores the original high-limit key value instead of the default high-limit key value. DB2 puts the last partition into a REORP state.

After the conversion to table-controlled partitioning, the SQL statements that you used to create the tables and indexes are no longer valid. For example, after dropping a partitioning index on an index-controlled partitioned table space, an attempt to recreate the index by issuing the same CREATE INDEX statement that you originally used would fail because the boundary partitions are now under the control of the table.

## Using nullable partitioning columns

DB2 lets you use nullable columns as partitioning columns. The use of nullable columns has different implications for table-controlled partitioning than for index-controlled partitioning.

With table-controlled partitioning, DB2 can restrict the insertion of null values into a table with nullable partitioning columns, depending on the order of the partitioning key:

- If the partitioning key is ascending and the highest value of the key column is not MAXVALUE, DB2 prevents the INSERT of a row with a null value for the key column. If the highest value of the key column is MAXVALUE, the row is inserted into the last partition.
- If the partitioning key is descending, DB2 allows the INSERT of a row with a null value for the key column. The row is inserted into the first partition.

**Example:** Assume that a partitioned table space is created with the following SQL statements:

```
CREATE TABLESPACE TS IN DB
  USING STOGROUP SG
  Numparts 4 BUFFERPOOL BP0;

CREATE TABLE TB (C01 CHAR(5),
  C02 CHAR(5) NOT NULL,
  C03 CHAR(5) NOT NULL)
  IN DB.TS
  PARTITION BY (C01)
  PARTITION 1 ENDING AT ('10000'),
  PARTITION 2 ENDING AT ('20000'),
  PARTITION 3 ENDING AT ('30000'),
  PARTITION 4 ENDING AT ('40000'));
```

Because the CREATE TABLE statement does not specify the order in which to put entries, DB2 puts them in ascending order by default. DB2 subsequently prevents any INSERT into the TB table of a row with a null value for partitioning column C01. If the CREATE TABLE statement had specified the key as descending, DB2 would subsequently have allowed an INSERT into the TB table of a row with a null value for partitioning column C01. DB2 would have inserted the row into partition 1.

With index-controlled partitioning, DB2 does not restrict the insertion of null values into a value with nullable partitioning columns.

**Example:** Assume that a partitioned table space is created with the following SQL statements:

```
CREATE TABLESPACE TS IN DB
  USING STOGROUP SG
  Numparts 4 BUFFERPOOL BP0;
```

```

CREATE TABLE TB (C01 CHAR(5),
                  C02 CHAR(5) NOT NULL,
                  C03 CHAR(5) NOT NULL)
IN DB.TS;

CREATE INDEX PI ON TB(C01) CLUSTER
(PARTITION 1 ENDING AT ('10000'),
 PARTITION 2 ENDING AT ('20000'),
 PARTITION 3 ENDING AT ('30000'),
 PARTITION 4 ENDING AT ('40000'));

```

Regardless of the entry order, DB2 allows an INSERT into the TB table of a row with a null value for partitioning column C01. If the entry order is ascending, DB2 inserts the row into partition 4; if the entry order is descending, DB2 inserts the row into partition 1. Only if the table space is created with the LARGE keyword does DB2 prevent the insertion of a null value into the C01 column.

---

## Implementing indexes

DB2 uses indexes not only to enforce uniqueness on column values, as for parent keys, but also to cluster data, to partition tables, to provide access paths to data for queries, and to order retrieved data without a sort.

This section discusses the following topics:

- “Types of indexes”
- “Using the NOT PADDED clause for indexes with varying-length columns” on page 57
- “Using indexes to avoid sorts” on page 58

### Types of indexes

This section describes the various types of indexes and summarizes what you should consider when creating a particular type:

- “Unique indexes”
- “Clustering indexes” on page 55
- “Partitioning indexes” on page 55
- “Secondary indexes” on page 56

This section uses a transaction table named TRANS to illustrate the various types of indexes. Assume that the table has many columns, but you are interested in only the following columns:

- ACCTID, which is the customer account ID
- STATE, which is the state of the customer location
- POSTED, which holds the date of the transaction

#### Unique indexes

When you define a *unique index* on a DB2 table, you ensure that no duplicate values of the index key exist in the table. For example, creating a unique index on the ACCTID column ensures that no duplicate values of the customer account ID are in the TRANS table:

```

CREATE UNIQUE INDEX IX1
ON TRANS (ACCTID);

```

If an index key allows nulls for some of its column values, you can use the WHERE NOT NULL clause to ensure that the nonnull values of the index key are unique.

Unique indexes are an important part of implementing referential constraints among the tables in your DB2 database. You cannot define a foreign key unless the corresponding primary key already exists and has a unique index defined on it. For more information, see “Altering a table for referential integrity” on page 77 and *The Official Introduction to DB2 UDB for z/OS*.

### Clustering indexes

When you define a *clustering index* on a DB2 table, you direct DB2 to insert rows into the table in the order of the clustering key values. The first index that you define on the table serves implicitly as the clustering index unless you explicitly specify CLUSTER when you create or alter another index. For example, if you first define a unique index on the ACCTID column of the TRANS table, DB2 inserts rows into the TRANS table in the order of the customer account number unless you explicitly define another index to be the clustering index.

You can specify CLUSTER for any index, whether or not it is a partitioning index. For example, suppose that you want the rows of the TRANS table to be ordered by the POSTED column. Issue the statement:

```
CREATE INDEX IX2
  ON TRANS (POSTED)
  CLUSTER;
```

For more information, see “Altering the clustering index” on page 93 and *The Official Introduction to DB2 UDB for z/OS*.

### Partitioning indexes

Before DB2 Version 8, when you defined a partitioning index on a table in a partitioned table space, you specified the partitioning key and the limit key values in the PART VALUES clause of the CREATE INDEX statement. This type of partitioning is referred to as index-controlled partitioning.

Beginning with DB2 Version 8, you can define table-controlled partitioning with the CREATE TABLE statement (which is described in “Implementing table-controlled partitioning” on page 51). A *partitioning index* is then defined to be an index where the leftmost columns are the partitioning columns of the table; the index can, but need not, be partitioned. If it is partitioned, a partitioning index is partitioned in the same way as the underlying data in the table.

For example, assume that the partitioning scheme for the TRANS table is defined by the CREATE TABLE statement in “Implementing table-controlled partitioning” on page 51. The rows in the table are partitioned by the transaction date in the POSTED column. The following statement defines an index where the column of the index is the same as the partitioning column of the table:

```
CREATE INDEX IX3
  ON TRANS (POSTED);
```

When you create a partitioning index, DB2 puts the last partition of the table space into a REORG-pending (REORP) state.

A partitioning index is optional; table-controlled partitioning is a replacement for index-controlled partitioning. For more information, see “Moving from index-controlled to table-controlled partitioning” on page 97.

## Secondary indexes

A *secondary index* is any index that is not a partitioning index. You can create an index on a table to enforce a uniqueness constraint, to cluster data, or most typically to provide access paths to data for queries.

The usefulness of an index depends on the columns in its key and on the cardinality of the key. Columns that you use frequently in performing selection, join, grouping, and ordering operations are good candidates for keys. In addition, the number of distinct values in an index key for a large table must be sufficient for DB2 to use the index for data retrieval; otherwise, DB2 could choose to perform a table space scan.

A secondary index can be partitioned or not. This section discusses the two types of secondary indexes:

- “Nonpartitioned secondary index (NPSI)”
- “Data-partitioned secondary index (DPSI)”

**Nonpartitioned secondary index (NPSI):** A *nonpartitioned secondary index* is any index that is not defined as a partitioning index or a partitioned index. You can create a nonpartitioned secondary index on a table that resides in a partitioned table space or a nonpartitioned table space. For example, assume that the transaction date in the POSTED column is the partitioning key of the TRANS table and that the rows are ordered by the transaction date. To create an index on the STATE column, issue the following statement:

```
CREATE INDEX IX4 ON TRANS(STATE);
```

DB2 can use this index to access data with a particular value for STATE. However, if the query includes a predicate that references only a single partition of the table, the keys for that partition are scattered throughout the index. A better solution to accessing single partitions is data-partitioned secondary indexes (DPSIs).

**Data-partitioned secondary index (DPSI):** A *data-partitioned secondary index* is any index that is not defined as a partitioning index but is defined as a partitioned index. You can create a partitioned secondary index only on a table that resides in a partitioned table space. The partitioning scheme is the same as that of the data in the underlying table. That is, the index entries that reference data in physical partition 1 of a table reside in physical partition 1 of the index, and so on.

DB2 puts a data-partitioned secondary index into a REBUILD-pending (RBDP) state if you create the index after performing any of the following actions:

- Create a partitioned table space
- Create a partitioning index
- Insert a row into a table

In this situation, the last partition of the table space is set to REORG-pending (REORP) restrictive status.

**Advantages and disadvantages of DPSIs:** The use of data-partitioned secondary indexes promotes partition independence and therefore provides the following performance advantages, among others:

- Eliminates contention between parallel LOAD PART jobs that target different partitions of a table space
- Facilitates partition-level operations such as adding a new partition or rotating the first partition to be the last partition
- Improves the recovery time of secondary indexes on partitioned table spaces

However, the use of data-partitioned secondary indexes does not always improve the performance of queries. For example, for queries with predicates that reference only the columns in the key of the DPSI, DB2 must probe each partition of the index for values that satisfy the predicate.

**Example:** Assume that the transaction date in the POSTED column is the partitioning key of the table and that the rows are ordered by the transaction date. You want an index on the STATE column that is partitioned the same as the data in the table. Issue the following statement:

```
CREATE INDEX IX5 ON TRANS(STATE)
PARTITIONED;
```

DB2 can use this index to access data with a particular value for STATE within partitions that are specified in a predicate of a query.

**Example:** Assume that the transaction date in the POSTED column is the partitioning key of the table. You want a clustering index on the ACCTID column that is partitioned the same as the data in the table. Issue the following statement:

```
CREATE INDEX IX6 ON TRANS(ACCTID)
PARTITIONED CLUSTER;
```

DB2 orders the rows of the table by the values of the columns in the clustering key and partitions the rows by the values of the limit key that is defined for the underlying table. The data rows are clustered within each partition by the key of the clustering index instead of by the partitioning key.

## Using the NOT PADDED clause for indexes with varying-length columns

If you specify the NOT PADDED clause on a CREATE INDEX statement, any varying-length columns in the index key are not padded to their maximum length. If an existing index key includes varying-length columns, you can consider altering the index to use the NOT PADDED clause (see “Altering how varying-length index columns are stored” on page 93).

Using the NOT PADDED clause has several advantages:

- DB2 can use index-only access for the varying-length columns within the index key, which enhances performance.
- DB2 stores only actual data, which reduces the storage requirements for the index key.

However, using the NOT PADDED clause might also have several disadvantages:

- Index key comparisons are slower because DB2 must compare each pair of corresponding varying-length columns individually instead of comparing the entire key when the columns are padded to their maximum length.
- DB2 stores an additional 2-byte length field for each varying-length column. Therefore, if the length of the padding (to the maximum length) is less than or equal to 2 bytes, the storage requirements could actually be greater for varying-length columns that are not padded.

**Recommendation:** Use the NOT PADDED clause to implement index-only access if your application typically accesses varying-length columns.

**Tip:** Use the PAD INDEXES BY DEFAULT option on installation panel DSNTIPE to control whether varying length columns are padded by default.

## Using indexes to avoid sorts

DB2 can use indexes to avoid sorts when processing queries with the ORDER BY clause. When a query contains an ORDER BY clause, DB2 looks for indexes that satisfy the order in the query. For DB2 to be able to use an index to access ordered data, you must define an index on the same columns as specified in the ORDER BY clause. For DB2 to use a forward index scan, the ordering must be exactly the same as in the ORDER BY clause. For DB2 to use a backward index scan, the ordering must be exactly the opposite of what is requested in the ORDER BY clause.

**Example:** For example, if you define an index by specifying DATE DESC, TIME ASC as the column names and order, DB2 can use this same index for both of the following ORDER BY clauses:

- Forward scan for ORDER BY DATE DESC, TIME ASC
- Backward scan for ORDER BY DATE ASC, TIME DESC

You do not need to create two indexes for the two ORDER BY clauses. DB2 can use the same index for both forward index scan and backward index scan.

**Optimization:** Suppose that the query includes a WHERE clause with a predicate of the form COL=*constant*. For example:

```
...  
WHERE CODE = 'A'  
ORDER BY CODE, DATE DESC, TIME ASC
```

DB2 can use any of the following index keys to satisfy the ordering:

- CODE, DATE DESC, TIME ASC
- CODE, DATE ASC, TIME DESC
- DATE DESC, TIME ASC
- DATE ASC, TIME DESC

DB2 can ignore the CODE column in the ORDER BY clause and the index because the value of the CODE column in the result table of the query has no effect on the order of the data. If the CODE column is included, it can be in any position in the ORDER BY clause and in the index.

---

## Using schemas

A *schema* is a collection of named objects. The objects that a schema can contain include tables, indexes, table spaces, distinct types, functions, stored procedures, and triggers. An object is assigned to a schema when it is created.

When a table, index, table space, distinct type, function, stored procedure, or trigger is created, it is given a qualified two-part name. The first part is the schema name (or the qualifier), which is either implicitly or explicitly specified. The default schema is the authorization ID of the owner of the plan or package. The second part is the name of the object.

## Creating a schema

You can create a schema with the schema processor by using the CREATE SCHEMA statement. CREATE SCHEMA cannot be embedded in a host program or executed interactively. To process the CREATE SCHEMA statement, you must use the schema processor, as described in “Processing schema definitions” on page 59. The ability to process schema definitions is provided for conformance to ISO/ANSI standards. The result of processing a schema definition is identical to the result of executing the SQL statements without a schema definition.

Outside of the schema processor, the order of statements is important. They must be arranged so that all referenced objects have been previously created. This restriction is relaxed when the statements are processed by the schema processor if the object table is created within the same CREATE SCHEMA. The requirement that all referenced objects have been previously created is not checked until all of the statements have been processed. For example, within the context of the schema processor, you can define a constraint that references a table that does not exist yet or GRANT an authorization on a table that does not exist yet.

Figure 5 is an example of schema processor input that includes the definition of a schema.

```
CREATE SCHEMA AUTHORIZATION SMITH

CREATE TABLE TESTSTUFF
  (TESTNO  CHAR(4),
   RESULT  CHAR(4),
   TESTTYPE CHAR(3))

CREATE TABLE STAFF
  (EMPNUM  CHAR(3) NOT NULL,
   EMPNAME CHAR(20),
   GRADE   DECIMAL(4),
   CITY    CHAR(15))

CREATE VIEW STAFFV1
  AS SELECT * FROM STAFF
     WHERE GRADE >= 12

GRANT INSERT ON TESTSTUFF TO PUBLIC

GRANT ALL PRIVILEGES ON STAFF
  TO PUBLIC
```

*Figure 5. Example of schema processor input*

## Authorization to process schema definitions

The schema processor sets the current SQLID to the value of the schema authorization ID before executing any of the statements in the schema definition. Therefore, that ID must have SYSADM or SYSCTRL authority, or it must be the primary or one of the secondary authorization IDs of the process that executes the schema processor. The same ID must have all the privileges that are needed to execute all the statements in the schema definition.

## Processing schema definitions

Run the schema processor (DSNHSP) as a batch job; use the sample JCL provided in member DSNTEJ1S of the SDSNSAMP library. The schema processor accepts only one schema definition in a single job. No statements that are outside the schema definition are accepted. Only SQL comments can precede the CREATE SCHEMA statement; the end of input ends the schema definition. SQL comments can also be used within and between SQL statements.

The processor takes the SQL from CREATE SCHEMA (the SYSIN data set), dynamically executes it, and prints the results in the SYSPRINT data set.

If a statement in the schema definition has an error, the schema processor processes the remaining statements but rolls back all the work at the end. In this case, you need to fix the statement in error and resubmit the entire schema definition.

---

## Chapter 5. Loading data into DB2 tables

This chapter provides an overview of how to load data into DB2 tables:

- “Loading tables with the LOAD utility”
- “Making corrections after LOAD” on page 63
- “Loading data using the SQL INSERT statement” on page 63
- “Loading data from DL/I” on page 65

You can use several methods to fill DB2 tables, but you will probably load most of your tables by using the LOAD utility. This utility loads data into DB2 persistent tables from sequential data sets by using BSAM. You can also use a cursor that is declared with an EXEC SQL utility control statement to load data from another SQL table with the DB2 UDB family cross-loader function. The LOAD utility cannot be used to load data into DB2 temporary tables or system-maintained materialized query tables. For information about the DB2 UDB family cross-loader function, see Chapter 15, Load of the *DB2 Utility Guide and Reference*.

When loading tables with indexes, referential constraints, or table check constraints, LOAD can perform several checks on the validity of data. If errors are found, the table space that is being loaded, its index spaces, and even other table spaces might be left in a restricted status. LOAD does not check the validity of informational referential constraints. Plan to make necessary corrections and remove restrictions after any LOAD job. For instructions, see “Making corrections after LOAD” on page 63.

You can also use an SQL INSERT statement to copy all or selected rows of another table, either by using the INSERT statement in an application program or interactively through SPUFI.

To reformat data from IMS DL/I databases and VSAM and SAM loading for the LOAD utility, use DB2 DataPropagator. See “Loading data from DL/I” on page 65.

For general guidance about running DB2 utility jobs, see *DB2 Utility Guide and Reference*. For information about DB2 DataPropagator, see *DB2 Universal Database Replication Guide and Reference*.

---

### Loading tables with the LOAD utility

Use LOAD to load one or more persistent tables of a table space, or one or more partitions of a table space. LOAD operates on a table space, so you must have authority for all tables in the table space when you run LOAD.

The LOAD utility loads records into the tables and builds or extends any indexes defined on them. If the table space already contains data, you can choose whether you want to add the new data to the existing data or replace the existing data.

Additionally, LOAD can be used to:

- Compress data and build a compression dictionary
- Convert data between compatible data types and between encoding schemes
- Load multiple tables in a single table space

| *Using delimited input and output files:* The LOAD and UNLOAD utilities can  
| accept or produce a delimited file, which is a sequential BSAM file with row  
| delimiters and column delimiters. You can unload data from other systems into  
| one or more files that use a delimited file format and then use these delimited files  
| as input for the LOAD utility. You can also unload DB2 data into delimited files by  
| using the UNLOAD utility and then use these files as input into another DB2  
| database.

*Using the INCURSOR option:* The INCURSOR option of the LOAD utility specifies a cursor for the input data set. Use the EXEC SQL utility control statement to declare the cursor before running the LOAD utility. You define the cursor so that it selects data from another DB2 table. The column names in the SELECT statement must be identical to the column names of the table that is being loaded. The INCURSOR option uses the DB2 UDB family cross-loader function.

*Using the CCSID option:* You can load input data into ASCII, EBCDIC, or Unicode tables. The ASCII, EBCDIC, and UNICODE options on the LOAD utility statement let you specify whether the format of the data in the input file is ASCII, EBCDIC, or Unicode. The CCSID option of the LOAD utility statement lets you specify the CCSIDs of the data in the input file. If the CCSID of the input data does not match the CCSID of the table space, the input fields are converted to the CCSID of the table space before they are loaded.

*Availability during load:* For nonpartitioned table spaces, data in the table space that is being loaded is unavailable to other application programs during the load operation with the exception of LOAD SHRLEVEL CHANGE. In addition, some SQL statements, such as CREATE, DROP, and ALTER, might experience contention when they run against another table space in the same DB2 database while the table is being loaded.

*Default values for columns:* When you load a table and do not supply a value for one or more of the columns, the action DB2 takes depends on the circumstances.

- If the column is not a ROWID or identity column, DB2 loads the default value of the column, which is specified by the DEFAULT clause of the CREATE or ALTER TABLE statement.
- If the column is a ROWID column that uses the GENERATED BY DEFAULT option, DB2 generates a unique value.
- If the column is an identity column that uses the GENERATED BY DEFAULT option, DB2 provides a specified value.

For ROWID or identity columns that use the GENERATED ALWAYS option, you cannot supply a value because this option means that DB2 always provides a value.

*LOB columns:* The LOAD utility treats LOB columns as varying-length data. The length value for a LOB column must be 4 bytes. The LOAD utility can be used to load LOB data if the length of the row, including the length of the LOB data, does not exceed 32 KB. The auxiliary tables are loaded when the base table is loaded. You cannot specify the name of the auxiliary table to load.

*Replacing or adding data:* You can use LOAD REPLACE to replace data in a single-table table space or in a multiple-table table space. You can replace all the data in a table space (using the REPLACE option), or you can load new records into a table space without destroying the rows that are already there (using the RESUME option).

---

## Making corrections after LOAD

LOAD can place a table space or index space into one of several kinds of restricted status. Your use of a table space in restricted status is severely limited. In general, you cannot access its data through SQL; you can only drop the table space or one of its tables, or perform some operation that resets the status.

To discover what spaces are in restricted status, use the command:

```
-DISPLAY DATABASE (*) SPACENAM (*) RESTRICT
```

***COPY-pending status:*** LOAD places a table space in the COPY-pending state if you load with LOG NO, which you might do to save space in the log. Immediately after that operation, DB2 cannot recover the table space. However, you can recover the table space by loading it again. Prepare for recovery, and remove the restriction, by making a full image copy using SHRLEVEL REFERENCE. (If you end the COPY job before it is finished, the table space is still in COPY-pending status.)

When you use REORG or LOAD REPLACE with the COPYDDN keyword, a full image copy data set (SHRLEVEL REF) is created during the execution of the REORG or LOAD utility. This full image copy is known as an *inline copy*. The table space is not left in COPY-pending state regardless of which LOG option is specified for the utility.

The inline copy is valid only if you replace the entire table space or partition. If you request an inline copy by specifying COPYDDN in a LOAD utility statement, an error message is issued, and the LOAD terminates if you specify LOAD RESUME YES or LOAD RESUME NO without REPLACE.

***REBUILD-pending status:*** LOAD places all the index spaces for a table space in the REBUILD-pending status if you end the job (using -TERM UTILITY) before it completes the INDEXVAL phase. It places the table space itself in RECOVER-pending status if you end the job before it completes the RELOAD phase.

***CHECK-pending status:*** LOAD places a table space in the CHECK-pending status if its referential or check integrity is in doubt. Because of this restriction, use of the CHECK DATA utility is recommended. That utility locates and, optionally, removes invalid data. If the CHECK DATA utility removes invalid data, the remaining data satisfies all referential and table check constraints, and the CHECK-pending restriction is lifted. LOAD does not set the CHECK-pending status for informational referential constraints.

---

## Loading data using the SQL INSERT statement

The information in this section, up to “Loading data from DL/I” on page 65, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437:

- “Inserting a single row” on page 64
- “Inserting multiple rows” on page 64
- “Special considerations when using INSERT statement to load tables” on page 64

Another way to load data into tables is with the SQL INSERT statement. You can issue the statement interactively or embed it in an application program.

## Inserting a single row

The simplest form of INSERT inserts a single row of data. In this form of the statement, you specify the table name, the columns into which the data is to be inserted, and the data itself.

**Example:** Suppose that you create a test table, TEMPDEPT, with the same characteristics as the department table:

```
CREATE TABLE SMITH.TEMPDEPT
  (DEPTNO CHAR(3) NOT NULL,
  DEPTNAME VARCHAR(36) NOT NULL,
  MGRNO CHAR(6) NOT NULL,
  ADMRDEPT CHAR(3) NOT NULL)
  IN DSN8D81A.DSN8S81D;
```

To add a row to table TEMPDEPT, you can enter:

```
INSERT INTO SMITH.TEMPDEPT
  VALUES ('X05','EDUCATION','000631','A01');
```

If you write an application program to load data into tables, you use that form of INSERT, probably with host variables instead of the actual values shown in this example.

## Inserting multiple rows

You can use a form of INSERT that copies rows from another table. For example, you can load TEMPDEPT with the following statement:

```
INSERT INTO SMITH.TEMPDEPT
  SELECT DEPTNO,DEPTNAME,MGRNO,ADMRDEPT
  FROM DSN8810.DEPT
  WHERE ADMRDEPT='D01';
```

The statement loads TEMPDEPT with data from the department table about all departments that report to department D01.

If you embed the INSERT statement in an application program, you can use a form of the statement that inserts multiple rows into a table from the values that are provided in host variable arrays. In this form, you specify the table name, the columns into which the data is to be inserted, and the arrays that contain the data. Each array corresponds to a column. For example, you can load TEMPDEPT with the number of rows in the host variable *num-rows* by using the following embedded INSERT statement:

```
EXEC SQL
  INSERT INTO SMITH.TEMPDEPT
  FOR :num-rows ROWS
  VALUES (:hva1, :hva2, :hva3, :hva4);
```

Assume that the host variable arrays *hva1*, *hva2*, *hva3*, and *hva4* are populated with the values that are to be inserted. The number of rows to insert must be less than or equal to the dimension of each host variable array.

## Special considerations when using INSERT statement to load tables

If you plan to use the INSERT statement to load tables, consider the following topics of special importance:

- If you are inserting a large number of rows, you can use the LOAD utility. Alternatively, use multiple INSERT statements with predicates that isolate the data that is to be loaded, and then commit after each insert operation.
  - When a table, whose indexes are already defined, is populated by using the INSERT statement, both the FREEPAGE and the PCTFREE parameters are ignored. FREEPAGE and PCTFREE are in effect only during a LOAD or REORG operation.
  - You can load a value for a ROWID column with an INSERT and fullselect only if the ROWID column is defined as GENERATED BY DEFAULT. If you have a table with a column that is defined as ROWID GENERATED ALWAYS, you can propagate non-ROWID columns from a table with the same definition.
  - You cannot use an INSERT statement on system-maintained materialized query tables. For information about materialized query tables, see “Registering or changing materialized query tables” on page 85.
  - REBUILD-pending (RBDP) status is set on a data-partitioned secondary index if you create the index after you insert a row into a table. In addition, the last partition of the table space is set to REORG-pending (REORP) restrictive status.
  - When you insert a row into a table that resides in a partitioned table space and the value of the first column of the limit key is null, the result of the INSERT depends on whether DB2 enforces the limit key of the last partition:
    - When DB2 enforces the limit key of the last partition, the INSERT fails if the first column is ascending and MAXVALUE was not specified as the highest value of the key in the last partition. If the first column is ascending and MAXVALUE was specified as the highest value of the key in the last partition, DB2 places NULLs into the last partition.
    - When DB2 enforces the limit key of the last partition, the rows are inserted into the first partition (if the first column is descending).
    - When DB2 does **not** enforce the limit key of the last partition, the rows are inserted into the last partition (if the first column is ascending) or the first partition (if the first column is descending).
- DB2 enforces the limit key of the last partition for the following table spaces:
- Table spaces using table-controlled or index-controlled partitioning that are large (DSSIZE greater than, or equal to, 4 GB)
  - Tables spaces using table-controlled partitioning that are large or non-large (any DSSIZE)

For the complete syntax of the INSERT statement, see Chapter 5 of *DB2 SQL Reference*.

---

## Loading data from DL/I

To convert data in IMS DL/I databases from a hierarchical structure to a relational structure so that it can be loaded into DB2 tables, you can use the DataRefresher™ licensed program.

---

## Chapter 6. Altering your database design

The information in this chapter is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

In addition, this chapter includes techniques for making the following changes:

- “Moving from index-controlled to table-controlled partitioning” on page 97
- “Changing the high-level qualifier for DB2 data sets” on page 98
- “Moving DB2 data” on page 105

**Recommendation:** If possible, use the SQL ALTER statement to change the definitions of DB2 objects. When you cannot make changes with the ALTER statement, you typically must:

1. Use the DROP statement to remove the object.
2. Use the COMMIT statement to commit the changes to the object.
3. Use the CREATE statement to re-create the object.

The DROP statement has a cascading effect; objects that are dependent on the dropped object are also dropped. For example, all authorities for those objects disappear, and plans or packages that reference deleted objects are marked invalid by DB2. For a more detailed description of this method, see “Changing data types by dropping and re-creating the table” on page 88.

---

### Altering DB2 storage groups

You can use the ALTER STOGROUP statement to specify whether you want SMS to manage your DB2 storage groups, or to add or remove volumes from a storage group:

- “Letting SMS manage your DB2 storage groups”
- “Adding or removing volumes from a DB2 storage group”

If you want to migrate to another device type or change the catalog name of the integrated catalog facility, you need to move the data (see “Moving DB2 data” on page 105).

### Letting SMS manage your DB2 storage groups

To let SMS manage the storage needed for the objects that the storage group supports, specify ADD VOLUMES (\*) and REMOVE VOLUMES (*current-vols*) in the ALTER STOGROUP statement, where *current-vols* is the list of the volumes that are currently assigned to the storage group:

```
ALTER STOGROUP DSN8G810
  REMOVE VOLUMES (VOL1)
  ADD VOLUMES ('*');
```

SMS manages every new data set that is created after the ALTER STOGROUP statement is executed; SMS does not manage data sets that are created before the execution of the statement. See “Migrating to DFSMSHsm” on page 35 for more considerations for using SMS to manage data sets.

### Adding or removing volumes from a DB2 storage group

When you add or remove volumes from a storage group, all the volumes in a storage group must be of the same type; and, when a storage group is used to

extend a data set, the volumes must have the same device type as the volumes that were used when the data set was defined.

The changes you make to the volume list by ALTER STOGROUP have no effect on existing storage. Changes take effect when new objects are defined or when the REORG, RECOVER, or LOAD REPLACE utilities are used on those objects. For example, if you use ALTER STOGROUP to remove volume 22222 from storage group DSN8G810, the DB2 data on that volume remains intact. However, when a new table space is defined using DSN8G810, volume 22222 is not available for space allocation.

To force a volume off and add a new volume, follow these steps:

1. Use the SYSIBM.SYSTABLEPART catalog table to determine which table spaces are associated with the storage group. For example, the following query indicates which table spaces use storage group DSN8G810:

```
SELECT TSNAME, DBNAME
   FROM SYSIBM.SYSTABLEPART
   WHERE STORNAME = 'DSN8G810' AND STORTYPE = 'I';
```

2. Make an image copy of each table space; for example, COPY TABLESPACE *dbname.tsname* DEVT SYSDA.
3. Ensure that the table space is not being updated in such a way that the data set might need to be extended. For example, you can stop the table space with the DB2 command STOP DATABASE (*dbname*) SPACENAM (*tsname*).
4. Use the ALTER STOGROUP statement to remove the volume that is associated with the old storage group and to add the new volume:

```
ALTER STOGROUP DSN8G810
  REMOVE VOLUMES (VOL1)
  ADD VOLUMES (VOL2);
```

**Important:** When a new volume is added, or when a storage group is used to extend a data set, the volumes must have the same device type as the volumes that were used when the data set was defined.

5. Start the table space with utility-only processing by using the DB2 command START DATABASE (*dbname*) SPACENAM (*tsname*) ACCESS(UT).
6. Use the RECOVER or REORG utility to move the data in each table space; for example, RECOVER *dbname.tsname*. (You can use only the RECOVER utility to move a LOB table space.)
7. Start the table space with START DATABASE (*dbname*) SPACENAM (*tsname*).

---

## Altering DB2 databases

The ALTER DATABASE statement allows you to change the following clauses that are used to create a database:

### STOGROUP

Lets you change the name of the default storage group to support disk space requirements for table spaces and indexes within the database. The new default DB2 storage group is used only for new table spaces and indexes; existing definitions do not change.

### BUFFERPOOL

Lets you change the name of the default buffer pool for table spaces and indexes within the database. Again, it applies only to new table spaces and indexes; existing definitions do not change.

## INDEXBP

Lets you change the name of the default buffer pool for the indexes within the database. The new default buffer pool is used only for new indexes; existing definitions do not change.

---

## Altering table spaces

If possible, use the ALTER TABLESPACE statement to modify the description of a table space. This statement can be embedded in an application program or issued interactively.

You cannot use ALTER TABLESPACE to change some attributes of your table space. For example, you must use other methods to change SEGSIZE or the number of partitions or to convert it to a large table space. The following topics describe these methods:

- “Changing the space allocation for user-managed data sets”
- “Dropping, re-creating, or converting a table space”

## Changing the space allocation for user-managed data sets

If the table space is supported by user-managed data sets, use this procedure to change the space allocation:

1. Run the REORG TABLESPACE utility, and specify the UNLOAD PAUSE option.
2. Make the table space unavailable with the STOP DATABASE command and the SPACENAM option after the utility completes the unload and stops.
3. Delete and redefine the data sets.
4. Resubmit the utility job with the RESTART(PHASE) parameter specified on the EXEC statement.

The job now uses the new data sets when reloading.

Use of the REORG utility to extend data sets causes the newly acquired free space to be distributed throughout the table space rather than to be clustered at the end.

## Dropping, re-creating, or converting a table space

To make changes to a table space, such as changing SEGSIZE or the number of partitions or to convert it to a large table space, you must first drop the table space and then re-create it. You must commit the DROP TABLESPACE statement before creating a table space or index with the same name. When you drop a table space, all entries for that table space are dropped from SYSIBM.SYSCOPY. This makes recovery for that table space impossible from previous image copies. You can change or convert your table spaces with the following steps:

1. Locate the original CREATE TABLE statement and all authorization statements for all tables in the table space (for example, TA1, TA2, TA3, ... in TS1). If you cannot find these statements, query the DB2 catalog to determine the table's description, the description of all indexes and views on it, and all users with privileges on the table.
2. In another table space (TS2, for example), create tables TB1, TB2, TB3, ... identical to TA1, TA2, TA3, .... For example, use statements like:  

```
CREATE TABLE TB1 LIKE TA1 IN TS2;
```
3. If necessary, unload the data using a statement such as:  

```
REORG TABLESPACE DSN8D81A.TS1 LOG NO SORTDATA UNLOAD EXTERNAL;
```

Another way of unloading data from your old tables and loading into the new tables is by using the INCURSOR option of the LOAD utility. This option uses the DB2 UDB family cross-loader function.

4. Alternatively, instead of unloading the data, you can insert the data from your old tables into the new tables by executing an INSERT statement for each table. For example:

```
INSERT INTO TB1
  SELECT * FROM TA1;
```

If a table contains a ROWID column or an identity column and you want to keep the existing column values, you must define that column as GENERATED BY DEFAULT. If the ROWID column or identity column is defined with GENERATED ALWAYS, and you want DB2 to generate new values for that column, specify OVERRIDING USER VALUE on the INSERT statement with the subselect.

5. Drop the table space by executing the statement:

```
DROP TABLESPACE TS1;
```

The compression dictionary for the table space is dropped, if one exists. All tables in TS1 are dropped automatically.

6. Commit the DROP statement.
7. Create the new table space, TS1, and grant the appropriate user privileges. You can also create a partitioned table space. You could use the following statements:

```
CREATE TABLESPACE TS1
  IN DSN8D81A
  USING STOGROUP DSN8G810
  PRIQTY 4000
  SECQTY 130
  ERASE NO
  NUMPARTS 95
  (PARTITION 45 USING STOGROUP DSN8G810
  PRIQTY 4000
  SECQTY 130
  COMPRESS YES,
  PARTITION 62 USING STOGROUP DSN8G810
  PRIQTY 4000
  SECQTY 130
  COMPRESS NO)
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE NO;
```

8. Create new tables TA1, TA2, TA3, ....
9. Re-create indexes on the tables, and re-grant user privileges on those tables. See "Implications of dropping a table" on page 89 for more information.
10. Execute an INSERT statement for each table. For example:

```
INSERT INTO TA1
  SELECT * FROM TB1;
```

If a table contains a ROWID column or an identity column and you want to keep the existing column values, you must define that column as GENERATED BY DEFAULT. If the ROWID column or identity column is defined with GENERATED ALWAYS, and you want DB2 to generate new values for that column, specify OVERRIDING USER VALUE on the INSERT statement with the subselect.

11. Drop table space TS2.

If a table in the table space has been created with RESTRICT ON DROP, you must alter that table to remove the restriction before you can drop the table space.

12. Notify users to re-create any synonyms they had on TA1, TA2, TA3, ....
13. REBIND plans and packages that were invalidated as a result of dropping the table space.

---

## Altering tables

When you alter a table, you do not change the data in the table; you merely change the specifications that you used in creating the table.

With the ALTER TABLE statement, you can:

- Add a new column to a table; see “Adding a new column to a table.”
- Change the data type of a column, with certain restrictions; see “Altering the data type of a column” on page 73.
- Add or drop a parent key or a foreign key; see “Altering a table for referential integrity” on page 77.
- Add or drop a table check constraint; see “Adding or dropping table check constraints” on page 80.
- Add a new partition to a table space; see “Adding a partition” on page 80.
- Change the boundary between partitions, extend the boundary of the last partition, or rotate partitions; see “Altering partitions” on page 82.
- Register an existing table as a materialized query table, change the attributes of a materialized query table, or change a materialized query table to a base table; see “Registering or changing materialized query tables” on page 85.
- Change the VALIDPROC clause; see “Altering the assignment of a validation routine” on page 86.
- Change the DATA CAPTURE clause; see “Altering a table for capture of changed data” on page 87.
- Change the AUDIT clause, using the options ALL, CHANGES, or NONE. For the effects of the AUDIT value, see Chapter 12, “Protecting data sets through RACF,” on page 281.
- Add or drop the restriction on dropping the table and the database and table space that contain the table; see *DB2 SQL Reference*.
- Alter the length of a VARCHAR column using the SET DATA TYPE VARCHAR clause; see *DB2 SQL Reference*.

In addition, this section includes techniques for making the following changes:

- “Changing an edit procedure or a field procedure” on page 87
- “Altering the subtype of a string column” on page 88
- “Altering the attributes of an identity column” on page 88
- “Changing data types by dropping and re-creating the table” on page 88
- “Moving a table to a table space of a different page size” on page 91

### Adding a new column to a table

When you use the ALTER TABLE statement to add a new column to a table, the new column becomes the rightmost column of the table, and if the table is versioned, the table space is placed in an advisory REORG-pending (AREO\*) state. The physical records are not actually changed until values are inserted in the new column. When you use the ALTER TABLE ADD COLUMN statement, plans and packages are not invalidated unless the data type of the new column is DATE,

# TIME, or TIMESTAMP, you also specify the DEFAULT keyword, and you do not  
 # specify a constant (that is, you use the system default value). However, to use the  
 # new column in a program, you need to modify and recompile the program, and  
 # bind the plan or package again. You also might need to modify any program  
 # containing a static SQL statement SELECT \*, which returns the new column after  
 # the plan or package is rebound. You also must modify any INSERT statement that  
 # does not contain a column list.

Access time to the table is not affected immediately, unless the record was previously fixed length. If the record was fixed length, the addition of a new column causes DB2 to treat the record as variable length and then access time is affected immediately. To change the records to fixed length, follow these steps:

1. Run REORG with COPY on the table space, using the inline copy.
2. Run the MODIFY utility with the DELETE option to delete records of all image copies that were made before the REORG you ran in step 1.
3. Create a unique index if you add a column that specifies PRIMARY KEY.

Inserting values in the new column might also degrade performance by forcing rows onto another physical page. You can avoid this situation by creating the table space with enough free space to accommodate normal expansion. If you already have this problem, run REORG on the table space to fix it.

You can define the new column as NOT NULL by using the DEFAULT clause unless the column has a ROWID data type or is an identity column. If the column has a ROWID data type or is an identity column, you must specify NOT NULL without the DEFAULT clause. You can let DB2 choose the default value, or you can specify a constant or the value of the CURRENT SQLID or USER special register as the value to be used as the default. When you retrieve an existing row from the table, a default value is provided for the new column. Except in the following cases, the value for retrieval is the same as the value for insert:

- For columns of data type DATE, TIME, and TIMESTAMP, the retrieval defaults are:

<b>Data type</b>	<b>Default for retrieval</b>
DATE	0001-01-01
TIME	00.00.00
TIMESTAMP	0001-01-01-00.00.00.000000

- For DEFAULT USER and DEFAULT CURRENT SQLID, the retrieved value for rows that existed before the column was added is the value of the special register when the column was added.

If the new column is a ROWID column, DB2 returns the same, unique row ID value for a row each time you access that row. Reorganizing a table space does not affect the values on a ROWID column. You cannot use the DEFAULT clause for ROWID columns.

If the new column is an identity column (a column that is defined with the AS IDENTITY clause), DB2 places the table space in REORG-pending (REORP) status, and access to the table space is restricted until the table space is reorganized. When the REORG utility is run, DB2

- Generates a unique value for the identity column of each existing row
- Physically stores these values in the database
- Removes the REORP status

You cannot use the DEFAULT clause for identity columns. For more information about identity columns, see *DB2 SQL Reference*.

If the new column is a short string column, you can specify a field procedure for it; see “Field procedures” on page 1093. If you do specify a field procedure, you cannot also specify NOT NULL.

The following example adds a new column to the table DSN8810.DEPT, which contains a location code for the department. The column name is LOCATION\_CODE, and its data type is CHAR (4).

```
ALTER TABLE DSN8810.DEPT
  ADD LOCATION_CODE CHAR (4);
```

## Altering the data type of a column

You can use the ALTER TABLE statement to change the data types of columns in existing tables in the following ways:

- Altering the length of fixed-length or varying-length character data types, and the length of fixed-length or varying-length graphic data types
- Switching between fixed-length and varying-length types for character and graphic data
- Switching between compatible numeric data types

In general, DB2 can alter a data type if the data can be converted from the old type to the new type without truncation or without losing arithmetic precision.

**Restrictions:** The column that you alter cannot be a part of a referential constraint, have a field procedure, be defined as an identity column, or be defined as a column of a materialized query table.

When you alter the data type of a column in a table, DB2 creates a new version for the table space that contains the data rows of the table, as described in “Table space versions” on page 76.

For specific information about valid conversions of data types, see the ALTER TABLE statement in Chapter 5 of *DB2 SQL Reference*. For information about other changes to data types, see “Changing data types by dropping and re-creating the table” on page 88.

## What happens to the column

When you change the data type of a column by using the ALTER TABLE statement, the new definition of the column is stored in the catalog. When you retrieve table rows, the columns are materialized in the format that is indicated by the catalog, but the data is not saved in that format. When you change or insert a row, the entire row is saved in the format that is indicated by the catalog. When you reorganize the table space (or perform a load replace), DB2 reloads the data in the table space according to the format of the current definitions in the catalog.

**Example:** Assume that a table contains basic account information for a small bank. The initial account table was created many years ago in the following manner:

```
CREATE TABLE ACCOUNTS (
  ACCTID      DECIMAL(4,0)   NOT NULL,
  NAME        CHAR(20)      NOT NULL,
  ADDRESS     CHAR(30)      NOT NULL,
  BALANCE     DECIMAL(10,2) NOT NULL)
IN dbname.tname;
```

The columns, as currently defined, have the following problems:

- The ACCTID column allows for only 9999 customers.

- The NAME and ADDRESS columns were defined as fixed-length columns, which means that some of the longer values are truncated and some of the shorter values are padded with blanks.
- The BALANCE column allows for amounts up to 99 999 999.99, but inflation rates demand that this column hold larger numbers.

By altering the column data types in the following ways, you can make the columns more appropriate for the data that they contain. The INSERT statement that follows shows the kinds of values that you can now store in the ACCOUNTS table.

```
ALTER TABLE ACCOUNTS ALTER COLUMN NAME SET DATA TYPE VARCHAR(40);
ALTER TABLE ACCOUNTS ALTER COLUMN ADDRESS SET DATA TYPE VARCHAR(60);
ALTER TABLE ACCOUNTS ALTER COLUMN BALANCE SET DATA TYPE DECIMAL(15,2);
ALTER TABLE ACCOUNTS ALTER COLUMN ACCTID SET DATA TYPE INTEGER;
COMMIT;

INSERT INTO ACCOUNTS (ACCTID, NAME, ADDRESS, BALANCE)
VALUES (123456, 'LAGOMARSINO, MAGDALENA',
'1275 WINTERGREEN ST, SAN FRANCISCO, CA, 95060', 0);
COMMIT;
```

The NAME and ADDRESS columns can now handle longer values without truncation, and the shorter values are no longer padded. The BALANCE column is extended to allow for larger dollar amounts. DB2 saves these new formats in the catalog and stores the inserted row in the new formats.

**Recommendation:** If you change both the length and the type of a column from fixed-length to varying-length by using one or more ALTER statements, issue the ALTER statements within the same unit of work. Reorganize immediately so that the format is consistent for all of the data rows in the table.

### What happens to an index on the column

Altering the data type of a column that is contained in an index has implications for the index.

*Example:* Assume that the following indexes are defined on the ACCOUNTS table.

```
CREATE INDEX IX1 ON ACCOUNTS(ACCTID);
CREATE INDEX IX2 ON ACCOUNTS(NAME);
```

When the data type of the ACCTID column is altered from DECIMAL(4,0) to INTEGER, the IX1 index is placed in a REBUILD-pending (RBDP) state. Similarly, when the data type of the NAME column is altered from CHAR(20) to VARCHAR(40), the IX2 index is placed in an RBDP state. These indexes cannot be accessed until they are rebuilt from the data.

*Index inaccessibility and data availability.* Whenever possible, DB2 tries to avoid using inaccessible indexes in an effort to increase data availability. Beginning in Version 8, DB2 allows you to insert into, and delete from, tables that have non-unique indexes which are currently in an RBDP state. DB2 also allows you to delete from tables that have unique indexes which are currently in an RBDP state.

In certain situations, when an index is inaccessible, DB2 can bypass the index to allow applications access to the underlying data. In these situations, DB2 offers accessibility at the expense of possibly-degraded performance. In making its determination of the best access path, DB2 can bypass an index under the following circumstances:

- Dynamic PREPAREs

DB2 avoids choosing an index that is in an RBDP state. Bypassing the index typically degrades performance, but provides availability that would not be possible otherwise.

- **Cached PREPAREs**

DB2 avoids choosing an index that is both in an RBDP state and within a cached PREPARE statement because the dynamic cache for the table is invalidated whenever an index is put into, or taken out of, an RBDP state. Avoiding indexes that are within cached PREPARE statements ensures that after an index is rebuilt, DB2 uses the index for all future queries.

- **PADDED and NOT PADDED indexes**

DB2 avoids choosing a PADDED index or a NOT PADDED index that is currently in an RBDP state for any static or dynamic SQL statements.

In the case of static BINDs, DB2 might choose an index that is currently in an RBDP state as the best access path. It does so by making the optimistic assumption that the index will be available by the time it is actually used. (If the index is not available at that time, an application can receive a resource unavailable message.)

*Padding.* Whether an index is padded or not padded depends on when the index was created and whether the index contains any varying length columns. In pre-Version 8 releases, an index is padded by default. In new-function mode for Version 8 or later, an index is not padded by default for new installations of DB2, but will be padded for migrated systems which came from at least Version 7 forward. In Version 8 or later, this default behavior is specified by the value of the PAD INDEX BY DEFAULT parameter on the DSNTIPE installation panel, which can be set to YES or NO.

When an index is not padded, the value of the PADDED column of the SYSINDEXES table is set to N. An index is only considered not padded when it is created with at least one varying length column and either:

- The NOT PADDED keyword is specified.
- The default padding value is NO.

When an index is padded, the value of the PADDED column of the SYSINDEXES table is set to Y. An index is padded if it is created with at least one varying length column and either:

- The PADDED keyword is specified
- The default padding is YES.

In the example of the ACCOUNTS table, the IX2 index retains its padding attribute. The padding attribute of an index is altered only if the value is inconsistent with the current state of the index. The value can be inconsistent, for example, if you change the value of the PADDED column in the SYSINDEXES table after creating the index.

Consider the following information when you migrate indexes from one version of DB2 to the next version, or when you install a new DB2 subsystem and create indexes:

- If the index was migrated from a pre-Version 8 release, the index is padded by default. In this case, the value of the PADDED column of the SYSINDEXES table is blank (*PADDED = ' '*). The PADDED column is also blank when there are no varying length columns.

- If a subsystem has been migrated from Version 7 to Version 8 compatibility mode or new-function mode, the default is to pad all indexes that have a key with at least one varying length column. In this case, the value of the PADDED column of the SYSINDEXES table is YES (*PADDED = 'Y'*).
- If an installed subsystem is new to Version 8 or later, and the install is done directly into new-function mode for Version 8 or later, indexes created with at least one varying length column are not padded by default. In this case, the PADDED column of the SYSINDEXES table is set to NO (*PADDED = 'N'*).

### Table space versions

DB2 creates a table space version each time you commit one or more of the following schema changes by using the ALTER TABLE statement:

- Extend the length of a character (char data type) or graphic (graphic data type) column
- Change the type of a column within character data types (char, varchar)
- Change the type of a column within graphic data types (graphic, vargraphic)
- Change the type of a column within numeric data types (small integer, integer, float, real, float8, double, decimal)
- Add a column to a table that has a version number greater than 0
- Extend the length of a varying character (varchar data type) or varying graphic (vargraphic data type) column, if the table is already versioned.

**Exceptions:** DB2 does not create a table space version under the following circumstances:

- When the table space was created with DEFINE NO
- When you extend the length of a varying character (varchar data type) or varying graphic (vargraphic data type) column, and the table is not already versioned.
- When you specify the same data type and length that a column currently has, such that its definition does not actually change

DB2 creates only one table space version if, in the same unit of work, you make multiple schema changes. If you make these same schema changes in separate units of work, each change results in a new table space version. For example, the first three ALTER TABLE statements in the following example are all associated with the same table space version. The scope of the first COMMIT statement encompasses all three schema changes. The last ALTER TABLE statement is associated with the next table space version. The scope of the second COMMIT statement encompasses a single schema change.

```
ALTER TABLE ACCOUNTS ALTER COLUMN NAME    SET DATA TYPE VARCHAR(40);
ALTER TABLE ACCOUNTS ALTER COLUMN ADDRESS SET DATA TYPE VARCHAR(60);
ALTER TABLE ACCOUNTS ALTER COLUMN BALANCE SET DATA TYPE DECIMAL(15,2);
COMMIT;

ALTER TABLE ACCOUNTS ALTER COLUMN ACCTID  SET DATA TYPE INTEGER;
COMMIT;
```

**Reorganizing table spaces:** After you commit a schema change, DB2 puts the affected table space into an advisory REORG-pending (AREO\*) state. The table space stays in this state until you run the REORG TABLESPACE utility, which reorganizes the table space and applies the schema changes.

DB2 uses table space versions to maximize data availability. Table space versions enable DB2 to keep track of schema changes and simultaneously, provide users

with access to data in altered table spaces. When users retrieve rows from an altered table, the data is displayed in the format that is described by the most recent schema definition, even though the data is not currently stored in this format. The most recent schema definition is associated with the *current* table space version.

Although data availability is maximized by the use of table space versions, performance might suffer because DB2 does not automatically reformat the data in the table space to conform to the most recent schema definition. DB2 defers any reformatting of existing data until you reorganize the table space with the REORG TABLESPACE utility. The more ALTER statements you commit between reorganizations, the more table space versions DB2 must track, and the more performance can suffer.

**Recommendation:** Run the REORG TABLESPACE utility as soon as possible after a schema change to correct any performance degradation that might occur and to keep performance at its highest level.

**Recycling table space version numbers:** DB2 can store up to 256 table space versions, numbered sequentially from 0 to 255. (The next consecutive version number after 255 is 1. Version number 0 is never reused; it is reserved for the original version of the table space.) The versions that are associated with schema changes that have not been applied yet are considered to be “in use,” and the range of used versions is stored in the catalog. In-use versions can be recovered from image copies of the table space, if necessary. To determine the range of version numbers currently in use for a table space, query the OLDEST\_VERSION and CURRENT\_VERSION columns of the SYSIBM.SYSTABLESPACE catalog table.

To prevent DB2 from running out of table space version numbers (and to prevent subsequent ALTER statements from failing), you must recycle unused table space version numbers regularly by running the MODIFY RECOVERY utility. Version numbers are considered to be “unused” if the schema changes that are associated with them have been applied and there are no image copies that contain data at those versions. If all reusable version numbers (1 to 255) are currently in use, you must reorganize the table space by running REORG TABLESPACE before you can recycle the version numbers. For more information about managing table space version numbers, see *DB2 Utility Guide and Reference*.

## Altering a table for referential integrity

You can alter a table to add, change, or remove referential constraints. If you plan to let DB2 enforce referential integrity in a set of tables, see Part 2 of *DB2 Application Programming and SQL Guide* for a description of the requirements for referential constraints. DB2 does not enforce informational referential constraints.

This section discusses these topics:

- “Adding referential constraints to existing tables”
- “Adding parent keys and foreign keys” on page 78
- “Dropping parent keys and foreign keys” on page 79

### Adding referential constraints to existing tables

Assume that the tables in the sample application already exist, have the appropriate column definitions, and are already populated. This section refers to the DB2 sample activity, project, project activity, employee, and department tables, which are described in Appendix A (Volume 2) of *DB2 Administration Guide*.

Suppose that you want to define relationships among the sample tables by adding primary and foreign keys with the ALTER TABLE statement. The rules for these relationships are as follows:

- An existing table must have a unique index on its primary key columns before you can add the primary key. The index becomes the primary index.
- The parent key of the parent table must be added before the corresponding foreign key of the dependent table.

You can build the same referential structure in several different ways. The following example sequence does not have the fewest number of possible operations, but it is perhaps the simplest to understand.

1. Create a unique index on the primary key columns for any table that does not already have one.
2. For each table, issue an ALTER TABLE statement to add its primary key.  
In the next steps, you issue an ALTER TABLE statement to add foreign keys for each table except the activity table. This leaves the table space in CHECK-pending status, which you reset by running the CHECK DATA utility with the DELETE(YES) option.  
CHECK DATA deletes are not bound by delete rules; they cascade to all descendants of a deleted row, which can be disastrous. For example, if you delete the row for department A00 from the department table, the delete might propagate through most of the referential structure. The remaining steps prevent deletion from more than one table at a time.
3. Add the foreign keys for the department table and run CHECK DATA DELETE(YES) on its table space. Correct any rows in the exception table, and use INSERT to replace them in the department table. This table is now consistent with existing data.
4. Drop the foreign key on MGRNO in the department table. This drops the association of the department table with the employee table, without changing the data of either table.
5. Add the foreign key to the employee table, run CHECK DATA again, and correct any errors. If errors are reported, be particularly careful not to make any row inconsistent with the department table when you make corrections.
6. Again, add the foreign key on MGRNO to the department table, which again leaves the table space in CHECK-pending status. Run CHECK DATA. If you have not changed the data since the previous check, you can use DELETE(YES) with no fear of cascading deletions.
7. For each of the following tables, in the order shown, add its foreign keys, run CHECK DATA DELETE(YES), and correct any rows that are in error:
  - a. Project table
  - b. Project activity table
  - c. Employee to project activity table

### **Adding parent keys and foreign keys**

You can add parent keys, both primary and unique, and foreign keys to an existing table.

*Adding a primary key:* To add a primary key to an existing table, use the PRIMARY KEY clause in an ALTER TABLE statement. For example, if the department table and its index XDEPT1 already exist, create its primary key by issuing the following statement:

```
ALTER TABLE DSN8810.DEPT  
  ADD PRIMARY KEY (DEPTNO);
```

**Adding a unique key:** To add a unique key to an existing table, use the UNIQUE clause of the ALTER TABLE statement. For example, if the department table has a unique index defined on column DEPTNAME, you can add a unique key constraint, KEY\_DEPTNAME, consisting of column DEPTNAME by issuing the following statement:

```
ALTER TABLE DSN8810.DEPT
  ADD CONSTRAINT KEY_DEPTNAME UNIQUE (DEPTNAME);
```

**Adding a foreign key:** To add a foreign key to an existing table, use the FOREIGN KEY clause of the ALTER TABLE statement. The parent key must exist in the parent table before you add the foreign key. For example, if the department table has a primary key defined on the DEPTNO column, you can add a referential constraint, REFKEY\_DEPTNO, on the DEPTNO column of the project table by issuing the following statement:

```
ALTER TABLE DSN8810.PROJ
  ADD CONSTRAINT REFKEY_DEPTNO FOREIGN KEY (DEPTNO) REFERENCES DSN8810.DEPT
  ON DELETE RESTRICT;
```

**Considerations:** Adding a parent key or a foreign key to an existing table has the following restrictions and implications:

- If you add a primary key, the table must already have a unique index on the key columns. If multiple unique indexes include the primary key columns, the index that was most recently created on the key columns becomes the primary index. Because of the unique index, no duplicate values of the key exist in the table; therefore you do not need to check the validity of the data.
- If you add a unique key, the table must already have a unique index with a key that is identical to the unique key. If multiple unique indexes include the primary key columns, DB2 arbitrarily chooses a unique index on the key columns to enforce the unique key. Because of the unique index, no duplicate values of the key exist in the table; therefore you do not need to check the validity of the data.
- You can use only one FOREIGN KEY clause in each ALTER TABLE statement; if you want to add two foreign keys to a table, you must execute two ALTER TABLE statements.
- If you add a foreign key, the parent key and unique index of the parent table must already exist. Adding the foreign key requires the ALTER privilege on the dependent table and either the ALTER or REFERENCES privilege on the parent table.
- Adding a foreign key establishes a referential constraint relationship, with the many implications that are described in Part 2 of *DB2 Application Programming and SQL Guide*. DB2 does not validate the data when you add the foreign key. Instead, if the table is populated (or, in the case of a nonsegmented table space, if the table space has ever been populated), the table space that contains the table is placed in CHECK-pending status, just as if it had been loaded with ENFORCE NO. In this case, you need to execute the CHECK DATA utility to clear the CHECK-pending status.
- You can add a foreign key with the NOT ENFORCED option to create an informational referential constraint. This action does not leave the table space in CHECK-pending status, and you do not need to execute CHECK DATA.

## Dropping parent keys and foreign keys

You can drop parent keys, both primary and unique, and foreign keys from an existing table. Before you drop a foreign key or a parent key, consider carefully the effects on your application programs. The primary key of a table serves as a permanent, unique identifier of the occurrences of the entities it describes.

Application programs often depend on that identifier. The foreign key defines a referential relationship and a delete rule. Without the key, your application programs must enforce the constraints.

***Dropping a foreign key:*** When you drop a foreign key using the DROP FOREIGN KEY clause of the ALTER TABLE statement, DB2 drops the corresponding referential relationships. (You must have the ALTER privilege on the dependent table and either the ALTER or REFERENCES privilege on the parent table.) If the referential constraint references a unique key that was created implicitly, and no other relationships are dependent on that unique key, the implicit unique key is also dropped.

***Dropping a unique key:*** When you drop a unique key using the DROP UNIQUE clause of the ALTER TABLE statement, DB2 drops all the referential relationships in which the unique key is a parent key. The dependent tables no longer have foreign keys. (You must have the ALTER privilege on any dependent tables.) The table's unique index that enforced the unique key no longer indicates that it enforces a unique key, although it is still a unique index.

***Dropping a primary key:*** When you drop a primary key using the DROP PRIMARY KEY clause of the ALTER TABLE statement, DB2 drops all the referential relationships in which the primary key is a parent key. The dependent tables no longer have foreign keys. (You must have the ALTER privilege on any dependent tables.) The table's primary index is no longer primary, although it is still a unique index.

## Adding or dropping table check constraints

You can define a check constraint on a table by using the ADD CHECK clause of the ALTER TABLE statement. If the table is empty, the check constraint is added to the description of the table.

If the table is not empty, what happens when you define the check constraint depends on the value of the CURRENT RULES special register, which can be either STD or DB2.

- If the value is STD, the check constraint is enforced immediately when it is defined. If a row does not conform, the table check constraint is not added to the table and an error occurs.
- If the value is DB2, the check constraint is added to the table description but its enforcement is deferred. Because some rows in the table might violate the check constraint, the table is placed in check-pending status.

The ALTER TABLE statement that is used to define a check constraint always fails if the table space or partition that contains the table is in a CHECK-pending status, the CURRENT RULES special register value is STD, and the table is not empty.

To remove a check constraint from a table, use the DROP CONSTRAINT or DROP CHECK clauses of the ALTER TABLE statement. You must not use DROP CONSTRAINT on the same ALTER TABLE statement as DROP FOREIGN KEY, DROP CHECK, DROP PRIMARY KEY, or DROP UNIQUE.

## Adding a partition

You can use the ALTER TABLE statement to add a partition to an existing partitioned table space and to each partitioned index in the table space.

**Restriction:** You cannot add a new partition to an existing partitioned table space if the table has LOB columns. Additionally, you cannot add or alter a partition for a materialized query table.

When you add a partition, DB2 uses the next physical partition that is not already in use until you reach the maximum number of partitions for the table space. When DB2 manages your data sets, the next available data set is allocated for the table space and for each partitioned index. When you manage your own data sets, you must first define the data sets for the table space and the partitioned indexes before issuing the ALTER TABLE ADD PARTITION statement.

**Example:** Assume that a table space that contains a transaction table named TRANS is divided into 10 partitions, and each partition contains one year of data. Partitioning is defined on the transaction date, and the limit key value is the end of the year. Table 18 shows a representation of the table space.

*Table 18. Initial table space with 10 partitions*

Partition	Limit value	Data set name that backs the partition
P001	12/31/1994	catname.DSNDBX.dbname.psname.I0001.A001
P002	12/31/1995	catname.DSNDBX.dbname.psname.I0001.A002
P003	12/31/1996	catname.DSNDBX.dbname.psname.I0001.A003
P004	12/31/1997	catname.DSNDBX.dbname.psname.I0001.A004
P005	12/31/1998	catname.DSNDBX.dbname.psname.I0001.A005
P006	12/31/1999	catname.DSNDBX.dbname.psname.I0001.A006
P007	12/31/2000	catname.DSNDBX.dbname.psname.I0001.A007
P008	12/31/2001	catname.DSNDBX.dbname.psname.I0001.A008
P009	12/31/2002	catname.DSNDBX.dbname.psname.I0001.A009
P010	12/31/2003	catname.DSNDBX.dbname.psname.I0001.A010

Assume that you want to add a new partition to handle the transactions for the next year. To add a partition, issue the following statement:

```
ALTER TABLE TRANS ADD PARTITION ENDING AT ('12/31/2004');
```

**What happens:**

- DB2 adds a new partition to the table space and to each partitioned index on the TRANS table. For the table space, DB2 uses the existing table space PRIQTY and SECQTY attributes of the previous partition for the space attributes of the new partition. For each partitioned index, DB2 uses the existing PRIQTY and SECQTY attributes of the previous index partition.
- When the ALTER completes, you can use the new partition immediately if the table space is a large table space. In this case, the partition is not placed in a REORG-pending (REORP) state because it extends the high-range values that were not previously used. For non-large table spaces, the partition is placed in a REORG-pending (REORP) state because the last partition boundary was not previously enforced.

Table 19 on page 82 shows a representative excerpt of the table space after the partition for the year 2004 was added.

Table 19. An excerpt of the table space after adding a new partition (P011)

Partition	Limit value	Data set name that backs the partition
P008	12/31/2001	catname.DSNDBx.dbname.psname.I0001.A008
P009	12/31/2002	catname.DSNDBx.dbname.psname.I0001.A009
P010	12/31/2003	catname.DSNDBx.dbname.psname.I0001.A010
P011	12/31/2004	catname.DSNDBx.dbname.psname.I0001.A011

**Specifying space attributes:** If you want to specify the space attributes for a new partition, use the ALTER TABLESPACE and ALTER INDEX statements. For example, suppose the new partition is PARTITION 11 for the table space and the index. Issue the following statements to specify quantities for the PRIQTY, SECQTY, FREEPAGE, and PCTFREE attributes:

```
ALTER TABLESPACE tsname ALTER PARTITION 11
  USING STOGROUP stogroup-name
  PRIQTY 200 SECQTY 200
  FREEPAGE 20 PCTFREE 10;

ALTER INDEX index-name ALTER PARTITION 11
  USING STOGROUP stogroup-name
  PRIQTY 100 SECQTY 100
  FREEPAGE 25 PCTFREE 5;
```

**Recommendation:** When you create your partitioned table space, you do not need to allocate extra partitions for expected growth. Instead, use ALTER TABLE ADD PARTITION to add partitions as needed.

## Altering partitions

You can use the ALTER TABLE statement to change the boundary between partitions, to rotate the first partition to be the last partition, or to extend the boundary of the last partition.

**Example:** Assume that a table space that contains a transaction table named TRANS is divided into 10 partitions, and each partition contains one year of data. Partitioning is defined on the transaction date, and the limit key value is the end of the year. Table 18 on page 81 shows a representation of the table space.

### Changing the boundary between partitions

Assume that the year 2003 resulted in more data than was projected so that the allocation for partition 10 reached its maximum of 4 GB. In addition, the year 2002 resulted in less data than was projected. You want to change the boundary between partition 9 and partition 10 so that some of the data in partition 10 becomes part of the data in partition 9.

To change the boundary, issue the following statement:

```
ALTER TABLE TRANS ALTER PARTITION 9 ENDING AT ('03/31/2003');
```

Now the data in the first quarter of the year 2003 is part of partition 9. The partitions on either side of the new boundary (partitions 9 and 10) are placed in REORG-pending (REORP) status and are not available until the partitions are reorganized.

Alternatively, you can rebalance the data in partitions 9 and 10 by using the REBALANCE option of the REORG utility:

```
REORG TABLESPACE dbname.tsname PART(9:10) REBALANCE
```

This method avoids leaving the partitions in a REORP state. When you use the REBALANCE option on partitions, DB2 automatically changes the limit key values.

## Rotating partitions

Assume that the partition structure of the table space is sufficient through the year 2004. Table 19 on page 82 shows a representation of the table space through the year 2004. When another partition is needed for the year 2005, you determine that the data for 1994 is no longer needed. You want to recycle the partition for the year 1994 to hold the transactions for the year 2005.

To rotate the first partition in the table TRANS to be the last partition, issue the following statement:

```
ALTER TABLE TRANS ROTATE PARTITION FIRST TO LAST
    ENDING AT ('12/31/2005') RESET;
```

For a table with limit values in ascending order, the data in the ENDING AT clause must be higher than the limit value for previous partitions. DB2 chooses the first partition to be the partition with the lowest limit value.

For a table with limit values in descending order, the data must be lower than the limit value for previous partitions. DB2 chooses the first partition to be the partition with the highest limit value.

The RESET keyword specifies that the existing data in the oldest partition is deleted, and no delete triggers are activated.

### *What happens:*

- Because the oldest (or first) partition is P001, DB2 assigns the new limit value to P001. This partition holds all rows in the range between the new limit value of 12/31/2005 and the previous limit value of 12/31/2004.
- The RESET operation deletes all existing data. You can use the partition immediately after the ALTER completes. The partition is not placed in REORG-pending (REORP) status because it extends the high-range values that were not previously used.

Table 20 shows a representation of the table space after the first partition is rotated to become the last partition.

*Table 20. Rotating the low partition to the end*

Partition	Limit value	Data set name that backs the partition
P002	12/31/1995	catname.DSNDBx.dbname.psname.I0001.A002
P003	12/31/1996	catname.DSNDBx.dbname.psname.I0001.A003
P004	12/31/1997	catname.DSNDBx.dbname.psname.I0001.A004
P005	12/31/1998	catname.DSNDBx.dbname.psname.I0001.A005
P006	12/31/1999	catname.DSNDBx.dbname.psname.I0001.A006
P007	12/31/2000	catname.DSNDBx.dbname.psname.I0001.A007
P008	12/31/2001	catname.DSNDBx.dbname.psname.I0001.A008
P009	12/31/2002	catname.DSNDBx.dbname.psname.I0001.A009
P010	12/31/2003	catname.DSNDBx.dbname.psname.I0001.A010
P011	12/31/2004	catname.DSNDBx.dbname.psname.I0001.A011
P001	12/31/2005	catname.DSNDBx.dbname.psname.I0001.A001

**Recommendation:** When you create a partitioned table space, you do not need to allocate extra partitions for expected growth. Instead, use either ALTER TABLE ADD PARTITION to add partitions as needed or, if rotating partitions is appropriate for your application, use ALTER TABLE ROTATE PARTITION to avoid adding another partition. Execute the RUNSTATS utility after rotating the partition.

**Nullable partitioning columns:** DB2 lets you use nullable columns as partitioning columns. But with table-controlled partitioning, DB2 can restrict the insertion of null values into a table with nullable partitioning columns, depending on the order of the partitioning key. After a rotate operation:

- If the partitioning key is ascending, DB2 prevents an INSERT of a row with a null value for the key column.
- If the partitioning key is descending, DB2 allows an INSERT of a row with a null value for the key column. The row is inserted into the first partition.

### Extending the boundary of the last partition

Assume that a decision has been made to save the data for the year 2005 and the data for the year 2006 into one partition. You have rotated the first partition to be the last partition. Table 20 on page 83 shows a representation of the table space through the year 2005.

To extend the boundary of the last partition, issue the following statement:

```
ALTER TABLE TRANS ALTER PARTITION 1 ENDING AT ('12/31/2006');
```

You can use the partition immediately after the ALTER completes. The partition is not placed in REORG-pending (REORP) status because it extends the high-range values that were not previously used.

**Changing back to the previous boundary:** Table 20 on page 83 shows a representation of the table space through the year 2005, where each year of data is saved into separate partitions. Assume that you changed the limit key for P001 to be 12/31/2006 so that the data for the year 2005 and the data for the year 2006 is saved into one partition.

To change the limit key back to 12/31/2005, issue the following statement:

```
ALTER TABLE TRANS ALTER PARTITION 1 ENDING AT ('12/31/2005');
```

This partition is placed in REORG-pending (REORP) status because some of the data could fall outside of the boundary that is defined by the limit key value of 12/31/2005. You can take either of the following corrective actions:

- Run REORG with the DISCARD option to clear the REORG-pending status, set the new partition boundary, and discard the data rows that fall outside of the new boundary.
- Add a new partition for the data rows that fall outside of the current partition boundaries.

**Adding a partition when the last partition is in REORP:** Assume that you extended the boundary of the last partition and then changed back to the previous boundary for that partition. Table 20 on page 83 shows a representation of the table space through the year 2005. The last partition is in REORP.

You want to add a new partition with a limit key value of 12/31/2006. You can use ALTER TABLE ADD PARTITION because this limit key value is higher than the previous limit key value of 12/31/2005.

Issue the following statement:

```
ALTER TABLE TRANS ADD PARTITION ENDING AT ('12/31/2006');
```

The new partition is placed in REORG-pending (REORP) status because it inherits the REORP state from the previous partition. You can now reorganize the table space or only the last two partitions without discarding any of the data rows.

## Registering or changing materialized query tables

You can use the ALTER TABLE statement to register an existing table as a materialized query table, to change a materialized query table to a base table, or to change the attributes of a materialized query table.

Materialized query tables enable DB2 to use automatic query rewrite to optimize queries. Automatic query rewrite is a process that DB2 uses to examine a query and, if appropriate, to rewrite the query so that it executes against a materialized query table that has been derived from the base tables in the submitted query. For additional information about the use of automatic query rewrite in query optimization, see Part 5 (Volume 2) of *DB2 Administration Guide*.

### Registering an existing table as a materialized query table

Assume that you have a very large transaction table named TRANS that contains one row for each transaction. The table has many columns, but you are interested in only the following columns:

- ACCTID, which is the customer account ID
- LOCID, which is the customer location ID
- YEAR, which holds the year of the transaction

You created another base table named TRANSCOUNT that consists of these columns and a count of the number of rows in TRANS that are grouped by the account, location, and year of the transaction. Suppose that you repopulate TRANSCOUNT periodically by deleting the rows and then by using the following INSERT statement:

```
INSERT INTO TRANSCOUNT (ACCTID, LOCID, YEAR, CNT)
  SELECT ACCTID, LOCID, YEAR, COUNT(*)
  FROM TRANS
  GROUP BY ACCTID, LOCID, YEAR;
```

You want to take advantage of automatic query rewrite for TRANSCOUNT by registering it as a materialized query table. You can do this by issuing the following ALTER TABLE statement:

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY AS (
  SELECT ACCTID, LOCID, YEAR, COUNT(*) AS CNT
  FROM TRANS
  GROUP BY ACCTID, LOCID, YEAR )
  DATA INITIALLY DEFERRED
  REFRESH DEFERRED
  MAINTAINED BY USER;
```

This statement registers TRANSCOUNT with its associated subselect as a materialized query table, and DB2 can now use it in automatic query rewrite. The data in TRANSCOUNT remains the same, as specified by the DATA INITIALLY DEFERRED option.

You can still maintain the data, as specified by the MAINTAINED BY USER option, which means that you can continue to load, insert, update, or delete data. You can also use the REFRESH TABLE statement to populate the table. REFRESH

DEFERRED indicates that the data in the table is the result of your most recent update or, if more recent, the result of a REFRESH TABLE statement.

The REFRESH TABLE statement deletes all the rows in a materialized query table, executes the fullselect in its definition, inserts the result into the table, and updates the catalog with the refresh timestamp and cardinality of the table. For more information about the REFRESH TABLE statement, see Chapter 5 of *DB2 SQL Reference*.

### Changing a materialized query table to a base table

You can use the ALTER TABLE statement to change a materialized query table into a base table. For example:

```
ALTER TABLE TRANSCOUNT DROP MATERIALIZED QUERY;
```

After you issue this statement, DB2 can no longer use the table for query optimization, and you cannot populate the table by using the REFRESH TABLE statement.

### Changing the attributes of a materialized query table

You can use the ALTER TABLE statement to change the following attributes of an existing materialized query table:

- You can enable or disable automatic query rewrite.

By default, when you create or register a materialized query table, DB2 enables it for automatic query rewrite. To disable automatic query rewrite, issue the following statement:

```
ALTER TABLE TRANSCOUNT DISABLE QUERY OPTIMIZATION;
```

To change back to automatic query rewrite, use the ENABLE QUERY OPTIMIZATION option.

- You can switch between system-maintained and user-maintained.

By default, a materialized query table is system-maintained; the only way you can change the data is by using the REFRESH TABLE statement. To change to a user-maintained materialized query table, issue the following statement:

```
ALTER TABLE TRANSCOUNT SET MAINTAINED BY USER;
```

To change back to a system-maintained materialized query table, use the MAINTAINED BY SYSTEM option.

### Changing the definition of a materialized query table

After you create a materialized query table, you can change the definition, as specified by the fullselect, in one of the following ways:

- Drop and re-create the materialized query table with a different definition.
- Use ALTER TABLE to change the materialized query table into a base table. Then, change it back to a materialized query table with a different but equivalent definition (that is, with a different but equivalent SELECT for the query).

## Altering the assignment of a validation routine

If you have a validation exit routine associated with a table, you can use the ALTER TABLE statement to make the following changes:

- Disassociate the validation routine from the table using the VALIDPROC NULL clause. The routine is no longer given control when DB2 accesses the table. For example:

```
ALTER TABLE DSN8810.EMP  
VALIDPROC NULL;
```

- Assign a new validation routine to the table using the VALIDPROC clause. (Only one validation routine can be connected to a table at a time; so if a validation routine already exists, DB2 disconnects the old one and connects the new routine.) Rows that existed before the connection of a new validation routine are not validated. In this example, the previous validation routine is disconnected and a new routine is connected with the program name EMPLNEWE:

```
ALTER TABLE DSN8810.EMP
  VALIDPROC EMPLNEWE;
```

To ensure that the rows of a table conform to a new validation routine, you must run the validation routine against the old rows. One way to accomplish this is to use the REORG and LOAD utilities as shown in the following steps:

1. Use REORG to reorganize the table space that contains the table with the new validation routine. Specify UNLOAD ONLY, as in this example:

```
REORG TABLESPACE DSN8D81A.DSN8S81E
  UNLOAD ONLY
```

This step creates a data set that is used as input to the LOAD utility.

2. Run LOAD with the REPLACE option, and specify a discard data set to hold any invalid records. For example:

```
LOAD INTO TABLE DSN8810.EMP
  REPLACE
  FORMAT UNLOAD
  DISCARD DN SYSDISC
```

The EMPLNEWE validation routine validates all rows after the LOAD step has completed. DB2 copies any invalid rows into the SYSDISC data set.

## Altering a table for capture of changed data

You can use the DATA CAPTURE CHANGES option on the ALTER TABLE statement to have data changes to that table written to the log in an expanded format. You can then retrieve the log by using a program such as the log apply feature of the Remote Recovery Data Facility (RRDF) program offering, or DB2 DataPropagator.

LOB values are not available for DATA CAPTURE CHANGES. To return a table back to normal logging, use DATA CAPTURE NONE.

## Changing an edit procedure or a field procedure

You cannot use ALTER TABLE to change the assignment of an edit procedure or a field procedure. However, with the assistance of DB2 utilities, you can change an existing edit procedure or field procedure.

To change an edit procedure or a field procedure for a table space in which the maximum record length is less than 32 KB, use the following procedure:

1. Run the UNLOAD utility or run the REORG TABLESPACE utility with the UNLOAD EXTERNAL option to unload the data and decode it using the existing edit procedure or field procedure.

These utilities generate a LOAD statement in the data set (specified by the PUNCHDDN option of the REORG TABLESPACE utility) that you can use to reload the data into the original table space.

If you are using the same edit procedure or field procedure for many tables, unload the data from all the table spaces that have tables that use the procedure.

2. Modify the code of the edit procedure or the field procedure.
3. After the unload operation is completed, stop DB2.
4. Link-edit the modified procedure, using its original name.
5. Start DB2.
6. Use the LOAD utility to reload the data. LOAD then uses the modified procedure or field procedure to encode the data.

To change an edit procedure or a field procedure for a table space in which the maximum record length is greater than 32 KB, use the DSNTIAUL sample program to unload the data.

## Altering the subtype of a string column

If you add a column with a string data type, you can specify its subtype in the ALTER TABLE statement. Subtypes are valid for string columns of data types CHAR and VARCHAR. SBCS and MIXED are valid subtypes for CLOB data.

The interpretation of the FOREIGNKEY column depends on whether the MIXED DATA install option is YES or NO.

Entering an M in the column when the MIXED DATA install option is NO specifies SBCS data, not MIXED data.

1. To alter the subtype of an existing string column, enter the following SQL statement:

```
ALTER TABLE table-name ALTER COLUMN column-name
SET DATA TYPE altered-data-type
```

## Altering the attributes of an identity column

At some point, you might need to change the attributes of an identity column. For example, you might want to allow or disallow identity column values to wrap. You can use the ALTER TABLE with the ALTER COLUMN clause to change all of the attributes of an identity column except the data type. However, if the ALTER TABLE statement is rolled back, a gap in the sequence of identity column values can occur because of unassigned cache values.

Changing the data type of an identity column, like changing some other data types, requires that you drop and then re-create the table (see “Changing data types by dropping and re-creating the table”).

See Chapter 5 of *DB2 SQL Reference* for more information about identity column attributes.

## Changing data types by dropping and re-creating the table

Some changes to a table cannot be made with the ALTER TABLE statement. For example, you must make the following changes by redefining the column (that is, dropping the table and then re-creating the table with the new definitions):

- An original specification of CHAR (25) to CHAR (20)
- A column defined as INTEGER to SMALLINT
- A column defined as NOT NULL to allow null values
- The data type of an identity column

To make such changes, you need to perform the following steps:

1. Unload the table.
2. Drop the table.

**Be very careful about dropping a table;** in most cases, recovering a dropped table is nearly impossible. If you decide to drop a table, remember that such changes might invalidate a plan or a package.

You must alter tables that have been created with RESTRICT ON DROP to remove the restriction before you can drop them.

3. Commit the changes.
4. Re-create the table.

If the table has an identity column:

- Choose carefully the new value for the START WITH attribute of the identity column in the CREATE TABLE statement if you want the first generated value for the identity column of the new table to resume the sequence after the last generated value for the table that was saved by the unload in step 1.
- Define the identity column as GENERATED BY DEFAULT so that the previously generated identity values can be reloaded into the new table.

5. Reload the table.

### Implications of dropping a table

The DROP TABLE statement deletes a table. For example, to drop the project table, execute the following statement:

```
DROP TABLE DSN8810.PROJ;
```

The statement deletes the row in the SYSIBM.SYSTABLES catalog table that contains information about DSN8810.PROJ. It also drops any other objects that depend on the project table. As a result:

- The column names of the table are dropped from SYSIBM.SYSCOLUMNS.
- If the dropped table has an identity column, the sequence attributes of the identity column are removed from SYSIBM.SYSSEQUENCES.
- If triggers are defined on the table, they are dropped, and the corresponding rows are removed from SYSIBM.SYSTRIGGERS and SYSIBM.SYSPACKAGES.
- Any views based on the table are dropped.
- Application plans or packages that involve the use of the table are invalidated.
- Cached dynamic statements that involve the use of the table are removed from the cache.
- Synonyms for the table are dropped from SYSIBM.SYSSYNONYMS.
- Indexes created on any columns of the table are dropped.
- Referential constraints that involve the table are dropped. In this case, the project table is no longer a dependent of the department and employee tables, nor is it a parent of the project activity table.
- Authorization information that is kept in the DB2 catalog authorization tables is updated to reflect the dropping of the table. Users who were previously authorized to use the table, or views on it, no longer have those privileges, because catalog rows are deleted.
- Access path statistics and space statistics for the table are deleted from the catalog.
- The storage space of the dropped table might be reclaimed.

If the table space containing the table is:

- Implicitly created (using CREATE TABLE without the TABLESPACE clause), the table space is also dropped. If the data sets are in a storage group, dropping the table space reclaims the space. For user-managed data sets, you must reclaim the space yourself.

- Partitioned, or contains only the one table, you can drop the table space.
- Segmented, DB2 reclaims the space.
- Simple, and contains other tables, you must run the REORG utility to reclaim the space.
- If the table contains a LOB column, the auxiliary table and the index on the auxiliary table are dropped. The LOB table space is dropped if it was created with SQLRULES(STD). See *DB2 SQL Reference* for details.

If a table has a partitioning index, you must drop the table space or use LOAD REPLACE when loading the redefined table. If the CREATE TABLE that is used to redefine the table creates a table space implicitly, commit the DROP statement before re-creating a table by the same name. You must also commit the DROP statement before you create any new indexes with the same name as the original indexes.

### Check objects that depend on the table

Before dropping a table, check to see what other objects are dependent on it. For example, the DB2 catalog tables SYSIBM.SYSVIEWDEP, SYSIBM.SYSPLANDEP, and SYSIBM.SYSPACKDEP indicate what views, application plans, and packages are dependent on different DB2 objects.

*Finding dependent views:* The following example query lists the views, with their creators, that are affected if you drop the project table:

```
SELECT DNAME, DCREATOR
   FROM SYSIBM.SYSVIEWDEP
   WHERE BNAME = 'PROJ'
   AND BCREATOR = 'DSN8810'
   AND BTYPE = 'T';
```

*Finding dependent packages:* The next example lists the packages, identified by the package name, collection ID, and consistency token (in hexadecimal representation), that are affected if you drop the project table:

```
SELECT DNAME, DCOLLID, HEX(DCONTOKEN)
   FROM SYSIBM.SYSPACKDEP
   WHERE BNAME = 'PROJ'
   AND BQUALIFIER = 'DSN8810'
   AND BTYPE = 'T';
```

*Finding dependent plans:* The next example lists the plans, identified by plan name, that are affected if you drop the project table:

```
SELECT DNAME
   FROM SYSIBM.SYSPLANDEP
   WHERE BNAME = 'PROJ'
   AND BCREATOR = 'DSN8810'
   AND BTYPE = 'T';
```

*Finding other dependencies:* In addition, the SYSIBM.SYSINDEXES table tells you what indexes currently exist on a table. From the SYSIBM.SYSTABAUTH table, you can determine which users are authorized to use the table. For more information about what you can retrieve from the DB2 catalog tables, see Appendix G of *DB2 SQL Reference*.

### Re-creating a table

To re-create a DB2 table to decrease the length attribute of a string column or the precision of a numeric column, follow these steps:

1. If you do not have the original CREATE TABLE statement and all authorization statements for the table (call it T1), query the catalog to determine its description, the description of all indexes and views on it, and all users with privileges on it.
2. Create a new table (call it T2) with the desired attributes.
3. Copy the data from the old table T1 into the new table T2 by using one of the following methods:
  - Execute the following INSERT statement:
 

```
INSERT INTO T2
  SELECT * FROM T1;
```
  - Load data from your old table into the new table by using the INCURSOR option of the LOAD utility. This option uses the DB2 UDB family cross-loader function.
4. Execute the statement DROP TABLE T1. If T1 is the only table in an explicitly created table space, and you do not mind losing the compression dictionary, if one exists, drop the table space instead, so that the space is reclaimed.
5. Commit the DROP statement.
6. Use the statement RENAME TABLE to rename table T2 to T1.
7. Run the REORG utility on the table space that contains table T1.
8. Notify users to re-create any synonyms, indexes, views, and authorizations they had on T1.

If you want to change a data type from string to numeric or from numeric to string (for example, INTEGER to CHAR or CHAR to INTEGER), use the CHAR and DECIMAL scalar functions in the SELECT statement to do the conversion. Another alternative is to use the following method:

1. Use UNLOAD or REORG UNLOAD EXTERNAL (if the data to unload is less than 32 KB) to save the data in a sequential file, and then
2. Use the LOAD utility to repopulate the table after re-creating it. When you reload the table, make sure you edit the LOAD statement to match the new column definition.

This method is particularly appealing when you are trying to re-create a large table.

## Moving a table to a table space of a different page size

You cannot alter a table to use a different page size. However, you can move a table to a table space of a different page size:

1. Unload the table using UNLOAD FROM TABLE or REORG UNLOAD EXTERNAL FROM TABLE.
2. Use CREATE TABLE LIKE on the table to re-create it in the table space of the new page size.
3. Use DB2 Control Center, DB2 Administration Tool, or catalog queries to determine the dependent objects: views, authorization, plans, packages, synonyms, triggers, referential integrity, and indexes.
4. Drop the original table.
5. Rename the new table to the name of the old table using RENAME TABLE.
6. Re-create all dependent objects.
7. Rebind plans and packages.

8. Reload the table using data from the SYSRECnn data set and the control statements from the SYSPUNCH data set, which was created when the table was unloaded.

---

## Altering indexes

You can add a new column to an index or change most of the index clauses for an existing index with the ALTER INDEX statement, including BUFFERPOOL, CLOSE, COPY, PIECESIZE, PADDED or NOT PADDED, CLUSTER or NOT CLUSTER, and those clauses that are associated with storage space, free space, and group buffer pool caching.

With the ALTER INDEX statement, you can:

- Add a new column to an index; see “Adding a new column to an index.”
- Alter the PADDED or NOT PADDED attribute to change how varying-length columns are stored in the index; see “Altering how varying-length index columns are stored” on page 93.
- Alter the CLUSTER or NOT CLUSTER attribute to change how data is stored; see “Altering the clustering index” on page 93.
- Change the limit key for index-controlled partitioning to rebalance data among the partitions in a partitioned table space; see “Rebalancing data in partitioned table spaces” on page 93.

For other changes, you must drop and re-create the index as described in “Dropping and redefining an index” on page 94.

When you add a new column to an index, change how varying-length columns are stored in the index, or change the data type of a column in the index, DB2 creates a new version of the index, as described in “Index versions” on page 94.

The ALTER INDEX statement can be embedded in an application program or issued interactively. For details on the ALTER INDEX statement, see Chapter 5 of *DB2 SQL Reference*.

### Adding a new column to an index

When you use ALTER INDEX to add a new column to an existing index, the new column becomes the rightmost column of the index key. If the column that is being added to the index is already part of the table on which the index is defined, the index is left in a REBUILD-pending (RBDP) status. However, if you add a new column to a table and to an existing index on that table within the same unit of work, the index is left in advisory REORG-pending (AREO\*) status and can be used immediately for data access.

For example, assume that you have a table that was created with columns that include ACCTID, STATE, and POSTED:

```
CREATE TABLE TRANS
  (ACCTID ...,
   STATE ...,
   POSTED ...,
   ... , ...)
...;
```

You have an existing index on the STATE column:

```
CREATE INDEX STATE_IX ON TRANS(STATE);
```

To add a ZIPCODE column to the table and the index, issue the following statements:

```
ALTER TABLE TRANS ADD COLUMN ZIPCODE CHAR(5);
ALTER INDEX STATE_IX ADD COLUMN (ZIPCODE);
COMMIT;
```

Because the ALTER TABLE and ALTER INDEX statements are executed within the same unit of work, DB2 can use the new index with the key STATE, ZIPCODE immediately for data access.

**Restriction:** You cannot add a column to an index that enforces a primary key, unique key, or referential constraint.

## Altering how varying-length index columns are stored

You can use the ALTER INDEX statement to change how varying-length column values are stored in an index:

- Use the NOT PADDED clause if you do not want column values to be padded to their maximum length.

This clause specifies that VARCHAR and VARGRAPHIC columns of an existing index are stored as varying-length columns. NOT PADDED is the default.

- Use the PADDED clause if you want column values to be padded to the maximum lengths of the columns.

This clause specifies that VARCHAR and VARGRAPHIC columns of an existing index are stored as fixed-length columns.

The ALTER INDEX statement is successful only if the index has at least one varying-length column.

When you alter the padding attribute of an index, the index is placed into a restricted REBUILD-pending (RBDP) state. When you alter the padding attribute of a nonpartitioned secondary index (NPSI), the index is placed into a page set REBUILD-pending (PSRBD) state. In both cases, the indexes cannot be accessed until they are rebuilt from the data.

## Altering the clustering index

You can use the ALTER INDEX statement to change the clustering index for a table:

- CLUSTER indicates that the index is to be used as the clustering index of the table. The change takes effect immediately. Any subsequently inserted rows use the new clustering index. Existing data remains clustered by the previous clustering index until the table space is reorganized.
- NOT CLUSTER indicates that the index is not to be used as the clustering index of the table. However, if the index was previously defined as the clustering index, it continues to be used as the clustering index until you explicitly specify CLUSTER for a different index.

## Rebalancing data in partitioned table spaces

When data becomes out of balance in partitioned table spaces, performance can decrease. It is possible to improve performance by rebalancing the partitions to redistribute the data.

If an index established the partitions for the table space, you can use the ALTER INDEX statement for that index and a REORG job to shift data among the affected

partitions. The result is that data is balanced according to your specifications. You can rebalance data by changing the limit key values of all or most of the partitions. The limit key is the highest value of the index key for a partition. You roll the changes through the partitions one or more at a time, making relatively small parts of the data unavailable at any given time. For more information about rebalancing data for index-controlled partitioned table spaces by using the ALTER INDEX statement, see *The Official Introduction to DB2 UDB for z/OS*.

In addition, for index-controlled and table-controlled partitioned table spaces, you can use the REBALANCE option of the REORG TABLESPACE utility to shift data among the partitions. When you use REORG TABLESPACE with REBALANCE, DB2 automatically changes the limit key values for the partitioned table space.

## Dropping and redefining an index

Dropping an index does not cause DB2 to drop any other objects. The consequence of dropping indexes is that DB2 invalidates application plans and packages that use the index and automatically rebinds them when they are next used.

If you want to drop a unique index, you must take additional steps before running a DROP INDEX statement. Any primary key, unique key, or referential constraints associated with the unique index must be dropped before you drop the unique index. However, you can drop a unique index for a unique key without dropping the unique constraint if the unique key was created before Version 8.

You must commit the DROP INDEX statement before you create any new table spaces or indexes by the same name. If an index is dropped and then an application program using that index is run (and thereby automatically rebound), that application program does not use the old index. If, at a later time, the index is re-created, and the application program is not rebound, the application program cannot take advantage of the new index.

## Index versions

DB2 creates at least one index version each time you commit one of the following schema changes:

- Change the data type of a non-numeric column that is contained in one or more indexes by using the ALTER TABLE statement  
DB2 creates a new index version for each index that is affected by this operation.
- Change the length of a VARCHAR column that is contained in one or more PADDED indexes by using the ALTER TABLE statement  
DB2 creates a new index version for each index that is affected by this operation.
- Add a column to an index by using the ALTER INDEX statement  
DB2 creates one new index version, because only one index is affected by this operation.

**Exceptions:** DB2 does not create an index version under the following circumstances:

- When the index was created with DEFINE NO
- When you extend the length of a varying character (varchar data type) or varying graphic (vargraphic data type) column that is contained in one or more NOT PADDED indexes
- When you specify the same data type and length that a column—which is contained in one or more indexes—currently has, such that its definition does not actually change

DB2 creates only one index version if, in the same unit of work, you make multiple schema changes to columns contained in the same index. If you make these same schema changes in separate units of work, each change results in a new index version.

**Reorganizing indexes:** DB2 uses index versions to maximize data availability. Index versions enable DB2 to keep track of schema changes and simultaneously, provide users with access to data in altered columns that are contained in one or more indexes. When users retrieve rows from a table with an altered column, the data is displayed in the format that is described by the most recent schema definition, even though the data is not currently stored in this format. The most recent schema definition is associated with the *current* index version.

Although data availability is maximized by the use of index versions, performance might suffer because DB2 does not automatically reformat the data in the index to conform to the most recent schema definition. DB2 defers any reformatting of existing data until you reorganize the index and apply the schema changes with the REORG INDEX utility. The more ALTER statements (which affect indexes) that you commit between reorganizations, the more index versions DB2 must track, and the more performance can suffer.

**Recommendation:** Run the REORG INDEX utility as soon as possible after a schema change that affects an index to correct any performance degradation that might occur and to keep performance at its highest level.

**Recycling index version numbers:** DB2 can store up to 16 index versions, numbered sequentially from 0 to 15. (The next consecutive version number after 15 is 1. Version number 0 is never reused; it is reserved for the original version of the index.) The versions that are associated with schema changes that have not been applied yet are considered to be “in use,” and the range of used versions is stored in the catalog. In-use versions can be recovered from image copies of the table space, if necessary. To determine the range of version numbers currently in use for an index, query the OLDEST\_VERSION and CURRENT\_VERSION columns of the SYSIBM.SYSINDEXES catalog table.

To prevent DB2 from running out of index version numbers (and to prevent subsequent ALTER statements from failing), you must recycle unused index version numbers regularly:

- For indexes defined as COPY YES, run the MODIFY RECOVERY utility.  
If all reusable version numbers (1 to 15) are currently in use, you must reorganize the index by running REORG INDEX before you can recycle the version numbers.
- For indexes defined as COPY NO, run the REORG TABLESPACE, REORG INDEX, LOAD REPLACE, or REBUILD INDEX utility.  
These utilities recycle the version numbers in the process of performing their primary functions.

Version numbers are considered to be unused if the schema changes that are associated with them have been applied and there are no image copies that contain data at those versions. For more information about managing index version numbers, see *DB2 Utility Guide and Reference*.

---

## Altering views

In many cases, changing user requirements can be satisfied by modifying an existing view. But no ALTER VIEW statement exists; the only way to change a view is by dropping the view, committing the drop, and re-creating the view. When you drop a view, DB2 also drops the dependent views.

When you drop a view, DB2 invalidates application plans and packages that are dependent on the view and revokes the privileges of users who are authorized to use it. DB2 attempts to rebind the package or plan the next time it is executed, and you receive an error if you do not re-create the view.

To tell how much rebinding and reauthorizing is needed if you drop a view, check the catalog tables in Table 21.

*Table 21. Catalog tables to check after dropping a view*

Catalog table	What to check
SYSIBM.SYSPLANDEP	Application plans dependent on the view
SYSIBM.SYSPACKDEP	Packages dependent on the view
SYSIBM.SYSVIEWDEP	Views dependent on the view
SYSIBM.SYSTABAUTH	Users authorized to use the view

For more information about defining and dropping views, see Chapter 5 of *DB2 SQL Reference*.

---

## Altering stored procedures

The ALTER PROCEDURE statement updates the description of a stored procedure. This example changes SYSPROC.MYPROC to run only in the WLM environment PARTSEC:

```
ALTER PROCEDURE SYSPROC.MYPROC
  WLM ENVIRONMENT PARTSEC;
```

If SYSPROC.MYPROC is defined with SECURITY DEFINER, the external security environment for the stored procedure uses the authorization ID of the owner of the stored procedure. This example changes the procedure to use the authorization ID of the person running it:

```
ALTER PROCEDURE SYSPROC.MYPROC
  SECURITY USER;
```

---

## Altering user-defined functions

The ALTER FUNCTION statement updates the description of user-defined functions. Changes take effect immediately.

In this example, two functions named CENTER exist in the SMITH schema. The first function has two input parameters with INTEGER and FLOAT data types, respectively. The specific name for the first function is FOCUS1. The second function has three parameters with CHAR(25), DEC(5,2), and INTEGER data types.

Using the specific name to identify the function, change the WLM environment in which the first function runs from WLMENVNAME1 to WLMENVNAME2:

```
ALTER SPECIFIC FUNCTION SMITH.FOCUS1
  WLM ENVIRONMENT WLMENVNAME2;
```

This example changes the second function when any arguments are null:

```
ALTER FUNCTION SMITH.CENTER (CHAR(25), DEC(5,2), INTEGER)
  RETURNS ON NULL CALL;
```

---

## Moving from index-controlled to table-controlled partitioning

This section describes how you can:

- Change an existing index-controlled partitioned table space to a table-controlled partitioned table space.

For a description of table-controlled partitioning, see “Implementing table-controlled partitioning” on page 51.

- Implement a partitioned clustering index on a table-controlled partitioned table space so that the index clusters the data within each partition.

This type of index is called a *data-partitioned secondary index* (DPSI). For more information about DPSIs, see “Data-partitioned secondary index (DPSI)” on page 56.

**Example:** Assume that you have a very large transaction table named TRANS that contains one row for each transaction. The table includes the following columns:

- ACCTID, which is the customer account ID
- POSTED, which holds the date of the transaction

The table space that contains TRANS is divided into 13 partitions, each of which contains one month of data. Two existing indexes are defined as follows:

- A partitioning index is defined on the transaction date by the following CREATE INDEX statement with a PARTITION ENDING AT clause:

```
CREATE INDEX IX1 ON TRANS(POSTED)
  CLUSTER
  (PARTITION 1 ENDING AT ('01/31/2002'),
   PARTITION 2 ENDING AT ('02/28/2002'),
   ...
   PARTITION 13 ENDING AT ('01/31/2003'));
```

The partitioning index is the clustering index, and the data rows in the table are in order by the transaction date. The partitioning index controls the partitioning of the data in the table space.

- A nonpartitioning index is defined on the customer account ID:

```
CREATE INDEX IX2 ON TRANS(ACCTID);
```

DB2 usually accesses the transaction table through the customer account ID by using the nonpartitioning index IX2. The partitioning index IX1 is not used for data access and is wasting space. In addition, you have a critical requirement for availability on the table, and you want to be able to run an online REORG job at the partition level with minimal disruption to data availability.

To save space and to facilitate reorganization of the table space, you can drop the partitioning index IX1, and you can replace the access index IX2 with a partitioned clustering index that matches the 13 data partitions in the table.

Issue the following statements:

```
DROP INDEX IX1;
CREATE INDEX IX3 ON TRANS(ACCTID)
  PARTITIONED CLUSTER;
```

```
COMMIT;  
  
DROP INDEX IX2;  
COMMIT;
```

**What happens:**

- When you drop the partitioning index IX1, DB2 converts the table space from index-controlled partitioning to table-controlled partitioning. DB2 changes the high limit key value that was originally specified to the highest value for the key column.
- When you create the index IX3, DB2 creates a partitioned index with 13 partitions that match the 13 data partitions in the table. Each index partition contains the account numbers for the transactions during that month, and those account numbers are ordered within each partition. For example, partition 11 of the index matches the table partition that contains the transactions for November, 2002, and it contains the ordered account numbers of those transactions.
- You drop the nonpartitioning index IX2 because it has been replaced by IX3.

You can now run an online REORG at the partition level with minimal impact on availability. For example:

```
REORG TABLESPACE dbname.tsname PART 11  
SHRLEVEL CHANGE
```

Running this utility reorganizes the data for partition 11 of *dbname.tsname*. The data rows are ordered within each partition to match the ordering of the clustering index.

**Recommendation:**

- Drop a partitioning index if it is used only to define partitions. When you drop a partitioning index, DB2 automatically converts the associated index-controlled partitioned table space to a table-controlled partitioned table space.
- You can create a data-partitioned secondary index (DPSI) as the clustering index so that the data rows are ordered within each partition of the table space to match the ordering of the keys of the DPSI.
- Create any new tables in a partitioned table space by using the PARTITION BY clause and the PARTITION ENDING AT clause in the CREATE TABLE statement to specify the partitioning key and the limit key values.

---

## Changing the high-level qualifier for DB2 data sets

The high-level qualifier for DB2 data sets is the catalog name of the integrated catalog facility, which is commonly called the “user catalog”. You cannot change this qualifier for DB2 data sets using the DB2 installation or migration update process. This section describes other ways to change this qualifier for both system data sets and user data sets.

These procedures do not actually move or copy data. For information about moving data, see “Moving DB2 data” on page 105.

Changing the high-level qualifier for DB2 data sets is a complex task; so, you should have experience both with DB2 and with managing user catalogs. The following tasks are described:

- “Defining a new integrated catalog alias” on page 99

- “Changing the qualifier for system data sets,” which includes the DB2 catalog, directory, active and archive logs, and the BSDS
- “Changing qualifiers for other databases and user data sets” on page 102, which includes the work file database (DSNDB07), the default database (DSNDB04), and other DB2 databases and user databases

To concentrate on DB2-related issues, this procedure assumes that the catalog alias resides in the *same* user catalog as the one that is currently used. If the new catalog alias resides in a *different* user catalog, see *DFSMS/MVS: Access Method Services for the Integrated Catalog* for information about planning such a move.

If the data sets are managed by the Storage Management Subsystem (SMS), make sure that automatic class selection routines are in place for the new data set name.

## Defining a new integrated catalog alias

This step can be done at any time before changing the high-level qualifier for system or user data sets.

Set up the new high-level qualifier as an alias to a current integrated catalog, using the following access method services command:

```
DEFINE ALIAS (NAME (newcat) RELATE (usercat) CATALOG (master-cat))
```

See *DFSMS/MVS: Access Method Services for the Integrated Catalog* for more information.

## Changing the qualifier for system data sets

In this task, you stop DB2, change the high-level qualifier in the system parameter load module (possibly DSNZPARM), and establish a new xxxxMSTR cataloged procedure before restarting DB2. These steps must be done in sequence.

### Step 1: Change the load module to reflect the new qualifier

To change the system parameter load module to specify the new qualifier for new archive data sets and the DB2 catalog and directory data sets, you must use the installation process.

1. Run the installation CLIST, and specify INSTALL TYPE=INSTALL and DATA SHARING FUNCTION=NONE.
2. Enter new values for the fields shown in Table 22.

Table 22. CLIST panels and fields to change to reflect new qualifier

Panel name	Field name	Comments
DSNTIPA1	INSTALL TYPE	Specify INSTALL. Do <i>not</i> specify a new default prefix for the input data sets listed on this panel.
DSNTIPA1	OUTPUT MEMBER NAME	
DSNTIPA2	CATALOG ALIAS	
DSNTIPH	COPY 1 NAME and COPY 2 NAME	These are the bootstrap data set names.
DSNTIPH	COPY 1 PREFIX and COPY 2 PREFIX	These fields appear for both active and archive log prefixes.

Table 22. CLIST panels and fields to change to reflect new qualifier (continued)

Panel name	Field name	Comments
DSNTIPT	SAMPLE LIBRARY	This field allows you to specify a field name for edited output of the installation CLIST. Avoid overlaying existing data sets by changing the middle node, NEW, to something else. The only members you use in this procedure are xxxxMSTR and DSNTIJUZ in the sample library.
DSNTIPO	PARAMETER MODULE	Change this value only if you want to preserve the existing member through the CLIST.

The output from the CLIST is a new set of tailored JCL with new cataloged procedures and a DSNTIJUZ job, which produces a new member.

- #
- #
- #
- #
- #
- #
- #
- #
- #
- #
- #
- #
- #
3. Run the first two job steps of DSNTIJUZ to update the subsystem parameter load module. Unless you have specified a new name for the load module, make sure the output load module does not go to the SDSNEXIT or SDSNLOAD library used by the active DB2 subsystem.
- If you are changing the subsystem ID in addition to the system data set name qualifier, you should also run job steps DSNTIZP and DSNTIZQ to update the DSNHDECP module (zparm parameter SSID). Make sure that the updated DSNHDECP module does not go to the SDSNEXIT or SDSNLOAD library used by the active DB2 subsystem. Use caution when changing the subsystem ID. For more information, see the heading "MVS PARMLIB updates panel: DSNTIPM" for the discussion of panel DSNTIPM for PARMLIB members where the subsystem ID has to be changed.
- Do not run the remaining steps of DSNTIJUZ.

## Step 2: Stop DB2 with no outstanding activity

In this step, make sure the subsystem does not have any outstanding activity, such as outstanding units of recovery or pending writes. This ensures that DB2 does not need to access the data sets on restart through the log, which contains the *old* data set qualifiers.

- Enter the following command:  
-STOP DB2 MODE(QUIESCE)  
This command allows DB2 to complete processing currently executing programs.
- Enter the following command:  
-START DB2 ACCESS(MAINT)
- Use the following commands to make sure the subsystem is in a consistent state. See Part 4, "Operation and recovery," on page 311 and Chapter 2 of *DB2 Command Reference* for more information about these commands.  
-DISPLAY THREAD(\*) TYPE(\*)  
-DISPLAY UTILITY (\*)  
-TERM UTILITY(\*)  
-DISPLAY DATABASE(\*) RESTRICT  
-DISPLAY DATABASE(\*) SPACENAM(\*) RESTRICT  
-RECOVER INDOUBT  
Correct any problems before continuing.
- Stop DB2, using the following command:  
-STOP DB2 MODE(QUIESCE)

5. Run the print log map utility (DSNJU004) to identify the current active log data set and the last checkpoint RBA. For information about the print log map utility, see Part 3 of *DB2 Utility Guide and Reference*.
6. Run DSN1LOGP with the SUMMARY (YES) option, using the last checkpoint RBA from the output of the print log map utility you ran in the previous step. For information about DSN1LOGP, see Part 3 of *DB2 Utility Guide and Reference*.  
The report headed DSN1157I RESTART SUMMARY identifies active units of recovery or pending writes. If either situation exists, do not attempt to continue. Start DB2 with ACCESS(MAINT), use the necessary commands to correct the problem, and repeat steps 4 through 6 until all activity is complete.

### Step 3: Rename system data sets with the new qualifier

All of the following steps assume that the new qualifier and the old qualifier reside in the same user catalog. Access method services does not allow ALTER where the new name does not match the existing catalog structure for an SMS-managed VSAM data set. If the data set is not managed by SMS, the rename succeeds, but DB2 cannot allocate it as described in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

DB2 table spaces are defined as linear data sets with DSNDBC as the second node of the name for the cluster and DSNDBD for the data component (as described in “Requirements for your own data sets” on page 38). The examples shown here assume the normal defaults for DB2 and VSAM data set names. Use access method services statements with a generic name (\*) to simplify the process. Access method services allows only one generic name per data set name string.

1. Using IDCAMS, change the names of the catalog and directory table spaces.  
Also, be sure to specify the instance qualifier of your data set, *y*, which can be either I or J:

```
ALTER oldcat.DSNDBC.DSNDB01.*.y0001.A001 -
  NEWNAME (newcat.DSNDBC.DSNDB01.*.y0001.A001)
ALTER oldcat.DSNDBD.DSNDB01.*.y0001.A001 -
  NEWNAME (newcat.DSNDBD.DSNDB01.*.y0001.A001)
ALTER oldcat.DSNDBC.DSNDB06.*.y0001.A001 -
  NEWNAME (newcat.DSNDBC.DSNDB06.*.y0001.A001)
ALTER oldcat.DSNDBD.DSNDB06.*.y0001.A001 -
  NEWNAME (newcat.DSNDBD.DSNDB06.*.y0001.A001)
```

2. Using IDCAMS, change the active log names. Active log data sets are named *oldcat.LOGCOPY1.COPY01* for the cluster component and *oldcat.LOGCOPY1.COPY01.DATA* for the data component.

```
ALTER oldcat.LOGCOPY1.* -
  NEWNAME (newcat.LOGCOPY1.*)
ALTER oldcat.LOGCOPY1.*.DATA -
  NEWNAME (newcat.LOGCOPY1.*.DATA)
ALTER oldcat.LOGCOPY2.* -
  NEWNAME (newcat.LOGCOPY2.*)
ALTER oldcat.LOGCOPY2.*.DATA -
  NEWNAME (newcat.LOGCOPY2.*.DATA)
```

3. Using IDCAMS, change the BSDS names.

```
ALTER oldcat.BSDS01 -
  NEWNAME (newcat.BSDS01)
ALTER oldcat.BSDS01.* -
  NEWNAME (newcat.BSDS01.*)
ALTER oldcat.BSDS02 -
  NEWNAME (newcat.BSDS02)
ALTER oldcat.BSDS02.* -
  NEWNAME (newcat.BSDS02.*)
```

## Step 4: Update the BSDS with the new qualifier

Update the first BSDS with the new alias and correct data set names for the active logs. This procedure does not attempt to change the names of existing archive log data sets. If these catalog entries or data sets will not be available in the future, copy all the table spaces in the DB2 subsystem to establish a new recovery point. You can optionally delete the entries from the BSDS. If you do not delete the entries, they will gradually be replaced by newer entries.

1. Run the change log inventory utility (DSNJU003).

Use the new qualifier for the BSDS because it has now been renamed. The following example illustrates the control statements required for three logs and dual copy is specified for the logs. This is only an example; the number of logs can vary and dual copy is an option. The starting and ending log RBAs are from the print log map report.

```
NEWCAT VSAMCAT=newcat
DELETE DSNNAME=oldcat.LOGCOPY1.DS01
DELETE DSNNAME=oldcat.LOGCOPY1.DS02
DELETE DSNNAME=oldcat.LOGCOPY1.DS03
DELETE DSNNAME=oldcat.LOGCOPY2.DS01
DELETE DSNNAME=oldcat.LOGCOPY2.DS02
DELETE DSNNAME=oldcat.LOGCOPY2.DS03
NEWLOG DSNNAME=newcat.LOGCOPY1.DS01,COPY1,STARTRBA=strtrba,ENDRBA=endrba
NEWLOG DSNNAME=newcat.LOGCOPY1.DS02,COPY1,STARTRBA=strtrba,ENDRBA=endrba
NEWLOG DSNNAME=newcat.LOGCOPY1.DS03,COPY1,STARTRBA=strtrba,ENDRBA=endrba
NEWLOG DSNNAME=newcat.LOGCOPY2.DS01,COPY2,STARTRBA=strtrba,ENDRBA=endrba
NEWLOG DSNNAME=newcat.LOGCOPY2.DS02,COPY2,STARTRBA=strtrba,ENDRBA=endrba
NEWLOG DSNNAME=newcat.LOGCOPY2.DS03,COPY2,STARTRBA=strtrba,ENDRBA=endrba
```

During startup, DB2 compares the *newcat* value with the value in the system parameter load module, and they must be the same.

2. Using the IDCAMS REPRO command, replace the contents of BSDS2 with the contents of BSDS01.
3. Run the print log map utility (DSNJU004) to verify your changes to the BSDS.
4. At a convenient time, change the DD statements for the BSDS in any of your offline utilities to use the new qualifier.

## Step 5: Establish a new xxxxMSTR cataloged procedure

Before you start DB2, follow these steps:

1. Update xxxxMSTR in SYS1.PROCLIB with the new BSDS data set names.
2. Copy the new system parameter load module to the active SDSNEXIT/SDSNLOAD library.

## Step 6: Start DB2 with the new xxxxMSTR and load module

Use the START DB2 command with the new load module name as shown here:

```
-START DB2 PARM(new_name)
```

If you stopped DSNDB01 or DSNDB06 in “Step 2: Stop DB2 with no outstanding activity” on page 100, you must explicitly start them in this step.

## Changing qualifiers for other databases and user data sets

This step changes qualifiers for DB2 databases other than the catalog and directory. DSNDB07 is a system database but contains no permanent data, and can be deleted and redefined with the new qualifier. If you are changing its qualifier, do that before the rest of the user databases.

Change the databases in the following list that apply to your environment:

- DSNDB07 (work file database)

- DSNDB04 (default database)
- DSNDDF (communications database)
- DSNRLST (resource limit facility database)
- DSNRGFDB (the database for data definition control)
- Any other application databases that use the old high-level qualifier

At this point, the DB2 catalog tables SYSSTOGROUP, SYSTABLEPART, and SYSINDEXPART contain information about the old integrated user catalog alias. To update those tables with the new alias, you must use the following procedures. Until you do so, the underlying resources are not available. The following procedures are described separately:

- “Changing your work database to use the new high-level qualifier”
- “Changing user-managed objects to use the new qualifier” on page 104
- “Changing DB2-managed objects to use the new qualifier” on page 104

Table spaces and indexes that span more than one data set require special procedures. Partitioned table spaces can have different partitions allocated to different DB2 storage groups. Nonpartitioned table spaces or indexes only have the additional data sets to rename (those with the lowest level name of A002, A003, and so on).

### Changing your work database to use the new high-level qualifier

You can use one of two methods to change the high-level qualifier for your work database or possibly DSNDB07. Which method you use depends on if you have a new installation or a migrated installation.

#### *New installation:*

1. Reallocate the database using the installation job DSNTIJTM from *prefix.SDSNSAMP*
2. Modify your existing job. Change the job to remove the BIND step for DSNTIAD and rename the data set names in the DSNTTMP step to your new names, making sure you include your current allocations.

*Migrated installations:* Migrated installations do not have a usable DSNTIJTM, because the IDCAMS allocation step is missing. For migrated installations, you must:

1. Stop the database, using the following command (for a database named DSNDB07):
2. Drop the database, using the following SQL statement:
3. Re-create the database, using the following SQL statement:
4. Define the clusters, using the following access method services commands. Also, be sure to specify the instance qualifier of your data set, *y*, which can be either I or J:

```
ALTER oldcat.DSNDBC.DSNDB07.DSN4K01.y0001.A001
NEWNAME newcat.DSNDBC.DSNDB07.DSN4K01.y0001.A001
ALTER oldcat.DSNDBC.DSNDB07.DSN32K01.y0001.A001
NEWNAME newcat.DSNDBC.DSNDB07.DSN32K01.y0001.A001
```

Repeat the preceding statements (with the appropriate table space name) for as many table spaces as you use.

5. Create the table spaces in DSNDB07.

```

CREATE TABLESPACE DSN4K01
  IN DSNDB07
  BUFFERPOOL BP0
  CLOSE NO
  USING VCAT DSNC810;
CREATE TABLESPACE DSN32K01
  IN DSNDB07
  BUFFERPOOL BP32K
  CLOSE NO
  USING VCAT DSNC810;

```

6. Start the database, using the following command:  
-START DATABASE (DSNDB07)

### Changing user-managed objects to use the new qualifier

1. Stop the table spaces and index spaces, using the following command:  
-STOP DATABASE(*dbname*) SPACENAM(\*)
2. Use the following SQL ALTER TABLESPACE and ALTER INDEX statements with the USING clause to specify the new qualifier:

```

ALTER TABLESPACE dbname.tsname
  USING VCAT newcat;
ALTER INDEX creator.index-name
  USING VCAT newcat;

```

Repeat this step for all the objects in the database.

3. Using IDCAMS, rename the data sets to the new qualifier. Also, be sure to specify the instance qualifier of your data set, *y*, which can be either I or J:

```

ALTER oldcat.DSNDBC.dbname.*.y0001.A001 -
  NEWNAME newcat.DSNDBC.dbname.*.y0001.A001
ALTER oldcat.DSNDBD.dbname.*.y0001.A001 -
  NEWNAME newcat.DSNDBD.dbname.*.y0001.A001

```

4. Start the table spaces and index spaces, using the following command:  
-START DATABASE(*dbname*) SPACENAM(\*)
5. Verify the success of the procedure by entering the following command:  
-DISPLAY DATABASE(*dbname*)
6. Using SQL, verify that you can access the data.

Renaming the data sets can be done while DB2 is down. They are included here because the names must be generated for each database, table space, and index space that is to change.

### Changing DB2-managed objects to use the new qualifier

Use this procedure when you want to keep the existing DB2 storage group, changing only the high-level qualifier. If you want to move the data to a new DB2 storage group, see “Moving a DB2 data set” on page 108.

1. Remove all table spaces and index spaces from the storage group by converting the data sets temporarily to user-managed data sets.
  - a. Stop each database that has data sets you are going to convert, using the following command:  
-STOP DATABASE(*dbname*) SPACENAM(\*)

```

#
#
#
#

```

**Note:** Some databases (such as DSNRTSDB) will have to be explicitly stopped to allow any alterations. For these, use the following command:  
-STOP DATABASE(*dbname*)

- b. Convert to user-managed data sets with the USING VCAT clause of the SQL ALTER TABLESPACE and ALTER INDEX statements, as shown in the following statements. Use the new catalog name for VCAT.

```
ALTER TABLESPACE dbname.tsname
    USING VCAT newcat;

ALTER INDEX creator.index-name
    USING VCAT newcat;
```

2. Drop the storage group, using the following statement:

```
DROP STOGROUP stogroup-name;
```

The DROP succeeds only if all the objects that referenced this STOGROUP are dropped or converted to user-managed (USING VCAT clause).

3. Re-create the storage group using the correct volumes and the new alias, using the following statement:

```
CREATE STOGROUP stogroup-name
    VOLUMES (VOL1,VOL2)
    VCAT newcat;
```

4. Using IDCAMS, rename the data sets for the index spaces and table spaces to use the new high-level qualifier. Also, be sure to specify the instance qualifier of your data set, *y*, which can be either I or J:

```
ALTER oldcat.DSNDBC.dbname.*.y0001.A001 -
    NEWNAME newcat.DSNDBC.dbname.*.y0001.A001
ALTER oldcat.DSNDBD.dbname.*.y0001.A001 -
    NEWNAME newcat.DSNDBD.dbname.*.y0001.A001
```

If your table space or index space spans more than one data set, be sure to rename those data sets also.

5. Convert the data sets back to DB2-managed data sets by using the new DB2 storage group. Use the following SQL ALTER TABLESPACE and ALTER INDEX statements:

```
ALTER TABLESPACE dbname.tsname
    USING STOGROUP stogroup-name
    PRIQTY priqty
    SECQTY secqty;

ALTER INDEX creator.index-name
    USING STOGROUP stogroup-name
    PRIQTY priqty
    SECQTY secqty;
```

If you specify USING STOGROUP without specifying the PRIQTY and SECQTY clauses, DB2 uses the default values. For more information about USING STOGROUP, see *DB2 SQL Reference*.

6. Start each database, using the following command:

```
-START DATABASE(dbname) SPACENAM(*)
```

7. Verify the success of the procedure by entering the following command:

```
-DISPLAY DATABASE(dbname)
```

8. Using SQL, verify that you can access the data.

---

## Moving DB2 data

This section discusses the following topics:

- “Tools for moving DB2 data” on page 106 introduces some of the tools available to make moving DB2 data easier.
- “Moving a DB2 data set” on page 108 describes moving a data set from one volume to another.

- “Copying a relational database” on page 109 describes copying a user-managed relational database, with its object definitions and its data, from one DB2 subsystem to another, on the same or different z/OS system.
- “Copying an entire DB2 subsystem” on page 109 describes copying a DB2 subsystem from one z/OS system to another. Copying a subsystem includes these items:
  - All the user data and object definitions
  - The DB2 system data sets:
    - The log
    - The bootstrap data set
    - Image copy data sets
    - The DB2 catalog
    - The integrated catalog that records all the DB2 data sets

## Tools for moving DB2 data

**Important:** Before copying any DB2 data, resolve any data that is in an inconsistent state. Use the DISPLAY DATABASE command to determine whether any inconsistent state exists, and the RECOVER INDOUBT command or the RECOVER utility to resolve the inconsistency. The copying process generally loses all traces of an inconsistency except the problems that result.

Although DB2 data sets are created using VSAM access method services, they are specially formatted for DB2 and cannot be processed by services that use VSAM record processing. They can be processed by VSAM utilities that use control-interval (CI) processing and, if they are linear data sets (LDSs), also by utilities that recognize the LDS type.

Furthermore, copying the data might not be enough. Some operations require copying DB2 object definitions. And when copying from one subsystem to another, you must consider internal values that appear in the DB2 catalog and the log, for example, the DB2 object identifiers (OBIDs) and log relative byte addresses (RBAs).

Fortunately, several tools exist that simplify the operations:

- The REORG and LOAD utilities move data sets from one disk device type to another within the same DB2 subsystem. For instructions on using LOAD and REORG, see Part 2 of *DB2 Utility Guide and Reference*.  
The INCURSOR option of the LOAD utility allows you to specify a cursor to select data from another DB2 table or tables, which can be on a remote DB2 system. Use the EXEC SQL utility control statement to declare the cursor before executing the LOAD utility. This option uses the DB2 UDB family cross-loader function.
- The COPY and RECOVER utilities allow you to recover an image copy of a DB2 table space or index space onto another disk device within the same subsystem. For instructions on using COPY and RECOVER, see Part 2 of *DB2 Utility Guide and Reference*.
- The UNLOAD or REORG UNLOAD EXTERNAL utility unloads a DB2 table into a sequential file and generates statements to allow the LOAD utility to load it elsewhere. For instructions on using UNLOAD or REORG UNLOAD EXTERNAL, see *DB2 Utility Guide and Reference*.
- The DSN1COPY utility copies the data set for a table space or index space to another data set. It can also translate the object identifiers and reset the log RBAs in the target data set. When you use the OBIDLAT option of DSN1COPY to move objects from one system to another, use REPAIR VERSIONS to update

the version information in the catalog and directory for the target table space or index. For instructions, see Part 3 of *DB2 Utility Guide and Reference*.

You might also want to use the following tools to move DB2 data:

- The DB2 DataPropagator is a licensed program that can extract data from DB2 tables, DL/I databases, VSAM files, and sequential files. For instructions, see “Loading data from DL/I” on page 65.
- DFSMS, which contains the following functional components:
  - Data Set Services (DFSMSdss)
 

Use DFSMSdss to copy data between disk devices. For instructions, see *Data Facility Data Set Services: User’s Guide and Reference*. You can use online panels to control this, through the Interactive Storage Management Facility (ISMF) that is available with DFSMS; for instructions, refer to *z/OS DFSMSdss Storage Administration Reference*.
  - Data Facility Product (DFSMSdftp)
 

This is a prerequisite for DB2. You can use access method services EXPORT and IMPORT commands with DB2 data sets when control interval processing (CIMODE) is used. For instructions on EXPORT and IMPORT, see *DFSMS/MVS: Access Method Services for the Integrated Catalog*.
  - Hierarchical Storage Manager (DFSMSHsm)
 

With the MIGRATE, HMIGRATE, or HRECALL commands, which can specify specific data set names, you can move data sets from one disk device type to another within the same DB2 subsystem. Do not migrate the DB2 directory, DB2 catalog, and the work file database (DSNDB07). Do not migrate any data sets that are in use frequently, such as the bootstrap data set and the active log. With the MIGRATE VOLUME command, you can move an entire disk volume from one device type to another. The program can be controlled using online panels, through the Interactive Storage Management Facility (ISMF). For instructions, see *z/OS DFSMSHsm Managing Your Own Data*.

Table 23 shows which tools are applicable to which operations.

*Table 23. Tools applicable to data-moving operations*

<b>Tool</b>	<b>Moving a data set</b>	<b>Copying a data base</b>	<b>Copying an entire subsystem</b>
REORG and LOAD	Yes	Yes	No
COPY and RECOVER	Yes	No	No
DSNTIAUL	Yes	Yes	No
DSN1COPY	Yes	Yes	No
DataRefresher or DXT™	Yes	Yes	No
DFSMSdss	Yes	No	Yes
DFSMSdftp	Yes	No	Yes
DFSMSHsm	Yes	No	No

Some of the listed tools rebuild the table space and index space data sets, and they therefore generally require longer to execute than the tools that merely copy them. The tools that rebuild are REORG and LOAD, RECOVER and REBUILD, DSNTIAUL, and DataRefresher. The tools that merely copy data sets are DSN1COPY, DFSMSdss, DFSMSdftp EXPORT and IMPORT, and DFSMSHsm.

DSN1COPY is fairly efficient in use, but somewhat complex to set up. It requires a separate job step to allocate the target data sets, one job step for each data set to copy the data, and a step to delete or rename the source data sets. DFSMSdss, DFSMSdftp, and DFSMSHsm all simplify the job setup significantly.

Although less efficient in execution, RECOVER is easy to set up if image copies and recover jobs already exist. You might only need to redefine the data sets involved and recover the objects as usual.

## Moving a DB2 data set

Moving DB2 data is accomplished by RECOVER, REORG, or DSN1COPY, or by the use of non-DB2 facilities, such as DFSMSdss. Both the DB2 utilities and the non-DB2 tools can be used while DB2 is running, but the space to be moved should be stopped to prevent users from accessing it.

The following procedures differ mainly in that the first one assumes you do not want to reorganize or recover the data. Generally, this means that the first procedure is faster. In all cases, make sure that there is enough space on the target volume to accommodate the data set.

**If you use storage groups**, then you can change the storage group definition to include the new volumes, as described in “Altering DB2 storage groups” on page 67.

### *Moving data without REORG or RECOVER:*

1. Stop the database.
2. Move the data, using DSN1COPY or a non-DB2 facility.
3. Issue the ALTER INDEX or ALTER TABLESPACE statement to use the new integrated catalog facility catalog name or DB2 storage group name.
4. Start the database.

**Moving DB2-managed data with REORG, RECOVER, or REBUILD:** With this procedure you create a storage group (possibly using a new catalog alias) and move the data to that new storage group.

1. Create a new storage group using the correct volumes and the new alias, as shown in the following statement:

```
CREATE STOGROUP stogroup-name
  VOLUMES (VOL1,VOL2)
  VCAT (newcat);
```

2. Prevent access to the data sets you are going to move, by entering the following command:  
-STOP DATABASE(*dbname*) SPACENAM(\*)
3. Enter the ALTER TABLESPACE and ALTER INDEX SQL statements to use the new storage group name, as shown in the following statements:

```
ALTER TABLESPACE dbname.tsname
  USING STOGROUP stogroup-name;
ALTER INDEX creator.index-name
  USING STOGROUP stogroup-name;
```

4. Using IDCAMS, rename the data sets for the index spaces and table spaces to use the new high-level qualifier. Also, be sure to specify the instance qualifier of your data set, *y*, which can be either I or J. If you have run REORG with SHRLEVEL CHANGE or SHRLEVEL REFERENCE on any table spaces or index spaces, the fifth-level qualifier might be J0001.

```
ALTER oldcat.DSNDBC.dbname.*.y0001.A001 -  
  NEWNAME newcat.DSNDBC.dbname.*.y0001.A001  
ALTER oldcat.DSNDBD.dbname.*.y0001.A001 -  
  NEWNAME newcat.DSNDBD.dbname.*.y0001.A001
```

5. Start the database for utility processing only, using the following command:  
-START DATABASE(*dbname*) SPACENAM(\*) ACCESS(UT)
6. Use the REORG or the RECOVER utility on the table space or index space, or use the REBUILD utility on the index space.
7. Start the database, using the following command:  
-START DATABASE(*dbname*) SPACENAM(\*)

## Copying a relational database

This operation involves not only copying data, but finding or generating, and executing, SQL statements to create storage groups, databases, table spaces, tables, indexes, views, synonyms, and aliases.

As with the other operations, DSN1COPY is likely to execute faster than the other applicable tools. It copies directly from one data set to another, while the other tools extract input for LOAD, which then loads table spaces and builds indexes. But again, DSN1COPY is more difficult to set up. In particular, you must know the internal DB2 object identifiers, which other tools translate automatically.

## Copying an entire DB2 subsystem

This operation involves copying an entire DB2 subsystem from one z/OS system to another. (Although you can have two DB2 subsystems on the same z/OS system, one cannot be a copy of the other.)

Only two of the tools listed are applicable: DFSMSdss DUMP and RESTORE, and DFSMSdfp EXPORT and IMPORT. Refer to the documentation on those programs for the most recent information about their use.

---

## Chapter 7. Estimating disk storage for user data

This chapter provides information about how to estimate the amount of disk storage you need for your data, including:

- “Factors that affect storage”
- “Calculating the space required for a table” on page 113
- “Calculating the space required for a dictionary” on page 116
- “Calculating the space required for an index” on page 117

**Recommendation:** Use DB2 Estimator to calculate space estimates for tables, indexes, and factors discussed in this chapter.

---

### Factors that affect storage

The amount of disk space you need for your data is not just the number of bytes of data; the true number is some multiple of that. That is,

$$\text{space required} = M \times (\text{number of bytes of data})$$

The multiplier M depends on your circumstances. It includes factors that are common to all data sets on disk, as well as others that are peculiar to DB2. It can vary significantly, from a low of about 1.25, to 4.0 or more. For a first approximation, set M=2, and skip to “Calculating the space required for a table” on page 113.

# Whether you use extended address volumes (EAV) is also a factor in estimating  
# storage. Although, the EAV factor is not a multiplier, you need to add 10 cylinders  
# for each object in the cylinder-managed space of an EAV. DB2 data sets might take  
# more space or grow faster on EAV compared to non-extended address volumes.  
# The reason is that the allocation unit in the extended addressing space (EAS) of  
# EAV is a multiple of 21 cylinders, and every allocation is rounded up to this  
# multiple. If you use EAV, the data set space estimation for an installation must take  
# this factor into account. The effect is more pronounced for smaller data sets.

For more accuracy, calculate M as the product of the following factors:

- Record overhead
- Free space
- Unusable space
- Data set excess
- Indexes

**Record overhead:** Allows for eight bytes of record header and control data, plus space wasted for records that do not fit exactly into a DB2 page. For the second consideration, see “Choosing a page size” on page 45. The factor can range from about 1.01 (for a careful space-saving design) to as great as 4.0. A typical value is about 1.10.

**Free space:** Allows for space intentionally left empty to allow for inserts and updates. You can specify this factor on the CREATE TABLESPACE statement; see “Specifying free space on pages” on page 658 for more information. The factor can range from 1.0 (for no free space) to 200 (99% of each page used left free, and a free page following each used page). With default values, the factor is about 1.05.

**Unusable space:** Track lengths in excess of the nearest multiple of page lengths. Table 24 shows the track size, number of pages per track, and the value of the unusable-space factor for several different device types.

Table 24. Unusable space factor by device type

Device type	Track size	Pages per track	Factor value
3380	47476	10	1.16
3390	56664	12	1.15

**Data set excess:** Allows for unused space within allocated data sets, occurring as unused tracks or part of a track at the end of any data set. The amount of unused space depends upon the volatility of the data, the amount of space management done, and the size of the data set. Generally, large data sets can be managed more closely, and those that do not change in size are easier to manage. The factor can range without limit above 1.02. A typical value is 1.10.

**Indexes:** Allows for storage for indexes to data. For data with no indexes, the factor is 1.0. For a single index on a short column, the factor is 1.01. If every column is indexed, the factor can be greater than 2.0. A typical value is 1.20. For further discussion of the factor, see “Calculating the space required for an index” on page 117.

Table 25 shows calculations of the multiplier M for three different database designs:

- The *tight* design is carefully chosen to save space and allows only one index on a single, short field.
- The *loose* design allows a large value for every factor, but still well short of the maximum. Free space adds 30% to the estimate, and indexes add 40%.
- The *medium* design has values between the other two. You might want to use these values in an early stage of database design.

In each design, the device type is assumed to be a 3390. Therefore, the unusable-space factor is 1.15. M is always the product of the five factors.

Table 25. Calculations for different database designs

Factor	Tight design	Medium design	Loose design
Record overhead ×	1.02	1.10	1.30
Free space ×	1.00	1.05	1.30
Unusable space ×	1.15	1.15	1.15
Data set excess ×	1.02	1.10	1.30
Indexes =	1.02	1.20	1.40
Multiplier M	1.22	1.75	3.54

In addition to the space for your data, external storage devices are required for:

- Image copies of data sets, which can be on tape
- System libraries, system databases, and the system log
- Temporary work files for utility and sort jobs

A rough estimate of the additional external storage needed is three times the amount calculated for disk storage.

#

Also, you need to add the EAV factor.

---

## Calculating the space required for a table

This section provides information about how to calculate the space required for a table, including:

- “Calculating record lengths and pages”
- “Saving space with data compression” on page 114
- “Estimating storage for LOBs” on page 114
- “Estimating storage when using the LOAD utility” on page 115

Space allocation parameters are specified in kilobytes (KB).

### Calculating record lengths and pages

An important consideration in the design of a table is the record size. In DB2, a record is the storage representation of a row. Records are stored within pages that are 4 KB, 8 KB, 16 KB, or 32 KB. Generally, you cannot create a table in which the maximum record size is greater than the page size.

Also consider:

- Normalizing your entities
- Using larger page sizes
- Using LOB data types if a single column in a table is greater than 32 K

In addition to the bytes of actual data in the row (not including LOB data, which is not stored in the base row or included in the total length of the row), each record has:

- A six-byte prefix
- One additional byte for each column that can contain null values
- Two additional bytes for each varying-length column or ROWID column
- Six bytes of descriptive information in the base table for each LOB column

The sum of each column's length is the *record length*, which is the length of data that is physically stored in the table. You can retrieve the value of the `AVGROWLEN` column in the `SYSIBM.SYSTABLES` catalog table to determine the average length of rows within a table. The *logical record length* can be longer, for example, if the table contains LOBs.

Every data page has:

- A 22-byte header
- A 2-byte directory entry for each record stored in the page

To simplify the calculation of record and page length, consider the directory entry as part of the record. Then, every record has a fixed overhead of 8 bytes, and the space available to store records in a 4 KB page is 4074 bytes. Achieving that maximum in practice is not always simple. For example, if you are using the default values, the LOAD utility leaves approximately 5 percent of a page as free space when loading more than one record per page. Therefore, if two records are to fit in a page, each record cannot be longer than 1934 bytes (approximately  $0.95 \times 4074 \times 0.5$ ).

Furthermore, the page size of the table space in which the table is defined limits the record length. If the table space is 4 KB, the record length of each record cannot be greater than 4056 bytes. Because of the 8-byte overhead for each record, the sum of column lengths cannot be greater than 4048 bytes (4056 minus the 8-byte overhead for a record).

DB2 provides three larger page sizes to allow for longer records. You can improve performance by using pages for record lengths that best suit your needs. For details on selecting an appropriate page size, see “Choosing a page size” on page 45.

As shown in Table 26, the maximum record size for each page size depends on the size of the table space and on whether you specified the EDITPROC clause.

Table 26. Maximum record size (in bytes)

EDITPROC	4-KB page	8-KB page	16-KB page	32-KB page
NO	4056	8138	16330	32714
YES	4046	8128	16320	32704

Creating a table using CREATE TABLE LIKE in a table space of a larger page size changes the specification of LONG VARCHAR to VARCHAR and LONG VARGRAPHIC to VARGRAPHIC. You can also use CREATE TABLE LIKE to create a table with a smaller page size in a table space if the maximum record size is within the allowable record size of the new table space.

## Saving space with data compression

You can reduce the space required for a table by using data compression if your system meets the requirements. To find out how much space you can save by compressing your data, run the DSN1COMP utility on your data sets. Message DSN1940I of DSN1COMP reports an estimate of the percentage of kilobytes that would be saved by using data compression. You cannot compress data in a LOB table space. See Part 3 of *DB2 Utility Guide and Reference* for more information about the DSN1COMP utility.

The disk saved by data compression is countered by the disk required for a *dictionary*. Every compressed table space or partition requires a dictionary. See “Calculating the space required for a dictionary” on page 116 to figure the disk requirements and the virtual storage requirements for a dictionary.

## Estimating storage for LOBs

Tables with large object data types (LOBs) can store byte strings up to 2 GB. A base table can be defined with one or more LOB columns. The LOB columns are logically part of the base table but are physically stored in an auxiliary table. In place of each LOB column, there is an *indicator column*, which is a column with descriptive information about the LOB. When a base table has LOB columns, then each row of the table has a *row identifier*, which is a varying-length 17-byte field. You must consider the overhead of the indicator column and row identifiers when estimating table size. If the LOB column is NULL or has a value of zero, no space is allocated in the auxiliary table.

When estimating the storage required for LOB table spaces, begin with your estimates from other table spaces, round up to the next page size, and then multiply by 1.1. One page never contains more than one LOB. When a LOB value is deleted, the space occupied by that value remains allocated as long as any application might access that value.

An auxiliary table resides in a LOB table space. There can be only one auxiliary table in a LOB table space. An auxiliary table can store only one LOB column of a base table and there must be one and only one index on this column.

See *DB2 Installation Guide* for information about storage options for LOB values.

## Estimating storage when using the LOAD utility

For a table to be loaded by the LOAD utility, the value can be estimated as follows:

- Let FLOOR be the operation of discarding the decimal portion of a real number.
- Let CEILING be the operation of rounding a real number up to the next highest integer.
- Let *number of records* be the total number of records to be loaded.
- Let *average record size* be the sum of the lengths of the fields in each record, using an average value for varying-length fields, and including the following amounts for overhead:
  - 8 bytes for the total record
  - 1 byte for each field that allows nulls
  - 2 bytes for each varying-length field

See the CREATE TABLE statement in Chapter 5 of *DB2 SQL Reference* for information about how many bytes are required for different column types.

- Let *percsave* be the percentage of kilobytes saved by compression (as reported by the DSN1COMP utility in message DSN1940I)
- Let *compression ratio* be  $\text{percsave}/100$

Then calculate as follows:

1. *Usable page size* is the page size minus a number of bytes of overhead (that is, 4 KB – 40 for 4 KB pages, 8 KB – 54 for 8 KB pages, 16 KB – 54 for 16 KB pages, or 32 KB – 54 for 32 KB pages) multiplied by  $(100-p) / 100$ , where  $p$  is the value of PCTFREE. If your average record size is less than 16, then usable page size is 255 (maximum records per page) multiplied by average record size multiplied by  $(100-p) / 100$ .
2. *Records per page* is  $\text{MIN}(\text{MAXROWS}, \text{FLOOR}(\text{usable page size} / \text{average record size}))$ , but cannot exceed 255 and cannot exceed the value you specify for MAXROWS.
3. *Pages used* is  $2 + \text{CEILING}(\text{number of records} / \text{records per page})$ .
4. *Total pages* is  $\text{FLOOR}(\text{pages used} \times (1 + fp) / fp)$ , where  $fp$  is the (nonzero) value of FREEPAGE. If FREEPAGE is 0, then *total pages* is equal to *pages used*. (See “Free space” on page 111 for more information about FREEPAGE.) If you are using data compression, you need additional pages to store the dictionary. See “Calculating the space required for a dictionary” on page 116 to figure how many pages the dictionary requires.
5. Estimated number of kilobytes required for a table:
  - **If you do not use data compression**, the estimated number of kilobytes is  $\text{total pages} \times \text{page size}$  (4 KB, 8 KB, 16 KB, or 32 KB).
  - **If you use data compression**, the estimated number of kilobytes is  $\text{total pages} \times \text{page size}$  (4 KB, 8 KB, 16 KB, or 32 KB)  $\times (1 - \text{compression ratio})$ .

For example, consider a table space containing a single table with the following characteristics:

- *Number of records* = 100000
- *Average record size* = 80 bytes
- *Page size* = 4 KB
- PCTFREE = 5 (5% of space is left free on each page)
- FREEPAGE = 20 (one page is left free for each 20 pages used)
- MAXROWS = 255

If the data is not compressed, you get the following results:

- Usable page size =  $4056 \times 0.95 = 3853$  bytes
- Records per page =  $\text{MIN}(\text{MAXROWS}, \text{FLOOR}(3853 / 80)) = 48$
- Pages used =  $2 + \text{CEILING}(100000 / 48) = 2085$
- Total pages =  $\text{FLOOR}(2085 \times 21 / 20) = 2189$
- Estimated number of kilobytes =  $2189 \times 4 = 8756$

If the data is compressed, multiply the estimated number of kilobytes for an uncompressed table by  $(1 - \text{compression ratio})$  for the estimated number of kilobytes required for the compressed table.

---

## Calculating the space required for a dictionary

This section helps you calculate the disk space required by a *dictionary* and the virtual storage required in the xxxxDBM1 address space when a dictionary is read into storage from a buffer pool. A dictionary contains the information used for compressing and decompressing the data in a table space or partition, and it resides in that table space or partition. You can skip this section if you are not going to compress data. Space allocation parameters are specified in pages (either 4 KB, 8 KB, 16 KB, or 32 KB).

The following topics provide additional information:

- “Disk requirements”
- “Virtual storage requirements” on page 117

### Disk requirements

This section helps you calculate the disk requirements for a dictionary associated with a compressed nonsegmented table space and for a dictionary associated with a compressed segmented table space.

**Nonsegmented table space:** The dictionary contains 4096 entries in most cases. This means you need to allocate an additional sixteen 4-KB pages, eight 8-KB pages, four 16-KB pages, or two 32-KB pages. Although it is possible that your dictionary can contain fewer entries, allocate enough space to accommodate a dictionary with 4096 entries. For 32-KB pages, one segment (minimum of four pages) is sufficient to contain the dictionary. Use Table 27 to determine how many 4-KB pages, 8-KB pages, 16-KB pages, or 32-KB pages to allocate for the dictionary of a compressed nonsegmented table space.

Table 27. Pages required for the dictionary of a compressed nonsegmented table space

Table space page size (KB)	Dictionary size (512 entries)	Dictionary size (1024 entries)	Dictionary size (2048 entries)	Dictionary size (4096 entries)	Dictionary size (8192 entries)
4	2	4	8	16	32
8	1	2	4	8	16
16	1	1	2	4	8
32	1	1	1	2	4

**Segmented table space:** The size of the dictionary depends on the size of your segments. Assuming 4096 entries is recommended. Use Table 28 on page 117 to determine how many 4-KB pages to allocate for the dictionary of a compressed segmented table space.

Table 28. Pages required for the dictionary of a compressed segmented table space

Segment size (4-KB pages)	Dictionary size (512 entries)	Dictionary size (1024 entries)	Dictionary size (2048 entries)	Dictionary size (4096 entries)	Dictionary size (8192 entries)
4	4	4	8	16	32
8	8	8	8	16	32
12	12	12	12	24	36
≥16	Segment size	Segment size	Segment size	Segment size	Segment size

## Virtual storage requirements

You can calculate how much storage is needed in the xxxxDBM1 address space for each dictionary with this formula:

$$\text{dictionary size (number of entries)} \times 16 \text{ bytes}$$

When a dictionary is read into storage from a buffer pool, the *whole* dictionary is read, and it remains there as long as the compressed table space is being accessed.

---

## Calculating the space required for an index

This section describes the levels of index pages and helps you calculate the storage required for an index, including:

- “Levels of index pages”
- “Estimating storage from number of index pages” on page 118

### Levels of index pages

Indexes can have more than one level of pages. Index pages that point directly to the data in tables are called *leaf pages* and are said to be on *level 0*. In addition to data pointers, leaf pages contain the key and record-ID (RID).

If an index has more than one leaf page, it must have at least one nonleaf page that contains entries that point to the leaf pages. If the index has more than one nonleaf page, then the nonleaf pages whose entries point to leaf pages are said to be on *level 1*. If an index has a second level of nonleaf pages whose entries point to nonleaf pages on level 1, then those nonleaf pages are said to be on *level 2*, and so on. The highest level of an index contains a single page, which DB2 creates when it first builds the index. This page is called the *root page*. The root page is a 4-KB index page. Figure 6 on page 118 shows, in schematic form, a typical index.

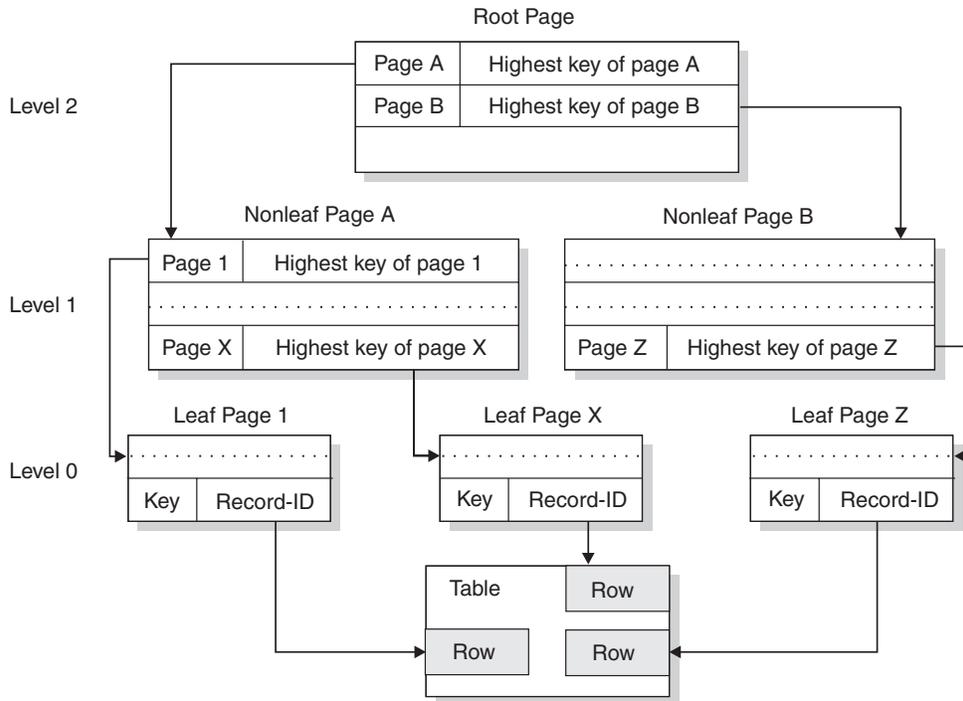

Figure 6. Sample index structure and pointers (three-level index)

If you insert data with a constantly increasing key, DB2 adds the new highest key to the top of a new page. Be aware, however, that DB2 treats nulls as the highest value. When the existing high key contains a null value in the first column that differentiates it from the new key that is inserted, the inserted nonnull index entries cannot take advantage of the *highest-value* split.

## Estimating storage from number of index pages

Space allocation parameters are specified in kilobytes. For an index to be loaded by the LOAD utility, you should estimate the future storage requirements of the index.

Estimating the space requirements for DB2 objects is easier if you collect and maintain a statistical history of those objects. The accuracy of your estimates depends on the currentness of the statistical data. To ensure that the statistics history is current, use the MODIFY STATISTICS utility to delete outdated statistical data from the catalog history tables.

The storage required for an index, newly built by the LOAD utility, depends on the number of index pages at all levels. That, in turn, depends on whether the index is unique or not. The numbers of leaf pages (index pages that point directly to the data in your tables) and of nonleaf pages (index pages that contain the page number and the highest key of each page in the next-level index) are calculated separately.

An index key on an auxiliary table used for LOBs is 19 bytes and uses the same formula as other indexes. The RID value stored within the index is 5 bytes, the same as for large table spaces (defined with DSSIZE greater than or equal to 4 GB).

In general, the length of the index key is the sum of the lengths of all the columns of the key, plus the number of columns that allow nulls. The length of a

varying-length column is the maximum length if the index is padded. Otherwise, if an index is not padded, estimate the length of a varying-length column to be the average length of the column data, and add a two-byte length field to the estimate. You can retrieve the value of the AVGKEYLEN column in the SYSIBM.SYSINDEXES catalog table to determine the average length of keys within an index.

The following index calculations are intended only to help you estimate the storage required for an index. Because there is no way to predict the exact number of duplicate keys that can occur in an index, the results of these calculations are not absolute. It is possible, for example, that for a nonunique index, more index entries than the calculations indicate might fit on an index page. The calculations are divided into cases using a unique index and using a nonunique index.

In the following calculations, let:

- $k$  = the length of the index key.
- $n$  = the average number of data records per distinct key value of a nonunique index. For example:
  - $a$  = number of data records per index
  - $b$  = number of distinct key values per index
  - $n = a / b$
- $f$  = the value of PCTFREE.
- $p$  = the value of FREEPAGE.
- $r$  = record identifier (RID) length. Let  $r = 4$  for indexes on nonlarge table spaces and  $r = 5$  for indexes on large spaces (defined with DSSIZE greater than or equal to 4 GB) and on auxiliary tables.
- FLOOR = the operation of discarding the decimal portion of a real number.
- CEILING = the operation of rounding a real number up to the next highest integer.
- MAX = the operation of selecting the highest integer value.

**Calculate pages for a unique index:** Use the following calculations to estimate the number of leaf and nonleaf pages in a unique index.

Calculate the *total leaf pages*:

1. *Space per key*  $\cong k + r + 3$
2. *Usable space per page*  $\cong \text{FLOOR}((100 - f) \times 4038 / 100)$
3. *Entries per page*  $\cong \text{FLOOR}(\text{usable space per page} / \text{space per key})$
4. **Total leaf pages**  $\cong \text{CEILING}(\text{number of table rows} / \text{entries per page})$

Calculate the *total nonleaf pages*:

1. *Space per key*  $\cong k + 7$
2. *Usable space per page*  $\cong \text{FLOOR}(\text{MAX}(90, (100 - f)) \times 4046 / 100)$
3. *Entries per page*  $\cong \text{FLOOR}(\text{usable space per page} / \text{space per key})$
4. *Minimum child pages*  $\cong \text{MAX}(2, (\text{entries per page} + 1))$
5. *Level 2 pages*  $\cong \text{CEILING}(\text{total leaf pages} / \text{minimum child pages})$
6. *Level 3 pages*  $\cong \text{CEILING}(\text{level 2 pages} / \text{minimum child pages})$
7. *Level x pages*  $\cong \text{CEILING}(\text{previous level pages} / \text{minimum child pages})$
8. **Total nonleaf pages**  $\cong (\text{level 2 pages} + \text{level 3 pages} + \dots + \text{level } x \text{ pages until the number of level } x \text{ pages} = 1)$

**Calculate pages for a nonunique index:** Use the following calculations to estimate the number of leaf and nonleaf pages for a nonunique index.

Calculate the *total leaf pages*:

1. *Space per key*  $\cong 4 + k + (n \times (r+1))$

2. Usable space per page  $\cong \text{FLOOR}((100 - f) \times 4038 / 100)$
3. Key entries per page  $\cong n \times (\text{usable space per page} / \text{space per key})$
4. Remaining space per page  $\cong \text{usable space per page} - (\text{key entries per page} / n) \times \text{space per key}$
5. Data records per partial entry  $\cong \text{FLOOR}((\text{remaining space per page} - (k + 4)) / 5)$
6. Partial entries per page  $\cong (n / \text{CEILING}(n / \text{data records per partial entry}))$  if data records per partial entry  $\geq 1$ , or 0 if data records per partial entry  $< 1$
7. Entries per page  $\cong \text{MAX}(1, (\text{key entries per page} + \text{partial entries per page}))$
8. **Total leaf pages**  $\cong \text{CEILING}(\text{number of table rows} / \text{entries per page})$

Calculate the total nonleaf pages:

- #
1. Space per key  $\cong k + r + 7$
  2. Usable space per page  $\cong \text{FLOOR}(\text{MAX}(90, (100 - f)) \times 4046 / 100)$
  3. Entries per page  $\cong \text{FLOOR}((\text{usable space per page} / \text{space per key}))$
  4. Minimum child pages  $\cong \text{MAX}(2, (\text{entries per page} + 1))$
  5. Level 2 pages  $\cong \text{CEILING}(\text{total leaf pages} / \text{minimum child pages})$
  6. Level 3 pages  $\cong \text{CEILING}(\text{level 2 pages} / \text{minimum child pages})$
  7. Level x pages  $\cong \text{CEILING}(\text{previous level pages} / \text{minimum child pages})$
  8. **Total nonleaf pages**  $\cong (\text{level 2 pages} + \text{level 3 pages} + \dots + \text{level x pages until } x = 1)$

**Calculate the total space requirement:** Finally, calculate the number of kilobytes required for an index built by LOAD.

1. Free pages  $\cong \text{FLOOR}(\text{total leaf pages} / p)$ , or 0 if  $p = 0$
2. Space map pages  $\cong \text{CEILING}((\text{tree pages} + \text{free pages}) / 8131)$
3. Tree pages  $\cong \text{MAX}(2, (\text{total leaf pages} + \text{total nonleaf pages}))$
4. Total index pages  $\cong \text{MAX}(4, (1 + \text{tree pages} + \text{free pages} + \text{space map pages}))$
5. Total space requirement  $\cong 4 \times (\text{total index pages} + 2)$

In the following example of the entire calculation, assume that an index is defined with these characteristics:

- It is unique.
- The table it indexes has 100000 rows.
- The key is a single column defined as CHAR(10) NOT NULL.
- The value of PCTFREE is 5.
- The value of FREEPAGE is 4.

The calculations are shown in Table 29.

Table 29. The total space requirement for an index

Quantity	Calculation	Result
Length of key	$k$	10
Average number of duplicate keys	$n$	1
PCTFREE	$f$	5
FREEPAGE	$p$	4
<b>Calculate total leaf pages</b>		
Space per key	$k + 7$	17
Usable space per page	$\text{FLOOR}((100 - f) \times 4038/100)$	3844
Entries per page	$\text{FLOOR}(\text{usable space per page} / \text{space per key})$	225
Total leaf pages	$\text{CEILING}(\text{number of table rows} / \text{entries per page})$	445

Table 29. The total space requirement for an index (continued)

Quantity	Calculation	Result
<b># Calculate total nonleaf pages</b>		
# Space per key	$k + 7$	17
# Usable space per page	$\text{FLOOR}(\text{MAX}(90, (100 - f)) \times 4046/100)$	3843
# Entries per page	$\text{FLOOR}(\text{usable space per page} / \text{space per key})$	226
# Minimum child pages	$\text{MAX}(2, (\text{entries per page} + 1))$	227
# Level 2 pages	$\text{CEILING}(\text{total leaf pages} / \text{minimum child pages})$	2
# Level 3 pages	$\text{CEILING}(\text{level 2 pages} / \text{minimum child pages})$	1
#		
# Total nonleaf pages	$(\text{level 2 pages} + \text{level 3 pages} + \dots + \text{level } x \text{ pages until } x = 1)$	3
<b>Calculate total space required</b>		
Free pages	$\text{FLOOR}(\text{total leaf pages} / p)$ , or 0 if $p = 0$	111
Tree pages	$\text{MAX}(2, (\text{total leaf pages} + \text{total nonleaf pages}))$	448
Space map pages	$\text{CEILING}((\text{tree pages} + \text{free pages})/8131)$	1
Total index pages	$\text{MAX}(4, (1 + \text{tree pages} + \text{free pages} + \text{space map pages}))$	561
TOTAL SPACE REQUIRED, in KB	$4 \times (\text{total index pages} + 2)$	2252

## Chapter 8. Introduction to security and auditing in DB2

The two topics of security and auditing overlap a great deal, but not completely.

*Security* covers control of access, whether to the DB2 subsystem, its data, or its resources. A security plan sets objectives for a security system, determining who has access to what, and under which circumstances. The security plan also describes how to meet the objectives by using functions of DB2, functions of other programs, and administrative procedures.

*Auditing* is how you determine whether the security plan is working and who has accessed data. Auditing includes questions, such as:

- Have attempts been made to gain unauthorized access?
- Is the data in the subsystem accurate and consistent?
- Are system resources used efficiently?

Because the two topics are not the same, this chapter suggests different ways to approach the information about security and auditing.

The following topics provide additional information:

- “Reading strategies for security”
- “Reading strategies for auditing” on page 128
- “Controlling data access” on page 128

---

### Reading strategies for security

If you have any sensitive data in your DB2 subsystem, you must plan carefully to protect your data. The security plan sets objectives for allowing and preventing access, and it describes the means of achieving these objectives. Because the nature of the security plan depends entirely on the data that you are protecting, there is no single way to approach the task. Consider the suggestions in the following sections:

- “If you are new to DB2”
- “If you have used DB2 before” on page 128

#### If you are new to DB2

Use the following guidelines to learn about security:

1. Read “Controlling data access” on page 128 carefully.
2. Skim Chapter 9, “Controlling access to DB2 objects,” on page 133 through Chapter 13, “Auditing,” on page 285. These chapters describe the tools that you use to implement your plan, but they probably contain more detail than you want during your first reading.
3. Read the case study in Chapter 14, “A sample security plan for employee data,” on page 301. The sample plan describes the type of data access decisions that you must make for your own data.
4. Skim Table 37 on page 137 through Table 34 on page 136 for a brief overview of the range of objects that DB2 protects.
5. List your security objectives and the means that you will use to achieve them.

6. Reread the sections that describe the functions that you expect to use. Ensure that you can achieve the objectives that you have set, or adjust your plan accordingly.

## If you have used DB2 before

This section contains a summary of the changes in Version 8 for security and auditing.

**Multilevel security:** You can use multilevel security for object-level access control, and you can use multilevel security with row-level granularity. For information about multilevel security, see “Multilevel security” on page 192.

**Encryption:** You can use new built-in functions for data encryption and decryption that let you protect sensitive data as it is stored in or retrieved from a DB2 subsystem. For more information about encryption, see “Data encryption through built-in functions” on page 207.

**Session variables and special registers:** You can use new special registers and session variables to facilitate information sharing between applications. You can also use these new values to help enforce a security policy. For more information about new session variables and special registers, see Chapter 9, “Controlling access to DB2 objects,” on page 133.

**Authorization:** You can now return secondary authorization IDs to applications and control authorization on materialized query tables and sequences. For information about these changes to authorization, see Chapter 9, “Controlling access to DB2 objects,” on page 133.

---

## Reading strategies for auditing

For specific information about auditing, read Chapter 13, “Auditing,” on page 285.

If you are also interested in controlling data access, first read “Controlling data access.” Then read Chapter 9, “Controlling access to DB2 objects,” on page 133. Finally, read Chapter 13, “Auditing,” on page 285.

---

## Controlling data access

Access to data includes, but is not limited to, access by a person that is engaged in an interactive terminal session. For example, access can be from a program that is running in batch mode, or from an IMS or CICS transaction. Hence, so as not to focus your attention too narrowly, this chapter uses the term *process* to represent all access to data.

Several routes exist from a process to DB2 data. DB2 controls each route except the data set protection route, as shown in Figure 7 on page 129.

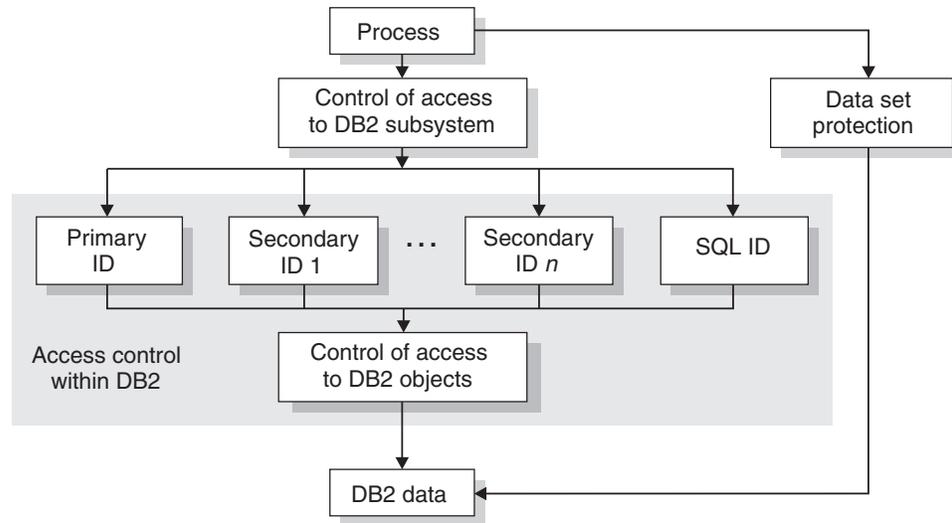

Figure 7. DB2 data access control

One of the ways that DB2 controls access to data is through the use of identifiers (IDs). Four types of IDs exist:

**Primary authorization ID**

Generally, the primary authorization ID identifies a process. For example, statistics and performance trace records use a primary authorization ID to identify a process.

**Secondary authorization ID**

A secondary authorization ID, which is optional, can hold additional privileges that are available to the process. For example, a secondary authorization ID can be a Resource Access Control Facility (RACF) group ID.

**SQL ID**

An SQL ID holds the privileges that are exercised when certain dynamic SQL statements are issued. The SQL ID can be set equal to the primary ID or any of the secondary IDs. If an authorization ID of a process has SYSADM authority, the process can set its SQL ID to any authorization ID.

**RACF ID**

The RACF ID is generally the source of the primary and secondary authorization IDs (RACF groups). When you use the RACF Access Control Module or multilevel security, the RACF ID is used directly.

**Access control within DB2**

Within the DB2 subsystem, a process can be represented by a primary authorization ID, one or more secondary IDs, or an SQL ID. Your security and network systems and the choices that you make for DB2 connections affect the use of these IDs.

DB2 relies only on IDs to determine whether to allow or prohibit certain processes. An ID can hold privileges that allow the ID to take certain actions and that prohibit the ID from taking other actions. DB2 does not determine access control based on the process or the person accessing data. Therefore, if the same set of IDs are associated with two different accesses to DB2, DB2 cannot determine whether the IDs involve the same process.

**Example:** You might know that someone else is using your ID. However, DB2 recognizes only the ID; DB2 does not recognize that someone else is using your ID.

Therefore, this book uses phrases like “an ID owns an object” instead of “a person owns an object” to discuss access control within DB2.

## Granting privileges within DB2

DB2 allows you a wide range of granularity when you grant privileges to an ID within DB2. You can grant all of the privileges over a table to an ID, or you can grant an ID individual privileges. For example, you could, separately and specifically, grant an ID the privilege to retrieve data from the table, to insert rows, to delete rows, or to update specific columns. By granting or not granting privileges over views of the table, you can determine exactly what an ID can do to the table, down to the granularity of specific fields. You can also grant an ID specific privileges over databases, plans, packages, and the entire DB2 subsystem.

DB2 also defines sets of related privileges, called *administrative authorities*. When you grant one of the administrative authorities to a person’s ID, that person has all of the privileges that are associated with that administrative authority. You can efficiently grant many privileges by granting one administrative authority.

You can also efficiently grant multiple privileges by granting the privilege to execute an application plan or a package. When an ID executes a plan or package, the ID implicitly uses all of the privileges that the owner needed when binding the plan or package. Therefore, granting to an ID the privilege to execute a plan or package can provide a finely detailed set of privileges and can eliminate the need to grant other privileges separately.

*Example of granting the privilege to execute:* Assume that an application plan issues the INSERT and SELECT statements on several tables. You need to grant INSERT and SELECT privileges only to the plan owner. However, any authorization ID that is later granted the EXECUTE privilege on the plan can perform those same INSERT and SELECT statements by executing the plan. You do not need to explicitly grant the INSERT and SELECT privileges to the ID.

For more information about granting privileges to execute a plan or package, see “Privileges exercised through a plan or a package” on page 148.

**Recommendation:** Instead of granting privileges to many primary authorization IDs, consider associating each of those primary IDs with the same secondary ID. Then grant the privileges to the secondary ID. You can associate a primary ID with one or more secondary IDs when the primary ID gains access to the DB2 subsystem. DB2 makes the association within an exit routine. The assignment of privileges to the secondary ID is controlled entirely within DB2.

## Using ownership privileges within DB2

Ownership of an object carries with it a set of related privileges over the object. For a summary of implicit ownership privileges by type of object, see Table 43 on page 147.

DB2 provides separate controls for creation and ownership of objects. When you create an object, your ID can own the object, or another ID can own the object.

## Using multilevel security

Multilevel security allows you to classify objects and users with security labels that are based on hierarchical security levels and non-hierarchical security categories.

Multilevel security prevents unauthorized users from accessing information at a higher classification than their authorization, and prevents users from declassifying information. Using multilevel security with row-level granularity, you can define security for DB2 objects and perform security checks, including row-level security checks. Row-level security checks allow you to control which users have authorization to view, modify, or perform other actions on specific rows of data.

For more information about multilevel security, see “Multilevel security” on page 192

### **Disabling access control within DB2**

If security is not important for your data, you can disable access control within DB2 by setting USE PROTECTION to NO when you install DB2 or update installation settings. If protection in DB2 is disabled, any user that gains access can do anything. However, no user can issue GRANT statements or REVOKE statements when access control within DB2 is disabled.

### **Using an exit routine to control authorization checking**

You can control authorization checking by using a DB2-supplied exit routine or an exit routine that you write. If your installation uses one of these access control authorization exit routines, the exit routine might control authorization checking instead of the authorization checks that are described in this section. For more information about access control authorization exit routines, see Appendix B, “Writing exit routines,” on page 1055.

## **Controlling access to a DB2 subsystem**

You can control whether a process can gain access to a specific DB2 subsystem from outside of DB2. A common approach is to grant access only through RACF or some similar security system. Profiles for access to DB2 from various environments and DB2 address spaces are defined as resources to RACF. Each request to access DB2 is associated with an ID. RACF determines whether the ID is authorized for DB2 resources. If the ID is authorized, RACF permits access to DB2.

The RACF system provides several advantages of its own. For example, RACF can:

- Identify and verify the identifier that is associated with a process
- Connect those identifiers to RACF group names
- Log and report unauthorized attempts to access protected resources

### **Controlling access at a local DB2 subsystem**

Local DB2 users are often subject to several checks before they reach DB2. For example, if you run DB2 under TSO and use the TSO logon ID as the DB2 primary authorization ID, TSO verifies your ID when you log on.

When a user gains access to DB2, a user-written or IBM-supplied DSN3@ATH exit routine that is connected to DB2 can perform the following actions:

- Check the authorization ID again
- Change the authorization ID
- Associate the authorization ID with secondary IDs

After these actions are performed, the authorization ID can use the services of an external security system again. For more detailed instructions, see Chapter 11, “Controlling access to a DB2 subsystem,” on page 231.

## Controlling access from a remote application

You can require remote users to pass several access checks before they reach DB2. For example, you can use RACF or a similar security subsystem to control access from a remote location.

While controlling access from a remote locations, RACF can do the following:

- Verify an ID that is associated with a remote attachment request and check the ID with a password.
- Generate *PassTickets* on the sending side. *PassTickets* can be used instead of passwords. A *PassTicket* lets a user gain access to a host system without sending the RACF password across the network. For more information about RACF *PassTickets*, see “Sending RACF *PassTickets*” on page 263.

**The communications database:** You can also control access authentication by using the DB2 communications database (CDB). The CDB is a set of tables in the DB2 catalog that are used to establish conversations with remote database management systems. The CDB can translate IDs before it sends the IDs to the remote system. For more information about CDB requests, see “The communications database for the requester” on page 253. For more information about CDB controls on the server, see “The communications database for the server” on page 240.

## Data set protection

The data in a DB2 subsystem is contained in data sets. As Figure 7 on page 129 suggests, those data sets can be accessed without going through DB2. If your data is sensitive, you want to control any route to DB2 data that DB2 does not control.

If you use RACF or a similar security system to control access to DB2, the simplest way to controlling data set access outside of DB2 is to use RACF. If you want to use RACF for data set protection outside of DB2, define RACF profiles for data sets, and permit access to the data sets for certain DB2 IDs.

If your data is very sensitive, consider encrypting the data. Encryption protects against unauthorized access to data sets and to backup copies outside of DB2. You have the following encryption options for protecting sensitive data:

- Built-in data encryption functions, which are described in “Data encryption through built-in functions” on page 207.
- DB2 edit procedures or field procedures, which can use the Integrated Cryptographic Service Facility (ICSF). For information about the ICSF, see *z/OS ICSF Overview*.
- The IBM Data Encryption for IMS and DB2 Databases tool, which is described in *IBM Data Encryption for IMS and DB2 Databases User's Guide*.

Data compression is not a substitute for encryption. In some cases, the compression method does not actually shorten the data. In those cases, the data is left uncompressed and readable. If you encrypt and compress your data, compress it first. After you obtain the maximum compression, encrypt the result. When you retrieve your data, first decrypt the data. After the data is decrypted, decompress the result.

---

## Chapter 9. Controlling access to DB2 objects

The information in this chapter is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

DB2 controls access to its objects by a set of *privileges*. Each privilege allows a specific action to be taken on some object. Figure 8 shows the four primary ways within DB2 to give an ID access to data.<sup>1</sup>

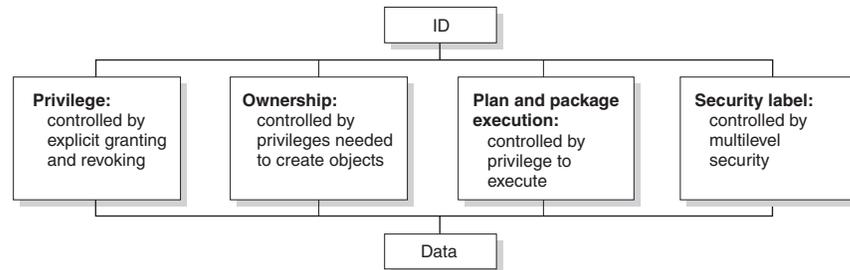

Figure 8. Access to data within DB2

As a security planner, you must be aware of every way to allow access to data.

Before you write a security plan, see the following sections:

- “Explicit privileges and authorities”
- “Implicit privileges of ownership” on page 145
- “Privileges exercised through a plan or a package” on page 148
- “Access control for user-defined functions and stored procedures” on page 154
- “Multilevel security” on page 192
- “Data encryption through built-in functions” on page 207

DB2 has primary authorization IDs, secondary authorization IDs, and SQL IDs. Some privileges can be exercised only by one type of ID; other privileges can be exercised by more than one. To decide which IDs should hold specific privileges, see “Which IDs can exercise which privileges” on page 161.

After you decide which IDs should hold specific privileges, you can implement a security plan. Before you begin your plan, you can see what others have done in “Matching job titles with privileges” on page 171 and “Examples of granting and revoking privileges” on page 173.

The DB2 catalog records the privileges that IDs are granted and the objects that IDs own. To check the implementation of your security plan, see “Finding catalog information about privileges” on page 187.

---

### Explicit privileges and authorities

You can control access within DB2 by granting, not granting, or revoking explicit privileges and authorities. Privileges, explicit privileges, and administrative authorities are defined as follows:

---

1. Certain authorities are assigned when DB2 is installed, and can be reassigned by changing the subsystem parameter (DSNZPARM). You can consider changing the DSNZPARM value to be a fifth way of granting data access in DB2.

### Privilege

A privilege allows the capability to perform a specific operation, sometimes on a specific object.

### Explicit privilege

An explicit privilege is a specific type of privilege. Each explicit privilege has a name and is the result of a GRANT statement or a REVOKE statement. For example, the SELECT privilege.

### Administrative authority

An administrative authority is a set of privileges, often covering a related set of objects. Authorities often include privileges that are not explicit, have no name, and cannot be specifically granted. For example, when an ID is granted the SYSOPR administrative authority, the ID is implicitly granted the ability to terminate any utility job.

Privileges and authorities are held by authorization IDs.

## Authorization IDs

Every process that connects to or signs on to DB2 is represented by a set of one or more DB2 short identifiers that are called *authorization IDs*. Authorization IDs can be assigned to a process by default procedures or by user-written exit routines. Methods of assigning those IDs are described in detail in Chapter 11, “Controlling access to a DB2 subsystem,” on page 231; see especially Table 70 on page 233 and Table 71 on page 234.

When authorization IDs are assigned, every process receives exactly one ID that is called the *primary authorization ID*. All other IDs are *secondary authorization IDs*.

Furthermore, one ID (either primary or secondary) is designated as the *current SQL ID*. You can change the value of the SQL ID during your session.

**Example of changing the SQL ID:** Suppose that ALPHA is your primary authorization ID or one of your secondary authorization IDs. You can make it your current SQL ID by issuing the following SQL statement:

```
SET CURRENT SQLID = 'ALPHA';
```

If you issue the statement through the distributed data facility (DDF), ALPHA must be one of the IDs that are associated with your process at the location where the statement runs. Your primary ID can be translated before it is sent to a remote location. Secondary IDs are associated with your process at the remote location. The current SQL ID, however, is not translated. For more information about authorization IDs and remote locations, see “Controlling requests from remote applications” on page 238.

An ID with SYSADM authority can set the current SQL ID to any string whose length is less than or equal to 8 bytes.

| Authorization IDs that are sent to a connecting server must conform to the security  
| management product guidelines of the server. See the documentation of the  
| security product for the connecting server.

## Granting explicit privileges

You can use explicit privileges to grant privileges over objects to IDs. When you grant explicit privileges, you have fine control over which privileges you grant.

This section describes the explicit privileges that you can grant on objects. The descriptions of the explicit privileges are grouped by object and usage:

- Collections in Table 30 on page 135
- Databases in Table 31 on page 135
- Packages in Table 32 on page 136
- Plans in Table 33 on page 136
- Routines in Table 34 on page 136
- Schemas in Table 35 on page 136
- Systems in Table 36 on page 136
- Tables and views in Table 37 on page 137
- Usage in Table 38 on page 138
- Use in Table 39 on page 138

Table 30 shows the collection privileges that DB2 allows.

*Table 30. Explicit collection privileges*

Collection privilege	Operations allowed for a named package collection
CREATE IN	The BIND PACKAGE subcommand, to name the collection

Table 31 shows the database privileges that DB2 allows.

*Table 31. Explicit database privileges*

Database privilege	Operations allowed on a named database
CREATETAB	The CREATE TABLE statement, to create tables in the database
CREATETS	The CREATE TABLESPACE statement, to create table spaces in the database
DISPLAYDB	The DISPLAY DATABASE command, to display the database status
DROP	The DROP and ALTER DATABASE statements, to drop or alter the database
IMAGCOPY	The QUIESCE, COPY, and MERGECOPY utilities, to prepare for, make, and merge copies of table spaces in the database; the MODIFY RECOVERY utility, to remove records of copies
LOAD	The LOAD utility, to load tables in the database
RECOVERDB	The RECOVER, REBUILD INDEX, and REPORT utilities, to recover objects in the database and report their recovery status
REORG	The REORG utility, to reorganize objects in the database
REPAIR	The REPAIR and DIAGNOSE utilities (except REPAIR DBD and DIAGNOSE WAIT) to generate diagnostic information about, and repair data in, objects in the database
STARTDB	The START DATABASE command, to start the database
STATS	The RUNSTATS, CHECK, LOAD, REBUILD INDEX, REORG INDEX, REORG TABLESPACE and MODIFY STATISTICS utilities, to gather statistics, check indexes and referential constraints for objects in the database, and delete unwanted statistics history records from the corresponding catalog tables
STOPDB	The STOP DATABASE command, to stop the database

#

#  
#  
#  
#  
#  
#

Table 32 shows the package privileges that DB2 allows.

*Table 32. Explicit package privileges*

<b>Package privilege</b>	<b>Operations allowed for a named package</b>
BIND	The BIND, REBIND, and FREE PACKAGE subcommands, and the DROP PACKAGE statement, to bind or free the package, and, depending on the installation option BIND NEW PACKAGE, to bind a new version of a package
COPY	The COPY option of BIND PACKAGE, to copy a package
EXECUTE	Inclusion of the package in the PKLIST option of BIND PLAN
GRANT ALL	All package privileges

Table 33 shows the plan privileges that DB2 allows.

*Table 33. Explicit plan privileges*

<b>Plan privilege</b>	<b>Subcommands allowed for a named application plan</b>
BIND	BIND, REBIND, and FREE PLAN, to bind or free the plan
EXECUTE	RUN, to use the plan when running the application

Table 34 shows the routine privileges that DB2 allows.

*Table 34. Explicit routine privileges*

<b>Routine privileges</b>	<b>Objects available for usage</b>
EXECUTE ON FUNCTION	A user-defined function
EXECUTE ON PROCEDURE	A stored procedure

Table 35 shows the schema privileges that DB2 allows.

*Table 35. Explicit schema privileges*

<b>Schema privileges</b>	<b>Operations available for usage</b>
CREATEIN	Create distinct types, user-defined functions, triggers, and stored procedures in the designated schemas
ALTERIN	Alter user-defined functions or stored procedures, or specify a comment for distinct types, user-defined functions, triggers, and stored procedures in the designated schemas
DROPIN	Drop distinct types, user-defined functions, triggers, and stored procedures in the designated schemas

Table 36 shows the system privileges that DB2 allows.

*Table 36. Explicit system privileges*

<b>System privilege</b>	<b>Operations allowed on the system</b>
ARCHIVE	The ARCHIVE LOG command, to archive the current active log, the DISPLAY ARCHIVE command, to give information about input archive logs, the SET LOG command, to modify the checkpoint frequency specified during installation, and the SET ARCHIVE command, to control allocation and deallocation of tape units for archive processing.

Table 36. Explicit system privileges (continued)

System privilege	Operations allowed on the system
BINDADD	The BIND subcommand with the ADD option, to create new plans and packages
BINDAGENT	The BIND, REBIND, and FREE subcommands, and the DROP PACKAGE statement, to bind, rebind, or free a plan or package, or copy a package, on behalf of the grantor. The BINDAGENT privilege is intended for separation of function, not for added security. A bind agent with the EXECUTE privilege might be able to gain all the authority of the grantor of BINDAGENT.
BSDS	The RECOVER BSDS command, to recover the bootstrap data set
CREATEALIAS	The CREATE ALIAS statement, to create an alias for a table or view name
CREATEDBA	The CREATE DATABASE statement, to create a database and have DBADM authority over it
CREATEDBC	The CREATE DATABASE statement, to create a database and have DBCTRL authority over it
CREATESG	The CREATE STOGROUP statement, to create a storage group
CREATETMTAB	The CREATE GLOBAL TEMPORARY TABLE statement, to define a created temporary table
DISPLAY	The DISPLAY ARCHIVE, DISPLAY BUFFERPOOL, DISPLAY DATABASE, DISPLAY LOCATION, DISPLAY LOG, DISPLAY THREAD, and DISPLAY TRACE commands, to display system information
MONITOR1	Receive trace data that is not potentially sensitive
MONITOR2	Receive all trace data
RECOVER	The RECOVER INDOUBT command, to recover threads
STOPALL	The STOP DB2 command, to stop DB2
STOSPACE	The STOSPACE utility, to obtain data about space usage
TRACE	The START TRACE, STOP TRACE, and MODIFY TRACE commands, to control tracing

Table 37 shows the table and view privileges that DB2 allows.

Table 37. Explicit table and view privileges

Table or view privilege	SQL statements allowed for a named table or view
ALTER	ALTER TABLE, to change the table definition
DELETE	DELETE, to delete rows
INDEX	CREATE INDEX, to create an index on the table
INSERT	INSERT, to insert rows
REFERENCES	ALTER or CREATE TABLE, to add or remove a referential constraint referring to the named table or to a list of columns in the table
SELECT	SELECT, to retrieve data from the table
TRIGGER	CREATE TRIGGER, to define a trigger on a table

Table 37. Explicit table and view privileges (continued)

Table or view privilege	SQL statements allowed for a named table or view
UPDATE	UPDATE, to update all columns or a specific list of columns
GRANT ALL	SQL statements of all table privileges

Table 38 shows the usage privileges that DB2 allows.

Table 38. Explicit usage privileges

Usage privileges	Objects available for usage
USAGE ON DISTINCT TYPE	A distinct type
USAGE ON JAR (Java class for a routine)	A Java class
USAGE ON SEQUENCE	A sequence

Table 39 shows the use privileges that DB2 allows.

Table 39. Explicit use privileges

Use privileges	Objects available for use
USE OF BUFFERPOOL	A buffer pool
USE OF STOGROUP	A storage group
USE OF TABLESPACE	A table space

*Privileges needed for statements, commands, and utility jobs:* For lists of all privileges and authorities that let you perform the following actions, consult the appropriate resource:

- To execute a particular SQL statement, see the description of the statement in Chapter 5 of *DB2 SQL Reference*.
- To issue a particular DB2 command, see the description of the command in Chapter 2 of *DB2 Command Reference*.
- To run a particular type of utility job, see the description of the utility in *DB2 Utility Guide and Reference*.

## Administrative authorities

Figure 9 on page 139 shows how privileges are grouped into authorities and how the authorities form a branched hierarchy. Table 41 on page 140 supplements Figure 9 on page 139 and includes the capabilities of each authority.

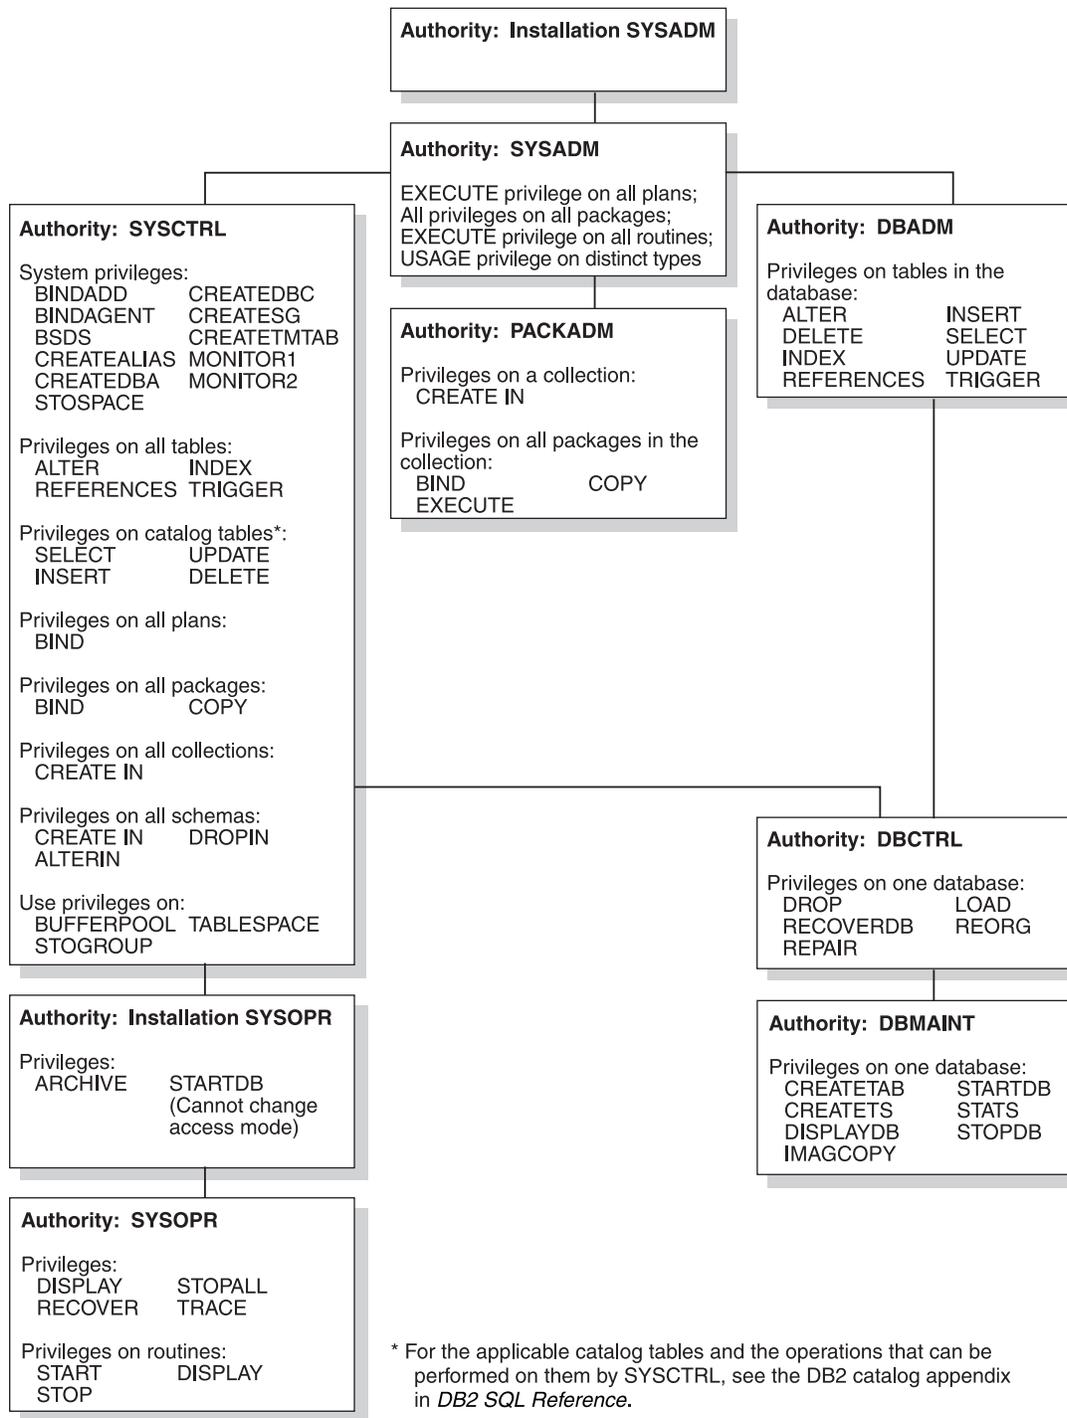

Figure 9. Individual privileges of administrative authorities. Each authority includes the privileges in its box and all of the privileges of each authority in the boxes that are beneath it. Installation SYSOPR authority is an exception; it can do some things that SYSADM and SYSCTRL cannot do.

Table 41 on page 140 shows DB2 authorities and the actions that they are allowed to perform.

Table 41. DB2 authorities

Authority	Description
SYSOPR	<p>System operator:</p> <ul style="list-style-type: none"> <li>• Can issue most DB2 commands</li> <li>• <b>Cannot</b> issue ARCHIVE LOG, START DATABASE, STOP DATABASE, and RECOVER BSDS</li> <li>• Can terminate any utility job</li> <li>• Can run the DSN1SDMP utility</li> </ul> <p>If held with the GRANT option, SYSOPR can grant these privileges to others.</p>
Installation SYSOPR	<p>One or two IDs are assigned this authority when DB2 is installed. They have all the privileges of SYSOPR, plus:</p> <ul style="list-style-type: none"> <li>• The authority is <b>not</b> recorded in the DB2 catalog. Therefore, the catalog does not need to be available to check the Installation SYSOPR authority.</li> <li>• No ID can revoke the authority; it can be removed only by changing the module that contains the subsystem initialization parameters (typically DSNZPARM).</li> </ul> <p>IDs with Installation SYSOPR authority can also:</p> <ul style="list-style-type: none"> <li>• Access DB2 when the subsystem is started with ACCESS(MAINT).</li> <li>• Run all allowable utilities on the directory and catalog databases (DSNDB01 and DSNDB06).</li> <li>• Run the REPAIR utility with the DBD statement.</li> <li>• Start and stop the database that contains the application registration table (ART) and the object registration table (ORT). For more information on these tables, see Chapter 10, "Controlling access through a closed application," on page 215.</li> <li>• Issue dynamic SQL statements that are not controlled by the DB2 governor.</li> <li>• Issue a START DATABASE command to recover objects that have LPL entries or group buffer pool recovery-pending status. These IDs cannot change the access mode.</li> </ul>
PACKADM	<p>Package administrator:</p> <ul style="list-style-type: none"> <li>• Has all package privileges on all packages in specific collections</li> <li>• Has the CREATE IN privilege on those specific collections</li> </ul> <p>If PACKADM authority is held with the GRANT option, PACKADM can grant those privileges to others.</p> <p>If the installation option BIND NEW PACKAGE is BIND, PACKADM also has the privilege to add new packages or new versions of existing packages.</p>
DBMAINT	<p>Database maintenance authority allows privileges over a specific database to an ID. DBMAINT can perform the following actions within a specific database:</p> <ul style="list-style-type: none"> <li>• Create objects</li> <li>• Run utilities that don't change data</li> <li>• Issue commands</li> <li>• Terminate all utilities on the database except DIAGNOSE, REPORT, and STOSPACE</li> </ul> <p>If held with the GRANT option, DBMAINT can grant those privileges to others.</p>

Table 41. DB2 authorities (continued)

Authority	Description
DBCTRL	<p>Database controller authority includes DBMAINT privileges over a specific database. Additionally, DBCTRL has database privileges to run utilities that can change the data.</p> <p>If the value of field DBADM CREATE AUTH on installation panel DSNTIPP was set to YES during DB2 installation, the ID with DBCTRL authority can create an alias for another user ID on any table in the database.</p> <p>If held with the GRANT option, DBCTRL can grant those privileges to others.</p>
DBADM	<p>Database administrator authority includes DBCTRL privileges over a specific database. Additionally, DBADM has privileges to access any tables in a specific database by using SQL statements.</p> <p>DBADM can also perform the following actions:</p> <ul style="list-style-type: none"> <li>• Drop or alter any table space, table, or index in the database</li> <li>• Issue a COMMENT, LABEL, or LOCK TABLE statement for any table in the database</li> <li>• Issue a COMMENT statement for any index in the database</li> </ul> <p>If the value of field DBADM CREATE AUTH on installation panel DSNTIPP was set to YES during DB2 installation, an ID with DBADM authority can create the following objects:</p> <ul style="list-style-type: none"> <li>• A view for another ID. The view must be based on at least one table, and that table must be in the database under DBADM authority. For more information about creating views, see the description of the CREATE VIEW statement in <i>DB2 SQL Reference</i>.</li> <li>• An alias for another ID on any table in the database.</li> </ul> <p>An ID with DBADM authority on one database can create a view on tables and views in that database and other databases only if the ID has all the privileges that are required to create the view. For example, an ID with DBADM authority cannot create a view on a view that is owned by another ID.</p> <p>If held with the GRANT option, DBADM can grant these privileges to others.</p>

Table 41. DB2 authorities (continued)

Authority	Description
SYSCTRL	<p>The system controller authority is designed for administering a system that contains sensitive data. The system controller has nearly complete control of the DB2 subsystem. However, the system controller <b>cannot</b> access user data directly unless the privilege to do so is explicitly granted. SYSCTRL can:</p> <ul style="list-style-type: none"> <li>• Act as installation SYSOPR (when the catalog is available) or DBCTRL over any database</li> <li>• Run any allowable utility on any database</li> <li>• Issue a COMMENT ON, LABEL ON, or LOCK TABLE statement for any table</li> <li>• Create a view on any catalog table for itself or for other IDs</li> <li>• Create tables and aliases for itself or for others IDs</li> <li>• Bind a new plan or package and name any ID as the owner of the plan or package</li> </ul> <p>Without additional privileges, SYSCTRL <b>cannot</b>:</p> <ul style="list-style-type: none"> <li>• Execute DML statements on user tables or views</li> <li>• Run plans or packages</li> <li>• Set the current SQL ID to a value that is not one of its primary or secondary IDs</li> <li>• Start or stop the database that contains the ART and the ORT</li> <li>• Act fully as SYSADM or as DBADM over any database</li> <li>• Access DB2 when the subsystem is started with ACCESS(MAINT)</li> </ul> <p>SYSCTRL authority is intended to separate system control functions from administrative functions. However, SYSCTRL is not a complete solution for a high-security system. If any plans have their EXECUTE privilege granted to PUBLIC, an ID with SYSCTRL authority can grant itself SYSADM authority. The only control over such actions is to audit the activity of IDs with high levels of authority.</p>
SYSADM	<p>System administrator authority includes all SYSCTRL, PACKADM, and DBADM privileges, including access to all data. SYSADM can perform the following actions and grant other IDs the privilege to perform these actions:</p> <ul style="list-style-type: none"> <li>• Use all the privileges of DBADM over any database</li> <li>• Use EXECUTE and BIND on any plan or package and COPY on any package</li> <li>• Use privileges over views that are owned by others</li> <li>• Set the current SQL ID to any valid value</li> <li>• Create and drop synonyms and views for other IDs on any table</li> <li>• Use any valid value for OWNER in BIND or REBIND</li> <li>• Drop database DSNDB07</li> </ul> <p>SYSADM can perform the following actions, but <b>cannot</b> grant other IDs the privilege to perform the following actions:</p> <ul style="list-style-type: none"> <li>• Drop or alter any DB2 object, except system databases</li> <li>• Issue a COMMENT ON or LABEL ON statement for any table or view</li> <li>• Terminate any utility job</li> </ul> <p>Although SYSADM cannot grant the preceding privileges explicitly, SYSADM can grant these privileges to other IDs by granting them SYSADM authority.</p>

Table 41. DB2 authorities (continued)

Authority	Description
Installation SYSADM	<p>One or two IDs are assigned installation SYSADM authority when DB2 is installed. They have all the privileges of SYSADM, plus:</p> <ul style="list-style-type: none"> <li>• DB2 does <b>not</b> record the authority in the catalog. Therefore, the catalog does not need to be available to check installation SYSADM authority. (The authority outside of the catalog is crucial. For example, if the directory table space DBD01 or the catalog table space SYSDBAUT is stopped, DB2 might not be able to check the authority to start it again. Only an installation SYSADM can start it.)</li> <li>• No ID can revoke installation SYSADM authority. You can remove the authority only by changing the module that contains the subsystem initialization parameters (typically DSNZPARM).</li> </ul> <p>IDs with installation SYSADM authority can also perform the following actions:</p> <ul style="list-style-type: none"> <li>• Run the CATMAINT utility</li> <li>• Access DB2 when the subsystem is started with ACCESS(MAINT)</li> <li>• Start databases DSNDB01 and DSNDB06 when they are stopped or in restricted status</li> <li>• Run the DIAGNOSE utility with the WAIT statement</li> <li>• Start and stop the database that contains the ART and the ORT</li> </ul>

## Field-level access control by views

Any of the table privileges except ALTER, REFERENCES, TRIGGER, and INDEX can be granted on a view. By creating a view and granting privileges on it, you can give an ID access to only a specific combination of data. The capability is sometimes called “field-level access control” or “field-level sensitivity.”

**Example:** Suppose that you want the ID MATH110 to be able to extract the following column data from the sample employee table for statistical investigation: HIREDATE, JOB, EDLEVEL, SEX, SALARY, BONUS, and COMM for DSN8810.EMP. However, you want to impose the following restrictions:

- No access to employee names or identification numbers
- No access to data for employees hired before 1996
- No access to data for employees with an education level less than 13
- No access to data for employees whose job is MANAGER or PRES

To do that, create and name a view that shows exactly that combination of data. You can create the view with the following CREATE statement:

```
CREATE VIEW SALARIES AS
  SELECT HIREDATE, JOB, EDLEVEL, SEX, SALARY, BONUS, COMM
  FROM DSN8810.EMP
  WHERE HIREDATE > '1995-12-31' AND
        EDLEVEL >= 13 AND
        JOB <> 'MANAGER' AND
        JOB <> 'PRES';
```

Then grant the SELECT privilege on the view SALARIES to MATH110 with the following statement:

```
GRANT SELECT ON SALARIES TO MATH110;
```

After you grant the privilege, MATH110 can execute SELECT statements on the restricted set of data only.

Alternatively, you can give an ID access to only a specific combination of data by using multilevel security with row-level granularity. For information about multilevel security with row-level granularity, see “Multilevel security” on page 192.

## Authority over the catalog and directory

The DB2 catalog is in the DSNDB06 database. An ID with SYSCTRL or SYSADM authority can control access to the catalog in the following ways:

- Grant privileges or authorities on that database or on its tables or views
- Bind plans or packages that access the catalog

However, unlike SYSADM, SYSCTRL cannot act as DBADM over database DSNDB06.

Authorities that are granted on DSNDB06 also cover database DSNDB01, which contains the DB2 directory. An ID with SYSADM authority can control access to the directory by granting privileges to run utilities (that are listed in Table 42) on DSNDB06, but cannot grant privileges on DSNDB01 directly.

Table 42 shows which utilities IDs with different authorities can run on the DSNDB01 and DSNDB06 databases.

*Table 42. Utility privileges on the DB2 catalog and directory*

Utilities	Authorities		
	Installation SYSOPR, SYSCTRL, SYSADM, Installation SYSADM	DBCTRL, DBADM on DSNDB06	DBMAINT on DSNDB06
LOAD <sup>1</sup>	No	No	No
REPAIR DBD	No	No	No
CHECK DATA	Yes	No	No
CHECK LOB	Yes	No	No
REORG TABLESPACE	Yes	No	No
STOSPACE	Yes	No	No
REBUILD INDEX	Yes	Yes	No
RECOVER	Yes	Yes	No
REORG INDEX	Yes	Yes	No
REPAIR	Yes	Yes	No
REPORT	Yes	Yes	No
CHECK INDEX	Yes	Yes	Yes
COPY	Yes	Yes	Yes
MERGECOPY	Yes	Yes	Yes
MODIFY	Yes	Yes	Yes
QUIESCE	Yes	Yes	Yes
RUNSTATS	Yes	Yes	Yes

**Note:** LOAD can be used to add lines to SYSIBM.SYSSTRINGS. LOAD cannot be run on other DSNDB01 or DSNDB06 tables.

---

## Implicit privileges of ownership

When you create a DB2 object by issuing an SQL statement, you establish its name and its ownership. The owner of an object implicitly holds certain privileges over that object.

**Exception:** Plans and packages are not created with SQL CREATE statements, and they have unique features of their own. For information about these features, see “Privileges exercised through a plan or a package” on page 148 and “Access control for user-defined functions and stored procedures” on page 154.

### Establishing ownership of objects with unqualified names

If an object name is unqualified, the type of object determines how ownership of the object is established.

If the name of a table, view, index, alias, or synonym is unqualified, you establish the object's ownership in the following ways:

- If you issue the CREATE statement dynamically, perhaps using SPUFI, QMF, or some similar program, the owner of the created object is your current SQL ID. That ID must have the privileges that are needed to create the object.
- If you issue the CREATE statement statically, by running a plan or package that contains it, the ownership of the created object depends on the option used for the bind operation. You can bind the plan or package with either the QUALIFIER option, the OWNER option, or both.
  - If the plan or package is bound with the QUALIFIER option only, the QUALIFIER is the owner of the object. The QUALIFIER option allows the binder to name a qualifier to use for all unqualified names of tables, views, indexes, aliases, or synonyms that appear in the plan or package.
  - If the plan or package is bound with the OWNER option only, the OWNER is the owner of the object.
  - If the plan or package is bound with both the QUALIFIER option and the OWNER option, the QUALIFIER is the owner of the object.
  - If neither option is specified, the binder of the plan or package is implicitly the object owner.

In addition, the plan or package owner must have all required privileges on the objects designated by the qualified names.

If the name of a user-defined function, stored procedure, distinct type, or trigger is unqualified, you establish the ownership of one of these objects in these ways:

- If you issue the CREATE statement dynamically, the owner of the created object is your current SQL ID. That ID must have the privileges that are needed to create the object.
- If you issue the CREATE statement statically, by running a plan or package that contains it, the owner of the object is the plan or package owner. You can use the OWNER bind option to explicitly name the object owner. If you do not use the OWNER bind option, the binder of the package or plan is implicitly the object owner.

If the name of a user-defined function, stored procedure, distinct type, sequence, or trigger is unqualified, the implicit qualifier is determined as described in “Qualifying unqualified names” on page 149.

The owner of a JAR (Java class for a routine) that is used by a stored procedure or a user-defined function is the current SQL ID of the process that performs the `INSTALL_JAR` function. For information about installing a JAR, see *DB2 Application Programming Guide and Reference for Java*.

## Establishing ownership of objects with qualified names

If an object name is qualified, the type of object determines how ownership of the object is established.

If you create a table, view, index, or alias with a qualified name, the qualifier becomes the owner of the object, subject to these restrictions for specifying the qualifier:

- If you issue the `CREATE` statement dynamically, and have no administrative authority, the qualifier must be your primary ID or one of your secondary IDs. However, if your current SQL ID has at least `DBCTRL` authority, you can use any qualifier for a table or an index. If your current SQL ID has at least `DBADM` authority and the value of field `DBADM CREATE AUTH` on installation panel `DSNTIPP` was set to `YES` during DB2 installation, you can also use any qualifier for a view.
- If you issue the `CREATE` statement statically, and the owner of the plan or package that contains the statement has no administrative authority, the qualifier can only be the owner. However, if the owner has at least `DBCTRL` authority, the plan or package can use any qualifier for a table or for an index. If the owner of the plan or package has at least `DBADM` authority and the value of field `DBADM CREATE AUTH` on installation panel `DSNTIPP` was set to `YES` during DB2 installation, the owner can also use any qualifier for a view.

If you create a distinct type, user-defined function, stored procedure, sequence, or trigger with a qualified name, the qualifier is the *schema name*. The schema name identifies the schema to which the object belongs. You can consider all of objects that are qualified by the same schema name as a group of related objects. Unlike other objects, however, the qualifier for these objects does not identify the owner of the object. You establish ownership of a distinct type, user-defined function, stored procedure, or trigger in these ways:

- If you issue the `CREATE` statement dynamically, the owner of the created object is your current SQL ID. That ID must have the privileges that are needed to create the object.
- If you issue the `CREATE` statement statically by running a plan or package that contains it, the owner of the plan or package implicitly becomes the owner of the object. If you want to explicitly name the object owner, you can use the `OWNER` bind option when you run the plan or package.

The owner of a JAR (Java class for a routine) that is used by a stored procedure or a user-defined function is the current SQL ID of the process that performs the `INSTALL_JAR` function. For information about installing a JAR, see *DB2 Application Programming Guide and Reference for Java*.

## Privileges by type of object

When you own a DB2 object, you have implicit privileges over that object. Table 43 on page 147 lists the implicit privileges of ownership for each type of object.

Table 43. Implicit privileges of ownership by object type

Object type	Implicit privileges of ownership
Alias	To drop the alias
Database	DBCTRL or DBADM authority over the database, depending on the privilege (CREATEDBC or CREATEDBA) that is used to create it. DBCTRL authority does <b>not</b> include the privilege to access data in tables in the database.
Distinct type	To use or drop a distinct type
Index	To alter, comment on, or drop the index
JAR (Java class for a routine)	To replace, use, or drop the JAR
Package	To bind, rebind, free, copy, execute, or drop the package
Plan	To bind, rebind, free, or execute the plan
Sequence	To alter, comment on, use, or drop the sequence
Storage group	To alter or drop the group and to name it in the USING clause of a CREATE INDEX or CREATE TABLESPACE statement
Stored procedure	To execute, alter, drop, start, stop, or display a stored procedure
Synonym	To use or drop the synonym
Table	<ul style="list-style-type: none"> <li>• To alter or drop the table or any indexes on it</li> <li>• To lock the table, comment on it, or label it</li> <li>• To create an index or view for the table</li> <li>• To select or update any row or column</li> <li>• To insert or delete any row</li> <li>• To use the LOAD utility for the table</li> <li>• To define referential constraints on any table or set of columns</li> <li>• To create a trigger on the table</li> </ul>
Table space	To alter or drop the table space and to name it in the IN clause of a CREATE TABLE statement
User-defined functions	To execute, alter, drop, start, stop, or display a user-defined function
View	To drop, comment on, or label the view, or to select any row or column

Implicit privileges do not apply to multilevel security. For information about multilevel security, see “Multilevel security” on page 192.

## Granting implicit privileges

Some implicit privileges of ownership correspond to privileges that can be granted by a GRANT statement. For those that do correspond, the owner of the object can grant the privilege to another user.

**Example:** The owner of a table can grant the SELECT privilege on the table to any other user. To grant the SELECT privilege on TABLE3 to USER4, the owner of the table can issue the following statement:

```
GRANT SELECT ON TABLE3 TO USER4
```

## Changing ownership

The privileges that are implicit in ownership cannot be revoked. Therefore, you cannot replace an object’s owner while the object exists.

If you want to change ownership of an object, follow these steps:

1. Drop the object, which usually deletes all privileges on it<sup>2</sup>.
2. Re-create the object with a new owner.

**Exception:** You can change package or plan ownership while a package or plan exists. For more information about changing package or plan ownership, see “Establishing or changing ownership of a plan or a package.”

You might want to share ownership privileges on an object instead of replacing an old owner with a new owner. If so, make the owning ID a secondary ID to which several primary IDs are connected. You can change the list of primary IDs connected to the secondary ID without dropping and re-creating the object.

---

## Privileges exercised through a plan or a package

This section describes the privileges that are required for executing plans and packages. User-defined function and stored procedure packages, also known as routine packages, have unique requirements that are described in “Access control for user-defined functions and stored procedures” on page 154.

The owner of the plan or package must hold privileges for every action an application plan or package performs. However, the owner of a plan or package can grant the privilege to execute a plan or package to any ID. When the EXECUTE privilege on a plan or package is granted to an ID, that ID can execute a plan or package without holding the privileges for every action that the plan or package performs. However, the ID is restricted by the SQL statements in the original program.

**Example:** The program might contain the following statement:

```
EXEC SQL
  SELECT * INTO :EMPREC FROM DSN8810.EMP
  WHERE EMPNO='000010';
```

The statement puts the data for employee number 000010 into the host structure EMPREC. The data comes from table DSN8810.EMP, but the ID does not have unlimited access to DSN8810.EMP. Instead, the ID that has EXECUTE privilege for this plan can access rows in the DSN8810.EMP table only when EMPNO = '000010'.

If any of the privileges that are required by the plan or package are revoked from the owner, the plan or the package is invalidated. The plan or package must be rebound, and the new owner must have the required privileges.

## Establishing or changing ownership of a plan or a package

The BIND and REBIND subcommands create or change an application plan or a package. On either subcommand, you can use the OWNER option to name the owner of the resulting plan or package. Consider these points when naming an owner:

- Any user can name the primary ID or any secondary ID.
- An ID with the BINDAGENT privilege can name the grantor of that privilege.
- An ID with SYSCTRL or SYSADM authority can name any authorization ID on a BIND command, but not on a REBIND command.

If you omit the OWNER option:

---

2. Dropping a package does not delete all privileges on it if another version of the package still remains in the catalog.

- On BIND, your primary ID becomes the owner.
- On REBIND, the previous owner retains ownership.

Some systems that can bind a package at a DB2 system do not support the OWNER option. When the OWNER option is not supported, the primary authorization ID is always the owner of the package because a secondary ID cannot be named as the owner.

## Qualifying unqualified names

A plan or package can contain SQL statements that use unqualified table and view names. For static SQL, the default qualifier for those names is the owner of the plan or package. However, you can use the QUALIFIER option of the BIND command to specify a different qualifier.

When you perform bind operations on plans or packages that contain static SQL, the BINDAGENT privilege and the OWNER and QUALIFIER options give you considerable flexibility.

**Example:** Suppose that ALPHA has the BINDAGENT privilege from BETA, and BETA has privileges on tables that are owned by GAMMA. ALPHA can bind a plan using OWNER (BETA) and QUALIFIER (GAMMA). ALPHA does not need to have privileges on the tables to bind the plan. However, ALPHA does not have the privilege to execute the plan.

For plans or packages that contain dynamic SQL, DYNAMICRULES behavior determines how DB2 qualifies unqualified object names. See “Authorization for dynamic SQL statements” on page 164 for more information.

For unqualified distinct types, user-defined functions, stored procedures, sequences, and trigger names in dynamic SQL statements, DB2 uses the schema name as the qualifier. DB2 finds the schema name in the CURRENT PATH special register. For static statements, the PATH bind option determines the path that DB2 searches to resolve unqualified distinct types, user-defined functions, stored procedures, sequences, and trigger names.

**Exception:** ALTER, CREATE, DROP, COMMENT ON, GRANT, and REVOKE statements follow different conventions for assigning qualifiers. For static SQL, you must specify the qualifier for these statements in the QUALIFIER bind option. For dynamic SQL, the qualifier for these statements is the authorization ID of the CURRENT SQLID special register. See Chapter 2 of *DB2 SQL Reference* for more information about unqualified names.

## Authorization to execute

The plan or package owner must have authorization to execute all static SQL statements that are embedded in the plan or package. However, you do not need to have the authorization when the plan or package is bound. The objects to which the plan or package refers do not even need to exist at bind time.

A bind operation always checks whether a local object exists and whether the owner has the required privileges on it. Any failure results in a message. However, you can choose whether the failure prevents the bind operation from completing by using the VALIDATE option on the BIND PLAN and BIND PACKAGE commands. The following values for the VALIDATE option determine how DB2 is to handle existence and authorization errors:

- RUN** If you choose RUN for the VALIDATE option, the bind succeeds even when existence or authorization errors exist. DB2 checks existence and authorization at run time.
- BIND** If you choose BIND for the VALIDATE option, the bind fails when existence or authorization errors exist.  
**Exception:** If you use the SQLERROR(CONTINUE) option on the BIND PACKAGE command, the bind succeeds, but the package's SQL statements that have errors cannot execute.

The corresponding existence and authorization checks for remote objects are always made at run time.

Authorization to execute dynamic SQL statements is also checked at run time. Table 46 on page 161 shows which IDs can supply the authorizations that are required for different types of statements.

Applications that use the Resource Recovery Services attachment facility (RRSAF) to connect to DB2 do not require a plan. If the requesting application is an RRSF application, DB2 follows the rules described in "Checking authorization to execute an RRSF application without a plan" on page 151 to check authorizations.

### Checking authorization at a second DB2 server

Authorization for execution at a second DB2 server (also known as a "double-hop" situation) is a special case of system-directed access when bind option DBPROTOCOL (PRIVATE) is in effect. Figure 10 shows the process for execution at a second DB2 server.

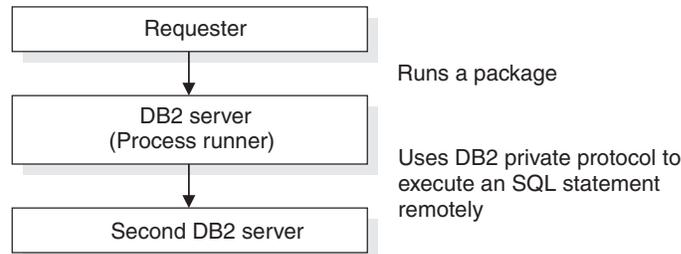

Figure 10. Execution at a second DB2 server

In the figure, a remote requester, either a DB2 UDB for z/OS or some other requesting system, runs a package at the DB2 server. A statement in the package uses an alias or a three-part name to request services from a second DB2 UDB for z/OS server. The ID that is checked for the privileges that are needed to run at the second server can be:

- The owner of the plan that is running at the requester (if the requester is DB2 UDB for z/OS or OS/390)
- The owner of the package that is running at the DB2 server
- The authorization ID of the process that runs the package at the first DB2 server (the "process runner")

In addition, if a remote alias is used in the SQL, the alias must be defined at the requester site. The ID that is used depends on these four factors:

- Whether the requester is DB2 UDB for z/OS or OS/390, or a different system.
- The value of the bind option DYNAMICRULES. See "Authorization for dynamic SQL statements" on page 164 for detailed information about the DYNAMICRULES options.

- Whether the parameter HOPAATH at the DB2 server site was set to BOTH or RUNNER when the installation job DSNTIJUZ was run. The default value is BOTH.
- Whether the statement that is executed at the second server is static or dynamic SQL.

**Hop situation with non-DB2 UDB for z/OS or OS/390 server:** Using DBPROTOCOL(DRDA), a three-part name statement can hop to a server other than DB2 UDB for z/OS or OS/390. In this hop situation, only package authorization information is passed to the second server.

A hop is not allowed on a connection that matches the LUWID of another existing DRDA thread. For example, in a hop situation from site A to site B to site C to site A, a hop is not allowed to site A again.

Table 44 shows how these factors determine the ID that must hold the required privileges when bind option DBPROTOCOL (PRIVATE) is in effect.

Table 44. The authorization ID that must hold required privileges for the double-hop situation

Requester	DYNAMICRULES	HOPAATH	Statement	Authorization ID
DB2 UDB for z/OS	Run behavior (default) <sup>1</sup>	n/a	Static	Plan owner
			Dynamic	Process runner
	Bind behavior <sup>1</sup>	n/a	Either	Plan owner
Different system or RRSF application without a plan	Run behavior (default) <sup>1</sup>	YES (default)	Static	Package owner
			Dynamic	Process runner
	Bind behavior <sup>1</sup>	NO	Either	Process runner
			Either	Package owner

**Note:** <sup>1</sup> If DYNAMICRULES define behavior is in effect, DB2 converts to DYNAMICRULES bind behavior. If DYNAMICRULES invoke behavior is in effect, DB2 converts to DYNAMICRULES run behavior.

### Checking authorization to execute an RRSF application without a plan

RRSAF provides the capability for an application to connect to DB2 and run without a DB2 plan. If an RRSF application does not have a plan, the following authorization rules are true:

- For the following types of packages, the primary or secondary authorization ID of the process is used for checking authorization to execute the package:
  - A local package
  - A remote package that is on a DB2 UDB for z/OS or OS/390 system and is accessed using DRDA
- At a DB2 UDB for z/OS or OS/390 system, the authorization to execute the DESCRIBE TABLE statement includes checking the primary and secondary authorization IDs.
- For a double hop situation, the authorization ID that must hold the required privileges to execute SQL statements at the second server is determined as if the requester is not a DB2 UDB for z/OS or OS/390 system. Table 44 lists the specific privileges.

### Caching authorization IDs for best performance

You can specify that DB2 cache authorization IDs for plans, packages, or routines (user-defined functions and stored procedures). Caching IDs can greatly improve

performance, especially when IDs are reused frequently. One cache exists for each plan, one global cache exists for packages, and a global cache exists for routines. The global cache for packages and routines are allocated at DB2 startup. For a data sharing group, each member does its own authorization caching.

**Caching IDs for plans:** Authorization checking is fastest when the EXECUTE privilege is granted to PUBLIC and, after that, when the plan is reused by an ID that already appears in the cache.

You can set the size of the plan authorization cache by using the BIND PLAN subcommand. For suggestions on setting this cache size, see Part 5 of *DB2 Application Programming and SQL Guide*. The default cache size is specified by an installation option, with an initial default setting of 3072 bytes.

**Caching IDs for packages:** This performance enhancement provides a run-time benefit for:

- Stored procedures
- Remotely bound packages
- Local packages in a package list in which the plan owner does not have execute authority on the package at bind time, but does at run time
- Local packages that are not explicitly listed in a package list, but are implicitly listed by *collection-id.\**, *\*.\**, or *\*.package-id*

You can set the size of the package authorization cache using the PACKAGE AUTH CACHE field on installation panel DSNTIPP. The default value, 100 KB, is enough storage to support about 690 *collection-id.package-id* entries or *collection-id.\** entries.

You can cache more package authorization information by using any of the following strategies:

- Granting package execute authority to *collection.\**
- Granting package execute authority to PUBLIC for some packages or collections
- Increasing the size of the cache

The QTPACAUT field in the package accounting trace indicates how often DB2 succeeds at reading package authorization information from the cache.

**Caching IDs for routines:** The routine authorization cache stores authorization IDs with the EXECUTE privilege on a specific routine. A routine is identified as *schema.routine-name.type*, where the routine name is one of the following names:

- The specific function name for user-defined functions
- The procedure name for stored procedures
- *'\*\*'* for all routines in the schema

You can set the size of the routine authorization cache by using the ROUTINE AUTH CACHE field on installation panel DSNTIPP. The initial default setting of 100 KB is enough storage to support about 690 *schema.routine.type* or *schema.\*.type* entries.

You can cache more authorization information about routines by using the following strategies:

- Granting EXECUTE on *schema.\**
- Granting routine execute authority to PUBLIC for some or all routines in the schema

- Increasing the size of the cache

**Caching and multilevel security:** Caching is used with multilevel security with row-level granularity to improve performance. DB2 caches all security labels that are checked (successfully and unsuccessfully) during processing. At commit or rollback, the security labels are removed from the cache. If a security policy that employs multilevel security with row-level granularity requires an immediate change and long-running applications have not committed or rolled back, you might need to cancel the application. For more information about multilevel security with row-level granularity, see “Working with data in a multilevel-secure environment” on page 199.

## Controls in the program

Because an ID executes a package or an application plan by running a program, implementing control measures in the program can be useful.

**Example:** Consider the SQL statement in “Privileges exercised through a plan or a package” on page 148, which permits access to the row of the employee table WHERE EMPNO='000010'. If you replace the value 000010 with a host variable, the program could supply the value of the variable and permit access to various employee numbers. Routines in the program could limit that access to certain IDs, certain times of the day, certain days of the week, or other special circumstances.

Stored procedures provide an alternative to controls in the program. By encapsulating several SQL statements into a single message to the DB2 server, a stored procedure can protect sensitive portions of the application program. Also, stored procedures can include access to non-DB2 resources, as well as DB2.

### Recommendation against use of controls in the program

Do not use programs to extend security. Whenever possible, use other techniques, such as stored procedures or views, as a security mechanism. Using programs to extend security has the following drawbacks:

- Program controls are separate from other access controls, can be difficult to implement properly, are difficult to audit, and are relatively simple to bypass.
- Almost any debugging facility can be used to bypass security checks in a program.
- Other programs might use the plan without doing the needed checking.
- Errors in the program checks might allow unauthorized access.
- Because the routines that check security might be quite separate from the SQL statement, the security check could be entirely disabled without requiring a bind operation for a new plan.
- A BIND REPLACE operation for an existing plan does not necessarily revoke the existing EXECUTE privileges on the plan. (Revoking those privileges is the default, but the plan owner has the option to retain them. For packages, the EXECUTE privileges are always retained.)

For those reasons, if the program accesses any sensitive data, the EXECUTE privileges on the plan and on packages are also sensitive. They should be granted only to a carefully planned list of IDs.

### Restricting a plan or a package to particular systems

If you use controls in the program, limit the use of a plan or package to the particular systems for which it was designed. DB2 does not ensure that only specific programs are used with a plan, but program-to-plan control can be

enforced in IMS and CICS. DB2 provides a consistency check to avoid accidental mismatches between program and plan, but the consistency check is not a security check.

**The ENABLE and DISABLE options:** You can limit the use of plans and packages by using the ENABLE and DISABLE options on the BIND and REBIND subcommands.

**Example:** The ENABLE IMS option allows the plan or package to run from any IMS connection. Unless other systems are also named, ENABLE IMS does not allow the plan or package to run from any other type of connection.

**Example:** DISABLE BATCH prevents a plan or package from running through a batch job, but it allows the plan or package to run from all other types of connection.

You can exercise even finer control with the ENABLE and DISABLE options. You can enable or disable particular IMS connection names, CICS application IDs, requesting locations, and so forth. For details, see the syntax of the BIND and REBIND subcommands in *DB2 Command Reference*.

## Privileges required for remote packages

Generally, the privileges that are required for a remote bind (BIND PACKAGE *location.collection*) must be granted at the server location. That is, the ID that owns the package must have all of the privileges that are required to run the package at the server, and BINDADD<sup>3</sup> and CREATE IN privileges at the server.

### Exceptions:

- For a BIND COPY operation, the owner must have the COPY privilege at the local DB2 site or subsystem, where the package that is being copied resides.
- If the creator of the package is not the owner, the creator must have SYSCTRL authority or higher, or must have been granted the BINDAGENT privilege by the owner. That authority or privilege is granted at the local DB2.

Binding a plan with a package list (BIND PLAN PKLIST) is done at the local DB2, and bind privileges must be held there. Authorization to execute a package at a remote location is checked at execution time, as follows:

- For DB2 private protocol, the owner of the plan at the requesting DB2 must have EXECUTE privilege for the package at the DB2 server.
- For DRDA, if the server is a DB2 UDB for z/OS subsystem, the authorization ID of the process (primary ID or any secondary ID) must have EXECUTE privilege for the package at the DB2 server.
- If the server is not DB2 UDB for z/OS, the primary authorization ID must have whatever privileges are needed. Check that product's documentation.

---

## Access control for user-defined functions and stored procedures

A number of steps are involved in implementing, defining, and invoking user-defined functions and stored procedures, which are also called *routines*. This section explains those steps and the authorizations that they require. The common tasks and required privileges for routines are summarized in Table 45 on page 155.

---

3. Or BIND, depending on the installation option BIND NEW PACKAGE.

Table 45. Common tasks and required privileges for routines

Role	Tasks	Required privileges
Implementer	<p>If SQL is in the routine: codes, precompiles, compiles, and link-edits the program to use as the routine. Binds the program as the routine package.</p> <p>If no SQL is in the routine: codes, compiles, and link-edits the program.</p>	If binding a package, BINDADD system privilege and CREATE IN on the collection.
Definer	Issues a CREATE FUNCTION statement to define a user-defined function or CREATE PROCEDURE statement to define a stored procedure.	CREATEIN privilege on the schema. EXECUTE authority on the routine package when invoked.
Invoker	Invokes a routine from an SQL application.	EXECUTE authority on the routine.

The routine *implementer* typically codes the routine in a program and precompiles the program. If the program contains SQL statements, the implementer binds the DBRM. In general, the authorization ID that binds the DBRM into a package is the package owner. The implementer is the routine package owner. As package owner, the implementer implicitly has EXECUTE authority on the package and has the authority to grant EXECUTE privileges to other users to execute the code within the package.

The implementer grants EXECUTE authority on the routine package to the definer. EXECUTE authority is necessary only if the package contains SQL. For user-defined functions, the definer requires EXECUTE authority on the package. For stored procedures, the EXECUTE privilege on the package is checked for the definer and other IDs. For information about these additional IDs, see the CALL statement in *DB2 SQL Reference*.

The *definer* is the routine owner. The definer issues a CREATE FUNCTION statement to define a user-defined function or a CREATE PROCEDURE statement to define a stored procedure. The definer of a routine is determined as follows:

- If the SQL statement is embedded in an application program, the definer is the authorization ID of the owner of the plan or package.
- If the SQL statement is dynamically prepared, the definer is the SQL authorization ID that is contained in the CURRENT SQLID special register.

The definer grants EXECUTE authority on the routine to the invoker, that is, any user ID that needs to invoke the routine.

The *invoker* invokes the routine from an SQL statement in the invoking plan or package. The invoker for a routine is determined as follows:

- For a static statement, the invoker is the authorization ID of the plan or package owner.
- For a dynamic statement, the invoker depends on DYNAMICRULES behavior. See “Authorization for dynamic SQL statements” on page 164 for a description of the options.

See *DB2 SQL Reference* for more information about the CREATE FUNCTION and CREATE PROCEDURE statements.

## Additional authorization for stored procedures

Prior to Version 8, stored procedures were defined to DB2 by inserting rows into catalog table SYSIBM.SYSPROCEDURES. Starting in Version 8, a stored procedure is defined with the CREATE PROCEDURE statement.

The CALL statement invokes a stored procedure. The privileges that are required to execute a stored procedure that is invoked by the CALL statement are described in Chapter 5 of *DB2 SQL Reference*.

Chapter 5 of *DB2 SQL Reference* also describes additional privileges that are required on each package that the stored procedure uses during its execution. The database server determines the privileges that are required and the authorization ID that must have the privileges.

## Controlling access to catalog tables for stored procedures

The SYSROUTINES\_SRC and SYSROUTINES\_OPTS catalog tables contain source code and build options for generated routines that are created by coding tools like the DB2 Stored Procedure Builder. Because a variety of users can use these coding tools, you need to control access to these catalog tables by performing the following steps:

- Determine criteria for limiting each application programmer's access to a subset of the SYSROUTINES\_SRC and SYSROUTINES\_OPTS rows.
- Create a view for each programmer by using these criteria.
- Grant the SELECT, INSERT, UPDATE, and DELETE privileges on each view to the appropriate programmer.

**Example:** Suppose that Alan is a programmer and that his ID is A1. Alan is working on a set of stored procedures for project B1. You want to create views that limit Alan's access to specific rows in SYSROUTINES\_SRC and SYSROUTINES\_OPTS. You can require that Alan use schema names that begin with the characters A1B1. Then you can create views that limit Alan's access to rows where the SCHEMA value begins with A1B1. The following CREATE statement creates a view on SYSROUTINES\_SRC:

```
CREATE VIEW A1.B1GRSRC AS
  SELECT SCHEMA, ROUTINENAME, VERSION,
         SEQNO, IBMREQD, CREATSTMT
  FROM SYSIBM.SYSROUTINE_SRC
  WHERE SCHEMA LIKE 'A1B1%'
  WITH CHECK OPTION;
```

The following CREATE statement creates a view on SYSROUTINES\_OPTS:

```
CREATE VIEW A1.B1GROPTS AS
  SELECT SCHEMA, ROUTINENAME, VERSION,
         BUILDSHEMA, BUILDNAME, BUILDOWNER, IBMREQD,
         PRECOMPILE_OPTS, COMPILE_OPTS, PRELINK_OPTS,
         LINK_OPTS, BIND_OPTS, SOURCEDSN
  FROM SYSIBM.SYSROUTINE_OPTS
  WHERE SCHEMA LIKE 'A1B1%'
  WITH CHECK OPTION;
```

Finally, you can use the following statement to let Alan view or update the appropriate SYSROUTINE\_SRC and SYSROUTINE\_OPTS rows:

```
GRANT SELECT, INSERT, DELETE, UPDATE
  ON (A1.B1GRSRC,A1.B1GROPTS)
  TO A1;
```

After a set of generated routines goes into production, you can decide to regain control over the routine definitions in SYSROUTINES\_SRC and SYSROUTINES\_OPTS by revoking the INSERT, DELETE, and UPDATE privileges on the appropriate views. You can allow programmers to keep the SELECT privilege on their views, so that they can use the old rows for reference when they define new generated routines.

#

## Example of roles and authorizations for a routine

This example describes how to get a routine up and running, and how to use and assign the required privileges and authorizations. The routine in the example is an external user-defined function. The steps in the example are divided into the following roles:

- The implementer role is described in “Implementing the user-defined function.”
- The definer role is described in “Defining the user-defined function” on page 159.
- The invoker role is described in “Using the user-defined function” on page 160.

Finally, DB2’s role in defining authorization IDs is described in “How DB2 determines authorization IDs” on page 161.

### Implementing the user-defined function

To implement a user-defined function, the implementer performs the following steps:

1. The implementer codes a program that implements the user-defined function. Assume that the implementer codes the following external user-defined function in C and names the function C\_SALARY:

```

/*****
* This routine accepts an employee serial number and a percent raise. *
* If the employee is a manager, the raise is not applied. Otherwise, *
* the new salary is computed, truncated if it exceeds the employee's *
* manager's salary, and then applied to the database. *
*****/
void C_SALARY                               /* main routine */
( char      *employeeSerial                 /* in: employee serial no. */
  decimal   *percentRaise                  /* in: percentage raise */
  decimal   *newSalary,                    /* out: employee's new salary */
  short int *niEmployeeSerial              /* in: indic var, empl ser */
  short int *niPercentRaise                /* in: indic var, % raise */
  short int *niNewSalary,                  /* out: indic var, new salary */
  char      *sqlstate,                     /* out: SQLSTATE */
  char      *fnName,                       /* in: family name of function */
  char      *specificName,                 /* in: specific name of func */
  char      *message                        /* out: diagnostic message */
)
{
EXEC SQL BEGIN DECLARE SECTION;
char      hvEMPNO-7-;                      /* host var for empl serial */
decimal   hvSALARY;                        /* host var for empl salary */
char      hvWORKDEPT-3-;                   /* host var for empl dept no. */
decimal   hvManagerSalary;                 /* host var, emp's mgr's salry*/
EXEC SQL END DECLARE SECTION;

sqlstate = 0;
memset( message,0,70 );
/*****
* Copy the employee's serial into a host variable *
*****/
strcpy( hvEMPNO,employeeSerial );
/*****
* Get the employee's work department and current salary *
*****/
EXEC SQL SELECT  WORKDEPT, SALARY
                INTO :hvWORKDEPT, :hvSALARY
                FROM  EMP
                WHERE EMPNO = :hvEMPNO;
/*****
* See if the employee is a manager *
*****/
EXEC SQL SELECT  DEPTNO
                INTO :hvWORKDEPT
                FROM  DEPT
                WHERE MGRNO = :hvEMPNO;
/*****
* If the employee is a manager, do not apply the raise *
*****/
if( SQLCODE == 0 )
{
    newSalary = hvSALARY;
}
}

```

Figure 11. Example of a user-defined function (Part 1 of 2)

```

/*****
* Otherwise, compute and apply the raise such that it does not
* exceed the employee's manager's salary
*****/
else
{
/*****
* Get the employee's manager's salary
*****/
EXEC SQL SELECT SALARY
        INTO :hvManagerSalary
        FROM EMP
        WHERE EMPNO = (SELECT MGRNO
                        FROM DSN8610.DEPT
                        WHERE DEPTNO = :hvWORKDEPT);
/*****
* Compute proposed raise for the employee
*****/
newSalary = hvSALARY * (1 + percentRaise/100);
/*****
* Don't let the proposed raise exceed the manager's salary
*****/
if( newSalary > hvManagerSalary
    newSalary = hvManagerSalary;
/*****
* Apply the raise
*****/
hvSALARY = newSalary;
EXEC SQL UPDATE EMP
        SET SALARY = :hvSALARY
        WHERE EMPNO = :hvEMPNO;
}

return;
} /* end C_SALARY */

```

Figure 11. Example of a user-defined function (Part 2 of 2)

The implementer requires the UPDATE privilege on table EMP. Users with the EXECUTE privilege on function C\_SALARY do not need the UPDATE privilege on the table.

2. Because this program contains SQL, the implementer performs the following steps:
  - a. Precompile the program that implements the user-defined function.
  - b. Link-edit the user-defined function with DSNRLI (RRS attachment facility), and name the program's load module C\_SALARY.
  - c. Bind the DBRM into package MYCOLLID.C\_SALARY.

After performing these steps, the implementer is the *function package owner*.

3. The implementer then grants EXECUTE privilege on the user-defined function package to the definer.

```

GRANT EXECUTE ON PACKAGE MYCOLLID.C_SALARY
TO definer

```

As package owner, the implementer can grant execute privileges to other users, which allows those users to execute code within the package. For example:

```

GRANT EXECUTE ON PACKAGE MYCOLLID.C_SALARY
TO other_user

```

## Defining the user-defined function

To define a user-defined function, the definer performs the following steps:

1. The definer executes the following CREATE FUNCTION statement to define the user-defined function salary\_change to DB2:

```
CREATE FUNCTION
  SALARY_CHANGE(
    VARCHAR( 6 )
    DECIMAL( 5,2 ) )
  RETURNS
    DECIMAL( 9,2 )
  SPECIFIC schema.SALCHANGE
  LANGUAGE C
  DETERMINISTIC
  MODIFIES SQL DATA
  EXTERNAL NAME C_SALARY
  PARAMETER STYLE_DB2SQL
  RETURNS NULL ON NULL CALL
  NO EXTERNAL ACTION
  NO SCRATCHPAD
  NO FINAL CALL
  ALLOW PARALLEL
  NO COLLID
  ASUTIME LIMIT 1
  STAY RESIDENT NO
  PROGRAM TYPE SUB
  WLM ENVIRONMENT WLMENV
  SECURITY DB2
  NO DBINFO;
```

After executing the CREATE FUNCTION statement, the definer owns the user-defined function. The definer can execute the user-defined function package because the user-defined function package owner, in this case the implementer, granted to the definer the EXECUTE privilege on the package that contains the user-defined function.

2. The definer then grants the EXECUTE privilege on SALARY\_CHANGE to all function invokers.

```
GRANT EXECUTE ON FUNCTION SALARY_CHANGE
  TO invoker1, invoker2, invoker3, invoker4
```

## Using the user-defined function

To use a user-defined function, the invoker performs the following steps:

1. The invoker codes an application program, named SALARY\_ADJ. The application program contains a static SQL statement that invokes the user-defined function SALARY\_CHANGE. SALARY\_CHANGE gives an employee a 10% raise if the employee is not a manager. The static SQL statement follows:

```
EXEC SQL SELECT  FIRSTNME,
                 LASTNAME
                 SALARY_CHANGE( :hvEMPNO, 10.0 )
  INTO :hvFIRSTNME,
       :hvLASTNAME,
       :hvSALARY
  FROM  EMP
  WHERE EMPNO = :hvEMPNO;
```

2. The invoker then precompiles, compiles, link-edits, and binds the invoking application's DBRM into the *invoking package* or *invoking plan*. An invoking package or invoking plan is the package or plan that contains the SQL that invokes the user-defined function. After performing these steps, the invoker is the owner of the invoking plan or package.

**Restriction:** The invoker must hold the SELECT privilege on the table EMP and the EXECUTE privilege on the function SALARY\_CHANGE.

## How DB2 determines authorization IDs

In this example, the invoking package SALARY\_ADJ contains a static SQL SELECT statement that invokes the user-defined function SALARY\_CHANGE. Therefore, DB2 uses the rules for static SQL to determine the authorization ID (invoker) that executes the user-defined function package C\_SALARY. For a static statement, the invoker is the authorization ID of the plan or package owner.

- While execution occurs in invoking package SALARY\_ADJ, DB2 uses the authorization ID of the invoker (the package owner).

The invoker requires the EXECUTE privilege on the user-defined function SALARY\_CHANGE, which the package SALARY\_ADJ invokes. Because the user-defined function definer has the EXECUTE privilege on the user-defined function package C\_SALARY, the invoker does not require the explicit EXECUTE privilege.

- When execution changes to the user-defined function package C\_SALARY, DB2 uses the authorization ID of the implementer (the package owner). The package owner is the authorization ID with authority to execute all static SQL in the user-defined function package C\_SALARY.

For an example of determining authorization IDs for dynamic SQL, see “Example of determining authorization IDs for dynamic SQL statements in routines” on page 168.

---

## Which IDs can exercise which privileges

When a process gains access to DB2, it has a primary authorization ID, an SQL ID, and perhaps one or more secondary authorization IDs. A plan or package also has an owner ID. To perform some actions, one specific ID must hold the required privileges. To perform other actions, any one or several of the IDs must hold the required privileges.

**Performance hints:** Consider the following performance hints when granting privileges to IDs:

- Limit the number of secondary IDs in your catalog table. For some actions, DB2 searches a catalog table for each ID until it finds a required privilege. A process can have up to 1012 secondary IDs. The more secondary IDs that must be checked, the longer the check takes.
- Ensure that the current SQL ID has the necessary privileges for dynamic SQL. Because the current SQL ID is checked first, the operation is fastest if that ID has all the necessary privileges.

Table 46 and Table 47 on page 162 summarize, for different actions, which IDs can provide the necessary privileges. For more specific details about any statement or command, see *DB2 SQL Reference* or *DB2 Command Reference*.

*Table 46. Required privileges for basic operations on dynamic SQL statements*

Operation	ID	Required privileges
GRANT	Current SQL ID	Any of the following privileges: <ul style="list-style-type: none"><li>• The applicable privilege with the grant option</li><li>• An authority that includes the privilege, with the grant option (not needed for SYSADM or SYSCTRL)</li><li>• Ownership that implicitly includes the privilege</li></ul>

Table 46. Required privileges for basic operations on dynamic SQL statements (continued)

Operation	ID	Required privileges
REVOKE	Current SQL ID	Must either have granted the privilege that is being revoked, or hold SYSCTRL or SYSADM authority.
CREATE, for unqualified object name	Current SQL ID	Applicable table, database, or schema privilege
Qualify name of object created	ID named as owner	Applicable table or database privilege. If the current SQL ID has SYSADM authority, the qualifier can be any ID at all, and need not have any privilege.
Other dynamic SQL if DYNAMICRULES uses run behavior	All primary IDs and secondary IDs and the current SQL ID together	As required by the statement; see "Composite privileges" on page 171. Unqualified object names are qualified by the value of the special register CURRENT SQLID. See "Authorization for dynamic SQL statements" on page 164.
Other dynamic SQL if DYNAMICRULES uses bind behavior	Plan or package owner	As required by the statement; see "Composite privileges" on page 171. DYNAMICRULES behavior determines how unqualified object names are qualified; see "Authorization for dynamic SQL statements" on page 164.
Other dynamic SQL if DYNAMICRULES uses define behavior	Function or procedure owner	As required by the statement; see "Composite privileges" on page 171. DYNAMICRULES behavior determines how unqualified object names are qualified; see "Authorization for dynamic SQL statements" on page 164.
Other dynamic SQL if DYNAMICRULES uses invoke behavior	ID of the SQL statement that invoked the function or procedure	As required by the statement; see "Composite privileges" on page 171. DYNAMICRULES behavior determines how unqualified object names are qualified; see "Authorization for dynamic SQL statements" on page 164.

Table 47. Required privileges for basic operations on plans and packages

Operation	ID	Required privileges
Execute a plan	Primary ID or any secondary ID	Any of the following privileges: <ul style="list-style-type: none"> <li>• Ownership of the plan</li> <li>• EXECUTE privilege for the plan</li> <li>• SYSADM authority</li> </ul>
Bind embedded SQL statements, for any bind operation	Plan or package owner	Any of the following privileges: <ul style="list-style-type: none"> <li>• Applicable privileges required by the statements</li> <li>• Authorities that include the privileges</li> <li>• Ownership that implicitly includes the privileges</li> </ul> <p>Object names include the value of QUALIFIER, where it applies.</p>

Table 47. Required privileges for basic operations on plans and packages (continued)

Operation	ID	Required privileges
Include package in PKLIST <sup>1</sup>	Plan owner	Any of the following privileges: <ul style="list-style-type: none"> <li>• Ownership of the package</li> <li>• EXECUTE privilege for the package</li> <li>• PACKADM authority over the package collection</li> <li>• SYSADM authority</li> </ul>
BIND a new plan using the default owner or primary authorization ID	Primary ID	BINDADD privilege, or SYSCTRL or SYSADM authority
BIND a new package using the default owner or primary authorization ID	Primary ID	<p>If the value of the field BIND NEW PACKAGE on installation panel DSNTIPP is BIND, any of the following privileges:</p> <ul style="list-style-type: none"> <li>• BINDADD privilege and CREATE IN privilege for the collection</li> <li>• PACKADM authority for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul> <p>If BIND NEW PACKAGE is BINDADD, any of the following privileges:</p> <ul style="list-style-type: none"> <li>• BINDADD privilege and either the CREATE IN or PACKADM privilege for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul>
BIND REPLACE or REBIND for a plan or package using the default owner or primary authorization ID	Primary ID or any secondary ID	<p>Any of the following privileges:</p> <ul style="list-style-type: none"> <li>• Ownership of the plan or package</li> <li>• BIND privilege for the plan or package</li> <li>• BINDAGENT from the plan or package owner</li> <li>• PACKADM authority for the collection (for a package only)</li> <li>• SYSADM or SYSCTRL authority</li> </ul> <p>See also “Multiple actions in one statement” on page 171.</p>
BIND a new version of a package, with default owner	Primary ID	<p>If BIND NEW PACKAGE is BIND, any of the following privileges:</p> <ul style="list-style-type: none"> <li>• BIND privilege on the package or collection</li> <li>• BINDADD privilege and CREATE IN privilege for the collection</li> <li>• PACKADM authority for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul> <p>If BIND NEW PACKAGE is BINDADD, any of the following:</p> <ul style="list-style-type: none"> <li>• BINDADD privilege and either the CREATE IN or PACKADM privilege for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul>
FREE or DROP a package <sup>2</sup>	Primary ID or any secondary ID	Any of the following privileges: <ul style="list-style-type: none"> <li>• Ownership of the package</li> <li>• BINDAGENT from the package owner</li> <li>• PACKADM authority for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul>

Table 47. Required privileges for basic operations on plans and packages (continued)

Operation	ID	Required privileges
COPY a package	Primary ID or any secondary ID	Any of the following: <ul style="list-style-type: none"> <li>• Ownership of the package</li> <li>• COPY privilege for the package</li> <li>• BINDAGENT from the package owner</li> <li>• PACKADM authority for the collection</li> <li>• SYSADM or SYSCTRL authority</li> </ul>
FREE a plan	Primary ID or any secondary ID	Any of the following privileges: <ul style="list-style-type: none"> <li>• Ownership of the plan</li> <li>• BIND privilege for the plan</li> <li>• BINDAGENT from the plan owner</li> <li>• SYSADM or SYSCTRL authority</li> </ul>
Name a new OWNER other than the primary authorization ID for any bind operation	Primary ID or any secondary ID	Any of the following privileges: <ul style="list-style-type: none"> <li>• New owner is the primary or any secondary ID</li> <li>• BINDAGENT from the new owner</li> <li>• SYSADM or SYSCTRL authority</li> </ul>

**Notes:**

1. A user-defined function, stored procedure, or trigger package does not need to be included in a package list.
2. A trigger package cannot be deleted by FREE PACKAGE or DROP PACKAGE. The DROP TRIGGER statement must be used to delete the trigger package.

## Authorization for dynamic SQL statements

This section explains authorization behavior for dynamic SQL statements. The two key factors that influence authorization behavior are the DYNAMICRULES value and the run time environment of a package.

The DYNAMICRULES option on the BIND or REBIND command determines what values apply at run time for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

The DYNAMICRULES option also determines whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the DYNAMICRULES value, the run-time environment of a package controls how dynamic SQL statements behave at run time. The two possible run-time environments are:

- The package runs as part of a stand-alone program.
- The package runs as a stored procedure or user-defined function package, or runs under a stored procedure or user-defined function.

A package that runs under a stored procedure or user-defined function is a package whose associated program meets one of the following conditions:

- The program is called by a stored procedure or user-defined function.
- The program is in a series of nested calls that start with a stored procedure or user-defined function.

The combination of the DYNAMICRULES value and the run-time environment determine the values for the dynamic SQL attributes. Those attribute values are called the dynamic SQL statement **behaviors**. The four behaviors are:

- “Run behavior”
- “Bind behavior”
- “Define behavior”
- “Invoke behavior” on page 166

The behaviors are summarized in “Common attribute values for bind, define, and invoke behavior” on page 166.

### **Run behavior**

DB2 processes dynamic SQL statements using the standard attribute values for dynamic SQL statements. These attributes are collectively called run behavior and consist of the following attributes:

- DB2 uses the authorization ID of the application process and the current SQL ID to:
  - Check for authorization of dynamic SQL statements
  - Serve as the implicit qualifier of table, view, index, and alias names
- Dynamic SQL statements use the values of application programming options that were specified during installation. The installation option USE FOR DYNAMICRULES has no effect.
- GRANT, REVOKE, CREATE, ALTER, DROP, and RENAME statements can be executed dynamically.

### **Bind behavior**

DB2 processes dynamic SQL statements using bind behavior. Bind behavior consists of the following attributes:

- DB2 uses the authorization ID of the plan or package for authorization checking of dynamic SQL statements.
- Unqualified table, view, index, and alias names in dynamic SQL statements are implicitly qualified with value of the bind option QUALIFIER; if you do not specify QUALIFIER, DB2 uses the authorization ID of the plan or package owner as the implicit qualifier.
- Bind behavior consists of the attribute values that are described in “Common attribute values for bind, define, and invoke behavior” on page 166.

The values of the authorization ID and the qualifier for unqualified objects are the same as those that are used for embedded or static SQL statements.

### **Define behavior**

When the package is run as or under a stored procedure or user-defined function package, DB2 processes dynamic SQL statements using define behavior. Define behavior consists of the following attribute values:

- DB2 uses the authorization ID of the user-defined function or the stored procedure owner for authorization checking of dynamic SQL statements in the application package.
- The default qualifier for unqualified objects is the user-defined function or the stored procedure owner.
- Define behavior consists of the attribute values that are described in “Common attribute values for bind, define, and invoke behavior” on page 166.

When the package is run as a stand-alone program, DB2 processes dynamic SQL statements using bind behavior or run behavior, depending on the DYNAMICRULES value specified.

### Invoke behavior

When the package is run as or under a stored procedure or user-defined function package, DB2 processes dynamic SQL statements using invoke behavior. Invoke behavior consists of the following attribute values:

- DB2 uses the authorization ID of the user-defined function or the stored procedure invoker for authorization checking of dynamic SQL statements in the application package.  
If the invoker is the primary authorization ID of the process or the current SQL ID, the following rules apply:
  - The ID of the invoker is checked for the required authorization.
  - Secondary authorization IDs are also checked if they are needed for the required authorization.
- The default qualifier for unqualified objects is the user-defined function or the stored procedure invoker.
- Invoke behavior consists of the attribute values that are described in “Common attribute values for bind, define, and invoke behavior.”

When the package is run as a stand-alone program, DB2 processes dynamic SQL statements using bind behavior or run behavior, depending on the DYNAMICRULES specified value.

### Common attribute values for bind, define, and invoke behavior

The following attribute values apply to dynamic SQL statements in plans or packages that have bind, define, or invoke behavior:

- You can execute the statement SET CURRENT SQLID in a package or plan that is bound with any DYNAMICRULES value. However, DB2 does not use the current SQL ID as the authorization ID for dynamic SQL statements.  
DB2 always uses the current SQL ID as the qualifier for the EXPLAIN output PLAN\_TABLE.
- If the value of installation option USE FOR DYNAMICRULES is YES, DB2 uses the application programming default values that were specified during installation to parse and semantically verify dynamic SQL statements. If the value of USE for DYNAMICRULES is NO, DB2 uses the precompiler options to parse and semantically verify dynamic SQL statements. For a list of the application programming defaults that USE FOR DYNAMICRULES affects, see Part 5 of *DB2 Application Programming and SQL Guide*.
- GRANT, REVOKE, CREATE, ALTER, DROP, and RENAME statements cannot be executed dynamically.

Table 48 shows DYNAMICRULES values, run-time environments, and the dynamic SQL behaviors that they yield.

Table 48. How DYNAMICRULES and the run-time environment determine dynamic SQL statement behavior

DYNAMICRULES value	Behavior of dynamic SQL statements	
	Stand-alone program environment	User-defined function or stored procedure environment
BIND	Bind behavior	Bind behavior
RUN	Run behavior	Run behavior

Table 48. How DYNAMICRULES and the run-time environment determine dynamic SQL statement behavior (continued)

DYNAMICRULES value	Behavior of dynamic SQL statements	
	Stand-alone program environment	User-defined function or stored procedure environment
DEFINEBIND	Bind behavior	Define behavior
DEFINERUN	Run behavior	Define behavior
INVOKEBIND	Bind behavior	Invoke behavior
INVOKERUN	Run behavior	Invoke behavior

**Note:** The BIND and RUN values can be specified for packages and plans. The other values can be specified only for packages.

Table 49 shows the dynamic SQL attribute values for each type of dynamic SQL behavior.

Table 49. Definitions of dynamic SQL statement behaviors

Dynamic SQL attribute	Setting for dynamic SQL attributes			
	Bind behavior	Run behavior	Define behavior	Invoke behavior
Authorization ID	Plan or package owner	Current SQLID	User-defined function or stored procedure owner	Authorization ID of invoker <sup>1</sup>
Default qualifier for unqualified objects	Bind OWNER or QUALIFIER value	Current SQLID	User-defined function or stored procedure owner	Authorization ID of invoker
CURRENT SQLID <sup>2</sup>	Not applicable	Applies	Not applicable	Not applicable
Source for application programming options	Determined by DSNHDECP parameter DYNRULS <sup>3</sup>	Install panel DSNTIPF	Determined by DSNHDECP parameter DYNRULS <sup>3</sup>	Determined by DSNHDECP parameter DYNRULS <sup>3</sup>
Can execute GRANT, REVOKE, CREATE, ALTER, DROP, RENAME?	No	Yes	No	No

**Notes:**

1. If the invoker is the primary authorization ID of the process or the current SQL ID, the following rules apply:
  - The ID of the invoker is checked for the required authorization.
  - Secondary authorization IDs are also checked if they are needed for the required authorization.
2. DB2 uses the current SQL ID as the authorization ID for dynamic SQL statements only for plans and packages that have DYNAMICRULES run behavior. For the other dynamic SQL behaviors, DB2 uses the authorization ID that is associated with each dynamic SQL behavior, as shown in this table.

The initial current SQL ID is independent of the dynamic SQL behavior. For stand-alone programs, the current SQL ID is initialized to the primary authorization ID. See *DB2 Application Programming and SQL Guide* for information about initialization of current SQL ID for user-defined functions and stored procedures.

You can execute the SET CURRENT SQLID statement to change the current SQL ID for packages with any dynamic SQL behavior, but DB2 uses the current SQL ID only for plans and packages with run behavior.

3. The value of DSNHDECP parameter DYNRULS, which you specify in field USE FOR DYNAMICRULES in installation panel DSNTIPF, determines whether DB2 uses the precompiler options or the application programming defaults for dynamic SQL statements. See Part 5 of *DB2 Application Programming and SQL Guide* for more information.

## Example of determining authorization IDs for dynamic SQL statements in routines

Suppose that A is a stored procedure and C is a program that is neither a user-defined function nor a stored procedure. Also suppose that subroutine B is called by both stored procedure A and program C. Subroutine B, which is invoked by a language call, is neither a user-defined function nor a stored procedure. AP is the package that is associated with stored procedure A, and BP is the package that is associated with subroutine B. A, B, and C execute as shown in Figure 12.

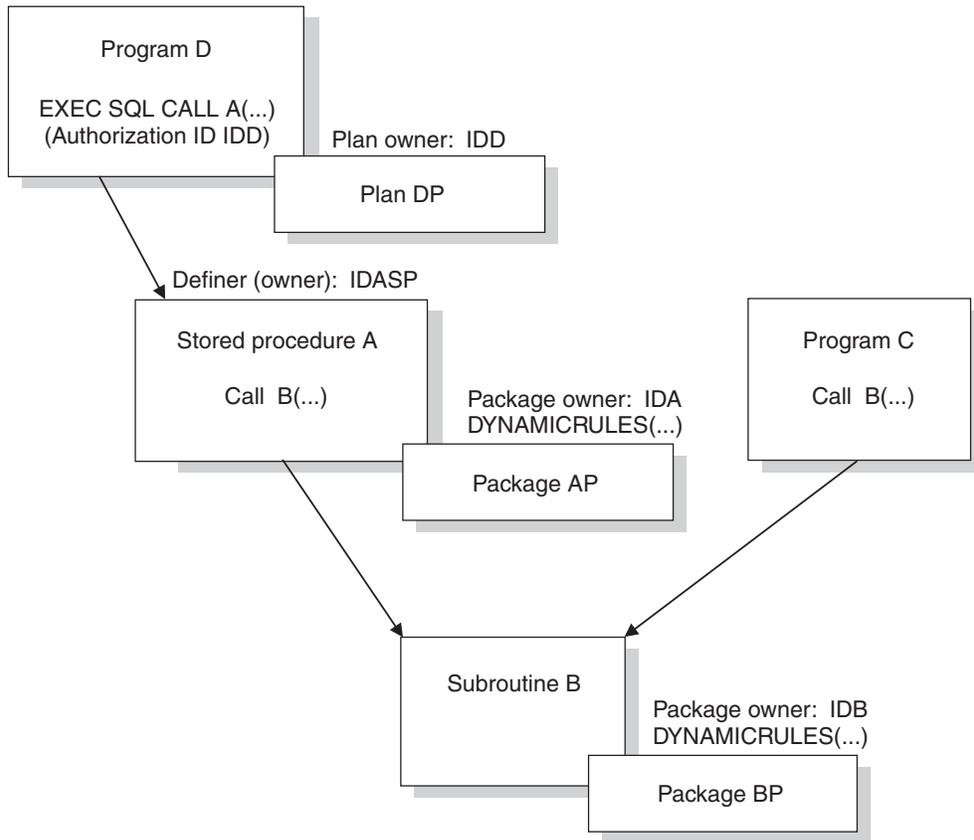

Figure 12. Authorization for dynamic SQL statements in programs and routines

Stored procedure A was defined by IDASP and is therefore owned by IDASP. The stored procedure package AP was bound by IDA and is therefore owned by IDA. Package BP was bound by IDB and is therefore owned by IDB. The authorization ID under which EXEC SQL CALL A runs is IDD, the owner of plan DP.

The authorization ID under which dynamic SQL statements in package AP run is determined in the following way:

- If package AP uses DYNAMICRULES bind behavior, the authorization ID for dynamic SQL statements in package AP is IDA, the owner of package AP.
- If package AP uses DYNAMICRULES run behavior, the authorization ID for dynamic SQL statements in package AP is the value of CURRENT SQLID when the statements execute.
- If package AP uses DYNAMICRULES define behavior, the authorization ID for dynamic SQL statements in package AP is IDASP, the definer (owner) of stored procedure A.

- If package AP uses DYNAMICRULES invoke behavior, the authorization ID for dynamic SQL statements in package AP is IDD, the invoker of stored procedure A.

The authorization ID under which dynamic SQL statements in package BP run is determined in the following way:

- If package BP uses DYNAMICRULES bind behavior, the authorization ID for dynamic SQL statements in package BP is IDB, the owner of package BP.
- If package BP uses DYNAMICRULES run behavior, the authorization ID for dynamic SQL statements in package BP is the value of CURRENT SQLID when the statements execute.
- If package BP uses DYNAMICRULES define behavior:
  - When subroutine B is called by stored procedure A, the authorization ID for dynamic SQL statements in package BP is IDASP, the definer of stored procedure A.
  - When subroutine B is called by program C:
    - If package BP uses the DYNAMICRULES option DEFINERUN, DB2 executes package BP using DYNAMICRULES run behavior, which means that the authorization ID for dynamic SQL statements in package BP is the value of CURRENT SQLID when the statements execute.
    - If package BP uses the DYNAMICRULES option DEFINEBIND, DB2 executes package BP using DYNAMICRULES bind behavior, which means that the authorization ID for dynamic SQL statements in package BP is IDB, the owner of package BP.
- If package BP uses DYNAMICRULES invoke behavior:
  - When subroutine B is called by stored procedure A, the authorization ID for dynamic SQL statements in package BP is IDD, the authorization ID under which EXEC SQL CALL A executed.
  - When subroutine B is called by program C:
    - If package BP uses the DYNAMICRULES option INVOKERUN, DB2 executes package BP using DYNAMICRULES run behavior, which means that the authorization ID for dynamic SQL statements in package BP is the value of CURRENT SQLID when the statements execute.
    - If package BP uses the DYNAMICRULES option INVOKEBIND, DB2 executes package BP using DYNAMICRULES bind behavior, which means that the authorization ID for dynamic SQL statements in package BP is IDB, the owner of package BP.

Now suppose that B is a user-defined function, as shown in Figure 13 on page 170.

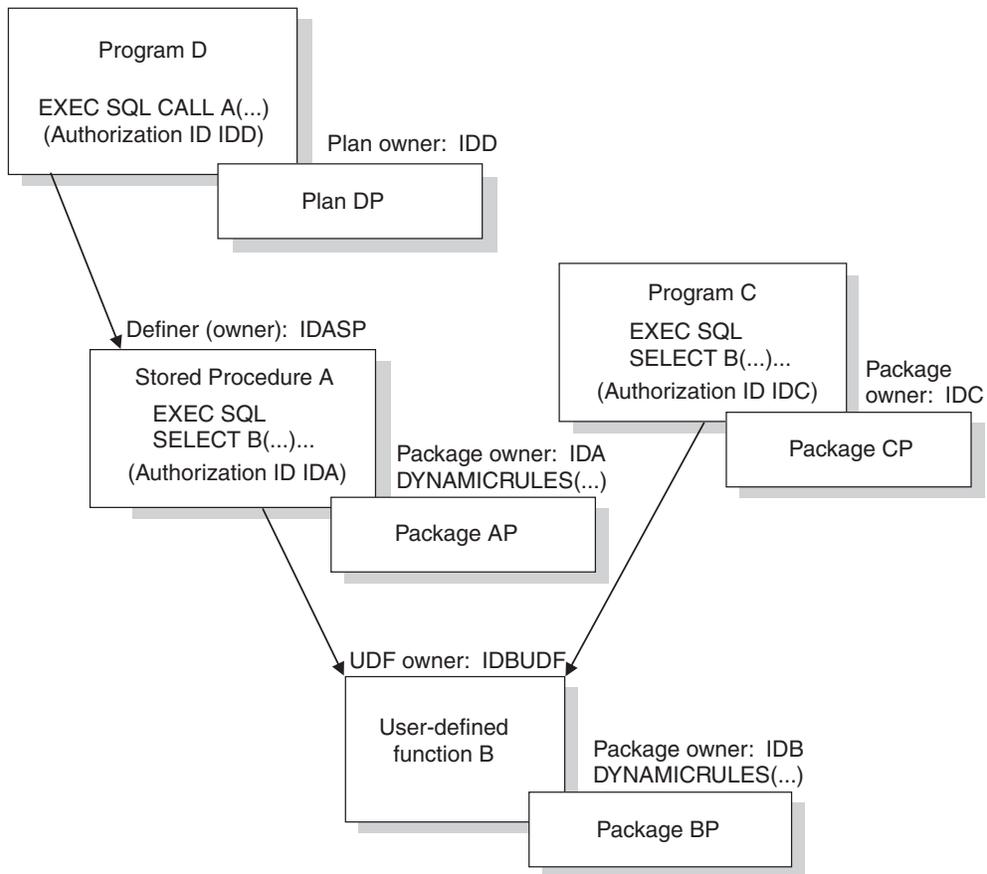

Figure 13. Authorization for dynamic SQL statements in programs and nested routines

User-defined function B was defined by `IDBUDF` and is therefore owned by ID `IDBUDF`. Stored procedure A invokes user-defined function B under authorization ID `IDA`. Program C invokes user-defined function B under authorization ID `IDC`. In both cases, the invoking SQL statement (`EXEC SQL SELECT B`) is static.

The authorization ID under which dynamic SQL statements in package BP run is determined in the following way:

- If package BP uses `DYNAMICRULES` bind behavior, the authorization ID for dynamic SQL statements in package BP is `IDB`, the owner of package BP.
- If package BP uses `DYNAMICRULES` run behavior, the authorization ID for dynamic SQL statements in package BP is the value of `CURRENT SQLID` when the statements execute.
- If package BP uses `DYNAMICRULES` define behavior, the authorization ID for dynamic SQL statements in package BP is `IDBUDF`, the definer of user-defined function B.
- If package BP uses `DYNAMICRULES` invoke behavior:
  - When user-defined function B is invoked by stored procedure A, the authorization ID for dynamic SQL statements in package BP is `IDA`, the authorization ID under which B is invoked in stored procedure A.
  - When user-defined function B is invoked by program C, the authorization ID for dynamic SQL statements in package BP is `IDC`, the owner of package CP, and is the authorization ID under which B is invoked in program C.

## Simplifying authorization

You can simplify authorization in several ways. However, you should ensure that you do not violate any of the authorization standards at your installation. Consider the following strategies to simplify authorization:

- Have the implementer bind the user-defined function package using DYNAMICRULES define behavior. With this behavior in effect, DB2 only needs to check the definer's ID to execute dynamic SQL statements in the routine. Otherwise, DB2 needs to check the many different IDs that invoke the user-defined function.
- If you have many different routines, group those routines into schemas. Then grant EXECUTE on the routines in the schema to the appropriate users. Users have execute authority on any functions that you add to that schema.

**Example:** To grant the EXECUTE privilege on a schema to PUBLIC, issue the following statement:

```
GRANT EXECUTE ON FUNCTION schemaname.* TO PUBLIC;
```

## Composite privileges

An SQL statement can name more than one object. For example, a SELECT operation can join two or more tables, or an INSERT can use a subquery. Those operations require privileges on all of the tables that are involved in the statement. However, you might be able to issue such a statement dynamically even though one of your IDs alone does not have all the required privileges.

If DYNAMICRULES run behavior is in effect when the dynamic statement is prepared and your primary ID or any of your secondary IDs have all the needed privileges, the statement is validated. However, if you embed the same statement in a host program and try to bind it into a plan or package, the validation fails. The validation also fails for the dynamic statement if DYNAMICRULES bind, define, or invoke behavior is in effect when you issue the dynamic statement. In each case, all the required privileges must be held by the single authorization ID, determined by DYNAMICRULES behavior.

## Multiple actions in one statement

A REBIND or FREE subcommand can name more than one plan or package. If no owner is named, the set of privileges associated with the primary ID and the secondary IDs must include the BIND privilege for each object.

**Example:** Suppose that a user with an ID of FREDDY has the BIND privilege on plan P1 and that a user with an ID of REUBEN has the BIND privilege on plan P2. Assume that someone with FREDDY and REUBEN as secondary authorization IDs issues the following command:

```
REBIND PLAN(P1,P2)
```

P1 and P2 are successfully rebound, even though neither the FREDDY ID nor the REUBEN ID has the BIND privilege for both plans.

---

## Matching job titles with privileges

The names of some authorities suggest job titles. For example, you might expect a system administrator to have SYSADM authority. But not all organizations divide job responsibilities in the same way. Table 50 on page 172 lists some other common job titles, the tasks that usually go with them, and the DB2 authorities or privileges that are needed to carry out those tasks.

Table 50. Some common jobs, tasks, and required privileges

Job title	Tasks	Required privileges
System Operator	Issues commands to: <ul style="list-style-type: none"> <li>• Start and stop DB2</li> <li>• Control traces</li> <li>• Display databases and threads</li> <li>• Recover indoubt threads</li> <li>• Start, stop, and display routines</li> </ul>	SYSOPR authority
System Administrator	Performs emergency backup, with access to all data.	SYSADM authority
Security Administrator	Authorizes other users, for some or all levels below.	SYSCTRL authority
Database Administrator	Designs, creates, loads, reorganizes, and monitors databases, tables, and other objects.	<ul style="list-style-type: none"> <li>• DBADM authority over a database</li> <li>• Use of storage groups and buffer pools</li> </ul>
System Programmer	<ul style="list-style-type: none"> <li>• Installs a DB2 subsystem.</li> <li>• Recovers the DB2 catalog.</li> <li>• Repairs data.</li> </ul>	Installation SYSADM, which is assigned when DB2 is installed. (Consider securing the password for an ID with this authority so that the authority is available only when needed.)
Application Programmer	<ul style="list-style-type: none"> <li>• Develops and tests DB2 application programs.</li> <li>• Creates tables of test data.</li> </ul>	<ul style="list-style-type: none"> <li>• BIND on existing plans or packages, or BINDADD</li> <li>• CREATE IN on some collections</li> <li>• Privileges on some objects</li> <li>• CREATETAB on some database, with a default table space provided</li> </ul>
Production Binder	Binds, rebinds, and frees application packages and plans	Secondary ID or RACF group with BINDADD, CREATE IN privileges required by application packages and plans
Package Administrator	Manages collections and the packages in them, and delegates the responsibilities.	PACKADM authority
User Analyst	Defines the data requirements for an application program, by examining the DB2 catalog.	<ul style="list-style-type: none"> <li>• SELECT on the SYSTABLES, SYSCOLUMNS, and SYSVIEWS catalog tables</li> <li>• CREATETMTAB system privilege to create temporary tables</li> </ul>
Program End User	Executes an application program.	EXECUTE for the application plan
Information Center Consultant	<ul style="list-style-type: none"> <li>• Defines the data requirements for a query user.</li> <li>• Provides the data by creating tables and views, loading tables, and granting access.</li> </ul>	<ul style="list-style-type: none"> <li>• DBADM authority over some databases</li> <li>• SELECT on the SYSTABLES, SYSCOLUMNS, and SYSVIEWS catalog tables</li> </ul>

Table 50. Some common jobs, tasks, and required privileges (continued)

Job title	Tasks	Required privileges
Query User	<ul style="list-style-type: none"> <li>Issues SQL statements to retrieve, add, or change data.</li> <li>Saves results as tables or in global temporary tables.</li> </ul>	<ul style="list-style-type: none"> <li>SELECT, INSERT, UPDATE, DELETE on some tables and views</li> <li>CREATETAB, to create tables in other than the default database</li> <li>CREATETMTAB system privilege to create temporary tables</li> <li>SELECT on SYSTABLES, SYSCOLUMNS, or views thereof. QMF provides the views.</li> </ul>

## Examples of granting and revoking privileges

The SQL GRANT statement lets you grant privileges explicitly. The REVOKE statement lets you take them away. You can revoke only privileges that have been specifically granted. You cannot use either statement unless authorization checking was enabled when DB2 was installed.

You can grant and revoke privileges to and from a single ID, or you can name several IDs on one GRANT or REVOKE statement. Additionally, you can grant privileges to the ID PUBLIC. When you grant privileges to PUBLIC, the privileges become available to all IDs at the local DB2, including the owner IDs of packages that are bound from a remote location.

When you grant any privilege to PUBLIC, DB2 catalog tables record the grantee of the privilege as PUBLIC. Implicit table privileges are also granted to PUBLIC for declared temporary tables. Because PUBLIC is a special identifier that is used by DB2 internally, you should not use PUBLIC as a primary ID or secondary ID. When a privilege is revoked from PUBLIC, authorization IDs to which the privilege was specifically granted retain the privilege.

However, when an ID uses PUBLIC privileges to perform actions, those actions and their resulting objects depend on PUBLIC not losing its privileges. If PUBLIC loses a privilege, objects that are created with that privilege might be dropped or invalidated. The following examples demonstrate how certain objects depend on PUBLIC not losing its privileges.

**Example:** Suppose that Juan has the ID USER1 and that Meg has the ID USER2. Juan creates a table TAB1 and grants ALL PRIVILEGES on it to PUBLIC. Juan does not explicitly grant any privileges on the table to Meg's ID, USER2. Using the PUBLIC privileges, Meg creates a view on TAB1. Because the ID USER2 requires the SELECT privilege on TAB1 to create the view, the view is dropped if PUBLIC loses the privilege.

**Example:** Suppose that Kim has the ID USER3. Kim binds a plan and names it PLAN1. PLAN1 contains a program that refers to TAB1 from the previous example. PLAN1 is not valid unless all of the proper privileges are held on objects to which the plan refers, including TAB1. Although Kim does not have any privileges on TAB1, Kim can bind the plan by using the PUBLIC privileges on TAB1. However, if PUBLIC loses its privilege, the plan is invalidated.

You can grant privileges in the following ways:

- Grant a specific privilege on one object in a single statement

- Grant a list of privileges
- Grant privileges over a list of objects
- Grant ALL, for all the privileges of accessing a single table, or for all privileges that are associated with a specific package

DB2 ignores duplicate grants and keeps only one record of a grant in the catalog.

**Example:** Suppose that Susan grants the SELECT privilege on the EMP table to Ray. Then suppose that Susan grants the same privilege to Ray again, without revoking the first grant. When Susan issues the second grant, DB2 ignores it and maintains the record of the first grant in the catalog.

The suppression of duplicate records applies not only to explicit grants, but also to the implicit grants of privileges that are made when a package is created.

*Granting privileges to remote users:* A query that arrives at your local DB2 through the distributed data facility (DDF) is accompanied by an authorization ID. That ID can go through connection or sign-on processing when it arrives, it can be translated to another value, and it can be associated with secondary authorization IDs. (For the details of all these processes, see “Controlling requests from remote applications” on page 238.)

As the end result of these processes, the remote query is associated with a set of IDs that is known to your local DB2 subsystem. You assign privileges to these IDs in the same way that you assign privileges to IDs that are associated with local queries.

You can grant a table privilege to any ID anywhere that uses DB2 private protocol access to your data, by issuing the following command:

```
GRANT privilege TO PUBLIC AT ALL LOCATIONS;
```

You can grant SELECT, INSERT, UPDATE, and DELETE table privileges.

If you grant a privilege to PUBLIC AT ALL LOCATIONS, the grantee is PUBLIC\*. Because PUBLIC\* is a special identifier that is used by DB2 internally, you should not use PUBLIC\* as a primary or secondary authorization ID. When a privilege is revoked from PUBLIC AT ALL LOCATIONS, authorization IDs to which the privilege was specifically granted still retain the privilege.

Some differences exist in the privileges for a query that uses system-directed access:

- Although the query can use privileges granted TO PUBLIC AT ALL LOCATIONS, it cannot use privileges granted TO PUBLIC.
- The query can exercise only the SELECT, INSERT, UPDATE, and DELETE privileges at the remote location.

These restrictions do not apply to queries that are run by a package that is bound at your local DB2 subsystem. Those queries can use any privilege that is granted to their associated IDs or any privilege that is granted to PUBLIC.

#

## Examples using the GRANT statement

The following examples show how to use different types of GRANT statements. This example does not demonstrate how to design a security plan for critical data. Instead, the example focuses on demonstrating a variety of situations in which you might use the GRANT statement.

Suppose that the Spiffy Computer Company wants to create a database to hold information that is usually posted on hallway bulletin boards. For example, the database might hold notices of upcoming holidays and bowling scores. Because the president of the Spiffy Computer Company is an excellent bowler, she wants everyone in the company to have access to her scores.

To create and maintain the tables and programs that are needed for this application, Spiffy Computer Company develops the security plan shown in Figure 14.

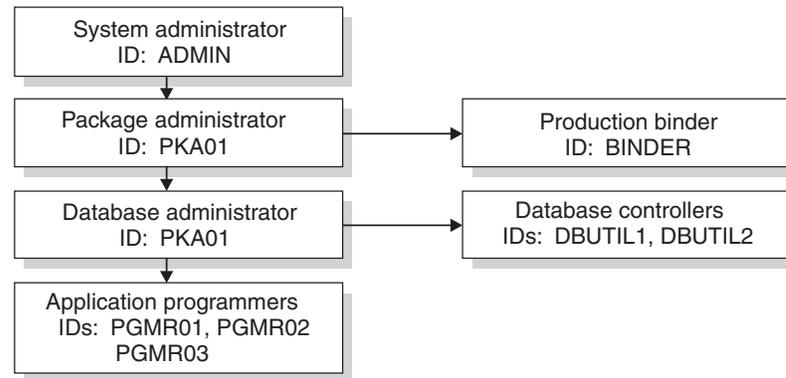

Figure 14. Security plan for the Spiffy Computer Company. Lines connect the grantor of a privilege or authority to the grantee.

Spiffy Computer Company's system of privileges and authorities associates each role with an authorization ID. For example, the System Administrator role has the ADMIN authorization ID.

## System administrator's privileges

User ID: ADMIN Authority: SYSADM Privileges: Ownership of SG1
---------------------------------------------------------------------

The system administrator uses the ADMIN authorization ID, which has SYSADM authority, to create a storage group (SG1) and to issue the following statements:

1. GRANT PACKADM ON COLLECTION BOWLS TO PKA01 WITH GRANT OPTION;  
 This statement grants to PKA01 the CREATE IN privilege on the collection BOWLS and BIND, EXECUTE, and COPY privileges on all packages in the collection. Because ADMIN used the WITH GRANT OPTION clause, PKA01 can grant those privileges to others.
2. GRANT CREATEDBA TO DBA01;  
 This statement grants to DBA01 the privilege to create a database and to have DBADM authority over that database.
3. GRANT USE OF STOGROUP SG1 TO DBA01 WITH GRANT OPTION;  
 This statement allows DBA01 to use storage group SG1 and to grant that privilege to others.
4. GRANT USE OF BUFFERPOOL BP0, BP1 TO DBA01 WITH GRANT OPTION;  
 This statement allows DBA01 to use buffer pools BP0 and BP1 and to grant that privilege to others.

## Package administrator's privileges

```
User ID: PKA01
Authority: PACKADM over the collection BOWLS
```

The package administrator, PKA01, controls the binding of packages into collections. PKA01 can use the CREATE IN privilege on the collection BOWLS and the BIND, EXECUTE, and COPY privileges on all packages in the collection. PKA01 also has the authority to grant these privileges to others.

## Database administrator's privileges

```
User ID: DBA01
Authority: DBADM over DB1
Privileges: CREATEDBA
           Use of SG1 with GRANT
           Use of BP0 and BP1 with GRANT
           Ownership of DB1
```

The database administrator, DBA01, using the CREATEDBA privilege, creates the database DB1. When DBA01 creates DB1, DBA01 automatically has DBADM authority over the database.

## Database controller's privileges

```
User ID: DBUTIL1, DBUTIL2
Authority: DBCTRL over DB1
```

The database administrator at Spiffy Computer Company wants help with running the COPY and RECOVER utilities. Therefore DBA01 grants DBCTRL authority over database DB1 to DBUTIL1 and DBUTIL2.

To grant DBCTRL authority, the database administrator issues the following statement:

```
GRANT DBCTRL ON DATABASE DB1 TO DBUTIL1, DBUTIL2;
```

## Examples with secondary IDs

The Spiffy Computer Company uses RACF (or a similar external security system). Therefore, Spiffy can use secondary authorization IDs to define user groups and associate primary authorization IDs with those user groups. The primary authorization IDs are the RACF user IDs. The secondary authorization IDs are the names of the groups with which the primary IDs are associated.

Spiffy can grant DB2 privileges to primary IDs indirectly, by granting privileges to secondary IDs that are associated with the primary IDs. This approach associates privileges with a *functional ID* rather than an *individual ID*. Functional IDs, also called group IDs, are granted privileges based on the function that certain job roles serve in the system. Multiple primary IDs can be associated with a functional ID and receive the privileges that are granted to that functional ID. In contrast, individual IDs are connected to specific people. Their privileges need to be updated as people join the company, leave the company, or serve different roles within the company. Functional IDs have the following advantages:

- Functional IDs reduce system maintenance because they are more permanent than individual IDs. Individual IDs require frequent updates, but each functional ID can remain in place until Spiffy redesigns its procedures.

**Example:** Suppose that Joe retires from the Spiffy Computer Company. Joe is replaced by Mary. If Joe's privileges are associated with functional ID DEPT4,

those privileges are maintained in the system even after Joe's individual ID is removed from the system. When Mary enters the system, she will have all of Joe's privileges after her ID is associated with the functional ID DEPT4.

- Functional IDs reduce the number of grants that are needed because functional IDs often represent groups of individuals.
- Functional IDs reduce the need to revoke privileges and re-create objects when they change ownership.

**Example:** Suppose that Bob changes jobs within the Spiffy Computer Company. Bob's individual ID has privileges on many objects in the system and owns three databases. When Bob's job changes, he no longer needs privileges over these objects or ownership of these databases. Because Bob's privileges are associated with his individual ID, a system administrator needs to revoke all of Bob's privileges on objects and drop and re-create Bob's databases with a new owner. If Bob received privileges by association with a functional ID, the system administrator would only need to remove Bob's association with the functional ID.

### Application programmers' privileges

The database administrator at Spiffy wants several employees in the Software Support department to create tables in the DB1 database. The database administrator creates DEVGROUP as a RACF group ID for this purpose. To simplify the process, the database administrator decides that each CREATE TABLE statement should implicitly create a unique table space for the table. Hence, DEVGROUP needs the CREATETAB privilege, the CREATETS privilege, the privilege to use the SG1 storage group and, the privilege to use one of the buffer pools, BP0, for the implicitly created table spaces. The following graphic shows this group and their privileges:

RACF Group ID: DEVGROUP
Privileges: (All without GRANT)
CREATETAB on DB1
CREATETS on DB1
Use of SG1
Use of BP0

The database administrator, DBA01, owns database DB1 and has the privileges to use storage group SG1 and buffer pool BP0. The database administrator holds both of these privileges with the GRANT option. The database administrator issues the following statements:

1. GRANT CREATETAB, CREATETS ON DATABASE DB1 TO DEVGROUP;
2. GRANT USE OF STOGROUP SG1 TO DEVGROUP;
3. GRANT USE OF BUFFERPOOL BP0 TO DEVGROUP;

Because the system and database administrators at Spiffy still need to control the use of those resources, the preceding statements are issued without the GRANT option.

Three programmers in the Software Support department write and test a new program, PROGRAM1. Their IDs are PGMR01, PGMR02, and PGMR03. Each programmer needs to create test tables, use the SG1 storage group, and use one of the buffer pools. All of those resources are controlled by DEVGROUP, which is a RACF group ID.

Therefore, granting privileges over those resources specifically to PGMR01, PGMR02, and PGMR03 is unnecessary. Each ID should be associated with the RACF group DEVGROUP and receive the privileges that are associated with that

functional ID. The following graphic shows the DEVGROUP and its members:

RACF group ID: DEVGROUP Group members: PGMR01, PGMR02, PGMR03
------------------------------------------------------------------

The security administrator connects as many members as desired to the group DEVGROUP. Each member can exercise all the privileges that are granted to the group ID.

This example assumes that the installed connection and sign-on procedures allow secondary authorization IDs. For examples of RACF commands that connect IDs to RACF groups, and for a description of the connection and sign-on procedures, see Chapter 11, “Controlling access to a DB2 subsystem,” on page 231.

### Privileges for binding the plan

Three programmers can now share the tasks that are done by the ID DEVGROUP. Someone creates a test table, DEVGROUP.T1, in database DB1 and loads it with test data. Someone writes a program, PROGRAM1, to display bowling scores that are contained in T1. Someone must bind the plan and packages that accompany the program. Binding requires an additional privilege. ADMIN, who has SYSADM authority, grants the required privilege by issuing the following statement:

```
GRANT BINDADD TO DEVGROUP;
```

With that privilege, any member of the RACF group DEVGROUP can bind plans and packages that are to be owned by DEVGROUP. Any member of the group can rebind a plan or package that is owned by DEVGROUP. The following graphic shows the BINDADD privilege granted to the group:

RACF group ID: DEVGROUP Privilege: BINDADD
-----------------------------------------------

The Software Support department proceeds to create and test the program.

### Moving PROGRAM1 into production

Spiffy has a different set of tables, which contain actual data that is owned by another group ID, PRODCN. PROGRAM1 was written with unqualified table names. For example, table T1 was referred to as simply T1, not DEVGROUP.T1. The new packages and plan must refer to table PRODCN.T1. To move the completed program into production, someone must perform the following steps:

- Rebind the application plan with the owner PRODCN.
- Rebind the packages into the collection BOWLS, again with the owner PRODCN.

Spiffy gives that job to a production binder with the ID BINDER. BINDER needs privileges to bind a plan or package that DEVGROUP owns, to bind a plan or package with OWNER (PRODCN), and to add a package to the collection BOWLS. BINDER acquires these abilities through its RACF DEVGROUP and PRODCN groups. These groups need to have all the necessary privileges.

Suppose that BINDER is a member of the RACF DEVGROUP and PRODCN groups, and the PRODCN group has the following privileges:

RACF group ID:	PRODC TN
Privileges:	BINDADD CREATE IN collection BOWLS Privileges on SQL objects referenced in application

BINDER can bind plans and packages for owner PRODC TN because it is a member of the RACF PRODC TN group.

PACKADM, the package administrator for BOWLS, can grant the CREATE privilege with the following statement:

```
GRANT CREATE ON COLLECTION BOWLS TO PRODC TN;
```

With the plan in place, the database administrator at Spiffy wants to make the PROGRAM1 plan available to all employees by issuing the following statement:

```
GRANT EXECUTE ON PLAN PROGRAM1 TO PUBLIC;
```

More than one ID has the authority or privileges that are necessary to issue this statement. For example, ADMIN has SYSADM authority and can grant the EXECUTE privilege. Also, BINDER (or any other members of the PRODC TN group) can set CURRENT SQLID to PRODC TN, which owns PROGRAM1, and issue the statement. When EXECUTE is granted to PUBLIC, other IDs do not need any explicit authority on T1.

Finally, the plan to display bowling scores at Spiffy Computer Company is complete. The production plan, PROGRAM1, is created, and all IDs have the authority to execute the plan.

### **Spiffy Computer Company's approach to distributed data**

Some time after the system and database administrators at Spiffy install their security plan, the president of Spiffy Computer Company tells them that other applications on other systems must connect to the local DB2 subsystem. She wants people at every location to be able to access bowling scores through PROGRAM1 on the local subsystem.

To enable access from all Spiffy locations, administrators perform the following steps:

1. Add a CONNECT statement to the program, naming the location at which table PRODC TN.T1 resides. (In this case, the table and the package reside at only the central location.)

2. Issue the following statement:

```
GRANT CREATE IN COLLECTION BOWLS TO DEVGROUP;
```

PKA01, who has PACKADM authority, grants the required privileges to DEVGROUP by issuing this statement.

3. Bind the SQL statements in PROGRAM1 as a package.

After the steps are completed, the package owner can issue the following statement:

```
GRANT EXECUTE ON PACKAGE PROGRAM1 TO PUBLIC;
```

Any system that is connected to the original DB2 location can then run PROGRAM1 and execute the package by using DRDA access.

**Restriction:** If the remote system is another DB2, a plan must be bound there that includes the package in its package list.

The preceding steps represent a simplified scenario that focuses on granting appropriate privileges and authorities. In practice, you would also need to consider questions like these:

- Is the performance of a remote query acceptable for this application?
- If other DBMSs are not DB2 subsystems, will the non-SQL portions of PROGRAM1 run in their environments?

## # Examples using the REVOKE statement

An ID that has granted a privilege can revoke the privilege by issuing the REVOKE statement like the following statement:

```
REVOKE authorization-specification FROM auth-id
```

An ID with SYSADM or SYSCTRL authority can revoke a privilege that has been granted by another ID with the following statement:

```
REVOKE authorization-specification FROM auth-id BY auth-id
```

The BY clause specifies the authorization ID that originally granted the privilege. If two or more grantors grant the same privilege to an ID, executing a single REVOKE statement does not remove the privilege. To remove it, each grant of the privilege must be revoked.

The WITH GRANT OPTION clause of the GRANT statement allows an ID to pass the granted privilege to others. If the privilege is removed from the ID, its deletion can cascade to others, with side effects that are not immediately evident. For example, when a privilege is removed from authorization ID X, it is also removed from any ID to which X granted it, unless that ID also has the privilege from some other source.

**Example:** Suppose that DBA01 grants DBCTRL authority with the GRANT option on database DB1 to DBUTIL1. Then DBUTIL1 grants the CREATETAB privilege on DB1 to PGMR01. If DBA01 revokes DBCTRL from DBUTIL1, PGMR01 loses the CREATETAB privilege. If PGMR01 also granted the CREATETAB privilege to OPER1 and OPER2, they also lose the privilege.

**Example:** Suppose that PGMR01 from the preceding example created table T1 while holding the CREATETAB privilege. If PGMR01 loses the CREATETAB privilege, table T1 is not dropped, and the privileges that PGMR01 has as owner of the table are not deleted. Furthermore, the privileges that PGMR01 grants on T1 are not deleted. For example, PGMR01 can grant SELECT on T1 to OPER1 as long as PGMR01 owns the table. Even when the privilege to create the table is revoked, the table remains, the privilege remains, and OPER1 can still access T1.

**Example:** Consider the following REVOKE scenario:

1. Grant #1: SYSADM, SA01, grants SELECT on TABLE1 to USER01 with the GRANT option.
2. Grant #2: USER01 grants SELECT on TABLE1 to USER02 with the GRANT option.
3. Grant #3: USER02 grants SELECT on TABLE1 back to SA01.
4. USER02 then revokes SELECT on TABLE1 from SA01.

The cascade REVOKE process of Grant #3 determines if SA01 granted SELECT to anyone else. It locates Grant #1. Because SA01 did not have SELECT from any

---

4. DB2 does not cascade a revoke of SYSADM authority from the installation SYSADM authorization IDs.

other source, this grant is revoked. The cascade REVOKE process then locates Grant #2 and revokes it for the same reason. In this scenario, the single REVOKE action by USER02 triggers and results in the cascade removal of all the grants even though SA01 has the SYSADM authority. The SYSADM authority is not considered.

### Privileges granted from two or more IDs

In addition to the CREATETAB privilege that DBUTIL1 grants to PGMR01, suppose that DBUTIL2 also grants the CREATETAB privilege to PGMR01. The second grant is recorded in the catalog, with its date and time, but it has no other effect until the grant from DBUTIL1 to PGMR01 is revoked. After the first grant is revoked, DB2 must determine which authority PGMR01 used to grant CREATETAB to OPER1. Figure 15 diagrams the situation; arrows represent the granting of the CREATETAB privilege.

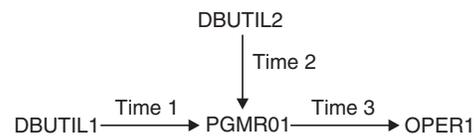

Figure 15. Authorization granted by two or more IDs

As in the diagram, suppose that DBUTIL1 issues the GRANT statement at Time 1 and that DBUTIL2 issues the GRANT statement at Time 2. DBUTIL1 and DBUTIL2 both use the following statement to issue the grant:

```
GRANT CREATETAB ON DATABASE DB1 TO PGMR01 WITH GRANT OPTION;
```

At Time 3, PGMR01 grants the privilege to OPER1 by using the following statement:

```
GRANT CREATETAB ON DATABASE DB1 TO OPER1;
```

After Time 3, DBUTIL1's authority is revoked, along with all of the privileges and authorities that DBUTIL1 granted. However, PGMR01 also has the CREATETAB privilege from DBUTIL2, so PGMR01 does not lose the privilege. The following criteria determine whether OPER1 loses the CREATETAB privilege when DBUTIL1's authority is revoked:

- If Time 3 *comes after* Time 2, OPER1 does not lose the privilege. The recorded dates and times show that, at Time 3, PGMR01 could have granted the privilege entirely on the basis of the privilege that was granted by DBUTIL2. That privilege was not revoked.
- If Time 3 is *precedes* Time 2, OPER1 does lose the privilege. The recorded dates and times show that, at Time 3, PGMR01 could have granted the privilege only on the basis of the privilege that was granted by DBUTIL1. That privilege was revoked, so the privileges that are dependent on it are also revoked.

### Revoking privileges granted by other IDs

An ID with SYSADM or SYSCTRL authority can revoke privileges that are granted by other IDs.

To revoke CREATETAB privileges that are granted to PGMR01 on database DB1 by all IDs, use the following statement:

```
REVOKE CREATETAB ON DATABASE DB1 FROM PGMR01 BY ALL;
```

However, you might want to revoke only privileges that are granted by a certain ID. To revoke privileges that are granted by DBUTIL1 and to leave intact the same privileges if they were granted by any other ID, use the following statement:

```
REVOKE CREATETAB, CREATETS ON DATABASE DB1 FROM PGMR01 BY DBUTIL1;
```

## Restricting revocation of privileges

Whether specified or not, the RESTRICT clause of the REVOKE always applies to the following objects:

- User-defined functions
- JARs (Java classes for a routine)
- Stored procedures
- Distinct types
- Sequences

When an attempt is made to revoke a privilege on one of these objects, DB2 determines whether the revokee owns an object that is dependent on the privilege. If such a dependency exists, the REVOKE statement proceeds only if the revokee also holds this privilege from another grantor or holds this privilege indirectly (such as if PUBLIC has this privilege, or if the revokee has SYSADM authority).

**Example:** Consider the following scenario:

1. UserA creates a user-defined function named UserA.UDFA.
2. UserA grants EXECUTE on UserA.UDFA to UserB.
3. User B then creates a user-defined function UserB.UDFB that is sourced on UserA.UDFA.

At this point, UserA attempts to revoke the EXECUTE privilege on UserA.UDFA from UserB. The revoke succeeds or fails based on the following criteria:

- If UserB has the EXECUTE privilege on UserA.UDFA only from UserA, the revoke fails with an accompanying message that indicates that a dependency on this privilege.
- If UserB has the EXECUTE privilege on UserA.UDFA from another source, directly or indirectly, the EXECUTE privilege that was granted by UserA is revoked successfully.

For distinct types, the following objects that are owned by the revokee can have dependencies:

- A table that has a column that is defined as a distinct type
- A user-defined function that has a parameter that is defined as a distinct type
- A stored procedure that has a parameter that is defined as a distinct type
- A sequence that has a parameter that is defined as a distinct type

For user-defined functions, the following objects that are owned by the revokee can have dependencies:

- Another user-defined function that is sourced on the user-defined function
- A view that uses the user-defined function
- A table that uses the user-defined function in a check constraint or user-defined default clause
- A trigger package that uses the user-defined function

For JARs (Java classes for a routine), the following objects that are owned by the revokee can have dependencies:

- A Java user-defined function that uses a JAR
- A Java stored procedure that uses a JAR

For stored procedures, a trigger package that refers to the stored procedure in a CALL statement can have dependencies.

For sequences, the following objects that are owned by the revokee can have dependencies:

- Triggers that contain NEXT VALUE or PREVIOUS VALUE expressions that specify a sequence
- Inline SQL routines that contain NEXT VALUE or PREVIOUS VALUE expressions that specify a sequence

One way to ensure that the REVOKE statement succeeds is to drop the object that has a dependency on the privilege. To determine which objects are dependent on which privileges before attempting the revoke, use the following SELECT statements.

For a distinct type:

- List all tables that are owned by the revokee USRT002 that contain columns that use the distinct type USRT001.UDT1:

```
SELECT * FROM SYSIBM.SYSCOLUMNS WHERE
  TBCreator = 'USRT002'      AND
  Typeschema = 'USRT001'    AND
  TypeName = 'UDT1'         AND
  ColType = 'DISTINCT';
```

- List the user-defined functions that are owned by the revokee USRT002 that contain a parameter that is defined as distinct type USRT001.UDT1:

```
SELECT * FROM SYSIBM.SYSPARMS WHERE
  Owner = 'USRT002'         AND
  Typeschema = 'USRT001'    AND
  TypeName = 'UDT1'         AND
  RoutineType = 'F';
```

- List the stored procedures that are owned by the revokee USRT002 that contain a parameter that is defined as distinct type USRT001.UDT1:

```
SELECT * FROM SYSIBM.SYSPARMS WHERE
  Owner = 'USRT002'         AND
  Typeschema = 'USRT001'    AND
  TypeName = 'UDT1'         AND
  RoutineType = 'P';
```

- List the sequences that are owned by the revokee USRT002 that contain a parameter that is defined as distinct type USRT001.UDT1:

```
SELECT SYSIBM.SYSSEQUENCES.SCHEMA, SYSIBM.SYSSEQUENCES.NAME
FROM SYSIBM.SYSSEQUENCES, SYSIBM.SYSDATATYPES WHERE
  SYSIBM.SYSSEQUENCES.DATATYPEID = SYSIBM.SYSDATATYPES.DATATYPEID AND
  SYSIBM.SYSDATATYPES.SCHEMA = 'USRT001' AND
  SYSIBM.SYSDATATYPES.NAME = 'UDT1';
```

For a user-defined function:

- List the user-defined functions that are owned by the revokee USRT002 that are sourced on user-defined function USRT001.SPECUDF1:

```
SELECT * FROM SYSIBM.SYSROUTINES WHERE
  Owner = 'USRT002'         AND
  SourceSchema = 'USRT001'  AND
  SourceSpecific = 'SPECUDF1' AND
  RoutineType = 'F';
```

- List the views that are owned by the revokee USRT002 that use user-defined function USRT001.SPECUDF1:

```

SELECT * FROM SYSIBM.SYSVIEWDEP WHERE
  DCREATOR = 'USRT002'      AND
  BSHEMA = 'USRT001'      AND
  BNAME = 'SPECUDF1'      AND
  BTYPE = 'F';

```

- List the tables that are owned by the revokee USRT002 that use user-defined function USRT001.A\_INTEGER in a check constraint or user-defined default clause:

```

SELECT * FROM SYSIBM.SYSCONSTDEP WHERE
  DTBCREATOR = 'USRT002'  AND
  BSHEMA = 'USRT001'      AND
  BNAME = 'A_INTEGER'     AND
  BTYPE = 'F';

```

- List the trigger packages that are owned by the revokee USRT002 that use user-defined function USRT001.UDF4:

```

SELECT * FROM SYSIBM.SYSPACKDEP WHERE
  DOWNER = 'USRT002'      AND
  BQUALIFIER = 'USRT001'  AND
  BNAME = 'UDF4'          AND
  BTYPE = 'F';

```

For a JAR (Java class for a routine):

List the routines that are owned by the revokee USRT002 and that use a JAR named USRT001.SPJAR:

```

SELECT * FROM SYSIBM.SYSROUTINES WHERE
  OWNER = 'USRT002'      AND
  JARCHEMA = 'USRT001'  AND
  JAR_ID = 'SPJAR';

```

For a stored procedure that is used in a trigger package:

List the trigger packages that refer to the stored procedure USRT001.WLMOCN2 that is owned by the revokee USRT002:

```

SELECT * FROM SYSIBM.SYSPACKDEP WHERE
  DOWNER = 'USRT002'      AND
  BQUALIFIER = 'USRT001'  AND
  BNAME = 'WLMOCN2'      AND
  BTYPE = 'O';

```

For a sequence:

- List the sequences that are owned by the revokee USRT002 and that use a trigger named USRT001.SEQ1:

```

SELECT * FROM SYSIBM.SYSPACKDEP WHERE
  BNAME = 'SEQ1'
  BQUALIFIER = 'USRT001'
  BTYPE = 'Q'
  DOWNER = 'USRT002'
  DTYPE = 'T';

```

- List the sequences that are owned by the revokee USRT002 and that use an inline SQL routine named USRT001.SEQ1:

```

SELECT * FROM SYSIBM.SYSSEQUENCESDEP WHERE
  DCREATOR = 'USRT002'
  DTYPE = 'F'
  BNAME = 'SEQ1'
  BSHEMA = 'USRT001';

```

## Other implications of the REVOKE statement

This section discusses some of the indirect implications of issuing a REVOKE statement.

**Views and privileges:** If a table privilege is revoked from the owner of a view on the table, the corresponding privilege on the view is revoked. The privilege on the view is revoked not only from the owner of the view, but also from all other IDs to which the owner granted the privilege.

If the SELECT privilege on the base table is revoked from the owner of the view, the view is dropped. However, if another grantor granted the SELECT privilege to the view owner before the view was created, the view is not dropped.

**Example:** Suppose that OPER2 has the SELECT and INSERT privileges on table T1 and creates a view of the table. If the INSERT privilege on T1 is revoked from OPER2, all insert privileges on the view are revoked. If the SELECT privilege on T1 is revoked from OPER2, and if OPER2 did not have the SELECT privilege from another grantor before the view was created, the view is dropped.

If a view uses a user-defined function, the view owner must have the EXECUTE privilege on the function. If the EXECUTE privilege is revoked, the revoke fails because the view is using the privilege and the RESTRICT clause prevents the revoke.

| **Materialized query tables and privileges:** If the SELECT privilege on a source table is revoked from the owner of a materialized query table, the corresponding privilege on the materialized query table is revoked. The SELECT privilege on the materialized query table is revoked not only from the owner of the materialized query table, but also from all other IDs to which the owner granted the SELECT privilege.

| If the SELECT privilege on the source table is revoked from the owner of a materialized query table, the materialized query table is dropped. However, if another grantor granted the SELECT privilege to the materialized query table owner before the materialized query table was created, the materialized query table is not dropped.

| **Example:** Suppose that OPER7 has the SELECT privilege on table T1 and creates a materialized query table T2 by selecting from T1. If the SELECT privilege on T1 is revoked from OPER7, and if OPER7 did not have the SELECT privilege from another grantor before T2 was created, T2 is dropped.

| If a materialized query table uses a user-defined function, the owner of the materialized query table must have the EXECUTE privilege on the function. If the EXECUTE privilege is revoked, the revoke fails because the materialized query table is using the privilege and the RESTRICT clause prevents the revoke.

| **Views created by SYSADM:** An authorization ID with SYSADM authority can create a view for another authorization ID. In this case, the view could have both a creator and an owner. The owner is automatically given the SELECT privilege on the view. However, the privilege on the base table determines whether the view is dropped.

| **Example:** Suppose that IDADM, with SYSADM authority, creates a view on TABLX with OPER as the owner of the view. OPER now has the SELECT privilege on the

view, but not necessarily any privileges on the base table. If SYSADM is revoked from IDADM, the SELECT privilege on TABLX is gone and the view is dropped.

If one ID creates a view for another ID, the catalog table SYSIBM.SYSTABAUTH needs either one or two rows to record the associated privileges. The number of rows that DB2 uses to record the privilege is determined by the following criteria:

- If IDADM creates a view for OPER when OPER has enough privileges to create the view by itself, only one row is inserted in SYSTABAUTH. The row shows only that OPER granted the required privileges.
- If IDADM creates a view for OPER when OPER does not have enough privileges to create the view by itself, two rows are inserted in SYSTABAUTH. One row shows IDADM as GRANTOR and OPER as GRANTEE of the SELECT privilege. The other row shows any other privileges that OPER might have on the view because of privileges that are held on the base table.

***Invalidated and inoperative application plans and packages:*** If the owner of an application plan or package loses a privilege that is required by the plan or package, and the owner does not have that privilege from another source, DB2 invalidates the plan or package.

**Example:** Suppose that OPER2 has the SELECT and INSERT privileges on table T1 and creates a plan that uses SELECT, but not INSERT. When privileges are revoked from OPER2, the plan is affected in the following ways:

- If the SELECT privilege is revoked, DB2 invalidates the plan.
- If the INSERT privilege is revoked, the plan is unaffected.
- If the revoked privilege was EXECUTE on a user-defined function, DB2 marks the plan or package **inoperative** instead of invalid.

***Implications for caching:*** If authorization data is cached for a package and an ID loses EXECUTE authority on the package, that ID is removed from the cache.

Similarly, if authorization data is cached for routines, a revoke or cascaded revoke of EXECUTE authority on a routine, or on all routines in a schema (schema.\*), from any ID causes the ID to be removed from the cache.

If authorization data is cached for plans, a revoke of EXECUTE authority on the plan from any ID causes the authorization cache to be invalidated.

If an application is caching dynamic SQL statements, and a privilege is revoked that was needed when the statement was originally prepared and cached, that statement is removed from the cache. Subsequent PREPARE requests for that statement do not find it in the cache and therefore execute a full PREPARE. If the plan or package is bound with KEEP\_DYNAMIC(YES), which means that the application does not need to explicitly re-prepare the statement after a commit operation, you might get an error on an OPEN, DESCRIBE, or EXECUTE of that statement following the next commit operation. The error can occur because a prepare operation is performed implicitly by DB2. If you no longer have sufficient authority for the prepare, the OPEN, DESCRIBE, or EXECUTE request fails.

***Revoking SYSADM from installation SYSADM:*** If you REVOKE SYSADM authority from an ID with installation SYSADM authority, DB2 does not cascade the revoke. Therefore, you can change the ID that holds installation SYSADM authority or delete extraneous IDs with SYSADM authority without cascading the revoke that these processes required.

To change the ID that holds installation SYSADM authority, perform the following steps:

1. Select a new ID that you will grant installation SYSADM authority.
2. Grant SYSADM authority to the ID that you selected.
3. Revoke SYSADM authority from the ID that currently holds installation SYSADM authority.
4. Update the SYSTEM ADMIN 1 or SYSTEM ADMIN 2 field on installation panel DSNTIPP with the new ID that you want to grant installation SYSADM authority.

To delete extraneous IDs with SYSADM authority, perform the following steps:

1. Write down the ID that currently holds installation SYSADM authority.
2. Change the authority of the ID that you want to delete from SYSADM to installation SYSADM. You can change the authority by updating the SYSTEM ADMIN 1 or SYSTEM ADMIN 2 field on installation panel DSNTIPP. Replace the ID that you wrote down in step 1 with the ID that you want to delete.
3. Revoke SYSADM authority from the ID that you want to delete.
4. Change the SYSTEM ADMIN 1 or SYSTEM ADMIN 2 field on installation panel DSNTIPP back to its original value.

For more information on installation panel DSNTIPP, see *DB2 Installation Guide*.

---

## Finding catalog information about privileges

The following catalog tables contain information about the privileges that IDs can hold.

*Table 51. Privileges information in DB2 catalog tables*

Table name	Records privileges held for
SYSIBM.SYSCOLAUTH	Updating columns
SYSIBM.SYSDBAUTH	Databases
SYSIBM.SYSPLANAUTH	Plans
SYSIBM.SYSPACKAUTH	Packages
SYSIBM.SYSRESAUTH	Buffer pools, storage groups, collections, table spaces, JARs, and distinct types
SYSIBM.SYSROUTINEAUTH	User-defined functions and stored procedures
SYSIBM.SYSSCHEMAAUTH	Schemas
SYSIBM.SYSTABAUTH	Tables and views
SYSIBM.SYSUSERAUTH	System authorities
SYSIBM.SYSSEQUENCEAUTH	Sequences

For descriptions of the columns of each table, see Appendix F of *DB2 SQL Reference*.

## Retrieving information in the catalog

You can query the DB2 catalog tables by using SQL SELECT statements. Executing these SQL statements requires appropriate privileges and authorities. You can control access to the catalog by granting and revoking these privileges and authorities. For suggestions about controlling the security of the catalog, see “Creating views of the DB2 catalog tables” on page 191.

## Retrieving all DB2 authorization IDs with granted privileges

Some of the catalog tables listed in Table 51 on page 187 include columns named GRANTEE and GRANTEETYPE. If GRANTEETYPE is blank, the value of GRANTEE is an ID that has been granted a privilege. No single catalog table contains information about all privileges. However, to retrieve all IDs with privileges, you can issue SQL code as shown in the following example:

```
SELECT GRANTEE, 'PACKAGE ' FROM SYSIBM.SYSPACKAUTH
      WHERE GRANTEETYPE = ' '
UNION
SELECT GRANTEE, 'TABLE   ' FROM SYSIBM.SYSTABAUTH
      WHERE GRANTEETYPE = ' '
UNION
SELECT GRANTEE, 'COLUMN  ' FROM SYSIBM.SYSCOLAUTH
      WHERE GRANTEETYPE = ' '
UNION
SELECT GRANTEE, 'ROUTINE ' FROM SYSIBM.SYSROUTINEAUTH
      WHERE GRANTEETYPE = ' '
UNION
SELECT GRANTEE, 'PLAN    ' FROM SYSIBM.SYSPLANAUTH
UNION
SELECT GRANTEE, 'SYSTEM  ' FROM SYSIBM.SYSUSERAUTH
UNION
SELECT GRANTEE, 'DATABASE' FROM SYSIBM.SYSDBAUTH
UNION
SELECT GRANTEE, 'SCHEMA  ' FROM SYSIBM.SYSSCHEMAAUTH
UNION
SELECT GRANTEE, 'USE     ' FROM SYSIBM.SYSRESAUTH
UNION
SELECT GRANTEE, 'SEQUENCE' FROM SYSIBM.SYSSEQUENCEAUTH;
```

Periodically, you should compare the list of IDs that is retrieved by this SQL code with the following lists:

- Lists of users from subsystems that connect to DB2 (such as IMS, CICS, and TSO)
- Lists of RACF groups
- Lists of users from other DBMSs that access your DB2

If DB2 lists IDs that do not exist elsewhere, you should revoke their privileges.

## Retrieving multiple grants of the same authorization

If several grantors grant the same privilege to the same grantee, the catalog can become cluttered with similar data. This similar data is often unnecessary, and it might cause poor performance.

**Example:** Suppose that Judy, Kate, and Patti all grant the SELECT privilege on TABLE1 to Chris. If you care that Chris's ID has the privilege but not who granted the privilege, you might consider two of the SELECT grants to be redundant and unnecessary performance liabilities.

However, you might want to maintain information about authorities that are granted from several different IDs, especially when privileges are revoked.

**Example:** Suppose that the SELECT privilege from the previous example is revoked from Judy. If Chris has the SELECT privilege from only Judy, Chris loses the SELECT privilege. However, Chris retains the SELECT privilege because Kate and Patti also granted the SELECT privilege to Chris. In this case, the similar grants prove not to be redundant.

You can query the catalog to find duplicate grants on objects. If multiple grants clutter your catalog, consider eliminating unnecessary grants. You can use the following SQL statement to retrieve duplicate grants on plans:

```
SELECT GRANTEE, NAME, COUNT(*)
  FROM SYSIBM.SYSPLANAUTH
  GROUP BY GRANTEE, NAME
  HAVING COUNT(*) > 2
  ORDER BY 3 DESC;
```

This statement orders the duplicate grants by frequency, so that you can easily identify the most duplicated grants. Similar statements for other catalog tables can retrieve information about multiple grants on other types of objects.

### Retrieving all IDs with DBADM authority

To retrieve all IDs that have DBADM authority, issue the following statement:

```
SELECT DISTINCT GRANTEE
  FROM SYSIBM.SYSDBAUTH
  WHERE DBADMAUTH <> ' ' AND GRANTEETYPE = ' ';
```

### Retrieving IDs authorized to access a table

To retrieve all IDs that are explicitly authorized to access the sample employee table (DSN8810.EMP in database DSN8D81A), issue the following statement:

```
SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
  WHERE TTNAME = 'EMP' AND TCREATOR = 'DSN8810'
  AND GRANTEETYPE = ' ';
```

To retrieve all IDs that can change the sample employee table (IDs with administrative authorities and IDs to which authority is explicitly granted), issue the following statement:

```
SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
  WHERE TTNAME = 'EMP' AND
  TCREATOR = 'DSN8810' AND
  GRANTEETYPE = ' ' AND
  (ALTERAUTH <> ' ' OR
  DELETEAUTH <> ' ' OR
  INSERTAUTH <> ' ' OR
  UPDATEAUTH <> ' ')
UNION
SELECT GRANTEE FROM SYSIBM.SYSUSERAUTH
  WHERE SYSADMAUTH <> ' '
UNION
SELECT GRANTEE FROM SYSIBM.SYSDBAUTH
  WHERE DBADMAUTH <> ' ' AND NAME = 'DSN8D81A';
```

To retrieve the columns of DSN8810.EMP for which update privileges have been granted on a specific set of columns, issue the following statement:

```
SELECT DISTINCT COLNAME, GRANTEE, GRANTEETYPE FROM SYSIBM.SYSCOLAUTH
  WHERE CREATOR='DSN8810' AND TNAME='EMP'
  ORDER BY COLNAME;
```

The character in the GRANTEETYPE column shows whether the privileges have been granted to an authorization ID (blank) or are used by an application plan or package (P).

To retrieve the IDs that have been granted the privilege of updating one or more columns of DSN8810.EMP, issue the following statement:

```

SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
  WHERE TTNAME = 'EMP' AND
         TCREATOR='DSN8810' AND
         GRANTEETYPE=' ' AND
         UPDATEAUTH <> ' ';

```

The query returns only the IDs to which update privileges have been specifically granted. It does not return IDs that have the privilege because of SYSADM or DBADM authority. You could include them by forming a union with additional queries, as shown in the following example:

```

SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
  WHERE TTNAME = 'EMP' AND
         TCREATOR = 'DSN8810' AND
         GRANTEETYPE = ' ' AND
         UPDATEAUTH <> ' '
UNION
SELECT GRANTEE FROM SYSIBM.SYSUSERAUTH
  WHERE SYSADMAUTH <> ' '
UNION
SELECT GRANTEE FROM SYSIBM.SYSDBAUTH
  WHERE DBADMAUTH <> ' ' AND NAME = 'DSN8D81A';

```

### Retrieving IDs authorized to access a routine

To retrieve the IDs that are authorized to access stored procedure PROCA in schema SCHEMA1, issue the following statement:

```

SELECT DISTINCT GRANTEE FROM SYSIBM.SYSROUTINEAUTH
  WHERE SPECIFICNAME='PROCA' AND
         SCHEMA='SCHEMA1' AND
         GRANTEETYPE=' ' AND
         ROUTINETYPE = 'P';

```

You can write a similar statement to retrieve the IDs that are authorized to access a user-defined function. To retrieve the IDs that are authorized to access user-defined function UDFA in schema SCHEMA1, issue the following statement:

```

SELECT DISTINCT GRANTEE FROM SYSIBM.SYSROUTINEAUTH
  WHERE SPECIFICNAME='UDFA' AND
         SCHEMA='SCHEMA1' AND
         GRANTEETYPE=' ' AND
         ROUTINETYPE = 'F';

```

### Retrieving the tables an ID is authorized to access

To retrieve the list of tables and views that PGM001 can access, issue the following statement:

```

SELECT DISTINCT TCREATOR, TTNAME FROM SYSIBM.SYSTABAUTH
  WHERE GRANTEE = 'PGMR001' AND GRANTEETYPE = ' ';

```

To retrieve the tables, views, and aliases that PGM001 owns, issue the following statement:

```

SELECT NAME FROM SYSIBM.SYSTABLES
  WHERE CREATOR = 'PGMR001';

```

### Retrieving the plans and packages that access a table

To retrieve the names of application plans and packages that refer to table DSN8810.EMP directly, issue the following statement:

```

SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
  WHERE GRANTEETYPE = 'P' AND
         TCREATOR = 'DSN8810' AND
         TTNAME = 'EMP';

```

The preceding query does not distinguish between plans and packages. To identify a package, use the COLLID column of table SYSTABAUTH, which names the collection in which a package resides and is blank for a plan.

A plan or package can refer to the table indirectly, through a view. To find all views that refer to the table, perform the following steps:

1. Issue the following query:

```
SELECT DISTINCT DNAME FROM SYSIBM.SYSVIEWDEP
WHERE BTYPE = 'T' AND
      BCREATOR = 'DSN8810' AND
      BNAME = 'EMP';
```

2. Write down the names of the views that satisfy the query. These values are instances of *DNAME\_list*.
3. Find all plans and packages that refer to those views by issuing a series of SQL statements. For each instance of *DNAME\_list*, issue the following statement:

```
SELECT DISTINCT GRANTEE FROM SYSIBM.SYSTABAUTH
WHERE GRANTEETYPE = 'P' AND
      TCREATOR = 'DSN8810' AND
      TTNAME = DNAME_list;
```

#

## Creating views of the DB2 catalog tables

Only an ID with SYSADM or SYSCTRL authority automatically has the privilege of retrieving data from catalog tables. If you do not want to grant the SELECT privilege on all catalog tables to PUBLIC, consider using views to let each ID retrieve information about its own privileges.

For example, the following view includes the owner and the name of every table on which a user's primary authorization ID has the SELECT privilege:

```
CREATE VIEW MYSELECTS AS
SELECT TCREATOR, TTNAME FROM SYSIBM.SYSTABAUTH
WHERE SELECTAUTH <> ' ' AND
      GRANTEETYPE = ' ' AND
      GRANTEE IN (USER, 'PUBLIC', 'PUBLIC*', CURRENT SQLID);
```

The keyword USER in that statement is equal to the value of the primary authorization ID. To include tables that can be read by a secondary ID, set the current SQLID to that secondary ID before querying the view.

To make the view available to every ID, issue the following GRANT statement:

```
GRANT SELECT ON MYSELECTS TO PUBLIC;
```

Similar views can show other privileges. This view shows privileges over columns:

```
CREATE VIEW MYCOLS (OWNER, TNAME, CNAME, REMARKS, LABEL)
AS SELECT DISTINCT TBCREATOR, TBNAME, NAME, REMARKS, LABEL
FROM SYSIBM.SYSCOLUMNS, SYSIBM.SYSTABAUTH
WHERE TCREATOR = TBCREATOR AND
      TTNAME = TBNAME AND
      GRANTEETYPE = ' ' AND
      GRANTEE IN (USER, 'PUBLIC', CURRENT SQLID, 'PUBLIC*');
```

---

## Multilevel security

### Important

The following information about multilevel security is specific to DB2. It does not describe all aspects of multilevel security. However, this specific information assumes that you have general knowledge of multilevel security. Before implementing multilevel security on your DB2 subsystem, read *z/OS Planning for Multilevel Security and the Common Criteria*.

## Introduction to multilevel security

*Multilevel security* is a security policy that allows you to classify objects and users based on a system of hierarchical security levels and a system of non-hierarchical security categories. Multilevel security provides the capability to prevent unauthorized users from accessing information at a higher classification than their authorization, and prevents users from declassifying information.

**Advantages of multilevel security:** Multilevel security offers the following advantages:

- Multilevel security enforcement is mandatory and automatic.
- Multilevel security can use methods that are difficult to express through traditional SQL views or queries.
- Multilevel security does not rely on special views or database variables to provide row-level security control.
- Multilevel security controls are consistent and integrated across the system, so that you can avoid defining users and authorizations more than once.
- Multilevel security does not allow users to declassify information.

Using multilevel security, you can define security for DB2 objects and perform other checks, including row-level security checks. Row-level security checks allow you to control which users have authorization to view, modify, or perform other actions on specific rows of data. For complete information about RACF and multilevel security, including defining security labels, and establishing, auditing, and operating a multilevel-secure environment, see *z/OS Planning for Multilevel Security and the Common Criteria*.

## Users and objects in multilevel security

In multilevel security, the relationship between users and objects is important. In the context of multilevel security, a user is any entity that requires access to system resources. The term *user* includes human users, but is not limited to people.

Examples of users include:

- Human users
- Stored procedures
- Batch jobs

In the context of multilevel security, an object is any system resource to which access must be controlled. Examples of objects include:

- Data sets
- Tables
- Rows
- Commands

## Security labels

Multilevel security restricts access to an object or a row based on the security label of the object or row and the security label of the user.

For local connections, the security label of the user is the security label that the user specified during sign-on. This security label is associated with the DB2 primary authorization ID and accessed from the RACF ACEE control block. If no security label is specified during sign-on, the security label is the user's default security label.

For TCP/IP connections, the security label of the user can be defined by the security zone. IP addresses are grouped into security zones on the DB2 server. Users that come in on an IP address have the security label that is associated with the security zone that the IP address is grouped under.

For SNA connections, the default security label for the user is used instead of the security label that the user signed on with.

Security labels are based on security levels and security categories. You can use the Common Criteria (COMCRIT) environment's subsystem parameter to require that all tables created in the subsystem are defined with security labels.

When defining security labels, do not include national characters, such as @, #, and \$. Use of these characters in security labels may cause CCSID conversions to terminate abnormally.

**Security levels:** Along with security categories, hierarchical security levels are used as a basis for mandatory access checking decisions. When you define the security level of an object, you define the degree of sensitivity of that object. Security levels ensure that an object of a certain security level is protected from access by a user of a lower security level.

For information about defining security levels, see *z/OS Security Server RACF Security Administrator's Guide*.

**Security categories:** Security categories are the non-hierarchical basis for mandatory access checking decisions. When making security decisions, mandatory access control checks whether one set of security categories includes the security categories that are defined in a second set of security categories.

## Mandatory access checking

Mandatory access checking evaluates dominance and determines whether to allow certain actions, based on the following rules:

- If the security label of the user dominates the security label of the object, the user can read from the object.
- If the security label of a user and the security label of the object are equivalent, the user can read from and write to the object.
- If the security label of the object dominates the security label of the user or the security labels are incompatible, the user cannot read or write from the object.

**Exception:** IDs with Install SYSADM authority bypass mandatory access checking at the DB2 object level because actions by Install SYSADM do not invoke the external access control exit routine (DSNX@XAC). However, multilevel security with row-level granularity is enforced for IDs with Install SYSADM authority.

| *Discretionary access checking:* Once the user passes the mandatory access check, a  
| discretionary check follows. The discretionary access check restricts access to  
| objects based on the identity of a user and the groups to which the user belongs.  
| The discretionary access check ensures that the user is identified as having a “need  
| to know” for the requested resource. The check is discretionary because a user  
| with a certain access permission is capable of passing that permission to any other  
| user.

## | **Dominant, reverse dominant, equivalent, and disjoint security labels**

| Mandatory access checking is based on the *dominance* relationships between user  
| security labels and object security labels. One security label dominates another  
| security label when both of the following conditions are true:

- | • The security level that defines the first security label is greater than or equal to  
| the security level that defines the second security label.
- | • The set of security categories that defines one security label includes the set of  
| security categories that defines the other security label.

# Comparisons between user security labels and object security labels can result in  
# four types of relationships:

### # **Dominant**

# One security label dominates another security label when both of the  
# following conditions are true:

- # • The security level that defines the first security label is greater than or  
# equal to the security level that defines the second security label.
- # • The set of security categories that defines the first security label includes  
# the set of security categories that defines the other security label.

# Reading data requires that the user security label dominates the data  
# security label.

### # **Reverse dominant**

# One security label reverse dominates another security label when both of  
# the following conditions are true:

- # • The security level that defines the first security label is less than or equal  
# to the security level that defines the second security label.
- # • The set of security categories that defines the first security label is a  
# subset of the security categories that defines the other security label.

### # **Equivalent**

# One security label is equivalent to another security label when they are the  
# same or have the same level and set of categories. If both dominance and  
# reverse dominance are true for two security labels, they are equivalent. The  
# user security label must be equivalent to the data security label to be able  
# to read and write data without being able to write down.

### # **Disjoint**

# A security label is disjoint or incompatible with another security label if  
# incompatible security categories cause neither security label to dominate  
# the other security label. Two security labels are disjoint when each of them  
# has at least one category that the other does not have. Disjoint access is not  
# allowed, even when a user is allowed to write down. If a user security  
# label that is disjoint to the data security label issues an INSERT, UPDATE,  
# or LOAD command, DB2 issues an error.

**Example:** Suppose that the security level "secret" for the security label HIGH is greater than the security level "sensitive" for the security label MEDIUM. Also, suppose that the security label HIGH includes the security categories Project\_A, Project\_B, and Project\_C, and that the security label MEDIUM includes the security categories Project\_A and Project\_B. The security label HIGH dominates the security label MEDIUM because both conditions for dominance are true.

**Example:** Suppose that the security label HIGH includes the security categories Project\_A, Project\_B, and Project\_C, and that the security label MEDIUM includes the security categories Project\_A and Project\_Z. In this case, the security label HIGH does not dominate the security label MEDIUM because the set of security categories that define the security label HIGH does not contain the security category Project\_Z. The security labels are disjoint.

### **Write-down control**

Mandatory access checking prevents users from declassifying information by not allowing a user to write to an object unless the security label of the user and the security label of the object are equivalent. You can override this security feature, known as write-down control, for specific users by granting write-down privilege to those users.

**Example:** Suppose that user1 has a security label of HIGH and that row\_x has a security label of MEDIUM. Because the security label of the user and the security label of the row are not equivalent, user\_1 cannot write to row\_x. Therefore, write-down control prevents user1 from declassifying the information that is in row\_x.

**Example:** Suppose that user2 has a security label of MEDIUM and that row\_x has a security label of MEDIUM. Because the security label of the user and the security label of the row are equivalent, user1 can read from and write to row\_x. However, user2 cannot change the security label for row\_x unless user2 has write-down privilege. Therefore write-down control prevents user2 from declassifying the information that is in row\_x.

**Granting write-down privilege:** To grant write-down privilege to users, you need to define a profile and then allow users to access the profile.

**Example:** To grant write down privilege to users, perform the following steps:

1. Define a profile. The following RACF command defines the IRR.WRITEDOWN.BYUSER profile:  

```
RDEFINE FACILITY IRR.WRITEDOWN.BYUSER UACC(NONE)
```
2. Allow specified users to access the profile. The following RACF command allows a group of users to access the IRR.WRITEDOWN.BYUSER profile:  

```
PERMIT IRR.WRITEDOWN.BYUSER ID(USRT051 USRT052 USRT054 USRT056 -  
USRT058 USRT060 USRT062 USRT064 USRT066 USRT068 USRT041) -  
ACCESS(UPDATE) CLASS(FACILITY)
```

## **Implementing multilevel security with DB2**

You can implement multilevel security with the following combinations:

### **DB2 authorization with multilevel security with row-level granularity**

In this combination, DB2 grants are used for authorization at the DB2 object level (database, table, and so forth). Multilevel security is implemented only on the row level within DB2.

## External access control and multilevel security with row-level granularity

In this combination, external access control (such as the RACF access control module) is used for authorization at the DB2 object level. External access control also uses security labels to perform mandatory access checking on DB2 objects as part of multilevel security. Multilevel security is also implemented on the row level within DB2. For information about the access control authorization exit, see "Access control authorization exit routine" on page 1065 and *DB2 RACF Access Control Module Guide*.

## Implementing multilevel security at the object level

To implement multilevel security with DB2 at the object level, perform the following steps:

1. Define security labels in RACF for all DB2 objects that require mandatory access checking by using the RDEFINE command. Define security labels for the following RACF resource classes:
  - DSNADM (administrative authorities)
  - DSNR (access to DB2 subsystems)
  - MDSNBP and GSNBP (buffer pools)
  - MDSNCL and GDSNCL (collections)
  - MDSNJR and MDSNJR (JAR)
  - MDSNPN and GDSNPN (plans)
  - MDSNSC and GDSNSC (schema)
  - MDSNSG and GDSNSG (storage groups)
  - MDSNSM and GDSNSM (system privileges)
  - MDSNSP and GDSNSP (stored procedures)
  - MDSNSQ and GDSNSQ (sequences)
  - MDSNTB and GDSNTB (tables, views, indexes)
  - MDSNTS and GDSNTS (table spaces)
  - MDSNUF and GDSNUF (user-defined functions)

You are responsible for ensuring a proper hierarchy of security labels. In general, the security label of an object that is higher in the object hierarchy should dominate the security labels of objects that are lower in the hierarchy. RACF and DB2 do not enforce the hierarchy; they merely enforce the dominance rules that you establish.

You can use RACF to define security labels for the DB2 objects in the following object hierarchy:

- Subsystem or data sharing group
  - Database
    - Table space
      - Table
        - Column
        - Row
  - View
  - Storage group
  - Buffer pool
  - Plan
  - Collection
    - Package
  - Schema
    - Stored procedure or user-defined function
    - Java Archive (JAR)
    - Distinct type
    - Sequence

The following examples suggest dominance relationships among objects in the DB2 object hierarchy.

**Example:** A collection should dominate a package.

**Example:** A subsystem should dominate a database. That database should dominate a table space. That table space should dominate a table. That table should dominate a column.

**Example:** If a view is based on a single table, the table should dominate the view. However, if a view is based on multiple tables, the view should dominate the tables.

**Recommendation:** Define the security label SYSMULTI for DB2 subsystems that are accessed by users with different security labels and tables that require row-level granularity.

2. Define security labels and associate users with the security labels in RACF. If you are using a TCP/IP connection, you need to define security labels in RACF for the security zones into which IP addresses are grouped. These IP addresses represent remote users.

**Recommendation:** Give users with SYSADM, SYSCTRL, and SYSOPR authority the security label of SYSHIGH.

3. Activate the SECLABEL class in RACF. If you want to enforce write-down control, turn on write-down control in RACF.
4. Install the external security access control authorization exit routine (DSNX@XAC), such as the RACF access control module.

### Implementing multilevel security with row-level granularity

Many applications need row-level security within the relational database, so that access can be restricted to a specific set of rows. This security control often needs to be mandatory, so that users, including application programmers and database administrators, are unable to bypass the row-level security mechanism. Using mandatory controls with z/OS and RACF provides consistency across the system.

You can implement multilevel security with row-level granularity with or without implementing multilevel security on the object level. If you implement multilevel security on the object level, you must perform step 1 and step 4 in “Implementing multilevel security at the object level” on page 196. If you do not use the access control authorization exit routine or RACF access control, you can use DB2 native authorization control.

**Recommendation:** Use multilevel security at the object level with multilevel security with row-level granularity. Using RACF with multilevel security provides an independent check at run time and always checks the authorization of a user to the data.

DB2 performs multilevel security with row-level granularity by comparing the security label of the user to the security label of the row that is accessed. Because security labels can be equivalent without being identical, DB2 uses the RACROUTE REQUEST=DIRAUTH macro to make this comparison when the two security labels are not the same. For read operations, such as SELECT, DB2 uses ACCESS=READ. For update operations, DB2 uses ACCESS=READWRITE.

The write-down privilege for multilevel security with row-level granularity has the following properties:

- A user with the write-down privilege can update the security label of a row to any valid value. The user can make this update independent of the user’s dominance relationship with the row.
- DB2 requires that a user have the write-down privilege to perform certain utilities.

- If write-down control is not enabled, all users with valid security labels are equivalent to users with the write-down privilege.

**Requirement:** You must have z/OS Version 1 Release 5 or later to use DB2 authorization with multilevel security with row-level granularity.

**Defining multilevel security on tables:** You can use multilevel security with row-level checking to control table access by creating or altering a table to have a column with the AS SECURITY LABEL attribute. Tables with multilevel security in effect can be dropped by using the DROP TABLE statement. Users must have a valid security label to execute CREATE TABLE, ALTER TABLE, and DROP TABLE statements on tables with multilevel security enabled. For information about defining security labels and enabling the security label class, see *z/OS Planning for Multilevel Security*.

**Indexing the security label column:** The performance of tables that you create and alter can suffer if the security label is not included in indexes. The security label column is used whenever a table with multilevel security enabled is accessed. Therefore, the security label column should be included in indexes on the table. If you do not index the security label column, you cannot maintain index-only access.

**CREATE TABLE:** When a user with a valid security label creates a table, the user can implement row-level security by including a security label column. The security label column can have any name, but it must be defined as CHAR(8) and NOT NULL WITH DEFAULT. It also must be defined with the AS SECURITY LABEL clause.

**Example:** To create a table that is named TABLEMLS1 and that has row-level security enabled, issue the following statement:

```
CREATE TABLE TABLEMLS1
  (EMPNO      CHAR(6)      NOT NULL,
   EMPNAME    VARCHAR(20)  NOT NULL,
   DEPTNO     VARCHAR(5)
   SECURITY   CHAR(8)      NOT NULL WITH DEFAULT AS SECURITY LABEL,
   PRIMARY KEY (EMPNO)
)
IN DSN8D71A.DSN8S71D;
```

After the user specifies the AS SECURITY LABEL clause on a column, users can indicate the security label for each row by entering values in that column. When a user creates a table and includes a security label column, SYSIBM.SYSTABLES indicates that the table has row-level security enabled. Once a user creates a table with a security label column, the security on the table cannot be disabled. The table must be dropped and recreated to remove this protection.

**ALTER TABLE:** A user with a valid security label can implement row-level security on an existing table by adding a security label column to the existing table. The security label column can have any name, but it must be defined as CHAR(8) and NOT NULL WITH DEFAULT. It also must be defined with the AS SECURITY LABEL clause.

**Example:** Suppose that the table EMP does not have row-level security enabled. To alter EMP so that it has row-level security enabled, issue the following statement:

```
ALTER TABLE EMP
  ADD SECURITY   CHAR(8)      NOT NULL WITH DEFAULT AS SECURITY LABEL;
```

After a user specifies the AS SECURITY LABEL clause on a column, row-level security is enabled on the table and cannot be disabled. The security label for

existing rows in the table at the time of the alter is the same as the security label of the user that issued the ALTER TABLE statement.

**Important:** Plans, packages, and dynamic statements are invalidated when a table is altered to add a security label column.

**DROP TABLE:** When a user with a valid security label drops a table that has row-level security in effect, the system generates an audit record. Row-level security does not affect the success of a DROP statement; the user's privilege on the table determines whether the statement succeeds.

For more information about these SQL statements and multilevel security, see the *DB2 SQL Reference*.

## Working with data in a multilevel-secure environment

Multilevel security with row-level checking affects the results of SELECT, INSERT, UPDATE, and DELETE statements and some utilities. For example, row-level checking ensures that DB2 does not return rows that have a HIGH security label to a user that has a LOW security label. Users must have a valid security label to execute SELECT, INSERT, UPDATE, and DELETE statements and some utilities on tables with multilevel security enabled.

In addition to SQL statements and utilities, this section discusses the following topics:

- “Using views to restrict access” on page 205
- “Global temporary tables with multilevel security” on page 205
- “Materialized query tables with multilevel security” on page 205
- “Constraints and multilevel security” on page 206
- “Field procedures, edit procedures, validation procedures, and multilevel security” on page 206
- “Triggers and multilevel security” on page 206

For information about defining security labels and enabling the security label class, see *z/OS Planning for Multilevel Security*.

### Using the SELECT statement with multilevel security

When a user with a valid security label selects data from a table or tables with row-level security enabled, DB2 compares the security label of the user to the security label of each row. Results are returned according to the following rules:

- If the security label of the user dominates the security label of the row, DB2 returns the row.
- If the security label of the user does not dominate the security label of the row, DB2 does not return the data from that row, and DB2 does not generate an error report.

**Example:** Suppose that Alan has a security label of HIGH, Beth has a security label of MEDIUM, and Carlos has a security label of LOW. Suppose that DSN8710.EMP contains the data that is shown in Table 52 and that the SECURITY column has been declared with the AS SECURITY LABEL clause.

Table 52. Sample data from DSN8710.EMP

EMPNO	LASTNAME	WORKDEPT	SECURITY
000010	HAAS	A00	LOW

Table 52. Sample data from DSN8710.EMP (continued)

EMPNO	LASTNAME	WORKDEPT	SECURITY
000190	BROWN	D11	HIGH
000200	JONES	D11	MEDIUM
000210	LUTZ	D11	LOW
000330	LEE	E21	MEDIUM

Now, suppose that Alan, Beth, and Carlos each submit the following SELECT statement:

```
SELECT LASTNAME  
FROM EMP  
ORDER BY LASTNAME;
```

Because Alan has the security label HIGH, he receives the following result:

```
BROWN  
HAAS  
JONES  
LEE  
LUTZ
```

Because Beth has the security label MEDIUM, she receives the following result:

```
HAAS  
JONES  
LEE  
LUTZ
```

Beth does not see BROWN in her result set because the row with that information has a security label of HIGH.

Because Carlos has the security label LOW, he receives the following result:

```
HAAS  
LUTZ
```

Carlos does not see BROWN, JONES, or LEE in his result set because the rows with that information have security labels that dominate Carlos's security label.

Although Beth and Carlos do not receive the full result set for the query, DB2 does not return an error code to Beth or Carlos.

### Using the INSERT statement with multilevel security

When a user with a valid security label inserts data into a table with row-level security enabled, the security label of the row is determined according to the following rules:

- If the user has write-down privilege or write-down control is not enabled, the user can set the security label for the row to any valid security label. If the user does not specify a value for the security label, the security label of the row becomes the same as the security label of the user.
- If the user does not have write-down privilege and write-down control is enabled, the security label of the row becomes the same as the security label of the user.

**Example:** Suppose that Alan has a security label of HIGH, that Beth has a security label of MEDIUM and write-down privilege defined in RACF, and that Carlos has a security label of LOW. Write-down control is enabled.

Now, suppose that Alan, Beth, and Carlos each submit the following INSERT statement:

```
INSERT INTO DSN8710.EMP(EMPNO, LASTNAME, WORKDEPT, SECURITY)
VALUES('099990', 'SMITH', 'C01', 'MEDIUM');
```

Because Alan does not have write-down privilege, Alan cannot choose the security label of the row that he inserts. Therefore DB2 ignores the security label of MEDIUM that is specified in the statement. The security label of the row becomes HIGH because Alan's security label is HIGH.

Because Beth has write-down privilege on the table, she can specify the security label of the new row. In this case, the security label of the new row is MEDIUM. If Beth submits a similar INSERT statement that specifies a value of LOW for the security column, the security label for the row becomes LOW.

Because Carlos does not have write-down privilege, Carlos cannot choose the security label of the row that he inserts. Therefore DB2 ignores the security label of MEDIUM that is specified in the statement. The security label of the row becomes LOW because Carlos's security label is LOW.

**Considerations for INSERT from a fullselect:** For statements that insert the result of a fullselect, DB2 does not return an error code if the fullselect contains a table with a security label column.

**Considerations for SELECT...FROM...INSERT statements:** For statements that insert rows and select the inserted rows, DB2 avoids returning some error codes. If the fullselect includes a table with a security label column and the object of the insert does not contain a security label column, DB2 does not return an error code.

If the user has write-down privilege or write-down is not in effect, the security label of the user might not dominate the security label of the row. For statements that insert rows and select the inserted rows, the INSERT statement succeeds in this. However, the inserted row is not returned.

**Considerations for INSERT with subselect:** If you insert data into a table that does not have a security label column, but a subselect in the INSERT statement does include a table with a security label column, row-level checking is performed for the subselect. However, the inserted rows will not be stored with a security label column.

## Using the UPDATE statement with multilevel security

When a user with a valid security label updates a table with row-level security enabled, DB2 compares the security label of the user to the security label of the row. The update proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is updated and the value of the security label is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the user can set the security label of the row to any valid security label.
  - If the user does not have write-down privilege and write-down control is enabled, the security label of the row is set to the value of the security label of the user.
- If the security label of the user dominates the security label of the row, the result of the UPDATE statement is determined by whether the user has write-down privilege:

- If the user has write-down privilege or write-down control is not enabled, the row is updated and the user can set the security label of the row to any valid security label.
- If the user does not have write-down privilege and write-down control is enabled, the row is not updated.
- If the security label of the row dominates the security label of the user, the row is not updated.

**Example:** Suppose that Alan has a security label of HIGH and write-down privilege defined in RACF, that Beth has a security label of MEDIUM and write-down privilege defined in RACF, and that Carlos has a security label of LOW. Write-down control is enabled.

Suppose that DSN8710.EMP contains the data that is shown in Table 53 and that the SECURITY column has been declared with the AS SECURITY LABEL clause.

*Table 53. Sample data from DSN8710.EMP*

EMPNO	LASTNAME	WORKDEPT	SECURITY
000190	BROWN	D11	HIGH
000200	JONES	D11	MEDIUM
000210	LUTZ	D11	LOW

Now, suppose that Alan, Beth, and Carlos each submit the following UPDATE statement:

```
UPDATE DSN8710.EMP
  SET DEPTNO='X55', SECURITY='MEDIUM'
  WHERE DEPTNO='D11';
```

Because Alan has a security label that is equivalent to the security label of the row with HIGH security, the update on that row succeeds. Because Alan has a security label that dominates the rows with security labels of MEDIUM and LOW, his write-down privilege determines whether these rows are updated. Alan has the write-down privilege that is required to set the security label to any value, so the update succeeds for these rows and the security label for all of the rows becomes MEDIUM. The results of Alan's update are shown in Table 54.

*Table 54. Sample data from DSN8710.EMP after Alan's update*

EMPNO	EMPNAME	DEPTNO	SECURITY
000190	BROWN	X55	MEDIUM
000200	JONES	X55	MEDIUM
000210	LUTZ	X55	MEDIUM

Because the row with the security label of HIGH dominates Beth's security label, the update fails for that row, which causes the entire update to fail.

Because the rows with the security labels of MEDIUM and HIGH dominate Carlos's security label, the update fails for those rows, which causes the entire update to fail.

**Recommendation:** To avoid failed updates, qualify the rows that you want to update with the following predicate, for the security label column SECLABEL:

```
WHERE SECLABEL=GETVARIABLE('SYSIBM.SECLABEL');
```

Using this predicate avoids failed updates because it ensures that the user's security label is equivalent to the security label of the rows that DB2 attempts to update.

### Using the DELETE statement with multilevel security

When a user with a valid security label deletes data from a table with row-level security enabled, DB2 compares the security label of the user to the security label of the row. The delete proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is deleted.
- If the security label of the user dominates the security label of the row, the user's write-down privilege determines the result of the DELETE statement:
  - If the user has write-down privilege or write-down control is not enabled, the row is deleted.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not deleted.
- If the security label of the row dominates the security label of the user, the row is not deleted.

**Example:** Suppose that Alan has a security label of HIGH, that Beth has a security label of MEDIUM and write-down privilege defined in RACF, and that Carlos has a security label of LOW. Write-down control is enabled.

Suppose that DSN8710.EMP contains the data that is shown in Table 55 and that the SECURITY column has been declared with the AS SECURITY LABEL clause.

Table 55. Sample data from DSN8710.EMP

EMPNO	LASTNAME	WORKDEPT	SECURITY
000190	BROWN	D11	HIGH
000200	JONES	D11	MEDIUM
000210	LUTZ	D11	LOW

Now, suppose that Alan, Beth, and Carlos each submit the following DELETE statement:

```
DELETE FROM DSN8710.EMP
WHERE DEPTNO='D11';
```

Because Alan has a security label that dominates the rows with security labels of MEDIUM and LOW, his write-down privilege determines whether these rows are deleted. Alan does not have write-down privilege, so the delete fails for these rows. Because Alan has a security label that is equivalent to the security label of the row with HIGH security, the delete on that row succeeds. The results of Alan's delete are shown in Table 56.

Table 56. Sample data from DSN8710.EMP after Alan's delete

EMPNO	EMPNAME	DEPTNO	SECURITY
000200	JONES	D11	MEDIUM
000210	LUTZ	D11	LOW

Because Beth has a security label that dominates the row with a security label of LOW, her write-down privilege determines whether this row is deleted. Beth has write-down privilege, so the delete succeeds for this row. Because Beth has a

security label that is equivalent to the security label of the row with MEDIUM security, the delete succeeds for that row. Because the row with the security label of HIGH dominates Beth's security label, the delete fails for that row. The results of Beth's delete are shown in Table 57.

Table 57. Sample data from DSN8710.EMP after Beth's delete

EMPNO	EMPNAME	DEPTNO	SECURITY
000190	BROWN	D11	HIGH

Because Carlos's security label is LOW, the delete fails for the rows with security labels of MEDIUM and HIGH. Because Carlos has a security label that is equivalent to the security label of the row with LOW security, the delete on that row succeeds. The results of Carlos's delete are shown in Table 58.

Table 58. Sample data from DSN8710.EMP after Carlos's delete

EMPNO	EMPNAME	DEPTNO	SECURITY
000190	BROWN	D11	HIGH
000200	JONES	D11	MEDIUM

**Important:** Do not omit the WHERE clause from DELETE statements. If you omit the WHERE clause from the DELETE statement, checking occurs for rows that have security labels. This checking behavior might have a negative impact on performance.

For more information about these SQL statements and multilevel security, see the *DB2 SQL Reference*.

### Using utilities with multilevel security

You need a valid security label and additional authorizations to run certain LOAD, UNLOAD, and REORG TABLESPACE jobs on tables that have multilevel security enabled. All other utilities check only for authorization to operate on the table space; they do not check for row-level authorization.

**LOAD:** You must have the write-down privilege to run LOAD REPLACE on a table space that contains a table with multilevel security enabled. In this case, you can specify the values for the security label column.

When you run LOAD RESUME, you must have the write-down privilege to specify values for the security label column. If you run a LOAD RESUME job and do not have the write-down privilege, DB2 assigns your security label as the value for each row in the security label column.

**UNLOAD:** Additional restrictions apply to UNLOAD jobs on tables that have multilevel security enabled. Each row is unloaded only if the security label of the user dominates the security label of the row. If security label of the user does not dominate the security label of the row, the row is not unloaded and DB2 does not issue an error message.

**REORG TABLESPACE:** REORG TABLESPACE jobs on tables that have multilevel security enabled have the following restrictions:

- For jobs with the UNLOAD EXTERNAL option, each row is unloaded only if the security label of the user dominates the security label of the row. If the

security label of the user does not dominate the security label of the row, the row is not unloaded and DB2 does not issue an error message.

- For jobs with the DISCARD option, a qualifying row is discarded only if the user has the write-down privilege and the security label of the user dominates the security label of the row.

For more information about utilities and multilevel security, see *DB2 Utility Guide and Reference*.

## Using views to restrict access

If you do not want users to see a security label column, create views that do not include the column.

**Example:** Suppose that the ORDER table has the following columns: ORDERNO, PRODNO, CUSTNO, SECURITY. Suppose that SECURITY is the security label column, and that you do not want users to see the SECURITY column. Use the following statement to create a view that hides the security label column from users:

```
CREATE VIEW V1 AS
  SELECT ORDERNO, PRODNO, CUSTNO FROM ORDER;
```

Alternatively, you can create views that give each user access only to the rows that include that user's security label column. To do that, retrieve the value of the SYSIBM.SECLABEL session variable, and create a view that includes only the rows that match the session variable value.

**Example:** To allow access only to the rows that match the user's security label, use the following CREATE statement:

```
CREATE VIEW V2 AS SELECT * FROM ORDER
  WHERE SECURITY=GETVARIABLE('SYSIBM.SECLABEL');
```

## Global temporary tables with multilevel security

For a declared temporary table with a column definition, no syntax exists to specify a security label on a DECLARE GLOBAL TEMPORARY TABLE statement. An attempt to specify a security label results in an error.

If a DECLARE GLOBAL TEMPORARY TABLE statement uses a fullselect or a LIKE predicate or a CREATE GLOBAL TEMPORARY TABLE statement uses a LIKE predicate, the resulting temporary table can inherit the security label column from the referenced table or view. However, the temporary table **does not** inherit any security attributes on that column. That means that the inherited column in the temporary table is not defined AS SECURITY LABEL. The column in the temporary table is defined as NOT NULL, with no default. Therefore, any statements that insert data in the temporary table must provide a value for the inherited column.

## Materialized query tables with multilevel security

Materialized query tables are tables that contain information that is derived and summarized from other tables. If one or more of the source tables for a materialized query table has multilevel security with row-level granularity enabled, some additional rules apply to working with the materialized query table and the source tables. For information about materialized query tables and these multilevel security rules, see "Using multilevel security with materialized query tables" on page 892.

## Constraints and multilevel security

Constraints operate in an multilevel-secure environment in the following ways:

- A unique constraint is allowed on a security label column.
- A referential constraint is not allowed on a security label column.
- A check constraint is not allowed on a security label column.

Multilevel security with row-level checking is not enforced when DB2 checks a referential constraint. Although a referential constraint is not allowed for the security label column, DB2 enforces referential constraints for other columns in the table that are not defined with a security label.

## Field procedures, edit procedures, validation procedures, and multilevel security

Field procedures, edit procedures, and validation procedures operate in an multilevel-secure environment in the following ways:

- Field procedures and edit procedures are not allowed on a security label column.
- Validation procedures are allowed on a table that is defined with a security label column. When an authorized user with write-down privilege makes an INSERT or UPDATE request for a row, the validation procedure passes the new row with the security label of the user. If the authorized user does not have write-down privilege, the security label of the row remains the same.

## Triggers and multilevel security

When a transition table is generated as the result of a trigger, the security label of the table or row from the original table is not inherited by the transition table. Therefore, multilevel security with row-level checking is not enforced for transition tables and transition values.

If an ALTER TABLE statement is used to add a security label column to a table with a trigger on it, the same rules apply to the new security label column that would apply to any column that is added to the table with the trigger on it.

When a BEFORE trigger is activated, the value of the NEW transition variable that corresponds to the security label column is set to the security label of the user if either of the following criteria are met:

- Write-down control is in effect and the user does not have the write-down privilege
- The value of the security label column is not specified

## Implementing multilevel security in a distributed environment

SQL statements that originate from remote requesters can participate in a multilevel secure environment if all information on the requester has the same security label and all users of the requester are permitted to that security label. Management of multilevel security in a distributed environment requires physical control of the participating systems and careful management of the network. Managed systems must be prevented from communicating with other systems that do not have equivalent security labels. For more information about configuring a DB2 server to use multilevel security in a distributed environment, see *z/OS Communications Server: IP Configuration Guide*.

## TCP/IP support for multilevel security

A Communications Server IP stack that runs in a multilevel secure environment can be configured as either a restricted stack or an unrestricted stack.

**Recommendation:** Use an unrestricted stack for DB2. An unrestricted stack is configured with an ID that is defined with a security label of SYSMULTI. A single z/OS system can concurrently run a mix of restricted and unrestricted stacks. Unrestricted stacks allow DB2 to use any security label to open sockets.

All users on a TCP/IP connection have the security label that is associated with the IP address that is defined on the server. If a user requires a different security label, the user must enter through an IP address that has that security label associated with it. If you require multiple IP addresses on a remote z/OS server, a workstation, or a gateway, you can configure multiple virtual IP addresses. This strategy can increase the number of security labels that are available on a client.

Remote users that access DB2 by using a TCP/IP network connection use the security label that is associated with the RACF SERVAUTH class profile when the remote user is authenticated. Security labels are assigned to the database access thread when the DB2 server authenticates the remote server by using the RACROUTE REQUEST = VERIFY service.

### **SNA support for multilevel security**

Security labels are assigned to the database access thread when the DB2 server authenticates the remote server by using the RACROUTE REQUEST = VERIFY service. The service establishes a security label to the authorization ID that is associated with the database access thread. For SNA connections, this security label is the default security label that is defined for the remote user.

---

## **Data encryption through built-in functions**

**Prerequisite:** To use built-in functions for data encryption and decryption, the Integrated Cryptographic Service Facility must be installed. For more specific information about this prerequisite, see *DB2 Program Directory*.

DB2 provides built-in data encryption functions that you can use to encrypt sensitive data, such as credit card numbers and medical record numbers. When you use data encryption, DB2 requires the correct password to retrieve the data in a decrypted format. If an incorrect password is provided, DB2 does not decrypt the data.

**Attention:** DB2 cannot decrypt data without the encryption password, and DB2 does not store encryption passwords in an accessible format. If you forget the encryption password, you cannot decrypt the data.

The ENCRYPT keyword encrypts data. The DECRYPT\_BIT, DECRYPT\_CHAR, and DECRYPT\_DB keywords decrypt data. These functions work like other built-in functions. To use these functions on data, the column that holds the data must be properly defined, as described in “Defining columns for encrypted data” on page 208.

You can encrypt data by using two different methods. These methods are described in the following sections:

- “Defining encryption at the column level” on page 208
- “Defining encryption at the value level” on page 210

This section also discusses the following topics:

- “Ensuring accurate predicate evaluation for encrypted data” on page 211
- “Encrypting non-character values” on page 211
- “Performance recommendations for data encryption” on page 212

**Important:** Built-in encryption functions work for data that is stored within DB2 subsystem and is retrieved from within that same DB2 subsystem. The encryption functions do not work for data that is passed into and out of a DB2 subsystem. This task is handled by DRDA data encryption, and it is separate from built-in data encryption functions.

## Defining columns for encrypted data

When data is encrypted, it is stored as a binary data string. Therefore, encrypted data should be stored in columns that are defined as VARCHAR FOR BIT DATA. Columns that hold encrypted data also require additional bytes to hold a header and to reach a multiple of 8 bytes.

**Example:** Suppose that you have non-encrypted data in a column that is defined as VARCHAR(6). Use the following calculation to determine the column definition for storing the data in encrypted format:

Maximum length of non-encrypted data	6 bytes
Number of bytes to the next multiple of 8	2 bytes
24 bytes for encryption key	24 bytes
	-----
Encrypted data column length	32 bytes

Therefore, define the column for encrypted data as VARCHAR(32) FOR BIT DATA.

If you use a password hint, DB2 requires an additional 32 bytes to store the hint.

**Example:** Suppose that you have non-encrypted data in a column that is defined as VARCHAR(10). Use the following calculation to determine the column definition for storing the data in encrypted format with a password hint:

Maximum length of non-encrypted data	10 bytes
Number of bytes to the next multiple of 8	6 bytes
24 bytes for encryption key	24 bytes
32 bytes for password hint	32 bytes
	-----
Encrypted data column length	72 bytes

Therefore, define the column for encrypted data as VARCHAR(72) FOR BIT DATA.

For more information about encryption password hints, see “Using password hints with column-level encryption” on page 210 and “Using password hints with value-level encryption” on page 211.

## Defining encryption at the column level

For *column-level encryption*, all encrypted values in a column are encrypted with the same password. Column-level encryption uses the SET ENCRYPTION PASSWORD statement to manage passwords and hints, the ENCRYPT keyword to indicate which data should be encrypted, and the DECRYPT\_BIT, DECRYPT\_CHAR, or DECRYPT\_DB keyword to decrypt data. The following statement and keywords are used with column-level encryption:

### SET ENCRYPTION PASSWORD

Sets the password (and optionally sets the password hint) that DB2 holds for encryption and decryption. DB2 holds this value until it is replaced or until the application finishes.

**Recommendation:** Use host variables instead of literal values for all passwords and password hints. If statements contain literal values for

passwords and password hints, the security of the encrypted data can be compromised in the DB2 catalog and in a trace report.

### ENCRYPT

Indicates which column or columns require encryption. DB2 sets the password on the indicated data to the password that DB2 holds at the time a statement with the ENCRYPT keyword is issued.

### DECRYPT\_BIT, DECRYPT\_CHAR, DECRYPT\_DB

Checks for the correct password and decrypts data when the data is selected. For more information about the different decryption functions, see *DB2 SQL Reference*.

When encrypted data is selected, DB2 must hold the same password that was held at the time of encryption to decrypt the data. To ensure that DB2 holds the correct password, issue a SET ENCRYPTION PASSWORD statement with the correct password immediately before selecting encrypted data.

**Example:** Suppose that you need to create an employee table EMP that contains employee ID numbers in encrypted format. Suppose also that you want to set the password for all rows in an encrypted column to the host variable hv\_pass. Finally, suppose that you want to select employee ID numbers in decrypted format. Perform the following steps:

1. Create the EMP table with the EMPNO column. The EMPNO column must be defined with the VARCHAR data type, must be defined FOR BIT DATA, and must be long enough to hold the encrypted data. The following statement creates the EMP table:

```
CREATE TABLE EMP (EMPNO VARCHAR(32) FOR BIT DATA);
```

2. Set the encryption password. The following statement sets the encryption password to the host variable :hv\_pass:

```
SET ENCRYPTION PASSWORD = :hv_pass;
```

3. Use the ENCRYPT keyword to insert encrypted data into the EMP table by issuing the following statements:

```
INSERT INTO EMP (EMPNO) VALUES(ENCRYPT('47138'));  
INSERT INTO EMP (EMPNO) VALUES(ENCRYPT('99514'));  
INSERT INTO EMP (EMPNO) VALUES(ENCRYPT('67391'));
```

4. Select the employee ID numbers in decrypted format:

```
SELECT DECRYPT_CHAR(EMPNO) FROM EMP;
```

If you provide the correct password, DB2 returns the employee ID numbers in decrypted format.

### Using column-level encryption with views

You can use column-level encryption in combination with views to create a view that selects decrypted data from a table. To do this, define the view with a decryption function in the defining fullselect. If the correct password is provided when the view is queried, DB2 will return decrypted data.

**Example:** Suppose that you want to create a view that contains decrypted employee ID numbers from the EMP table.

1. Create a view on the EMP table by using the following statement:

```
CREATE VIEW CLR_EMP (EMPNO) AS SELECT DECRYPT_CHAR(EMPNO) FROM EMP;
```

2. Set the encryption password, so that the fullselect in the view definition can retrieve decrypted data. Use the following statement:

```
SET ENCRYPTION PASSWORD = :hv_pass;
```

3. Select the desired data from the view by using the following statement:

```
SELECT EMPNO FROM CLR_EMP;
```

### Using password hints with column-level encryption

DB2 can store encryption password hints to help with forgotten encryption passwords. Each password hint uses 32 bytes in the encrypted column. For column-level encryption, the password hint is set with the SET ENCRYPTION PASSWORD statement. The GETHINT function returns the password hint.

**Example:** Use the following statement to set the password hint to the host variable hv\_hint:

```
SET ENCRYPTION PASSWORD = :hv_pass WITH HINT = :hv_hint;
```

**Example:** Suppose that the EMPNO column in the EMP table contains encrypted data and that you submitted a password hint when you inserted the data. Suppose that you cannot remember the encryption password for the data. Use the following statement to return the password hint:

```
SELECT GETHINT (EMPNO) FROM EMP;
```

## Defining encryption at the value level

When you use value-level encryption, each value in a given column can be encrypted with a different password. You set the password for each value by using the ENCRYPT keyword with the password. The following keywords are used with value-level encryption:

### ENCRYPT

Indicates which data requires encryption. Also, encryption passwords, and optionally password hints, are indicated as part of the ENCRYPT keyword for value-level encryption.

**Recommendation:** Use host variables instead of literal values for all passwords and password hints. If statements contain literal values for passwords and password hints, the security of the encrypted data can be compromised in the DB2 catalog and in a trace report.

### DECRYPT\_BIT, DECRYPT\_CHAR, DECRYPT\_DB

Checks for the correct password and decrypts data when the data is selected. For more information about the different decryption functions, see *DB2 SQL Reference*.

**Example:** Suppose that a web application collects user information about a customer. This information includes the customer name, which is stored in host variable custname; the credit card number, which is stored in a host variable cardnum; and the password for the card number value, which is stored in a host variable userpswd. The application uses the following statement to insert the customer information:

```
INSERT INTO CUSTOMER (CCN, NAME)
VALUES(ENCRYPT(:cardnum, :userpswd), :custname);
```

Before the application displays the credit card number for a customer, the customer must enter the password. The application retrieves the credit card number by using the following statement:

```
SELECT DECRYPT_CHAR(CCN, :userpswd) FROM CUSTOMER WHERE NAME = :custname;
```

## Using password hints with value-level encryption

DB2 can store encryption password hints to help with forgotten encryption passwords. Each password hint uses 32 bytes in the encrypted column. For value-level encryption, the password hint is set with the ENCRYPT keyword. The GETHINT function returns the password hint.

**Recommendation:** Use host variables instead of literal values for all passwords and password hints. If the statements contain literal values for passwords and password hints, the security of the encrypted data can be compromised in the DB2 catalog and in a trace report.

**Example:** Suppose that you want the application from the previous example to use a hint to help customers remember their passwords. The application stores the hint in the host variable pswdhint. For this example, assume the values 'Tahoe' for userpswd and 'Ski Holiday' for pswdhint. The application uses the following statement to insert the customer information:

```
INSERT INTO CUSTOMER (CCN, NAME)
VALUES(ENCRYPT(:cardnum, :userpswd, :pswdhint), :custname);
```

If the customer requests a hint about the password, the following query is used:

```
SELECT GETHINT(CCN) INTO :pswdhint FROM CUSTOMER WHERE NAME = :custname;
```

The value for pswdhint is set to 'Ski Holiday' and returned to the customer. Hopefully the customer can remember the password 'Tahoe' from this hint.

## Ensuring accurate predicate evaluation for encrypted data

When data is encrypted, only = and <> predicates provide accurate results. Predicates such as >, <, and LIKE will return inaccurate results for encrypted data.

**Example:** Suppose that the value 1234 is encrypted as H71G. Also suppose that the value 5678 is encrypted as BF62. If you use a <> predicate to compare these two values in encrypted format, you receive the same result as you will if you compare these two values in decrypted format:

```
Decrypted: 1234 <> 5678    True
Encrypted: H71G <> BF62    True
```

In both case, they are not equal.

**Example:** However, if you use a < predicate to compare these values in encrypted format, you receive a different result than you will if you compare these two values in decrypted format:

```
Decrypted: 1234 < 5678    True
Encrypted: H71G < BF62    False
```

To ensure that predicates such as >, <, and LIKE return accurate results, you must first decrypt the data.

## Encrypting non-character values

DB2 supports encryption for numeric and datetime data types indirectly through casting. If non-character data is cast as VARCHAR or CHAR, the data can be encrypted. For more information about casting, see *DB2 SQL Reference*.

**Example:** Suppose that you need to encrypt timestamp data and retrieve it in decrypted format. Perform the following steps:

1. Create a table to store the encrypted values and set the column-level encryption password by using the following statements:
 

```
CREATE TABLE ETEMP (C1 VARCHAR(124) FOR BIT DATA);
SET ENCRYPTION PASSWORD :hv_pass;
```
2. Cast, encrypt, and insert the timestamp data by using the following statement:
 

```
INSERT INTO ETEMP VALUES ENCRYPT(CHAR(CURRENT_TIMESTAMP));
```
3. Recast, decrypt, and select the timestamp data by using the following statement:
 

```
SELECT TIMESTAMP(DECRYPT_CHAR(C1)) FROM ETEMP;
```

## Performance recommendations for data encryption

Encryption, by its nature, degrades the performance of most SQL statements. Decryption requires extra processing, and encrypted data requires more space in DB2. If a predicate requires decryption, the predicate is a stage 2 predicate, which can degrade performance. Encrypted data can also impact your database design, which can indirectly impact performance. To minimize performance degradation, use encryption only in cases that require encryption.

**Recommendation:** Encrypt only a few highly sensitive data elements, such as credit card numbers and medical record numbers.

Some data values are poor candidates for encryption. For example, boolean values and other small value sets, such as the integers 1 through 10, are poor candidates for encryption. Because few values are possible, these types of data can be easy to guess even when they are encrypted. In most cases, encryption is not a good security option for this type of data.

**Data encryption and indexes:** Creating indexes on encrypted data can improve performance in some cases. Exact matches and joins of encrypted data (if both tables use the same encryption key to encrypt the same data) can use the indexes that you create. Because encrypted data is binary data, range checking of encrypted data requires table space scans. Range checking requires all the row values for a column to be decrypted. Therefore, range checking should be avoided, or at least tuned appropriately.

**Encryption performance scenario:** The following scenario contains a series of examples that demonstrate how to improve performance while working with encrypted data.

**Example:** Suppose that you must store EMPNO in encrypted form in the EMP table and in the EMPPROJ table. To define tables and indexes for the encrypted data, use the following statements:

```
CREATE TABLE EMP (EMPNO VARCHAR(48) FOR BIT DATA, NAME VARCHAR(48));
CREATE TABLE EMPPROJ(EMPNO VARCHAR(48) FOR BIT DATA, PROJECTNAME VARCHAR(48));
CREATE INDEX IXEMPPRJ ON EMPPROJ(EMPNO);
```

**Example:** Next, suppose that one employee can work on multiple projects, and that you want to insert employee and project data into the table. To set the encryption password and insert data into the tables, use the following statements:

```
SET ENCRYPTION PASSWORD = :hv_pass;
SELECT INTO :hv_enc_val FROM FINAL TABLE
  (INSERT INTO EMP VALUES (ENCRYPT('A7513'),'Super Prog'));
INSERT INTO EMPPROJ VALUES (:hv_enc_val,'UDDI Project');
INSERT INTO EMPPROJ VALUES (:hv_enc_val,'DB2 UDB Version 10');
```

```

SELECT INTO :hv_enc_val FROM FINAL TABLE
  (INSERT INTO EMP VALUES (ENCRYPT('4NF18'),'Novice Prog'));
INSERT INTO EMP PROJ VALUES (:hv_enc_val,'UDDI Project');

```

You can improve the performance of INSERT statements by avoiding unnecessary repetition of encryption processing. Note how the host variable hv\_enc\_val is defined in the SELECT INTO statement and then used in subsequent INSERT statements. If you need to insert a large number of rows that contain the same encrypted value, you might find that the repetitive encryption processing degrades performance. However, you can dramatically improve performance by encrypting the data, storing the encrypted data in a host variable, and inserting the host variable.

**Example:** Next, suppose that you want to find the programmers who are working on the UDDI Project. Consider the following pair of SELECT statements:

- **Poor performance:** The following query shows how not to write the query for good performance:

```

SELECT A.NAME, DECRYPT_CHAR(A.EMPNO) FROM EMP A, EMP PROJ B
  WHERE DECRYPT_CHAR(A.EMPNO) = DECRYPT_CHAR(B.EMPNO) AND
        B.PROJECT = 'UDDI Project';

```

Although the preceding query returns the correct results, it decrypts every EMPNO value in the EMP table and every EMPNO value in the EMP PROJ table where PROJECT = 'UDDI Project' to perform the join. For large tables, this unnecessary decryption is a significant performance problem.

- **Good performance:** The following query produces the same result as the preceding query, but with significantly better performance. To find the programmers who are working on the UDDI Project, use the following statement:

```

SELECT A.NAME, DECRYPT_CHAR(A.EMPNO) FROM EMP A, EMP PROJ B
  WHERE A.EMPNO = B.EMPNO AND B.PROJECT = 'UDDI Project';

```

**Example:** Next, suppose that you want to find the projects that the programmer with employee ID A7513 is working on. Consider the following pair of SELECT statements:

- **Poor performance:** The following query requires DB2 to decrypt every EMPNO value in the EMP PROJ table to perform the join:

```

SELECT PROJECTNAME FROM EMP PROJ WHERE DECRYPT_CHAR(EMPNO) = 'A7513';

```

- **Good performance:** The following query encrypts the literal value in the predicate so that DB2 can compare it to encrypted values that are stored in the EMPNO column without decrypting the whole column. To find the projects that the programmer with employee ID A7513 is working on, use the following statement:

```

SELECT PROJECTNAME FROM EMP PROJ WHERE EMPNO = ENCRYPT('A7513');

```

---

## Chapter 10. Controlling access through a closed application

A *closed application* is an application that requires DB2 objects to be managed solely through external interfaces.

**Example:** Consider an application process that uses DB2 as a repository for changing data. The application process does more than write to and read from a fixed set of tables. The application process also creates, alters, and drops DB2 objects to deal with new data formats. If an application is not closed, a database administrator has the privileges to do these operations at any time. However, in a closed application, the operations must be performed through a specific application. The application is “closed” because it requires exclusive control over data definition statements for some set of objects.

If you install *data definition control support* on the DSNTIPZ installation panel, you can control how specific plans or package collections can use data definition statements. Data definition control support does not replace existing authorization checks; it imposes additional checks. Table 59 lists the specific statements that are controlled by using data definition control support.

Table 59. Statements that are controlled by data definition control support

Object	CREATE statement	ALTER statement	DROP statement
Alias	CREATE ALIAS		DROP ALIAS
Database	CREATE DATABASE	ALTER DATABASE	DROP DATABASE
Index	CREATE INDEX	ALTER INDEX	DROP INDEX
Storage group	CREATE STOGROUP	ALTER STOGROUP	DROP STOGROUP
Synonym	CREATE SYNONYM		DROP SYNONYM
Table	CREATE TABLE	ALTER TABLE	DROP TABLE
Table space	CREATE TABLESPACE	ALTER TABLESPACE	DROP TABLESPACE
View	CREATE VIEW		DROP VIEW

**Note:** Data definition control support also controls COMMENT statements and LABEL statements.

The statements in Table 59 are a subset of statements that are referred to as “data definition language.” In this chapter, data definition language refers only to this subset of statements. For information about how to impose several degrees of control over data definition in applications and objects, see “Controlling data definition” on page 218.

This chapter provides information on the following topics:

- “Registration tables” on page 216 describes the columns of the ART and ORT.
- “Controlling data definition” on page 218 describes various methods for controlling data definition.
- “Managing the registration tables and their indexes” on page 226 describes how to create and manage the ART and ORT.

---

## Registration tables

If you use data definition control support, you must create and maintain the *application registration table* (ART) and the *object registration table* (ORT). You register plans and package collections in the ART. You register the objects that are associated with the plans and collections in the ORT. DB2 consults these two registration tables before accepting a data definition statement from a process. If the registration tables indicate that the process is not allowed to create, alter, or drop a particular object, DB2 does not allow it.

“Columns of the ART” and “Columns of the ORT” on page 217 describe the columns of the two registration tables. For more information about maintaining the ART and the ORT, see “Managing the registration tables and their indexes” on page 226.

### Columns of the ART

Table 60 shows the columns of the ART. For information about creating the ART, see “Creating the tables and indexes” on page 226.

Table 60. Columns of the ART

Column name	Description
APPLIDENT	Indicates the collection-ID of the package that executes the data definition language. If no package exists, it indicates the name of the plan that executes the data definition language.
APPLIDENTTYPE	Indicates the type of application identifier.
APPLICATIONDESC <sup>1</sup>	Optional data. Provides a more meaningful description of each application than the eight-byte APPLIDENT column can contain.
DEFAULTAPPL	Indicates whether all data definition language should be accepted from this application.
QUALIFIEROK	Indicates whether the application can supply a missing name part for objects that are named in the ORT. Applies only if REQUIRE FULL NAMES = NO.
CREATOR <sup>1,2</sup>	Optional data. Indicates the authorization ID that created the row.
CREATETIMESTAMP <sup>1</sup>	Optional data. Indicates when a row was created. If you use CURRENT TIMESTAMP, DB2 automatically enters the value of CURRENT TIMESTAMP When you load or insert a row.
CHANGER <sup>1,2</sup>	Optional data. Indicates the authorization ID that last changed the row.
CHANGETIMESTAMP <sup>1</sup>	Optional data. Indicates when a row was changed. If you use CURRENT TIMESTAMP, DB2 automatically enters the value of CURRENT TIMESTAMP When you update a row.

Table 60. Columns of the ART (continued)

Column name	Description
<b>Notes:</b>	
1.	Optional columns are for administrator use. DB2 does not use these columns.
2.	Because the CREATOR and CHANGER columns are CHAR(26), they are large enough for a three-part authorization ID. Separate each 8-byte part of the ID with a period in byte 9 and in byte 18. If you enter only the primary authorization ID, consider entering it right-justified in the field (that is, preceded by 18 blanks).

## Columns of the ORT

Table 61 shows the columns of the ORT. For information about creating the ORT, see “Creating the tables and indexes” on page 226.

Table 61. Columns of the ORT

Column name	Description
QUALIFIER	Indicates the object name qualifier.
NAME	Indicates the unqualified object name.
TYPE	Indicates the type of object.
APPLMATCHREQ	Indicates whether an application that names this object must match the one that is named in the APPLIDENT column.
APPLIDENT	Collection-ID of the plan or package that executes the data definition language.
APPLIDENTTYPE	Indicates the type of application identifier.
APPLICATIONDESC <sup>1</sup>	Optional data. Provides a more meaningful description of each application than the eight-byte APPLIDENT column can contain.
CREATOR <sup>1, 2</sup>	Optional data. Indicates the authorization ID that created the row.
CREATETIMESTAMP <sup>1</sup>	Optional data. Indicates when a row was created. If you use CURRENT TIMESTAMP, DB2 automatically enters the value of CURRENT TIMESTAMP When you load or insert a row.
CHANGER <sup>1, 2</sup>	Optional data. Indicates the authorization ID that last changed the row.
CHANGETIMESTAMP <sup>1</sup>	Optional data. Indicates when a row was changed. If you use CURRENT TIMESTAMP, DB2 automatically enters the value of CURRENT TIMESTAMP When you update a row.

**Notes:**

- Optional columns are for administrator use. DB2 does not use these columns.
- Because the CREATOR and CHANGER columns are CHAR(26), they are large enough for a three-part authorization ID. Separate each 8-byte part of the ID with a period in byte 9 and in byte 18. If you enter only the primary authorization ID, consider entering it right-justified in the field (that is, preceded by 18 blanks).

## Controlling data definition

You can control the use of data definition through several installation options and through the ART and ORT. To install data definition control support and to control data definition behavior, specify the appropriate values on the DSNTIPZ installation panel, as shown with default values in Figure 16.

```
DSNTIPZ      INSTALL DB2 - DATA DEFINITION CONTROL SUPPORT
===>

Enter data below:

 1 INSTALL DD CONTROL SUPT. ===> NO          YES - activate the support
                                     NO - omit DD control support
 2 CONTROL ALL APPLICATIONS ===> NO          YES or NO
 3 REQUIRE FULL NAMES         ===> YES       YES or NO
 4 UNREGISTERED DDL DEFAULT   ===> ACCEPT    Action for unregistered DDL:
                                     ACCEPT - allow it
                                     REJECT - prohibit it
                                     APPL - consult ART
                                     Used in ART/ORT Searches
 5 ART/ORT ESCAPE CHARACTER   ===>
 6 REGISTRATION OWNER         ===> DSNRGCOL   Qualifier for ART and ORT
 7 REGISTRATION DATABASE      ===> DSNRGFDB   Database name
 8 APPL REGISTRATION TABLE   ===> DSN_REGISTER_APPL Table name
 9 OBJT REGISTRATION TABLE   ===> DSN_REGISTER_OBJT Table name

Note: ART = Application Registration Table
      ORT = Object Registration Table

PRESS: ENTER to continue RETURN to exit HELP for more information
```

Figure 16. DSNTIPZ installation panel with default values

After you specify values on the installation panel, you enter the appropriate information in the ART and ORT to enable data definition control support.

This section explains what values to enter on the DSNTIPZ installation panel and what data to enter in the ART and ORT. This section first explains the basic installation options in “Installing data definition control support” on page 219. Then, the section explains the specific options for the following four methods of controlling data definition control support:

- “Controlling data definition by application name” on page 220 describes the simplest of the four methods for implementing data definition control.
- “Controlling data definition by application name with exceptions” on page 221 describes how to give one or more applications almost total control over data definition.
- “Controlling data definition by object name” on page 222 describes how to register all of the objects in a subsystem and have several applications control specific sets of objects.
- “Controlling data definition by object name with exceptions” on page 224 describes how to control registered and unregistered objects.

Finally, the section describes the optional task of registering sets of objects in “Registering sets of objects” on page 225.

**Recommendation:** As you read through the relevant sections in this chapter, use the template in Figure 17 on page 219 to record the values that you specify on the DSNTIPZ installation panel.

```

DSNTIPZ      INSTALL DB2 - DATA DEFINITION CONTROL SUPPORT
====>

Enter data below:

 1 INSTALL DD CONTROL SUPT. ====>      YES - activate the support
                                         NO  - omit DD control support
 2 CONTROL ALL APPLICATIONS ====>      YES or NO
 3 REQUIRE FULL NAMES      ====>      YES or NO
 4 UNREGISTERED DDL DEFAULT ====>      Action for unregistered DDL:
                                         ACCEPT - allow it
                                         REJECT - prohibit it
                                         APPL  - consult ART
                                         Used in ART/ORT Searches
 5 ART/ORT ESCAPE CHARACTER ====>      Qualifier for ART and ORT
 6 REGISTRATION OWNER      ====>      Database name
 7 REGISTRATION DATABASE   ====>      Table name
 8 APPL REGISTRATION TABLE ====>      Table name
 9 OBJT REGISTRATION TABLE ====>      Table name

Note: ART = Application Registration Table
      ORT = Object      Registration Table

PRESS: ENTER to continue  RETURN to exit  HELP for more information

```

Figure 17. DSNTIPZ installation panel

### Installing data definition control support

To install data definition control support, perform the following steps:

1. Enter YES for the first option on the DSNTIPZ installation panel, as shown:
 

```
1 INSTALL DD CONTROL SUPT. ====> YES
```
2. Enter the names for the registration tables in your DB2 subsystem, their owners, and the databases in which they reside for options 6, 7, 8, and 9 on the DSNTIPZ installation panel. The default names are as follows:

```

6 REGISTRATION OWNER      ====> DSNRGCOL
7 REGISTRATION DATABASE   ====> DSNRGFDB
8 APPL REGISTRATION TABLE ====> DSN_REGISTER_APPL
9 OBJT REGISTRATION TABLE ====> DSN_REGISTER_OBJT

```

You can accept the default names or assign names of your own. If you specify your own table names, each name can have a maximum of 17 characters. This chapter uses the default names.

3. If you want to use the percent character (%) or the underscore character (\_) as a regular character in the ART or ORT, enter an escape character for option 5 on the DSNTIPZ installation panel. You can use any special character other than underscore or percent as the escape character.

**Example:** To use the pound sign (#) as an escape character, fill in option 5 as follows:

```
5 ART/ORT ESCAPE CHARACTER ====> #
```

After you specify the pound sign as an escape character, the pound sign can be used in names in the same way that an escape character is used in an SQL LIKE predicate.

For more information about escape characters and the percent and underscore characters, see *DB2 SQL Reference*.

4. Register plans, packages, and objects in the ART and ORT, and enter values for the three other options on the DSNTIPZ installation panel as follows:

```
2 CONTROL ALL APPLICATIONS ====>
3 REQUIRE FULL NAMES          ====>
4 UNREGISTERED DDL DEFAULT    ====>
```

Choose the values to enter and the plans, packages, and objects to register based on the control method that you plan to use:

- If you want to control data definition by **application name**, perform the steps in one of the following sections:
  - For registered applications that have total control over all data definition language in the DB2 subsystem, see “Controlling data definition by application name.”
  - For registered applications that have total control with some exceptions, see “Controlling data definition by application name with exceptions” on page 221. If you also want to control data definition by **registering sets of objects**, perform the steps in “Registering sets of objects” on page 225.
- If you want to control data definition by **object name**, perform the steps in one of the following sections:
  - For subsystems in which all objects are registered and controlled by name, see “Controlling data definition by object name” on page 222. If you also want to control data definition by **registering sets of objects**, perform the steps in “Registering sets of objects” on page 225.
  - For subsystems in which some specific objects are registered and controlled, and data definition language is accepted for objects that are not registered, see “Controlling data definition by object name with exceptions” on page 224. If you also want to control data definition by **registering sets of objects**, perform the steps in “Registering sets of objects” on page 225.

## Controlling data definition by application name

The simplest of the four methods for implementing data definition control is to give one or more applications total control over the use of data definition language in the subsystem. To control data definition by application name, perform the following steps:

1. Enter YES for the first option on the DSNTIPZ installation panel, as shown:  
2 CONTROL ALL APPLICATIONS ====> YES

When you specify YES, only package collections or plans that are registered in the ART are allowed to use data definition statements.

2. In the ART, register all package collections and plans that you will allow to issue DDL statements, and enter the value Y in the DEFAULTAPPL column for these package collections. You must supply values for the APPLIDENT, APPLIDENTTYPE, and DEFAULTAPPL columns of the ART. You can enter information in other columns for your own use as indicated in Table 60 on page 216.

**Example:** Suppose that you want all data definition language in your subsystem to be issued only through certain applications. The applications are identified by the following application plan names, collection-IDs, and patterns:

<b>PLANA</b>	The name of an application plan
<b>PACKB</b>	The collection-ID of a package
<b>TRULY%</b>	A pattern name for any plan name beginning with TRULY
<b>TR%</b>	A pattern name for any plan name beginning with TR

Table 62 shows the entries that you need in your ART.

Table 62. Table DSN\_REGISTER\_APPL for total subsystem control

APPLIDENT	APPLIDENTTYPE	DEFAULTAPPL
PLANA	P	Y
PACKB	C	Y
TRULY%	P	Y
TR%	P	Y

*An inactive table entry:* If the row with TR% for APPLIDENT in Table 62 contains the value Y for DEFAULTAPPL, any plan with a name beginning with TR can execute data definition language. If DEFAULTAPPL is later changed to N to disallow that use, the changed row **does not prevent** plans beginning with TR from using data definition language; the row merely fails to allow that specific use. In this case, the plan TRXYZ is not allowed to use data definition language. However, the plan TRULYXYZ is allowed to use data definition language, by the row with TRULY% specified for APPLIDENT.

## Controlling data definition by application name with exceptions

Registering application names with some exceptions is one of four methods for controlling data definition. If you want to give one or more applications **almost** total control over data definition language on all objects, you can reserve a few objects that can be created, altered, or dropped by applications that are not registered in the ART. To control data definition by application name with exceptions, perform the following steps:

1. Choose not to control all applications. On the DSNTIPZ installation panel, specify the following value for option 2:

```
2 CONTROL ALL APPLICATIONS ==> NO
```

When you specify NO, you allow unregistered applications to use data definition statements on some objects.

2. On the DSNTIPZ installation panel, specify the following for option 4:

```
4 UNREGISTERED DDL DEFAULT ==> APPL
```

When you specify APPL, you restrict the use of data definition statements for objects that are **not** registered in the ORT. If an object is registered in the ORT, any applications that are not registered in the ART can use data definition language on the object. However, if an object is not registered in the ORT, only applications that are registered in the ART can use data definition language on the object.

3. In the ART, register package collections and plans that you will allow to issue data definition statements on any object. Enter the value Y in the DEFAULTAPPL column for these package collections. Applications that are registered in the ART retain almost total control over data definition. Objects that are registered in the ORT are the only exceptions. See step 2 of “Controlling data definition by application name” on page 220 for more information about registering package collections and plans in the ART.
4. In the ORT, register all objects that are exceptions to the subsystem data definition control that you defined in the ART. You must supply values for the QUALIFIER, NAME, TYPE, APPLMATCHREQ, APPLIDENT, and

APPLIDENTTYPE columns of the ORT. You can enter information in other columns of the ORT for your own use as indicated in Table 61 on page 217.

**Example:** Suppose that you want almost all of the data definition language in your subsystem to be issued only through an application plan (PLANA) and a package collection (PACKB).

Table 63 shows the entries that you need in your ART.

*Table 63. Table DSN\_REGISTER\_APPL for total subsystem control with exceptions*

APPLIDENT	APPLIDENTTYPE	DEFAULTAPPL
PLANA	P	Y
PACKB	C	Y

However, you also want the following specific exceptions:

- Object KIM.VIEW1 can be created, altered, or dropped by the application plan PLANC.
- Object BOB.ALIAS can be created, altered, or dropped only by the package collection PACKD.
- Object FENG.TABLE2 can be created, altered, or dropped by **any** plan or package collection.
- Objects with names that begin with SPIFFY.MSTR and exactly one following character can be created, altered, or dropped by any plan that matches the name pattern TRULY%. For example, the plan TRULYJKL can create, alter, or drop the object SPIFFY.MSTRA.

Table 64 shows the entries that are needed to register these exceptions in the ORT.

*Table 64. Table DSN\_REGISTER\_OBJT for subsystem control with exceptions*

QUALIFIER	NAME	TYPE	APPLMATCHREQ	APPLIDENT	APPLIDENTTYPE
KIM	VIEW1	C	Y	PLANC	P
BOB	ALIAS	C	Y	PACKD	C
FENG	TABLE2	C	N		
SPIFFY	MSTR_	C	Y	TRULY%	P

You can register objects in the ORT individually, or you can register sets of objects. For information about registering sets of objects, see “Registering sets of objects” on page 225.

## Controlling data definition by object name

Registering object names is one of four methods for controlling data definition. If you want all objects in the subsystem to be registered and you want several applications to control specific sets of objects, you need to control by object name. When you control by object name, all objects are registered regardless of whether they are controlled by specific applications. To control data definition by object name, perform the following steps:

1. Choose not to control all applications. On the DSNTIPZ installation panel, specify the following value for option 2:  
2 CONTROL ALL APPLICATIONS ==> NO

When you specify NO, you allow unregistered applications to use data definition statements on some objects.

2. On the DSNTIPZ installation panel, fill in option 4 as follows:

```
4 UNREGISTERED DDL DEFAULT ==> REJECT
```

When you specify REJECT for option 4, you totally restrict the use of data definition statements for objects that are not registered in the ORT. Therefore, **no** application can use data definition language for any unregistered object.

3. In the ORT, register all of the objects in the subsystem, and enter Y in the APPLMATCHREQ column. You must supply values for the QUALIFIER, NAME, TYPE, APPLMATCHREQ, APPLIDENT, and APPLIDENTTYPE columns of the ORT. You can enter information in other columns of the ORT for your own use as indicated in Table 61 on page 217.
4. In the ART, register any plan or package collection that can use a set of objects that you register in the ORT with an incomplete name. Enter the value Y in the QUALIFIEROK column. These plans or package collections can use data definition language on sets of objects regardless of whether a set of objects has a value of Y in the APPLMATCHREQ column.

**Example:** Table 65 on page 224 shows entries in the ORT for a DB2 subsystem that contains the following objects that are controlled by object name:

- Two storage groups (STOG1 and STOG2) and a database (DATB1) that are not controlled by a specific application. These objects can be created, altered, or dropped by a user with the appropriate authority by using any application, such as SPUFI or QMF.
- Two table spaces (TBSP1 and TBSP2) that are not controlled by a specific application. Their names are qualified by the name of the database in which they reside (DATB1).
- Three objects (OBJ1, OBJ2, and OBJ3) whose names are qualified by the authorization IDs of their owners. Those objects might be tables, views, indexes, synonyms, or aliases. Data definition statements for OBJ1 and OBJ2 can be issued only through the application plan named PLANX. Data definition statements for OBJ3 can be issued only through the package collection named PACKX.
- Objects that match the qualifier pattern E%D and the name OBJ4 can be created, altered, or deleted by application plan SPUFI. For example, the objects EDWARD.OBJ4, ED.OBJ4, and EBHARD.OBJ4, can be created, altered, or deleted by application plan SPUFI. Entry E%D in the QUALIFIER column represents all three objects.
- Objects with names that begin with TRULY.MY\_, where the underscore character is actually part of the name. Assuming that you specify # as the escape character, all of the objects with this name pattern can be created, altered, or dropped only by plans with names that begin with TRULY.

Assume the following installation option:

```
3 REQUIRE FULL NAMES ==> YES
```

Entries in Table 65 on page 224 do not specify incomplete names. Hence, objects that are not represented in the table cannot be created in the subsystem, except by an ID with installation SYSADM authority.

Table 65. Table DSN\_REGISTER\_OBJT for total control by object

QUALIFIER	NAME	TYPE	APPLMATCHREQ	APPLIDENT	APPLIDENTTYPE
	STOG1	S	N		
	STOG2	S	N		
	DATB1	D	N		
DATB1	TBSP1	T	N		
DATB1	TBSP2	T	N		
KIM	OBJ1	C	Y	PLANX	P
FENG	OBJ2	C	Y	PLANX	P
QUENTIN	OBJ3	C	Y	PACKX	C
E%D	OBJ4	C	Y	SPUFI	P
TRULY	MY#_%	C	Y	TRULY%	P

You can register objects in the ORT individually, or you can register sets of objects. For information about registering sets of objects, see “Registering sets of objects” on page 225.

## Controlling data definition by object name with exceptions

Registering object names with some exceptions is one of four methods for controlling data definition. If you want several applications to control specific sets of registered objects and you want to allow other applications to use data definition statements for unregistered objects, perform the following steps:

1. Choose not to control all applications. On the DSNTIPZ installation panel, specify the following value for option 2:

```
2 CONTROL ALL APPLICATIONS ==> NO
```

When you specify NO, you allow unregistered applications to use data definition statements on some objects.

2. On the DSNTIPZ installation panel, fill in option 4 as follows:

```
4 UNREGISTERED DDL DEFAULT ==> ACCEPT
```

This option **does not** restrict the use of data definition statements for objects that are not registered in the ORT. Therefore, **any** application can use data definition language for any unregistered object.

3. Register all controlled objects in the ORT. Use a name and qualifier to identify a single object. Use only one part of a two-part name to identify a set of objects that share just that part of the name. For each controlled object, use APPLMATCHREQ = Y. Enter the name of the plan or package collection that controls the object in the APPLIDENT column.
4. For each set of controlled objects (identified by only a simple name in the ORT), register the controlling application in the ART. You must supply values for the APPLIDENT, APPLIDENTTYPE, and QUALIFIEROK columns of the ART.

**Example:** The following two tables assume that the installation option REQUIRE FULL NAMES is set to NO, as described in “Registering sets of objects” on page 225. Table 66 on page 225 shows entries in the ORT for the following controlled objects:

- The objects KIM.OBJ1, FENG.OBJ2, QUENTIN.OBJ3, and EDWARD.OBJ4, all of which are controlled by PLANX or PACKX, as described under “Controlling data definition by object name” on page 222. DB2 cannot interpret the object names as incomplete names because the objects that control them, PLANX and PACKX, are registered in Table 67 with QUALIFIEROK=N.
- Two sets of objects, \*.TABA and \*.TABB, which are controlled by PLANA and PACKB, respectively.

Table 66. Table DSN\_REGISTER\_OBJT for object control with exceptions

QUALIFIER	NAME	TYPE	APPLMATCHREQ	APPLIDENT	APPLIDENTTYPE
KIM	OBJ1	C	Y	PLANX	P
FENG	OBJ2	C	Y	PLANX	P
QUENTIN	OBJ3	C	Y	PACKX	C
EDWARD	OBJ4	C	Y	PACKX	C
	TABA	C	Y	PLANA	P
	TABB	C	Y	PACKB	C

Table 67 shows the entries in the corresponding ART.

Table 67. Table DSN\_REGISTER\_APPL for object control with exceptions

APPLIDENT	APPLIDENTTYPE	DEFAULTAPPL	QUALIFIEROK
PLANX	P	N	N
PACKX	C	N	N
PLANA	P	N	Y
PACKB	C	N	Y

In this situation, with the combination of installation options shown previously, any application can use data definition language for objects that are **not** covered by entries in the ORT. For example, if HOWARD has the CREATETAB privilege, HOWARD can create the table HOWARD.TABLE10 through any application.

You can register objects in the ORT individually, or you can register sets of objects. For information about registering sets of objects, see “Registering sets of objects.”

## Registering sets of objects

Registering sets of objects is not a data definition control method; you must install one of the following data definition control methods before registering sets of objects:

- “Controlling data definition by application name with exceptions” on page 221
- “Controlling data definition by object name” on page 222
- “Controlling data definition by object name with exceptions” on page 224

Registering sets of objects allows you to save time and to simplify object registration. Because complete two-part names are not required for every object that is registered in the ORT, you can use incomplete names to register sets of objects. To use incomplete names and register sets of objects, fill in option 3 on the DSNTIPZ installation panel as follows:

```
3 REQUIRE FULL NAMES      ===> NO
```

The default value YES requires you to use both parts of the name for each registered object. If you specify the value NO, an incomplete name in the ORT

represents a set of objects that all share the same value for one part of a two-part name. Objects that are represented by incomplete names in the ORT require an authorizing entry in the ART.

**Example:** If you specify NO for option 3, you can include entries with incomplete names in the ORT. Table 68 shows entries in the ORT for the following objects:

- Two sets of objects, \*.TABA and \*.TABB, which are controlled by PLANX and PACKY, respectively. Only PLANX can create, alter, or drop any object whose name is \*.TABA. Only PACKY can create, alter, or drop any object whose name is \*.TABB. PLANX and PACKY must also be registered in the ART with QUALIFIEROK set to Y, as shown in Table 69. That setting allows the applications to use sets of objects that are registered in the ORT with an incomplete name.
- Tables, views, indexes, or aliases with names like SYSADM.\*.
- Table spaces with names like DBSYSADM.\*; that is, table spaces in database DBSYSADM.
- Tables with names like USER1.\* **and** tables with names like \*.TABLEX.

Table 68. Table DSN\_REGISTER\_OBJT for objects with incomplete names

QUALIFIER	NAME	TYPE	APPLMATCHREQ	APPLIDENT	APPLIDENTTYPE
	TABA	C	Y	PLANX	P
	TABB	C	Y	PACKY	C
SYSADM		C	N		
DBSYSADM		T	N		
USER1	TABLEX	C	N		

*ART entries for objects with incomplete names in the ORT:* APPLMATCHREQ=N and objects SYSADM.\*, DBSYSADM.\*, USER1.\*, and \*.TABLEX can be created, altered, or dropped by any package collection or application plan. However, the collection or plan that creates, alters, or drops such an object must be registered in the ART with QUALIFIEROK=Y to allow it to use incomplete object names.

Table 69 shows that PLANA and PACKB are registered in the ART to use sets of objects that are registered in the ORT with incomplete names.

Table 69. Table DSN\_REGISTER\_APPL for plans that use sets of objects

APPLIDENT	APPLIDENTTYPE	DEFAULTAPPL	QUALIFIEROK
PLANA	P	N	Y
PACKB	C	N	Y

---

## Managing the registration tables and their indexes

This section explains how to create and maintain the ART and the ORT. For a description of all of the columns in these tables, see “Columns of the ART” on page 216 and “Columns of the ORT” on page 217.

### Creating the tables and indexes

The ART, the ORT, and the required unique indexes on them are created when you install data definition control support. If you drop any of these objects, you can re-create them using the CREATE statements shown here:

### CREATE statements for the ART and its index:

```
CREATE TABLE DSNRGCOL.DSN_REGISTER_APPL
  (APPLIDENT      VARCHAR(128) NOT NULL WITH DEFAULT,
   APPLIDENTTYPE  CHAR(1)     NOT NULL WITH DEFAULT,
   APPLICATIONDESC VARCHAR(30)  NOT NULL WITH DEFAULT,
   DEFAULTAPPL    CHAR(1)     NOT NULL WITH DEFAULT,
   QUALIFIEROK    CHAR(1)     NOT NULL WITH DEFAULT,
   CREATOR        CHAR(26)    NOT NULL WITH DEFAULT,
   CREATETIMESTAMP  TIMESTAMP  NOT NULL WITH DEFAULT,
   CHANGER        CHAR(26)    NOT NULL WITH DEFAULT,
   CHANGETIMESTAMP  TIMESTAMP  NOT NULL WITH DEFAULT)
IN DSNRGFDB.DSNRGFTS;

CREATE UNIQUE INDEX DSNRGCOL.DSN_REGISTER_APPLI
ON DSNRGCOL.DSN_REGISTER_APPL
  (APPLIDENT, APPLIDENTTYPE, DEFAULTAPPL DESC, QUALIFIEROK DESC)
CLUSTER;
```

### CREATE statements for the ORT and its index:

```
CREATE TABLE DSNRGCOL.DSN_REGISTER_OBJT
  (QUALIFIER      CHAR(8)     NOT NULL WITH DEFAULT,
   NAME           CHAR(18)    NOT NULL WITH DEFAULT,
   TYPE           CHAR(1)     NOT NULL WITH DEFAULT,
   APPLMATCHREQ   CHAR(1)     NOT NULL WITH DEFAULT,
   APPLIDENT      VARCHAR(128) NOT NULL WITH DEFAULT,
   APPLIDENTTYPE  CHAR(1)     NOT NULL WITH DEFAULT,
   APPLICATIONDESC VARCHAR(30)  NOT NULL WITH DEFAULT,
   CREATOR        CHAR(26)    NOT NULL WITH DEFAULT,
   CREATETIMESTAMP  TIMESTAMP  NOT NULL WITH DEFAULT,
   CHANGER        CHAR(26)    NOT NULL WITH DEFAULT,
   CHANGETIMESTAMP  TIMESTAMP  NOT NULL WITH DEFAULT)
IN DSNRGFDB.DSNRGFTS;

CREATE UNIQUE INDEX DSNRGCOL.DSN_REGISTER_OBJTI
ON DSNRGCOL.DSN_REGISTER_OBJT
  (QUALIFIER, NAME, TYPE) CLUSTER;
```

You can alter these CREATE statements in the following ways:

- Add columns to the ends of the tables
- Assign an auditing status
- Choose buffer pool or storage options for indexes
- Declare table check constraints to limit the types of entries that are allowed

## Naming registration tables and indexes

Every member of a data sharing group must have the same names for the ART and ORT tables.

**Recommendation:** Avoid changing ART and ORT table names. If you change either of the table names, their owner, or their database, you must reinstall DB2 in update mode and make the corresponding changes on the DSNTIPZ installation panel.

Name the required index by adding the letter I to the corresponding table name. For example, suppose that you are naming a required index for the ART named ABC. You should name the required index ABCI.

## Dropping registration tables and indexes

If you drop any of the registration tables or their indexes, most data definition statements are rejected until the dropped objects are re-created. The only data definition statements that are allowed under such circumstances are those that create the following objects:

- Registration tables that are defined during installation

- Indexes of the registration tables that are defined during installation
- Table spaces that contain the registration tables that are defined during installation
- The database that contains the registration tables that are defined during installation

### Creating a table space for the ART and ORT

The installation job DSNTIJSJG creates a segmented table space to hold the ART and ORT, using this statement:

```
CREATE TABLESPACE DSNRGFTS IN DSNRGFDB SEGSIZE 4 CLOSE NO;
```

If you want to use a table space with a different name or different attributes, you can modify job DSNTIJSJG before installing DB2. Alternatively, you can drop the table space and re-create it, the two tables, and their indexes.

### Adding columns

You can add columns to either registration table for your own use, by using the ALTER TABLE statement. If you add columns, the additional columns must come at the end of the table, after existing columns.

**Recommendation:** Use a special character, such as the plus sign (+), in your column names to avoid possible conflict. If IBM adds columns to the ART or the ORT in future releases, the column names will contain only letters and numbers.

### Updating the tables

You can update either the ART or the ORT with the LOAD utility, or with SQL INSERT, UPDATE, or DELETE statements.

**Recommendation:** Because security provisions are important, allow only a restricted set of authorization IDs, or perhaps only those with SYSADM authority, to update the ART. Consider assigning a validation exit routine to the ORT, to allow applications to change only those rows that have the same application identifier in the APPLIDENT column. A registration table cannot be updated until all jobs whose data definition statements are controlled by the table have completed.

### Stopping data definition control

When data definition control is active, only IDs with installation SYSADM or installation SYSOPR authority are able to stop the database, a table space, or an index space that contains a registration table or index. When the object is stopped, only an ID with one of those authorities can start it again.

**Bypassing data definition control:** An ID with install SYSADM authority can execute data definition statements regardless of whether data definition control is active, and regardless of whether the ART or ORT is available. To bypass data definition control, an ID with install SYSADM authority can use the following methods:

- If the ID is the owner of the plan or package that contains the statement, the ID can bypass data definition control by using a static SQL statement.
- If the ID is the current SQL ID, the ID can bypass data definition control through a dynamic CREATE statement.

- If the ID is the current SQL ID, the primary ID, or any secondary ID of the executing process, the ID can bypass data definition control through a dynamic ALTER or DROP statement.

---

## Chapter 11. Controlling access to a DB2 subsystem

This chapter explains how to control access to the DB2 subsystem from different environments and how to associate a process with an intended set of authorization IDs.

**Recommendation for external security system:** Control access through an external security system, for which Resource Access Control Facility (RACF) is the model. “Establishing RACF protection for DB2” on page 264 describes how to make DB2 and its IDs known to RACF.

If you are using RACF, you can also define multilevel security for DB2 resources, which is described in “Multilevel security” on page 192.

Control by RACF is not strictly necessary, and some alternatives are described under “Other methods of controlling access” on page 279. However, most of the information in this chapter assumes that RACF, or an equivalent product, is already in place.

**Local requests only:** If you do not accept requests from or send requests to remote locations, begin reading this chapter with “Controlling local requests” on page 232. When you reach “Controlling requests from remote applications” on page 238, you can skip forward to “Establishing RACF protection for DB2” on page 264.

**Remote requests:** If you accept requests from remote applications, read “Controlling requests from remote applications” on page 238. “Controlling requests from remote applications” on page 238 describes the security checks that a remote request is subject to before it can access your DB2 subsystem. The level of security differs depending on whether the requesting application is using SNA or Transmission Control Protocol/Internet Protocol (TCP/IP) protocols to access DB2. After the local system authenticates the incoming ID, it treats the ID like a local connection request or a local sign-on request. You can process the ID with your connection or sign-on exit routine and associate secondary authorization IDs with the ID. For more information about local connection requests, see “Controlling local requests” on page 232.

If you are sending requests to a remote DB2 subsystem, that subsystem can subject your requests to various security checks. For suggestions on how to plan for these checks, see “Planning to send remote requests” on page 252. If you send requests to a remote DBMS that is not DB2 UDB for z/OS, use the documentation for that DRDA database server.

### **Topics covered in this chapter:**

- “Controlling local requests” on page 232
- “Processing connections” on page 232
- “Processing sign-ons” on page 236
- “Controlling requests from remote applications” on page 238
- “Planning to send remote requests” on page 252
- “Establishing RACF protection for DB2” on page 264
- “Establishing Kerberos authentication through RACF” on page 278
- “Other methods of controlling access” on page 279

---

## Controlling local requests

Different local processes enter the access control procedure at different points, depending on the environment in which they originate. The following processes go through connection processing only:

- Requests originating in TSO foreground and background (including online utilities and requests through the call attachment facility)
- JES-initiated batch jobs
- Requests through started task control address spaces (from the z/OS START command)

The following processes go through connection processing and can later go through the sign-on exit also.

- The IMS control region.
- The CICS recovery coordination task.
- DL/I batch.
- Applications that connect using the Resource Recovery Services attachment facility (RRSAF). (See Part 6 of *DB2 Application Programming and SQL Guide* for more information.)

The following processes go through sign-on processing:

- Requests from IMS dependent regions (including MPP, BMP, and Fast Path)
- CICS transaction subtasks

For instructions on controlling the IDs that are associated with connection requests, see “Processing connections.” For instructions on controlling the IDs that are associated with sign-on requests, see “Processing sign-ons” on page 236.

IMS, CICS, RRSAP, and DDF-to-DDF connections can send a sign-on request, typically to execute an application plan. That request must provide a primary ID, and can also provide secondary IDs. After a plan is allocated, it need not be deallocated until a new plan is required. A different transaction can use the same plan by issuing a new sign-on request with a new primary ID.

---

## Processing connections

A connection request makes a new connection to DB2; it does not reuse an application plan that is already allocated. Therefore, an essential step in processing the request is to check that the ID is authorized to use DB2 resources, as shown in Figure 18.

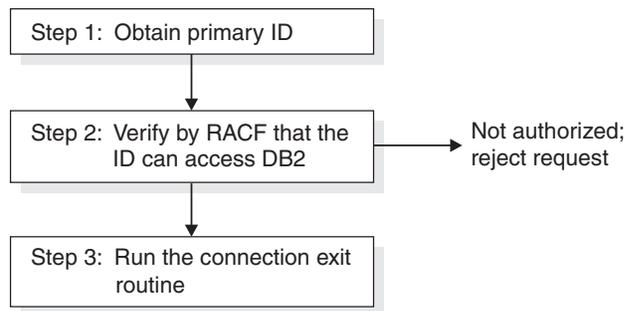

Figure 18. Connection processing

## Steps in processing connections

Processing connections involves the following steps:

1. DB2 obtains the initial primary authorization ID. Table 70 shows how the source of the ID depends on the type of address space from which the connection was made.

Table 70. Sources of initial primary authorization IDs

Source	Initial primary authorization ID
TSO	TSO logon ID.
BATCH	USER parameter on JOB statement.
IMS control region or CICS	USER parameter on JOB statement.
IMS or CICS started task	Entries in the started task control table.
Remote access requests	Depends on the security mechanism used. See “Overview of security mechanisms for DRDA and SNA” on page 238 for more details.

2. RACF is called through the z/OS system authorization facility (SAF) to check whether the ID that is associated with the address space is authorized to use the following resources:
  - The DB2 resource class (CLASS=DSNR)
  - The DB2 subsystem (SUBSYS=*ssnm*)
  - The requested connection type

For instructions on authorizing the use of these resources, see “Permitting RACF access” on page 267.

The SAF return code (RC) from the invocation determines the next step, as follows:

- **If RC > 4**, RACF determined that the RACF user ID is not valid or does not have the necessary authorization to access the resource name. DB2 rejects the request for a connection.
  - **If RC = 4**, the RACF return code is checked.
    - If RACF return code value is **equal to 4**, the resource name is not defined to RACF and DB2 rejects the request with reason code X'00F30013'. For instructions on defining the resource name, see “Defining DB2 resources to RACF” on page 265.
    - If RACF return code value is **not equal to 4**, RACF is not active. DB2 continues with the next step, but the connection request and the user are not verified.
  - **If RC = 0**, RACF is active and has verified the RACF user ID; DB2 continues with the next step.
3. If RACF is active and has verified the RACF user ID, DB2 runs the connection exit routine. To use DB2 secondary IDs, you must replace the exit routine. See “Supplying secondary IDs for connection requests” on page 234.

If you do not want to use secondary IDs, do nothing. The IBM-supplied default connection exit routine continues the connection processing. The process has the following effects:

- The DB2 primary authorization ID is set based on the following rules:
  - If a value for the initial primary authorization ID exists, the value becomes the DB2 primary ID.
  - If no value exists (the value is blank), the primary ID is set by default, as shown in Table 71 on page 234.

Table 71. Sources of default authorization identifiers

Source	Default primary authorization ID
TSO	TSO logon ID
BATCH	USER parameter on JOB statement
Started task, or batch job with no USER parameter	Default authorization ID set when DB2 was installed (UNKNOWN AUTHID on installation panel DSNTIPP)
Remote request	None. The user ID is required and is provided by the DRDA requester.

- The SQL ID is set equal to the primary ID.
- No secondary IDs exist.

If you want to use secondary IDs, see the description in “Supplying secondary IDs for connection requests.” Of course, you can also replace the exit routine with one that provides different default values for the DB2 primary ID. If you have written such a routine for an earlier release of DB2, it will probably work for this release with no change.

## Supplying secondary IDs for connection requests

If you want to use DB2 secondary authorization IDs, you must replace the default connection exit routine. If you want to use RACF group names as DB2 secondary IDs, as illustrated in “Examples of granting and revoking privileges” on page 173,, the easiest method is to use the IBM-supplied sample routine.

The difference between the default connection exit routine and the sample connection exit routine are shown in Table 72.

Table 72. Differences between default connection exit routine and sample connection exit routine

Default connection exit routine	Sample connection exit routine
Supplied as object code.	Supplied as source code. You can change the code.
Installed as part of the normal DB2 installation procedure.	Must be compiled and placed in the DB2 library.
Provides values for primary IDs and SQL IDs, but does not provide values for secondary IDs.	Provides values for primary IDs, secondary IDs, and SQL IDs.

Installation job DSNTIJEX replaces the default connection exit routine with the sample connection exit routine; for more information, see Part 2 of *DB2 Installation Guide*.

The sample connection exit routine has the following effects:

- The sample connection exit routine sets the DB2 primary ID in the same way that the default routine sets the DB2 primary ID, and according to the following rules:
  - If the initial primary ID is not blank, the initial ID becomes the DB2 primary ID.
  - If the initial primary ID is blank, the sample routine provides the same default value as does the default routine.

- If the sample routine cannot find a nonblank primary ID, DB2 uses the default ID (UNKNOWN AUTHID) from the DSNTIPP installation panel. In this case, no secondary IDs are supplied.
- The sample connection exit routine sets the SQL ID based on the following criteria:
  - The routine sets the SQL ID to the TSO data set name prefix in the TSO user profile table if the following conditions are true:
    - The connection request is from a TSO-managed address space, including the call attachment facility, the TSO foreground, and the TSO background.
    - The TSO data set name prefix is equal to the primary ID or one of the secondary IDs.
  - In all other cases, the routine sets the SQL ID equal to the primary ID.
- The secondary authorization IDs depend on RACF options:
  - If RACF is not active, no secondary IDs exist.
  - If RACF is active but its “list of groups” option is not active, one secondary ID exists (the default connected group name) if the attachment facility supplied the default connected group name.
  - If RACF is active and the “list of groups” option is active, the routine sets the list of DB2 secondary IDs to the list of group names to which the RACF user ID is connected. Those RACF user IDs that are in REVOKE status do not become DB2 secondary IDs. The maximum number of groups is 1012. The list of group names is obtained from RACF and includes the default connected group name.

If the default connection exit routine and the sample connection exit routine do not provide the flexibility and features that your subsystem requires, you can write your own exit routine. For instructions on writing your own exit routine, see Appendix B, “Writing exit routines,” on page 1055.

## Required CICS specifications

For a CICS transaction to use the sample connection or sign-on exit routines, the external security system, such as RACF, must be defined to CICS with the following specifications:

- The CICS system initialization table must specify external security.
  - For CICS Version 4 or later, specify SEC=YES.
  - For earlier releases of CICS, specify EXTSEC=YES.

If you are using the CICS multiple region option (MRO), you must specify SEC=YES or EXTSEC=YES for every CICS system that is connected by interregion communication (IRC).

- If your version of CICS uses a sign-on table (SNT), the CICS sign-on table must specify EXTSEC=YES for each signed on user that uses the sign-on exit.
- When the user signs on to a CICS terminal-owning region, the terminal-owning region must propagate the authorization ID to the CICS application-owning region. For more information on that propagation, see the description of ATTACHSEC in the applicable version of the *CICS Intercommunication Guide*.

You must change the sample sign-on exit routine (DSN3SSGN) before using it if the following conditions are all true:

- You have the RACF list-of-groups option active.
- You have transactions whose initial primary authorization ID is not defined to RACF.

For instructions on changing the sample sign-on exit routine, see “Sample connection and sign-on routines” on page 1056.

---

## Processing sign-ons

For requests from IMS dependent regions, CICS transaction subtasks, or RRS connections, the initial primary ID is not obtained until just before allocating a plan for a transaction. A new sign-on request can run the same plan without deallocating the plan and reallocating it. Nevertheless, the new sign-on request can change the primary ID.

Unlike connection processing, sign-on processing does not check the RACF user ID of the address space. The steps in processing sign-ons are shown in Figure 19.

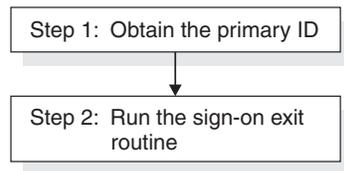

Figure 19. Sign-on processing

### Steps in processing sign-ons

DB2 takes the following steps in processing sign-ons:

1. DB2 determines the initial primary ID as follows:

**For IMS sign-ons** from message-driven regions, if the user has signed on, the initial primary authorization ID is the user's sign-on ID.

IMS passes to DB2 the IMS sign-on ID and the associated RACF connected group name, if one exists.

If the user has not signed on, the primary ID is the LTERM name, or if that is not available, the PSB name.

For a batch-oriented region, the primary ID is the value of the USER parameter on the job statement, if that is available. If that is not available, the primary ID is the program's PSB name.

For information about authorization IDs, CICS, and RDO, see the following books:

- *CICS Transaction Server for OS/390 Resource Definition Guide*
- *CICS Transaction Server for z/OS DB2 Guide*

**For remote requests**, the source of the initial primary ID is determined by entries in the SYSIBM.USERNAMES table. “Accepting a remote attachment request” on page 242 explains how to control the ID.

**For connections using Resource Recovery Services attachment facility**, the processing depends on the type of signon request:

- SIGNON
- AUTH SIGNON
- CONTEXT SIGNON

For SIGNON, the primary authorization ID is retrieved from ACEEUSRI if an ACEE is associated with the TCB (TCBSENV). This is the normal case.

However, if an ACEE is not associated with the TCB, SIGNON uses the primary authorization ID that is associated with the address space, that is, from the ASXB. If the new primary authorization ID was retrieved from the ACEE

that is associated with the TCB and ACEEGRPN is not null, DB2 uses ACEEGRPN to establish secondary authorization IDs.

With AUTH SIGNON, an APF-authorized program can pass a primary authorization ID for the connection. If a primary authorization ID is passed, AUTH SIGNON also uses the value that is passed in the secondary authorization ID parameter to establish secondary authorization IDs. If the primary authorization ID is not passed, but a valid ACEE is passed, AUTH SIGNON uses the value in ACEEUSRI for the primary authorization ID if ACEEUSRL is not 0. If ACEEUSRI is used for the primary authorization ID, AUTH SIGNON uses the value in ACEEGRPN as the secondary authorization ID if ACEEGRPL is not 0.

For CONTEXT SIGNON, the primary authorization ID is retrieved from data that is associated with the current RRS context using the context\_key, which is supplied as input. CONTEXT SIGNON uses the CTXSDTA and CTXRDTA functions of RRS context services. An authorized function must use CTXSDTA to store a primary authorization ID prior to invoking CONTEXT SIGNON. Optionally, CTXSDTA can be used to store the address of an ACEE in the context data that has a context\_key that was supplied as input to CONTEXT SIGNON. DB2 uses CTXRDTA to retrieve context data. If an ACEE address is passed, CONTEXT SIGNON uses the value in ACEEGRPN as the secondary authorization ID if ACEEGRPL is not 0.

For more information, see Part 6 of *DB2 Application Programming and SQL Guide*.

2. DB2 runs the sign-on exit routine. **User action:** To use DB2 secondary IDs, you must replace the exit routine.

If you **do not** want to use secondary IDs, do nothing. Sign-on processing is then continued by the IBM-supplied default sign-on exit routine, which has the following effects:

- The initial primary authorization ID remains the primary ID.
- The SQL ID is set equal to the primary ID.
- No secondary IDs exist.

You can replace the exit routine with one of your own, even if it has nothing to do with secondary IDs. If you do, remember that IMS and CICS recovery coordinators, their dependent regions, and RRSAF take the exit routine only if they have provided a user ID in the sign-on parameter list.

If you *do* want to use secondary IDs, see the description that follows.

## Supplying secondary IDs for sign-on requests

If you want the primary authorization ID to be associated with DB2 secondary authorization IDs, you must replace the default sign-on exit routine. The procedure is like that for connection processing: If you want to use RACF group names as DB2 secondary IDs, the easiest method is to use the IBM-supplied sample routine. An installation job can automatically replace the default routine with the sample routine; to run it, see “Installation Step 6: Define User Authorization Exit Routines: DSNTIJEX” in Part 2 of *DB2 Installation Guide*.

Distinguish carefully between the two routines. The default sign-on routine provides no secondary IDs and has the effects described in step 2 of “Processing sign-ons” on page 236. The sample sign-on routine supports DB2 secondary IDs, and is like the sample connection routine.

The sample sign-on routine has the following effects:

- The initial primary authorization ID is left unchanged as the DB2 primary ID.

- The SQL ID is made equal to the DB2 primary ID.
- The secondary authorization IDs depend on RACF options:
  - If RACF is not active, no secondary IDs exist.
  - If RACF is active but its “list of groups” option is not active, one secondary ID exists; it is the name passed by CICS or by IMS.
  - If RACF is active and you have selected the option for a list of groups, the routine sets the list of DB2 secondary IDs to the list of group names to which the RACF user ID is connected, up to a limit of 1012 groups. The list of group names includes the default connected group name.

## Controlling requests from remote applications

If you are controlling requests from remote applications, your DB2 subsystem might be accepting requests from applications that use SNA network protocols, TCP/IP network protocols, or both. This section describes the methods that the DB2 server can use to control access from those applications. To understand what is described here, you must be familiar with the communications database, which is part of the DB2 catalog. This section describes the following topics:

- “Overview of security mechanisms for DRDA and SNA”
- “The communications database for the server” on page 240
- “Controlling inbound connections that use SNA protocols” on page 242
- “Controlling inbound connections that use TCP/IP protocols” on page 249

## Overview of security mechanisms for DRDA and SNA

SNA and DRDA have different security mechanisms. DRDA lets a user be authenticated using SNA security mechanisms or DRDA mechanisms, which are independent of the underlying network protocol. For an SNA network connection, a DRDA requester can send security tokens using a SNA attach or using DRDA commands. DB2 UDB for z/OS as a requester uses SNA security mechanisms if it uses a SNA network connection (except for Kerberos) and DRDA security mechanisms for TCP/IP network connections (or when Kerberos authentication is chosen, regardless of the network type).

### Mechanisms used by DB2 UDB for z/OS as a requester

DB2 UDB for z/OS as a requester chooses SNA or DRDA security mechanisms based on the network protocol and the authentication mechanisms you use. If you use SNA protocols, DB2 supports the following SNA authentication mechanisms:

- User ID only (already verified)
- User ID and password, described in “Sending passwords” on page 262
- User ID and PassTicket, described in “Sending RACF PassTickets” on page 263

Authentication is performed based on SNA protocols, which means that the authentication tokens are sent in an SNA attach (FMH-5).

If you use TCP/IP protocols, DB2 supports the following DRDA authentication mechanisms:

- User ID only (already verified)
- User ID and password, described in “Sending passwords” on page 262
- User ID and PassTicket, described in “Sending RACF PassTickets” on page 263

If you use TCP/IP protocols with the z/OS Integrated Cryptographic Service Facility, DB2 also supports the following DRDA authentication mechanisms:

- Encrypted user ID and encrypted password
- Encrypted user ID and encrypted security-sensitive data
- Encrypted user ID, encrypted password, and encrypted security-sensitive data

|  
|  
|  
|  
|

- Encrypted user ID, encrypted password, encrypted new password, and encrypted security-sensitive data

Authentication is performed based on DRDA protocols, which means that the authentication tokens are sent in DRDA security flows.

If you use a requester other than DB2 UDB for z/OS, refer to that product's documentation.

### **Mechanisms accepted by DB2 UDB for z/OS as a server**

As a server, DB2 UDB for z/OS can accept either SNA or DRDA authentication mechanisms. This means that DB2 can authenticate remote users from either the security tokens obtained from the SNA ATTACH (FMH-5) or from the DRDA security commands described by each of the protocols. It accepts connection requests from remote clients that use AES or DES encryption algorithm to protect user IDs and passwords over a TCP/IP network.

Specifically, DB2 UDB for z/OS as a server supports the following authentication methods:

- User ID only (already verified at the requester)
- User ID and password, described in “Sending passwords” on page 262
- User ID and PassTicket, described in “Sending RACF PassTickets” on page 263
- Kerberos tickets, described in “Establishing Kerberos authentication through RACF” on page 278
- Unencrypted user ID and encrypted password, described in “Sending encrypted passwords from workstation clients” on page 263
- Encrypted user ID and encrypted password, described in “Sending encrypted passwords from workstation clients” on page 263
- User ID, password, and new password, described in “Allowing users to change expired passwords”

DB2 UDB for z/OS as a server also supports the following authentication mechanisms if the z/OS Integrated Cryptographic Service Facility is installed and active:

- Encrypted user ID and encrypted security-sensitive data
- Encrypted user ID, encrypted password, and encrypted security-sensitive data

**Allowing users to change expired passwords:** DB2 can return to the DRDA requester information about errors and expired passwords. To allow this, specify YES in the EXTENDED SECURITY field of installation panel DSNTIPR.

When the DRDA requester is notified that the RACF password has expired, and the requester has implemented function to allow passwords to be changed, the requester can prompt the end user for the old password and a new password. The requester sends the old and new passwords to the DB2 server. This function is supported through DB2 Connect.

With the extended security option, DB2 passes the old and new passwords to RACF. If the old password is correct, and the new password meets the installation's password requirements, the end user's password is changed and the DRDA connection request is honored.

When a user changes a password, the user ID, the old password, and the new password are sent to DB2 by the client system. The client system can optionally encrypt these three tokens before they are sent.

**Detecting authorization failures (EXTENDED SECURITY):** If the DB2 server is installed with YES for the EXTENDED SECURITY field of installation panel DSNTIPR, detailed reason codes are returned to a DRDA client when a DDF connection request fails because of security errors. When using SNA protocols, the requester must have included support for extended security sense codes. One such product is DB2 Connect.

If the proper requester support is present, the requester generates SQLCODE -30082 (SQLSTATE '08001') with a specific indication for the failure. Otherwise, a generic security failure code is returned.

## The communications database for the server

The information in this section, up to “Controlling inbound connections that use SNA protocols” on page 242, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The communications database (CDB) is a set of DB2 catalog tables that let you control aspects of how requests leave this DB2 and how requests come in. This section concentrates on the columns of the communications database that pertain to security on the inbound side (the server).

The SYSIBM.IPNAMES table is not described in this section, because that table is not used to control inbound TCP/IP requests.

### Columns used in SYSIBM.LUNAMES

This table is used only for requests that use SNA protocols.

LUNAME CHAR(8)

The LUNAME of the remote system. A blank value identifies a default row that serves requests from any system that is not specifically listed elsewhere in the column.

SECURITY\_IN CHAR(1)

The *acceptance option* for a remote request from the corresponding LUNAME:

- V The option is “verify.” An incoming request must include one of the following authentication entities:
  - User ID and password
  - User ID and RACF PassTicket, described in “Sending RACF PassTickets” on page 263
  - User ID and RACF encrypted password (not recommended)
  - Kerberos security tickets, described in “Establishing Kerberos authentication through RACF” on page 278
  - User ID and DRDA encrypted password, described in “Sending encrypted passwords from workstation clients” on page 263
  - User ID, password, and new password, described in “Allowing users to change expired passwords” on page 239
  - User ID and encrypted password, or encrypted user ID and encrypted password, described in “Allowing users to change expired passwords” on page 239
- A The option is “already verified.” This is the default. With A, a request does not need an authentication token, although the token is checked if it is sent.

With this option, an incoming connection request is accepted if it includes any of the following authentication tokens:

- User ID only
- All authentication methods that option V supports

If the USERNAMES column of SYSIBM.LUNAMES contains I or B, RACF is not invoked to validate incoming connection requests that contain only a user ID.

#### ENCRYPTPSWDS CHAR(1)

This column only applies to DB2 UDB for z/OS or DB2 UDB for z/OS partners when passwords are used as authentication tokens. It indicates whether passwords received from and sent to the corresponding LUNAME are encrypted:

- Y Yes, passwords are encrypted. For outbound requests, the encrypted password is extracted from RACF and sent to the server. For inbound requests, the password is treated as if it is encrypted.
- N No, passwords are not encrypted. This is the default; any character other than Y is treated as N. Specify N for CONNECT statements that contain a USER parameter.

**Recommendation:** When you connect to a DB2 UDB for z/OS partner that is at Version 5 or a subsequent release, use RACF PassTickets (SECURITY\_OUT='R') instead of using passwords.

#### USERNAMES CHAR(1)

This column indicates whether an ID accompanying a remote request, sent from or to the corresponding LUNAME, is subject to translation and “come from” checking. When you specify I, O, or B, use the SYSIBM.USERNAMES table to perform the translation.

- I An inbound ID is subject to translation.
- O An outbound ID, sent to the corresponding LUNAME, is subject to translation.
- B Both inbound and outbound IDs are subject to translation.
- blank No IDs are translated.

### Columns used in SYSIBM.USERNAMES

This table is used by both SNA and TCP/IP connections.

#### TYPE CHAR(1)

Indicates whether the row is used for inbound or outbound translation:

- I The row applies to inbound IDs (not applicable for TCP/IP connections).
- O The row applies to outbound IDs.

The field should contain only I or O. Any other character, including blank, causes the row to be ignored.

#### AUTHID VARCHAR(128)

An authorization ID that is permitted and perhaps translated. If blank, any authorization ID is permitted with the corresponding LINKNAME; all authorization IDs are translated in the same way. Outbound translation is not performed on CONNECT statements that contain an authorization ID for the value of the USER parameter.

#### LINKNAME CHAR(8)

Identifies the VTAM or TCP/IP network locations that are associated with this row. A blank value in this column indicates that this name translation rule applies to any TCP/IP or SNA partner.

If you specify a nonblank value for this column, one or both of the following situations must be true:

- A row exists in table SYSIBM.LUNAMES that has an LUNAME value that matches the LINKNAME value that appears in this column.
- A row exists in table SYSIBM.IPNAMES that has a LINKNAME value that matches the LINKNAME value that appears in this column.

#### NEWAUTHID VARCHAR(128)

The translated authorization ID. If blank, no translation occurs.

## Controlling inbound connections that use SNA protocols

Requests from a remote LU are subject to two security checks before they come into contact with DB2. Those checks control what LUs can attach to the network and verify the identity of a partner LU.

Finally, DB2 itself imposes several checks before accepting an attachment request.

If using private protocols, the LOCATIONS table controls the locations that can access DB2. To allow a remote location to access DB2, the remote location name must be specified in the SYSIBM.LOCATIONS table. This check is only supported for connections using private protocols.

### Controlling what LUs can attach to the network

This check is carried out by VTAM, to prevent an unauthorized LU from attaching to the network and presenting itself to other LUs as an acceptable partner in communication. It requires each LU that attaches to the network to identify itself by a password. If that requirement is in effect for your network, your DB2 subsystem, like every other LU on the network, must:

1. Choose a VTAM password.
2. Code the password with the PRTCT parameter of the VTAM APPL statement, when you define your DB2 to VTAM. The APPL statement is described in detail in Part 3 of *DB2 Installation Guide*.

### Verifying a partner LU

This check is carried out by RACF and VTAM, to check the identity of an LU sending a request to your DB2.

**Recommendation:** Specify partner-LU verification, which requires the following steps:

1. Code VERIFY=REQUIRED on the VTAM APPL statement, when you define your DB2 to VTAM. The APPL statement is described in detail in Part 3 of *DB2 Installation Guide*.
2. Establish a RACF profile for each LU from which you permit a request. For the steps required, see “Enable partner-LU verification” on page 267.

### Accepting a remote attachment request

When VTAM has established a conversation for a remote application, that application sends a *remote request*, which is a request to attach to your local DB2. (Do not confuse the *remote* request with a *local* attachment request that comes through one of the DB2 attachment facilities—IMS, CICS, TSO, and so on. A

remote attachment request is defined by Systems Network Architecture and LU 6.2 protocols; specifically, it is an SNA Function Management Header 5.)

This section tells what security checks you can impose on remote attachment requests.

**Conversation-level security:** This section assumes that you have defined your DB2 to VTAM with the conversation-level security set to “already verified”. (To do that, you coded SECACPT=ALREADYV on the VTAM APPL statement, as described in Part 3 of *DB2 Installation Guide*. That value provides more options than does “conversation” (SECACPT=CONV), which is not recommended.)

**Steps, tools, and decisions:** The steps an attachment request goes through before acceptance allow much flexibility in choosing security checks. See Figure 20 on page 245 to see what is possible.

The primary tools for controlling remote attachment requests are entries in tables SYSIBM.LUNAMES and SYSIBM.USERNAMES in the communications database. You need a row in SYSIBM.LUNAMES for each system that sends attachment requests, a dummy row that allows *any* system to send attachment requests, or both. You might need rows in SYSIBM.USERNAMES to permit requests from specific IDs or specific LUNAMES, or to provide translations for permitted IDs.

When planning to control remote requests, answer the questions posed by the following topics for each remote LU that can send a request.

- “Do you permit access?”
- “Do you manage inbound IDs through DB2 or RACF?”
- “Do you trust the partner LU?” on page 244
- “If you use passwords, are they encrypted?” on page 244
- “If you use Kerberos, are users authenticated?” on page 244
- “Do you translate inbound IDs?” on page 247
- “How do you associate inbound IDs with secondary IDs?” on page 249

### **Do you permit access?**

To permit attachment requests from a particular LU, you need a row in your SYSIBM.LUNAMES table. The row must either give the specific LUNAME or it must be a dummy row with the LUNAME blank. (The table can have only one dummy row, which is used by all LUs for which no specific row exists, when making requests.) Without one of those rows, the attachment request is rejected.

### **Do you manage inbound IDs through DB2 or RACF?**

If you manage incoming IDs through RACF, you must register every acceptable ID with RACF, and DB2 must call RACF to process every request. If you manage incoming IDs through RACF, either RACF or Kerberos can authenticate the user. Kerberos cannot be used if you do not have RACF on the system.

If you manage incoming IDs through DB2, you can avoid calls to RACF and can specify acceptance of many IDs by a single row in the SYSIBM.USERNAMES table.

To manage incoming IDs through DB2, put an I in the USERNAMES column of SYSIBM.LUNAMES for the particular LU. (Or, if an O is there already because you are also sending requests *to* that LU, change O to B.) Attachment requests from that LU now go through sign-on processing, and its IDs are subject to translation. (For more information about translating IDs, see “Do you translate inbound IDs?” on page 247.)

To manage incoming IDs through RACF, leave USERNAMES blank for that LU (or leave the O unchanged). Requests from that LU go through connection processing, and its IDs are not subject to translation.

### **Do you trust the partner LU?**

Presumably, RACF has already validated the identity of the other LU (described in “Verifying a partner LU” on page 242). If you trust incoming IDs from that LU, you do not need to validate them by an authentication token. Put an A in the SECURITY\_IN column of the row in SYSIBM.LUNAMES that corresponds to the other LU; your acceptance level for requests from that LU is now “already verified”. Requests from that LU are accepted without an authentication token. (In order to use this option, you must have defined DB2 to VTAM with SECACPT=ALREADYV, as described in 243.)

If an authentication token **does** accompany a request, DB2 calls RACF to check the authorization ID against it. To require an authentication token from a particular LU, put a V in the SECURITY\_IN column in SYSIBM.LUNAMES; your acceptance level for requests from that LU is now “verify”. You must also register every acceptable incoming ID and its password with RACF.

*Performance considerations:* Each request to RACF to validate authentication tokens results in an I/O operation, which has a high performance cost.

**Recommendation:** To eliminate the I/O, allow RACF to cache security information in VLF. To activate this option, add the IRRACEE class to the end of z/OS VLF member COFVLFxx in SYS1.PARMLIB, as follows:

```
CLASS NAME(IRRACEE)  
EMAJ (ACEE)
```

### **If you use passwords, are they encrypted?**

Passwords can be encrypted through:

- RACF using PassTickets, described in “Sending RACF PassTickets” on page 263.
- DRDA password encryption support. DB2 UDB for z/OS as a server supports DRDA encrypted passwords and encrypted user IDs with encrypted passwords. See “Sending encrypted passwords from workstation clients” on page 263 for more information.
- The SET ENCRYPTION PASSWORD statement. This encryption method should not be used for distributed access because the unencrypted passwords in the SET ENCRYPTION PASSWORD statement flow from the client to the server. For more information about the SET ENCRYPTION PASSWORD statement, see *DB2 SQL Reference*.

### **If you use Kerberos, are users authenticated?**

If your distributed environment uses Kerberos to manage users and perform user authentication, DB2 UDB for z/OS can use Kerberos security services to authenticate remote users. See “Establishing Kerberos authentication through RACF” on page 278.

### Activity at the DB2 server

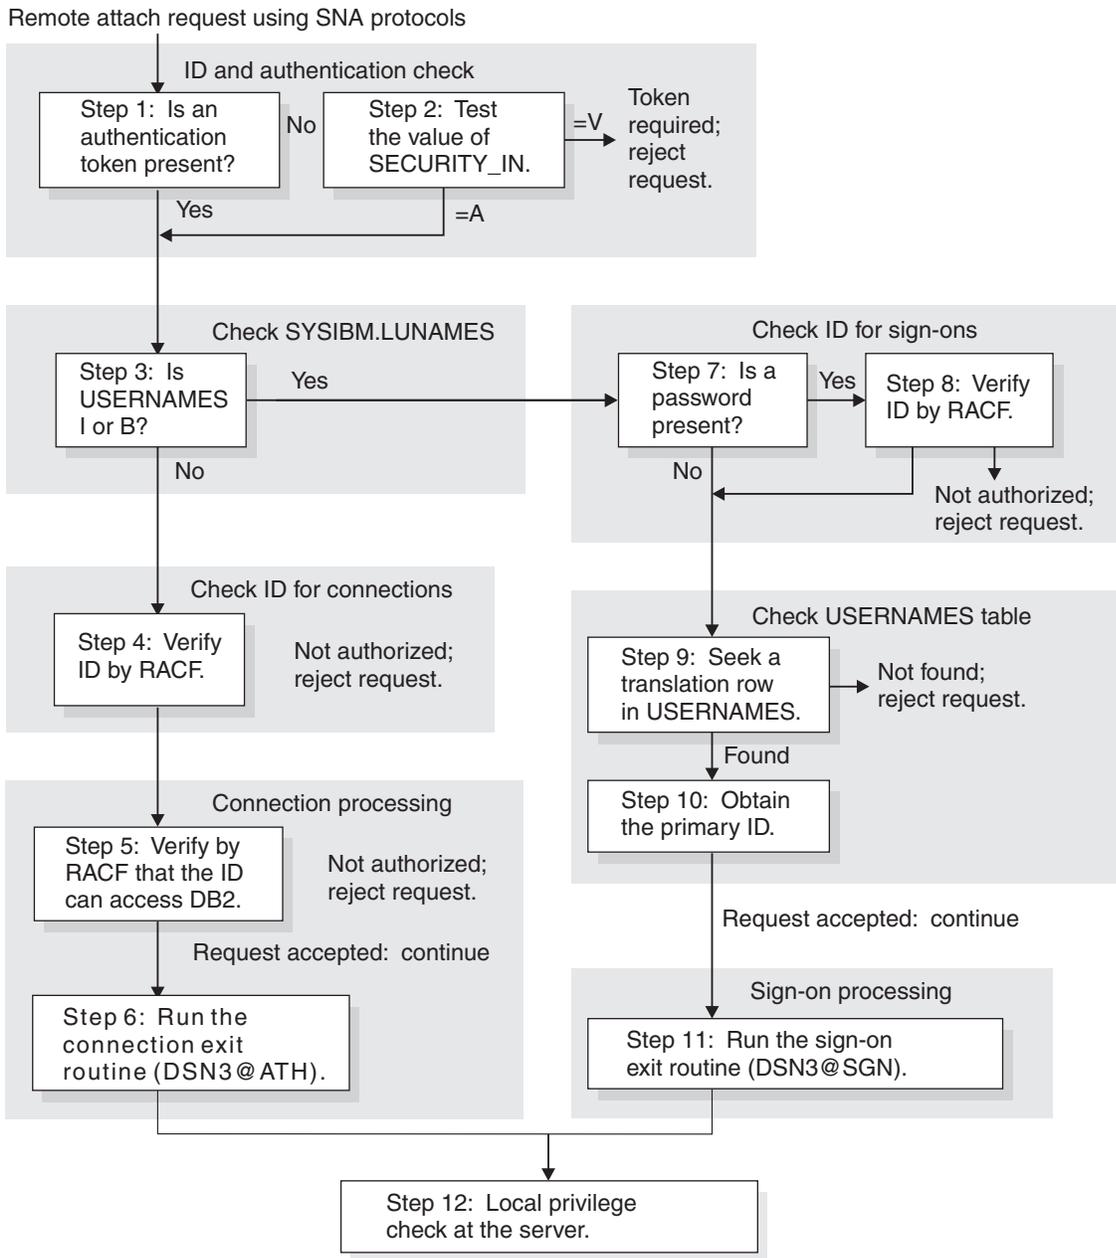

Figure 20. Steps in accepting a remote attachment request from requester that is using SNA

#### Details of remote attachment request processing:

1. If the remote request has no authentication token, DB2 checks the security acceptance option in the SECURITY\_IN column of table SYSIBM.LUNAMES. No password is sent or checked for the plan or package owner that is sent from a DB2 subsystem.
2. If the acceptance option is “verify” (SECURITY\_IN = V), a security token is required to authenticate the user. DB2 rejects the request if the token missing.
3. If the USERNAMES column of SYSIBM.LUNAMES contains I or B, the authorization ID, and the plan or package owner that is sent by a DB2

subsystem, are subject to translation under control of the SYSIBM.USERNAMES table. If the request is allowed, it eventually goes through sign-on processing.

If USERNAMES does not contain I or B, the authorization ID is not translated.

4. DB2 calls RACF by the RACROUTE macro with REQUEST=VERIFY to check the ID. DB2 uses the PASSCHK=NO option if no password is specified and ENCRYPT=YES if the ENCRYPTPSWDS column of SYSIBM.LUNAMES contains Y. If the ID, password, or PassTicket cannot be verified, DB2 rejects the request.

In addition, depending on your RACF environment, the following RACF checks may also be performed:

- If the RACF APPL class is active, RACF verifies that the ID has been given access to the DB2 APPL. The APPL resource that is checked is the LU name that the requester used when the attachment request was issued. This is either the local DB2 LU name or the generic LU name.
  - If the RACF APPCPORT class is active, RACF verifies that the ID is authorized to access z/OS from the Port of Entry (POE). The POE that RACF uses in the verify call is the requesting LU name.
5. The remote request is now treated like a local connection request with a DIST environment for the DSNR resource class; for details, see “Processing connections” on page 232. DB2 calls RACF by the RACROUTE macro with REQUEST=AUTH, to check whether the authorization ID is allowed to use DB2 resources that are defined to RACF.  
The RACROUTE macro call also verifies that the user is authorized to use DB2 resources from the requesting system, known as the port of entry (POE); for details, see “Allowing access from remote requesters” on page 272.
  6. DB2 invokes the connection exit routine. The parameter list that is passed to the routine describes where a remote request originated.
  7. If no password exists, RACF is not called. The ID is checked in SYSIBM.USERNAMES.
  8. If a password exists, DB2 calls RACF through the RACROUTE macro with REQUEST=VERIFY to verify that the ID is known with the password. ENCRYPT=YES is used if the ENCRYPTPSWDS column of SYSIBM.LUNAMES contains Y. If DB2 cannot verify the ID or password, the request is rejected.
  9. DB2 searches SYSIBM.USERNAMES for a row that indicates how to translate the ID. The need for a row that applies to a particular ID and sending location imposes a “come-from” check on the ID: If no such row exists, DB2 rejects the request.
  10. If an appropriate row is found, DB2 translates the ID as follows:
    - If a nonblank value of NEWAUTHID exists in the row, that value becomes the primary authorization ID.
    - If NEWAUTHID is blank, the primary authorization ID remains unchanged.
  11. The remote request is now treated like a local sign-on request; for details, see “Processing sign-ons” on page 236. DB2 invokes the sign-on exit routine. The parameter list that is passed to the routine describes where a remote request originated. For details, see “Connection routines and sign-on routines” on page 1055.
  12. The remote request now has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID. A request from a remote DB2 is also known by a plan or package owner. Privileges and authorities that are granted to those IDs at the DB2 server govern the actions that the request can take.

## Do you translate inbound IDs?

Ideally, each of your authorization IDs has the same meaning throughout your entire network. In practice, that might not be so, and the duplication of IDs on different LUs is a security exposure.

**Example:** Suppose that the ID DBADM1 is known to the local DB2 and has DBADM authority over certain databases there; suppose also that the same ID exists in some remote LU. If an attachment request comes in from DBADM1, and if nothing is done to alter the ID, the wrong user can exercise privileges of DBADM1 in the local DB2. The way to protect against that exposure is to translate the remote ID into a different ID before the attachment request is accepted.

You must be prepared to translate the IDs of plan owners, package owners, and the primary IDs of processes that make remote requests. For the IDs that are sent to you by other DB2 LUs, see “What IDs you send” on page 257. (Do not plan to translate all IDs in the connection exit routine—the routine does not receive plan and package owner IDs.)

If you have decided to manage inbound IDs through DB2, you can translate an inbound ID to some other value. Within DB2, you grant privileges and authorities only to the translated value. As Figure 20 on page 245 shows, that “translation” is not affected by anything you do in your connection or sign-on exit routine. The *output* of the translation becomes the *input* to your sign-on exit routine.

**Recommendation:** Do not translate inbound IDs in an exit routine; translate them only through the SYSIBM.USERNAMES table.

The examples in Table 73 shows the possibilities for translation and how to control translation by SYSIBM.USERNAMES. You can use entries to allow requests only from particular LUs or particular IDs, or from combinations of an ID and an LU. You can also translate any incoming ID to another value. Table 75 on page 249 shows the search order of the SYSIBM.USERNAMES table.

**Performance considerations:** In the process of accepting remote attachment requests, any step that calls RACF is likely to have a relatively high performance cost. To trade some of that cost for a somewhat greater security exposure, have RACF check the identity of the other LU just once, as described under “Verifying a partner LU” on page 242. Then trust the partner LU, translating the inbound IDs and not requiring or using passwords. In this case, no calls are made to RACF from within DB2; the penalty is only that you make the partner LU responsible for verifying IDs.

**Update considerations:** If you update tables in the CDB while the distributed data facility is running, the changes might not take effect immediately. For details, see Part 3 of *DB2 Installation Guide*.

**Example:** Table 73 shows how USERNAMES translates inbound IDs.

Table 73. Your SYSIBM.USERNAMES table. (Row numbers are added for reference.)

Row	TYPE	AUTHID	LINKNAME	NEWAUTHID
1	I	blank	LUSNFRAN	blank
2	I	BETTY	LUSNFRAN	ELIZA
3	I	CHARLES	blank	CHUCK
4	I	ALBERT	LUDALLAS	blank

Table 73. Your SYSIBM.USERNAMES table (continued). (Row numbers are added for reference.)

Row	TYPE	AUTHID	LINKNAME	NEWAUTHID
5	I	BETTY	blank	blank

DB2 searches SYSIBM.USERNAMES to determine how to translate for each of the requests that are listed in Table 74.

Table 74. How DB2 translates inbound authorization ids

Request	How DB2 translates request
ALBERT requests from LUDALLAS	DB2 searches for an entry for AUTHID=ALBERT and LINKNAME=LUDALLAS. DB2 finds one in row 4, so the request is accepted. The value of NEWAUTHID in that row is blank, so ALBERT is left unchanged.
BETTY requests from LUDALLAS	DB2 searches for an entry for AUTHID=BETTY and LINKNAME=LUDALLAS; none exists. DB2 then searches for AUTHID=BETTY and LINKNAME=blank. It finds that entry in row 5, so the request is accepted. The value of NEWAUTHID in that row is blank, so BETTY is left unchanged.
CHARLES requests from LUDALLAS	DB2 searches for AUTHID=CHARLES and LINKNAME=LUDALLAS; no such entry exists. DB2 then searches for AUTHID=CHARLES and LINKNAME=blank. The search ends at row 3; the request is accepted. The value of NEWAUTHID in that row is CHUCK, so CHARLES is translated to CHUCK.
ALBERT requests from LUSNFRAN	DB2 searches for AUTHID=ALBERT and LINKNAME=LUSNFRAN; no such entry exists. DB2 then searches for AUTHID=ALBERT and LINKNAME=blank; again no entry exists. Finally, DB2 searches for AUTHID=blank and LINKNAME=LUSNFRAN, finds that entry in row 1, and the request is accepted. The value of NEWAUTHID in that row is blank, so ALBERT is left unchanged.
BETTY requests from LUSNFRAN	DB2 finds row 2, and BETTY is translated to ELIZA.
CHARLES requests from LUSNFRAN	DB2 finds row 3 before row 1; CHARLES is translated to CHUCK.
WILBUR requests from LUSNFRAN	No provision is made for WILBUR, but row 1 of the SYSIBM.USERNAMES table allows any ID to make a request from LUSNFRAN and to pass without translation. The acceptance level for LUSNFRAN is "already verified", so WILBUR can pass without a password check by RACF. After accessing DB2, WILBUR can use only the privileges that are granted to WILBUR and to PUBLIC (for DRDA access) or to PUBLIC AT ALL LOCATIONS (for DB2 private-protocol access).
WILBUR requests from LUDALLAS	Because the acceptance level for LUDALLAS is "verify" as recorded in the SYSIBM.LUNAMES table, WILBUR must be known to the local RACF. DB2 searches in succession for one of the combinations WILBUR/LUDALLAS, WILBUR/blank, or blank/LUDALLAS. None of those is in the table, so the request is rejected. The absence of a row permitting WILBUR to request from LUDALLAS imposes a "come-from" check: WILBUR can attach from some locations (LUSNFRAN), and some IDs (ALBERT, BETTY, and CHARLES) can attach from LUDALLAS, but WILBUR cannot attach if coming from LUDALLAS.

Table 75 shows the search order for the SYSIBM.USERNAMES table:

Table 75. Precedence search order for SYSIBM.USERNAMES table

AUTHID	LINKNAME	Result
Name	Name	If NEWAUTHID is specified, AUTHID is translated to NEWAUTHID for the specified LINKNAME.
Name	Blank	If NEWAUTHID is specified, AUTHID is translated to NEWAUTHID for all LINKNAMEs.
Blank	Name	If NEWAUTHID is specified, it is substituted for AUTHID for the specified LINKNAME.
Blank	Blank	Unavailable resource message (SQLCODE -904) is returned.

#  
#  
#  
#  
#  
#  
#

**Encryption considerations:** If incoming authorization IDs are managed through DB2 and if the ICSF is installed and properly configured, you can use the DSNLEUSR stored procedure to encrypt translated authorization IDs and store them in the NEWAUTHID column of the SYSIBM.USERNAMES table. DB2 decrypts the translated authorization IDs during connection processing. For more information about the DSNLEUSR stored procedure, see Appendix J, “DB2-supplied stored procedures,” on page 1261.

### How do you associate inbound IDs with secondary IDs?

Your decisions on the previous questions determine what value is used for the primary authorization ID on an attachment request. They also determine whether those requests are next treated as connection requests or as sign-on requests. That means that the remote request next goes through the same processing as a local request, and that you have the opportunity to associate the primary ID with a list of secondary IDs in the same way you do for local requests. For more information about processing connections and sign-ons, see “Processing connections” on page 232 and “Processing sign-ons” on page 236.

## Controlling inbound connections that use TCP/IP protocols

DRDA connections that use TCP/IP have fewer security controls than do connections that use SNA protocols. When planning to control inbound TCP/IP connections, consider the following issues:

**Do you permit access by TCP/IP?** If the serving DB2 UDB for z/OS subsystem has a DRDA port and resynchronization port specified in the BSDS, DB2 is enabled for TCP/IP connections.

**Do you manage inbound IDs through DB2 or RACF?** All IDs must be passed to RACF or Kerberos for processing. No option exists to handle incoming IDs through DB2.

**Do you trust the partner?** TCP/IP does not verify partner LUs as SNA does. If your requesters support mutual authentication, use Kerberos to handle this on the requester side.

**If you use passwords, are they encrypted?** Passwords can be encrypted through:

- RACF using PassTickets, described in “Sending RACF PassTickets” on page 263.

- DRDA password encryption support. DB2 UDB for z/OS as a server supports DRDA encrypted passwords and encrypted user IDs with encrypted passwords. See “Sending encrypted passwords from workstation clients” on page 263 for more information.

*If you use Kerberos, are users authenticated?* If your distributed environment uses Kerberos to manage users and perform user authentication, DB2 UDB for z/OS can use Kerberos security services to authenticate remote users. See “Establishing Kerberos authentication through RACF” on page 278.

*Do you translate inbound IDs?* Inbound IDs are not translated when you use TCP/IP.

*How do you associate inbound IDs with secondary IDs?* To associate an inbound ID with secondary IDs, modify the default connection exit routine (DSN3@ATH). TCP/IP requests do not use the sign-on exit routine.

### Steps, tools, and decisions

See Figure 21 on page 251 for an overview of how incoming requests are handled. See “Detecting authorization failures (EXTENDED SECURITY)” on page 240 for information about security diagnostics.

1. You must first decide whether you want incoming requests to have authentication information, such as RACF passwords, RACF PassTickets, and Kerberos tickets, passed along with the authorization ID.  
To indicate that you require this authentication information, specify NO on the TCP/IP ALREADY VERIFIED field of installation panel DSNTIP5, which is the default option. If you do not specify NO, all incoming TCP/IP requests can connect to DB2 without any authentication.
2. If you require authentication, ensure that the security subsystem at your server is properly configured to handle the authentication information that is passed to it.
  - For requests that use RACF passwords or PassTickets, enter the following RACF command to indicate which user IDs that use TCP/IP are authorized to access DDF (the distributed data facility address space):  

```
PERMIT ssnm.DIST CLASS(DSNR) ID(yyy) ACCESS(READ)
  WHEN(APPCPORT(TCPIP))
```

### Activity at the DB2 server

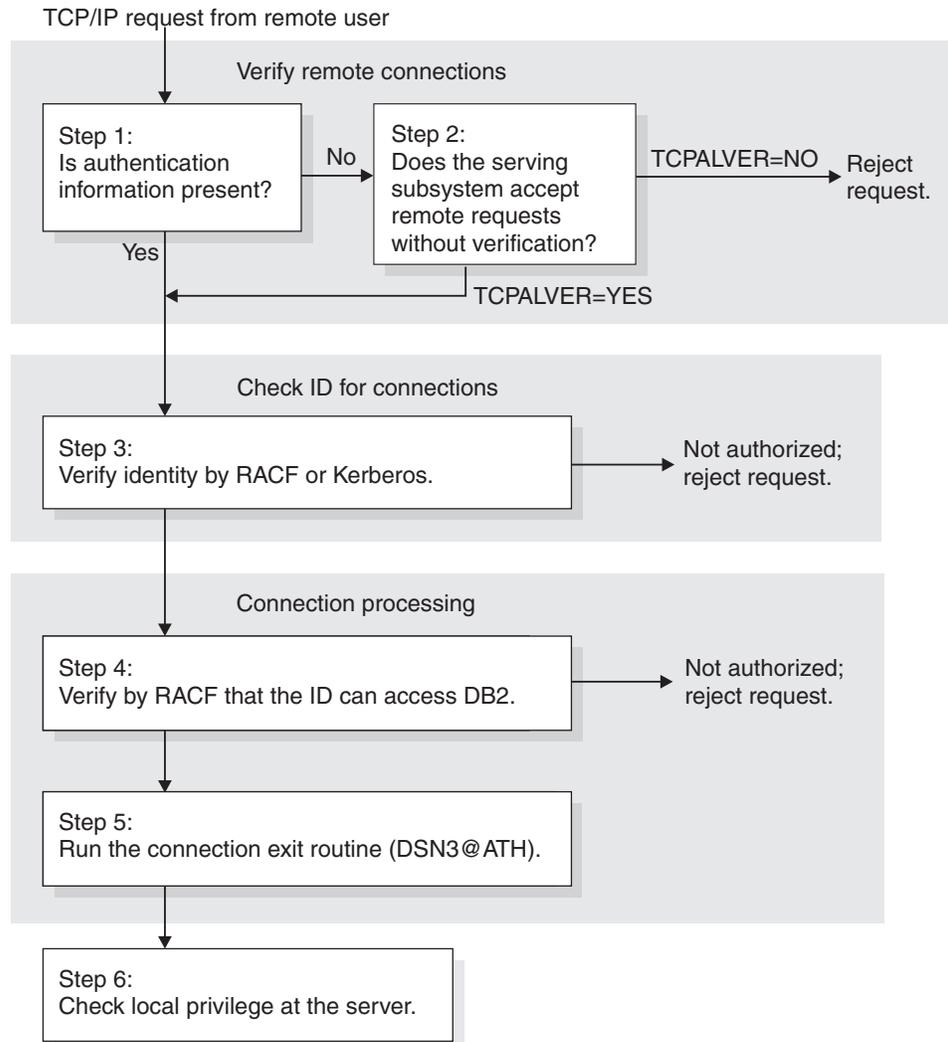

Figure 21. Steps in accepting a request from TCP/IP.

**Details of steps:** These notes explain the steps shown in Figure 21.

1. DB2 checks to see if an authentication token (RACF encrypted password, RACF PassTicket, DRDA encrypted password, or Kerberos ticket) accompanies the remote request.
2. If no authentication token is supplied, DB2 checks the TCPALVER subsystem parameter to see if DB2 accepts IDs without authentication information. If TCPALVER=NO, authentication information must accompany all requests, and DB2 rejects the request. If TCPALVER=YES, DB2 accepts the request without authentication.
3. The identity is a RACF ID that is authenticated by RACF if a password or PassTicket is provided, or the identity is a Kerberos principal that is validated by Kerberos Security Server, if a Kerberos ticket is provided. Ensure that the ID is defined to RACF in all cases. When Kerberos tickets are used, the RACF ID is derived from the Kerberos principal identity. To use Kerberos tickets, ensure that you map Kerberos principal names with RACF IDs, as described in “Establishing Kerberos authentication through RACF” on page 278.

In addition, depending on your RACF environment, the following RACF checks may also be performed:

- If the RACF APPL class is active, RACF verifies that the ID has access to the DB2 APPL. The APPL resource that is checked is the LU name that the requester used when the attachment request was issued. This is either the local DB2 LU name or the generic LU name.
- If the RACF APPCPORT class is active, RACF verifies that the ID is authorized to access z/OS from the port of entry (POE). The POE that RACF uses in the RACROUTE VERIFY call depends on whether all the following conditions are true:
  - The current operating system is z/OS V1.5 or later
  - The TCP/IP Network Access Control is configured
  - The RACF SERVAUTH class is active

If all these conditions are true, RACF uses the remote client's POE security zone name that is defined in the TCP/IP Network Access Control file. If one or more of these conditions is not true, RACF uses the literal string 'TCPIP'.

If this is a request to change a password, the password is changed.

For more information about the RACF SERVAUTH class, see *z/OS V1.5 Security Server RACF Security Administrator's Guide*. For more information about TCP/IP Network Access Control, see *z/OS Communications Server: IP Configuration Guide* and "Allowing access from remote requesters" on page 272.

4. The remote request is now treated like a local connection request (using the DIST environment for the DSNR resource class). DB2 calls RACF to check the ID's authorization against the *ssnm.DIST* resource.
5. DB2 invokes the connection exit routine. The parameter list that is passed to the routine describes where the remote request originated.
6. The remote request has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID. (The SQL ID cannot be translated.) The plan or package owner ID also accompanies the request. Privileges and authorities that are granted to those IDs at the DB2 server govern the actions that the request can take.

---

## Planning to send remote requests

If you are planning to send requests to another DB2 subsystem, consider that the security administrator of that subsystem might have chosen any of the options described in "Controlling requests from remote applications" on page 238. You need to know what those choices are and make entries in your CDB to correspond to them. You can also choose some things independently of what the other subsystem requires.

If you are planning to send remote requests to a DBMS that is not DB2 UDB for z/OS, you need to satisfy the requirements of that system. You probably need documentation for the particular type of system; some of the choices that are described in this section might not apply.

**Network protocols and authentication tokens:** DB2 chooses how to send authentication tokens based on the network protocols that are used (SNA or TCP/IP). If the request is sent using SNA, the authentication tokens are sent in the SNA attachment request (FMH5), unless you are using Kerberos. If you use Kerberos, authentication tokens are sent with DRDA security commands.

If the request uses TCP/IP, the authentication tokens are always sent using DRDA security commands.

## The communications database for the requester

The information in this section, up to “What IDs you send” on page 257, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The communications database (CDB) is a set of DB2 catalog tables that let you control aspects of remote requests. This section concentrates on the columns of the communications database that pertain to security issues related to the requesting system. (SYSIBM.IPLIST is not related to security and therefore not described in this topic.)

### Columns used in SYSIBM.LUNAMES

This table is used only for requests that use SNA protocols.

#### LUNAME CHAR(8)

The LUNAME of the remote system. A blank value identifies a default row that serves requests from any system that is not specifically listed elsewhere in the column.

#### SECURITY\_OUT (CHAR 1)

Indicates the security option that is used when local DB2 SQL applications connect to any remote server that is associated with the corresponding LUNAME.

**A** The letter A signifies the security option of already verified, and it is the default. With A, outbound connection requests contain an authorization ID and no authentication token. The value that is used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending on the value in the USERNAMES column.

**R** The letter R signifies the RACF PassTicket security option. Outbound connection requests contain a user ID and a RACF PassTicket. The LUNAME column is used as the RACF PassTicket application name.

The value that is used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending on the value in the USERNAMES column. The translated ID is used to build the RACF PassTicket. Do not specify R for CONNECT statements with a USER parameter.

**P** The letter P signifies the password security option. Outbound connection requests contain an authorization ID and a password. The password is obtained from RACF if ENCRYPTPSWDS=Y, or from SYSIBM.USERNAMES if ENCRYPTPSWDS=N. If you get the password from SYSIBM.USERNAMES, the USERNAMES column of SYSIBM.LUNAMES must contain B or O. The value that is used for an outbound request is the translated ID.

#### ENCRYPTPSWDS CHAR(1)

Indicates whether passwords received from and sent to the corresponding LUNAME are encrypted. This column only applies to DB2 UDB for z/OS and DB2 UDB for z/OS partners when passwords are used as authentication tokens.

**Y** Yes, passwords are encrypted. For outbound requests, the encrypted password is extracted from RACF and sent to the server. For inbound requests, the password is treated as encrypted.

**N** No, passwords are not encrypted. This is the default; any character but Y is treated as N.

**Recommendation:** When you connect to a DB2 UDB for z/OS partner that is at Version 5 or a subsequent release, use RACF PassTickets (SECURITY\_OUT='R') instead of encrypting passwords.

#### **USERNAMES CHAR(1)**

Indicates whether an ID accompanying a remote attachment request, which is received from or sent to the corresponding LUNAME, is subject to translation and "come from" checking. When you specify I, O, or B, use the SYSIBM.USERNAMES table to perform the translation.

**I** An inbound ID is subject to translation.

**O** An outbound ID, sent to the corresponding LUNAME, is subject to translation.

**B** Both inbound and outbound IDs are subject to translation.

**blank** No IDs are translated.

#### **Columns used in SYSIBM.IPNAMES**

This table is used only for requests that use TCP/IP protocols.

#### **LINKNAME CHAR(8)**

The name used in the LINKNAME column of SYSIBM.LOCATIONS to identify the remote system.

#### **SECURITY\_OUT**

Indicates the DRDA security option that is used when local DB2 SQL applications connect to any remote server that is associated with this TCP/IP host.

**A** The letter A signifies the security option of already verified, and it is the default. Outbound connection requests contain an authorization ID and no password. The value that is used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending on the value in the USERNAMES column.

The authorization ID is not encrypted when it is sent to the partner. For encryption, see option D.

**R** The letter R signifies the RACF PassTicket security option. Outbound connection requests contain a user ID and a RACF PassTicket. The LINKNAME column must contain the server's LU name, which is used as the RACF PassTicket application name to generate the PassTicket.

The value that is used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending on the value in the USERNAMES column. The translated ID is used to build the RACF PassTicket. Do not specify R for CONNECT statements with a USER parameter.

The authorization ID is not encrypted when it is sent to the partner.

**D** The letter D signifies the security option of user ID and security-sensitive data encryption. Outbound connection requests contain an authorization ID and no password. The authorization

ID that is used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending on the USER NAMES column.

This option indicates that the user ID and the security-sensitive data are to be encrypted. If you do not require encryption, see option A.

**E** The letter E signifies the security option of user ID, password, and security-sensitive data encryption. Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USER NAMES table. The USER NAMES column must specify "O".

This option indicates that the user ID, password, and security-sensitive data are to be encrypted. If you do not require security-sensitive data encryption, see option P.

**P** The letter P signifies the password security option. Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USER NAMES table. If you specify P, the USER NAMES column must specify "O".

If you specify P and the server supports encryption, the user ID and the password are encrypted. If the server does not support encryption, the user ID and the password are sent to the partner in clear text. If you also need to encrypt security-sensitive data, see option E.

#### **USER NAMES CHAR(1)**

This column indicates whether an outbound request translates the authorization ID. When you specify O, use the SYSIBM.USER NAMES table to perform the translation.

**O** An outbound ID, sent to the corresponding LUNAME, is subject to translation.

**blank** No translation is done.

#### **Columns used in SYSIBM.USER NAMES**

This table is used by both SNA and TCP/IP connections.

#### **TYPE CHAR(1)**

Indicates whether the row is used for inbound or outbound translation:

**I** The row applies to inbound IDs.

**O** The row applies to outbound IDs.

The field should contain only I or O. Any other character, including blank, causes the row to be ignored.

#### **AUTHID VARCHAR(128)**

An authorization ID that is permitted and perhaps translated. If blank, any authorization ID is permitted with the corresponding LINKNAME, and all authorization IDs are translated in the same way.

#### **LINKNAME CHAR(8)**

Identifies the VTAM or TCP/IP network locations that are associated with this row. A blank value in this column indicates that this name translation rule applies to any TCP/IP or SNA partner.

If you specify a nonblank value for this column, one or both of the following situations must be true:

- A row exists in table SYSIBM.LUNAMES that has an LUNAME value that matches the LINKNAME value that appears in this column.
- A row exists in table SYSIBM.IPNAMES that has a LINKNAME value that matches the LINKNAME value that appears in this column.

#### **NEWAUTHID VARCHAR(128)**

The translated authorization ID. If blank, no translation occurs.

#### **PASSWORD CHAR(8)**

A password that is sent with outbound requests. This password is not provided by RACF and cannot be encrypted.

### **Columns used in SYSIBM.LOCATIONS**

This table contains a row for every accessible remote server. Each row associates a LOCATION name with the TCP/IP or SNA network attributes for the remote server. Requesters are not defined in this table.

#### **LOCATION CHAR(16)**

Indicates the unique location name by which the the remote server is known to local DB2 SQL applications.

#### **LINKNAME CHAR(8)**

Identifies the VTAM or TCP/IP network locations that are associated with this row. A blank value in this column indicates that this name translation rule applies to any TCP/IP or SNA partner.

If you specify a nonblank value for this column, one or both of the following situations must be true:

- A row exists in table SYSIBM.LUNAMES that has an LUNAME value that matches the LINKNAME value that appears in this column.
- A row exists in table SYSIBM.IPNAMES that has a LINKNAME value that matches the LINKNAME value that appears in this column.

#### **PORT CHAR(32)**

TCP/IP is used for outbound DRDA connections when the following statement is true:

- A row exists in SYSIBM.IPNAMES, where the LINKNAME column matches the value specified in the SYSIBM.LOCATIONS LINKNAME column.

If the previously mentioned row is found, the value of the PORT column is interpreted as follows:

- If PORT is blank, the default DRDA port (446) is used.
- If PORT is nonblank, the value specified for PORT can take one of two forms:
  - If the value in PORT is left justified with one to five numeric characters, the value is assumed to be the TCP/IP port number of the remote database server.
  - Any other value is assumed to be a TCP/IP service name, which can be converted to a TCP/IP port number using the TCP/IP getservbyname socket call. TCP/IP service names are not case-sensitive.

#### **TPN VARCHAR(64)**

Used only when the local DB2 begins an SNA conversation with another server. When used, TPN indicates the SNA LU 6.2 transaction program

name (TPN) that will allocate the conversation. A length of zero for the column indicates the default TPN. For DRDA conversations, this is the DRDA default, which is X'07F6C4C2'.

For DB2 private protocol conversations, this column is not used. For an SQL/DS™ server, TPN should contain the resource ID of the SQL/DS machine.

#### DBALIAS(128)

This name is used to access a remote database server. If DBALIAS is blank, the location name is used to access the remote database server. This column does not change the name of any database objects sent to the remote site that contains the location qualifier.

## What IDs you send

At least one authorization ID is always sent to the server to be used for authentication. That ID is one of the following values:

- The primary authorization ID of the process.
- If you connect to the server using a CONNECT statement with the USER keyword, the ID that you specify as the USER ID. The CONNECT statement allows non-RACF user IDs on the USER keyword. If connecting to a remote location, the user ID is not authenticated by RACF.

However, other IDs can accompany some requests. You need to understand what other IDs are sent because they are subject to translation. You must include these other IDs in table SYSIBM.USERNAMES to avoid an error when you use outbound translation. Table 76 shows the IDs you need to send in different situations.

*Table 76. IDs that accompany the primary ID on a remote request*

In this situation:	You send this ID also:
An SQL query, using DB2 private-protocol or DRDA-protocol access	The plan owner
A remote BIND, COPY, or REBIND PACKAGE command	The package owner

For DRDA, if you use the SYSIBM.USERNAMES table that contains the plan owner ID, the plan owner ID is sent to the z/OS server as part of its accounting data. If the connection is to a remote non-DB2 for z/OS server using DRDA protocol and if the outbound translation is specified, a row for the plan owner in the USERNAMES table is optional.

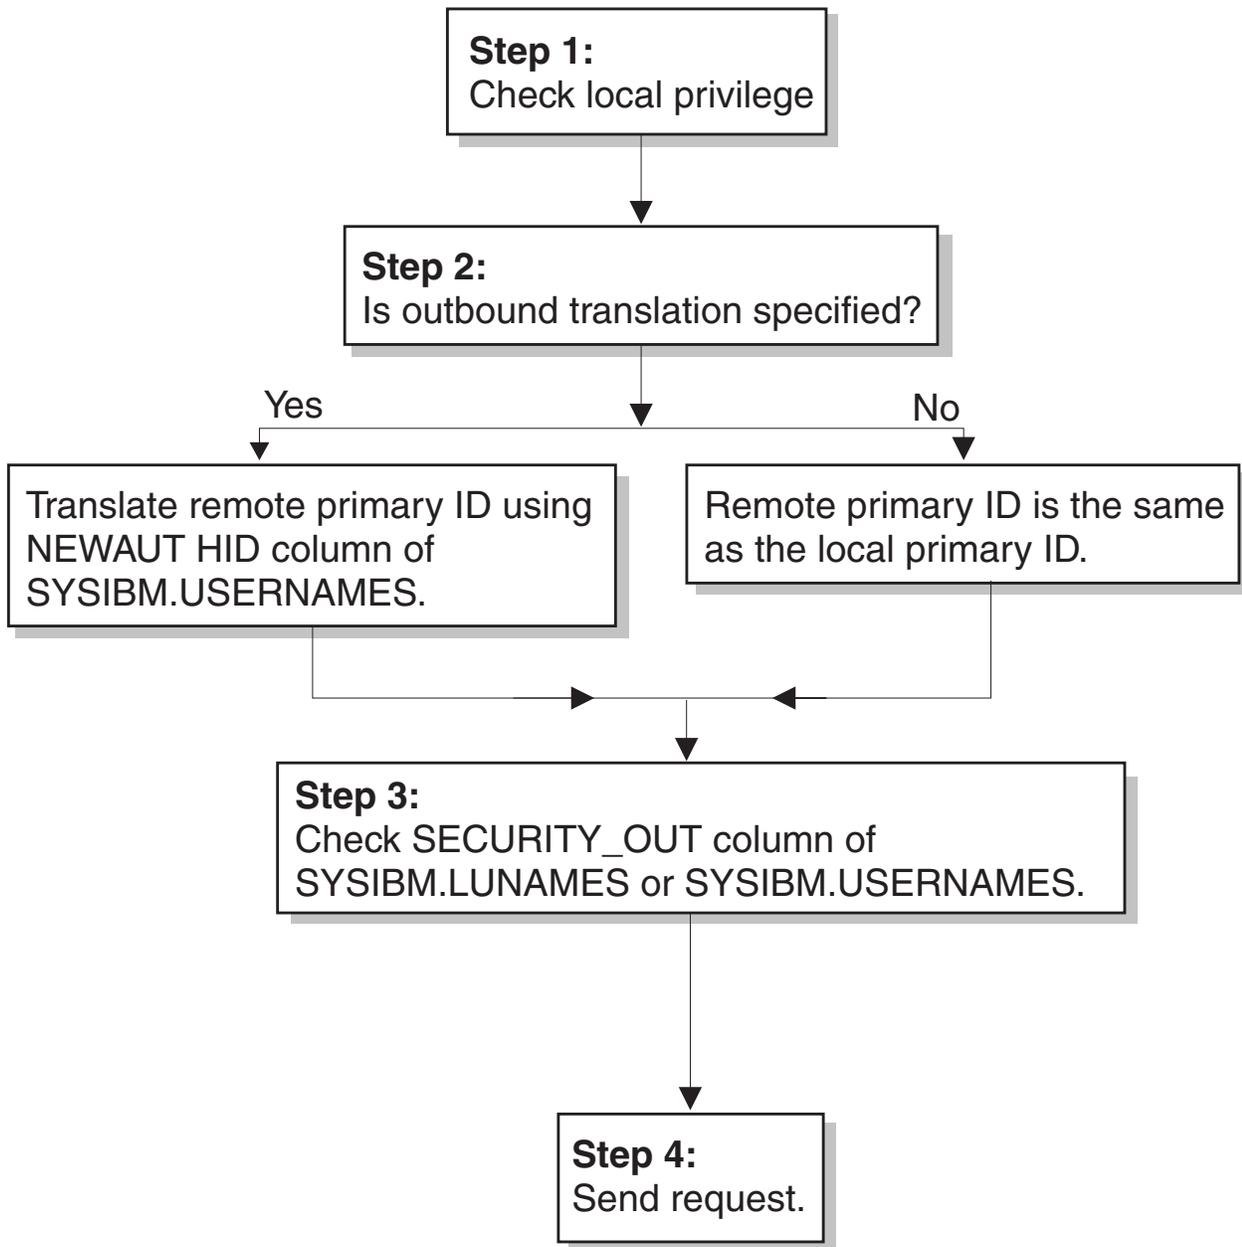

Figure 22. Steps in sending a request from a DB2 subsystem

*Details of steps in sending a request from DB2:* These notes explain the steps in Figure 22.

1. The DB2 subsystem that sends the request checks whether the primary authorization ID has the privilege to execute the plan or package.  
DB2 determines which value in the LINKNAME column of the SYSIBM.LOCATIONS table matches either the LUNAME column in the SYSIBM.LUNAMES table or the LINKNAME column in the SYSIBM.IPNAMES table. This check determines whether SNA or TCP/IP protocols are used to carry the DRDA request. (Statements that use DB2 private protocol, not DRDA, always use SNA.)
2. When a plan is executed, the authorization ID of the plan owner is sent with the primary authorization ID. When a package is bound, the authorization ID of the package owner is sent with the primary authorization ID. If the

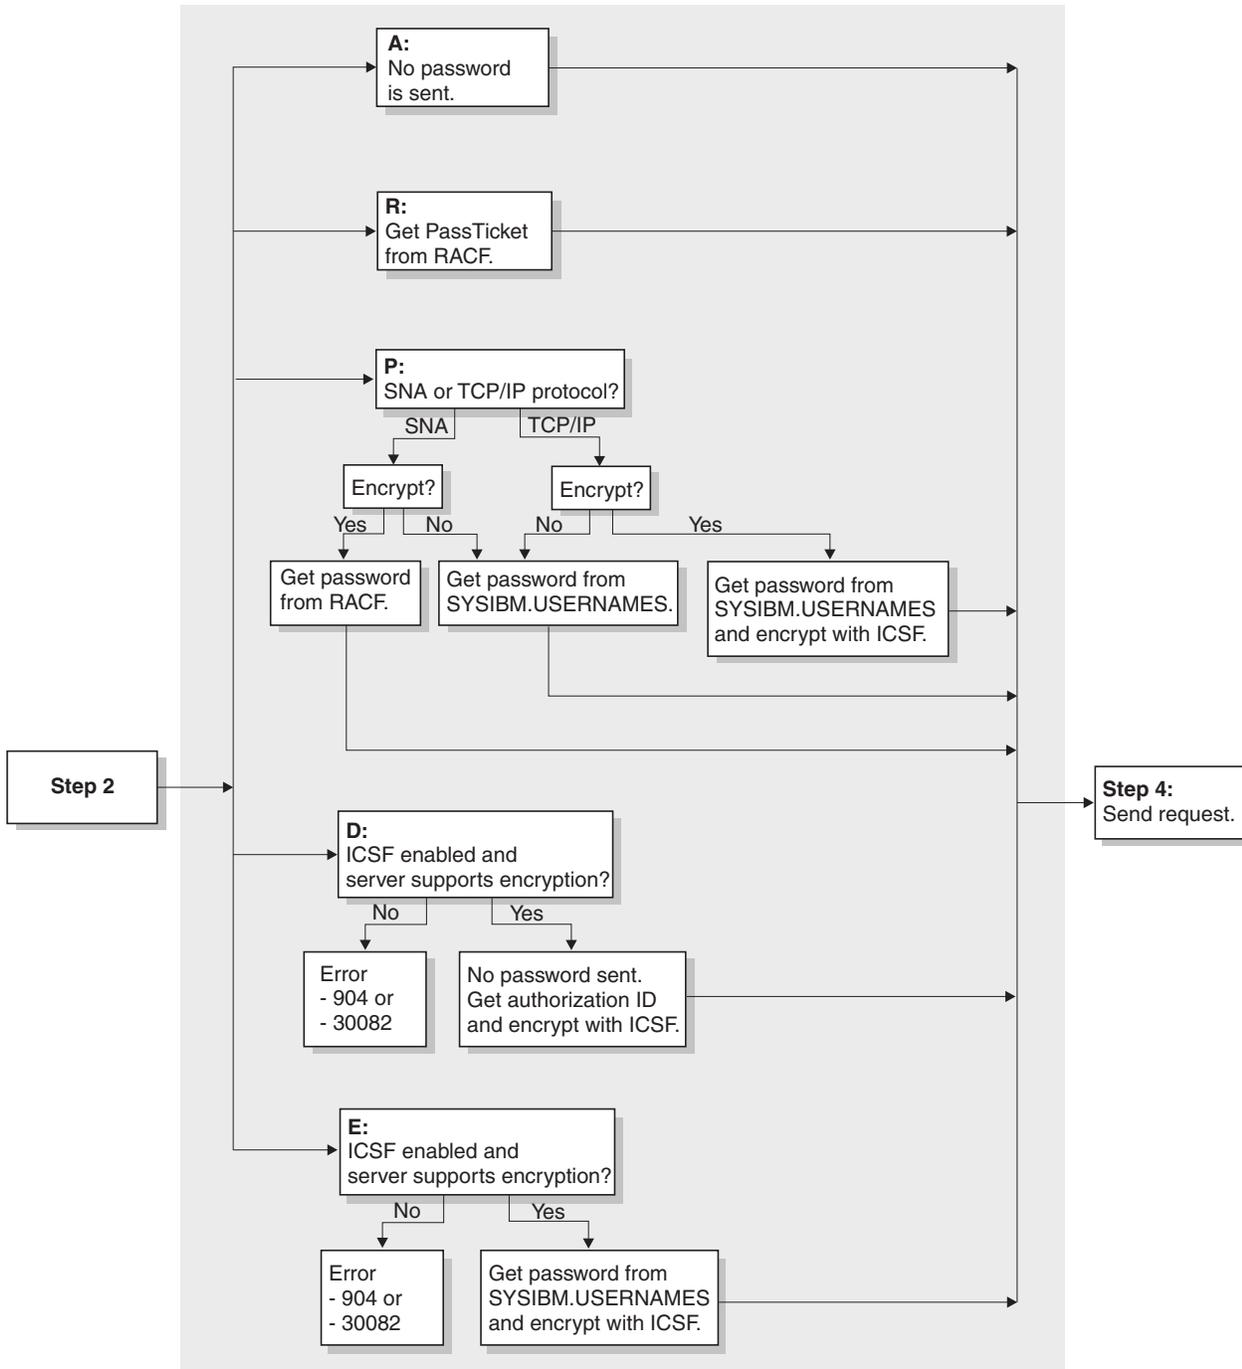

Figure 23. Details of step 3

## Translating outbound IDs

If an ID on your system is duplicated on a remote system, you can translate outbound IDs to avoid confusion. You can also translate IDs to ensure that they are accepted by the remote system.

To indicate that you want to translate outbound user IDs, perform the following steps:

1. Specify an O in the USERNAMES column of table SYSIBM.IPNAMES or SYSIBM.LUNAMES.
2. Use the NEWAUTHID column of SYSIBM.USERNAMES to specify the ID to which the outbound ID is translated.

**Example 1:** Suppose that the remote system accepts from you only the IDs XXGALE, GROUP1, and HOMER.

1. Specify that outbound translation is in effect for the remote system LUXXX by specifying in SYSIBM.LUNAMES the values that are shown in Table 77.

*Table 77. SYSIBM.LUNAMES to specify that outbound translation is in effect for the remote system LUXXX*

LUNAME	USERNAMES
LUXX	O

If your row for LUXXX already has I for the USERNAMES column (because you translate inbound IDs that come from LUXXX), change I to B for both inbound and outbound translation.

2. Translate the ID GALE to XXGALE on all outbound requests to LUXXX by specifying in SYSIBM.USERNAMES the values that are shown in Table 78.

*Table 78. Values in SYSIBM. USERNAMES to translate GALE to XXGALE on outbound requests to LUXXX*

TYPE	AUTHID	LINKNAME	NEWAUTHID	PASSWORD
O	GALE	LUXX	XXGALE	GALEPASS

3. Translate EVAN and FRED to GROUP1 on all outbound requests to LUXXX by specifying in SYSIBM.USERNAMES the values that are shown in Table 79.

*Table 79. Values in SYSIBM. USERNAMES to translate EVAN and FRED to GROUP1 on outbound requests to LUXXX*

TYPE	AUTHID	LINKNAME	NEWAUTHID	PASSWORD
O	EVAN	LUXXX	GROUP1	GRP1PASS
O	FRED	LUXXX	GROUP1	GRP1PASS

4. Do not translate the ID HOMER on outbound requests to LUXXX. (HOMER is assumed to be an ID on your DB2, and on LUXXX.) Specify in SYSIBM.USERNAMES the values that are shown in Table 80.

*Table 80. Values in SYSIBM. USERNAMES to not translate HOMER on outbound requests to LUXXX*

TYPE	AUTHID	LINKNAME	NEWAUTHID	PASSWORD
O	HOMER	LUXXX	(blank)	HOMERSPW

5. Reject any requests from BASIL to LUXXX before they are sent. To do that, leave SYSIBM.USERNAMES empty. If no row indicates what to do with the ID BASIL on an outbound request to LUXXX, the request is rejected.

**Example 2:** If you send requests to another LU, such as LUYYY, you generally need another set of rows to indicate how your IDs are to be translated on outbound requests to LUYYY.

However, you can use a single row to specify a translation that is to be in effect on requests to all other LUs. For example, if HOMER is to be sent untranslated everywhere, and DOROTHY is to be translated to GROUP1 everywhere, specify in SYSIBM.USERNAMES the values that are shown in Table 81.

Table 81. Values in SYSIBM.USERNAMES to not translate HOMER and to translate DOROTHY to GROUP1

TYPE	AUTHID	LINKNAME	NEWAUTHID	PASSWORD
O	HOMER	(blank)	(blank)	HOMERSPW
O	DOROTHY	(blank)	GROUP1	GRP1PASS

You can also use a single row to specify that all IDs that accompany requests to a single remote system must be translated. For example, if every one of your IDs is to be translated to THEIRS on requests to LUYYY, specify in SYSIBM.USERNAMES the values that are shown in Table 82.

Table 82. Values in SYSIBM.USERNAMES to translate every ID to THEIRS

TYPE	AUTHID	LINKNAME	NEWAUTHID	PASSWORD
O	(blank)	LUYYY	THEIR	THEPASS

#  
#  
#  
#  
#  
#

If the ICSF is installed and properly configured, you can use the DSNLEUSR stored procedure to encrypt the translated outbound IDs that are specified in the NEWAUTHID column of SYSIBM.USERNAMES. DB2 decrypts the translated outbound IDs during connection processing. For more information about the DSNLEUSR stored procedure, see Appendix J, "DB2-supplied stored procedures," on page 1261.

## Sending passwords

**Recommendation:** For the tightest security, do not send passwords through the network. Instead, use one of the following security mechanisms:

- RACF encrypted passwords, described in "Sending RACF encrypted passwords" on page 263
- RACF PassTickets, described in "Sending RACF PassTickets" on page 263
- Kerberos tickets, described in "Establishing Kerberos authentication through RACF" on page 278
- DRDA encrypted passwords or DRDA encrypted user IDs with encrypted passwords, described in "Sending encrypted passwords from workstation clients" on page 263

If send passwords through the network, you can put the password for an ID in the PASSWORD column of SYSIBM.USERNAMES.

#  
#  
#  
#  
#  
#

**Recommendation:** Use the DSNLEUSR stored procedure to encrypt passwords in SYSIBM.USERNAMES. If the ICSF is installed and properly configured, you can use the DSNLEUSR stored procedure to encrypt passwords in the SYSIBM.USERNAMES table. DB2 decrypts the password during connection processing. For more information about the DSNLEUSR stored procedure, see Appendix J, "DB2-supplied stored procedures," on page 1261.

DB2 UDB for z/OS allows the use of RACF encrypted passwords or RACF PassTickets. However, workstations, such as Windows workstations, do not support these security mechanisms. RACF encrypted passwords are not a secure mechanism because they can be replayed.

**Recommendation:** Do not use RACF encrypted passwords unless you are connecting to a previous release of DB2 UDB for z/OS.

### **Sending RACF encrypted passwords**

For DB2 subsystems that communicate with each other by using SNA protocols, you can specify password encryption in SYSIBM.LUNAMES, as shown in Table 83.

*Table 83. Specifying password encryption in SYSIBM.LUNAMES*

LUNAME	USERNAMES	ENCRYPTPSWDS
LUXXX	O	Y

The partner DB2 must also specify password encryption in its SYSIBM.LUNAMES table. Both partners must register each ID and its password with RACF. Then, for every request to LUXXX, your DB2 calls RACF to supply an encrypted password to accompany the ID. With password encryption, you do not use the PASSWORD column of SYSIBM.USERNAMES, so the security of that table becomes less critical.

### **Sending RACF PassTickets**

To send RACF PassTickets with your remote requests to a particular remote system, enter R in the SECURITY\_OUT column of the SYSIBM.IPNAMES or SYSIBM.LUNAMES table for that system.

To set up RACF to generate PassTickets, define and activate a RACF PassTicket data class (PTKTDATA). This class must contain a RACF profile for each remote DB2 subsystem to which you send requests.

1. Activate the RACF PTKTDATA class by issuing the following RACF commands:
 

```
SETROPTS CLASSACT(PTKTDATA)
SETROPTS RACLIST(PTKTDATA)
```
2. Define profiles for the remote systems by entering the name of each remote system as it appears in the LINKNAME column of table SYSIBM.LOCATIONS. For example, the following command defines a profile for a remote system, DB2A, in the RACF PTKTDATA class:
 

```
RDEFINE PTKTDATA DB2A SSIGNON(KEYMASKED(E001193519561977))
```
3. Refresh the RACF PTKTDATA definition with the new profile by issuing the following command:
 

```
SETROPTS RACLIST(PTKTDATA) REFRESH
```

See *z/OS Security Server Security Administrator's Guide* for more information about RACF PassTickets.

### **Sending encrypted passwords from workstation clients**

# As a server, DB2 UDB for z/OS can accept requests from remote workstation  
 # clients that use 256-bit Advanced Encryption Standard (AES) or 56-bit Data  
 # Encryption Standards (DES) encryption security over a TCP/IP network  
 # connection.

# As a server in new function mode, DB2 UDB for z/OS accepts AES security tokens  
 # if a client is configured to explicitly request for AES encryption and decryption. To

# enable the DB2 UDB for z/OS AES server support, you must install and configure  
 # z/OS Integrated Cryptographic Services Facility (ICSF). During DB2 startup,  
 # DSNXINIT invokes the MVS LOAD macro service to load various ICSF services,  
 # including the ICSF CSNESYE and CSNESYD modules that DB2 calls for processing  
 # AES encryption and decryption requests. If ICSF is not installed or if ICSF services  
 # are not available, DB2 will not be able to provide AES support.

# If a client does not explicitly requests AES, DB2 UDB for z/OS uses the default  
 # DES encryption algorithm for processing remote requests. To use the DES  
 # encryption and decryption, you must install and configure z/OS ICSF. You can  
 # enable DB2 Connect to send encrypted passwords by setting database connection  
 # services (DCS) authentication to DCS\_ENCRYPT in the DCS directory entry. When  
 # a client application issues an SQL CONNECT, the client negotiates this support  
 # with the database server. If supported, a shared private key is generated by the  
 # client and server using the Diffie-Hellman public key technology and the password  
 # is encrypted using 56-bit DES with the shared private key. The encrypted password  
 # is non-replayable, and the shared private key is generated on every connection. If  
 # the server does not support password encryption, the application receives  
 # SQLCODE -30073 (DRDA security manager level 6 is not supported).

## Establishing RACF protection for DB2

For purposes of illustration, suppose that the system of RACF IDs that is shown in Figure 24 is used to control DB2 usage.

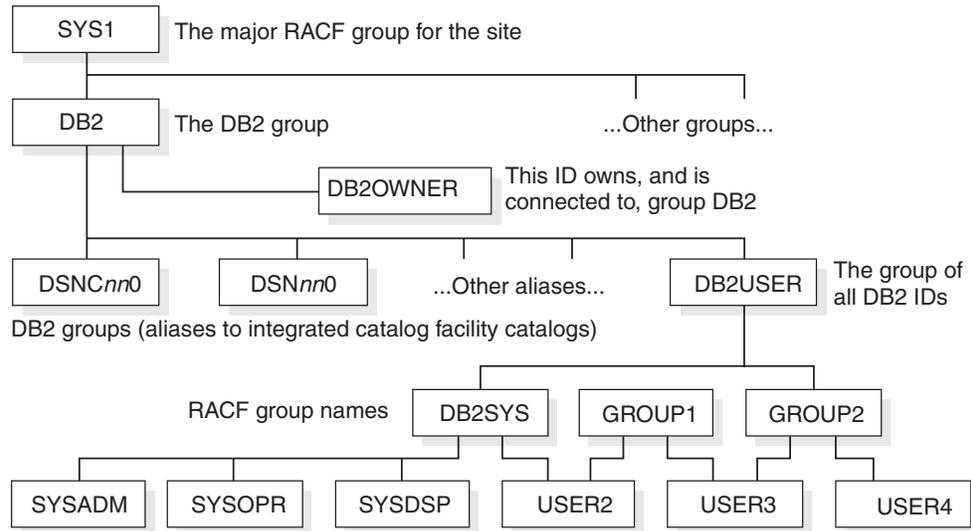

Figure 24. Sample DB2–RACF environment

Figure 24 shows some of the relationships among the names that are shown in Table 84.

Table 84. RACF relationships

RACF ID	Use
SYS1	Major RACF group ID
DB2	DB2 group
DB2OWNER	Owner of the DB2 group
DSNC810	Group to control databases and recovery logs

Table 84. RACF relationships (continued)

RACF ID	Use
DSN810	Group to control installation data sets
DB2USER	Group of all DB2 users
SYSADM	ID with DB2 installation SYSADM authority
SYSOPR	ID with DB2 installation SYSOPR authority
DB2SYS, GROUP1, GROUP2	RACF group names
SYSDSP	RACF user ID for DB2 started tasks
USER1, USER2, USER3	RACF user IDs.

**Note:** These RACF group names and user IDs do not appear in the figure; they are listed in Table 85 on page 268.

To establish RACF protection for DB2, perform the steps that are described in the following sections:

- “Defining DB2 resources to RACF” includes steps that tell RACF what to protect.
- “Permitting RACF access” on page 267 includes steps that make the protected resources available to processes.

Some steps are required and some steps are optional, depending on your circumstances. All steps presume that RACF is already installed. The steps do not need to be taken strictly in the order in which they are shown here.

For a more thorough description of RACF facilities, see *z/OS Security Server Security Administrator’s Guide*.

For information about using RACF for multilevel security with row-level granularity, see “Multilevel security” on page 192.

## Defining DB2 resources to RACF

To define DB2 resources to the RACF system, perform the following required steps in any order:

- “Define the names of protected access profiles” on page 266
- “Enable RACF checking for the DSNR and SERVER classes” on page 266

No one can access the DB2 subsystem until you instruct RACF to permit access.

Other tasks you might want to perform include:

- Controlling whether two DBMSs using VTAM LU 6.2 can establish sessions with each other, as described in “Enable partner-LU verification” on page 267.
- Ensure that IDs that are associated with stored procedures address spaces are authorized to run the appropriate attachment facility, as described in “Step 1: Control access by using the attachment facilities (required)” on page 274.
- If you are using TCP/IP, ensure that the ID that is associated with the DDF address space is authorized to use z/OS UNIX System Services, as described in “Establishing RACF protection for TCP/IP” on page 278.

## Define the names of protected access profiles

The RACF resource class for DB2 is DSNR, and that class is contained in the RACF class descriptor table. Profiles in that class protect access to a DB2 subsystem from one of these environments—IMS, CICS, the distributed data facility (DDF), TSO, CAF, or batch.

Each profile has a name of the form *subsystem.environment*, where:

- *subsystem* is the name of a DB2 subsystem, of one to four characters; for example, DSN or DB2T.
- *environment* denotes the environment, by one of the following terms:
  - MASS for IMS (including MPP, BMP, Fast Path, and DL/I batch).
  - SASS for CICS.
  - DIST for DDF.
  - RRSAF for Resource Recovery Services attachment facility. Stored procedures use RRSAF in WLM-established address spaces.
  - BATCH for all others, including TSO, CAF, batch, all utility jobs, DB2-established stored procedures address space, and requests that come through the call attachment facility.

To control access, you need to define a profile, as a member of class DSNR, for every combination of subsystem and environment you want to use. For example, suppose that you want to access:

- Subsystem DSN from TSO and DDF
- Subsystem DB2P from TSO, DDF, IMS, and RRSAF
- Subsystem DB2T from TSO, DDF, CICS, and RRSAF

Then define the profiles with the following names:

```
DSN.BATCH  DSN.DIST
DB2P.BATCH DB2P.DIST DB2P.MASS DB2P.RRSAF
DB2T.BATCH DB2T.DIST DB2T.SASS DB2T.RRSAF
```

You can do that with a single RACF command, which also names an owner for the resources:

```
RDEFINE DSNR (DSN.BATCH DSN.DIST DB2P.BATCH DB2P.DIST DB2P.MASS DB2P.RRSAF
              DB2T.BATCH DB2T.DIST DB2T.SASS DB2T.RRSAF) OWNER(DB2OWNER)
```

In order to access a subsystem in a particular environment, a user must be on the access list of the corresponding profile. You add users to the access list with the RACF PERMIT command. If you do not want to limit access to particular users or groups, you can give universal access to a profile with a command like this:

```
RDEFINE DSNR (DSN.BATCH) OWNER(DB2OWNER) UACC(READ)
```

## Enable RACF checking for the DSNR and SERVER classes

To enable RACF access checking for resources in the DSNR resource class, issue this RACF command:

```
SETROPTS CLASSACT(DSNR)
```

Only users with the SPECIAL attribute can issue the command.

If you are using stored procedures in a WLM-established address space, you might also need to enable RACF checking for the SERVER class. See “Step 2: Control access to WLM (optional)” on page 275.

## Enable partner-LU verification

With RACF and VTAM, you can control whether two LUs that use LU 6.2 can connect to each other.

Each member of a connecting pair must establish a profile for the other member. For example, if LUAAA and LUBBB are to connect and know each other by those LUNAMES, issue RACF commands similar to these:

```
At LUAAA: RDEFINE APPCLU netid.LUAAA.LUBBB UACC(NONE) ...
At LUBBB: RDEFINE APPCLU netid.LUBBB.LUAAA UACC(NONE) ...
```

Here, *netid* is the network ID, given by the VTAM start option NETID.

When you create those profiles with RACF, use the SESSION operand to supply:

- The VTAM password as a session key (SESSKEY suboperand)
- The maximum number of days between changes of the session key (INTERVAL suboperand)
- An indication of whether the LU pair is locked (LOCK suboperand)

For details, see *z/OS Security Server RACF Security Administrator's Guide*.

Finally, to enable RACF checking for the new APPCLU resources, issue this RACF command at both LUAAA and LUBBB:

```
SETROPTS CLASSACT(APPCLU)
```

## Permitting RACF access

To let processes use the protected resources, take the steps described in the following sections:

1. "Define RACF user IDs for DB2 started tasks"
2. "Add RACF groups" on page 270
3. "Permit access for users and groups" on page 271

### Define RACF user IDs for DB2 started tasks

A DB2 subsystem has the following started-task address spaces:

- *ssnm*DBM1 for database services
- *ssnm*MSTR for system services
- *ssnm*DIST for the distributed data facility
- *ssnm*SPAS for the DB2-established stored procedures address space
- Names for your WLM-established address spaces for stored procedures

You must associate each of these address spaces with a RACF user ID. Each of them can also be assigned a RACF group name. The DB2 address spaces **cannot** be started with batch jobs.

If you have IMS or CICS applications issuing DB2 SQL requests, you must associate RACF user IDs, and can associate group names, with:

- The IMS control region
- The CICS address space
- The four DB2 address spaces

If the IMS and CICS address spaces are started as batch jobs, provide their RACF IDs and group names with the USER and GROUP parameters on the JOB statement. If they are started as started tasks, assign the IDs and group names as you do for the DB2 address spaces, by changing the RACF STARTED class or the RACF started procedures table.

**Stored procedures:** Entries for stored procedures address spaces are required in the RACF started procedures table. The associated RACF user ID and group name

do not need to match those that are used for the DB2 address spaces, but they must be authorized to run the call attachment facility (for the DB2-established stored procedures address space) or Resource Recovery Services attachment facility (for WLM-established stored procedures address spaces). Note: WLM-established stored procedures started tasks IDs require an OMVS segment.

**Changing the RACF started-procedures table:** To change the RACF started-procedures table (ICHRIN03), change, reassemble, and link edit the resulting object code to z/OS. Figure 25 on page 269 shows the sample entries for three DB2 subsystems and optional entries for CICS and IMS. (Refer to *z/OS Security Server RACF System Programmer's Guide* for a description of how to code a RACF started-procedures table.) The example provides the DB2 started tasks for each of three DB2 subsystems, named DSN, DB2T, and DB2P, and for CICS and an IMS control region.

The IDs and group names associated with the address spaces are shown in Table 85.

*Table 85. DB2 address space IDs and associated RACF user IDs and group names*

Address Space	RACF User ID	RACF Group Name
DSNMSTR	SYSDSP	DB2SYS
DSNDBM1	SYSDSP	DB2SYS
DSNDIST	SYSDSP	DB2SYS
DSNSPAS	SYSDSP	DB2SYS
DSNWLM	SYSDSP	DB2SYS
DB2TMSTR	SYSDSPT	DB2TEST
DB2TDBM1	SYSDSPT	DB2TEST
DB2TDIST	SYSDSPT	DB2TEST
DB2TSPAS	SYSDSPT	DB2TEST
DB2PMSTR	SYSDSPD	DB2PROD
DB2PDBM1	SYSDSPD	DB2PROD
DB2PDIST	SYSDSPD	DB2PROD
DB2PSPAS	SYSDSPD	DB2PROD
CICSSYS	CICS	CICSGRP
IMSCNTL	IMS	IMSGRP

Figure 25 on page 269 shows a sample job that reassembles and link edits the RACF started-procedures table (ICHRIN03):

```

/**
/** REASSEMBLE AND LINKEDIT THE RACF STARTED-PROCEDURES
/** TABLE ICHRIN03 TO INCLUDE USERIDS AND GROUP NAMES
/** FOR EACH DB2 CATALOGED PROCEDURE. OPTIONALLY, ENTRIES
/** FOR AN IMS OR CICS SYSTEM MIGHT BE INCLUDED.
/**
/** AN IPL WITH A CLPA (OR AN MLPA SPECIFYING THE LOAD
/** MODULE) IS REQUIRED FOR THESE CHANGES TO TAKE EFFECT.

Figure 25. Sample job to reassemble the RACF started-procedures table (Part 2 of 2)

## Add RACF groups

The details of this step depend on the groups that you define. To add the user DB2OWNER, issue the following RACF command:

```
ADDUSER DB2OWNER CLAUTH(DSNR USER) UACC(NONE)
```

That gives class authorization to DB2OWNER for DSNR and USER. DB2OWNER can add users to RACF and issue the RDEFINE command to define resources in class DSNR. DB2OWNER has control over and responsibility for the entire DB2 security plan in RACF.

The RACF group SYS1 already exists. To add group DB2 and make DB2OWNER its owner, issue the following RACF command:

```
ADDDGROUP DB2 SUPGROUP(SYS1) OWNER(DB2OWNER)
```

To connect DB2OWNER to group DB2 with the authority to create new subgroups, add users, and manipulate profiles, issue the following RACF command:

```
CONNECT DB2OWNER GROUP(DB2) AUTHORITY(JOIN) UACC(NONE)
```

To make DB2 the default group for commands issued by DB2OWNER, issue the following RACF command:

```
ALTUSER DB2OWNER DFLTGRP(DB2)
```

To create the group DB2USER and add five users to it, issue the following RACF commands:

```
ADDGROUP DB2USER SUPGROUP(DB2)
ADDUSER (USER1 USER2 USER3 USER4 USER5) DFLTGRP(DB2USER)
```

To define a user to RACF, use the RACF ADDUSER command. That invalidates the current password. You can then log on as a TSO user to change the password.

#### *DB2 considerations when using RACF groups:*

- When a user is newly connected to, or disconnected from, a RACF group, the change is not effective until the next logon. Therefore, before using a new group name as a secondary authorization ID, a TSO user must log off and log on, or a CICS or IMS user must sign on again.
- A user with the SPECIAL, JOIN, or GROUP-SPECIAL RACF attribute can define new groups with any name that RACF accepts and can connect any user to them. Because the group name can become a secondary authorization ID, you should control the use of those RACF attributes.
- Existing RACF group names can duplicate existing DB2 authorization IDs. That duplication is unlikely for the following reasons:
  - A group name cannot be the same as a user name.
  - Authorization IDs that are known to DB2 are usually known to RACF.

However, you can create a table with an owner name that is the same as a RACF group name and use the IBM-supplied sample connection exit routine. Then any TSO user with the group name as a secondary ID has ownership privileges on the table. You can prevent that situation by designing the connection exit routine to stop unwanted group names from being passed to DB2.

### **Permit access for users and groups**

In this scenario, DB2OWNER is authorized for class DSNR, owns the profiles, and has the right to change them. The following commands let users that are members of the group DB2USER, the system administrators, and operators to be TSO users. These users can run batch jobs and DB2 utilities on the three systems: DSN, DB2P, and DB2T. The ACCESS(READ) operand allows use of DB2 without the ability to manipulate profiles.

```
PERMIT DSN.BATCH CLASS(DSNR) ID(DB2USER) ACCESS(READ)
PERMIT DB2P.BATCH CLASS(DSNR) ID(DB2USER) ACCESS(READ)
PERMIT DB2T.BATCH CLASS(DSNR) ID(DB2USER) ACCESS(READ)
```

*Defining profiles for IMS and CICS:* You want the IDs for attaching systems to use the appropriate access profile. For example, to let the IMS user ID use the access profile for IMS on system DB2P, issue the following RACF command:

```
PERMIT DB2P.MASS CLASS(DSNR) ID(IMS) ACCESS(READ)
```

To let the CICS group ID use the access profile for CICS on system DB2T, issue the following RACF command:

```
PERMIT DB2T.SASS CLASS(DSNR) ID(CICSGRP) ACCESS(READ)
```

*Providing installation authorities to default IDs:* When DB2 is installed, IDs are named to have special authorities—one or two IDs for SYSADM and one or two IDs for SYSOPR. Those IDs can be connected to the group DB2USER; if they are not, you need to give them access. The next command permits the default IDs for the SYSADM and SYSOPR authorities to use subsystem DSN through TSO:

```
PERMIT DSN.BATCH CLASS(DSNR) ID(SYSADM,SYSOPR) ACCESS(READ)
```

IDs also can be group names.

**Using secondary IDs:** You can use secondary authorization IDs to define a RACF group. After you define the RACF group, you can assign privileges to it that are shared by multiple primary IDs. For example, suppose that DB2OWNER wants to create a group GROUP1 and to give the ID USER1 administrative authority over the group. USER1 should be able to connect other existing users to the group. To create the group, DB2OWNER issues this RACF command:

```
ADDGROUP GROUP1 OWNER(USER1) DATA('GROUP FOR DEPT. G1')
```

To let the group connect to the DSN system through TSO, DB2OWNER issues this RACF command:

```
PERMIT DSN.BATCH CLASS(DSNR) ID(GROUP1) ACCESS(READ)
```

USER1 can now connect other existing IDs to the group GROUP1 by using the RACF CONNECT command:

```
CONNECT (USER2 EPSILON1 EPSILON2) GROUP(GROUP1)
```

If you add or update secondary IDs for CICS transactions, you must start and stop the CICS attachment facility to ensure that all threads sign on and get the correct security information.

**Allowing users to create data sets:** Chapter 13, “Auditing,” on page 285 recommends using RACF to protect the data sets that store DB2 data. If you use that method, when you create a new group of DB2 users, you might want to connect it to a group that can create data sets. To allow USER1 to create and control data sets, DB2OWNER creates a generic profile and permits complete control to USER1 and to the four administrators. The SYSDSP parameter also gives control to DB2. See “Creating generic profiles for data sets” on page 281.

```
ADDSD 'DSNC810.DSNDBC.ST*' UACC(NONE)
```

```
PERMIT 'DSNC810.DSNDBC.ST*'
      ID(USER1 SYSDSP SYSAD1 SYSAD2 SYSOP1 SYSOP2) ACCESS(ALTER)
```

**Allowing access from remote requesters:** The recommended way of controlling access from remote requesters is to use the DSNR RACF class with a PERMIT command to access the distributed data address space (such as DSN.DIST).

The following RACF commands let the users in the group DB2USER access DDF on the DSN subsystem. These DDF requests can originate from any partner in the network.

**Example:** To permit READ access on profile DSN.DIST in the DSNR class to DB2USER, issue the following RACF command:

```
PERMIT DSN.DIST CLASS(DSNR) ID(DB2USER) ACCESS(READ)
```

If you want to ensure that a specific user can access only when the request originates from a specific LU name, you can use WHEN(APPCPORT) on the PERMIT command.

**Example:** To permit access to DB2 distributed processing on subsystem DSN when the request comes from USER5 at LUNAME equal to NEWYORK, issue the following RACF command:

```
PERMIT DSN.DIST CLASS(DSNR) ID(USER5) ACCESS(READ) +
      WHEN(APPCPORT(NEWYORK))
```

For connections that come through TCP/IP, use the RACF APPCPORT class, the RACF SERVAUTH class, or both classes, with TCP/IP Network Access Control to protect unauthorized access to DB2.

**Example:** To use the RACF APPCPORT class, perform the following steps:

1. Activate the ACCPORT class by issuing the following RACF command:  
`SETRPTS CLASSACT(APPCPORT) REFRESH`
2. Define the general resource profile and name it TCPIP. Specify NONE for universal access and APPCPORT for class. Issue the following RACF command:  
`RDEFINE APPCPORT (TCPIP) UACC(NONE)`
3. Permit READ access on profile TCPIP in the APPCPORT class. To permit READ access to USER5, issue the following RACF command:  
`PERMIT TCPIP ACCESS(READ) CLASS(APPCPORT) ID(USER5)`
4. Permit READ access on profile DSN.DIST in the DSNR class. To permit READ access to USER5, issue the following RACF command:  
`PERMIT DSN.DIST CLASS(DSNR) ID(USER5) ACCESS(READ) +  
WHEN(APPCPORT(TCPIP))`
5. Refresh the APPCPORT class by issuing the following RACF command:  
`SETRPTS CLASSACT(APPCPORT) REFRESH RACLIST(APPCPORT)`

If the RACF APPCPORT class is active on your system, and a resource profile for the requesting LU name already exists, you must permit READ access to the APPCPORT resource profile for the user IDs that DB2 uses. You must permit READ access even when you are using the DSNR resource class. Similarly, if you are using the RACF APPL class and that class restricts access to the local DB2 LU name or generic LU name, you must permit READ access to the APPL resource for the user IDs that DB2 uses.

**Requirement:** To use the RACF SERVAUTH class and TCP/IP Network Access Control, you must have z/OS V1.5 (or later) installed.

**Example:** To use the RACF SERVAUTH class and TCP/IP Network Access Control, perform the following steps:

1. Set up and configure TCP/IP Network Access Control by using the NETACCESS statement that is in your TCP/IP profile.  
For example, suppose that you need to allow z/OS system access only to IP addresses from 9.0.0.0 to 9.255.255.255. You want to define these IP addresses as a security zone, and you want to name the security zone IBM. Suppose also that you need to deny access to all IP addressed outside of the IBM security zone, and that you want to define these IP addresses as a separate security zone. You want to name this second security zone WORLD. To establish these security zones, use the following NETACCESS clause:

```
NETACCESS INBOUND OUTBOUND
; NETWORK/MASK      SAF
  9.0.0.0/8         IBM
  DEFAULT           WORLD
ENDNETACCESS
```

Now, suppose that USER5 has an IP address of 9.1.2.3. TCP/IP Network Access Control would determine that USER5 has an IP address that belongs to the IBM security zone. USER5 would be granted access to the system. Alternatively, suppose that USER6 has an IP address of 1.1.1.1. TCP/IP Network Access Control would determine that USER6 has an IP address that belongs to the WORLD security zone. USER6 would not be granted access to the system.

2. Activate the SERVAUTH class by issuing the following TSO command:

```
SETROPTS CLASSACT(SERVAUTH)
```

3. Activate RACLIST processing for the SERVAUTH class by issuing the following TSO command:

```
SETROPTS RACLIST(SERVAUTH)
```

4. Define the IBM and WORLD general resource profiles in RACF to protect the IBM and WORLD security zones by issuing the following commands:

```
RDEFINE SERVAUTH (EZB.NETACCESS.ZOSV1R5.TCPIP.IBM) UACC(NONE)  
RDEFINE SERVAUTH (EZB.NETACCESS.ZOSV1R5.TCPIP.WORLD) UACC(NONE)
```

5. Permit USER5 and SYSDSP read access to the IBM profile by using the following commands.

```
PERMIT EZB.NETACCESS.ZOSV1R5.TCPIP.IBM ACCESS READ CLASS(SERVAUTH) ID(USER5)  
PERMIT EZB.NETACCESS.ZOSV1R5.TCPIP.IBM ACCESS READ CLASS(SERVAUTH) ID(SYSDSP)
```

6. Permit SYSDSP read access to the WORLD profile by using the following command:

```
PERMIT EZB.NETACCESS.ZOSV1R5.TCPIP.WORLD ACCESS READ CLASS(SERVAUTH) ID(USER5)
```

7. For these permissions to take effect, refresh the RACF database by using the following command:

```
SETROPTS CLASSACT(SERVAUTH) REFRESH RACLIST(SERVAUTH)
```

For more information about the NETACCESS statement, see *z/OS V1.5 Communications Server: IP Configuration Reference*.

## Issuing DB2 commands

IDs must be authorized to issue DB2 commands. If you authorize IDs by issuing DB2 GRANT statements, the GRANTs must be made to a primary authorization ID, to a secondary authorization ID, or to PUBLIC.

When RACF is used for access control, an ID must have appropriate RACF authorization on DB2 commands or must be granted authorization for DB2 commands to issue commands from a logged-on MVS console or from TSO SDSF.

You can ensure that an ID can issue DB2 commands from logged-on MVS consoles or TSO SDSF by using one of the following methods:

- Grant authorization for DB2 commands to the primary or secondary authorization ID.
- Define RACF classes and permits for DB2 commands.
- Grant SYSOPR authority to appropriate IDs.

## Establishing RACF protection for stored procedures

This section summarizes the procedures that you can follow for establishing RACF protection for stored procedures that run on your DB2 subsystem.

This section contains the following procedures:

- “Step 1: Control access by using the attachment facilities (required)”
- “Step 2: Control access to WLM (optional)” on page 275
- “Step 3: Control access to non-DB2 resources (optional)” on page 277

### Step 1: Control access by using the attachment facilities (required)

The user ID that is associated with the DB2-established address space must be authorized to run the DB2 call attachment facility. It must be associated with the *ssnm*.BATCH profile, as described in “Define the names of protected access profiles” on page 266.

The user ID that is associated with the WLM-established stored procedures address space must be authorized to run Resource Recovery Services attachment facility (RRSAF). The user id is also associated with the *ssnm*.RRSAF profile that you create.

Control access to the DB2 subsystem through RRSAF by performing the following steps:

1. If you have not already established a profile for controlling access from the RRS attachment facility as described in “Define the names of protected access profiles” on page 266, define *ssnm*.RRSAF in the DSNR resource class with a universal access authority of NONE, as shown in the following command:

```
RDEFINE DSNR (DB2P.RRSAF DB2T.RRSAF) UACC(NONE)
```

2. Activate the resource class; use the following command:

```
SETRPTS RACLIST(DSNR) REFRESH
```

3. Add user IDs that are associated with the stored procedures address spaces to the RACF Started Procedures Table, as shown in this example:

```

.
.
.
DC   CL8'DSNWLM'           WLM-ESTABLISHED S.P. ADDRESS SPACE
DC   CL8'SYSDSP'           USERID
DC   CL8'DB2SYS'           GROUP NAME
DC   X'00'                 NO PRIVILEGED ATTRIBUTE
DC   XL7'00'               RESERVED BYTES
.
.
.

```

4. Give read access to *ssnm*.RRSAF to the user ID that is associated with the stored procedures address space:

```
PERMIT DB2P.RRSAF CLASS(DSNR) ID(SYSDSP) ACCESS(READ)
```

## Step 2: Control access to WLM (optional)

You can control which address spaces can be WLM-established server address spaces that run stored procedures. To do this, use the server resource class, which WLM uses to identify valid address spaces to which work can be sent. If the server class is not defined or activated, any address space is allowed to connect to WLM as a server address space and to identify itself as a server address space that runs stored procedures.

To use the server resource class, perform the following steps:

1. Run a version of RACF in which the resource class SERVER is included as part of the predefined resource classes (RACF Version 2 Release 2 and subsequent releases).
2. Define a RACF profile for the server resource class named SERVER, as follows:

```
RDEFINE SERVER (DB2.ssnm.applenv)
```

*applenv* is the name of the application environment that is associated with the stored procedure. See “Assigning procedures and functions to WLM application environments” on page 1024 for more information about application environments.

Assume that you want to define the following profile names:

- DB2.DB2T.TESTPROC
- DB2.DB2P.PAYROLL
- DB2.DB2P.QUERY

Use the following RACF command:

```
RDEFINE SERVER (DB2.DB2T.TESTPROC DB2.DB2P.PAYROLL DB2.DB2P.QUERY)
```

3. Activate the resource class SERVER as follows:

```
SETOPTS RACLIST(SERVER) REFRESH
```

4. Permit read access to the server resource name to the user IDs that are associated with the stored procedures address space as follows.

```
PERMIT DB2.DB2T.TESTPROC CLASS(SERVER) ID(SYSDSP) ACCESS(READ)
PERMIT DB2.DB2P.PAYROLL CLASS(SERVER) ID(SYSDSP) ACCESS(READ)
PERMIT DB2.DB2P.QUERY CLASS(SERVER) ID(SYSDSP) ACCESS(READ)
```

**Control of stored procedures in a WLM environment:** Programs can be grouped together and isolated in different WLM environments based on application security requirements. For example, payroll applications might be isolated in one WLM environment because they contain sensitive data, such as employee salaries.

To prevent users from creating a stored procedure in a sensitive WLM environment, DB2 invokes RACF to determine if the user is allowed to create stored procedures in the specified WLM environment. The WLM ENVIRONMENT keyword on the CREATE PROCEDURE statement identifies the WLM environment to use for running a given stored procedure. Attempts to create a stored procedure fail if the user is not properly authorized.

DB2 performs a resource authorization check using the DSNR RACF class as follows:

- In a DB2 data sharing environment, DB2 uses the following RACF resource name:  
db2\_groupname.WLMENV.wlm\_environment
- In a non-data sharing environment, DB2 checks the following RACF resource name:  
db2\_subsystem\_id.WLMENV.wlm\_environment

You can use the RACF RDEFINE command to create RACF profiles that prevent users from creating stored procedures and user-defined functions in sensitive WLM environments. For example, you can prevent all users on DB2 subsystem DB2A (non-data sharing) from creating a stored procedure or user-defined function in the WLM environment named PAYROLL; to do this, use the following command:

```
RDEFINE DSNR (DB2A.WLMENV.PAYROLL) UACC(NONE)
```

The RACF PERMIT command authorizes a user to create a stored procedure or user-defined function in a WLM environment. For example, you can authorize a DB2 user (DB2USER1) to create stored procedures on DB2 subsystem DB2A (non-data sharing) in the WLM environment named PAYROLL:

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

**Control of stored procedures in a DB2-established stored procedures address space:** DB2 invokes RACF to determine if a user is allowed to create a stored procedure in a DB2-established stored procedure address space. The NO WLM ENVIRONMENT keyword on the CREATE PROCEDURE statement indicates that a given stored procedure will run in a DB2-established stored procedures address space. Attempts to create a procedure fail if the user is not authorized, or if there is no DB2-established stored procedures address space exists.

The RACF PERMIT command authorizes a user to create a stored procedure in a DB2-established stored procedures address space. For example, you can authorize a DB2 user (DB2USER1) to create stored procedures on DB2 subsystem DB2A in the stored procedures address space named DB2ASPAS:

```
PERMIT DB2A.WLMENV.DB2ASPAS CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

### Step 3: Control access to non-DB2 resources (optional)

With stored procedures that run in a DB2-established address space, the user ID of the stored procedures address space (from the started procedures table of RACF) is used to access non-DB2 resources such as IMS or CICS transactions, APPC conversations, or VSAM files.

With WLM-established address spaces, you can specify that access to non-DB2 resources is controlled by the authorization ID of the caller rather than that of the stored procedure address space. To do this, specify U in the SECURITY column of table SYSIBM.SYSROUTINES for the stored procedure.

When you specify U for SECURITY, a separate RACF environment is established for that stored procedure. Use SECURITY=U only when the caller must access resources outside of DB2. Figure 26 shows the user ID that is associated with each part of a stored procedure.

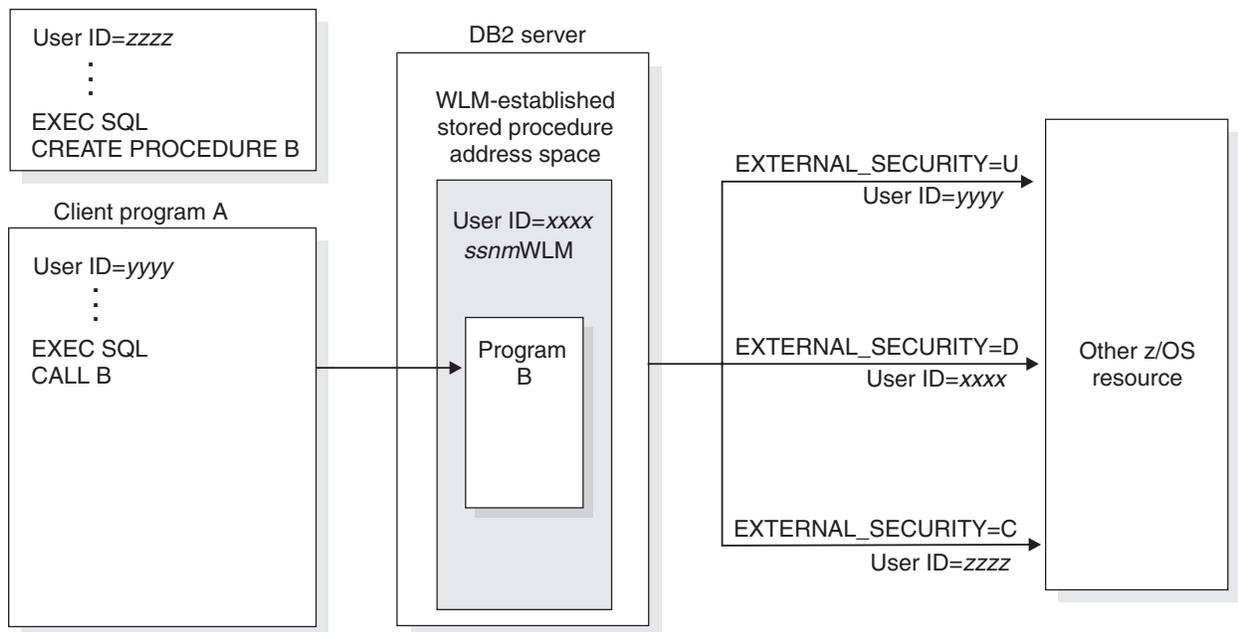

Figure 26. Accessing non-DB2 resources from a stored procedure

For WLM-established stored procedures address spaces, enable the RACF check for the caller's ID when you want to access non-DB2 resources by performing the following steps:

1. Use the ALTER PROCEDURE statement with the SECURITY USER clause.
2. Ensure that the ID of the stored procedure's caller has RACF authority to the resources.
3. For the best performance, cache the RACF profiles in the virtual look-aside facility (VLF) of z/OS. Do this by specifying the following keywords in the COFVLFxx member of library SYS1.PARMLIB.

```
CLASS NAME(IRRACEE)
EMAJ(ACEE)
```

## Establishing RACF protection for TCP/IP

The ID that is associated with the DB2 distributed address space must be authorized to use UNIX system services if your DB2 subsystem is going to send or accept any requests over TCP/IP. To do this, you must create an OMVS segment in the RACF user profile, as follows:

```
ALTUSER (SYSDSP) OMVS(UID(0))
```

To give root authority to the DDF address space, you must specify a UID of 0.

---

## Establishing Kerberos authentication through RACF

Kerberos security is a network security technology that was developed at the Massachusetts Institute of Technology. DB2 can use Kerberos security services to authenticate remote users. With Kerberos security services, remote end users access DB2 when they issue their Kerberos name and password. This same name and password is used for access throughout the network, so a separate password to access DB2 is not necessary.

The Kerberos security technology does not require passwords to flow in readable text, so it provides security even for client/server environments. This flexibility is possible because Kerberos uses an authentication technology that uses encrypted tickets that contain authentication information for the end user.

For information about Kerberos security, z/OS, and DB2 see the following books:

- *z/OS SecureWay Security Server Network Authentication Server Administration*
- *z/OS SecureWay Security Server Network Authentication Server Programming*
- *z/OS Security Server Security Administrator's Guide*
- *z/OS Security Server Command Language Reference*

For information about Kerberos security, OS/390, and DB2, see the following books:

- *OS/390 SecureWay Security Server Network Authentication and Privacy Administration Guide*
- *OS/390 SecureWay Security Server (RACF) Security Administrator's Guide*
- *OS/390 Security Server (RACF) Command Language Reference*

Each remote user who is authenticated to DB2 by means of Kerberos authentication must be registered in RACF profiles. Each organization wishing to run a Kerberos server establishes its own *realm*. The name of the realm in which a client is registered is part of the client's name and can be used by the application server to decide whether to honor a request. Follow these steps to authenticate and register a remote user:

1. Define the Kerberos realm to RACF. The name of the local realm must be supplied in the definition. You must also supply a Kerberos password for RACF to grant Kerberos ticket-granting tickets. Define a Kerberos realm with the following command:

```
RDEFINE REALM KERBDFLT KERB(KERBNAME(localrealm) PASSWORD(mykerpw)
```

2. Define local principals to RACF. Change RACF passwords before the principals become active Kerberos users. Define a Kerberos principal with the following commands:

```
AU RONTOMS KERB(KERBNAME(rontoms))  
ALU RONTOMS PASSWORD(new1pw) NOEXPIRE
```

3. Map foreign Kerberos principals by defining KERBLINK profiles to RACF with a command similar to the following command:

```
RDEFINE KERBLINK /.../KERB390.ENDICOTT.IBM.COM/RWH APPLDATA('RONTOMS')
```

You must also define a principal name for the user ID used in the *ssnmDIST* started task address space. This step is required because the *ssnmDIST* address space must have the RACF authority to use its SAF ticket parsing service.

```
ALU SYSDSP PASSWORD(pw) NOEXPIRE KERB(KERBNAME(SYSDSP))
```

In this example, the user ID that is used for the *ssnmDIST* started task address space is SYSDSP. See “Define RACF user IDs for DB2 started tasks” on page 267 for more information, including how to determine the user ID for the *ssnmDIST* started task.

4. Define foreign Kerberos authentication servers to the local Kerberos authentication server by using REALM profiles. You must supply a password for the key to be generated. REALM profiles define the trust relationship between the local realm and the foreign Kerberos authentication servers. PASSWORD is a required keyword, so all REALM profiles have a KERB segment. The command is similar to the following command:

```
RDEFINE REALM /.../KERB390.ENDICOTT.IBM.COM/KRBTGT/KER2000.ENDICOTT.IBM.COM +  
KERB(PASSWORD(realmpw))
```

The z/OS SecureWay Kerberos Security Server rejects ticket requests from users with revoked or expired passwords; therefore, plan password resets that use a method that avoids a password change at a subsequent logon. For example, use the TSO logon panel the PASSWORD command without a specified ID operand, or the ALTUSER command with NOEXPIRE specified.

**Data sharing environment:** Data sharing Sysplex environments that use Kerberos security must have a Kerberos Security Server instance running on each system in the Sysplex. The instances must either be in the same realm and share the same RACF database, or have different RACF databases and be in different realms.

---

## Other methods of controlling access

You can also help control access to DB2 from within IMS or CICS.

- IMS security

IMS terminal security lets you limit the entry of a transaction code to a particular logical terminal (LTERM) or group of LTERMs in the system. To protect a particular program, you can authorize a transaction code that is to be entered only from any terminal on a list of LTERMs. Alternatively, you can associate each LTERM with a list of the transaction codes that a user can enter from that LTERM. IMS then passes the validated LTERM name to DB2 as the initial primary authorization ID.

- CICS security

CICS transaction code security works with RACF to control the transactions and programs that can access DB2. Within DB2, you can use the ENABLE and DISABLE options of the bind operation to limit access to specific CICS subsystems.

#

---

## # Chapter 12. Protecting data sets through RACF

# To fully protect the data in DB2, you must take steps to ensure that no other  
# process has access to the data sets in which DB2 data resides.

# Use RACF, or a similar external security system, to control access to the data sets  
# just as RACF controls access to the DB2 subsystem. This section explains how to  
# create RACF profiles for data sets and allow their use through DB2.

# Assume that the RACF groups DB2 and DB2USER, and the RACF user ID  
# DB2OWNER, have been set up for DB2 IDs, as described under “Defining DB2  
# resources to RACF” on page 265 (and shown in Figure 24 on page 264). Given that  
# setting, the examples that follow show you how to:

- # • Add RACF groups to control data sets that use the default DB2 qualifiers
- # • Create generic profiles for different types of DB2 data sets and permit their use  
# by DB2 started tasks
- # • Permit use of the profiles by specific IDs
- # • Allow certain IDs to create data sets.

# The following topics provide additional information:

- # • “Adding groups to control DB2 data sets”
- # • “Creating generic profiles for data sets”
- # • “Permitting DB2 authorization IDs to use the profiles” on page 283
- # • “Allowing DB2 authorization IDs to create data sets” on page 283

---

### # Adding groups to control DB2 data sets

# The default high-level qualifier for data sets that contain DB2 databases and  
# recovery logs is DSN810; for distribution, target, SMP, and other installation data  
# sets, the default high-level qualifier is DSN810. The DB2OWNER user ID can  
# create groups that control those data sets by issuing the following commands:

```
# ADDGROUP DSN810 SUPGROUP(DB2) OWNER(DB2OWNER)  
# ADDGROUP DSN810 SUPGROUP(DB2) OWNER(DB2OWNER)
```

---

### # Creating generic profiles for data sets

# DB2 uses specific names to identify data sets for special purposes. In “Define  
# RACF user IDs for DB2 started tasks” on page 267, SYSDSP is the RACF user ID  
# for DB2 started tasks. DB2OWNER can issue the following commands to create  
# generic profiles for the data sets and give complete control over the data sets to  
# DB2 started tasks:

- # • For active logs, issue the following commands:

```
# ADDSD 'DSNC810.LOGCOPY*' UACC(NONE)  
# PERMIT 'DSNC810.LOGCOPY*' ID(SYSDSP) ACCESS(ALTER)
```

- # • For archive logs, issue the following commands:

```
# ADDSD 'DSNC810.ARCHLOG*' UACC(NONE)  
# PERMIT 'DSNC810.ARCHLOG*' ID(SYSDSP) ACCESS(ALTER)
```

- # • For bootstrap data sets, issue the following commands:

```
# ADDSD 'DSNC810.BSDS*' UACC(NONE)  
# PERMIT 'DSNC810.BSDS*' ID(SYSDSP) ACCESS(ALTER)
```

```

#           • For table spaces and index spaces, issue the following commands:
#           ADDSD 'DSNC810.DSNDBC.*' UACC(NONE)
#           PERMIT 'DSNC810.DSNDBC.*' ID(SYSDSP) ACCESS(ALTER)
#
#           • For installation libraries, issue the following command:
#           ADDSD 'DSN810.*'          UACC(READ)
#
#           Started tasks do not need control.
#
#           • For other general data sets, issue the following commands:
#           ADDSD 'DSNC810.*'        UACC(NONE)
#           PERMIT 'DSNC810.*'        ID(SYSDSP) ACCESS(ALTER)
#
#           Although all of those commands are not absolutely necessary, the sample shows
#           how you can create generic profiles for different types of data sets. Some
#           parameters, such as universal access, could vary among the types. In the example,
#           installation data sets (DSN810.*) are universally available for read access.
#
#           If you use generic profiles, specify NO on installation panel DSNTIPP for
#           ARCHIVE LOG RACF, or you might get a z/OS error when DB2 tries to create the
#           archive log data set. If you specify YES, DB2 asks RACF to create a separate profile
#           for each archive log that is created, which means that you cannot use generic
#           profiles for these data sets.
#
#           To protect VSAM data sets, use the cluster name. You do not need to protect the
#           data component names, because the cluster name is used for RACF checking.
#
#           Access by stand-alone DB2 utilities: The following DB2 utilities access objects that
#           are outside of DB2 control:
#
#           • DSN1COPY and DSN1PRNT: table space and index space data sets
#           • DSN1LOGP: active logs, archive logs, and bootstrap data sets
#           • DSN1CHKR: DB2 directory and catalog table spaces
#           • Change Log Inventory (DSNJU003) and Print Log Map (DSNJU004): bootstrap
#             data sets
#
#           The Change Log Inventory and Print Log Map utilities run as batch jobs that are
#           protected by the USER and PASSWORD options on the JOB statement. To provide
#           a value for the USER option, for example SVCAID, issue the following commands:
#
#           • For DSN1COPY:
#             PERMIT 'DSNC810.*' ID(SVCAID) ACCESS(CONTROL)
#
#           • For DSN1PRNT:
#             PERMIT 'DSNC810.*' ID(SVCAID) ACCESS(READ)
#
#           • For DSN1LOGP:
#             PERMIT 'DSNC810.LOGCOPY*' ID(SVCAID) ACCESS(READ)
#             PERMIT 'DSNC810.ARCHLOG*' ID(SVCAID) ACCESS(READ)
#             PERMIT 'DSNC810.BSDS*'   ID(SVCAID) ACCESS(READ)
#
#           • For DSN1CHKR:
#             PERMIT 'DSNC810.DSNDBC.*' ID(SVCAID) ACCESS(READ)
#
#           • For Change Log Inventory:
#             PERMIT 'DSNC810.BSDS*' ID(SVCAID) ACCESS(CONTROL)
#
#           • For Print Log Map:
#             PERMIT 'DSNC810.BSDS*' ID(SVCAID) ACCESS(READ)

```

# The level of access depends on the intended use, not on the type of data set  
# (VSAM KSDS, VSAM linear, or sequential). For update operations,  
# ACCESS(CONTROL) is required; for read-only operations, ACCESS(READ) is  
# sufficient.

# You can use RACF to permit programs, rather than user IDs, to access objects.  
# When you use RACF in this manner, IDs that are not authorized to access the log  
# data sets might be able to do so by running the DSN1LOGP utility. Permit access  
# to database data sets through DSN1PRNT or DSN1COPY.

---

## # **Permitting DB2 authorization IDs to use the profiles**

# Authorization IDs with installation SYSADM or installation SYSOPR authority  
# need access to most DB2 data sets. (For a list of the privileges that go with those  
# authorities, see “Explicit privileges and authorities” on page 133.) The following  
# command adds the two default IDs that have the SYSADM and SYSOPR  
# authorities if no other IDs are named when DB2 is installed:  
#  
# ADDUSER (SYSADM SYSOPR)

# The next two commands connect those IDs to the groups that control data sets,  
# with the authority to create new RACF database profiles. The ID that has  
# installation SYSOPR authority (SYSOPR) does not need that authority for the  
# installation data sets.

```
# CONNECT (SYSADM SYSOPR) GROUP(DSNC810) AUTHORITY(CREATE) UACC(NONE)
# CONNECT (SYSADM) GROUP(DSN810) AUTHORITY(CREATE) UACC(NONE)
```

# The following set of commands gives the IDs complete control over DSNC810 data  
# sets. The system administrator IDs also have complete control over the installation  
# libraries. Additionally, you can give the system programmer IDs the same control.

```
# PERMIT 'DSNC810.LOGCOPY*' ID(SYSADM SYSOPR) ACCESS(ALTER)
# PERMIT 'DSNC810.ARCHLOG*' ID(SYSADM SYSOPR) ACCESS(ALTER)
# PERMIT 'DSNC810.BSDS*' ID(SYSADM SYSOPR) ACCESS(ALTER)
# PERMIT 'DSNC810.DSNDBC.*' ID(SYSADM SYSOPR) ACCESS(ALTER)
# PERMIT 'DSNC810.*' ID(SYSADM SYSOPR) ACCESS(ALTER)
# PERMIT 'DSN810.*' ID(SYSADM) ACCESS(ALTER)
```

---

## # **Allowing DB2 authorization IDs to create data sets**

# The following command connects several IDs, which are already connected to the  
# DB2USER group, to group DSNC810 with CREATE authority:

```
# CONNECT (USER1 USER2 USER3 USER4 USER5)
# GROUP(DSNC810) AUTHORITY(CREATE) UACC(NONE)
```

# Those IDs can now explicitly create data sets whose names have DSNC810 as the  
# high-level qualifier. Any such data sets that are created by DB2 or by these RACF  
# user IDs are protected by RACF. Other RACF user IDs are prevented by RACF  
# from creating such data sets.

# If no option is supplied for PASSWORD on the ADDUSER command that adds  
# those IDs, the first password for the new IDs is the name of the default group,  
# DB2USER. The first time that the IDs sign on, they all use that password, but they  
# must change the password during their first session.

---

## Chapter 13. Auditing

This chapter provides answers to some fundamental auditing questions. Foremost among them are the following questions:

1. Who is privileged to access what objects?
2. Who has actually accessed the data?

*Who is privileged?* You can find answers to the first question in the DB2 catalog, which is the primary audit trail for the DB2 subsystem. Most of the catalog tables describe the DB2 objects, such as tables, views, table spaces, packages, and plans. Several other tables (every table with the character string "AUTH" in its name) hold records of every granted privilege or authority. Every catalog record of a grant contains the following information:

- Name of the object
- Type of privilege
- IDs that receive the privilege
- ID that grants the privilege
- Time of the grant
- Other information

You can retrieve data from catalog tables by writing SQL queries. For examples, see "Finding catalog information about privileges" on page 187.

*Who accessed data?* You can find answers to the second question by using the audit trace, another important audit trail for DB2. The audit trace can record:

- Changes in authorization IDs
- Changes to the structure of data (such as dropping a table)
- Changes to data values (such as updating or inserting records)
- Access attempts by unauthorized IDs
- Results of GRANT statements and REVOKE statements
- Mapping of Kerberos security tickets to IDs
- Other activities that are of interest to auditors

This chapter presents the following topics:

- "Using the audit trace"
- "The role of authorization IDs in auditing" on page 289
- "Using audit records" on page 290.
- "Using other sources of audit information" on page 292
- "Determining which security measures are enabled" on page 292
- "Ensuring data accuracy and consistency" on page 293
- "Determining whether data is consistent" on page 296

---

### Using the audit trace

The information in this chapter is General-use Programming Interface and Associated Guidance Information, as defined in "Notices" on page 1437.

The DB2 audit trace can indicate who has accessed data. When started, the audit trace records certain types of actions and sends the report to a named destination. As with other DB2 traces, you can choose the following options for the audit trace:

- Categories of events to trace
- Particular authorization IDs or plan IDs to audit
- Ways to start and stop the trace

- Destinations for audit records

You can choose whether to audit the activity on a table by specifying an option of the CREATE and ALTER statements.

## Starting the audit trace

You can automatically start an audit trace whenever DB2 is started by setting the AUDIT TRACE field on the DSNTIPN installation panel to one of the following options:

- \* (an asterisk) to provide a complete audit trace.
- NO, the default, if you do not want an audit trace to start automatically.
- YES to start a trace automatically for the default class (class 1: access denials) and the default destination (the SMF data set).
- A list of audit trace classes (for example, 1,3,5) to start a trace automatically for those classes. This option uses the default destination.

*The START TRACE command:* As with other DB2 traces, you can start an audit trace at any time with the START TRACE command. You can choose the audit classes to trace and the destination for trace records. You can also include an identifying comment.

**Example:** The following command starts an audit trace for classes 4 and 6 with distributed activity:

```
-START TRACE (AUDIT) CLASS (4,6) DEST (GTF) LOCATION (*)
  COMMENT ('Trace data changes; include text of dynamic DML statements.')
```

## Stopping the audit trace

You can have several different traces that run at the same time, including more than one audit trace. One way to stop a particular trace is to issue the STOP TRACE command with the same options that were used for START TRACE. You must include enough options to uniquely identify a particular trace.

**Example:** The following command stops the trace that the example in “Starting the audit trace” started:

```
-STOP TRACE (AUDIT) CLASS (4,6) DEST (GTF)
```

If you did not save the START command, you can determine the trace number and stop the trace by its number. Use DISPLAY TRACE to find the number.

**Example:** DISPLAY TRACE (AUDIT) might return a message like the following output:

TNO	TYPE	CLASS	DEST	QUAL
01	AUDIT	01	SMF	NO
02	AUDIT	04,06	GTF	YES

The message indicates that two audit traces are active. Trace 1 traces events in class 1 and sends records to the SMF data set. Trace 1 can be a trace that starts automatically whenever DB2 starts. Trace 2 traces events in classes 4 and 6 and sends records to GTF.

You can stop either trace by using its identifying number (TNO).

**Example:** To stop trace 1, use the following command:

```
-STOP TRACE AUDIT TNO(1)
```

## Audit class descriptions

When you start the trace, you choose which events to audit by specifying one or more audit classes. The trace records are limited to 5000 bytes, so descriptions that contain long SQL statements might be truncated. Table 86 describes the available classes and the events that they include.

Table 86. Audit classes and the events that they trace

Audit class	Events that are traced
1	Access attempts that DB2 denies because of inadequate authorization. This class is the default.
2	Explicit GRANT and REVOKE statements and their results. This class does not trace implicit grants and revokes.
3	CREATE, ALTER, and DROP statements that affect audited tables, and the results of these statements. This class traces the dropping of a table that is caused by DROP TABLESPACE or DROP DATABASE and the creation of a table with AUDIT CHANGES or AUDIT ALL. ALTER TABLE statements are audited only when they change the AUDIT option for the table.
4	Changes to audited tables. Only the first attempt to change a table, within a unit of recovery, is recorded. (If the agent or the transaction issues more than one COMMIT statement, the number of audit records increases accordingly.) The changed data is not recorded, only the attempt to make a change is recorded. If the change is not successful and is rolled back, the audit record remains; it is not deleted. This class includes access by the LOAD utility. Accesses to a dependent table that are caused by attempted deletions from a parent table are also audited. The audit record is written even if the delete rule is RESTRICT, which prevents the deletion from the parent table. The audit record is also written when the rule is CASCADE or SET NULL, which can result in deletions that cascade to the dependent table.
5	All read accesses to tables that are identified with the AUDIT ALL clause. As in class 4, only the first access within a DB2 unit of recovery is recorded. References to a parent table are also audited.
6	The bind of static and dynamic SQL statements of the following types: <ul style="list-style-type: none"><li>• INSERT, UPDATE, DELETE, CREATE VIEW, and LOCK TABLE statements for audited tables. Except for the values of host variables, the audit record contains the entire SQL statement.</li><li>• SELECT statements on tables that are identified with the AUDIT ALL clause. Except for the values of host variables, the audit record contains the entire SQL statement.</li></ul>
7	Assignment or change of an authorization ID because of the following reasons: <ul style="list-style-type: none"><li>• Changes through an exit routine (default or user-written)</li><li>• Changes through a SET CURRENT SQLID statement</li><li>• An outbound or inbound authorization ID translation</li><li>• An ID that is being mapped to a RACF ID from a Kerberos security ticket</li></ul>
8	The start of a utility job, and the end of each phase of the utility.
9	Various types of records that are written to IFCID 0146 by the IFI WRITE function.

## Limitations of the audit trace

The audit trace does not record everything, as the following list of limitations indicates:

#

- The auditing that is described in this chapter takes place only when the audit trace is on.
- The trace does not record old data after it is changed because the log records old data.
- If an agent or transaction accesses a table more than once in a single unit of recovery, the audit trace records only the first access.
- The audit trace does not record accesses if you do not start the audit trace for the appropriate class of events.
- Except class 8, the audit trace does not audit certain utilities. The trace audits the first access of a table with the LOAD utility, but it does not audit access by the COPY, RECOVER, and REPAIR utilities. The audit trace does not audit access by stand-alone utilities, such as DSN1CHKR and DSN1PRNT.
- The trace audits only the tables that you specifically choose to audit.
- You cannot audit access to auxiliary tables.
- You cannot audit the catalog tables because you cannot create or alter catalog tables.

This auditing coverage is consistent with the goal of providing a moderate volume of audit data with a low impact on performance. However, when you choose classes of events to audit, consider that you might ask for more data than you are willing to process.

## Auditing in a distributed data environment

The DB2 audit trace records any access to your data, whether the request is from a remote location or from your local DB2. The trace record for a remote request reports the authorization ID as the final result of one of the following conditions:

- An outbound translation
- An inbound translation
- Activity of an authorization exit routine

Essentially, the ID on a trace record for a remote request is the same as the ID to which you grant access privileges for your data.

Requests from your location to a remote DB2 are audited only if an audit trace is active at the remote location. The output from the trace appears only in the records at that location.

## Auditing a specific table

To audit a table, use the AUDIT clause in the CREATE TABLE statement or the ALTER TABLE statement.

**Example:** DB2 audits the department table whenever the audit trace is on if you create the table with the following statement:

```
CREATE TABLE DSN8810.DEPT
  (DEPTNO CHAR(3) NOT NULL,
   DEPTNAME VARCHAR(36) NOT NULL,
   MGRNO CHAR(6) ,
   ADMRDEPT CHAR(3) NOT NULL,
   LOCATION CHAR(16) ,
   PRIMARY KEY (DEPTNO) )
IN DSN8D81A.DSN8S81D
AUDIT CHANGES;
```

Because this statement includes the AUDIT CHANGES option, DB2 audits the table for each access that inserts, updates, or deletes data (trace class 4).

**Example:** To also audit the table for read accesses (class 5), issue the following statement:

```
ALTER TABLE DSN8810.DEPT
  AUDIT ALL;
```

The statement is effective regardless of whether the table was previously chosen for auditing.

**Example:** To prevent all auditing of the table, issue the following statement:

```
ALTER TABLE DSN8810.DEPT
  AUDIT NONE;
```

For the CREATE TABLE statement, the default audit option is NONE. For the ALTER TABLE statement, no default option exists. If you do not use the AUDIT clause in an ALTER TABLE statement, the audit option for the table is unchanged.

When CREATE TABLE statements or ALTER TABLE statements affect the audit of a table, you can audit those statements. However, the results of those audits are in audit class 3, not in class 4 or class 5. Use audit class 3 to determine whether auditing was turned off for a table for an interval of time.

If an ALTER TABLE statement turns auditing on or off for a specific table, any plans and packages that use the table are invalidated and must be rebound. If you change the auditing status, the change does not affect plans, packages, or dynamic SQL statements that are currently running. The change is effective only for plans, packages, or dynamic SQL statements that begin running after the ALTER TABLE statement has completed.

---

## The role of authorization IDs in auditing

In general, audit traces identify a process by its primary authorization ID. The audit trace records the primary ID before and after invocation of an authorization exit routine. Therefore, you can identify the primary ID that is associated with a change.

**Exception:** If a primary ID has been translated many times, you might not be able to identify the primary ID that is associated with a change.

**Example:** Suppose that the server does not recognize the translated ID from the requesting site. In this case, you cannot use the primary ID to gather all audit records for a user that accesses remote data.

The AUTHCHG record shows the values of all secondary authorization IDs that are established by an exit routine. See “Audit class descriptions” on page 287, Audit Class 7, for a description of the AUTHCHG record.

With the audit trace, you can also determine which primary ID is responsible for the action of a secondary ID or a current SQL ID.

**Example:** Suppose that the user with primary ID SMITHJ sets the current SQL ID to TESTGRP to grant privileges over the table TESTGRP.TABLE01 to another user. The DB2 catalog records the grantor of the privileges as TESTGRP. However, the audit trace shows that SMITHJ issued the grant statement.

**Recommendation:** Consider carefully the consequences of altering that ID by using an exit routine because the trace identifies a process by its primary ID. If the

primary ID identifies a unique user, individual accountability is possible. However, if several users share the same primary ID, you cannot tell which user issues a particular GRANT statement or runs a particular application plan.

## Auditing specific IDs

As with other DB2 traces, you can start an audit trace for a particular plan name, a particular primary authorization ID, or a combination of the two. For examples of auditing specific IDs, see “DB2 trace” on page 1195. You might consider having audit traces on at all times for IDs with SYSADM authority because they have complete access to every table. If you have a network of DB2 subsystems, you might need to trace multiple authorization IDs if primary authorization ID are translated several times. For embedded SQL, the audited ID is the primary authorization ID of the person who bound the plan or package. For dynamic SQL, the audited ID is the primary authorization ID.

## Determining which IDs hold privileges and authorities

Auditors must be aware of the privileges and authorities that are associated with IDs in the DB2 subsystem. To determine which IDs hold privileges and authorities, use the following methods:

- Query the DB2 catalog to determine which IDs hold particular privileges. See “Finding catalog information about privileges” on page 187 for information about querying the catalog.
- Check on individual IDs that are associated with group IDs. Some authorization IDs that you encounter are probably group IDs, to which many individual IDs can be connected. To see which IDs are connected to a group, obtain a report from RACF or from whatever external security system you are using. These reports can tell you which IDs have the required privileges to use DB2 data sets and other resources. For instructions on how to obtain such reports, see *z/OS Security Server RACF System Programmer's Guide* or the documentation for your external security system.

See Chapter 9, “Controlling access to DB2 objects,” on page 133 for more information about privileges and authorities.

---

## Using audit records

You can prepare the System Management Facility (SMF) or Generalized Trace Facility (GTF) to accept audit trace records in the same way that you prepare performance or accounting trace records. See “Recording SMF trace data” on page 1199 and “Recording GTF trace data” on page 1201 for information. The records are of SMF type 102, as are performance trace records.

IFCIDs identify all DB2 trace records. For instructions on interpreting trace output and mapping records for the IFCIDs, see Appendix D, “Interpreting DB2 trace output,” on page 1139. Chapter 2 of *DB2 Command Reference* lists the IFCIDs for each trace class and the description of the START TRACE command.

If you send trace records to SMF (the default), data might be lost in the following circumstances:

- SMF fails while DB2 continues to run.
- An unexpected abend (such as a TSO interrupt) occurs while DB2 is transferring records to SMF.

In those circumstances, SMF records the number of records that are lost. z/OS provides an option to stop the system rather than to lose SMF data.

## The contents of audit records

Among other things, the audit trace records can indicate the following information:

- The ID that initiated the activity
- The LOCATION of the ID that initiated the activity (if the access was initiated from a remote location)
- The type of activity and the time that the activity occurred
- The DB2 objects that were affected
- Whether access was denied
- The owner of a particular plan and package
- The database alias (DBALIAS) that was used to access a remote location or a location alias that was accepted from a remote application

## Formatting audit records

To extract, format, and print the records, you can use any of the following methods:

- Use the DB2 Performance Expert. See “OMEGAMON” on page 1202 for more information.
- Write your own application program to access the SMF data.
- Use the instrumentation facility interface (IFI) as an online resource to retrieve audit records. For more information about using the IFI, see Appendix E, “Programming for the Instrumentation Facility Interface (IFI),” on page 1157.

## Suggested audit trace reports

If you regularly start the audit trace for all classes, you accumulate data from which to make reports. Consider producing audit trace reports that focus on the following important security events:

### Use of sensitive data

You should define tables that contain sensitive data, such as employee salary records, with the AUDIT ALL option. You can report use by table and by authorization ID to look for access by unusual IDs, at unusual times, or of unexpected types. You should also record any ALTER or DROP operations that affect the data. Use audit classes 3, 4, and 5.

### Grants of critical privileges

Carefully monitor IDs with special authorities, such as SYSADM and DBADM. Also carefully monitor IDs with privileges over sensitive data, such as an update privilege on records of accounts payable. You can query the DB2 catalog to determine which IDs hold privileges and authorities at a particular time. To determine which IDs received privileges and then had them revoked, use audit class 2 and consult the audit records.

### Unsuccessful access attempts

Investigate all unsuccessful access attempts. Although some access failures are only user errors, others can be attempts to violate security. If you have sensitive data, always use trace audit class 1. You can report by table or by authorization ID.

---

## Using other sources of audit information

In addition to the audit trace, DB2 offers the following other sources of audit information:

### Additional DB2 traces

DB2 accounting, statistics, and performance traces are also available. You can read about the accounting trace, the statistics trace, and performance traces in “DB2 trace” on page 1195. You can also use DB2 Performance Expert to print reports of these traces. See “OMEGAMON” on page 1202. for information about DB2 Performance Expert.

### Recovery log

Although the recovery log is not an all-purpose log, it can be useful for auditing. You can print information from the log by using the DSN1LOGP utility. For example, the summary report can show which table spaces have been updated within the range of the log that you scan. The REPORT utility can indicate what log information is available and where it is located. For information about running DSN1LOGP and REPORT, see *DB2 Utility Guide and Reference*.

### Image copies of table spaces

Typical recovery procedures generate image copies of table spaces. You can inspect these copies, or use them with the RECOVER utility to recover a table space to a particular point in time. If you recover to a point in time, you narrow the time period during which a particular change could have been made. For guidance in using COPY and RECOVER, see Chapter 21, “Backing up and recovering databases,” on page 475.

### z/OS console log

The z/OS console log contains messages about exceptional conditions that are encountered during DB2 operation. Inspect this log for symptoms of problems.

### Audit trail

Whenever you install a new version, release, or maintenance of DB2, an automatic record provides an audit trail. The audit trail helps you determine whether the changes are appropriate and whether authorized personnel made them. The audit trail can also aid in investigation of application-related problems.

---

## Determining which security measures are enabled

Auditors must know which security measures are enabled on the DB2 subsystem. You can determine whether DB2 authorization checking, the audit trace, and data definition control are enabled in the following ways:

### Audit trace

To see whether the trace is running, display the status of the trace by the command `DISPLAY TRACE(AUDIT)`.

### DB2 Authorization checking

Follow the instructions for changing DB2 installation parameters in “The Update Process” in Part 2 of *DB2 Installation Guide*. Without changing anything, look at panel DSNTIPP. If the value of the USE PROTECTION field is YES, DB2 checks privileges and authorities before permitting any activity.

### Data definition control

Data definition control is a security measure that provides additional

constraints to existing authorization checks. With it, you control how specific plans or collections of packages can use data definition statements. Read Chapter 10, “Controlling access through a closed application,” on page 215 for a description of this function. To determine whether data definition control is active, look at option 1 on the DSNTIPZ installation panel.

---

## Ensuring data accuracy and consistency

DB2 provides many controls that you can apply to data entry and update. Some of the controls are automatic; some are optional. All of the controls prohibit certain operations and provide error or warning messages if those operations are attempted. This section describes typical auditing concerns for ensuring data accuracy and consistency.

The set of techniques in this section is not exhaustive. Other combinations of techniques are possible. For example, you can use table check constraints or a view with the check option to ensure that data values are members of a certain set. Or you can set up a master table and define referential constraints. You can also enforce the controls through application programs, and restrict the INSERT and UPDATE privileges only to those programs.

### Ensuring that the required data is present

To ensure that the required data is present, define columns with the NOT NULL clause.

You can also control the type of data by assigning column data types and lengths.

**Example:** Alphabetic data cannot be entered into a column with one of the numeric data types. Data that is inserted into a DATE column or a TIME column must have an acceptable format, and so on.

For suggestions about assigning column data types and the NOT NULL attribute, see *DB2 SQL Reference*.

### Ensuring that data is unique

In some cases, you must ensure that the data in a column or a set of columns is unique. The preferred method for ensuring that data values are unique is to create a unique index on a column or set of columns. See *The Official Introduction to DB2 UDB for z/OS* for suggestions about indexes.

### Ensuring that data fits a pattern or value range

Triggers and table check constraints enhance the ability to control data integrity.

Triggers are very powerful for defining and enforcing rules that involve different states of DB2 data. For example, a rule can prevent a salary column from more than a ten percent increase. A trigger can enforce this rule and provide the value of the salary before and after the increase for comparison. See Chapter 5 of *DB2 SQL Reference* for information using the CREATE TRIGGER statement to create a trigger.

A check constraint designates the values that specific columns of a base table can contain. A check constraint can express simple constraints, such as a required pattern or a specific range, and rules that refer to other columns of the same table.

As an auditor, you might check that the table definition expresses required constraints on column values as table check constraints. For a full description of the rules for those constraints, see the CREATE TABLE information in Chapter 5 of *DB2 SQL Reference*.

An alternative technique is to create a view with the check option, and then insert or update values only through that view.

**Example:** Suppose that, in table T, data in column C1 must be a number between 10 and 20. Suppose also that data in column C2 is an alphanumeric code that must begin with A or B. Create view V1 with the following statement:

```
CREATE VIEW V1 AS
  SELECT * FROM T
    WHERE C1 BETWEEN 10 AND 20
      AND (C2 LIKE 'A%' OR C2 LIKE 'B%')
  WITH CHECK OPTION;
```

Because of the CHECK OPTION, view V1 allows only data that satisfies the WHERE clause.

You cannot use the LOAD utility with a view, but that restriction does not apply to user-written exit routines. Several types of user-written routines are pertinent here:

#### **Validation routines**

You can use validation routines to validate data values. Validation routines access an entire row of data, check the current plan name, and return a nonzero code to DB2 to indicate an invalid row.

#### **Edit routines**

Edit routines have the same access as validation routines, and can also change the row that is to be inserted. Auditors typically use edit routines to encrypt data and to substitute codes for lengthy fields. However, edit routines can also validate data and return nonzero codes.

#### **Field procedures**

Field procedures access data that is intended for a single column; they apply only to short-string columns. However, they accept input parameters, so generalized procedures are possible. A column that is defined with a field procedure can be compared only to another column that uses the same procedure.

See Appendix B, “Writing exit routines,” on page 1055 for information about using exit routines.

## **Ensuring that data is consistent**

Referential integrity ensures that data is consistent across tables. When you define primary and foreign keys, DB2 automatically enforces referential integrity. Therefore, every value of a foreign key in a dependent table must be a value of a primary key in the appropriate parent table.

**Recommendation:** Use referential integrity to ensure that a column allows only specific values. Set up a master table of allowable values, and define its primary key. Define foreign keys in other tables that must have matching values in their columns. In most cases, you should use the SET NULL delete rule.

DB2 does not enforce informational referential constraints across subsystems. For information about the means, implications, and limitations of enforcing referential integrity, see *DB2 Application Programming and SQL Guide*.

## Ensuring that changes are tracked

Triggers offer an efficient means of maintaining an audit trail. You can define a trigger to activate in response to certain DELETE, INSERT, or UPDATE statements that change data.

You can qualify a trigger by providing a list of column names when you define the trigger. The qualified trigger is activated only when one of the named columns is changed. A trigger that performs validation for changes that are made in an UPDATE operation must access column values both before and after the update. Transition variables (available only to row triggers) contain the column values of the row change that activated the trigger. The old column values and the column values from after the triggering operation are both available.

See *DB2 SQL Reference* for information about when to use triggers.

## Ensuring that concurrent users access consistent data

Locks can ensure that data remains consistent, even when multiple users try to access the same data at the same time. From an auditing standpoint, you can use locks to ensure that only one user is privileged to change data at a given time. You can also ensure that no users are privileged to access uncommitted data.

If you use repeatable read (RR), read stability (RS), or cursor stability (CS) as your isolation level, DB2 automatically controls access to data by using locks. However, if you use uncommitted read (UR) as your isolation level, users can access uncommitted data and introduce inconsistent data. Auditors must know which applications use UR isolation, and they must know whether these applications can introduce inconsistent data or create security risks.

For static SQL, you can determine which plans and packages use UR isolation by querying the catalog.

**Example:** For static SQL statements, use the following query to determine which plans use UR isolation:

```
SELECT DISTINCT Y.PLNAME
  FROM SYSIBM.SYSPLAN X, SYSIBM.SYSSTMT Y
 WHERE (X.NAME = Y.PLNAME AND X.ISOLATION = 'U')
        OR Y.ISOLATION = 'U'
 ORDER BY Y.PLNAME;
```

**Example:** For static SQL statements, use the following query to determine which packages use UR isolation:

```
SELECT DISTINCT Y.COLLID, Y.NAME, Y.VERSION
  FROM SYSIBM.SYSPACKAGE X, SYSIBM.SYSPACKSTMT Y
 WHERE (X.LOCATION = Y.LOCATION AND
        X.LOCATION = ' ' AND
        X.COLLID = Y.COLLID AND
        X.NAME = Y.NAME AND
        X.VERSION = Y.VERSION AND
        X.ISOLATION = 'U')
        OR Y.ISOLATION = 'U'
 ORDER BY Y.COLLID, Y.NAME, Y.VERSION;
```

For dynamic SQL statements, turn on performance trace class 3 to determine which plans and packages use UR isolation.

For more information about locks and concurrency, see Chapter 31, “Improving concurrency,” on page 813.

*Consistency between systems:* When an application program writes data to both DB2 and IMS, or to both DB2 and CICS, the subsystems prevent concurrent use of data until the program declares a point of consistency. For a detailed description of how data remains consistent between systems, see “Multiple system consistency” on page 459.

## Checking for lost and incomplete transactions

Database balancing is a technique that can alert you to lost and incomplete transactions. Database balancing determines, for each set of data, whether the opening balance, the control totals, and the processed transactions equal the closing balance and control totals.

DB2 has no automatic mechanism to calculate control totals and column balances and compare them with transaction counts and field totals. Therefore, to use database balancing, you must design these mechanisms into the application program.

**Example:** Use your application program to maintain a control table. The control table contains information to balance the control totals and field balances for update transactions against a user's view. The control table might contain these columns:

- View name
- Authorization ID
- Number of logical rows in the view (not the same as the number of physical rows in the table)
- Number of insert transactions and update transactions
- Opening balances
- Totals of insert transaction amounts and update transaction amounts
- Relevant audit trail information such as date, time, workstation ID, and job name

The program updates the transaction counts and amounts in the control table each time it completes an insert or update to the view. To maintain coordination during recovery, the program commits the work only after it updates the control table. After the application processes all transactions, the application writes a report that verifies the control total and balancing information.

---

## Determining whether data is consistent

When you control data entry, you perform only part of a complete security and auditing policy. You must also verify the results when data is accessed and changed. The following sections describe methods for determining whether your data is consistent:

- “Automatically checking the consistency of data” on page 297
- “Submitting SQL queries to check data consistency” on page 297
- “Checking data consistency with the CHECK utility” on page 297
- “Checking data consistency with the DISPLAY DATABASE command” on page 298
- “Checking data consistency with the REPORT utility” on page 298
- “Checking data consistency with the operation log” on page 298
- “Using internal integrity reports to check data consistency” on page 298

#

## Automatically checking the consistency of data

Whenever an operation changes the contents of a data page or an index page, DB2 verifies that the modifications do not produce inconsistent data. Additionally, you can run the DSN1CHKR utility to verify the integrity of the DB2 catalog and the directory table spaces. You can also run this utility to scan the specified table space for broken links, damaged hash chains, or orphan entries. For more information, see Part 3 of *DB2 Utility Guide and Reference*.

#

## Submitting SQL queries to check data consistency

### General-use Programming Interface

If you suspect that a table contains inconsistent data, you can submit an SQL query to search for a specific type of error.

**Example:** Consider the view that is created in “Ensuring that data fits a pattern or value range” on page 293. The view allows an insert or update to table T1 only if the value in column C1 is between 10 and 20 and if the value in C2 begins with A or B. To check that the control has not been bypassed, issue the following statement:

```
SELECT * FROM T1
  WHERE NOT (C1 BETWEEN 10 AND 20
    AND (C2 LIKE 'A%' OR C2 LIKE 'B%'));
```

If the control has not been bypassed, DB2 returns no rows and thereby confirms that the contents of the view are valid.

You can also use SQL statements to get information from the DB2 catalog about referential constraints that exist. For several examples, see *DB2 SQL Reference*.

### End of General-use Programming Interface

#

## Checking data consistency with the CHECK utility

The CHECK utility helps to ensure data consistency in the following ways:

### CHECK INDEX

The CHECK INDEX utility checks the consistency of indexes with the data to which the indexes point. It determines whether each index pointer points to a data row with the same value as the index key. If an index key points to a LOB, the CHECK INDEX utility determines whether the index key points to the correct LOB.

### CHECK DATA

The CHECK DATA utility checks referential constraints (but not informational referential constraints). It determines whether each foreign key value in each row is a value of the primary key in the appropriate parent table.

The CHECK DATA utility also checks table check constraints and checks the consistency between a base table space and any associated LOB table spaces. It determines whether each value in a row is within the range that was specified for that column when the table was created.

### CHECK LOB

The CHECK LOB utility checks the consistency of a LOB table space. It determines whether any LOBs in the LOB table space are invalid.

See *DB2 Utility Guide and Reference* for more information about the CHECK utility.

## # **Checking data consistency with the DISPLAY DATABASE command**

If you allow a table to be loaded without enforcing referential constraints on its foreign key columns, the table might contain data that violates the constraints. DB2 places the table space that contains the table in the CHECK-pending status. You can determine which table spaces are in CHECK-pending status by using the DISPLAY DATABASE command with the RESTRICT option. You can also use the DISPLAY DATABASE command to display table spaces with invalid LOBs. See Chapter 2 of *DB2 Command Reference* for information about using this command.

## # **Checking data consistency with the REPORT utility**

You can use the REPORT utility to determine:

- Which table spaces contain a set of tables that are interconnected by referential constraints
- Which LOB table spaces are associated with which base tables

See *DB2 Utility Guide and Reference* for information about using the REPORT utility.

## # **Checking data consistency with the operation log**

You can use the operation log to verify that DB2 is operated reliably, and to reveal unauthorized operations and overrides. The operation log consists of an automated log of DB2 operator commands (such as those that start or stop the subsystem or its databases) and any abend of DB2. The operation log records the following information:

- Command or condition type
- Date and time when the command was issued
- Authorization ID that issued the command
- Database connection code

You can obtain this information from the system log (SYSLOG), the SMF data set, or the automated job scheduling system. To obtain the information, use SMF reporting, job-scheduler reporting, or a user-developed program. You should review the log report daily and keep a history file for comparison. Because abnormal DB2 termination can indicate integrity problems, you should implement an immediate notification procedure to alert the appropriate personnel (DBA, systems supervisor, and so on) of abnormal DB2 terminations.

## **Using internal integrity reports to check data consistency**

You can generate internal integrity reports for application programs and for utilities.

**For application programs:** You should record any DB2 return codes that indicate possible data integrity problems, such as inconsistency between index and table information, physical errors on database disk, and so on. All programs must check the SQLCODE or the SQLSTATE for the return code that is issued after an SQL statement is run. DB2 records, on SMF, the occurrence (but not the cause) of physical disk errors and application program abends. The program can retrieve and report this information; the system log (SYSLOG) and the DB2 job output also have this information. However, in some cases, only the program can provide enough detail to identify the exact nature of problem.

You can incorporate these integrity reports into application programs, or you can use them separately as part of an interface. The integrity report records the incident in a history file and writes a message to the operator's console, a database administrator's TSO terminal, or a dedicated printer for certain codes. The recorded information includes:

- Date
- Time
- Authorization ID
- Terminal ID or job name
- Application
- Affected view or affected table
- Error code
- Error description

Review reports frequently by time and by authorization ID.

*For utilities:* When a DB2 utility reorganizes or reconstructs data in the database, it produces statistics to verify record counts and to report errors. The LOAD and REORG utilities produce data record counts and index counts to verify that no records were lost. In addition to that, keep a history log of any DB2 utility that updates data, particularly REPAIR. Regularly produce and review these reports, which you can obtain through SMF customized reporting or a user-developed program.

---

## Chapter 14. A sample security plan for employee data

This chapter shows one approach to enforcing a security plan by using authorization IDs, implicit privileges, granted privileges and authorities, and the audit trace. Do not view this sample security plan as an exact model for your security plan. Instead, use this sample to understand various possibilities and problem areas that you might encounter when you implement your security plan.

Suppose that the Spiffy Computer Company management team determines the following security objectives:

- Managers can see, but not update, all of the employee data for members of their own departments. Managers of managers can see all of the data for employees of departments that report to them.
- The employee table resides at a central location. Managers at remote locations can query the data in that table.
- The payroll operations department makes changes to the employee table. Members of the payroll operations department can update any column of the employee table except for the salary, bonus, and commission columns. Furthermore, members of payroll operations can update any row except for rows that are for members of their own department. Because changes to the table are made only from a central location, distributed access does not affect payroll operations.
- Changes to the salary, bonus, and commission columns are made through a process that involves the payroll update table. When an employee's compensation changes, a member of the payroll operations department can insert rows in the payroll update table. For example, a member of the payroll operations department might insert a row in the compensation table that lists an employee ID and an updated salary. Next, the payroll management group can verify inserted rows and transfer the changes to the employee table.
- No one else can see the employee data. The security plan cannot fully achieve this objective because some ID must occasionally exercise SYSADM authority. While exercising SYSADM authority, an ID can retrieve any data in the system. The security plan uses the trace facility to monitor the use of that power.

The following sections discuss how to implement a security plan that accomplishes the objectives:

- "Securing manager access"
- "Securing payroll operations access" on page 305
- "Securing administrator, owner, and other access" on page 308

---

### Securing manager access

The Spiffy Computer Company imposes the following security restrictions on managers:

- Managers can retrieve, but not change, all information in the employee table for members of their own departments.
- Managers of managers have the same privileges for their own departments and for the departments that directly report to them.

Spiffy Computer Company can most easily implement these restrictions by using views.

**Example:** To create a view of employee data for every employee that reports to a manager, the Spiffy security planners perform the following steps:

1. Add a column that contains manager IDs to DSN8810.DEPT, as shown in the following statement:

```
ALTER TABLE DSN8810.DEPT
  ADD MGRID CHAR(8) FOR SBCS DATA NOT NULL WITH DEFAULT;
```

2. Create a view that selects employee information about employees that work for a given manager, as shown in the following statement:

```
CREATE VIEW DEPTMGR AS
  SELECT * FROM DSN8810.EMP, DSN8810.DEPT
  WHERE WORKDEPT = DEPTNO
  AND MGRID = USER;
```

3. Ensure that every manager has the SELECT privilege on the view. See “Granting the SELECT privilege to managers” for information about ensuring that every manager has the appropriate SELECT privilege.

## Granting the SELECT privilege to managers

The security planners for Spiffy Computer Company can take one of two approaches when they grant the SELECT privilege on a view to managers:

### Individual approach

Grant privileges to individual IDs, and revoke them if the user of the ID leaves the company or transfers to another position.

### Functional approach

Create RACF groups, and grant privileges to the group IDs, with the intention of never revoking them. When an individual ID needs those privileges, connect that ID to the group; disconnect the ID when its user leaves or transfers.

The Spiffy security planners know that the functional approach is usually more convenient in the following situations:

- Each function, such as the manager function, requires many different privileges. When functional privileges are revoked from one user, they must be granted to another user.
- Several users need the same set of privileges.
- The privileges are given with the grant option, or the privileges let users create objects that must persist after their original owners leave or transfer. In both cases, revoking the privileges might not be appropriate. The revokes cascade to other users. To change ownership, you might need to drop objects and re-create them.

Some of the Spiffy requirements for securing manager access suggest the functional approach. However, in this case, the function needs only one privilege. The privilege does not carry the grant option, and the privilege does not allow new objects to be created.

Therefore, the Spiffy security planners choose the individual approach, and plan to re-examine their decision later. Spiffy security planners grant all managers the SELECT privilege on the views for their departments.

**Example:** To grant the SELECT privilege on the DEPTMGR view to the manager with ID EMP0060, they use the following GRANT statement:

```
GRANT SELECT ON DEPTMGR TO EMP0060;
```

## Securing distributed access

Some managers must use views to query data in the central employee table from remote locations. Furthermore, the security plan must ensure that this type of distributed access is secure. To secure distributed access to employee data, the Spiffy security planners must address the following questions:

- Which IDs should hold privileges on which views?
- How do the central location and the remote locations divide security responsibilities for IDs?

The Spiffy security planners answer those questions with the following decisions:

- IDs that are managed at the central location hold privileges on views for departments that are at remote locations. For example, the ID MGRD11 has the SELECT privilege on the view DEPTD11.
- If the manager of Department D11 uses a remote system, the ID at that system must be translated to MGRD11. Then a request is sent to the central system. All other IDs are translated to CLERK before they are sent to the central system.
- The communications database (CDB) manages the translated IDs, like MGRD11.
- An ID from a remote system must be authenticated on any request to the central system.

The following sections describe how the Spiffy security planners plan to implement their distributed access plan:

- “Actions at the central server location”
- “Actions at remote locations” on page 304.

### Actions at the central server location

The following actions must occur at the central server location to enable distributed access that the Spiffy security plan requires:

- The central DB2 subsystem must authenticate every incoming ID with RACF.
- For SNA connections, the Spiffy security planners must include an entry in table SYSIBM.LUNAMES in the CDB; the entry in the LUNAME column identifies the LU name of every remote location. The entry must specify that connections must be verified.

**Example:** Table 87 shows an entry in SYSIBM.LUNAMES for LUREMOTE.

Table 87. The SYSIBM.LUNAMES table at the central location

LUNAME	USERNAMES	SECURITY_IN	ENCRYPTPSWDS
LUREMOTE	blank	V	N

The value of V for SECURITY\_IN indicates that incoming remote connections must include verification. The value of N for ENCRYPTPSWDS indicates that passwords are not in internal RACF encrypted format.

The security plan treats all remote locations alike, so it does not require encrypted passwords. The option to require encrypted passwords is available only between two DB2 subsystems that use SNA connections.

- For TCP/IP connections, the Spiffy security planners must set the TCP/IP ALREADY VERIFIED field of installation panel DSNTIP5 to NO. This setting ensures that the incoming requests that use TCP/IP are not accepted without authentication.
- The Spiffy security planners must grant all privileges and authorities that are required by the manager of Department D11 to the ID, MGRD11. The security planners must grant similar privileges to IDs that correspond to the remaining managers.

## Actions at remote locations

The following actions must occur at the remote locations to enable distributed access for the Spiffy security plan:

- For SNA connections, the Spiffy security planners must include an entry in table SYSIBM.LUNAMES for the LU name of the central location. The entry must specify an outbound ID translation for attachment requests to that location.

**Example:** Table 88 shows an entry in SYSIBM.LUNAMES for LUCENTRAL.

*Table 88. The SYSIBM.LUNAMES table at the remote location*

LUNAME	USERNAMES	SECURITY_OUT
LUCENTRAL	O	R

The value of O for USERNAMES indicates that translation checking is performed on outbound IDs, but not on inbound IDs. The value of R for SECURITY\_OUT indicates that outbound connection requests contain a user ID and a RACF PassTicket.

- For TCP/IP connections, the Spiffy security planners must include an entry in table SYSIBM.IPNAMES for the LU name that is used by the central location. The content of the LUNAME column is used to generate RACF PassTickets. The entry must specify outbound ID translation for requests to that location.

**Example:** Table 89 shows an entry in SYSIBM.IPNAMES for LUCENTRAL.

*Table 89. The SYSIBM.IPNAMES table at the remote location*

LINKNAME	USERNAMES	SECURITY_OUT	IPADDR
LUCENTRAL	O	R	central.vnet.ibm.com

- The Spiffy security planners must include entries in table SYSIBM.USERNAMES to translate outbound IDs.

**Example:** Table 90 shows two entries in SYSIBM.USERNAMES.

*Table 90. The SYSIBM.USERNAMES table at the remote location*

TYPE	AUTHID	LINKNAME	NEWAUTHID
O	MEL1234	LUCENTRAL	MGRD11
O	blank	LUCENTRAL	CLERK

MEL1234 is translated to MGRD11 before it is sent to the LU that is specified in the LINKNAME column. All other IDs are translated to CLERK before they are sent to that LU.

**Exception:** For a product other than DB2 UDB for z/OS, the actions at the remote location might be different. If you use a different product, check the documentation for that product. The remote product must satisfy the requirements that are imposed by the central subsystem.

## Auditing manager use

Because Spiffy payroll data is extremely sensitive, the security plan requires that the audit trace is automatically started for all classes whenever DB2 is started. To ensure that an audit record exists for every access to the employee table, the Spiffy security planners create the employee table with AUDIT ALL. Every week, the security planners scan the records and determine the number of accesses by each manager.

The report highlights any number of accesses outside an expected range. The Spiffy system operator makes a summary of the reports every two months, and

scans it for unusual patterns of access. A large number of accesses or an unusual pattern might reveal use of a manager's logon ID by an unauthorized employee.

---

## Securing payroll operations access

The Spiffy Computer Company imposes the following restrictions on members of the payroll operations department:

- Members of the payroll operations department can update any column of the employee table except for SALARY, BONUS, and COMM.
- Members of payroll operations can update any row except for rows that are for members of their own department.

Because changes to the table are made only from the central location, distributed access does not affect payroll operations.

The Spiffy security planners can most easily implement these security objectives for members of the payroll operations department by using views. The PAYDEPT view shows all the columns of the employee table except for job, salary, bonus, and commission. The view does not show the rows for members of the payroll operations department.

**Example:** The WORKDEPT value for the payroll operations department is P013. The owner of the employee table uses the following statement to create the PAYDEPT view:

```
CREATE VIEW PAYDEPT AS
  SELECT EMPNO, FIRSTNME, MIDINT, LASTNAME, WORKDEPT,
         PHONENO, HIREDATE, JOB, EDLEVEL, SEX, BIRTHDATE
  FROM DSN8810.EMP
  WHERE WORKDEPT<>'P013'
  WITH CHECK OPTION;
```

The CHECK OPTION ensures that every row that is inserted or updated through the view conforms to the definition of the view.

A second view, the PAYMGR view, gives Spiffy payroll managers access to any record, including records for the members of the payroll operations department.

**Example:** The owner of the employee table uses the following statement to create the PAYMGR view:

```
CREATE VIEW PAYMGR AS
  SELECT EMPNO, FIRSTNME, MIDINT, LASTNAME, WORKDEPT,
         PHONENO, HIREDATE, JOB, EDLEVEL, SEX, BIRTHDATE
  FROM DSN8810.EMP
  WITH CHECK OPTION;
```

Neither PAYDEPT nor PAYMGR provides access to compensation amounts. When a row is inserted for a new employee, the compensation amounts remain null. An update process can change these values at a later time. The owner of the employee table creates, owns, and grants privileges on both views. For information about granting privileges on these views, see “Granting privileges to payroll operations and payroll management” on page 307.

## Securing compensation updates

The Spiffy security plan does not allow members of payroll operations to update compensation amounts directly. Instead, a separate payroll update table contains the employee ID, job, salary, bonus, and commission. Members of payroll operations make all job, salary, and bonus changes to the payroll update table,

except those for their own department. After they verify the prospective changes, the managers of payroll operations run an application program. The program reads the payroll update table and makes the corresponding changes to the employee table. Only the payroll update program has the privilege of updating job, salary, and bonus in the employee table.

Spiffy Computer Company calculates commission amounts separately by using a complicated formula. The formula considers the employee's job, department, years of service with the company, and responsibilities for various projects. The formula is embedded in the commission program, which is run regularly to insert new commission amounts in the payroll update table. The plan owner must have the SELECT privilege on the employee table and other tables to run the commission program.

## Additional controls for compensation updates

By separating potential salary changes into the payroll update table, the Spiffy security planners allow payroll management to verify changes before they go into effect. At Spiffy Computer Company, managers check the changes against a written change request that is signed by a required level of management. The Spiffy security planners consider that check to be the most important control on salary updates, but the plan also includes the following controls:

- The employee ID in the payroll update table is a foreign key column that refers to the employee ID in the employee table. Enforcing the referential constraint prevents an employee ID from being changed to an invalid value.
- The employee ID in the payroll update table is also a primary key for that table. Therefore, the values in the employee ID column must be unique. Because of enforced uniqueness, every change that is made for any one employee during a given operating period must appear in the same row of the table. No two rows can carry conflicting changes.

The Spiffy security plan documents an allowable range of salaries, bonuses, and commissions for each job level. To keep the values within the allowable ranges, the Spiffy security planners use table check constraints for the salaries, bonuses, and commissions. The planners use this approach because it is both simple and easy to control. See Part 1 of *DB2 Application Programming and SQL Guide* for information about using table check constraints.

In a similar situation, you might also consider the following ways to ensure that updates and inserts stay within certain ranges:

- Keep the ranges in a separate DB2 table. To verify changes, query the payroll update table and the table of ranges. Retrieve any rows for which the planned update is outside the allowed range.
- Build the ranges into a validation routine. Apply the validation routine to the payroll update table to automatically reject any insert or update that is outside the allowed range.
- Embody the ranges in a view of the payroll table, using WITH CHECK OPTION, and make all updates to the view. The ID that owns the employee table also owns the view.
- Create a trigger to prevent salaries, bonuses, and commissions from increasing by more than the percent that is allowed for each job level. See *DB2 SQL Reference* for more information about using triggers.

## Granting privileges to payroll operations and payroll management

The Spiffy security plan for the payroll operations department strongly suggests the functional approach, for the following reasons:

- Payroll operations members require several privileges, including the SELECT, INSERT, UPDATE, and DELETE privileges on the PAYDEPT view.
- Several members of the department require the same set of privileges.
- If members of the department leave, others are hired or transferred to replace the departing members.

Therefore, the security plan calls for a RACF group for the payroll operations department. DB2USER can define the group, as described in “Add RACF groups” on page 270. DB2USER can retain ownership of the group, or it can assign the ownership to an ID that is used by payroll management.

The owner of the employee table can grant the privileges that the group requires. The owner grants all required privileges to the group ID, with the intent not to revoke them. The primary IDs of new members of the department are connected to the group ID, which becomes a secondary ID for each of them. The primary IDs of members who leave the department are disconnected from the group ID.

**Example:** The following statement grants the SELECT, INSERT, UPDATE, and DELETE privileges on the PAYDEPT view to the payroll operations group ID PAYOPS:

```
GRANT SELECT, INSERT, UPDATE, DELETE ON PAYDEPT TO PAYOPS;
```

This statement grants the privileges without the GRANT OPTION to keep members of payroll operations from granting privileges to other users.

The payroll managers require different privileges and a different RACF group ID. The Spiffy security planners add a RACF group for payroll managers and name it PAYMGRS. The security planners associate the payroll managers’ primary IDs with the PAYMGRS secondary ID. Next, privileges on the PAYMGR view, the compensation application, and the payroll update application are granted to PAYMGRS. The payroll update application must have the appropriate privileges on the update table.

**Example:** The following statement grants the SELECT, INSERT, UPDATE, and DELETE privileges on the PAYMGR view to the payroll managers’ group ID PAYMGRS:

```
GRANT SELECT, INSERT, UPDATE, DELETE ON PAYMGR TO PAYMGRS;
```

**Example:** The following statement grants the EXECUTE privilege on the compensation application:

```
GRANT EXECUTE ON PLAN COMPENS TO PAYMGRS;
```

## Auditing payroll operations and payroll management

Like the employee table, the payroll update table is created with AUDIT ALL. For both tables, the audit trace reports the number of accesses by the payroll operations and payroll management groups. The Spiffy security planners scan the reports of payroll access for large numbers or unusual patterns of access.

---

## Securing administrator, owner, and other access

In addition to the privileges of managers, the payroll operations department, and payroll management, the security plan considers the privileges of the following roles:

- “Securing access by IDs with database administrator authority”
- “Securing access by IDs with system administrator authority”
- “Securing access by owners with implicit privileges on objects” on page 309
- “Securing access by other users” on page 310

### Securing access by IDs with database administrator authority

An ID with DBADM authority over a database has many privileges on that database and its tables. These privileges include the SELECT, INSERT, DELETE, UPDATE, and ALTER statements on any table in the database, and the CREATE and DROP statements on indexes for those tables. For security reasons, the Spiffy security planners prefer not to grant all of the privileges that come with DBADM authority on DSN8D81A. DSN8D81A is the database that holds the employee table and the payroll update table.

The Spiffy security planners prefer to grant DBCTRL authority on the database because granting DBCTRL authority does not expose as many security risks as granting DBADM authority. DBCTRL authority allows an ID to support the database without allowing the ID to retrieve or change the data in the tables. However, database DSN8D81A contains several additional tables (see Appendix A, “DB2 sample tables,” on page 1035). These additional tables require some of the privileges that are included in DBADM authority but not included in DBCTRL authority.

The Spiffy security planners decide to compromise between the greater security of granting DBCTRL authority and the greater flexibility of granting DBADM authority. To balance the benefits of each authority, the Spiffy security planners create an administrative ID with some, but not all of the DBADM privileges. The security plan calls for a RACF group ID with the following authorities and privileges:

- DBCTRL authority over DSN8D81A
- The INDEX privilege on all tables in the database except the employee table and the payroll update table
- The SELECT, INSERT, UPDATE, and DELETE privileges on certain tables, excluding the employee table and the payroll update table

An ID with SYSADM authority grants the privileges to the group ID.

In a similar situation, you also might consider putting the employee table and the payroll update table in a separate database. Then you can grant DBADM authority on DSN8D81A, and grant DBCTRL authority on the database that contains the employee table and the payroll update table.

### Securing access by IDs with system administrator authority

An ID with SYSADM authority can access data from any table in the entire DB2 subsystem, including the employee table and the payroll update table. The Spiffy security planners want to minimize the security risk that is associated with granting SYSADM authority by granting the authority to as few users as possible. They know that the subsystem might require SYSADM authority only for certain

tasks and only for relatively short periods. They also know that the privileges that are associated with the SYSADM authority give an ID control over all of the data in a subsystem.

To limit the number of users with SYSADM authority, the Spiffy security plan grants the authority to DB2OWNER, the ID that is responsible for DB2 security. That does not mean that only IDs that are connected to DB2OWNER can exercise privileges that are associated with SYSADM authority. Instead, DB2OWNER can grant privileges to a group, connect other IDs to the group as needed, and later disconnect them.

The Spiffy security planners prefer to have multiple IDs with SYSCTRL authority instead of multiple IDs with SYSADM authority. IDs with SYSCTRL authority can exercise most of the SYSADM privileges and can assume much of the day-to-day work. IDs with SYSCTRL authority cannot access data directly or run plans unless the privileges for those actions are explicitly granted to them. However, they can run utilities, examine the output data sets, and grant privileges that allow other IDs to access data. Therefore, IDs with SYSCTRL authority can access some sensitive data, but they cannot easily access the data. As part of the Spiffy security plan, DB2OWNER grants SYSCTRL authority to selected IDs.

The Spiffy security planners also use RACF group IDs or secondary IDs to relieve the need to have SYSADM authority continuously available. SYSADM grants the necessary privileges to a RACF group or secondary ID. IDs that belong to the group can then bind plans and packages on their own behalf.

## **Securing access by owners with implicit privileges on objects**

The Spiffy security plan must consider the ID that owns and grants privileges on the tables, views, and programs. The ID that owns these objects has many implicit privileges on the objects, including the SELECT and UPDATE privileges on the employee table. The owner of the objects can also grant privileges on the objects to other users.

The Spiffy security planners want to limit the number of IDs that have privileges on the employee table and the payroll update table to the smallest convenient value. To meet that objective, they decide that the owner of the employee table should issue all of the CREATE VIEW and GRANT statements. They also decide to have the owner of the employee table own the plans and packages that are associated with employee data. The employee table owner implicitly has the following privileges, which the plans and packages require:

- The owner of the payroll update program must have the SELECT privilege on the payroll update table and the UPDATE privilege on the employee table.
- The owner of the commission program must have the UPDATE privilege on the payroll update table and the SELECT privilege on the employee table.
- The owners of several other payroll programs must have the proper privileges to do payroll processing, such as printing payroll checks, writing summary reports, and so on.

To bind these plans and packages, an ID must have the BIND or BINDADD privileges.

The list of privileges that are required by the owner of the employee table suggests the functional approach. The Spiffy security planners create a RACF group for the owner of the employee table.

## Securing access by other users

Exceptions occur when any user other than the following users accesses the employee table or the payroll table:

- Department managers
- Members of the payroll operations department
- Payroll managers
- The payroll update program

The audit report lists each exception in full. Auditors check each exception to determine whether it was a planned operation by the users with SYSADM or DBADM authority, or the employee table owner.

The audit report also lists denials of access to the tables. Those denials represent attempts by unauthorized IDs to use the tables. Some are possibly accidental; others can be attempts to violate the security system.

After running the periodic reports, the security planners archive the audit records. The archives provide a complete audit trail of access to the employee data through DB2.

Restarting CICS . . . . .	388
Displaying indoubt units of recovery . . . . .	389
Recovering indoubt units of recovery manually . . . . .	389
Displaying postponed units of recovery . . . . .	389
Controlling CICS connections . . . . .	389
Defining CICS threads . . . . .	390
Monitoring the threads . . . . .	390
Disconnecting applications . . . . .	390
Disconnecting from CICS . . . . .	391
Orderly termination . . . . .	391
Forced termination . . . . .	391
Controlling IMS connections . . . . .	392
Connecting to the IMS control region . . . . .	392
Thread attachment . . . . .	393
Thread termination . . . . .	394
Displaying indoubt units of recovery . . . . .	394
Recovering indoubt units of recovery . . . . .	395
Displaying postponed units of recovery . . . . .	395
Duplicate correlation IDs . . . . .	396
Resolving residual recovery entries . . . . .	396
Controlling IMS dependent region connections . . . . .	397
Connecting from dependent regions . . . . .	397
Monitoring the activity on connections . . . . .	398
Disconnecting from dependent regions . . . . .	400
Disconnecting from IMS . . . . .	400
Controlling RRS connections . . . . .	401
Connecting to RRS using RRSF . . . . .	401
Restarting DB2 and RRS. . . . .	402
Displaying indoubt units of recovery . . . . .	402
Recovering indoubt units of recovery manually . . . . .	402
Displaying postponed units of recovery . . . . .	403
Monitoring RRSF connections . . . . .	403
Displaying RRSF connections . . . . .	403
Disconnecting RRSF applications from DB2 . . . . .	404
Controlling connections to remote systems . . . . .	404
Starting the DDF . . . . .	405
Suspending and resuming DDF server activity . . . . .	405
Monitoring connections to other systems . . . . .	406
The command DISPLAY DDF . . . . .	406
The command DISPLAY LOCATION . . . . .	407
The command DISPLAY THREAD . . . . .	409
Canceling dynamic SQL from a client application . . . . .	414
The command CANCEL THREAD . . . . .	415
Using VTAM commands to cancel threads . . . . .	416
Monitoring and controlling stored procedures . . . . .	417
Displaying information about stored procedures and their environment . . . . .	417
Refreshing the environment for stored procedures or user-defined functions . . . . .	419
Obtaining diagnostic information about stored procedures . . . . .	419
Using NetView to monitor errors . . . . .	420
Stopping the DDF . . . . .	421
Controlling traces . . . . .	422

Controlling the DB2 trace . . . . .	423
Diagnostic traces for attachment facilities . . . . .	424
Diagnostic trace for the IRLM . . . . .	424
Controlling the resource limit facility (governor) . . . . .	425
Changing subsystem parameter values . . . . .	425

**Chapter 18. Managing the log and the bootstrap data set . . . . . 427**

How database changes are made . . . . .	427
Units of recovery . . . . .	427
Rolling back work . . . . .	428
Establishing the logging environment . . . . .	429
Creation of log records . . . . .	429
Retrieval of log records . . . . .	429
Writing the active log. . . . .	430
Writing the archive log (offloading) . . . . .	430
Triggering offload . . . . .	431
The offloading process . . . . .	431
Archive log data sets . . . . .	433
Controlling the log . . . . .	435
Archiving the log . . . . .	435
Dynamically changing the checkpoint frequency . . . . .	437
Monitoring the system checkpoint . . . . .	438
Setting limits for archive log tape units. . . . .	438
Displaying log information . . . . .	438
Resetting the log RBA . . . . .	438
Log RBA range . . . . .	439
Resetting the log RBA value in a data sharing environment. . . . .	439
Resetting the log RBA value in a non-data sharing environment . . . . .	440
Managing the bootstrap data set (BSDS) . . . . .	441
BSDS copies with archive log data sets . . . . .	442
Changing the BSDS log inventory . . . . .	442
Discarding archive log records. . . . .	443
Deleting archive logs automatically . . . . .	443
Locating archive log data sets . . . . .	444

**Chapter 19. Restarting DB2 after termination . . . . . 447**

Termination . . . . .	447
Normal termination . . . . .	447
Abends . . . . .	448
Normal restart and recovery . . . . .	448
Phase 1: Log initialization . . . . .	449
Phase 2: Current status rebuild . . . . .	450
Phase 3: Forward log recovery. . . . .	451
Phase 4: Backward log recovery . . . . .	452
Restarting automatically. . . . .	453
Deferring restart processing . . . . .	454
Restarting with conditions . . . . .	455
Resolving postponed units of recovery . . . . .	456
Errors encountered during RECOVER POSTPONED processing . . . . .	456
Output from RECOVER POSTPONED processing . . . . .	457
Choosing recovery operations for conditional restart . . . . .	457
Conditional restart records . . . . .	458

**Chapter 20. Maintaining consistency across multiple systems . . . . . 459**

Multiple system consistency . . . . .	459	Actions to take . . . . .	490
The two-phase commit process . . . . .	459	Actions to avoid . . . . .	491
Illustration of two-phase commit . . . . .	460	Running the RECOVER utility in parallel . . . . .	492
Maintaining consistency after termination or failure . . . . .	461	Using fast log apply during RECOVER . . . . .	493
Termination for multiple systems . . . . .	462	Reading the log without RECOVER . . . . .	493
Normal restart and recovery for multiple systems . . . . .	462	Copying page sets and data sets . . . . .	493
Phase 1: Log initialization . . . . .	462	Backing up with DFSMS . . . . .	495
Phase 2: Current status rebuild . . . . .	462	Backing up with RVA storage control or Enterprise Storage Server . . . . .	495

---

## Chapter 15. Basic operation

The information under this heading, up to “Running IMS application programs” on page 328, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The simplest elements of operation for DB2 UDB for z/OS are described in this chapter; they include:

- “Entering commands”
- “Starting and stopping DB2” on page 324
- “Submitting work” on page 327
- “Receiving messages” on page 331

Normal operation also requires more complex tasks. They are described in:

- Chapter 17, “Monitoring and controlling DB2 and its connections,” on page 367, which considers the control of connections to IRLM, to TSO, to IMS, and to CICS, as well as connections to other database management systems.
- Chapter 18, “Managing the log and the bootstrap data set,” on page 427, which describes the roles of the log and the bootstrap data set in preparing for restart and recovery.
- Chapter 19, “Restarting DB2 after termination,” on page 447, which tells what happens when DB2 terminates normally or abnormally and how to restart it while maintaining data integrity.
- Chapter 20, “Maintaining consistency across multiple systems,” on page 459, which explains the two-phase commit process and the resolution of indoubt units of recovery.
- Chapter 21, “Backing up and recovering databases,” on page 475, which explains how to prepare for recovery as well as how to recover.

Recovery after various types of failure is described in:

- Chapter 22, “Recovery scenarios,” on page 521
- Chapter 23, “Recovery from BSDS or log failure during restart,” on page 597

*Operating a data sharing group:* Although many of the commands and operational procedures described here are the same in a data sharing environment, some special considerations are described in Chapter 5 of *DB2 Data Sharing: Planning and Administration*. Consider the following issues when you are operating a data sharing group

- New commands used for data sharing, and the concept of command scope
- Logging and recovery operations
- Restart after an abnormal termination
- Disaster recovery procedures
- Recovery procedures for coupling facility resources

---

### Entering commands

You can control most of the operational environment by using DB2 commands. You might need to use other types of commands, including:

- IMS commands that control IMS connections
- CICS commands that control CICS connections

- IMS and CICS commands that allow you to start and stop connections to DB2 and display activity on the connections
- z/OS commands that allow you to start, stop, and change the internal resource lock manager (IRLM)

Using these commands is described in Chapter 17, “Monitoring and controlling DB2 and its connections,” on page 367. For a full description of the commands available, see Chapter 2 of *DB2 Command Reference*.

## DB2 operator commands

The DB2 commands, as well as their functions, are:

### **ALTER BUFFERPOOL**

Sets or alters buffer pool size while DB2 is online.

### **ALTER GROUPBUFFERPOOL**

Alters attributes of group buffer pools, which are used in a data sharing environment.

### **ALTER UTILITY**

Alters the parameter values of an active REORG utility job.

### **ARCHIVE LOG**

Archives (offloads) the current active log.

### **CANCEL THREAD**

Cancels processing for specific local or distributed threads. It can be used for parallel task threads.

### **DISPLAY ARCHIVE**

Displays information about the specifications for archive parameters, status of allocated dedicated tape units, volume and data set names associated with all active tape units, and correlation ID of the requester.

### **DISPLAY BUFFERPOOL**

Displays buffer pool information while DB2 is online.

### **DISPLAY DATABASE**

Displays the status of a database.

### **DISPLAY DDF**

Displays information about the status and configuration of the distributed data facility (DDF), and about the connections or threads controlled by DDF.

### **DISPLAY FUNCTION SPECIFIC**

Displays the statistics about external user-defined functions accessed by DB2 applications.

### **DISPLAY GROUP**

Displays information about the data sharing group to which a DB2 subsystem belongs.

### **DISPLAY GROUPBUFFERPOOL**

Displays status and statistical information about DB2 group buffer pools, which are used in a data sharing environment.

### **DISPLAY LOCATION**

Displays statistics about threads and conversations between remote DB2 subsystem and the local subsystem.

**DISPLAY LOG**

Displays the current checkpoint frequency (CHKFREQ) value, information about the current active log data sets, and the status of the offload task.

**DISPLAY PROCEDURE**

Displays statistics about stored procedures accessed by DB2 applications.

**DISPLAY RLIMIT**

Displays the status of the resource limit facility (governor).

**DISPLAY THREAD**

Displays information about DB2, distributed subsystem connections, and parallel tasks.

**DISPLAY TRACE**

Displays the status of DB2 traces.

**DISPLAY UTILITY**

Displays the status of a utility.

**MODIFY TRACE**

Changes the trace events (IFCIDs) being traced for a specified active trace.

**RECOVER BSDS**

Reestablishes dual bootstrap data sets.

**RECOVER INDOUBT**

Recovers threads left indoubt after DB2 is restarted.

**RECOVER POSTPONED**

Completes backout processing for units of recovery (URs) whose backout was postponed during an earlier restart, or cancels backout processing of the postponed URs if the CANCEL option is used.

**RESET INDOUBT**

Purges DB2 information about indoubt threads.

**SET ARCHIVE**

Controls or sets the limits for the allocation and the deallocation time of the tape units for archive log processing.

**SET LOG**

Modifies the checkpoint frequency (CHKFREQ) value dynamically without changing the value in the subsystem parameter load module.

**SET SYSPARM**

Loads the subsystem parameter module specified in the command.

**START DATABASE**

Starts a list of databases or table spaces and index spaces.

**START DB2**

Initializes the DB2 subsystem.

**START DDF**

Starts the distributed data facility.

**START FUNCTION SPECIFIC**

Activates an external function that is stopped.

**START PROCEDURE**

Starts a stored procedure that is stopped.

**START RLIMIT**

Starts the resource limit facility (governor).

**START TRACE**

Starts DB2 traces.

**STOP DATABASE**

Stops a list of databases or table spaces and index spaces.

**STOP DB2**

Stops the DB2 subsystem.

**STOP DDF**

Stops or suspends the distributed data facility.

**STOP FUNCTION SPECIFIC**

Prevents DB2 from accepting SQL statements with invocations of the specified functions.

**STOP PROCEDURE**

Prevents DB2 from accepting SQL CALL statements for a stored procedure.

**STOP RLIMIT**

Stops the resource limit facility (governor).

**STOP TRACE**

Stops traces.

**TERM UTILITY**

Terminates execution of a utility.

**Where DB2 commands are entered**

You can enter commands from the following sources:

- A z/OS console or z/OS application program
- An IMS terminal or program
- A CICS terminal
- A TSO terminal
- An APF-authorized program
- An IFI application program

*From a z/OS console or z/OS application program:* You can enter all DB2 commands from a z/OS console or a z/OS application program. The START DB2 command must be issued from a z/OS console (or from an APF-authorized program, such as SDSF, that passes the START DB2 to the z/OS console). The command group authorization level must be SYS.

More than one DB2 subsystem can run under z/OS. You prefix a DB2 command with special characters that identify which subsystem to direct the command to. The 1- to 8-character prefix is called the *command prefix*. Specify the command prefix on installation panel DSNTIPM. The default character for the command prefix is -DSN1. Examples in this book use the hyphen (-) for the command prefix.

*From an IMS terminal or program:* You can enter all DB2 commands except START DB2 from either an IMS terminal or program. The terminal or program must be authorized to enter the /SSR command.

An IMS subsystem can attach to more than one DB2 subsystem, so you must prefix a command that is directed from IMS to DB2 with a special character that tells which subsystem to direct the command to. That character is called the *command recognition character* (CRC); specify it when you define DB2 to IMS, in the subsystem member entry in IMS.PROCLIB. (For details, see Part 2 of *DB2 Installation Guide*.)

**Recommendation:** Use the same character for the CRC and the command prefix for a single DB2 subsystem. You need to use a command prefix of one character or you cannot match these identifiers.

The examples in this book assume that both the command prefix and the CRC are the hyphen (-) . However, if you can attach to more than one DB2 subsystem, you must issue your commands using the appropriate CRC. In the following example, the CRC is a question mark character:

You enter:

```
/SSR ?DISPLAY THREAD
```

DB2 returns the following messages:

```
DFS058  SSR COMMAND COMPLETED
DSNV401I ? DISPLAY THREAD REPORT FOLLOWS -
DSNV402I ? ACTIVE THREADS -
:
```

**From a CICS terminal:** You can enter all DB2 commands except START DB2 from a CICS terminal authorized to enter the DSNB transaction code.

For example, you enter:

```
DSNB -DISPLAY THREAD
```

DB2 returns the following messages:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV402I - ACTIVE THREADS -
:
```

CICS can attach to only one DB2 subsystem at a time; therefore CICS does not use the DB2 command prefix. Instead, each command entered through the CICS attachment facility must be preceded by a hyphen (-), as in previous the example. The CICS attachment facility routes the commands to the connected DB2 subsystem and obtains the command responses.

**From a TSO terminal:** You can enter all DB2 commands except START DB2 from a DSN session.

**Example:** The system displays:

```
READY
```

You enter:

```
DSN SYSTEM (subsystem-name)
```

The system displays:

```
DSN
```

You enter:

```
-DISPLAY THREAD
```

DB2 returns the following messages:

```

DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV402I - ACTIVE THREADS -
:

```

A TSO session can attach to only one DB2 subsystem at a time; therefore TSO does not use the DB2 command prefix. Instead, each command that is entered through the TSO attachment facility must be preceded by a hyphen (-), as the preceding example demonstrates. The TSO attachment facility routes the command to DB2 and obtains the command response.

All DB2 commands except START DB2 can also be entered from a DB2I panel using option 7, *DB2 Commands*. For more information about using DB2I, see “Using DB2I (DB2 Interactive)” on page 327.

#

```

**From an APF-authorized program:** As with IMS, DB2 commands (including START DB2) can be passed from an APF-authorized program to multiple DB2 subsystems by the MGCRC (SVC 34) z/OS service. Thus, the value of the command prefix identifies the particular subsystem to which the command is directed. The subsystem command prefix is specified, as in IMS, when DB2 is installed (in the SYS1.PARMLIB member IEFSSNxx). DB2 supports the z/OS WTO Command And Response Token (CART) to route individual DB2 command response messages back to the invoking application program. Use of the CART token is necessary if multiple DB2 commands are issued from a single application program.

For example, to issue DISPLAY THREAD to the default DB2 subsystem from an APF-authorized program run as a batch job, code:

```

MODESUPV DS    0H
          MODESET MODE=SUP,KEY=ZERO
SVC34    SR    0,0
          MGCRC  CMDPARM
          EJECT
CMDPARM  DS    0F
CMDFLG1  DC    X'00'
CMDLENG  DC    AL1(CMDEND-CMDPARM)
CMDFLG2  DC    X'0000'
CMDDATA  DC    C'-DISPLAY THREAD'
CMDEND   DS    0C

```

and DB2 returns the following messages:

```

DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV402I - ACTIVE THREADS -
:
DSN9022I - DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION

```

**From an IFI application program:** An application program can issue DB2 commands using the instrumentation facility interface (IFI). The IFI application program protocols are available through the IMS, CICS, TSO, and call attachment facility (CAF) attaches, and the Resource Recovery Services attachment facility. For an example in which the DB2 START TRACE command for monitor class 1 is issued, see “COMMAND: Syntax and usage with IFI” on page 1160.

## Where command responses go

In most cases, DB2 command responses are returned to the entering terminal or, for batch jobs, appear in the printed listing.

In CICS, you can direct command responses to another terminal. Name the other terminal as the destination (*dest*) in this command:

```

DSNC dest -START DATABASE

```

If a DB2 command is entered from an IMS or CICS terminal, the response messages can be directed to different terminals. If the response includes more than one message, the following cases are possible:

- If the messages are issued in a set, the entire set of messages is sent to the IMS or CICS terminal that entered the command. For example, DISPLAY THREAD issues a set of messages.
- If the messages are issued one after another, and not in a set, only the first message is sent to the terminal that entered the command. Later messages are routed to one or more z/OS consoles via the WTO function. For example, START DATABASE issues several messages one after another.

You can choose alternate consoles to receive the subsequent messages by assigning them the routing codes placed in the DSNZPxxx module when DB2 is installed. If you want to have all of the messages available to the person who sent the command, route the output to a console near the IMS or CICS master terminal.

For APF-authorized programs that run in batch jobs, command responses are returned to the master console and to the system log if hard copy logging is available. Hard copy logging is controlled by the z/OS system command VARY. See *z/OS MVS System Commands* for more information.

## Authorities for DB2 commands

The ability to issue DB2 commands, such as STOP DB2, and to use most other DB2 functions, requires the appropriate privilege or authority. Privileges and authorities can be granted to authorization IDs in many combinations and can also be revoked.

The individual authorities are listed in Figure 9 on page 139. Each administrative authority has the individual authorities shown in its box, and the individual authorities for all the levels beneath it. For example, DBADM has ALTER, DELETE, INDEX, INSERT, SELECT, and UPDATE authorities as well as those listed for DBCTRL and DBMAINT.

Any user with the STOPALL privilege can issue the STOP DB2 command. Besides those who have been granted STOPALL explicitly, the privilege belongs implicitly to anyone with SYSOPR authority or higher. When installing DB2, you can choose:

- One or two authorization IDs with installation SYSADM authority
- Zero, one, or two authorization IDs with installation SYSOPR authority

The IDs with those authorizations are contained in the load module for subsystem parameters (DSNZPxxx).

The START DB2 command can be entered only at a z/OS console authorized to enter z/OS system commands. The command group authorization level must be SYS.

DB2 commands entered from a logged-on z/OS console can be authorized using secondary authorization IDs. The authorization ID associated with a z/OS console is SYSOPR, which carries the authority to issue all DB2 commands except:

- RECOVER BSDS
- START DATABASE
- STOP DATABASE
- ARCHIVE LOG

# APF-authorized programs that issue commands through MGCRC (SVC 34) have  
# SYSOPR authority unless DB2 can determine the program's RACF user ID. In that  
# case, DB2 will use that user ID for authorization. To avoid errors, the user should  
# obtain SYSOPR authority for those DB2 instances.

The authority to start or stop any particular database must be specifically granted to an ID with SYSOPR authority. Likewise, an ID with SYSOPR authority must be granted specific authority to issue the RECOVER BSDS and ARCHIVE LOG commands.

The SQL GRANT statement can be used to grant SYSOPR authority to other user IDs such as the /SIGN user ID or the LTERM of the IMS master terminal.

For information about other DB2 authorization levels, see "Establishing RACF protection for DB2" on page 264. *DB2 Command Reference* also has authorization level information for specific commands.

---

## Starting and stopping DB2

Starting and stopping DB2 is a simple process, and one that you will probably not have to do often. Before DB2 is stopped, the system takes a shutdown checkpoint. This checkpoint and the recovery log give DB2 the information it needs to restart.

This section describes the START DB2 and STOP DB2 commands, explains how you can limit access to data at startup, and contains a brief overview of startup after an abend.

### Starting DB2

When installed, DB2 is defined as a formal z/OS subsystem. Afterward, the following message appears during any IPL of z/OS:

```
DSN3100I - DSN3UR00 - SUBSYSTEM ssnm READY FOR -START COMMAND
```

where *ssnm* is the DB2 subsystem name. At that point, you can start DB2 from a z/OS console that has been authorized to issue system control commands (z/OS command group SYS), by entering the command START DB2. The command must be entered from the authorized console and not submitted through JES or TSO.

It is *not* possible to start DB2 by a JES batch job or a z/OS START command. The attempt is likely to start an address space for DB2 that then abends, probably with reason code X'00E8000F'.

# You can also start DB2 from an APF-authorized program by passing a START DB2  
# command to the MGCRC (SVC 34) z/OS service.

### Messages at start

The system responds with some or all of the following messages depending on which parameters you chose:

```
$HASP373 xxxxMSTR STARTED  
DSNZ002I - SUBSYS ssnm SYSTEM PARAMETERS  
          LOAD MODULE NAME IS dsnzparm-name  
DSNY001I - SUBSYSTEM STARTING  
DSNJ127I - SYSTEM TIMESTAMP FOR BSDS=87.267 14:24:30.6  
DSNJ001I - csect CURRENT COPY n ACTIVE LOG DATA  
          SET IS DSNAME=...,  
          STARTRBA=..., ENDRBA=...  
DSNJ099I - LOG RECORDING TO COMMENCE WITH  
          STARTRBA = xxxxxxxxxxxx
```

```

$HASP373 xxxxDBM1 STARTED
DSNR001I - RESTART INITIATED
DSNR003I - RESTART...PRIOR CHECKPOINT RBA=xxxxxxxxxxxxx
DSNR004I - RESTART...UR STATUS COUNTS...
           IN COMMIT=nnnn, INDOUBT=nnnn, INFLIGHT=nnnn,
           IN ABORT=nnnn, POSTPONED ABORT=nnnn
DSNR005I - RESTART...COUNTS AFTER FORWARD RECOVERY
           IN COMMIT=nnnn, INDOUBT=nnnn
DSNR006I - RESTART...COUNTS AFTER BACKWARD RECOVERY
           INFLIGHT=nnnn, IN ABORT=nnnn, POSTPONED ABORT=nnnn
DSNR002I - RESTART COMPLETED
DSN9002I -DSNYASCP 'START DB2' NORMAL COMPLETION
DSNV434I - DSNVRP NO POSTPONED ABORT THREADS FOUND
DSN9022I - DSNVRP 'RECOVER POSTPONED' NORMAL COMPLETION

```

If any of the *nnnn* values in message DSNR004I are not zero, message DSNR007I is issued to provide the restart status table.

The START DB2 command starts the system services address space, the database services address space, and, depending upon specifications in the load module for subsystem parameters (DSNZPARM by default), the distributed data facility address space and the DB2-established stored procedures address space. Optionally, another address space, the internal resource lock manager (IRLM), can be started automatically.

### Options at start

Starting invokes the load module for subsystem parameters. This load module contains information specified when DB2 was installed. For example, the module contains the name of the IRLM to connect to. In addition, it indicates whether the distributed data facility (DDF) is available and, if it is, whether it should be automatically started when DB2 is started. For information about using a command to start DDF, see “Starting the DDF” on page 405. You can specify PARM (*module-name*) on the START DB2 command to provide a parameter module other than the one specified at installation.

There is a conditional restart operation, but there are no parameters to indicate normal or conditional restart on the START DB2 command. For information about conditional restart, see “Restarting with conditions” on page 455.

### Restricting access to data

You can restrict access to data with another option of the START DB2 command. Use:

#### ACCESS(MAINT)

To limit access to users who have installation SYSADM or installation SYSOPR authority.

Users with those authorities can do maintenance operations such as recovering a database or taking image copies. To restore access to all users, stop DB2 and then restart it. Either omit the ACCESS keyword or use:

#### ACCESS(\*)

To allow all authorized users to connect to DB2.

### Wait state at start

If a JCL error, such as device allocation or region size, occurs while trying to start the database services address space, DB2 goes into wait status. To end the wait, cancel the system services address space and the distributed data facility address

space from the console. After DB2 stops, check the start procedures of all three DB2 address spaces for correct JCL syntax. See *Data Sharing: Planning and Administration* for more information.

To accomplish the check, compare the expanded JCL in the SYSOUT output against the correct JCL provided in *z/OS MVS JCL User's Guide* or *z/OS MVS JCL Reference*. Then, take the member name of the erroneous JCL procedure also provided in the SYSOUT to the system programmer who maintains your procedure libraries. After finding out which proclib contains the JCL in question, locate the procedure and correct it.

### Starting after an abend

Starting DB2 after it abends is different from starting it after the command STOP DB2 has been issued. After STOP DB2, the system finishes its work in an orderly way and takes a shutdown checkpoint before stopping. When DB2 is restarted, it uses information from the system checkpoint and recovery log to determine the system status at shutdown.

When a power failure occurs, DB2 abends without being able to finish its work or take a shutdown checkpoint. When DB2 is restarted after an abend, it refreshes its knowledge of its status at termination using information on the recovery log and notifies the operator of the status of various units of recovery.

You can indicate that you want DB2 to postpone some of the backout work traditionally performed during system restart. You can delay the backout of long running units of recovery (URs) using installation options LIMIT BACKOUT and BACKOUT DURATION on panel DSNTIPL. For a description of these installation parameters, see Chapter 2 of *DB2 Installation Guide*.

Normally, the restart process resolves all inconsistent states. In some cases, you have to take specific steps to resolve inconsistencies. There are steps you can take to prepare for those actions. For example, you can limit the list of table spaces that are recovered automatically when DB2 is started. For an explanation of the causes of database inconsistencies and how you can prepare to recover from them, see Chapter 19, "Restarting DB2 after termination," on page 447.

## Stopping DB2

Before stopping, all DB2-related write to operator with reply (WTOR) messages must receive replies. Then one of the following commands terminates the subsystem:

```
-STOP DB2 MODE(QUIESCE)
-STOP DB2 MODE(FORCE)
```

For the effects of the QUIESCE and FORCE options, see "Normal termination" on page 447. In a data sharing environment, see *Data Sharing: Planning and Administration*.

The following messages are returned:

```
DSNY002I - SUBSYSTEM STOPPING
DSN9022I - DSNYASCP '-STOP DB2' NORMAL COMPLETION
DSN3104I - DSN3EC00 - TERMINATION COMPLETE
```

Before DB2 can be restarted, the following message must also be returned to the z/OS console that is authorized to enter the START DB2 command:

```
DSN3100I - DSN3EC00 - SUBSYSTEM ssnm READY FOR -START COMMAND
```

If the STOP DB2 command is not issued from a z/OS console, messages DSNY002I and DSN9022I are not sent to the IMS or CICS master terminal operator. They are routed only to the z/OS console that issued the START DB2 command.

---

## Submitting work

An application program running under TSO, IMS, or CICS can make use of DB2 resources by executing embedded SQL statements. How to run application programs from those environments is explained under:

- “Running TSO application programs” on page 327
- “Running IMS application programs” on page 328
- “Running CICS application programs” on page 329
- “Running batch application programs” on page 330
- “Running application programs using CAF” on page 330
- “Running application programs using RRSAP” on page 331

In each case, there are some conditions that the application program must meet to embed SQL statements and to authorize the use of DB2 resources and data.

All application programming defaults, including the subsystem name that the programming attachments discussed here use, are in the DSNHDECP load module. Make sure your JCL specifies the proper set of program libraries.

## Using DB2I (DB2 Interactive)

Using the interactive program DB2I, you can run application programs and perform many DB2 operations by entering values on panels. DB2I runs under TSO using ISPF (Interactive System Productivity Facility) services. To use it, follow your local procedures for logging on to TSO, and enter ISPF. The DB2I menu is shown in Part 1 of *DB2 Application Programming and SQL Guide*.

You control each operation by entering the parameters that describe it on the panels provided. DB2 also provides help panels to:

- Explain how to use each operation
- Provide the syntax for and examples of DSN subcommands, DB2 operator commands, and DB2 utility control statements

To access the help panels, press the HELP PF key. (The key can be set locally, but typically is PF1.)

## Running TSO application programs

To run TSO application programs:

1. Log on.
2. Enter the DSN command.
3. Respond to the prompt by entering the RUN subcommand.

The following example runs application program DSN8BC3. The program is in library *prefix*.RUNLIB.LOAD, the name assigned to the load module library.

```
DSN SYSTEM (subsystem-name)
RUN PROGRAM (DSN8BC3) PLAN(DSN8BH81) LIB ('prefix.RUNLIB.LOAD')
END
```

A TSO application program that you run in a DSN session must be link-edited with the TSO language interface program (DSNELI). The program cannot include IMS DL/I calls because that requires the IMS language interface module (DFSLI000).

The terminal monitor program (TMP) attaches the DB2-supplied DSN command processor, which in turn attaches the application program.

The DSN command starts a DSN session, which in turn provides a variety of subcommands and other functions. The DSN subcommands are:

**ABEND**

Causes the DSN session to terminate with a DB2 X'04E' abend completion code and with a DB2 abend reason code of X'00C50101'.

**BIND PACKAGE**

Generates an application package.

**BIND PLAN**

Generates an application plan.

**DCLGEN**

Produces SQL and host language declarations.

**END** Ends the DB2 connection and returns to TSO.

**FREE PACKAGE**

Deletes a specific version of a package.

**FREE PLAN**

Deletes an application plan.

**REBIND PACKAGE**

Regenerates an existing package.

**REBIND PLAN**

Regenerates an existing plan.

**RUN** Executes a user application program.

**SPUFI** Invokes a DB2I facility for executing SQL statements not embedded in an application program.

You can also issue the following DB2 and TSO commands from a DSN session:

- Any TSO command except TIME, TEST, FREE, and RUN.
- Any DB2 command except START DB2. For a list of those commands, see "DB2 operator commands" on page 318.

DB2 uses the following sources to find an authorization for access by the application program. DB2 checks the first source listed; if it is unavailable, it checks the second source, and so on.

1. RACF USER parameter supplied at logon
2. TSO logon user ID
3. Site-chosen default authorization ID
4. IBM-supplied default authorization ID

Either the RACF USER parameter or the TSO user ID can be modified by a locally defined authorization exit routine.

## Running IMS application programs

# To run IMS application programs, you can either enter transactions from an IMS  
# terminal or you can invoke IMS transactions and commands by using the  
# DB2-supplied stored procedures DSNAIMS or DSNAIMS2. Use DSNAIMS to send  
# commands and single-segment transactions, and use DSNAIMS2 to send  
# commands and multi-segment transactions. For more information about DSNAIMS  
# and DSNAIMS2, see Appendix J, "DB2-supplied stored procedures," on page 1261.

Application programs that contain SQL statements run in message processing program (MPP), batch message processing (BMP), Fast Path regions, or IMS batch regions.

The program must be link-edited with the IMS language interface module (DFSLI000). It can write to and read from other database management systems using the distributed data facility, in addition to accessing DL/I and Fast Path resources.

DB2 checks whether the authorization ID provided by IMS is valid. For message-driven regions, IMS uses the SIGNON-ID or LTERM as the authorization ID. For non-message-driven regions and batch regions, IMS uses the ASXBUSER field (if RACF or another security package is active). The ASXBUSER field is defined by z/OS as 7 characters. If the ASXBUSER field contains binary zeros or blanks (RACF or another security package is not active), IMS uses the PSB name instead. See Chapter 11, “Controlling access to a DB2 subsystem,” on page 231 for more information about DB2 authorization IDs.

An IMS terminal operator probably notices few differences between application programs that access DB2 data and programs that access DL/I data because no messages relating to DB2 are sent to a terminal operator by IMS. However, your program can signal DB2 error conditions with a message of your choice. For example, at the program’s first SQL statement, it receives an SQL error code if the resources to run the program are not available or if the operator is not authorized to use the resources. The program can interpret the code and issue an appropriate message to the operator.

**Running IMS batch work:** You can run batch DL/I jobs to access DB2 resources; DB2-DL/I batch support uses the IMS attach package.

See Part 5 of *DB2 Application Programming and SQL Guide* for more information about application programs and DL/I batch. See *IMS Application Programming: Design Guide* for more information about recovery and DL/I batch.

## Running CICS application programs

To run CICS applications, enter transactions from CICS terminals. You can also invoke CICS transactions by using the CICS transaction-invocation stored procedure. For information about this stored procedure, see Appendix J, “DB2-supplied stored procedures,” on page 1261

CICS transactions that issue SQL statements must be link-edited with the CICS attachment facility language interface module, DSNCLI, and the CICS command language interface module. CICS application programs can issue SQL, DL/I, or CICS commands. After CICS has connected to DB2, any authorized CICS transaction can issue SQL requests that can write to and read from multiple DB2 instances using the distributed data facility. The application programs run as CICS applications.

DB2 checks an authorization ID related to the transaction against a plan assigned to it. The authorization ID for the transaction can be the operator ID, terminal ID, transaction ID, RACF-authenticated USERID, or another identifier explicitly provided by the resource control table (RCT). See Chapter 11, “Controlling access to a DB2 subsystem,” on page 231 for more information about DB2 authorization IDs.

## Running batch application programs

Batch DB2 work can run in background under the TSO terminal monitor program (TMP) or in an IMS batch message processing (BMP) region. IMS batch regions can issue SQL statements.

Batch work is run in the TSO background under the TSO terminal monitor program (TMP). The input stream can invoke TSO command processors, particularly the DSN command processor for DB2, and can include DSN subcommands such as RUN. The following is an example of a TMP job:

```
//jobname JOB USER=SYSOPR ...
//GO EXEC PGM=IKJEFT01,DYNAMNBR=20
.
user DD statements
.
//SYSTSPRT DD SYSOUT=A
//SYSTSIN DD *
DSN SYSTEM (ssid)
.
subcommand (for example, RUN)
.
END
/*
```

In the example,

- IKJEFT01 identifies an entry point for TSO TMP invocation. Alternate entry points defined by TSO are also available to provide additional return code and ABEND termination processing options. These options permit the user to select the actions to be taken by the TMP upon completion of command or program execution.

Because invocation of the TSO TMP using the IKJEFT01 entry point might not be suitable for all user environments, refer to the TSO publications to determine which TMP entry point provides the termination processing options best suited to your batch execution environment.

- USER=SYSOPR identifies the user ID (SYSOPR in this case) for authorization checks.
- DYNAMNBR=20 indicates the maximum number of data sets (20 in this case) that can be dynamically allocated concurrently.
- z/OS checkpoint and restart facilities do not support the execution of SQL statements in batch programs invoked by RUN. If batch programs stop because of errors, DB2 backs out any changes made since the last commit point. For information about backup and recovery, see Chapter 21, “Backing up and recovering databases,” on page 475. For an explanation of backing out changes to data when a batch program run in the TSO background abends, see Part 5 of *DB2 Application Programming and SQL Guide*.
- (ssid) is the subsystem name or group attachment name.

## Running application programs using CAF

### General-use Programming Interface

The call attachment facility (CAF) allows you to customize and control your execution environments more extensively than the TSO, CICS, or IMS attachment facilities. Programs executing in TSO foreground or TSO background can use either the DSN session or CAF; each has advantages and disadvantages. z/OS batch and started task programs can use only CAF.

IMS batch applications can also access DB2 databases through CAF, though this method does not coordinate the commitment of work between the IMS and DB2 systems. Using the DB2 DL/I batch support for IMS batch applications is highly recommended.

To use CAF, you must first make available a load module known as the call attachment language interface or DSNALI. When the language interface is available, your program can use CAF to connect to DB2 in two ways:

- Implicitly, by including SQL statements or IFI calls in your program just as you would any program
- Explicitly, by writing CALL DSNALI statements

For an explanation of CAF's capabilities and how to use it, see Part 6 of *DB2 Application Programming and SQL Guide*.

End of General-use Programming Interface

## Running application programs using RRSAF

### General-use Programming Interface

The Resource Recovery Services attachment facility (RRSAF) is a DB2 attachment facility that relies on a z/OS component called Resource Recovery Services (z/OS RRS). z/OS RRS provides system-wide services for coordinating two-phase commit operations across z/OS products.

Before you can run an RRSAF application, z/OS RRS must be started. RRS runs in its own address space and can be started and stopped independently of DB2.

To use RRSAF, you must first make available a load module known as the RRSAF language interface or DSNRLI. When the language interface is available, your program can use RRSAF to connect to DB2 in two ways:

- Implicitly, by including SQL statements or IFI calls in your program just as you would any program.
- Explicitly, by using CALL DSNRLI statements to invoke RRSAF functions. Those functions establish a connection between DB2 and RRS and allocate DB2 resources.

See "Controlling RRS connections" on page 401 for a description of how applications connect to DB2 using RRSAF. For an explanation of RRSAF's capabilities and how to use it, see Part 6 of *DB2 Application Programming and SQL Guide*.

End of General-use Programming Interface

---

## Receiving messages

DB2 message identifiers have the form *DSNcxxx*, where:

**DSN** Is the unique DB2 message prefix.

**c** Is a 1-character code identifying the DB2 subcomponent that issued the message. For example:

**2** CICS attachment facility that is shipped with CICS

**M** IMS attachment facility

**U** Utilities

*xxx* Is the message number

*t* Is the message type, with these values and meanings:

<b>A</b>	Immediate action
<b>D</b>	Immediate decision
<b>E</b>	Eventual action
<b>I</b>	Information only

See *DB2 Messages* for an expanded description of message types.

A command prefix, identifying the DB2 subsystem, precedes the message identifier, except in messages from the CICS and IMS attachment facilities. (The CICS attachment facility issues messages in the form DSN2*xxx**t*, and the IMS attachment facility issues messages in the form DSNM*xxx**t*.) CICS and IMS attachment facility messages identify the z/OS subsystem that generated the message.

The IMS attachment facility issues messages that are identified as SSNM*xxxx* and as DFS<sup>™</sup> *xxxx*. The DFS*xxxx* messages are produced by IMS, under which the IMS attachment facility operates.

## Receiving unsolicited DB2 messages

Unsolicited subsystem messages are sent to the z/OS console issuing the START DB2 command, or to consoles assigned the routing codes that were listed in the DSNZP*xxx* module when installing DB2. But the following messages from the IMS and the CICS attachment facilities are exceptions to that rule:

- Specific IMS attachment facility messages are sent to the IMS master terminal.
- Unsolicited CICS messages are sent to the transient data entries specified in the RCT (ERRDEST).
- CICS statistics messages that are issued because of shutdown are sent to the transient data entry specified in the RCT (SHDDEST).

Some DB2 messages sent to the z/OS console are defined as critical using the WTO descriptor code (11). This code signifies “critical eventual action requested” by DB2. Preceded by an at sign (@) or an asterisk (\*), critical DB2 messages remain on the screen until specifically deleted. This prevents them from being missed by the operator, who is required to take a specific action.

## Determining operational control

Table 91 summarizes the operational control that is available at the operator console or terminal.

*Table 91. Operational control summary*

Type of operation	z/OS console	TSO terminal	IMS master terminal	Authorized CICS terminal
Issue DB2 commands and receive replies	Yes	Yes <sup>1</sup>	Yes <sup>1</sup>	Yes <sup>1</sup>
Receive DB2 unsolicited output	Yes	No	No	No
Issue IMS commands	Yes <sup>2</sup>	No	Yes	No

Table 91. Operational control summary (continued)

Type of operation	z/OS console	TSO terminal	IMS master terminal	Authorized CICS terminal
Receive IMS attachment facility unsolicited output	No <sup>3</sup>	No	Yes	No
Issue CICS commands	Yes <sup>4</sup>	No	No	Yes
Receive CICS attachment facility unsolicited output	No <sup>3</sup>	No	No	Yes <sup>5</sup>

**Notes:**

1. Except START DB2. Commands issued from IMS must have the prefix /SSR. Commands issued from CICS must have the prefix DSNC.
2. Using outstanding WTOR.
3. "Attachment facility unsolicited output" does not include "DB2 unsolicited output"; for the latter, see "Receiving unsolicited DB2 messages" on page 332.
4. Use the z/OS command MODIFY *jobname*, CICS command. The z/OS console must already be defined as a CICS terminal.
5. Specify the output destination for the unsolicited output of the CICS attachment facility in the RCT.

---

## Chapter 16. Scheduling administrative tasks

The administrative task scheduler runs tasks that are defined in a task list according to a requested schedule. Tasks can be stored procedures or JCL jobs.

You manage the scheduler task list through DB2 stored procedures that add and remove tasks. You can monitor the task list and the status of executed tasks through user-defined functions that are provided as part of DB2.

Tasks run according to a defined schedule, which can be based on an interval, a point in time, or an event. Activity can be further restricted by a limit on the number of invocations or by earliest and latest invocation dates.

---

### Interacting with the administrative task scheduler

The administrative task scheduler is based on scheduled tasks. DB2 users can add, remove and list scheduled tasks that are executed at planned points in time by the scheduler.

At each point in time when the scheduler detects that a task should be executed, it drives the task execution according to the work described in the task definition. There is no user interaction. The scheduler delegates the execution of the task to one of its execution threads, which executes the stored procedure or the JCL job described in the work definition of the task. The execution thread waits for the end of the execution and notifies the administrative task scheduler. The scheduler stores the execution status of the task in its redundant task lists, in relation with the task itself.

#### Adding a task

You can use the stored procedure `ADMIN_TASK_ADD` to define new scheduled tasks. The parameters that you use when you call the stored procedure define the schedule and the work for each task.

The request and the parameters are transmitted to the administrative task scheduler associated with the DB2 subsystem where the stored procedure has been called. The parameters are checked and if they are valid, the task is added into the scheduler task lists with a unique task name. The task name and the return code are returned to the stored procedure for output.

At the same time, the scheduler analyzes the task to schedule its next execution.

#### Scheduling capabilities of the administrative task scheduler

The administrative task scheduler can execute a task once or many times, at fixed points in time, or in response to events.

Five parameters define the scheduling behavior of the task, in one of four ways:

- *interval*: elapsed time between regular executions
- *point-in-time*: specific times for execution
- *trigger-task-name* alone: specific task to trigger execution
- *trigger-task-name* with *trigger-task-cond* and *trigger-task-code*: specific task with required result to trigger execution

Only one of these definitions can be specified for any single task. The other parameters must be null.

Table 92. Relationship of null and non-null values for scheduling parameters

Parameter specified	Required null parameters
<i>interval</i>	<i>point-in-time</i> <i>trigger-task-name</i> <i>trigger-task-cond</i> <i>trigger-task-code</i>
<i>point-in-time</i>	<i>interval</i> <i>trigger-task-name</i> <i>trigger-task-cond</i> <i>trigger-task-code</i>
<i>trigger-task-name</i> alone	<i>interval</i> <i>point-in-time</i> <i>trigger-task-cond</i> <i>trigger-task-code</i>
<i>trigger-task-name</i> with <i>trigger-task-cond</i> and <i>trigger-task-code</i>	<i>interval</i> <i>point-in-time</i>

If *interval*, *point-in-time*, *trigger-task-name*, *trigger-task-cond*, and *trigger-task-code* are all null, *max-invocations* must be set to 1.

You can restrict scheduled executions either by defining a window of time during which execution is permitted or by specifying how many times a task can execute. Three parameters control restrictions:

- *begin-timestamp*: earliest permitted execution time
- *end-timestamp*: latest permitted execution time
- *max-invocations*: maximum number of executions

The *begin-timestamp* and *end-timestamp* parameters are timestamps that define a window of time during which tasks can start. Before and after this window, the task will not start even if the schedule parameters are met. If *begin-timestamp* is null, the window begins at the time when the task is added, and executions can start immediately. If *end-timestamp* is null, the window extends infinitely into the future, so that repetitive or triggered executions are not limited by time. Timestamps must either be null values or future times, and *end-timestamp* cannot be earlier than *begin-timestamp*.

For repetitive or triggered tasks, the number of executions can be limited using the *max-invocations* parameter. In this case, the task executes no more than the number of times indicated by the parameter, even if the schedule and the window of time would require the task to be executed. Executions that are skipped because they overlap with previous executions that are still running are not counted toward *max-invocations*.

The *max-invocations* parameter defines a limit but no requirement. If the task is executed fewer times than indicated during its execution window, the maximum number of executions will never be reached.

## Defining task schedules

Use different combinations of parameters to define schedules for task executions.

The following ADMIN\_TASK\_ADD parameters provide control over when scheduled tasks execute:

- *interval*
- *point-in-time*
- *trigger-task-name*
- *trigger-task-cond*
- *trigger-task-code*
- *begin-timestamp*
- *end-timestamp*
- *max-invocations*

To define a new scheduled task, connect to the DB2 subsystem with sufficient authorization to call the stored procedure ADMIN\_TASK\_ADD. The following task definitions show some common scheduling options.

To define	Do this
<b>A task that executes one time only:</b>	<p>Set <i>max-invocations</i> to 1.</p> <p>Optionally, provide a value for the <i>begin-timestamp</i> parameter to control when execution happens. Leave other parameters null.</p> <p>For example, if <i>max-invocations</i> is set to 1 and <i>begin-timestamp</i> is set to 2008-05-27-06.30.0, the task executes at 6:30 AM on May 27, 2008.</p> <p>With this definition, the task executes one time. If <i>begin-timestamp</i> has been provided, execution happens as soon as permitted.</p>
<b>A regular repetitive execution:</b>	<p>Set <i>interval</i> to the number of minutes that you want to pass between the start of one execution and the start of the next execution.</p> <p>Optionally, provide values for the <i>max-invocations</i>, <i>begin-timestamp</i>, and <i>end-timestamp</i> parameters to limit execution. Leave other parameters null.</p> <p>For example, if <i>interval</i> is set to 5 and <i>begin-timestamp</i> is set to 2008-05-27-06.30.0, the task executes at 6:30 AM on May 27, 2008, then again at 6:35, 6:40, and so forth.</p> <p>With this definition, the task executes every <i>interval</i> minutes, so long as the previous execution has finished. If the previous execution is still in progress, the new execution is postponed <i>interval</i> minutes. Execution continues to be postponed until the running task completes.</p>

To define	Do this
<p><b>An irregular repetitive execution:</b></p>	<p>Set <i>point-in-time</i> to a valid UNIX cron format string. The string specifies a set of times.</p> <p>Optionally, provide values for the <i>max-invocations</i>, <i>begin-timestamp</i> and <i>end-timestamp</i> parameters to limit execution. Leave other parameters null.</p> <p>For example, if <i>point-in-time</i> is set to 0 22 * * 1,5, the task executes at 10:00 PM each Monday and Friday.</p> <p>With this definition, the task executes at each time specified, so long as the previous execution has finished. If the previous execution is still in progress, the new execution is skipped. Subsequent executions continue to be skipped until the running task completes.</p>
<p><b>An execution that is triggered when another task completes:</b></p>	<p>Set <i>trigger-task-name</i> to the name of the triggering task. Optionally set <i>trigger-task-cond</i> and <i>trigger-task-code</i> to limit execution based on the result of the triggering task. The <i>trigger-task-cond</i> and <i>trigger-task-code</i> parameters must either both be null or both be non-null.</p> <p>Optionally, provide values for the <i>max-invocations</i>, <i>begin-timestamp</i> and <i>end-timestamp</i> parameters to limit execution. Leave other parameters null.</p> <p>For example, assume that a scheduled INSERT job has a task name of test_task. If <i>trigger-task-name</i> is test_task, <i>trigger-task-cond</i> is EQ, and <i>trigger-task-code</i> is 0, then this task executes when the INSERT job completes with a return code of 0.</p> <p>With this definition, the task executes at each time specified, so long as the previous execution has finished. If the previous execution is still in progress, the new execution is skipped. Subsequent executions continue to be skipped until the running task completes.</p>

To define	Do this
An execution that is triggered when DB2 starts:	<p>Set <i>trigger-task-name</i> to DB2START.</p> <p>Optionally, provide values for the <i>max-invocations</i>, <i>begin-timestamp</i> and <i>end-timestamp</i> parameters to limit execution. Leave other parameters null.</p> <p>For example, if <i>trigger-task-name</i> is DB2START, <i>begin-timestamp</i> is 2008-01-01-00.00.0, and <i>end-timestamp</i> is 2009-01-01-00.00.0, the task executes each time that DB2 starts during 2008.</p> <p>With this definition, the task executes at each DB2 start, so long as the previous execution has finished. If the previous execution is still in progress, the new execution is skipped. Subsequent executions continue to be skipped until the running task completes.</p>
An execution that is triggered when DB2 stops:	<p>Set <i>trigger-task-name</i> to DB2STOP.</p> <p>Optionally, provide values for the <i>max-invocations</i>, <i>begin-timestamp</i> and <i>end-timestamp</i> parameters to limit execution. Leave other parameters null.</p> <p>With this definition, the task executes at each DB2 stop, so long as the previous execution has finished. If the previous execution is still in progress, the new execution is skipped. Subsequent executions continue to be skipped until the running task completes.</p>

## Choosing an administrative task scheduler in a data sharing environment

In a data sharing group, tasks can be added, removed, or executed in any of the administrative task schedulers with the same result. Tasks are not localized to a scheduler: a task can be added by one scheduler, and then executed by any of the schedulers in the data sharing group.

To force a task to be executed on a particular scheduler, specify the associated DB2 subsystem ID in the *DB2-SSID* parameter when you schedule the task.

### ADMIN\_TASK\_ADD

SYSPROC.ADMIN\_TASK\_ADD stored procedure adds a task to the scheduler task list.

**GUPI**

### Environment

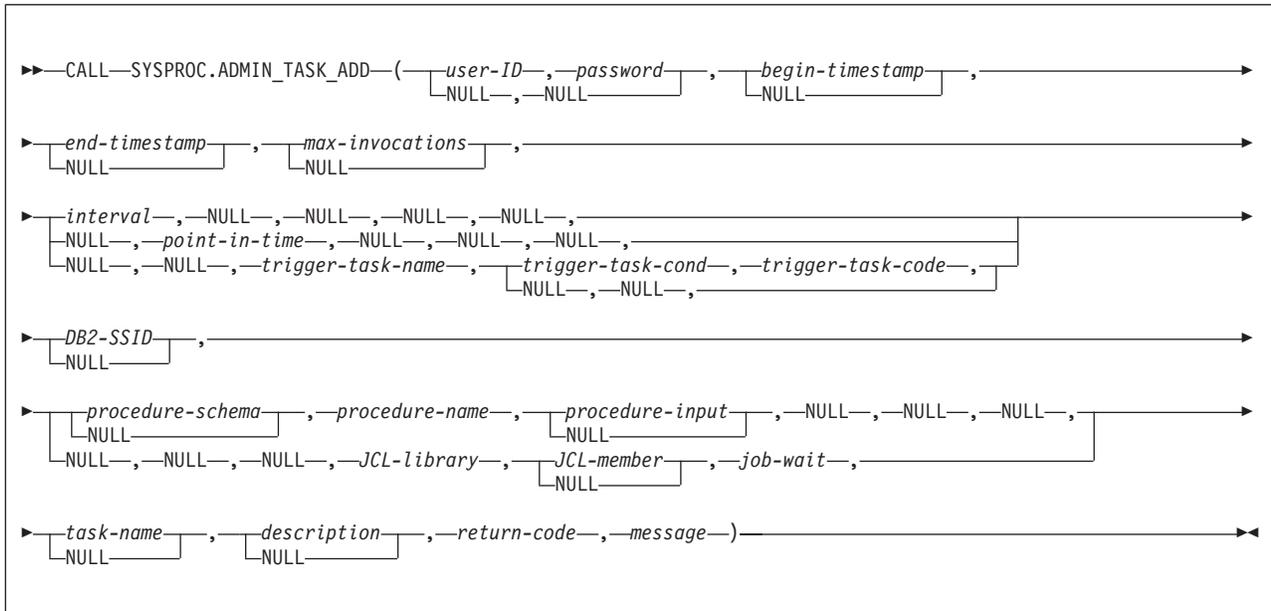

ADMIN\_TASK\_ADD runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

## Authorization

Anyone who can execute this DB2 stored procedure is allowed to add a task.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

## Option descriptions

### *user-ID*

Specifies the user ID under which the task execution is performed.

If this parameter is set to NULL, task execution is performed with the default authorization ID associated with the administrative task scheduler instead.

This is an input parameter of type VARCHAR(128).

### *password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

**Recommendation:** Have the application that invokes this stored procedure pass an encrypted single-use password called a *passticket*.

This is an input parameter of type VARCHAR(24). This parameter is NULL only when *user-ID* is set to NULL, and must be NULL when *user-ID* is NULL.

### *begin-timestamp*

Specifies when a task can first begin execution. When task execution begins depends on how this and other parameters are set:

**Non-null value for *begin-timestamp***

**At** *begin-timestamp*

The task execution begins at *begin-timestamp* if *point-in-time* and *trigger-task-name* are NULL.

**Next point in time defined at or after** *begin-timestamp*

The task execution begins at the next point in time defined at or after *begin-timestamp* if *point-in-time* is non-null.

**When** *trigger-task-name* **completes at or after** *begin-timestamp*

The task execution begins the next time that *trigger-task-name* completes at or after *begin-timestamp*.

**Null value for** *begin-timestamp*

**Immediately**

The task execution begins immediately if *point-in-time* and *trigger-task-name* are NULL.

**Next point in time defined**

The task execution begins at the next point in time defined if *point-in-time* is non-null.

**When** *trigger-task-name* **completes**

The task execution begins the next time that *trigger-task-name* completes.

The value of this parameter cannot be in the past, and it cannot be later than *end-timestamp*.

This is an input parameter of type `TIMESTAMP`.

*end-timestamp*

Specifies when a task can last begin execution. If this parameter is set to NULL, then the task can continue to execute as scheduled indefinitely.

The value of this parameter cannot be in the past, and it cannot be earlier than *begin-timestamp*.

This is an input parameter of type `TIMESTAMP`.

*max-invocations*

Specifies the maximum number of executions allowed for a task. This value applies to all schedules: triggered by events, recurring by time interval, and recurring by points in time. If this parameter is set to NULL, then there is no limit to the number of times this task can execute.

For tasks that execute only one time, *max-invocations* must be set to 1 and *interval*, *point-in-time* and *trigger-task-name* must be NULL.

If both *end-timestamp* and *max-invocations* are specified, the first limit reached takes precedence. That is, if *end-timestamp* is reached, even though the number of task executions so far has not reached *max-invocations*, the task will not be executed again. If *max-invocations* have occurred, the task will not be executed again even if *end-timestamp* is not reached.

This is an input parameter of type `INTEGER`.

*interval*

Defines a duration in minutes between two executions of a repetitive regular task. The first execution occurs at *begin-timestamp*. If this parameter is set to NULL, the task is not regularly executed. If this parameter contains a non-null value, the parameters *point-in-time* and *trigger-task-name* must be set to NULL.

This is an input parameter of type `INTEGER`.

*point-in-time*

Defines one or more points in time when a task is executed. If this parameter is set to NULL, the task is not scheduled at fixed points in time. If this parameter contains a non-null value, the parameters *interval* and *trigger-task-name* must be set to NULL.

The *point-in-time* string uses the UNIX cron format. The format contains the following pieces of information separated by blanks: given minute or minutes, given hour or hours, given day or days of the month, given month or months of the year, and given day or days of the week. For each part, you can specify one or several values, ranges, and so forth.

This is an input parameter of type VARCHAR(400).

*trigger-task-name*

Specifies the name of the task which, when its execution is complete, will trigger the execution of this task.

Task names of DB2START and DB2STOP are reserved for DB2 stop and start events respectively. Those events are handled by the scheduler associated with the DB2 subsystem that is starting or stopping.

If this parameter is set to NULL, the execution of this task will not be triggered by another task. If this parameter contains a non-null value, the parameters *interval* and *point-in-time* must be set to NULL.

This is an input parameter of type VARCHAR(128).

*trigger-task-cond*

Specifies the type of comparison to be made to the return code after the execution of task *trigger-task-name*. Possible values are:

- GT Greater than
- GE Greater than or equal to
- EQ Equal to
- LT Less than
- LE Less than or equal to
- NE Not equal to

If this parameter is set to NULL, the task execution is triggered without considering the return code of task *trigger-task-name*. This parameter must be set to NULL if *trigger-task-name* is set to NULL or is either DB2START or DB2STOP.

This is an input parameter of type CHAR(2).

*trigger-task-code*

Specifies the return code from executing *trigger-task-name*.

If the execution of this task is triggered by a stored procedure, *trigger-task-code* contains the SQLCODE that must be returned by the triggering stored procedure in order for this task to execute.

If the execution of this task is triggered by a JCL job, *trigger-task-code* contains the MAXRC that must be returned by the triggering job in order for this task to execute.

To find out what the MAXRC or SQLCODE of a task is after execution, invoke the user-defined function DSNADM. ADMIN\_TASK\_STATUS returns these information in the columns MAXRC and SQLCODE.

The following restrictions apply to the value of *trigger-task-code*:

- If *trigger-task-cond* is null, then *trigger-task-code* must also be null.
- If *trigger-task-cond* is non-null, then *trigger-task-code* must also be non-null.

If *trigger-task-cond* and *trigger-task-code* are not null, they are used to test the return code from executing *trigger-task-name* to determine whether to execute this task or not.

For example, if *trigger-task-cond* is set to "GE" and *trigger-task-code* is set to "8", then this task will execute if and only if the previous execution of *trigger-task-name* returned a MAXRC (for a JCL job) or an SQLCODE (for a stored procedure) greater than or equal to 8.

This is an input parameter of type INTEGER.

#### *DB2-SSID*

Specifies the DB2 subsystem ID whose associated scheduler should execute the task.

This parameter is used in a data sharing environment where, for example different DB2 members have different configurations and executing the task relies on a certain environment. However, specifying a value in *DB2-SSID* will prevent schedulers of other members to execute the task, so that the task can only be executed as long as the scheduler of *DB2-SSID* is running.

For a task being triggered by a DB2 start or DB2 stop event in *trigger-task-name*, specifying a value in *DB2-SSID* will let the task be executed only when the named subsystem is starting and stopping. If no value is given, each member that starts or stops will trigger a local execution of the task, provided that the executions are serialized.

If this parameter is set to NULL, any scheduler can execute the task.

This is an input parameter of type VARCHAR(4).

#### *procedure-schema*

Specifies the schema of the DB2 stored procedure this task will execute. If this parameter is set to NULL, DB2 uses a default schema. This parameter must be set to NULL if *procedure-name* is set to NULL.

This is an input parameter of type VARCHAR(128).

#### *procedure-name*

Specifies the name of the DB2 stored procedure this task will execute. If this parameter is set to NULL, no stored procedure will be called. In this case, a JCL job must be specified.

This is an input parameter of type VARCHAR(128).

#### *procedure-input*

Specifies the input parameters of the DB2 stored procedure this task will execute. This parameter must contain a DB2 SELECT statement that returns one row of data. The returned values will be passed as parameter to the stored procedure.

If this parameter is set to NULL, no parameters are passed to the stored procedure. This parameter must be set to NULL when *procedure-name* is set to NULL.

This is an input parameter of type VARCHAR(4096).

#### *JCL-library*

Specifies the name of the data set where the JCL job to be executed is saved.

If this parameter is set to NULL, no JCL job will be executed. In this case, a stored procedure must be specified.

This is an input parameter of type VARCHAR(44).

*JCL-member*

Specifies the name of the library member where JCL job to be executed is saved.

If this parameter is set to NULL, the data set specified in *JCL-library* must be sequential and contain the JCL job to be executed. This parameter must be set to NULL if *JCL-library* is set to NULL.

This is an input parameter of type VARCHAR(8).

*job-wait*

Specifies whether the job can be executed synchronously or not. This parameter can only be set to NULL if *JCL-library* is set to NULL. Otherwise, it must be one of the following values:

**NO** Asynchronous execution

**YES** Synchronous execution

**PURGE**

Synchronous execution after which the job status in z/OS is purged

This is an input parameter of type VARCHAR(8).

*task-name*

Specifies a unique name assigned to the task.

A unique task name is returned when the task is created with a NULL *task-name* value. This name is of the format "TASK\_ID\_xxxx" where xxxx is 0001 for the first task named, 0002 for the second task, and so forth.

The following task names are reserved and cannot be given as the value of *task-name*:

- Names starting with "TASK\_ID\_"
- DB2START
- DB2STOP

This is an input-output parameter of type VARCHAR(128).

*description*

Specifies a description assigned to the task.

This is an input parameter of type VARCHAR(128).

*return-code*

Provides the return code from the stored procedure. Possible values are:

**0** The call completed successfully.

**12** The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Output

The output of this stored procedure is the task name, *task-name* and the following output parameters, which are described in “Option descriptions” on page 340:

- *return-code*
- *message*

## UNIX cron format

The UNIX cron format is a way of specifying time for the *point-in-time* parameter of the ADMIN\_TASK\_ADD stored procedure.

The cron format has five time and date fields separated by at least one blank. There can be no blank within a field value. Scheduled tasks are executed when the minute, hour, and month of year fields match the current time and date, and at least one of the two day fields (day of month, or day of week) match the current date.

The allowed values for the time and date fields are:

### Field Allowed values

#### minute

0-59

#### hour

0-23

#### day of month

1-31

#### month

- 1-12, where 1 is January
- Upper-, lower-, or mixed-case three-character strings, based on the English name of the month: jan, feb, mar, apr, may, jun, jul, aug, sep, oct, nov, or dec.

#### day of week

- 0-7, where 0 or 7 is Sunday
- Upper-, lower-, or mixed-case three-character strings, based on the English name of the day: mon, tue, wed, thu, fri, sat, or sun.

## Ranges and lists

Ranges of numbers are allowed. Ranges are two numbers separated with a hyphen. The specified range is inclusive.

**Example:** The range 8-11 for an hour entry specifies execution at hours 8, 9, 10 and 11.

Lists are allowed. A list is a set of numbers or ranges separated by commas.

### Examples:

1,2,5,9

0-4,8-12

## Unrestricted range

A field can contain an asterisk (\*), which represents all possible values in the field.

The day of a command's execution can be specified by two fields: day of month and day of week. If both fields are restricted by the use of a value other than the asterisk, the command will run when either field matches the current time.

**Example:** The value 30 4 1,15 \* 5 causes a command to run at 4:30 AM on the 1st and 15th of each month, plus every Friday.

## Step values

Step values can be used in conjunction with ranges. The syntax *range/step* defines the range and an execution interval.

If you specify *first-last/step*, execution takes place at *first*, then at all successive values that are distant from *first* by *step*, until *last*.

**Example:** To specify command execution every other hour, use 0-23/2. This expression is equivalent to the value 0,2,4,6,8,10,12,14,16,18,20,22.

If you specify *\*/step*, execution takes place at every interval of *step* through the unrestricted range.

**Example:** As an alternative to 0-23/2 for execution every other hour, use \*/2.

## Listing scheduled tasks

You can use the function ADMIN\_TASK\_LIST to list tasks that are scheduled for execution by the administrative task scheduler.

To list scheduled tasks, connect to the DB2 subsystem with sufficient authorization to call the function ADMIN\_TASK\_LIST. See the information about ADMIN\_TASK\_LIST in DB2 SQL Reference.

The function contacts the scheduler in order to update the DB2 task list in the table SYSIBM.ADMIN\_TASKS if necessary, and then reads the tasks from the DB2 task list directly. The parameters that were used to create the task are column values of the returned table. The table also includes the authorization ID of the task creator, in the CREATOR column, and the time that the task was created, in the LAST\_MODIFIED column.

## Listing the last execution status of scheduled tasks

You can use the function ADMIN\_TASK\_STATUS to view the last execution status of scheduled tasks.

Before a task is first scheduled, all columns of its execution status contain null values, as returned by the table function ADMIN\_TASK\_STATUS. Afterwards, at least the TASK\_NAME, USERID, DB2\_SSID, STATUS, NUM\_INVOCATIONS and START\_TIMESTAMP columns contain a non-null value. This information indicates when and under which user ID the task status last changed, as well as the number of times this task was already executed. The rest of the execution status can be interpreted according to the different values of the STATUS column.

The table function ADMIN\_TASK\_STATUS contacts the administrative task scheduler in order to update the DB2 task list in table SYSIBM.ADMIN\_TASKS, if necessary, and then reads the tasks from this task list directly.

To determine the last execution status of a scheduled task:

1. Execute the table function ADMIN\_TASK\_STATUS to generate the status table. See the information about ADMIN\_TASK\_LIST in DB2 SQL Reference.
2. Select the rows in the table that correspond to the task name.

**Tip:** You can relate the task execution status to the task definition by joining the output tables from ADMIN\_TASK\_LIST and ADMIN\_TASK\_STATUS on the TASK\_NAME column.

The table created by ADMIN\_TASK\_STATUS indicates the last execution of scheduled tasks. Each row is indexed by the task name and contains the last execution status of the corresponding task.

If task execution has never been attempted, because the execution criteria have not been met, the STATUS column contains a null value.

If the scheduler was not able to start executing the task, the STATUS column contains NOTRUN. The START\_TIMESTAMP and END\_TIMESTAMP columns are the same, and the MSG column indicates why the task execution could not be started. All JCL job execution status columns are NULL, but the DB2 execution status columns contain values if the reason for the failure is related to DB2. (For example, a DB2 connection could not be established.)

If the scheduler started executing the task but the task has not yet completed, the STATUS column contains RUNNING. All other execution status columns contain null values.

If the task execution has completed, the STATUS column contains COMPLETED. The START\_TIMESTAMP and END\_TIMESTAMP columns contain the actual start and end times. The MSG column might contain informational or error messages. The DB2 and JCL columns are filled with values when they apply.

If the scheduler was stopped during the execution of a task, the status remains RUNNING until the scheduler is restarted. When the scheduler starts again, the status is changed to UNKNOWN, because the scheduler cannot determine if the task was completed.

## Removing a scheduled task

You can remove a scheduled task from the task list using the stored procedure ADMIN\_TASK\_REMOVE.

Even if a task has finished all of its executions and will never be executed again, it remains in the task list until it is explicitly removed through a call to the stored procedure ADMIN\_TASK\_REMOVE.

### Restrictions:

- Only the user who scheduled a task or a user with SYSOPR, SYSADM, or SYSCTRL authority can delete a task.
- A task cannot be removed while it is executing.
- A task that is the trigger for another task cannot be removed.

To remove a scheduled task:

1. Optional: Issue the following SQL statement to identify tasks that will never execute again:

```
SELECT T.TASK_NAME
FROM TABLE (DSNADM.ADMIN_TASK_LIST()) T,
     TABLE (DSNADM.ADMIN_TASK_STATUS()) S
WHERE T.TASK_NAME = S.TASK_NAME AND
      (S.NUM_INVOCATIONS = T.MAX_INVOCATIONS OR
       T.END_TIMESTAMP < CURRENT_TIMESTAMP) AND
      STATUS <> 'RUNNING'
```

2. Confirm the name of the task that you want to remove.
3. Call the stored procedure ADMIN\_TASK\_REMOVE. You must provide the task name as a parameter to the stored procedure. The scheduled task is removed from the task list and its last execution status is deleted. Listing the scheduled tasks and execution statuses no longer returns a row for this task. The task name is freed up for future reuse.

## ADMIN\_TASK\_REMOVE

The SYSPROC.ADMIN\_TASK\_REMOVE stored procedure removes a task from the task list of the administrative task scheduler.

If the task is currently running, it continues to execute until completion, and the task is not removed from the task list of the administrative task scheduler. If other tasks depend on the execution of the task to be removed, this task is not removed from the task list.

### GUPI

## Environment

See the recommended environment in the installation job DSNTIJRA.

## Authorization

Users with SYSOPR, SYSCTRL, or SYSADM authority can remove any task. Other users who have EXECUTE authority on this stored procedure can remove tasks that they added. Attempting to remove a task that was added by a different user returns an error in the output.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_TASK_REMOVE—(—task-name,—return-code,—message—)————▶▶
```

## Option descriptions

*task-name*

Specifies the task name of the task to be removed from the administrative task scheduler task list.

This is an input parameter of type VARCHAR(128) and cannot be null.

### *return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

### *message*

Contains messages describing the error encountered by the stored procedure. The first messages in this area, if any, are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following Java sample shows how to invoke ADMIN\_TASK\_REMOVE:

```
import java.sql.CallableStatement;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.Timestamp;
import java.sql.Types;

Connection con =
    DriverManager.getConnection("jdbc:db2://myserver:myport/mydatabase",
        "myuser", "mypassword");
CallableStatement callStmt =
    con.prepareCall("CALL SYSPROC.ADMIN_TASK_REMOVE(?, ?, ?)");
// provide the id of the task to be removed
callStmt.setString(1, "mytask");
// register output parameters for error management
callStmt.registerOutParameter(2, Types.INTEGER);
callStmt.registerOutParameter(3, Types.VARCHAR);
// execute the statement callStmt.execute();
// manage the return code
if ( callStmt.getInt(2) == 0 )
{
    System.out.print("\nSuccessfully removed task "
        + callStmt.getString(1));
}
else
{
    System.out.print("\nError code and message are: "
        + callStmt.getInt(2) + "/"
        + callStmt.getString(3));
}
```

## Output

The output of this stored procedure includes the following output parameters, which are described in “Option descriptions” on page 349:

- *return-code*
- *message*

## Manually starting the administrative task scheduler

The administrative task scheduler normally starts when DB2 starts, but you can start it manually if necessary.

Use one of the following commands to start the scheduler:

- To start a scheduler named *admtproc* from the operator's console using the default tracing option, issue the MVS system command:  
`start admtproc`
- To start a scheduler named *admtproc* from the operator's console with tracing enabled, issue the MVS system command:  
`start admtproc,trace=on`
- To start a scheduler named *admtproc* from the operator's console with tracing disabled, issue the MVS system command:  
`start admtproc,trace=off`

When the administrative task scheduler starts, message DSN671I displays on the console.

## Manually stopping the administrative task scheduler

You can stop the administrative task scheduler as part of problem determination or in preparation for maintenance.

To stop the scheduler, use one of the following commands.

- **Recommended method:** To stop a scheduler named *admtproc* from the operator's console, issue the MVS system command:  
`modify admtproc,appl=shutdown`
  - The scheduler stops accepting requests and will not start new task executions. It waits until the execution of all currently running tasks completes and then terminates.
  - Message DSN670I displays on the console.
- **Alternate method:** If the MODIFY command does not shut down the scheduler, issue the MVS system command:  
`stop admtproc`
  - Any task that was invoked by the scheduler and is currently executing is interrupted.
  - Message DSN670I displays on the console.

Interrupted tasks keep their status as RUNNING and are not rescheduled until the scheduler is started again. At startup, the status of the interrupted tasks is set to UNKNOWN and message DSN690I is written into the status. Look for UNKNOWN in the results of the ADMIN\_TASK\_STATUS user-defined function. If UNKNOWN is present in the STATUS column of the output table, then you should check to see if the task has completed. If an interrupted task has not completed, you should terminate the work.

## Synchronization between administrative task schedulers in a data sharing environment

The administrative task schedulers of a data sharing group synchronize themselves through their task lists.

When a task is added, the stored procedure ADMIN\_TASK\_ADD is called by a DB2 member. The scheduler associated with this DB2 member adds the task to the

common task list. The task list is shared among all schedulers associated with the data sharing group members. The next time a scheduler accesses the list, it will detect the new task.

All schedulers of the data sharing group access this task list once per minute, to check for new tasks. The scheduler that adds a task does not have to check the list, and can execute the task immediately. Any other scheduler can execute a task only after finding it in the updated task list. Any scheduler can remove a task without waiting.

In order to remove a task, the stored procedure `ADMIN_TASK_REMOVE` is called by a DB2 member. The scheduler associated with this DB2 member removes the task from the common task list. The next time a scheduler checks the list, within one minute after the task has been removed, it detects that the task has been deleted.

No scheduler can execute a task without first locking it in the task list. This locking prevents deleted tasks from being executed: the task is no longer present in the list, so it cannot be locked. Because it cannot be locked, it cannot be executed. The locking also prevents double executions: a task that one scheduler has in progress is already locked, so no other scheduler can lock the task.

## Troubleshooting the administrative task scheduler

Error and informational messages from the administrative task scheduler might display on the console. Error messages typically indicate a problem with the configuration of the scheduler itself or an error accessing its resources. Informational messages identify important steps in the life cycle of the scheduler: starting, stopping, automatically recovering one of the task lists, and so forth.

### Enabling tracing for administrative task scheduler problem determination

If you need to perform problem determination on the administrative task scheduler in response to a message, you can use a trace.

Use the MVS system command `MODIFY` to enable or disable tracing.

- To start a trace for a scheduler named *admtproc*, issue the following MVS system command:

```
modify admtproc,appl=trace=on
```

Substitute the name of your scheduler for *admtproc*.

- To stop a trace for a scheduler named *admtproc*, issue the following MVS system command:

```
modify admtproc,appl=trace=off
```

- To configure the system so that tracing starts automatically when the scheduler starts, modify the procedure parameter `TRACE` in the JCL job that starts the scheduler. This job has the name that was assigned when the scheduler was installed. The job was copied into one of the `PROCLIB` library during the installation. Specify `TRACE=ON`.

To disable tracing, change the parameter to `TRACE=OFF`.

### Recovering the administrative task scheduler task list

Two redundant, active copies of the task list exist in case of media failure. Console message `DSNA679I` indicates that one or both of these copies is not accessible or is corrupted. If this happens, you can recover the task list.

One copy of the task list is a shared VSAM data set, by default DSN910.TASKLIST, where DSN910 is the DB2 catalog prefix. The other copy is stored in the table ADMIN\_TASKS in the SYSIBM schema. Include these redundant copies as part of your backup and recovery plan.

**Tip:** If DB2 is offline, message DSN679I displays on the console. As soon as DB2 starts, the administrative task scheduler performs an autonomic recovery of the ADMIN\_TASKS table using the contents of the VSAM task list. When the recovery is complete, message DSN695I displays on the console to indicate that both task lists are again available. (By default, message DSN679I displays on the console once per minute when DB2 is offline. You can change the frequency of this message by modifying the ERRFREQ parameter either as part of the started task or with a console command.)

Use the following procedures to recover the task list if it is lost or damaged:

- To recover if the ADMIN\_TASKS task list is corrupted:
  1. Create a new and operable version of the table.
  2. Grant SELECT, UPDATE, INSERT and DELETE privileges on the table to the administrative task scheduler started task user.

As soon as the ADMIN\_TASKS table is accessible again, the scheduler performs an autonomic recovery of the table using the content of the VSAM task list.

- To recover if the VSAM file is corrupted, create an empty version of the VSAM task list. As soon as the VSAM task list is accessible again, the scheduler performs an autonomic recovery using the content of the ADMIN\_TASKS task list.
- If both task lists (the VSAM data set and the ADMIN\_TASKS table) are corrupted and inaccessible, the scheduler is no longer operable. Messages DSN681I and DSN683I display on the console and the scheduler terminates. To recover from this situation:
  1. Create an empty version of the VSAM task list.
  2. Recover the table space DSNADMDB.DSNADMTS, where the ADMIN\_TASKS table is located.
  3. Restart the administrative task scheduler.

As soon as both task lists are accessible again, the scheduler performs an autonomic recovery of the VSAM task list using the content of the recovered ADMIN\_TASKS table.

## Problem executing a task

When the administrative task scheduler tries to execute a task without success, or when an error is detected by the scheduler at the end of a task execution, the error description is written into the last execution status.

## Symptoms

A task was scheduled successfully, but the action did not complete or did not complete correctly.

## Diagnosing the problem

Use the function ADMIN\_TASK\_STATUS to review the last execution status of a task and identify any messages or return codes that were passed back to the scheduler.

**Important:** The task status is overwritten as soon as the next execution of the task starts.

## Resolving the problem

Correct the underlying problem and review the schedule. The task can now be executed successfully, but execution occurs only according to the schedule. Failed executions are not rescheduled. If the task is no longer scheduled, for example because it had a defined number of executions, you must remove it and add it again, with adjusted criteria. If the task is still scheduled, you do not need to take any further action unless the failed execution is required. You cannot adjust a schedule, so if you do require the failed execution and all future executions, you must remove the scheduled task and re-create it.

## Problem in user-defined table functions

An SQL code and a few characters of an SQL error message are returned in response to either ADMIN\_TASK\_LIST or ADMIN\_TASK\_STATUS.

### Symptoms

An SQL code is returned. When SQLCODE is -443, the error message cannot be read directly, because only a few characters are available.

### Diagnosing the problem

Problem diagnosis and resolution depends on the SQLCODE returned.

**-443** The SQLCODE of -443 indicates that an error occurred in the function. Use the message number, which is at the beginning of the truncated return string, to diagnose the problem.

#### Any other value

Any other SQLCODE indicates that the error is not in the function or in the scheduler. Troubleshoot the task itself.

## Problem in stored procedures

An SQL code and a few characters of an SQL error message are returned in response to either ADMIN\_TASK\_ADD or ADMIN\_TASK\_REMOVE.

### Symptoms

An SQL code is returned.

### Diagnosing the problem

An SQL code other than 0 indicates that DB2 encountered a problem calling the stored procedure.

An SQL code of 0 is accompanied by a return code and an error message in the output parameters RETURN\_CODE and MSG. The return code is 0 if the scheduled task could be added or removed successfully. If the return code is 12, an error occurred adding or removing the task, and the returned error message describes the cause. The first eight characters of the error message contain the error message ID.

### Resolving the problem

Errors can originate with the stored procedure itself or with the scheduler, in which case the error information is transmitted back to the stored procedure for output. Most error messages are clearly in one category or the other. For example, DSN650I *csect-name* CANNOT CONNECT TO ADMIN SCHEDULER *proc-name* indicates an error from the stored procedure. DSN652I *csect-name* THE USER *user-name* IS NOT ALLOWED TO ACCESS TASK *task-name* belongs to the administrative task scheduler, which is checking the parameters and authorization information passed to it.

Understanding the source of the error should be enough to correct the cause of the problem. Most problems are incorrect usage of the stored procedure or an invalid configuration.

Correct the underlying problem and resubmit the call to the stored procedure to add or remove the task.

---

## Architecture of the administrative task scheduler

The administrative task scheduler is a started task that can be seen as an additional DB2 address space, even if in a separate process. It is accessed through an SQL API and stores the scheduled tasks in two redundant task lists.

The scheduler is part of DB2 for z/OS. When properly configured, it is available and operable with the first DB2 start. The scheduler starts as a task on the z/OS system during DB2 startup. The scheduler has its own address space, named after the started task name.

Each DB2 subsystem has its own distinct scheduler connected to it. DB2 is aware of the scheduler whose name is defined in the subsystem parameter ADMTPROC. The scheduler is aware of DB2 by the subsystem name that is defined in the DB2SSID parameter of the started task.

The scheduler has an SQL interface consisting of stored procedures (ADMIN\_TASK\_ADD and ADMIN\_TASK\_REMOVE) and user-defined table functions (ADMIN\_TASK\_LIST and ADMIN\_TASK\_STATUS) defined in DB2. This SQL interface allows you to remotely add or remove administrative tasks and to list those tasks and their execution status.

The scheduler executes the tasks according to their defined schedules. The status of the last execution is stored in the task lists as well, and you can access it through the SQL interface.

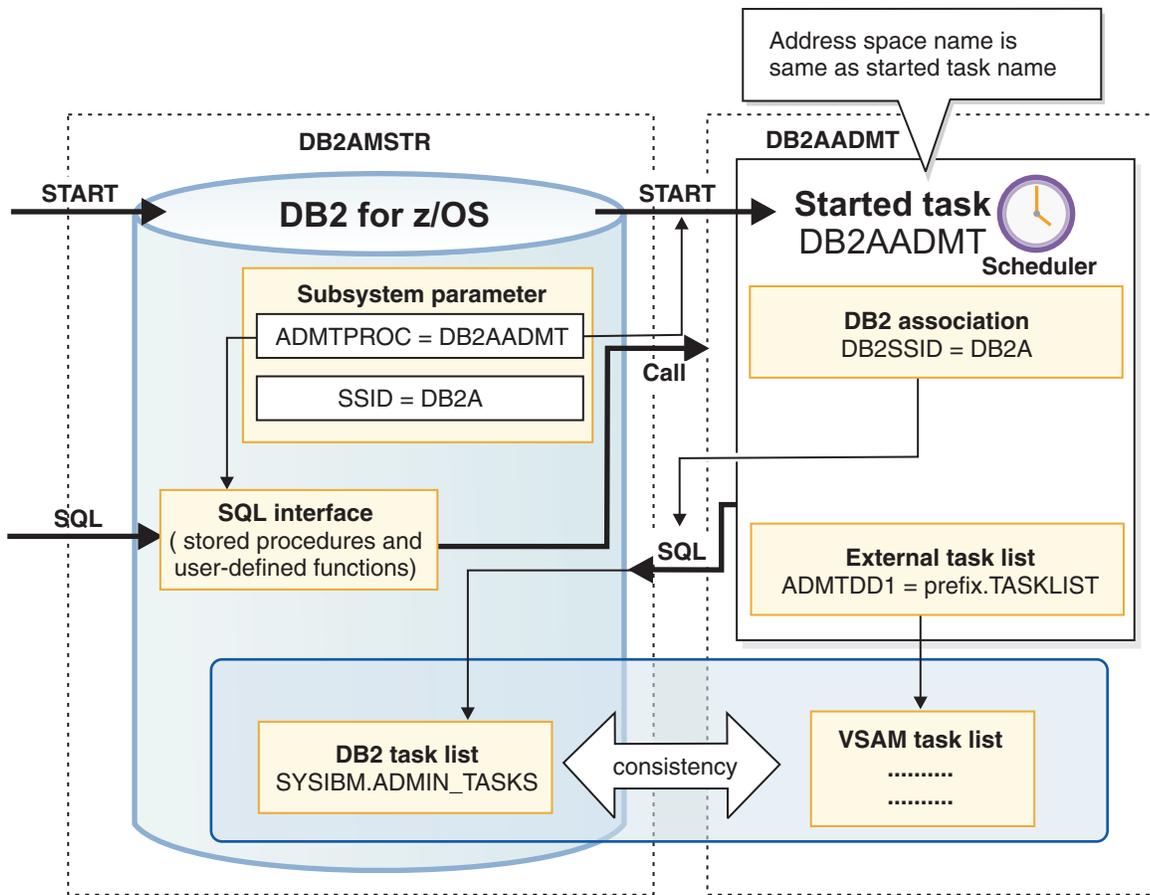

Figure 27. Architecture of the administrative task scheduler

## The lifecycle of the administrative task scheduler

The administrative task scheduler starts as a task on the z/OS system during DB2 startup or initialization. The administrative task scheduler remains active unless it is explicitly stopped, even when DB2 terminates.

Every DB2 subsystem has a coordinated administrative task scheduler address space that it can start with a z/OS started task procedure.

Two instances of the same administrative task scheduler cannot run simultaneously. To avoid starting up a duplicate administrative task scheduler, at start up the administrative task scheduler checks that there is no address space other than itself with the same name. If another address space with the same name is active, the new administrative task scheduler immediately shuts down and displays a console message (DSNA674I). The administrative task scheduler can check the address spaces only in the same system, not the entire Sysplex.

When DB2 terminates, the administrative task scheduler remains active so that scheduled JCL jobs can run. When DB2 starts again, it connects to the administrative task scheduler automatically. The administrative task scheduler does

not need to be restarted.

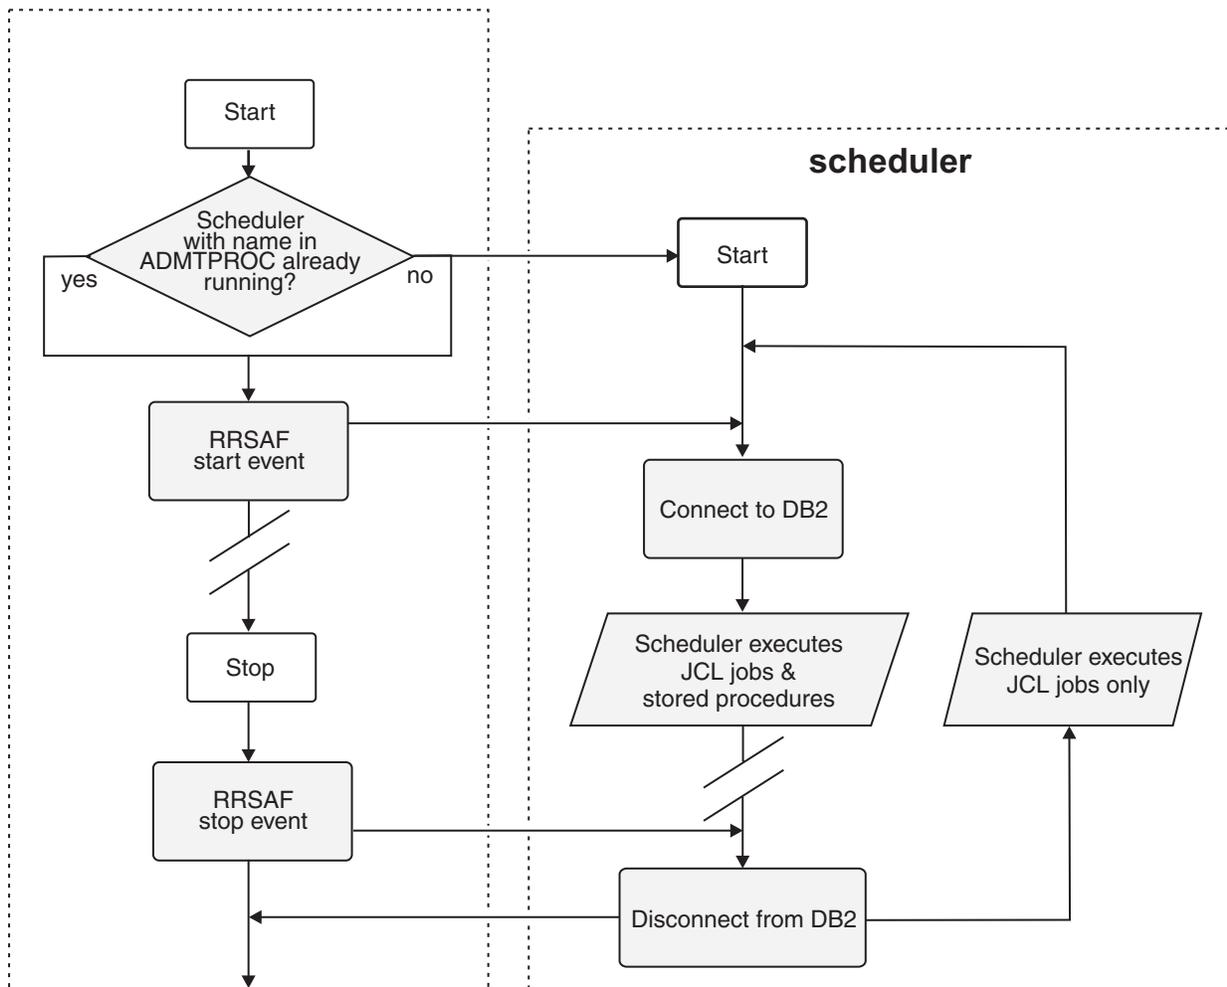

Figure 28. The lifecycle of the administrative task scheduler

If you do not want the administrative task scheduler to run when DB2 is stopped, you can specify the STOPONDB2STOP parameter in the started task before restarting the administrative task scheduler. This parameter has no value. You specify this parameter by entering STOPONDB2STOP without an equal sign (=) or a value. When you specify this parameter, the administrative task scheduler terminates after it finishes executing the tasks that are running and after executing the tasks that are triggered by DB2 stopping. When DB2 starts again, the administrative task scheduler is restarted.

**Important:** When you use the STOPONDB2STOP parameter to stop the administrative task scheduler when DB2 is stopped, JCL tasks will not run. These JCL tasks will not run, even if they could have run successfully had an administrative task scheduler remained active.

## Scheduler task lists

The administrative task scheduler manages tasks that are defined by users and stores them in two redundant task lists, so that the scheduler can continue working even if one task list is unavailable.

The two task lists are the DB2 table `SYSIBM.ADMIN_TASKS` and the VSAM data set that is indicated in the data definition `ADMTDD1` of the scheduler started task. The scheduler maintains consistency between the two task lists.

The DB2 task list `SYSIBM.ADMIN_TASKS` is accessed through a connection to the DB2 subsystem that is identified in the `DB2SSID` parameter of the scheduler started task.

The scheduler works and updates both task lists redundantly, and remains operable so long as at least one of the task lists is available. In this way, the scheduler continues working when DB2 is offline. If a task list becomes unavailable, the scheduler continues to update the task list. When both task lists are available again, the scheduler automatically synchronizes them.

## Architecture of the administrative task scheduler in a data sharing environment

In a data sharing environment, there is one administrative task scheduler for each DB2 for z/OS Version 8 or later member of a data sharing group, even when those members run in the same z/OS system. The schedulers share their resources and interface.

The scheduler task list is shared by all schedulers in a data sharing group, accessing a shared task file on shared storage (VSAM data set defaulting to `DSNC810.TASKLIST`, where `DSNC810` is the DB2 catalog prefix) and a redundant task list in the DB2 system table `SYSIBM.ADMIN_TASKS`.

The following figure shows a data sharing group with two DB2 members and their associated schedulers.

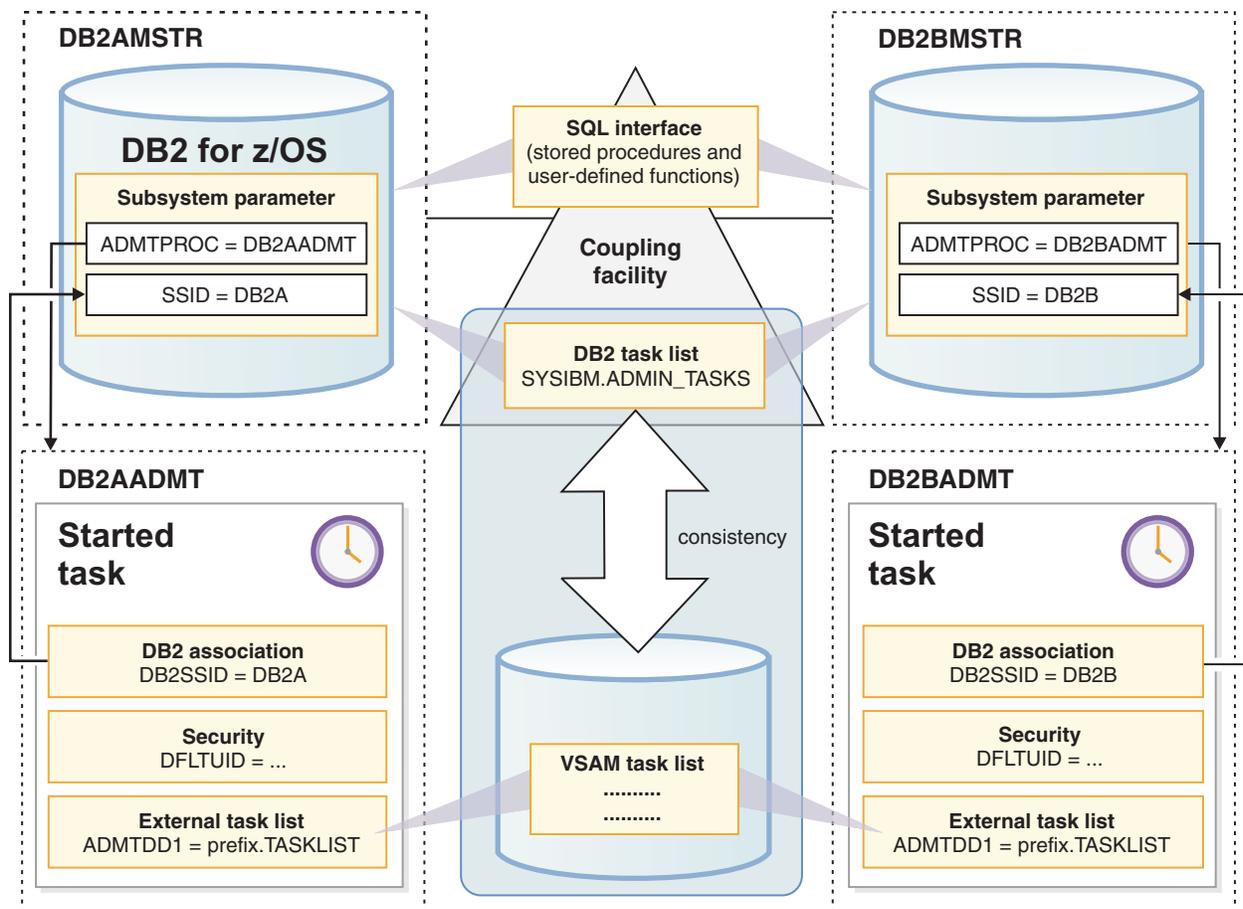

Figure 29. Administrative task schedulers in a data sharing group

Tasks are not localized to a scheduler. They can be added, removed, or executed in any of the schedulers in the data sharing group with the same result. However, you can force the task to execute on a given scheduler by specifying the associated DB2 subsystem ID in the `DB2SSID` parameter when you schedule the task. The tasks that have no affinity to a given DB2 subsystem are executed among all schedulers. Their distribution cannot be predicted.

## Security guidelines for the administrative task scheduler

The administrative task scheduler employs controls on access and execution to help maintain a secure environment.

Installation job `DSNTIJRA` is responsible for establishing the security environment for the administrative task scheduler. Installation job `DSNTIJSG` is responsible for establishing the security environment in DB2 for accessing the scheduler interface.

The following figure shows all of the security checkpoints that are associated with using the scheduler.

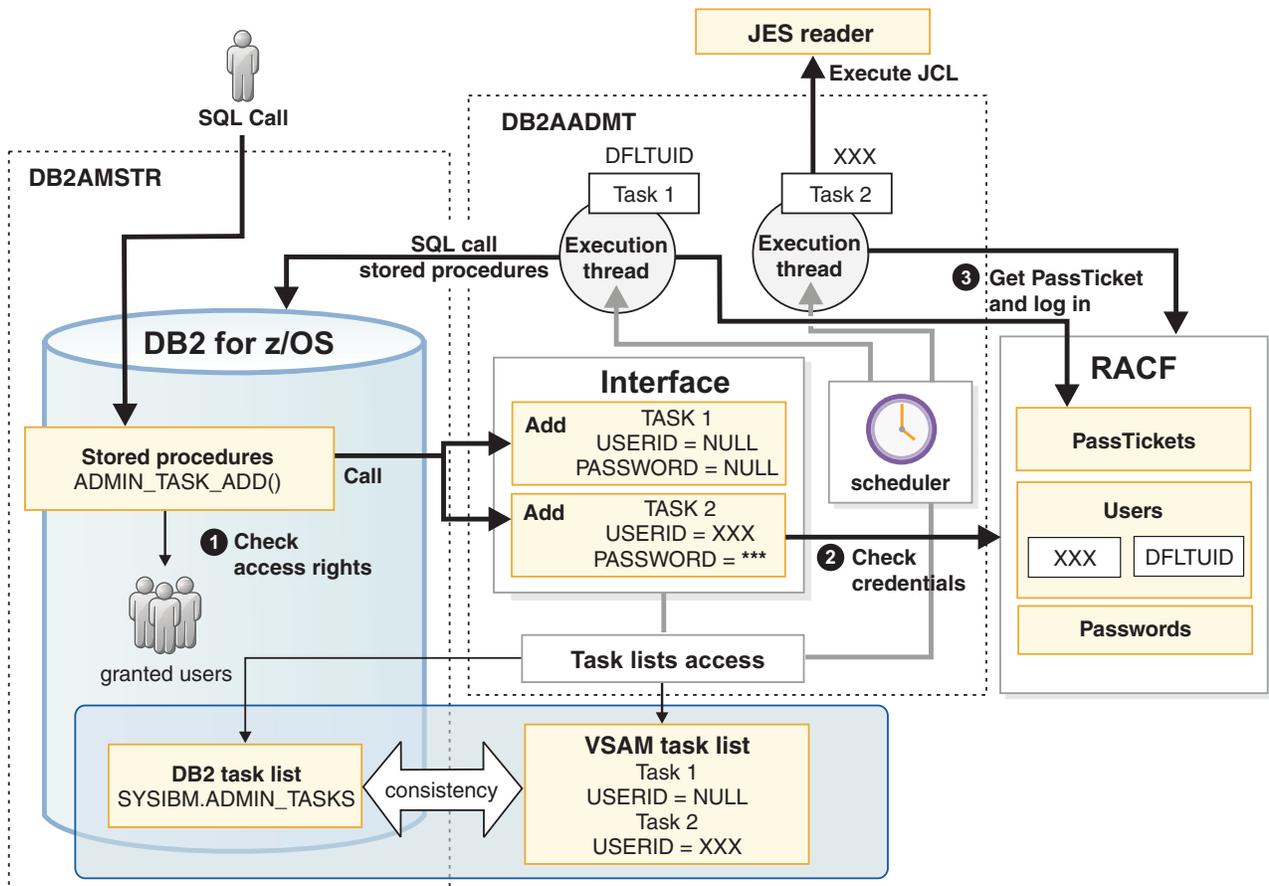

Figure 30. Security checkpoints for the administrative task scheduler

### Related information

[BPX.DAEMON FACILITY](#)

## User roles in the administrative task scheduler

Three user roles are involved in the use of the administrative task scheduler: the started task user, the interface users and the execution users.

The scheduler started task is associated to the user STARTUID in RACF, so that the scheduler is running in the security context of this user. This user, the started task user, should have access to the resources of the scheduler: it is granted UPDATE access on the DB2 table SYSIBM.ADMIN\_TASKS and it is allowed to write into the VSAM data set containing the redundant task list.

The users or groups of users who have access to the SQL interface of the scheduler are allowed to add, remove or list scheduled tasks. To specify who is authorized to add, remove or list a scheduled task, use the GRANT command in DB2. All interface users are granted EXECUTE access on the scheduler stored procedures and user-defined table functions. They also are granted READ access on the DB2 table SYSIBM.ADMIN\_TASKS.

Each scheduled task in the scheduler is associated with an execution user who will execute this task. When not explicitly given by the user, a default execution user DFLTUID defined in the scheduler started task is used. The scheduler execution threads switch to the security context of this user before executing the task.

## Protection of the interface of the administrative task scheduler

The administrative task scheduler interface is protected against unauthorized access by other users. Credentials of a task are checked but not stored.

Users with EXECUTE rights on one of the stored procedures or user-defined table functions of the scheduler interface are allowed to execute the corresponding functionality: adding a scheduled task, removing a scheduled task, or listing the scheduled tasks or their execution status. The entire interface is configured by default with PUBLIC access rights during the installation.

### Recommendations:

- Grant rights to groups or roles, rather than to individual authorization IDs.
- Restrict access to the ADMIN\_TASK\_ADD and ADMIN\_TASK\_REMOVE stored procedures to users with a business need for their use. Access to the user-defined table functions that list tasks and execution status can remain unrestricted.

The authorization ID of the DB2 thread that called the stored procedure ADMIN\_TASK\_ADD is passed to the scheduler and stored in the task list with the task definition. The ADMIN\_TASK\_ADD stored procedure gathers the authorities granted to this authorization ID from the subsystem parameters and from the catalog table, and passes them over to the scheduler. The same mechanism is used in ADMIN\_TASK\_REMOVE to verify that the user is permitted to remove the task.

A task in the scheduler task list can be removed by the owner of the task, or by any user that has SYSOPR, SYSCTRL, or SYSADM privileges. The owner of a task is the CURRENT SQLID of the process at the time the task was added to the task list.

## Protection of the resources of the administrative task scheduler

The administrative task scheduler task lists are protected against unauthorized use by other users than the started task execution user.

The VSAM resource (by default DSNC910.TASKLIST, where DSNC910 is the DB2 catalog prefix) that stores the task list of the administrative task scheduler must be protected in RACF against unauthorized access. Only the administrative task scheduler started task user has UPDATE authority on the VSAM resources. No other users should have any access.

A similar security concept is implemented for the SYSIBM.ADMIN\_TASKS table, which stores a redundant copy of the scheduled tasks. Only the administrative task scheduler started tasks user has SELECT, INSERT, DELETE, or UPDATE authority on this resource. Users with EXECUTE rights on the user-defined functions ADMIN\_TASK\_LIST and ADMIN\_TASK\_STATUS have only SELECT authority on the table SYSIBM.ADMIN\_TASKS.

## Secure execution of tasks in the administrative task scheduler

The administrative task scheduler execution threads always switch to the security context of the execution user before executing a task. The user is authenticated through the use of passtickets.

The first action that is taken by the scheduler when starting a task execution is to switch its security context to the context of the execution user. The execution user can be explicitly identified by the ADMIN\_TASK\_ADD *user-ID* parameter or can be the default user.

If the task must run under a certain authority, including an authority different from the caller of the stored procedure, credentials are passed on to the administrative task scheduler. These credentials are not stored anywhere. They are validated by RACF to ensure that the caller of the stored procedure at the task definition time has the right to assume the desired security context. Therefore you can use a *passticket* (encrypted single-use password) in the password parameter of the ADMIN\_TASK\_ADD stored procedure. If no credentials are provided, then the administrative task scheduler executes the tasks under its default execution user.

The scheduler generates and uses passtickets for executing the tasks under the corresponding authority. Each task executes after switching to the requested security context using the user ID and the generated passticket.

No password is stored in the task scheduler, but the scheduler is defined as a trusted program in RACF, and is allowed to get passtickets for any user. The scheduler sub-thread requires a passticket from RACF and logs in using this single-use password. The execution of the task then occurs in the switched security concept, allowing the task to have access to the resources defined for this execution user. After the execution, the security context is switched back to the scheduled task user.

The administrative task scheduler started task module (DSNADMT0) uses the pthread\_security\_np() function to switch users. If the BPX.DAEMON facility class is active, then DSNADMT0 must be defined to RACF program control. If the BPX.DAEMON facility class is not active or if the scheduler is not defined to RACF program control, error EDC5139I is returned when trying to switch to another security level.

The scheduler resources should be protected from unintended impact when executing a task. Therefore, the scheduler started task user STARTUID, which has access to the scheduler resources, must not be used as default execution user DFLTUID, and it should not be specified in the *user-ID* parameter. The scheduler will not start if the started task user and the default execution user are identical. The default execution user should have as few rights as possible, to avoid impacting any resources if no user is defined for a task.

The default execution user has no authority except to attach to DB2 and write to the JES reader.

---

## Execution of scheduled tasks in the administrative task scheduler

The administrative task scheduler manages the point in time, the security, the input parameters and the status of the task execution.

The scheduler work is based on scheduled tasks defined by the user. A task is mainly composed of a schedule definition and a work definition. The scheduler work is based on scheduled tasks, each scheduled task is a basic user-defined unit of work. Each task is associated with a unique task name. Up to 9999 tasks are supported in the scheduler at one time.

A scheduled task consists of a schedule and a work definition. The schedule part tells the scheduler when to execute the task. A user defines an execution window of time during which execution is permitted and either a time-based schedule or an event that triggers the execution of the job in this window. The work definition specifies what to execute, either a JCL job or a stored procedure, and the authority (user) under which to execute the task.

## Multi-threading in the administrative task scheduler

The administrative task scheduler uses a pool of execution threads that allow it to execute many tasks simultaneously.

The scheduler is multi-threaded in order to be able to simultaneously execute different tasks: it starts the execution of scheduled tasks and then waits for their completion. The execution of a task is delegated by the scheduler to one of its sub-threads that starts the execution, waits until the execution completes and gather the execution status. Each sub-thread can be used for any type of tasks.

The maximum number of sub-threads is determined by the parameter MAXTHD of the scheduler started task, which by default is 99. Therefore, up to 99 tasks can be executed simultaneously by the scheduler. To reduce the memory usage of the scheduler, reduce the number of sub-threads by specifying a lower MAXTHD parameter value.

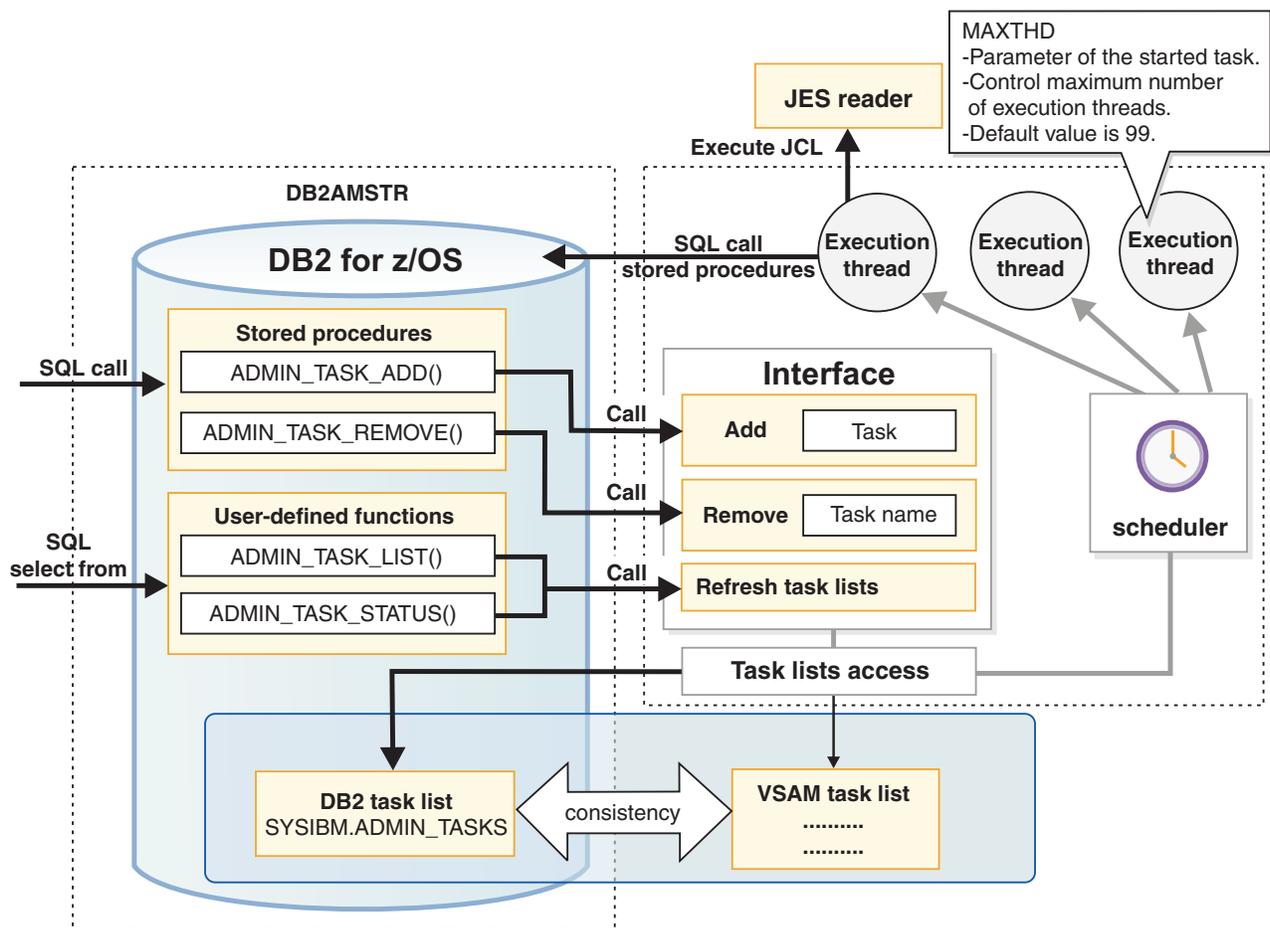

Figure 31. Multi-threading in the administrative task scheduler

The minimum permitted value for MAXTHD is 1, but should not be lower than the maximum number of tasks that you expect to execute simultaneously. If there are more tasks to be executed simultaneously than sub-threads available, some tasks will not start executing immediately. The scheduler will try to find an available sub-thread within one minute of when the task is scheduled for execution. As a result, multiple short tasks might be serialized in the same sub-thread, provided that their total execution time does not go over this minute.

The parameters of the scheduler started task are not positional. Place parameters in a single string separated by blank spaces.

If a task execution still cannot be started one minute after it should have been, the execution is skipped and the last execution status of this task is set to the NOTRUN state. The following message displays on the operator's console.

```
DSNA678I csect-name THE NUMBER OF TASKS TO BE CONCURRENTLY  
EXECUTED BY THE ADMIN SCHEDULER proc-name EXCEEDS max-threads
```

If this happens, increase the MAXTHD parameter value and restart the scheduler.

## Scheduled execution of a stored procedure

The scheduler gets parameter values for the stored procedure that is executing the given SQL select statement, and then calls the stored procedure in DB2.

One execution sub-thread of the scheduler is used to execute a task that describes a stored procedure call. The execution sub-thread first connects to the DB2 member indicated in the *DB2SSID* parameter of the scheduler started task. If the connection cannot be established, the execution is skipped, and the last execution status is set to the NOTRUN state.

After establishing a connection, the parameter values of the stored procedure are retrieved from DB2 by using the select statement that is defined in the task parameter *procedure-input*. If an error occurs retrieving those parameter values, the last execution status of the task is set to the error that is returned by DB2, and the stored procedure is not called.

Otherwise, the stored procedure is called with the retrieved parameter values. The stored procedure name is concatenated from the task parameters *procedure-schema* and *procedure-name*. The SQL CALL command is synchronous, and the execution thread is blocked until the stored procedure finishes execution. Then, the last execution status is set to the values that are returned by DB2. Finally, a COMMIT statement is issued, and the connection to DB2 is closed.

The execution status of DB2 stored procedures always contains null values in the JOB\_ID, MAXRC, COMPLETION\_TYPE, SYSTEM\_ABENDCD and USER\_ABENDCD fields. In the case of a DB2 error, the fields SQLCODE, SQLSTATE, SQLERRMC, and SQLERRP will contain the values that DB2 returned to the stored procedure.

## How the administrative task scheduler works with Unicode

The administrative task scheduler is able to retrieve and pass Unicode parameters to a DB2 stored procedure.

If the stored procedure accepts Unicode parameters, or if it does not accept Unicode parameters but the retrieved parameter values do not contain any special character that cannot be expressed in EBCDIC or ASCII, no character will be broken.

However, the Unicode values must be retrieved through a select statement expressed in EBCDIC, so that special characters cannot be used in the table names or in the column names where the parameter values are retrieved.

## Scheduled execution of a JCL job

The administrative task scheduler sends the JCL job to the JES reader. It can optionally wait for the job to terminate and purge it from the JES job list.

One execution sub-thread of the scheduler is used to execute a task that locates a data set containing a JCL job. The sub-thread reads the JCL job from the data set where it is stored, identified by the task parameters *JCL-library* and *JCL-member*. The data set can be sequential or partitioned. For a sequential data set, *JCL-member* is NULL.

In the case of an error, the error is written into the last execution status of the task. Otherwise, the job is submitted to the internal JES reader. According to the *job\_wait* parameter, the sub-thread waits for the execution completion or not. When the sub-thread waits for completion, the last execution status includes the complete returned values provided by the JES reader. Otherwise, it contains the JCL job ID and a success message.

- If *job\_wait* is set to NO, the sub-thread does not wait until the job completes execution and returns immediately after the job submission. The task execution status is set to the submission status, the result of the job execution itself will not be available.
- If *job\_wait* is set to YES, the sub-thread simulates a synchronous execution of the JCL job. It waits until the job execution completes, get the job status from the JES reader and fills in the last execution status of the task.
- If *job\_wait* is set to PURGE, the sub-thread purges the job output from the JES reader after execution. Execution is the same as for *job\_wait*=YES.

JCL job execution status always contains a null value in the SQLCODE, SQLSTATE, SQLERRMC, and SQLERRP fields. If the job can be submitted successfully to the JES reader, the field JOB\_ID contains the ID of the job in the JES reader. If the job is executed asynchronously, the MAXRC, COMPLETION\_TYPE, SYSTEM\_ABENDCD and USER\_ABENDCD fields will also be null values, because the sub-thread does not wait for job completion before writing the status. If the job was executed synchronously, those fields contain the values returned by the JES reader.

## Execution of scheduled tasks in a data sharing environment

All administrative task schedulers of the data sharing group cooperate in the execution of the scheduled tasks.

In a data sharing environment, several schedulers cooperate in the execution of the scheduled tasks. If a task has a member affinity, that is, if its parameter DB2-SSID contains the name of a DB2 member, only the scheduler that is associated with this DB2 member will execute this task. The task is executed as in a non-data sharing mode. If this scheduler is unavailable, the task will not be executed.

When a task has no member affinity, that is, if *DB2-SSID* is a null value, the scheduler that wakes first executes the task. If the task execution can complete on this scheduler, for example because its associated DB2 member is not running or because all of its execution threads are busy, other schedulers will not try executing this task. However, if the scheduler cannot start the execution, the other schedulers will try successively to start executing the task until one succeeds or all fail in executing the task.

The distribution of a task execution on the one or the other scheduler cannot be predicted. Successive executions of the same task can be done on different schedulers.

---

## Chapter 17. Monitoring and controlling DB2 and its connections

The information under this heading, up to “Controlling IMS connections” on page 392, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

Chapter 15, “Basic operation,” on page 317 tells you how to start DB2, submit work to be processed, and stop DB2. The following operations, described in this chapter, require more understanding of what DB2 is doing:

- “Controlling DB2 databases and buffer pools”
- “Controlling user-defined functions” on page 377
- “Controlling DB2 utilities” on page 379
- “Controlling the IRLM” on page 380

This chapter also introduces the concept of a *thread*, a DB2 structure that makes the connection between another subsystem and DB2. A thread describes an application’s connection, traces its progress, and delimits its accessibility to DB2 resources and services. Most DB2 functions execute under a thread structure. The use of threads in making, monitoring, and breaking connections is described in the following sections:

- “Monitoring threads” on page 383
- “Controlling TSO connections” on page 384
- “Controlling CICS connections” on page 387
- “Controlling IMS connections” on page 392
- “Controlling RRS connections” on page 401
- “Controlling connections to remote systems” on page 404

“Controlling traces” on page 422, tells you how to start and stop traces, and points to other books for help in analyzing their results.

“Controlling the resource limit facility (governor)” on page 425, tells how to start and stop the governor, and how to display its current status.

A final section, “Changing subsystem parameter values” on page 425, tells how to change subsystem parameters dynamically even when DB2 is running.

**Important:** Examples of commands in this chapter do not necessarily illustrate all the available options. For the complete syntax of any command or utility, see *DB2 Command Reference* or *DB2 Utility Guide and Reference*. For data sharing considerations, see *DB2 Data Sharing: Planning and Administration*.

---

### Controlling DB2 databases and buffer pools

DB2 databases are controlled by the following commands:

#### **START DATABASE**

Makes a database, or individual partitions, available. Also removes pages from the logical page list (LPL). For its use, see “Starting databases” on page 368.

## DISPLAY DATABASE

Displays status, user, and locking information for a database. For its use, see "Monitoring databases" on page 369.

## STOP DATABASE

Makes a database, or individual partitions, unavailable after existing users have quiesced. DB2 also closes and deallocates the data sets. For its use, see "Stopping databases" on page 375.

The START and STOP DATABASE commands can be used with the SPACENAM and PART options to control table spaces, index spaces, or partitions. For example, the following command starts two partitions of table space DSN8S81E in the database DSN8D81A:

```
-START DATABASE (DSN8D81A) SPACENAM (DSN8S81E) PART (1,2)
```

## Starting databases

The command START DATABASE (\*) starts all databases for which you have the STARTDB privilege. The privilege can be explicitly granted, or can belong implicitly to a level of authority (DBMAINT and above, as shown in Figure 9 on page 139). The command starts the database, but not necessarily all the objects it contains. Any table spaces or index spaces in a restricted mode remain in a restricted mode and are not started.

START DATABASE (\*) does not start the DB2 directory (DSNDB01), the DB2 catalog (DSNDB06), or the DB2 work file database (called DSNDB07, except in a data sharing environment). These databases have to be started explicitly using the SPACENAM option. Also, START DATABASE (\*) does not start table spaces or index spaces that have been explicitly stopped by the STOP DATABASE command.

The PART keyword of the command START DATABASE can be used to start individual partitions of a table space. It can also be used to start individual partitions of a partitioning index or logical partitions of a nonpartitioning index. The started or stopped state of other partitions is unchanged.

### Starting an object with a specific status

A database, table space, or an index space can be started with a specific status that limits access to it.

#### Status Provides this access

RW Read-write. This is the default value.  
RO Read only. You cannot change the data.  
UT Utility only. The object is available only to the DB2 utilities.

Databases, table spaces, and index spaces are started with RW status when they are created. You can make any of them unavailable by using the command STOP DATABASE. DB2 can also make them unavailable when it detects an error.

In cases when the object was explicitly stopped, you can make them available again using the command START DATABASE. For example, the following command starts all table spaces and index spaces in database DSN8D81A for read-only access:

```
-START DATABASE (DSN8D81A) SPACENAM(*) ACCESS(RO)
```

The system responds with this message:

```
DSN9022I - DSNTDDIS '-START DATABASE' NORMAL COMPLETION
```

## Starting a table space or index space that has restrictions

DB2 can make an object unavailable for a variety of reasons. Typically, in those cases, the data is unreliable and the object needs some attention before it can be started. An example of such a restriction is when the table space is placed in *copy pending* status. That status makes a table space or partition unavailable until an image copy has been made of it.

These restrictions are a necessary part of protecting the integrity of the data. **If you start an object that has restrictions, the data in the object might not be reliable.**

However, in certain circumstances, it might be reasonable to force availability. For example, a table might contain test data whose consistency is not critical. In those cases, the objects can be started by using the ACCESS(FORCE) option of START DATABASE. For example:

```
-START DATABASE (DSN8D81A) SPACENAM (DSN8S81E) ACCESS(FORCE)
```

The command releases most restrictions for the named objects. These objects must be explicitly named in a list following the SPACENAM option.

DB2 cannot process the START DATABASE ACCESS(FORCE) request if postponed abort or indoubt URs exist. The RESTP (restart-pending) status and the AREST (advisory restart-pending) status remain in effect until either automatic backout processing completes or you perform one of the following actions:

- Issue the RECOVER POSTPONED command to complete backout activity.
- Issue the RECOVER POSTPONED CANCEL command to cancel all of the postponed abort units of recovery.
- Conditionally restart or cold start DB2.

DB2 cannot apply the START DATABASE ACCESS(FORCE) command to that object, if a utility from a previous release of DB2 places an object in one of the following restrictive states:

- UTRO (utility restrictive state, read-only access allowed)
- UTRW (utility restrictive state, read and write access allowed)
- UTUT (utility restrictive state, utility exclusive control)

To reset these restrictive states, you must start the release of DB2 that originally ran the utility and terminate the utility from that release.

For more information about resolving postponed units of recovery, see “Resolving postponed units of recovery” on page 456.

## Monitoring databases

You can use the command DISPLAY DATABASE to obtain information about the status of databases and the table spaces and index spaces within each database. If applicable, the output also includes information about physical I/O errors for those objects.

Use DISPLAY DATABASE as follows:

```
-DISPLAY DATABASE (dbname)
```

This results in the following messages:

```

11:44:32 DSNT360I - *****
11:44:32 DSNT361I - * DISPLAY DATABASE SUMMARY
11:44:32          * report_type_list
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = dbname STATUS = xx
                   DBD LENGTH = yyyy

11:44:32 DSNT397I -

NAME      TYPE PART  STATUS          PHYERRLO  PHYERRHI CATALOG  PIECE
-----
D1        TS         RW,UTRO
D2        TS         RW
D3        TS         STOP
D4        IX         RO
D5        IX         STOP
D6        IX         UT
LOB1     LS         RW
***** DISPLAY OF DATABASE dbname ENDED *****
11:45:15 DSN9022I - DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION

```

In the preceding messages:

- *Report\_type\_list* indicates which options were included when the DISPLAY DATABASE command was issued. See Chapter 2 of *DB2 Command Reference* for detailed descriptions of options.
- *dbname* is an 8-byte character string indicating the database name. The pattern-matching character, \*, is allowed at the beginning, middle, and end of *dbname*.
- STATUS is a combination of one or more status codes delimited by a comma. The maximum length of the string is 17 characters. If the status exceeds 17 characters, those characters are wrapped onto the next status line. Anything that exceeds 17 characters on the second status line is truncated. See Chapter 2 of *DB2 Command Reference* for a list of status codes and their descriptions.

You can use the pattern-matching character, \*, in the commands DISPLAY DATABASE, START DATABASE, and STOP DATABASE. The pattern-matching character can be used in the beginning, middle, and end of the database and table space names.

**Using ONLY:** The keyword ONLY can be added to the command DISPLAY DATABASE. When ONLY is specified with the DATABASE keyword but not the SPACENAM keyword, all other keywords except RESTRICT, LIMIT, and AFTER are ignored. Use DISPLAY DATABASE ONLY as follows:

```
-DISPLAY DATABASE(*S*DB*) ONLY
```

This results in the following messages:

```

11:44:32 DSNT360I - *****
11:44:32 DSNT361I - * DISPLAY DATABASE SUMMARY
11:44:32          * GLOBAL
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = DSADB01 STATUS = RW
                   DBD LENGTH = 8066
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = DSADB04 STATUS = RW
                   DBD LENGTH = 21294
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = DSADB06 STATUS = RW
                   DBD LENGTH = 32985
11:45:15 DSN9022I - DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION

```

In the preceding messages:

- DATABASE (\*S\*DB\*) displays databases that begin with any letter, have the letter S followed by any letters, then the letters DB followed by any letters.
- ONLY restricts the display to databases names that fit the criteria.

See Chapter 2 of *DB2 Command Reference* for detailed descriptions of these and other options on the DISPLAY DATABASE command.

**Using RESTRICT:** You can use the RESTRICT option of the DISPLAY DATABASE command to limit the display to objects that are currently set to a restrictive status. You can additionally specify one or more keywords to limit the display further to include only objects that are set to a particular restrictive status. For information about resetting a restrictive status, see Appendix C of *DB2 Utility Guide and Reference*.

**Using ADVISORY:** You can use the ADVISORY option on the DISPLAY DATABASE command to limit the display to table spaces or indexes that require some corrective action. Use the DISPLAY DATABASE ADVISORY command without the RESTRICT option to determine when:

- An index space is in the informational copy pending (ICOPY) advisory status
- A base table space is in the auxiliary warning (AUXW) advisory status

For information about resetting an advisory status, see Appendix C of *DB2 Utility Guide and Reference*.

**Using OVERVIEW:** To display all objects within a database, you can use the OVERVIEW option of the DISPLAY DATABASE command. This option shows each object in the database on one line, does not break down an object by partition, and does not show exception states. The OVERVIEW option displays only object types and the number of data set partitions in each object. OVERVIEW is mutually exclusive with all keywords other than SPACENAM, LIMIT, and AFTER. Use DISPLAY DATABASE OVERVIEW as follows:

```
-DISPLAY DATABASE(DB486A) SPACENAM(*) OVERVIEW
```

This results in the following messages:

```
DSNT360I = *****
DSNT361I = * DISPLAY DATABASE SUMMARY 483
          * GLOBAL OVERVIEW
DSNT360I = *****
DSNT362I = DATABASE = DB486A STATUS = RW 485
          DBD LENGTH = 4028
DSNT397I = 486
NAME      TYPE PARTS
-----
TS486A    TS     0004
IX486A    IX     L0004
IX486B    IX     0004
TS486C    TS
IX486C    IX
***** DISPLAY OF DATABASE DB486A ENDED *****
DSN9022I = DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION
```

The display indicates that there are five objects in database DB486A, two table spaces and three indexes. Table space TS486A has four parts, and table space TS486C is nonpartitioned. Index IX486A is a nonpartitioning index for table space TS486A, and index IX486B is a partitioned index with four parts for table space TS486A. Index IX486C is a nonpartitioned index for table space TS486C.

## Obtaining information about application programs

You can obtain various kinds of information about application programs using particular databases or table or index spaces with the DISPLAY DATABASE command. This section describes how you can identify who or what is using the object and what locks are being held on the objects.

*Who and what is using the object?* You can obtain the following information:

- The names of the application programs currently using the database or space
- The authorization IDs of the users of these application programs
- The logical unit of work IDs of the database access threads accessing data on behalf of the remote locations specified.

To obtain this information, issue a command, for example, that names partitions 2, 3, and 4 in table space TPAUGF01 in database DBAUGF01:

```
-DISPLAY DATABASE (DBAUGF01) SPACENAM (TPAUGF01) PART (2:4) USE
```

DB2 returns a list similar to this one:

```
DSNT360I : *****
DSNT361I : * DISPLAY DATABASE SUMMARY
          * GLOBAL USE
DSNT360I : *****
DSNT362I : DATABASE = DBAUGF01 STATUS = RW
          DBD LENGTH = 8066
DSNT397I :
NAME     TYPE PART  STATUS          CONNID  CORRID  USERID
-----
TPAUGF01 TS    0002 RW            BATCH   S3341209  ADMF001
-
          MEMBER NAME V61A
TPAUGF01 TS    0003 RW            BATCH   S3341209  ADMF001
-
          MEMBER NAME V61A
TPAUGF01 TS    0004 RW            BATCH   S3341209  ADMF001
-
          MEMBER NAME V61A
***** DISPLAY OF DATABASE DBAUGF01 ENDED *****
DSN9022I : DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION
```

*Which programs are holding locks on the objects?* To determine which application programs are currently holding locks on the database or space, issue a command like the following, which names table space TSPART in database DB01:

```
-DISPLAY DATABASE(DB01) SPACENAM(TSPART) LOCKS
```

DB2 returns a list similar to this one:

```
17:45:42 DSNT360I - *****
17:45:42 DSNT361I - * DISPLAY DATABASE SUMMARY
17:45:42          * GLOBAL LOCKS
17:45:42 DSNT360I - *****
17:45:42 DSNT362I - DATABASE = DB01 STATUS = RW
17:45:42          DBD LENGTH = yyyy
17:45:42 DSNT397I -
NAME     TYPE PART  STATUS          CONNID  CORRID  LOCKINFO
-----
TSPART  TS    0001 RW            LSS001  DSN2SQL  H-IX,P,C
TSPART  TS    0002 RW            LSS001  DSN2SQL  H-IX,P,C
TSPART  TS    0003 RW            LSS001  DSN2SQL  H-IX,P,C
TSPART  TS    0004 RW            LSS001  DSN2SQL  H-IX,P,C
***** DISPLAY OF DATABASE DB01 ENDED *****
17:45:44 DSN9022I . DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION
```

For an explanation of the field LOCKINFO, see message DSNT396I in Part 2 of *DB2 Messages*.

Use the LOCKS ONLY keywords on the DISPLAY DATABASE command to display only spaces that have locks. The LOCKS keyword can be substituted with USE, CLAIMERS, LPL, or WEPR to display only databases that fit the criteria. Use DISPLAY DATABASE as follows:

```
-DISPLAY DATABASE (DSNDB06) SPACENAM(*) LOCKS ONLY
```

This results in the following messages:

```
11:44:32 DSNT360I - *****
11:44:32 DSNT361I - * DISPLAY DATABASE SUMMARY
11:44:32          * GLOBAL LOCKS
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = DSNDB06 STATUS = RW
                   DBD LENGTH = 60560

11:44:32 DSNT397I -
NAME      TYPE PART STATUS          CONNID   CORRID   LOCKINFO
-----
SYSDBASE TS          RW          DSN      020.DBCMD 06 H-IS,S,C
***** DISPLAY OF DATABASE DSNDB06 ENDED *****
11:45:15 DSN9022I - DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION
```

See Chapter 2 of *DB2 Command Reference* for detailed descriptions of these and other options of the DISPLAY DATABASE command.

## Obtaining information about pages in error

There are two ways that pages can be in error:

- A page is logically in error if its problem can be fixed without redefining new disk tracks or volumes. For example, if DB2 cannot write a page to disk because of a connectivity problem, the page is logically in error. DB2 inserts entries for pages that are logically in error in a *logical page list* (LPL).
- A page is physically in error if there are physical errors, such as device errors. Such errors appear on the *write error page range* (WEPR). The range has a low and high page, which are the same if only one page has errors.

If the cause of the problem is undetermined, the error is first recorded in the LPL. If recovery from the LPL is unsuccessful, the error is then recorded on the error page range.

Write errors for large object data type (LOB) table spaces defined with LOG NO cause the unit of work to be rolled back. Because the pages are written during normal deferred write processing, they can appear in the LPL and WEPR. The LOB data pages for a LOB table space with the LOG NO attribute are not written to LPL or WEPR. The space map pages are written during normal deferred write processing and can appear in the LPL and WEPR.

A program that tries to read data from a page listed on the LPL or WEPR receives an SQLCODE for “resource unavailable”. To access the page (or pages in the error range), you must first recover the data from the existing database copy and the log.

**Displaying the logical page list:** You can check the existence of LPL entries by issuing the DISPLAY DATABASE command with the LPL option. The ONLY option restricts the output to objects that have LPL pages. For example:

```
-DISPLAY DATABASE(DBFW8401) SPACENAM(*) LPL ONLY
```

The following output is produced:

```

DSNT360I = *****
DSNT361I = * DISPLAY DATABASE SUMMARY
          * GLOBAL LPL
DSNT360I = *****
DSNT362I = DATABASE = DBFW8401 STATUS = RW,LPL
          DBD LENGTH = 8066
DSNT397I =
NAME      TYPE PART STATUS          LPL PAGES
-----
TPFW8401 TS    0001 RW,LPL          000000-000004
ICFW8401 IX    L0001 RW,LPL          000000,000003
IXFW8402 IX              RW,LPL          000000,000003-000005
----
----
----
000007,000008-00000B
----
000080-000090
***** DISPLAY OF DATABASE DBFW8401 ENDED *****
DSN9022I = DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION

```

The display indicates that the pages listed in the LPL PAGES column are unavailable for access. For the syntax and description of DISPLAY DATABASE, see Chapter 2 of *DB2 Command Reference*.

**Removing pages from the LPL:** The DB2 subsystem always attempts automated recovery of LPL pages when the pages are added to the LPL. Manual recover can also be performed. When an object has pages on the LPL, there are several ways to manually remove those pages and make them available for access when DB2 is running:

- Start the object with access (RW) or (RO). That command is valid even if the table space is already started.  
When you issue the command START DATABASE, you see message DSNI006I, indicating that LPL recovery has begun. Message DSNIO22I is issued periodically to give you the progress of the recovery. When recovery is complete, you see DSNIO21I.  
When you issue the command START DATABASE for a LOB table space that is defined as LOG NO, and DB2 detects log records required for LPL recovery are missing due to the LOG NO attribute, the LOB table space is placed in AUXW status and the LOB is invalidated.
- Run the RECOVER or REBUILD INDEX utility on the object.  
The only exception to this is when a logical partition of a nonpartitioned index has both LPL and RECP status. If you want to recover the logical partition using REBUILD INDEX with the PART keyword, you must first use the command START DATABASE to clear the LPL pages.
- Run the LOAD utility with the REPLACE option on the object.
- Issue an SQL DROP statement for the object.

Only the following utilities can be run on an object with pages in the LPL:

```

LOAD with the REPLACE option
MERGECOPY
REBUILD INDEX
RECOVER, except:
    RECOVER...PAGE
    RECOVER...ERROR RANGE
REPAIR with the SET statement
REPORT

```

**Displaying a write error page range:** Use DISPLAY DATABASE to display the range of error pages. For example:

```
-DISPLAY DATABASE (DBPARTS) SPACENAM (TSPART01) WEPR
```

The preceding command might display the following list:

```
11:44:32 DSNT360I - *****
11:44:32 DSNT361I - * DISPLAY DATABASE SUMMARY
11:44:32          * GLOBAL WEPR
11:44:32 DSNT360I - *****
11:44:32 DSNT362I - DATABASE = DBPARTS STATUS = RW
                   DBD LENGTH = yyyy
11:44:32 DSNT397I -

NAME      TYPE PART STATUS          PHYERRLO PHYERRHI CATALOG PIECE
-----
TSPART01 TS 0001 RW,UTRO      00000002 00000004 DSNCAT 000
TSPART01 TS 0002 RW,UTRO      00000009 00000013 DSNCAT 001
TSPART01 TS 0003 RO
TSPART01 TS 0004 STOP
TSPART01 TS 0005 UT
***** DISPLAY OF DATABASE DBPARTS ENDED *****
11:45:15 DSN9022I - DSNTDDIS 'DISPLAY DATABASE' NORMAL COMPLETION
```

In the previous messages:

- PHYERRLO and PHYERRHI identify the range of pages that were being read when the I/O errors occurred. PHYERRLO is an 8-digit hexadecimal number representing the lowest page found in error, while PHYERRHI represents the highest page found in error.
- PIECE, a 3-digit integer, is a unique identifier for the data set supporting the page set that contains physical I/O errors.

For additional information about this list, see the description of message DSNT392I in Part 2 of *DB2 Messages*.

## Stopping databases

Databases, table spaces, and index spaces can be made unavailable with the STOP DATABASE command. You can also use STOP DATABASE with the PART option to stop the following types of partitions:

- Physical partitions within a table space
- Physical partitions within an index space
- Logical partitions within a nonpartitioning index associated with a partitioned table space.

This prevents access to individual partitions within a table or index space while allowing access to the others. When you specify the PART option with STOP DATABASE on physically partitioned spaces, the data sets supporting the given physical partitions are closed and do not affect the remaining partitions. However, STOP DATABASE with the PART option does not close data sets associated with logically partitioned spaces. To close these data sets, you must execute STOP DATABASE without the PART option.

The AT(COMMIT) option of STOP DATABASE stops objects quickly. The AT(COMMIT) option interrupts threads that are bound with RELEASE(DEALLOCATE) and is useful when thread reuse is high.

If you specify AT(COMMIT), DB2 takes over access to an object when all jobs release their claims on it and when all utilities release their drain locks on it. If you do not specify AT(COMMIT), the objects are not stopped until all existing applications have deallocated. New transactions continue to be scheduled, but they receive SQLCODE -904 SQLSTATE '57011' (resource unavailable) on the first SQL statement that references the object or when the plan is prepared for execution. STOP DATABASE waits for a lock on an object that it is attempting to stop. If the

wait time limit for locks (15 timeouts) is exceeded, then the STOP DATABASE command terminates abnormally and leaves the object in stop pending status (STOPP).

Database DSNDB01 and table spaces DSNDB01.DBD01 and DSNDB01.SYSLGRNX must be started before stopping user-defined databases or the work file database. A DSNI003I message tells you that the command was unable to stop an object. You must resolve the problem indicated by this message and run the job again. If an object is in STOPP status, you must first issue the START DATABASE command to remove the STOPP status and then issue the STOP DATABASE command.

DB2 subsystem databases (catalog, directory, work file) can also be stopped. After the directory is stopped, installation SYSADM authority is required to restart it.

The following examples illustrate ways to use the command:

**-STOP DATABASE (\*)**

Stops all databases for which you have STOPDB authorization, except the DB2 directory (DSNDB01), the DB2 catalog (DSNDB06), or the DB2 work file database (called DSNDB07, except in a data sharing environment), all of which must be stopped explicitly.

**-STOP DATABASE (dbname)**

Stops a database, and closes all of the data sets of the table spaces and index spaces in the database.

**-STOP DATABASE (dbname, ...)**

Stops the named databases and closes all of the table spaces and index spaces in the databases. If DSNDB01 is named in the database list, it should be last on the list because stopping the other databases requires that DSNDB01 be available.

**-STOP DATABASE (dbname) SPACENAM (\*)**

Stops and closes all of the data sets of the table spaces and index spaces in the database. The status of the named database does not change.

**-STOP DATABASE (dbname) SPACENAM (space-name, ...)**

Stops and closes the data sets of the named table space or index space. The status of the named database does not change.

**-STOP DATABASE (dbname) SPACENAM (space-name, ...) PART (integer)**

Stops and closes the specified partition of the named table space or index space. The status of the named database does not change. If the named index space is nonpartitioned, DB2 cannot close the specified logical partition.

The data sets containing a table space are closed and deallocated by the preceding commands.

## Altering buffer pools

DB2 stores buffer pool attributes in the DB2 bootstrap data set. You can use the ALTER BUFFERPOOL command to alter buffer pool attributes, which are initially defined during the DB2 installation process. These attributes include buffer pool sizes, sequential steal thresholds, deferred write thresholds, and parallel sequential thresholds. See Chapter 2 of *DB2 Command Reference* for descriptions of the options that you can use with this command. See “Tuning database buffer pools” on page 671 for guidance about using buffer pools and examples of ALTER BUFFERPOOL.

## Monitoring buffer pools

Use the DISPLAY BUFFERPOOL command to display the current status for one or more active or inactive buffer pools. You can request a summary or detail report.

For example:

```
-DISPLAY BUFFERPOOL(BP0)
```

might produce a summary report such as this:

```
|
| !DIS BUFFERPOOL(BP0)
| DSNB401I ! BUFFERPOOL NAME BP0, BUFFERPOOL ID 0, USE COUNT 27
| DSNB402I ! BUFFER POOL SIZE = 2000 BUFFERS
|           ALLOCATED           =      2000   TO BE DELETED   =           0
|           IN-USE/UPDATED      =           0
| DSNB406I ! PAGE STEALING METHOD = LRU
| DSNB404I ! THRESHOLDS -
|           VP SEQUENTIAL       =      80
|           DEFERRED WRITE      =      85   VERTICAL DEFERRED WRT = 10,15
|           PARALLEL SEQUENTIAL =      50   ASSISTING PARALLEL SEQT=  0
|
| DSN9022I ! DSNB1CMD '-DISPLAY BUFFERPOOL' NORMAL COMPLETION
```

See Chapter 2 of *DB2 Command Reference* for descriptions of the options you can use with this command and the information you find in the summary and detail reports.

---

## Controlling user-defined functions

User-defined functions are extensions to the SQL language. You can invoke user-defined functions in an SQL statement wherever you can use expressions or built-in functions. User-defined functions, like stored procedures, run in WLM-established address spaces. For information about creating, defining and invoking user-defined functions, see *DB2 SQL Reference*. For information about working with WLM-established address spaces, see “Monitoring and controlling stored procedures” on page 417.

DB2 user-defined functions are controlled by the following commands described in Chapter 2 of *DB2 Command Reference*:

### START FUNCTION SPECIFIC

Activates an external function that is stopped.

### DISPLAY FUNCTION SPECIFIC

Displays statistics about external user-defined functions accessed by DB2 applications.

### STOP FUNCTION SPECIFIC

Prevents DB2 from accepting SQL statements with invocations of the specified functions.

## Starting user-defined functions

The DB2 command START FUNCTION SPECIFIC activates an external function that is stopped. Built-in functions or user-defined functions that are sourced on another function cannot be started.

Use the START FUNCTION SPECIFIC command to activate all or a specific set of stopped external functions. For example, issue a command like the following, which starts functions USERFN1 and USERFN2 in the PAYROLL schema:

```
START FUNCTION SPECIFIC(PAYROLL.USERFN1,PAYROLL.USERFN2)
```

The following output is produced:

```
DSNX973I START FUNCTION SPECIFIC SUCCESSFUL FOR PAYROLL.USERFN1
DSNX973I START FUNCTION SPECIFIC SUCCESSFUL FOR PAYROLL.USERFN2
```

## Monitoring user-defined functions

The DB2 command DISPLAY FUNCTION SPECIFIC displays statistics about external user-defined functions accessed by DB2 applications. This command displays one output line for each function that has been accessed by a DB2 application. Information returned by this command reflect a dynamic status. By the time DB2 displays the information, the status might have changed. Built-in functions or user-defined functions that are sourced on another function are not applicable to this command.

Use the DISPLAY FUNCTION SPECIFIC command to list the range of functions that are stopped because of a STOP FUNCTION SPECIFIC command. For example, issue a command like the following, which displays information about functions in the PAYROLL schema and the HRPROD schema:

```
-DISPLAY FUNCTION SPECIFIC(PAYROLL.*,HRPROD.*)
```

The following output is produced:

```
DSNX975I DSNX9DIS - DISPLAY FUNCTION SPECIFIC REPORT FOLLOWS-
```

```
----- SCHEMA=PAYROLL
FUNCTION      STATUS  ACTIVE  QUED  MAXQ  TIMEOUT  FAIL  WLM_ENV
PAYRFNC1     STARTED    0     0     1     0     0  PAYROLL
PAYRFNC2     STOPQUE    0     5     5     3     0  PAYROLL
PAYRFNC3     STARTED    2     0     6     0     0  PAYROLL
USERFNC4     STOPREJ    0     0     1     0     1  SANDBOX

----- SCHEMA=HRPROD
FUNCTION      STATUS  ACTIVE  QUED  MAXQ  TIMEOUT  FAIL  WLM_ENV
HRFNC1       STARTED    0     0     1     0     0  HRFUNCS
HRFNC2       STOPREJ    0     0     1     0     0  HRFUNCS
```

```
DSNX9DIS DISPLAY FUNCTION SPECIFIC REPORT COMPLETE
DSN9022I - DSNX9COM '-DISPLAY FUNC' NORMAL COMPLETION
```

## Stopping user-defined functions

The DB2 command STOP FUNCTION SPECIFIC prevents DB2 from accepting SQL statements with invocations of the specified functions. This command does not prevent SQL statements with invocations of the functions from running if they have already been queued or scheduled by DB2. You cannot stop built-in functions or user-defined functions that are sourced on another function. While the STOP FUNCTION SPECIFIC command is in effect, attempts to execute the stopped functions are queued.

Use the STOP FUNCTION SPECIFIC command to stop access to all or a specific set of external functions. For example, issue a command like the following, which stops functions USERFN1 and USERFN3 in the PAYROLL schema:

```
STOP FUNCTION SPECIFIC(PAYROLL.USERFN1,PAYROLL.USERFN3)
```

The following output is produced:

---

## Controlling DB2 utilities

You can run DB2 utilities against databases, table spaces, indexes, index spaces, and partitions.

DB2 utilities are classified into two groups: online and stand-alone. The online utilities require DB2 to be running and can be invoked in several different ways. The stand-alone utilities do not require DB2 to be up, and they can be invoked only by means of JCL. The online utilities are described in Part 2 of *DB2 Utility Guide and Reference*, and the stand-alone utilities are described in Part 3 of *DB2 Utility Guide and Reference*.

### Starting online utilities

To start a DB2 utility, prepare an appropriate set of JCL statements for a utility job and include DB2 utility control statements in the input stream for that job. DB2 utilities can dynamically create object lists from a pattern-matching expression and can dynamically allocate the data sets required to process those objects.

### Monitoring online utilities

The following commands for monitoring and changing DB2 utility jobs are described in Chapter 2 of *DB2 Command Reference*.

#### ALTER UTILITY

Alters parameter values of an active REORG utility.

#### DISPLAY UTILITY

Displays the status of utility jobs.

#### TERM UTILITY

Terminates a utility job before its normal completion.

**If a utility is not running**, you need to determine whether the type of utility access is allowed on an object of a specific status. Table 93 shows the compatibility of utility types and object status.

Table 93. Compatibility of utility types and object status

Utility type	Object access
Read-only	RO
All	RW <sup>1</sup>
DB2	UT

#### Note:

1. RW is the default access type for an object.

**To change the status of an object**, use the ACCESS option of the START DATABASE command to start the object with a new status. For example:  
-START DATABASE (DSN8D61A) ACCESS(RO)

For more information about concurrency and compatibility of individual online utilities, see Part 2 of *DB2 Utility Guide and Reference*. For a general discussion about controlling concurrency for utilities, see Part 5 (Volume 2) of *DB2 Administration Guide*.

## Stand-alone utilities

The following stand-alone utilities can be run only by means of JCL:

- DSN1CHKR
- DSN1COPY
- DSN1COMP
- DSN1PRNT
- DSN1SDMP
- DSN1LOGP
- DSNJLOGF
- DSNJU003 (change log inventory)
- DSNJU004 (print log map)

Most of the stand-alone utilities can be used while DB2 is running. However, for consistency of output, the table spaces and index spaces must be stopped first because these utilities do not have access to the DB2 buffer pools. In some cases, DB2 *must* be running or stopped before you invoke the utility. See Part 3 of *DB2 Utility Guide and Reference* for detailed environmental information about these utilities.

Stand-alone utility job streams require that you code specific data set names in the JCL. To determine the fifth qualifier in the data set name, you need to query the DB2 catalog tables SYSIBM.SYSTABLEPART and SYSIBM.SYSINDEXPART to determine the IPREFIX column that corresponds to the required data set.

The *change log inventory utility* (DSNJU003) enables you to change the contents of the bootstrap data set (BSDS). This utility cannot be run while DB2 is running because inconsistencies could result. Use STOP DB2 MODE(QUIESCE) to stop the DB2 subsystem, run the utility, and then restart DB2 with the START DB2 command.

The *print log map utility* (DSNJU004) enables you to print the the bootstrap data set contents. The utility can be run when DB2 is active or inactive; however, when it is run with DB2 active, the user's JCL and the DB2 started task must both specify DISP=SHR for the BSDS data sets.

---

## Controlling the IRLM

The internal resource lock manager (IRLM) subsystem manages DB2 locks. The particular IRLM to which DB2 is connected is specified in DB2's load module for subsystem parameters. It is also identified as a z/OS subsystem in the SYS1.PARMLIB member IEFSSNxx. That name is used as the IRLM procedure name (*irlmproc*) in z/OS commands.

IMS and DB2 must use separate instances of IRLM.

**Data sharing:** In a data sharing environment, the IRLM handles global locking, and each DB2 member has its own corresponding IRLM. See *DB2 Data Sharing: Planning and Administration* for more information about configuring IRLM in a data sharing environment.

You can use the following z/OS commands to control the IRLM. *irlmproc* is the IRLM procedure name, and *irlmmn* is the IRLM subsystem name. See Chapter 2 of *DB2 Command Reference* for more information about these commands.

**MODIFY irlmproc,ABEND,DUMP**

Abends the IRLM and generates a dump.

**MODIFY *irlmproc*,ABEND,NODUMP**

Abends the IRLM but does not generate a dump.

**MODIFY *irlmproc*,DIAG**

Initiates diagnostic dumps for IRLM subsystems in a data sharing group when there is a delay.

**MODIFY *irlmproc*,SET**

Sets dynamically the maximum amount of PVT storage or the number of trace buffers used for this IRLM.

**MODIFY *irlmproc*,STATUS**

Displays the status for the subsystems on this IRLM.

**START *irlmproc***

Starts the IRLM.

**STOP *irlmproc***

Stops the IRLM normally.

**TRACE CT,OFF,COMP=*irlmnm***

Stops IRLM tracing.

**TRACE CT,ON,COMP=*irlmnm***

Starts IRLM tracing for all subtypes (DBM,SLM,XIT,XCF).

**TRACE CT,ON,COMP=*irlmnm*,SUB=(*subname*)**

Starts IRLM tracing for a single subtype.

## Starting the IRLM

The IRLM must be available when you start DB2.

When DB2 is installed, you normally specify that the IRLM be started automatically. Then, if the IRLM is not available when DB2 is started, DB2 starts it, and periodically checks whether it is up before attempting to connect. If the attempt to start the IRLM fails, DB2 terminates.

If an automatic IRLM start has not been specified, start the IRLM before starting DB2, using the z/OS START *irlmproc* command.

When started, the IRLM issues this message to the z/OS console:

```
DXR117I irlmnm INITIALIZATION COMPLETE
```

Consider starting the IRLM manually if you are having problems starting DB2 for either of these reasons:

- An IDENTIFY or CONNECT to a data sharing group fails.
- DB2 experiences a failure that involves the IRLM.

When you start the IRLM manually, you can generate a dump to collect diagnostic information because IRLM does not stop automatically.

## Modifying the IRLM

You can use the following z/OS commands to modify the IRLM. See Chapter 2 of *DB2 Command Reference* for more information about these commands.

**MODIFY *irlmproc*,SET,PVT=*nnn***

Sets the maximum amount of PVT storage that this IRLM can use for lock control structures.

**MODIFY *irlmproc*,SET,DEADLOCK=*n***

Sets the time for the local deadlock detection cycle.

**MODIFY *irlmproc*,SET,LTE=*n***

Sets the number of LOCK HASH entries that this IRLM can use on the next connect to the XCF LOCK structure. Use only for data sharing.

**MODIFY *irlmproc*,SET,TIMEOUT=*n*,*subsystem-name***

Sets the timeout value for the specified DB2 subsystem. Display the *subsystem-name* by using **MODIFY *irlmproc*,STATUS**.

**MODIFY *irlmproc*,SET,TRACE=*n***

Sets the maximum number of trace buffers used for this IRLM.

## Monitoring the IRLM connection

You can use the following z/OS commands to monitor the IRLM connection. See Chapter 2 of *DB2 Command Reference* for more information about these commands.

**MODIFY *irlmproc*,STATUS,*irlmnm***

Displays the status of a specific IRLM.

**MODIFY *irlmproc*,STATUS,ALLD**

Displays the status of all subsystems known to this IRLM in the data sharing group.

**MODIFY *irlmproc*,STATUS,ALLI**

Displays the status of all IRLMs known to this IRLM in the data sharing group.

**MODIFY *irlmproc*,STATUS,MAINT**

Displays the maintenance levels of IRLM load module CSECTs for the specified IRLM instance.

**MODIFY *irlmproc*,STATUS,STOR**

Displays the current and *high water* allocation for PVT storage, as well as storage that is above the 2 GB bar.

**MODIFY *irlmproc*,STATUS,TRACE**

Displays information about trace types of IRLM subcomponents.

## Stopping the IRLM

If the IRLM is started automatically by DB2, it stops automatically when DB2 is stopped. If the IRLM is not started automatically, you must stop it after DB2 stops.

If you try to stop the IRLM while DB2 or IMS is still using it, you get the following message:

```
DXR105E irlmnm STOP COMMAND REJECTED. AN IDENTIFIED SUBSYSTEM  
IS STILL ACTIVE
```

If that happens, issue the **STOP *irlmproc*** command again, when the subsystems are finished with the IRLM.

Alternatively, if you must stop the IRLM immediately, enter the following command to force the stop:

```
MODIFY irlmproc,ABEND,NODUMP
```

The system responds with this message:

```
DXR165I KRLM TERMINATED VIA IRLM MODIFY COMMAND.  
DXR121I KRLM END-OF-TASK CLEANUP SUCCESSFUL - HI-CSA 335K  
- HI-ACCT-CSA      0K
```

DB2 abends. An IMS subsystem using the IRLM does not abend and can be reconnected.

IRLM uses the z/OS Automatic Restart Manager (ARM) services. However, it de-registers from ARM for normal shutdowns. IRLM registers with ARM during initialization and provides ARM with an event exit. The event exit must be in the link list. It is part of the IRLM DXRRL183 load module. The event exit will make sure that the IRLM name is defined to z/OS when ARM restarts IRLM on a target z/OS that is different from the failing z/OS. The IRLM element name used for the ARM registration depends on the IRLM mode. For local mode IRLM, the element name is a concatenation of the IRLM subsystem name and the IRLM ID. For global mode IRLM, the element name is a concatenation of the IRLM data sharing group name, IRLM subsystem name, and the IRLM ID.

IRLM de-registers from ARM when one of the following events occurs:

- PURGE *irlmproc* is issued.
- MODIFY *irlmproc,ABEND,NODUMP* is issued.
- DB2 automatically stops IRLM.

The command MODIFY *irlmproc,ABEND,NODUMP* specifies that IRLM de-register from ARM before terminating, which prevents ARM from restarting IRLM. However, it does not prevent ARM from restarting DB2, and, if you set the automatic restart manager to restart IRLM, DB2 automatically starts IRLM.

---

## Monitoring threads

The DB2 command DISPLAY THREAD displays current information about the status of threads, including information about:

- Threads that are processing locally
- Threads that are processing distributed requests
- Stored procedures or user-defined functions if the thread is executing one of those
- Parallel tasks

Threads can be active or pooled:

- An active allied thread is a thread that is connected to DB2 from TSO, BATCH, IMS, CICS, CAF or RRSAP.
- An active database access thread is a thread connected through a network with another system and performing work on behalf of that system.
- A pooled database access thread is an idle thread that is waiting for a new unit of work from a connection to another system to begin. Pooled threads hold no database locks.

The output of the command DISPLAY THREAD can also indicate that a system quiesce is in effect as a result of the ARCHIVE LOG command. For more information, see “Archiving the log” on page 435.

The command DISPLAY THREAD allows you to select which type of information you wish to include in the display using one or more of the following standards:

- Active, indoubt, postponed abort, or pooled threads

- Allied threads associated with the address spaces whose connection-names are specified
- Allied threads
- Distributed threads
- Distributed threads associated with a specific remote location
- Detailed information about connections with remote locations
- A specific logical unit of work ID (LUWID).

The information returned by the DISPLAY THREAD command reflects a dynamic status. By the time the information is displayed, it is possible that the status could have changed. Moreover, the information is consistent only within one address space and is not necessarily consistent across all address spaces.

To use the TYPE, LOCATION, DETAIL, and LUWID keywords, you must have SYSOPR authority or higher. For detailed information, see Chapter 2 of *DB2 Command Reference*.

**Example:** The DISPLAY THREAD command displays information about active and pooled threads in the following format:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS:
DSNV402I - ACTIVE THREADS:
  NAME  ST  A   REQ      ID      AUTHID  PLAN   ASID  TOKEN
conn-name s * req-ct  corr-id  auth-id pname  asid  token
conn-name s * req-ct  corr-id  auth-id pname  asid  token
DISPLAY ACTIVE REPORT COMPLETE
DSN9022I - module_name '-DISPLAY THREAD' NORMAL COMPLETION
```

**Example:** The DISPLAY THREAD command displays information about indoubt threads in the following format:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV406I - INDOUBT THREADS -
COORDINATOR          STATUS      RESET URID          AUTHID
coordinator-name     status      yes/no urid         authid
DISPLAY INDOUBT REPORT COMPLETE
DSN9022I - DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION
```

**Example:** The DISPLAY THREAD command displays information about postponed aborted threads in the following format:

```
DSNV401I ! DISPLAY THREAD REPORT FOLLOWS -
DSNV431I ! POSTPONED ABORT THREADS -
COORDINATOR          STATUS      RESET URID          AUTHID
coordinator-name     ABORT-P      uridauthid
DISPLAY POSTPONED ABORT REPORT COMPLETE
DSN9022I ! DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION
```

More information about how to interpret this output can be found in the sections describing the individual connections and in the description of message DSNV408I in Part 2 of *DB2 Messages*.

---

## Controlling TSO connections

z/OS provides no commands for controlling or monitoring a connection to DB2. The connection is monitored instead by the DB2 command DISPLAY THREAD, which displays information about connections to DB2 (from other subsystems as well as from z/OS).

The command is generally entered from an z/OS console or an administrator's TSO session. See "Monitoring threads" on page 383 for more examples of its use.

## Connecting to DB2 from TSO

The z/OS operator is not involved in starting and stopping TSO connections. Those connections are made through the DSN command processor, which is invoked either

- Explicitly, by the DSN command, or
- Implicitly, through DB2I (DB2 Interactive)

When a DSN session is active, you can enter DSN subcommands, DB2 commands, and TSO commands, as described under “Running TSO application programs” on page 327.

The DSN command can be given in the foreground or background, when running under the TSO terminal monitor program (TMP). The full syntax of the command is:

```
DSN SYSTEM (subsystemid) RETRY (n1) TEST (n2)
```

The parameters are optional, and have the following meanings:

*subsystemid*

Is the subsystem ID of the DB2 subsystem to be connected

*n1* Is the number of times to attempt the connection if DB2 is not running (one attempt every 30 seconds)

*n2* Is the DSN tracing system control that can be used if a problem is suspected

For example, this invokes a DSN session, requesting 5 retries at 30-second intervals:

```
DSN SYSTEM (DB2) RETRY (5)
```

DB2I invokes a DSN session when you select any of these operations:

- SQL statements using SPUFI
- DCLGEN
- BIND/REBIND/FREE
- RUN
- DB2 commands
- Program preparation and execution

In carrying out those operations, the DB2I panels invoke CLISTs, which start the DSN session and invoke appropriate subcommands.

## Monitoring TSO and CAF connections

To display information about connections that use the TSO attach facility and call attach facility (CAF), issue the command DISPLAY THREAD. Table 94 summarizes how DISPLAY THREAD output differs for a TSO online application, a TSO batch application, a QMF session, and a call attach facility application.

Table 94. Differences in display thread information for TSO and batch

Connection	Name	AUTHID	Corr-ID <sup>1</sup>	Plan <sup>1</sup>
DSN (TSO Online)	TSO	Logon ID	Logon ID	RUN .. Plan(x)
DSN (TSO Batch)	BATCH	Job USER=	Job Name	RUN .. Plan(x)
QMF	DB2CALL	Logon ID	Logon ID	'QMFvr0'
CAF	DB2CALL	Logon ID	Logon ID	OPEN parm

Table 94. Differences in display thread information for TSO and batch (continued)

Connection	Name	AUTHID	Corr-ID <sup>1</sup>	Plan <sup>1</sup>
------------	------	--------	----------------------	-------------------

**Notes:**

1. After the application has connected to DB2 but before a plan has been allocated, this field is blank.

The name of the connection can have one of the following values:

Name	Connection to
TSO	Program running in TSO foreground
BATCH	Program running in TSO background
DB2CALL	Program using the call attachment facility and running in the same address space as a program using the TSO attachment facility

The correlation ID, *corr-id*, is either the foreground authorization ID or the background job name. For a complete description of the DISPLAY THREAD status information displayed, see the description of message DSNV404I in Part 2 of *DB2 Messages*.

The following command displays information about TSO and CAF threads, including those processing requests to or from remote locations:

```
-DISPLAY THREAD(BATCH,TSO,DB2CALL)
```

```
DSNV401I = DISPLAY THREAD REPORT FOLLOWS -
DSNV402I = ACTIVE THREADS -
NAME      ST A  REQ ID      AUTHID  PLAN      ASID TOKEN
1 BATCH   T *  2997 TEP2      SYSADM  DSNTPEP41 0019 18818
2 BATCH   RA *  1246 BINETEP2  SYSADM  DSNTPEP44 0022 20556
V445-DB2NET.LUND1.AB0C8FB44C4D=20556 ACCESSING DATA FOR SAN JOSE
3 TSO     T      12 SYSADM    SYSADM  DSNESPRR 0028 5570
4 DB2CALL T *  18472 CAFCOB2  SYSADM  CAFCOB2  001A 24979
5 BATCH   T *      1 PUPPY      SYSADM  DSNTPEP51 0025 20499
6         PT *    641 PUPPY      SYSADM  DSNTPEP51 002D 20500
7         PT *    592 PUPPY      SYSADM  DSNTPEP51 002D 20501
DISPLAY ACTIVE REPORT COMPLETE
DSN9022I = DSNVDT '-DIS THREAD' NORMAL COMPLETION
```

**Key:**

- 1 This is a TSO batch application.
- 2 This is a TSO batch application running at a remote location and accessing tables at this location.
- 3 This is a TSO online application.
- 4 This is a call attachment facility application.
- 5 This is an originating thread for a TSO batch application.
- 6 This is a parallel thread for the originating TSO batch application thread.
- 7 This is a parallel thread for the originating TSO batch application thread.

Figure 32. Display thread showing TSO and CAF connections

Detailed information for assisting the console operator in identifying threads involved in distributed processing can be found in “Monitoring threads” on page 383.

## Disconnecting from DB2 while under TSO

The connection to DB2 ends, and the thread is terminated, when:

- You enter the END subcommand.
- You enter DSN again. (A new connection is established immediately.)
- You enter the CANCEL THREAD command (for threads that are active or suspended in DB2).
- You enter the MVS CANCEL command.
- You press the attention key (PA1).
- Any of the following operations end:
  - SQL statements using SPUFI
  - DCLGEN
  - BIND/REBIND/FREE
  - RUN
- You are using any of the preceding operations and you enter END or RETURN.

*A simple session:* For example, the following command and subcommands establish a connection to DB2, run a program, and terminate the connection:

TSO displays:

READY

You enter:

DSN SYSTEM (DSN)

DSN displays:

DSN

You enter:

RUN PROGRAM (MYPROG)

DSN displays:

DSN

You enter:

END

TSO displays:

READY

---

## Controlling CICS connections

The following CICS attachment facility commands can be entered from a CICS terminal to control and monitor connections between CICS and DB2:

### **DSNC DISCONNECT**

Terminates threads using a specific DB2 plan.

### **DSNC DISPLAY**

Displays thread information or statistics.

### **DSNC MODIFY**

Modifies the maximum number of threads for a transaction or group.

### **DSNC STOP**

Disconnects CICS from DB2.

## DSNC STRT

Starts the CICS attachment facility.

CICS command responses are sent to the terminal from which the corresponding command was entered, unless the DSNC DISPLAY command specifies an alternative destination. For details on specifying alternate destinations for output, see the DSNC DISPLAY command in the *DB2 Command Reference*.

For detailed information about controlling CICS connections, see "Defining the CICS DB2 connection" in the CICS DB2 Guide.

## Connecting from CICS

A connection to DB2 can be started or restarted at any time after CICS initialization. The CICS attachment facility is a set of modules DB2 provides that are loaded into the CICS address space. Use the following command to start the attachment facility:

```
DSNC STRT ssid
```

*ssid* specifies a DB2 subsystem ID to override that specified in the CICS INITPARM macro.

You can also start the attachment facility automatically at CICS initialization using a program list table (PLT). For details, see Part 2 of *DB2 Installation Guide*.

## Restarting CICS

One function of the CICS attachment facility is to keep data in synchronization between the two systems. If DB2 completes phase 1 but does not start phase 2 of the commit process, the units of recovery being committed are termed *indoubt*. An indoubt unit of recovery might occur if DB2 terminates abnormally after completing phase 1 of the commit process. CICS might commit or roll back work without DB2's knowledge.

DB2 cannot resolve those indoubt units of recovery (that is, commit or roll back the changes made to DB2 resources) until the connection to CICS is restarted. This means that CICS should always be auto-started (START=AUTO in the DFHSIT table) to get all necessary information for indoubt thread resolution available from its log. Avoid cold starting. The START option can be specified in the DFHSIT table, as described in *CICS Transaction Server for z/OS Resource Definition Guide*.

If there are CICS requests active in DB2 when a DB2 connection terminates, the corresponding CICS tasks might remain suspended even after CICS is reconnected to DB2. You should purge those tasks from CICS using a CICS-supplied transaction such as:

```
CEMT SET TASK(nn) FORCE
```

See *CICS Transaction Server for z/OS CICS Supplied Transactions* for more information about transactions that CICS supplies.

If any unit of work is indoubt when the failure occurs, the CICS attachment facility automatically attempts to resolve the unit of work when CICS is reconnected to DB2. Under some circumstances, however, CICS cannot resolve indoubt units of recovery. You must manually recover these indoubt units of recovery (see "Recovering indoubt units of recovery manually" on page 389 for more information).

## Displaying indoubt units of recovery

To display a list of indoubt units of recovery, issue the command:

```
-DISPLAY THREAD (connection-name) TYPE (INDOUBT)
```

The command produces messages similar to these:

```
DSNV407I -STR INDOUBT THREADS - 480
COORDINATOR          STATUS      RESET URID          AUTHID
CICS41              INDOUBT      00019B8ADE9E      ADMF001
V449-HAS NID= CICS41.AACC9B739F125184 AND ID=GT00LE39
DISPLAY INDOUBT REPORT COMPLETE
DSN9022I -STR DSNVDT '-DIS THD' NORMAL COMPLETION
```

For an explanation of the displayed list, see the description of message DSNV408I in Part 2 of *DB2 Messages*.

## Recovering indoubt units of recovery manually

To recover an indoubt unit of recovery, issue one of the following commands:

```
-RECOVER INDOUBT (connection-name) ACTION (COMMIT) ID (correlation-id)
-RECOVER INDOUBT (connection-name) ACTION (ABORT) ID (correlation-id)
```

The default value for *connection-name* is the connection name from which you entered the command. *Correlation-id* is the correlation ID of the thread to be recovered. It can be determined by issuing the command DISPLAY THREAD. Your choice for the ACTION parameter tells whether to commit or roll back the associated unit of recovery. For more details, see “Resolving indoubt units of recovery” on page 463.

One of the following messages can be used after you use the RECOVER command:

```
DSNV414I - THREAD correlation-id COMMIT SCHEDULED
DSNV415I - THREAD correlation-id ABORT SCHEDULED
```

For more information about manually resolving indoubt units of recovery, see “Manually recovering CICS indoubt units of recovery” on page 531. For information about the two-phase commit process, as well as indoubt units of recovery, see “Multiple system consistency” on page 459.

## Displaying postponed units of recovery

To display a list of postponed units of recovery, issue the command:

```
-DISPLAY THREAD (connection-name) TYPE (POSTPONED)
```

The command produces messages similar to these:

```
DSNV431I -POSTPONED ABORT THREADS - 480
COORDINATOR          STATUS      RESET URID          AUTHID
CICS41              P-ABORT      00019B8ADE9E      ADMF001
V449-HAS NID= CICS41.AACC9B739F125184 AND ID=GT00LE39
DISPLAY POSTPONED ABORT REPORT COMPLETE
DSN9022I -STR DSNVDT '-DIS THD' NORMAL COMPLETION
```

For an explanation of the displayed list, see the description of message DSNV408I in Part 2 of *DB2 Messages*.

## Controlling CICS connections

This section describes how CICS threads are defined, how you can monitor those threads, and ways you can disconnect those threads.

## Defining CICS threads

Every CICS transaction that accesses DB2 requires a thread to service the DB2 requests. Each thread uses one z/OS subtask to execute DB2 code for the CICS application.

The DSNCLSTR command starts the CICS DB2 attachment facility, which allows CICS application programs to access DB2 databases.

Threads are created at the first DB2 request from the application if there is not one already available for the specific DB2 plan.

For complete information about defining CICS threads with DB2, see *CICS DB2 Guide*.

## Monitoring the threads

No operator intervention is required for connecting applications; CICS handles the threads dynamically. You can monitor threads using CICS attachment facility commands or DB2 commands.

*Using CICS attachment facility commands:* Any authorized CICS user can monitor the threads and change the connection parameters as needed. Operators can use the following CICS attachment facility commands to monitor one of the following the threads:

```
DSNC DISPLAY PLAN plan-name destination
DSNC DISPLAY TRANSACTION transaction-id destination
```

These commands display the threads that the resource or transaction is using. The following information is provided for each created thread:

- Authorization ID for the plan associated with the transaction (8 characters).
- PLAN/TRAN name (8 characters).
- A or I (1 character).

If **A** is displayed, the thread is within a unit of work. If **I** is displayed, the thread is waiting for a unit of work, and the authorization ID is blank.

The following CICS attachment facility command is used to monitor CICS:

```
DSNC DISPLAY STATISTICS destination
```

## Disconnecting applications

There is no way to disconnect a particular CICS transaction from DB2 without abending the transaction. Two ways to disconnect an application are described here:

- The DB2 command CANCEL THREAD can be used to cancel a particular thread. CANCEL THREAD requires that you know the *token* for any thread you want to cancel. Enter the following command to cancel the thread identified by the token indicated in the display output.

```
-CANCEL THREAD(46)
```

When you issue CANCEL THREAD for a thread, that thread is scheduled to be terminated in DB2.

- The command DSNCLSTR terminates the threads allocated to a plan ID, but it does not prevent new threads from being created. This command frees DB2 resources shared by the CICS transactions and allows exclusive access to them for special-purpose processes such as utilities or data definition statements. The thread is not canceled until the application releases it for reuse, either at SYNCPOINT or end-of-task.

| For complete information about the use of CICS attachment commands with  
| DB2, see *CICS DB2 Guide*.

## Disconnecting from CICS

This section describes how to do both an orderly and forced disconnection of the attachment to CICS.

### Orderly termination

It is recommended that you do orderly termination whenever possible. An orderly termination of the connection allows each CICS transaction to terminate before thread subtasks are detached. This means there should be no indoubt units of recovery at reconnection time. An orderly termination occurs when you:

- Enter the DSNB STOP QUIESCE command. CICS and DB2 remain active.
- Enter the CICS command CEMT PERFORM SHUTDOWN, and the CICS attachment facility is also named to shut down during program list table (PLT) processing. DB2 remains active. For information about the CEMT PERFORM SHUTDOWN command, see *CICS for MVS/ESA CICS-Supplied Transactions*.
- Enter the DB2 command CANCEL THREAD. The thread is abended.

The following example stops the DB2 subsystem (QUIESCE), allows the currently identified tasks to continue normal execution, and does not allow new tasks to identify themselves to DB2:

```
-STOP DB2 MODE (QUIESCE)
```

This message appears when the stop process starts and frees the entering terminal (option QUIESCE):

```
DSNC012I THE ATTACHMENT FACILITY STOP QUIESCE IS PROCEEDING
```

When the stop process ends and the connection is terminated, this message is added to the output from the CICS job:

```
DSNC025I THE ATTACHMENT FACILITY IS INACTIVE
```

### Forced termination

Although it is not recommended, there might be times when it is necessary to force the connection to end. A forced termination of the connection can abend CICS transactions connected to DB2. Therefore, indoubt units of recovery can exist at reconnect. A forced termination occurs in the following situations:

- You enter the DSNB STOP FORCE command. This command waits 15 seconds before detaching the thread subtasks, and, in some cases, can achieve an orderly termination. DB2 and CICS remain active.
- You enter the CICS command CEMT PERFORM SHUTDOWN IMMEDIATE. For information about this command, see *CICS for MVS/ESA CICS-Supplied Transactions*. DB2 remains active.
- You enter the DB2 command STOP DB2 MODE (FORCE). CICS remains active.
- A DB2 abend occurs. CICS remains active.
- A CICS abend occurs. DB2 remains active.
- STOP is issued to the DB2 or CICS attachment facility, and the CICS transaction overflows to the pool. The transaction issues an intermediate commit. The thread is terminated at commit time, and further DB2 access is not allowed.

This message appears when the stop process starts and frees the entering terminal (option FORCE):

```
DSNC022I THE ATTACHMENT FACILITY STOP FORCE IS PROCEEDING
```

When the stop process ends and the connection is terminated, this message is added to the output from the CICS job:

```
DSNC025I THE ATTACHMENT FACILITY IS INACTIVE
```

---

## Controlling IMS connections

IMS provides these operator commands for controlling and monitoring the connection to DB2:

### **/START SUBSYS**

Connects the IMS control region to a DB2 subsystem.

### **/TRACE**

Controls the IMS trace.

### **/DISPLAY SUBSYS**

Displays connection status and thread activity.

### **/DISPLAY OASN SUBSYS**

Displays outstanding units of recovery.

### **/CHANGE SUBSYS**

Deletes an indoubt unit of recovery from IMS.

### **/STOP SUBSYS**

Disconnects IMS from a DB2 subsystem.

For more information about those commands, see Chapter 2 of *DB2 Command Reference* or, in the IMS library, to *IMS Command Reference*.

IMS command responses are sent to the terminal from which the corresponding command was entered. Authorization to enter IMS commands is based on IMS security.

## Connecting to the IMS control region

IMS makes one connection to its control region from each DB2 subsystem. IMS can make the connection either:

- Automatically during IMS cold start initialization or at warm start of IMS if a DB2 connection was active when IMS is shut down
- In response to the command `/START SUBSYS ssid`, where *ssid* is the DB2 subsystem identifier

The command causes the following message to be displayed at the logical terminal (LTERM):

```
DFS058  START COMMAND COMPLETED
```

The message is issued regardless of whether DB2 is active and does not imply that the connection is established.

The order of starting IMS and DB2 is not vital. If IMS is started first, then when DB2 comes up, it posts the control region modify task, and IMS again tries to reconnect.

If DB2 is stopped by the `STOP DB2` command, the `/STOP SUBSYS` command, or a DB2 abend, then IMS cannot reconnect automatically. You must make the connection by using the `/START` command.

The following messages can be produced when IMS attempts to connect a DB2 subsystem:

- If DB2 is active, these messages are sent:
  - To the z/OS console:
 

```
DFS3613I ESS TCB INITIALIZATION COMPLETE
```
  - To the IMS master terminal:
 

```
DSNM001I IMS/TM imsid CONNECTED TO SUBSYSTEM ssnm
```
- If DB2 is not active, this message is sent to the master terminal:
 

```
DSNM003I IMS/TM imsid FAILED TO CONNECT TO SUBSYSTEM ssnm
RC=00 imsid
```

*imsid* is the IMS connection name. RC=00 means that a notify request has been queued. When DB2 starts, IMS is also notified.

No message goes to the z/OS console.

## Thread attachment

Execution of the program's first SQL statement causes the IMS attachment facility to create a thread and allocate a plan, whose name is associated with the IMS application program module name. DB2 sets up control blocks for the thread and loads the plan.

**Using the DB2 command DISPLAY THREAD:** The DB2 command DISPLAY THREAD can be used to display IMS attachment facility threads.

DISPLAY THREAD output for DB2 connections to IMS differs depending on whether DB2 is connected to a DL/I batch program, a control region, a message-driven program, or a nonmessage-driven program. Table 95 summarizes these differences.

Table 95. Differences in DISPLAY THREAD information for IMS connections

Connection	Name	AUTHID <sup>2</sup>	ID <sup>1,2</sup>	Plan <sup>1,2</sup>
DL/I Batch	DDITV02 statement	JOBUSER=	Job Name	DDITV02 statement
Control Region	IMSID	N/A	N/A	N/A
Message Driven	IMSID	Signon ID or ltermid	PST+ PSB	RTT or program
Non-message Driven	IMSID	AXBUSER or PSBNAME	PST+ PSB	RTT or program

### Notes:

1. After the application has connected to DB2 but before sign-on processing has completed, this field is blank.
2. After sign-on processing has completed but before a plan has been allocated, this field is blank.

The following command displays information about IMS threads, including those accessing data at remote locations:

```
-DISPLAY THREAD(imsid)
```

```

DSNV401I -STR DISPLAY THREAD REPORT FOLLOWS -
DSNV402I -STR ACTIVE THREADS -
NAME      ST A  REQ ID      AUTHID  PLAN      ASID TOKEN
1 SYS3    T *    3 0002BMP255  ADMF001  PROGHR1  0019  99
          SYS3    T *    4 0001BMP255  ADMF001  PROGHR2  0018  97
2 SYS3    N      5          SYSADM          0065    0
DISPLAY ACTIVE REPORT COMPLETE
DSN9022I -STR DSNVDT '-DIS THD' NORMAL COMPLETION

```

**Key:**

- 1 This is a message-driven BMP.
- 2 This thread has completed sign-on processing, but a DB2 plan has not been allocated.

Figure 33. DISPLAY THREAD output showing IMS connections

### Thread termination

When an application terminates, IMS invokes an exit routine to disconnect the application from DB2. There is no way to terminate a thread without abending the IMS application with which it is associated. Two ways of terminating an IMS application are described here:

- Termination of the application
 

The IMS commands /STOP REGION *reg#* ABDUMP or /STOP REGION *reg#* CANCEL can be used to terminate an application running in an online environment. For an application running in the DL/I batch environment, the z/OS command CANCEL can be used. See *IMS Command Reference* for more information about terminating IMS applications.
- Use of the DB2 command CANCEL THREAD
 

CANCEL THREAD can be used to cancel a particular thread or set of threads. CANCEL THREAD requires that you know the *token* for any thread you want to cancel. Enter the following command to cancel the thread identified by a token in the display output:

```
-CANCEL THREAD(46)
```

When you issue CANCEL THREAD for a thread, that thread is scheduled to be terminated in DB2.

### Displaying indoubt units of recovery

---

**General-use Programming Interface**

---

One function of the thread connecting DB2 to IMS is to keep data in synchronization between the two systems. If the application program requires it, a change to IMS data must also be made to DB2 data. If DB2 abends while connected to IMS, it is possible for IMS to commit or back out work without DB2 being aware of it. When DB2 restarts, that work is termed *indoubt*. Typically, some decision must be made about the status of the work.

The subject of indoubt units of recovery is treated in detail in Chapter 19, “Restarting DB2 after termination,” on page 447.

To display a list of indoubt units of recovery, issue the command:

```
-DISPLAY THREAD (imsid) TYPE (INDOUBT)
```

The command produces messages similar to these:

```

DSNV401I -STR DISPLAY THREAD REPORT FOLLOWS -
DSNV406I -STR POSTPONED ABORTT THREADS - 920
COORDINATOR          STATUS      RESET URID           AUTHID
SYS3                  P-ABORT          00017854FF6B ADMF001
V449-HAS NID= SYS3.400000000 AND ID= 0001BMP255
BATCH                 P-ABORT          00017854A8A0 ADMF001
V449-HAS NID= DSN:0001.0 AND ID= RUNP10
BATCH                 P-ABORT          00017854AA2E ADMF001
V449-HAS NID= DSN:0002.0 AND ID= RUNP90
BATCH                 P-ABORT          0001785CD711 ADMF001
V449-HAS NID= DSN:0004.0 AND ID= RUNP12
DISPLAY POSTPONED ABORT REPORT COMPLETE
DSNV9022I -STR DSNVDT '-DIS THD' NORMAL COMPLETION

```

For an explanation of the list displayed, see the description of message DSNV408I in Part 2 of *DB2 Messages*.

End of General-use Programming Interface

## Recovering indoubt units of recovery

General-use Programming Interface

To recover an indoubt unit, issue one of the following commands:

```

-RECOVER INDOUBT (imsid) ACTION (COMMIT) ID (pst#.psbname)
-RECOVER INDOUBT (imsid) ACTION (ABORT) ID (pst#.psbname)

```

Here *imsid* is the connection name and *pst#.psbname* is the correlation ID listed by the command DISPLAY THREAD. Your choice of the ACTION parameter tells whether to commit or roll back the associated unit of recovery. For more details, see “Resolving indoubt units of recovery” on page 463.

One of the following messages can be used after you issue the RECOVER command:

```

DSNV414I - THREAD pst#.psbname COMMIT SCHEDULED
DSNV415I - THREAD pst#.psbname ABORT SCHEDULED

```

End of General-use Programming Interface

## Displaying postponed units of recovery

General-use Programming Interface

The subject of postponed units of recovery is explained in detail in Chapter 19, “Restarting DB2 after termination,” on page 447. This chapter describes the operational steps that are used to list and recover postponed units in relatively simple cases.

To display a list of postponed units of recovery, issue the command:

```

-DISPLAY THREAD (imsid) TYPE (POSTPONED)

```

The command produces messages similar to these:

```

DSNV401I -STR DISPLAY THREAD REPORT FOLLOWS -
DSNV406I -STR POSTPONED ABORTT THREADS - 920
COORDINATOR          STATUS      RESET URID           AUTHID
SYS3                  P-ABORT          00017854FF6B ADMF001
V449-HAS NID= SYS3.400000000 AND ID= 0001BMP255
BATCH                 P-ABORT          00017854A8A0 ADMF001

```

```

V449-HAS NID= DSN:0001.0 AND ID= RUNP10
BATCH                P-ABORT                00017854AA2E ADMF001
V449-HAS NID= DSN:0002.0 AND ID= RUNP90
BATCH                P-ABORT                0001785CD711 ADMF001
V449-HAS NID= DSN:0004.0 AND ID= RUNP12
DISPLAY POSTPONED ABORT REPORT COMPLETE
DSN9022I -STR DSNVDT '-DIS THD' NORMAL COMPLETION

```

For an explanation of the displayed list, see the description of messages in Part 2 of *DB2 Messages*.

\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_

## Duplicate correlation IDs

### General-use Programming Interface

Two threads can have the same correlation ID (*pst#.psbname*) if all of these conditions occur:

- Connections have been broken several times.
- Indoubt units of recovery were not recovered.
- Applications were subsequently scheduled in the same region.

To uniquely identify threads which have the same correlation ID (*pst#.psbname*) requires that you be able to identify and understand the network ID (NID). For connections with IMS, you should also be able to identify and understand the IMS originating sequence number (OASN).

The NID is shown in a condensed form on the messages issued by the DB2 DISPLAY THREAD command processor. The IMS subsystem name (*imsid*) is displayed as the *net\_node*. The *net\_node* is followed by the 8-byte OASN, displayed in hexadecimal format (16 characters), with all leading zeros omitted. The *net\_node* and the OASN are separated by a period.

For example, if the *net\_node* is IMSA, and the OASN is 0003CA670000006E, the NID is displayed as IMSA.3CA670000006E on the DB2 DISPLAY THREAD command output.

If two threads have the same *corr-id*, use the NID instead of *corr-id* on the RECOVER INDOUBT command. The NID uniquely identifies the work unit.

The OASN is a 4-byte number that represents the number of IMS scheduling since the last IMS cold start. The OASN is occasionally found in an 8-byte format, where the first four bytes contain the scheduling number, and the last four bytes contain the number of IMS sync points (commits) during this schedule. The OASN is part of the NID.

The NID is a 16-byte network ID that originates from IMS. The NID contains the 4-byte IMS subsystem name, followed by four bytes of blanks, followed by the 8-byte version of the OASN. In communications between IMS and DB2, the NID serves as the recovery token.

\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_

## Resolving residual recovery entries

At given times, IMS builds a list of *residual recovery entries* (RREs). RREs are units of recovery about which DB2 could be in doubt. They arise in several situations:

- If DB2 is not operational, IMS has RREs that cannot be resolved until DB2 is operational. Those are not a problem.
- If DB2 is operational and connected to IMS, and if IMS rolled back the work that DB2 has committed, the IMS attachment facility issues message DSNM005I. If the data in the two systems must be consistent, this is a problem situation. Its resolution is discussed in “Resolution of indoubt units of recovery” on page 526.
- If DB2 is operational and connected to IMS, RREs can still exist, even though no messages have informed you of this problem. The only way to recognize this problem is to issue the IMS /DISPLAY OASN SUBSYS command after the DB2 connection to IMS has been established.

To display the RRE information, issue the command:

```
/DISPLAY OASN SUBSYS subsystem-name
```

To purge the RRE, issue one of these commands:

```
/CHANGE SUBSYS subsystem-name RESET
/CHANGE SUBSYS subsystem-name RESET OASN nnnn
```

where *nnnn* is the originating application sequence number listed in the display. That is the schedule number of the program instance, telling its place in the sequence of invocations of that program since the last cold start of IMS. IMS cannot have two indoubt units of recovery with the same schedule number.

Those commands reset the status of IMS; they do not result in any communication with DB2.

## Controlling IMS dependent region connections

Controlling IMS dependent region connections involves three activities:

- Connecting from dependent regions
- Monitoring the activity on connections
- Disconnecting from dependent regions

### Connecting from dependent regions

The IMS attachment facility used in the control region is also loaded into dependent regions. A connection is made from each dependent region to DB2. This connection is used to pass SQL statements and to coordinate the commitment of DB2 and IMS work. The following process is used by IMS to initialize and connect.

1. Read the SSM from IMS.PROCLIB.

A subsystem member can be specified on the dependent region EXEC parameter. If it is not specified, the control region SSM is used. If the region will never connect to DB2, specify a member with no entries to avoid loading the attachment facility.

2. Load the DB2 attachment facility from *prefix*.SDSNLOAD

For a batch message processing (BMP) program, the load is not done until the application issues its first SQL statement. At that time, IMS attempts to make the connection.

For a message processing program (MPP) region or IMS Fast Path (IFP) region, the connection is made when the IMS region is initialized, and an IMS transaction is available for scheduling in that region.

An IMS dependent region establishes two connections to DB2: a region connection and an application connection, which occurs at execution of the first SQL statement.

If DB2 is not active, or if resources are not available when the first SQL statement is issued from an application program, the action taken depends on the error option specified on the SSM user entry. The options are:

#### Option Action

- R The appropriate return code is sent to the application, and the SQL code is returned.
- Q The application is abended. This is a PSTOP transaction type; the input transaction is re-queued for processing and new transactions are queued.
- A The application is abended. This is a STOP transaction type; the input transaction is discarded and new transactions are not queued.

The region error option can be overridden at the program level via the resource translation table (RTT). See Part 2 of *DB2 Installation Guide* for further details.

### Monitoring the activity on connections

The information under this heading, up to “Disconnecting from dependent regions” on page 400, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

A thread is established from a dependent region when an application makes its first successful DB2 request. Information about connections and the applications currently using them can be displayed by issuing one of these commands:

#### From DB2:

```
-DISPLAY THREAD (imsid)
```

#### From IMS:

```
/SSR -DISPLAY THREAD (imsid)
```

Either command produces the following messages:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -  
DSNV402I - ACTIVE THREADS -  
NAME      ST  A  REQ  ID          AUTHID   PLAN    ASID   TOKEN  
conn-name s  *  req-ct corr-id  auth-id pname  asid  token  
conn-name s  *  req-ct corr-id  auth-id pname  asid  token  
DISPLAY ACTIVE REPORT COMPLETE  
DSN9022I - DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION
```

For an explanation of the DISPLAY THREAD status information displayed, see the description of message DSNV404I in Part 2 of *DB2 Messages*. More detailed information regarding use of this command and the reports it produces is available in “The command DISPLAY THREAD” on page 409.

IMS provides a display command to monitor the connection to DB2. In addition to showing which program is active on each dependent region connection, the display also shows the LTERM user name and gives the control region connection status. The command is:

```
/DISPLAY SUBSYS subsystem-name
```

The connection between IMS and DB2 is shown as one of the following states:

```
CONNECTED  
NOT CONNECTED  
CONNECT IN PROGRESS  
STOPPED
```

```

STOP IN PROGRESS
INVALID SUBSYSTEM NAME=name
SUBSYSTEM name NOT DEFINED BUT RECOVERY OUTSTANDING

```

The thread status from each dependent region is show as one of the following states:

```

CONN
CONN, ACTIVE (includes LTERM of user)

```

The following four examples show the output that might be generated when an IMS /DISPLAY SUBSYS command is issued.

Figure 34 shows the output that is returned for a DSN subsystem that is not connected. The IMS attachment facility issues message DSNM003I in this example.

```

0000 15.49.57          R 45,/DIS SUBSYS NEW

```

Figure 37. Example of output from IMS /DISPLAY SUBSYS processing for a DSN subsystem that is connected and the region ID (1) that is included.

## Disconnecting from dependent regions

Usually, IMS master terminal operators do not want to disconnect a dependent region explicitly. However, they might want to change values in the SSM member of IMS.PROCLIB. To do that, they can issue /STOP REGION, update the SSM member, and issue /START REGION.

## Disconnecting from IMS

The connection is ended when either IMS or DB2 terminates. Alternatively, the IMS master terminal operator can explicitly break the connection by entering this command:

```
/STOP SUBSYS subsystem-name
```

That command sends the following message to the terminal that entered it, usually the master terminal operator (MTO):

```
DFS058I STOP COMMAND IN PROGRESS
```

The /START SUBSYS *subsystem-name* command is required to reestablish the connection.

In implicit or explicit disconnect, this message is sent to the IMS master terminal:

```
DSNM002I IMS/TM imsid DISCONNECTED FROM SUBSYSTEM subsystem-name - RC=z
```

That message uses the following reason codes (RC):

### Code Meaning

- A IMS/TM is terminating normally (for instance, /CHE FREEZE<sup>3</sup>DUMPQ<sup>3</sup>PURGE). Connected threads complete.
- B IMS is abending. Connected threads are rolled back. DB2 data is backed out now; DL/I data is backed out on IMS restart.
- C DB2 is terminating normally after a STOP DB2 MODE (QUIESCE) command. Connected threads complete.
- D DB2 is terminating normally after a STOP DB2 MODE (FORCE) command, or DB2 is abending. Connected threads are rolled back. DL/I data is backed out now. DB2 data is backed out now if DB2 terminated normally; otherwise, at restart.
- E IMS is ending the connection because of a /STOP SUBSYS *subsystem-name* command. Connected threads complete.

If an application attempts to access DB2 after the connection ended and before a thread is established, the attempt is handled according to the region error option specification (R, Q, or A).

---

## Controlling RRS connections

---

### General-use Programming Interface

---

Application programs can use the following Resource Recovery Services attachment facility (RRSAF) functions to control connections to DB2:

#### IDENTIFY

Establishes the task (TCB) as a user of the named DB2 subsystem. When the first task within an address space issues a connection request, the address space is initialized as a user of DB2.

#### SIGNON

Provides a user ID and optionally, one or more secondary authorization IDs to be associated with the connection. Invokes the sign-on exit routine. Optionally, lets a thread join a global transaction. See “Recommendations for application design” on page 818 for more information about global transactions.

#### AUTH SIGNON

Provides a user ID, an ACEE, and optionally, one or more secondary authorization IDs to be associated with the connection. Invokes the sign-on exit.

#### CREATE THREAD

Allocates a plan. If you provide a plan name, DB2 allocates that plan. If you provide a collection name, DB2 allocates a special plan named ?RRSAF and a package list that contains the collection name.

After CREATE THREAD completes, DB2 can execute SQL statements.

#### TERMINATE THREAD

Deallocates the plan.

#### TERMINATE IDENTIFY

Removes the task as a user of DB2. If this is the last or only task in the address space with a DB2 connection, TERMINATE IDENTIFY terminates the address space connection to DB2.

#### TRANSLATE

Returns an SQL code and printable text, in the SQLCA, that describes a DB2 error reason code.

---

### End of General-use Programming Interface

---

For more information about those functions, see Part 6 of *DB2 Application Programming and SQL Guide*.

## Connecting to RRS using RRSAF

The information under this heading up to “Controlling connections to remote systems” on page 404 is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

An RRSAF connection can be started or restarted at any time after RRS is started. If RRS is not started, an IDENTIFY request fails with reason code X'00F30091'.

## Restarting DB2 and RRS

If DB2 abnormally terminates but RRS remains active, RRS might commit or roll back work without DB2's knowledge. In a similar manner, if RRS abnormally terminates after DB2 has completed phase 1 of commit processing for an application, then DB2 does not know whether to commit or roll back the work. In either case, when DB2 restarts, that work is termed *indoubt*.

DB2 cannot resolve those indoubt units of recovery (that is, commit or roll back the changes made to DB2 resources) until DB2 restarts with RRS.

If any unit of work is indoubt when a failure occurs, DB2 and RRS automatically resolve the unit of work when DB2 restarts with RRS.

## Displaying indoubt units of recovery

To display a list of indoubt units of recovery, issue the command:

```
-DISPLAY THREAD (RRSAF) TYPE (INDOUBT)
```

The command produces output similar to this:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV406I - INDOUBT THREADS -
COORDINATOR          STATUS          RESET URID          AUTHID
RRSAF                 INDOUBT          00019B8ADE9E      ADMF001
  V449-HAS NID= AD64101C7EED9000000000101010000 AND ID= ST47653RRS
DISPLAY INDOUBT REPORT COMPLETE
DSN9022I - DSNVDT '-DIS THD' NORMAL COMPLETION
```

For RRSAF connections, a network ID is the z/OS RRS Unit of Recovery ID (URID) that uniquely identifies a unit of work. A z/OS RRS URID is a 32 character number. For an explanation of the output, see the description of message DSNV408I in Part 2 of *DB2 Messages*.

## Recovering indoubt units of recovery manually

Manual recovery of an indoubt unit of recovery might be required if the RRS log is lost. When that happens, message DSN3011I is displayed on the z/OS console.

To recover an indoubt unit of recovery, issue one of the following commands:

```
-RECOVER INDOUBT (RRSAF) ACTION (COMMIT) ID (correlation-id)
```

or

```
-RECOVER INDOUBT (RRSAF) ACTION (ABORT) ID (correlation-id)
```

*correlation-id* is the correlation ID of the thread to be recovered. You can determine the correlation ID by issuing the DISPLAY THREAD command.

The ACTION parameter indicates whether to commit or roll back the associated unit of recovery. For more details, see "Resolving indoubt units of recovery" on page 463.

If you recover a thread that is part of a global transaction, all threads in the global transaction are recovered.

The following messages can occur when you issue the RECOVER INDOUBT command:

```
DSNV414I - THREAD correlation-id COMMIT SCHEDULED
DSNV415I - THREAD correlation-id ABORT SCHEDULED
```

If the following DSNV418I message is issued:

```
DSNV418I - RECOVER INDOUBT REJECTED FOR ID=correlation-id
```

You must use the following NID option of RECOVER INDOUBT:

```
-RECOVER INDOUBT(RRSAF) ACTION(action) NID(nid)
```

where *nid* is the 32-character field displayed in the DSNV449I message.

For information about the two-phase commit process, as well as indoubt units of recovery, see “Multiple system consistency” on page 459.

### Displaying postponed units of recovery

To display a list of postponed units of recovery, issue the command:

```
-DISPLAY THREAD (RRSAF) TYPE (POSTPONED)
```

The command produces output similar to this:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -  
DSNV406I - POSTPONED ABORT THREADS -  
COORDINATOR          STATUS      RESET URID          AUTHID  
RRSAF                P-ABORT          00019B8ADE9E      ADMF001  
V449-HAS NID= AD64101C7EED90000000000101010000 AND ID= ST47653RRS  
DISPLAY POSTPONED ABORT REPORT COMPLETE  
DSN9022I - DSNVDT '-DIS THD' NORMAL COMPLETION
```

For RRSAF connections, a network ID is the z/OS RRS Unit of Recovery ID (URID) that uniquely identifies a unit of work. A z/OS RRS URID is a 32-character number. For an explanation of the output, see the description of message DSNV408I in Part 2 of *DB2 Messages*.

## Monitoring RRSAF connections

RRSAF allows an application or application monitor to disassociate a DB2 thread from a TCB and later associate the thread with the same or different TCB within the same address space. RRSAF uses the RRS Switch Context (CTXSWCH) service to do this. Only authorized programs can execute CTXSWCH.

DB2 stores information in an RRS CONTEXT about an RRSAF thread so that DB2 can locate the thread later. An application or application monitor can then invoke CTXSWCH to dissociate the CONTEXT from the current TCB and then associate the CONTEXT with the same TCB or a different TCB.

### Displaying RRSAF connections

The following command displays information about RRSAF threads, including those that access data at remote locations:

```
-DISPLAY THREAD(RRSAF)
```

The command produces output similar to this:

```

DSNV401I = DISPLAY THREAD REPORT FOLLOWS -
DSNV402I = ACTIVE THREADS -
NAME      ST  A  REQ ID          AUTHID  PLAN      ASID  TOKEN
1  RRSAF  T      4  RRSTEST2-111  ADMF001  ?RRSAF  0024  13
2  RRSAF  T      6  RRSCDBTEST01  USRT001  TESTDBD  0024  63
3  RRSAF  DI     3  RRSTEST2-100  USRT002  ?RRSAF  001B  99
4  RRSAF  TR     9  GT01XP05     SYSADM  TESTP05  001B  235
      V444-DB2NET.LUND0.AA8007132465=16 ACCESSING DATA AT
      V446-SAN_JOSE:LUND1
DISPLAY ACTIVE REPORT COMPLETE

```

**Key:**

- 1** This is an application that used CREATE THREAD to allocate the special plan used by RRSAF (plan name = ?RRSAF).
- 2** This is an application that connected to DB2 and allocated a plan with the name TESTDBD.
- 3** This is an application that is currently not connected to a TCB (shown by status DI).
- 4** This is an active connection that is running plan TESTP05. The thread is accessing data at a remote site.

Figure 38. DISPLAY THREAD output showing RRSAF connections

### Disconnecting RRSAF applications from DB2

You cannot disconnect an RRSAF transaction from DB2 without abending the transaction. You can use the DB2 command CANCEL THREAD to cancel a particular thread. CANCEL THREAD requires that you know the *token* for any thread that you want to cancel. Issue the command DISPLAY THREAD to obtain the token number, then enter the following command to cancel the thread:

```
-CANCEL THREAD(token)
```

When you issue CANCEL THREAD, DB2 schedules the thread for termination.

---

## Controlling connections to remote systems

The information under this heading, up to “Using NetView to monitor errors” on page 420, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

You can control connections to remote systems, which use distributed data, by controlling the threads. Two types of threads are involved with connecting to other systems, *allied threads* and *database access threads*. An allied thread is a thread that is connected locally to your DB2 subsystem, that is from TSO, CICS, IMS, or a stored procedures address space. A database access thread is a thread initiated by a remote DBMS to your DB2 subsystem. The following topics are covered here:

- “Starting the DDF” on page 405
- “Suspending and resuming DDF server activity” on page 405
- “Monitoring connections to other systems” on page 406, which describes the use of the following commands:
  - DISPLAY DDF
  - DISPLAY LOCATION
  - DISPLAY THREAD
  - CANCEL THREAD
  - VARY NET,TERM (VTAM command)
- “Monitoring and controlling stored procedures” on page 417
- “Using NetView to monitor errors” on page 420
- “Stopping the DDF” on page 421

**Related information:** The following topics in this book contain information about distributed connections:

“Resolving indoubt units of recovery” on page 463

“Database access thread failure recovery” on page 560

Chapter 36, “Tuning and monitoring in a distributed environment,” on page 1007

## Starting the DDF

To start the distributed data facility (DDF), if it has not already been started, use the following command:

```
-START DDF
```

When DDF is started and is responsible for indoubt thread resolution with remote partners, one or both of messages DSNL432I and DSNL433I is generated. These messages summarize DDF’s responsibility for indoubt thread resolution with remote partners. See Chapter 20, “Maintaining consistency across multiple systems,” on page 459 for information about resolving indoubt threads.

Using the START DDF command requires authority of SYSOPR or higher. The following messages are associated with this command:

```
DSNL003I - DDF IS STARTING
```

```
DSNL004I - DDF START COMPLETE LOCATION locname  
LU netname.luname
```

```
GENERICLU netname.glname  
DOMAIN domain  
TCPPORT tcpport  
RESPORT resport
```

If the distributed data facility has not been properly installed, the START DDF command fails, and message DSN9032I, - REQUESTED FUNCTION IS NOT AVAILABLE is issued. If the distributed data facility has already been started, the START DDF command fails, and message DSNL001I, - DDF IS ALREADY STARTED is issued. Use the DISPLAY DDF command to display the status of DDF.

When you install DB2, you can request that the distributed data facility start automatically when DB2 starts. For information about starting the distributed data facility automatically, see Part 2 of *DB2 Installation Guide*.

## Suspending and resuming DDF server activity

You can use the STOP DDF MODE(SUSPEND) command to suspend DDF server threads temporarily. Suspending DDF server threads frees all resources held by the server threads and lets the following operations complete:

- CREATE
- ALTER
- DROP
- GRANT
- REVOKE

When you issue STOP DDF MODE(SUSPEND), DB2 waits for all active DDF database access threads to become pooled or to terminate. Two optional keywords on this command, WAIT and CANCEL, let you control how long DB2 waits and what action DB2 takes after a specified time period. To resume suspended DDF

server threads, issue the START DDF command. For more detailed information about the STOP DDF MODE(SUSPEND) command, see Chapter 2 of *DB2 Command Reference*.

## Monitoring connections to other systems

The following DB2 commands give you information about distributed threads:

### DISPLAY DDF

Displays information about the status and configuration of the distributed data facility (DDF), and about the connections or threads controlled by DDF. For its use, see “The command DISPLAY DDF.”

### DISPLAY LOCATION

Displays statistics about threads and conversations between remote DB2 subsystem and the local subsystem. For its use, see “The command DISPLAY LOCATION” on page 407.

### DISPLAY THREAD

Displays information about DB2, distributed subsystem connections, and parallel tasks. For its use, see “The command DISPLAY THREAD” on page 409.

## The command DISPLAY DDF

The command DISPLAY DDF displays information regarding the status of DDF and, in addition, any information that is displayed when DDF is started, such as the location name, the LU name, the IP address, and domain names. Using the DETAIL keyword provides additional configuration and statistical information.

To issue the DISPLAY DDF command, you must have SYSOPR authority or higher. Issue the following command:

```
-DISPLAY DDF
```

DB2 returns output similar to this sample when DDF is **not** started:

```
DSNL080I - DSNLTDDF DISPLAY DDF REPORT FOLLOWS-
DSNL081I 1 STATUS=STOPDQ
DSNL082I 2 LOCATION                3 LUNAME                4 GENERICCLU
DSNL083I   SVL650A                -NONE.SYEC650A        -NONE
DSNL084I 5 IPADDR                6 TCPPORT                7 RESPORT
DSNL085I   -NONE                    447                    5002
DSNL086I 8 SQL      DOMAIN=-NONE
DSNL086I 9 RESYNC  DOMAIN=-NONE
DSNL099I DSNLTDDF DISPLAY DDF REPORT COMPLETE
```

DB2 returns output similar to this sample when DDF is started:

```
DSNL080I - DSNLTDDF DISPLAY DDF REPORT FOLLOWS-
DSNL081I 1 STATUS=STARTD
DSNL082I 2 LOCATION                3 LUNAME                4 GENERICCLU
DSNL083I   SVL650A                USIBMSY.SYEC650A      -NONE
DSNL084I 5 IPADDR                6 TCPPORT                7 RESPORT
DSNL085I   8.110.115.106          447                    5002
DSNL086I 8 SQL      DOMAIN=v8ec103.svl.ibm.com
DSNL086I 9 RESYNC  DOMAIN=v8ec103.svl.ibm.com
DSNL099I DSNLTDDF DISPLAY DDF REPORT COMPLETE
```

Key	Description
1	The status of the distributed data facility (DDF)
2	The location name of DDF defined in the BSDS
3	The fully qualified LU name for DDF (that is, the network ID and LUNAME)
4	The fully qualified generic LU name for DDF

- 5** The IP address of DDF
- 6** The SQL listener TCP/IP port number
- 7** The two-phase commit resynchronization (resync) listener TCP/IP port number
- 8** The domain that accepts inbound SQL requests from remote partners
- 9** The domain that accepts inbound two-phase commit resynchronization requests

To use the DETAIL option, enter the following command:

```
-DISPLAY DDF DETAIL
```

DB2 returns additional lines of output:

```
DSNL080I - DSNLTDDF DISPLAY DDF REPORT FOLLOWS-
DSNL081I STATUS=STARTD
...
DSNL090I 10 DT=      A 11 CONDBAT= 64 12 MDBAT=  64
DSNL092I 13 ADBAT=  1 14 QUEDBAT=  0 15 IN1DBAT= 0 16 CONQUED=  0
DSNL093I 17 DSCDBAT= 0 18 IN2CONS=  0
DSNL099I DSNLTDDF DISPLAY DDF REPORT COMPLETE
```

**Key Description**

- 10** The DDF thread value:
  - A Indicates that DDF is configured with DDF THREADS ACTIVE
  - I Indicates that DDF is configured with DDF THREADS INACTIVE
- 11** The maximum number of inbound connections for database access threads
- 12** The maximum number of concurrent active DBATs that can execute SQL
- 13** The current number of active database access threads
- 14** The total number of queued database access threads. This count is cumulative and resets only when DB2 restarts.
- 15** The current number of inactive DBATs (type 1 inactive threads)
- 16** The current number of connection requests that are queued and waiting
- 17** The current number of pooled database access threads
- 18** The current number of inactive connections (type 2 inactive threads)

#  
#

For more DISPLAY DDF message information, see Part 2 of *DB2 Messages*.

The DISPLAY DDF DETAIL command is especially useful because it reflects the presence of new inbound connections that are not reflected by other commands. For example, if DDF is in INACTIVE MODE, as denoted by a DT value of I in the DSNL090I message, and DDF is stopped, suspended, or the maximum number of active data base access threads has been reached, then new inbound connections are not yet reflected in the DISPLAY THREAD report. However, the presence of these new connections is reflected in the DISPLAY DDF DETAIL report, although specific details regarding the origin of the connections, such as the client system IP address or LU name, are not available until the connections are actually associated with a database access thread.

**The command DISPLAY LOCATION**

The command DISPLAY LOCATION displays summary information about connections with other locations and can be used to display detailed information about DB2 system conversations. System conversations are used either for DB2 private protocol access or for supporting functions with DRDA access. Location names, SNA LU names or IP addresses, can be specified, and the DETAIL keyword is supported. To issue the DISPLAY LOCATION command, you must have SYSOPR authority or higher. Issue the following command:

```
-DISPLAY LOCATION(*)
```

DB2 returns output similar to this sample:

```
DSNL200I - DISPLAY LOCATION REPORT FOLLOWS-
LOCATION          PRDID    LINKNAME          REQUESTERS  SERVERS  CONVS
USIBMSTODB22    DSN05010 LUND0             1           0        3
USIBMSTODB23    DSN04010 LUND1             0           0        0
DRDALOC         SQL03030 124.63.51.17     3           0        3
124.63.51.17    SQL03030 124.63.51.17     0           15       15
DISPLAY LOCATION REPORT COMPLETE
```

You can use an asterisk (\*) in place of the end characters of a location name. For example, use DISPLAY LOCATION(SAN\*) to display information about all active connections between your DB2 and a remote location that begins with "SAN". This includes the number of conversations and the role for each non-system conversation, requester or server.

When DB2 connects with a remote location, information about that location, including LOCATION, PRDID and LINKNAME (LUNAME or IP address), persists in the report even if no active connections exist.

The DISPLAY LOCATION command displays the following types of information for each DBMS that has active threads, except for the local subsystem:

- The location name (or RDB\_NAME) of the other connected system. If the RDBNAME is not known, the LOCATION column contains one of the following identifiers:
  - A VTAM LU name in this format: '<luname>'.
  - A dotted decimal IP address in this format: 'nnn.nnn.nnn.nnn'.
- The PRDID, which identifies the database product at the location in the form *nnnvvrrm*:
  - *nnn* - identifies the database product
  - *vv* - product version
  - *rr* - product release
  - *m* - product modification level.
- The corresponding LUNAME or IP address of the system.
- The number of threads at the local system that are requesting data from the remote system.
- The number of threads at the local system that are acting as a server to the remote system.
- The total number of conversations in use between the local system and the remote system. For USIBMSTODB23, in the preceding sample output, the locations are connected and system conversations have been allocated, but currently there are no active threads between the two sites.

DB2 does not receive a location name from non-DB2 requesting DBMSs that are connected to DB2. In this case, it displays instead the LUNAME of the requesting DBMS, enclosed in less-than (<) and greater-than (>) symbols.

For example, suppose there are two threads at location USIBMSTODB21. One is a distributed access thread from a non-DB2 DBMS, and the other is an allied thread going from USIBMSTODB21 to the non-DB2 DBMS. The DISPLAY LOCATION command issued at USIBMSTODB21 displays the following output:

```
DSNL200I - DISPLAY LOCATION REPORT FOLLOWS -
LOCATION          PRDID    LINKNAME          REQUESTERS  SERVERS  CONVS
NONDB2DBMS      LUND1
<LULA>          DSN04010 LULA             0           1        1
DISPLAY LOCATION REPORT COMPLETE
```

The following output shows the result of a DISPLAY LOCATION(\*) command when DB2 is connected to the following DRDA partners:

- DB2A is connected to this DB2, using TCP/IP for DRDA connections and SNA for DB2 private protocol connections.
- DB2SERV is connected to this DB2 using only SNA.

```
DSNL200I - DISPLAY LOCATION REPORT FOLLOWS -
LOCATION          PRDID   LINKNAME          REQUESTERS  SERVERS  CONVS
DB2A             DSN05010 LUDB2A             3           4         9
DB2A             DSN05010 124.38.54.16       2           1         3
DB2SERV          DSN04010 LULA                1           1         3
DISPLAY LOCATION REPORT COMPLETE
```

The DISPLAY LOCATION command displays information for each remote location that currently is, or once was, in contact with DB2. If a location is displayed with zero conversations, one of the following conditions exist:

- Sessions currently exist with the partner location but there are currently no active conversations allocated to any of the sessions.
- Sessions no longer exist with the partner because contact with the partner has been lost.

If you use the DETAIL parameter, each line is followed by information about conversations owned by DB2 system threads, including those used for resynchronization of indoubt units of work.

### The command DISPLAY THREAD

*Displaying information by location:* Use the LOCATION keyword, followed by a list of location names, to display thread information for particular locations.

You can use an asterisk (\*) after the THD and LOCATION keywords just as in the DISPLAY LOCATION command previously described. For example, enter:

```
-DISPLAY THREAD(*) LOCATION(*) DETAIL
```

DB2 returns messages like these:

```

DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV402I - ACTIVE THREADS -
NAME      ST 1 A 2   REQ ID      AUTHID  PLAN      ASID TOKEN
SERVER    RA  *   2923 DB2BP      ADMF001 DISTSERV 0036  20 3
V437-WORKSTATION=ARRAKIS, USERID=ADMF001,
APPLICATION NAME=DB2BP
V436-PGM=NULLID.SQLC27A4, SEC=201, STMT=210
V445-09707265.01BE.889C28200037=203 ACCESSING DATA FOR 9.112.12.101
V447-LOCATION          SESSID      A ST TIME
V448-9.112.12.101 4 446:1300 5 W S2 9802812045091
DISPLAY ACTIVE REPORT COMPLETE
DSN9022I - DSNVDT '-DIS THD' NORMAL COMPLETION

```

#### Key Description

- 1 The ST (status) column contains characters that indicate the connection status of the local site. The *TR* indicates that an allied, distributed thread has been established. The *RA* indicates that a distributed thread has been established and is in receive mode. The *RD* indicates that a distributed thread is performing a remote access on behalf of another location (R) and is performing an operation involving DCE services (D). Currently, DB2 supports the optional use of DCE services to authenticate remote users.
- 2 The A (active) column contains an asterisk indicating that the thread is active within DB2. It is blank when the thread is inactive within DB2 (active or waiting within the application).
- 3 This LUWID is unique across all connected systems. This thread has a token of 20 (it appears in two places in the display output).
- 4 This is the location of the data that the local application is accessing. If the RDBNAME is not known, the location column contains either a VTAM LUNAME or a dotted decimal IP address.
- 5 If the connection uses TCP/IP, the sessid column contains "local:remote", where "local" specifies DB2's TCP/IP port number and "remote" specifies the partner's TCP/IP port number.

For more information about this sample output and connection status codes, see message DSNV404I, DSNV444I, and DSNV446I, in Part 2 of *DB2 Messages*.

**Displaying information for non-DB2 locations:** Because DB2 does not receive a location name from non-DB2 locations, you must enter the LUNAME or IP address of the location for which you want to display information. The LUNAME is enclosed by the less-than (<) and greater-than (>) symbols. The IP address is in the dotted decimal format. For example, if you wanted to display information about a non-DB2 DBMS with the LUNAME of LUSFOS2, you would enter the following command:

```
-DISPLAY THREAD (*) LOCATION (<LUSFOS2>)
```

DB2 uses the <LUNAME> notation or dotted decimal format in messages displaying information about non-DB2 requesters.

**Displaying conversation-level information about threads:** Use the *DETAIL* keyword with the *LOCATION* keyword to give you information about conversation activity when distribution information is displayed for active threads. This keyword has no effect on the display of indoubt threads. See Chapter 2 of *DB2 Command Reference* for more information about the *DETAIL* keyword.

For example, issue:

```
-DISPLAY THREAD(*) LOCATION(*) DETAIL
```

DB2 returns the following message, indicating that the local site application is waiting for a conversation to be allocated in DB2, and a DB2 server that is accessed by a DRDA client using TCP/IP.

```

DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV402I - ACTIVE THREADS -
NAME      ST A  REQ ID      AUTHID  PLAN  ASID  TOKEN

```

**Key Description**

- 1** The information on this line is part of message DSNV447I. The conversation A (active) column for the server is useful in determining when a DB2 thread is hung and whether processing is waiting in VTAM or in DB2. A value of W indicates that the thread is suspended in DB2 and is waiting for notification from VTAM that the event has completed. A value of V indicates that control of the conversation is in VTAM.
- 2** The information on this line is part of message DSNV448I. The A in the conversation ST (status) column for a serving site indicates a conversation is being allocated in DB2. The 1 indicates that the thread uses DB2 private protocol access. A 2 would indicate DRDA access. An R in the status column would indicate that the conversation is receiving or waiting to receive a request or reply. An S in this column for a server indicates that the application is sending or preparing to send a request or reply.
- 3** The information on this line is part of message DSNV448I. The SESSID column has changed as follows. If the connection uses VTAM, the SESSID column contains a VTAM session identifier. If the connection uses TCP/IP, the sessid column contains "local:remote", where "local" specifies the DB2 TCP/IP port number, and "remote" specifies the partner's TCP/IP port number.

For more DISPLAY THREAD message information, see messages DSNV447I and DSNV448I, Part 2 of *DB2 Messages*.

**Monitoring all DBMSs in a transaction:** The DETAIL keyword of the command DISPLAY THREAD allows you to monitor all of the requesting and serving DBMSs involved in a transaction.

For example, you could monitor an application running at USIBMSTODB21 requesting information from USIBMSTODB22, which must establish conversations with secondary servers USIBMSTODB23 and USIBMSTODB24 to provide the requested information. Figure 39 on page 412 depicts such an example. In this example, ADA refers to DRDA access and SDA refers to DB2 private protocol access. USIBMSTODB21 is considered to be *upstream* from USIBMSTODB22. USIBMSTODB22 is considered to be upstream from USIBMSTODB23. Conversely, USIBMSTODB23 and USIBMSTODB22 are *downstream* from USIBMSTODB22 and USIBMSTODB21 respectively.

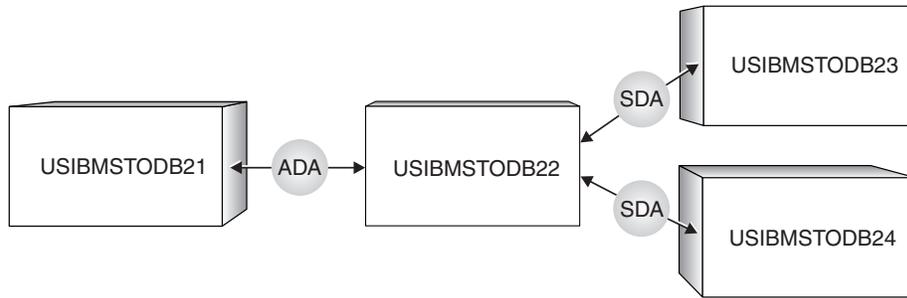

Figure 39. Example of a DB2 transaction involving four sites.

The application running at USIBMSTODB21 is connected to a server at USIBMSTODB22, using DRDA access. If you enter the DISPLAY THREAD command with the DETAIL keyword from USIBMSTODB21, you receive the output that Figure 40 depicts.

```

```

Figure 43. DISPLAY THREAD DETAIL output from USIBMSTODB24

This output indicates that the secondary server at USIBMSTODB24 is currently active.

The conversation status might not change for a long time. The conversation could be hung, or the processing could just be taking a long time. To see whether the conversation is hung, issue DISPLAY THREAD again and compare the new timestamp to the timestamps from previous output messages. If the timestamp is changing, but the status is not, the job is still processing. If you need to terminate a distributed job, perhaps because it is hung and has been holding database locks for a long period of time, you can use the CANCEL DDF THREAD command if the thread is in DB2 (whether active or suspended) or the VARY NET TERM command if the thread is within VTAM. See “The command CANCEL THREAD” on page 415.

**Displaying threads by LUWIDs:** Use the LUWID optional keyword, which is only valid when DDF has been started, to display threads by logical unit of work identifiers. The LUWIDs are assigned to the thread by the site that originated the thread.

You can use an asterisk (\*) in an LUWID as in a LOCATION name. For example, use -DISPLAY THREAD TYPE(INDOUBT) LUWID(NET1.\*) to display all the indoubt threads whose LUWID has a network name of NET1. The command

DISPLAY THREAD TYPE(INDOUBT) LUWID(IBM.NEW\*) displays all indoubt threads whose LUWID has a network name of "IBM" and whose LUNAME begins with "NEW."

The DETAIL keyword can also be used with the DISPLAY THREAD LUWID command to show the status of every conversation connected to each thread displayed and to indicate whether a conversation is using DRDA access or DB2 private protocol access.

To issue this command, enter:

```
-DIS THD(*) LUWID (luwid) DETAIL
```

DB2 returns the message that Figure 44 depicts.

```
-DIS THD(*) LUWID (luwid) DET

Key	Description
-----	-------------

- |   |                                                                                                                                                                                                                                             |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | In the preceding display output, you can see that the LUWID has been assigned a token of 2. You can use this token instead of the long version of the LUWID to cancel or display the given thread. For example:<br>-DIS THD(*) LUWID(2) DET |
| 2 | In addition, the status column for the serving site contains a value of S2. The S means that this thread can send a request or response, and the 2 means that this is an DRDA access conversation.                                          |

Figure 44. DISPLAY THREAD LUWID output

## Canceling dynamic SQL from a client application

You can use the CLI and ODBC function SQLCancel() or the JDBC cancel method to cancel a remote SQL request from a client application. To cancel SQL that is running on a remote DB2 server, use the following procedure:

1. Establish an additional remote connection from your application to the remote DB2 server.
2. From the connection you establish in step 1, issue SQLCancel() or invoke the JDBC cancel method.

When you cancel an SQL statement from a client application, you do not eliminate the original connection to the remote server. The original connection remains active to process additional SQL requests. Any cursor that is associated with the canceled statement is closed and the DB2 server returns an SQLCODE of -952 to the client application when you cancel a statement by using this method.

You can cancel only dynamic SQL that excludes transaction level statements (CONNECT, COMMIT, ROLLBACK) and bind statements from a client application.

For more information about SQLCancel(), see *DB2 ODBC Guide and Reference*. For more information about the JDBC cancel method, see *DB2 Application Programming Guide and Reference for Java*.

## The command CANCEL THREAD

You can use the command CANCEL THREAD to terminate threads that are active or suspended in DB2. The command has no effect if the thread is not active or suspended in DB2. If the thread is suspended in VTAM, you can use VTAM commands to terminate the conversations, as described in “Using VTAM commands to cancel threads” on page 416.

A database access thread can also be in the prepared state waiting for the commit decision from the coordinator. When you issue CANCEL THREAD for a database access thread in the prepared state, the thread is converted from active to indoubt. The conversation with the coordinator, and all conversations with downstream participants, are terminated and message DSNL450I is returned. The resources held by the thread are not released until the indoubt state is resolved. This is accomplished automatically by the coordinator or by using the command RECOVER INDOUBT. See “Resolving indoubt units of recovery” on page 463 for more information.

DISPLAY THREAD can be used to determine if a thread is hung in DB2 or VTAM. If in VTAM, there is no reason to use the CANCEL command.

Using CANCEL THREAD requires SYSOPR authority or higher.

When the command is entered at the DB2 subsystem that has a database access thread servicing requests from a DB2 subsystem that owns the allied thread, the database access thread is terminated. Any active SQL request, and all later requests, from the allied thread result in a “resource not available” return code.

To issue this command, enter:

```
-CANCEL THREAD (token)
```

Alternatively, you can use the following version of the command with either the token or LUW ID:

```
-CANCEL DDF THREAD (token or luwid)
```

The *token* is a 1-character to 5-character number that identifies the thread. When DB2 schedules the thread for termination, you will see the following message for a distributed thread:

```
DSNL010I - DDF THREAD token or luwid HAS BEEN CANCELED
```

For a non-distributed thread you will see the following message:

```
DSNV426I - csect THREAD token HAS BEEN CANCELED
```

For more information about CANCEL THREAD, see Chapter 2 of *DB2 Command Reference*.

**Diagnostic dumps:** CANCEL THREAD allows you to specify that a diagnostic dump be taken.

For more detailed information about diagnosing DDF failures, see Part 3 of *DB2 Diagnosis Guide and Reference*.

**Messages:** As a result of entering CANCEL THREAD, the following messages can be displayed:

```
DSNL009I  
DSNL010I
```

## Using VTAM commands to cancel threads

If the command CANCEL THREAD does not terminate the thread, it is possible that it is hung up in VTAM, not in DB2. Use the VTAM VARY NET,TERM command to cancel the thread's VTAM sessions. The VTAM commands only work with SNA VTAM connections, not TCP/IP connections.

To do this, you need to know the VTAM session IDs that correspond to the thread. Follow these steps:

1. Issue the DB2 command DISPLAY THREAD(*nnnn*) LOC(\*) DETAIL.

This gives you the VTAM session IDs that must be canceled. As is shown in the DISPLAY THREAD output in Figure 45, these sessions are identified by the column header SESSID.

```
-DIS THD LOC(*) DETAIL

DSNV401I - DISPLAY THREAD REPORT FOLLOWS -

IST314I END
```

Figure 46. Sample output for VTAM DISPLAY NET command

4. Issue the VTAM command VARY NET,TERM SID= for each of the VTAM SIDs associated with the DB2 thread. For more information about VTAM commands, see *VTAM for MVS/ESA Operation*.

## Monitoring and controlling stored procedures

Stored procedures are user-written SQL programs that run at a DB2 server. Stored procedures can run in DB2-established or WLM-established address spaces. To monitor and control stored procedures in WLM-established address spaces, you might need to use WLM commands, rather than DB2 commands. When you execute a WLM command on an z/OS system that is part of a Sysplex, the scope of that command is the Sysplex.

This section discusses the following topics:

- “Displaying information about stored procedures and their environment”
- “Refreshing the environment for stored procedures or user-defined functions” on page 419
- “Obtaining diagnostic information about stored procedures” on page 419

For more information about stored procedures, see Part 6 of *DB2 Application Programming and SQL Guide*.

### Displaying information about stored procedures and their environment

Use the DB2 commands `DISPLAY PROCEDURE` and `DISPLAY THREAD` to obtain information about a stored procedure while it is running. In the WLM-established environment, use the z/OS command `DISPLAY WLM` to obtain information about the application environment in which a stored procedure runs.

**The DB2 command `DISPLAY PROCEDURE`:** This command can display the following information about stored procedures:

- Status (started, stop-queue, stop-reject, stop-abend)
- Number of requests currently running and queued
- Maximum number of threads running a stored procedure load module and queued
- Count of timed-out SQL CALLs

The following command displays information about all stored procedures in all schemas that have been accessed by DB2 applications:

```
-DISPLAY PROCEDURE
DSNX940I csect - DISPLAY PROCEDURE REPORT FOLLOWS-

----- SCHEMA=PAYROLL
PROCEDURE      STATUS      ACTIVE  QUED  MAXQ  TIMEOUT  FAIL  WLM_ENV
PAYRPRC1
                STARTED          0    0    1     0     0  PAYROLL
PAYRPRC2
                STOPQUE          0    5    5     3     0  PAYROLL
PAYRPRC3
                STARTED          2    0    6     0     0  PAYROLL
USERPRC4
                STOPREJ          0    0    1     0     1  SANDBOX

----- SCHEMA=HRPROD
PROCEDURE      STATUS      ACTIVE  QUED  MAXQ  TIMEOUT  FAIL  WLM_ENV
HRPRC1
                STARTED          0    0    1     0     1  HRPROCS
HRPRC2
                STOPREJ          0    0    1     0     0  HRPROCS
DISPLAY PROCEDURE REPORT COMPLETE
DSN9022I = DSNX9COM '-DISPLAY PROC' NORMAL COMPLETION
```

This example shows two schemas (PAYROLL and HRPROD) that have been accessed by DB2 applications. You can also display information about specific stored procedures.

**The DB2 command DISPLAY THREAD:** This command tells whether:

- A thread is waiting for a stored procedure to be scheduled
- A thread is executing within a stored procedure

Here is an example of DISPLAY THREAD output that shows a thread that is executing a stored procedure:

```
!display thread(*) det
DSNV401I ! DISPLAY THREAD REPORT FOLLOWS -
DSNV402I ! ACTIVE THREADS -
NAME      ST A  REQ ID          AUTHID  PLAN      ASID TOKEN
BATCH    SP      3 CALLWLM      SYSADM  PLNAPPLX 0022   5
  V436-PGM=*.MYPROG, SEC=2, STMT=1
  V429 CALLING PROCEDURE=SYSADM .WLMSP
        PROC=V61AWLM1, ASID=0085, WLM_ENV=WLMENV1
DISPLAY ACTIVE REPORT COMPLETE
DSNV9022I ! DSNVDT '-DIS THD' NORMAL COMPLETION
```

The SP status indicates that the thread is executing within the stored procedure. An SW status indicates that the thread is waiting for the stored procedure to be scheduled.

Here is an example of DISPLAY THREAD output that shows a thread that is executing a user-defined function:

```
!display thd(*) det
DSNV401I ! DISPLAY THREAD REPORT FOLLOWS -
DSNV402I ! ACTIVE THREADS -
NAME      ST A  REQ ID          AUTHID  PLAN      ASID TOKEN
BATCH    SP      27 LI33FN1      SYSADM  DSNTEP3 0021   4
  V436-PGM=*.MYPROG, SEC=2, STMT=1
  V429 CALLING FUNCTION =SYSADM .FUNC1
        PROC=V61AWLM1, ASID=0085, WLM_ENV=WLMENV1
DISPLAY ACTIVE REPORT COMPLETE
DSNV9022I ! DSNVDT '-DISPLAY THD' NORMAL COMPLETION
```

**The z/OS command DISPLAY WLM:** Use the command DISPLAY WLM to determine the status of an application environment in which a stored procedure runs. The output from DISPLAY WLM lets you determine whether a stored procedure can be scheduled in an application environment.

For example, you can issue this command to determine the status of application environment WLMENV1:

```
D WLM,APPLENV=WLMENV1
```

You might get results like this:

```
IWM029I 15.22.22 WLM DISPLAY
APPLICATION ENVIRONMENT NAME      STATE      STATE DATA
WLMENV1                               AVAILABLE
ATTRIBUTES: PROC=DSNWLM1 SUBSYSTEM TYPE: DB2
```

The output tells you that WLMENV1 is available, so WLM can schedule stored procedures for execution in that environment.

## Refreshing the environment for stored procedures or user-defined functions

Depending on what has changed in a stored procedures environment, you might need to perform one or more of these tasks:

- Refresh Language Environment®.

Do this when someone has modified a load module for a stored procedure, and that load module is cached in a stored procedures address space. When you refresh Language Environment, the cached load module is purged. On the next invocation of the stored procedure, the new load module is loaded.

- Restart a stored procedures address space.

You might stop and then start a stored procedures address space because you need to make a change to the startup JCL for a stored procedures address space. You might need to start a stored procedures address space because the address space has abnormally terminated.

The method that you use to perform these tasks for stored procedures depends on whether you are using WLM-established or DB2-established address spaces.

*For DB2-established address spaces:* Use the DB2 commands START PROCEDURE and STOP PROCEDURE to perform all of these tasks.

*For WLM-established address spaces:* You use the VARY WLM command to complete the following tasks,

- To refresh the Language Environment when you need to load a new version of a stored procedure, use the z/OS command

```
VARY WLM,APPLENV=name,REFRESH
```

In this command, *name* represents the name of a WLM application environment that is associated with a group of stored procedures. You affect all stored procedures that are associated with the application environment when you refresh the Language Environment.

- To stop all stored procedures address spaces that are associated with WLM application environment *name*, use the following z/OS command:

```
VARY WLM,APPLENV=name,QUIESCE
```

- To start all stored procedures address spaces that are associated with WLM application environment *name*, use the following z/OS command:

```
VARY WLM,APPLENV=name,RESUME
```

You also need to use the VARY WLM command with the RESUME option when WLM puts an application environment in the unavailable state. An application environment in which stored procedures run becomes unavailable when WLM detects five abnormal terminations within 10 minutes. When an application environment is in the unavailable state, WLM does not schedule stored procedures for execution in it.

See *z/OS MVS Planning: Workload Management* for more information about the command VARY WLM.

## Obtaining diagnostic information about stored procedures

If the startup procedures for your stored procedures address spaces contain a DD statement for CEEDUMP, Language Environment writes a small diagnostic dump to CEEDUMP when a stored procedure terminates abnormally. The output waits to print until the stored procedures address space terminates.

You can obtain the dump information by stopping the stored procedures address space in which the stored procedure is running. See “Refreshing the environment for stored procedures or user-defined functions” on page 419 for information about how to stop and start stored procedures address spaces in the DB2-established and WLM-established environments.

## Using NetView to monitor errors

The NetView<sup>®</sup> program lets you have a single focal point from which to view problems in the network. DDF sends an alert to NetView when a remote location is either involved in the cause of the failure or affected by the failure. The following major events generate alerts:

- Conversation failures
- Distributed security failures
- DDF abends
- DDM protocol errors
- Database access thread abends
- Distributed allied thread abends

Alerts for DDF are displayed on NetView’s Hardware Monitor panels and are logged in the hardware monitor database. Figure 47 is an example of the Alerts-Static panel in NetView.

```

```

Figure 48. Recommended action for selected event panel in NetView. In this example, the AR (USIBMSTODB21) is reporting the problem, which is affecting the AS (USIBMSTODB22).

**Key Description**

- 1** The system reporting the error. The system reporting the error is always on the left side of the panel. That system's name appears first in the messages. Depending on who is reporting the error, either the LUNAME or the location name is used.
- 2** The system affected by the error. The system affected by the error is always displayed to the right of the system reporting the error. The affected system's name appears second in the messages. Depending on what type of system is reporting the error, either the LUNAME or the location name is used.  
  
If no other system is affected by the error, then this system will not appear on the panel.
- 3** DB2 reason code. For information about DB2 reason codes, see Part 3 of *DB2 Codes*. For diagnostic information, see Part 3 of *DB2 Diagnosis Guide and Reference*.

For more information about using NetView, see *Tivoli NetView for z/OS User's Guide*.

## Stopping the DDF

### General-use Programming Interface

You need SYSOPR authority or higher to stop the distributed data facility. Use one of the following commands:

```

-STOP DDF MODE (QUIESCE)
-STOP DDF MODE (FORCE)

```

Use the QUIESCE option whenever possible; it is the default. With QUIESCE, the STOP DDF command does not complete until all VTAM or TCP/IP requests have completed. In this case, no resynchronization work is necessary when you restart DDF. If there are indoubt units of work that require resynchronization, the QUIESCE option produces message DSNL035I. Use the FORCE option only when you must stop DDF quickly. Restart times are longer if you use FORCE.

When DDF is stopped with the FORCE option, and DDF has indoubt thread responsibilities with remote partners, one or both of messages DSNL432I and DSNL433I is generated.

DSNL432I shows the number of threads that DDF has coordination responsibility over with remote participants who could have indoubt threads. At these participants, database resources that are unavailable because of the indoubt threads remain unavailable until DDF is started and resolution occurs.

DSNL433I shows the number of threads that are indoubt locally and need resolution from remote coordinators. At the DDF location, database resources are unavailable because the indoubt threads remain unavailable until DDF is started and resolution occurs.

To force the completion of outstanding VTAM or TCP/IP requests, use the FORCE option, which cancels the threads associated with distributed requests.

When the FORCE option is specified with STOP DDF, database access threads in the prepared state that are waiting for the commit or abort decision from the coordinator are logically converted to the indoubt state. The conversation with the coordinator is terminated. If the thread is also a coordinator of downstream participants, these conversations are terminated. Automatic indoubt resolution is initiated when DDF is restarted. See “Resolving indoubt units of recovery” on page 463 for more information about this topic.

The STOP DDF command causes the following messages to appear:

```
DSNL005I - DDF IS STOPPING  
DSNL006I - DDF STOP COMPLETE
```

If the distributed data facility has already been stopped, the STOP DDF command fails and message DSNL002I - DDF IS ALREADY STOPPED appears.

**Stopping DDF using VTAM commands:** Another way to force DDF to stop is to issue the VTAM VARY NET,INACT command. This command makes VTAM unavailable and terminates DDF. VTAM forces the completion of any outstanding VTAM requests immediately.

The syntax for the command is as follows:

```
VARY NET,INACT,ID=db2lu,FORCE
```

where *db2lu* is the VTAM LU name for the local DB2 system.

When DDF has stopped, the following command must be issued before START DDF can be attempted:

```
VARY NET,ACT,ID=db2lu
```

---

## Controlling traces

These traces can be used for problem determination:

- DB2 trace
- IMS attachment facility trace
- CICS trace
- Three TSO attachment facility traces

CAF trace stream  
RRS trace stream  
z/OS component trace used for IRLM

## Controlling the DB2 trace

### General-use Programming Interface

DB2 trace allows you to trace and record subsystem data and events. There are five different types of trace. For classes of events traced by each type see the description of the START TRACE command in Chapter 2 of *DB2 Command Reference*. For more information about the trace output produced, see Appendix D, “Interpreting DB2 trace output,” on page 1139. In brief, DB2 records the following types of data:

#### Statistics

Data that allows you to conduct DB2 capacity planning and to tune the entire set of DB2 programs.

#### Accounting

Data that allows you to conduct DB2 capacity planning and to tune the entire set of DB2 programs.

#### Performance

Data about subsystem events, which can be used to do program, resource, user, and subsystem-related tuning.

**Audit** Data that can be used to monitor DB2 security and access to data.

#### Monitor

Data that can be used to monitor DB2 security and access to data.

DB2 provides commands for controlling the collection of this data. To use the trace commands you must have one of the following types of authority:

- SYSADM or SYSOPR authority
- Authorization to issue start and stop trace commands (the TRACE privilege)
- Authorization to issue the display trace command (the DISPLAY privilege).

The trace commands include:

#### START TRACE

Invokes one or more different types of trace.

#### DISPLAY TRACE

Displays the trace options that are in effect.

#### STOP TRACE

Stops any trace that was started by either the START TRACE command or the parameters specified when installing or migrating.

#### MODIFY TRACE

Changes the trace events (IFCIDs) being traced for a specified active trace.

Several parameters can be specified to further qualify the scope of a trace. Specific events within a trace type can be traced as well as events within specific DB2 plans, authorization IDs, resource manager IDs and location. The destination to which trace data is sent can also be controlled. For a discussion of trace commands, see Chapter 2 of *DB2 Command Reference*.

When you install DB2, you can request that any trace type and class start automatically when DB2 starts. For information about starting traces automatically, see Part 2 of *DB2 Installation Guide*.

End of General-use Programming Interface

## Diagnostic traces for attachment facilities

The following trace facilities are for diagnostic purposes only:

- IMS provides a trace facility that shows the flow of requests across the connections from the control and dependent regions to DB2. The trace is recorded on the IMS log if the appropriate options are specified, and then it is printed with DFSERA10 plus a formatting exit module. For more information about this trace facility, see *IMS Utilities Reference: System*.

In addition, the IMS attachment facility of DB2 provides an internal wrap-around trace table that is always active. When certain unusual error conditions occur, these trace entries are externalized on the IMS log.

- You can use the CICS trace facility to trace the CICS attachment facility.

Use the transaction CETR to control the CICS trace facility. CETR gives you a series of menus that you can use to set CICS trace options. For CICS 4.1 and later, to trace the CICS attachment facility, set these values in the Component Trace Options panel:

- For CICS 4.1, specify the value 2 in the FC field.
- For later releases, specify the value 2 in the RI field.

For information about using the CETR transaction to control CICS tracing, see *CICS Transaction Server for z/OS CICS Supplied Transactions*.

- The TSO attachment facility provides three tracing mechanisms:
  - The DSN trace stream
  - The CLIST trace facility
  - The SPUFI trace stream
- The call attachment facility trace stream uses the same *ddname* as the TSO DSN trace stream, but is independent of TSO.
- The RRSAF trace stream uses the same *ddname* as the TSO DSN trace stream, but is independent of TSO. An RRSAF internal trace will be included in any ABEND dump produced by RRSAF. This tracing facility provides a history of RRSAF usage that can aid in diagnosing errors in RRSAF.

## Diagnostic trace for the IRLM

The following z/OS commands control diagnostic traces for the IRLM:

### **MODIFY** *irlmproc*,**SET,TRACE**

Sets dynamically the maximum number of trace buffers for each trace type. This value is used only when the external component trace writer is not activated.

### **MODIFY** *irlmproc*,**STATUS,TRACE**

Displays the status of traces and the number of trace buffers used for each trace type. Also displays whether or not the external component trace writer is active for the trace.

### **START** *irlmproc*,**TRACE=YES**

Captures traces in wrap-around IRLM buffers at IRLM startup.

## TRACE CT

Starts, stops, or modifies a diagnostic trace for IRLM. The TRACE CT command does not know about traces that are started automatically during IRLM startup.

Recommendations:

- Do not use the external component trace writer to write traces to the data set.
- Activate all traces during IRLM startup. Use the command `START irlmproc,TRACE=YES` to activate all traces.

See Chapter 2 of *DB2 Command Reference* for detailed information.

---

## Controlling the resource limit facility (governor)

---

### General-use Programming Interface

---

The governor allows the system administrator to limit the amount of time permitted for the execution of the SELECT, UPDATE, DELETE, and INSERT dynamic SQL statements.

DB2 provides these commands for controlling the governor:

#### START RLIMIT

Starts the governor and identifies a resource limit specification table. You can also use START RLIMIT to switch resource limit specification tables.

#### DISPLAY RLIMIT

Displays the current status of the governor. If the governor has been started, it also identifies the resource limit specification table.

#### STOP RLIMIT

Stops the governor and removes any set limits.

The limits are defined in resource limit specification tables and can vary for different users. One resource limit specification table is used for each invocation of the governor and is identified on the START RLIMIT command.

See “Resource limit facility (governor)” on page 722 for more information about the governor.

---

### End of General-use Programming Interface

---

When you install DB2, you can request that the governor start automatically when DB2 starts. For information about starting the governor automatically, see Part 2 of *DB2 Installation Guide*.

---

## Changing subsystem parameter values

You can modify the values of subsystem parameters dynamically even while DB2 is running by using the following procedure:

1. Run the installation process in UPDATE mode, specifying any new parameter values. This process produces a new DSNTIJUZ job with the new values; it also saves these values in the file specified as the output member name on panel DSNTIPA1.

2. Assemble and link-edit the DSNTIJUZ job produced in Step 1, and then submit the job to create the new load module with the new subsystem parameter values.
3. Issue the SET SYSPARM command to change the subsystem parameters dynamically:

```
SET SYSPARM LOAD(load-module-name)
```

where you specify the *load-module-name* to be the same as the output member name in Step 1.

If you want to specify the load module name that is used during DB2 start up, you can issue the following command:

```
SET SYSPARM RELOAD
```

For more information, see Part 2 of *DB2 Installation Guide* and Chapter 2 of *DB2 Command Reference*.

---

## Chapter 18. Managing the log and the bootstrap data set

The DB2 log registers data changes and significant events as they occur. The bootstrap data set (BSDS) is a repository of information about the data sets that contain the log.

DB2 writes each log record to a disk data set called the *active log*. When the active log is full, DB2 copies its contents to a disk or tape data set called the *archive log*. That process is called *offloading*. This chapter describes:

“How database changes are made”

“Establishing the logging environment” on page 429

“Managing the bootstrap data set (BSDS)” on page 441

“Discarding archive log records” on page 443

For information about the physical and logical records that make up the log, see Appendix C, “Reading log records,” on page 1115. That appendix also contains information about how to write a program to read log records.

---

### How database changes are made

Before you can fully understand how logging works, you need to be familiar with how database changes are made to ensure consistency. This section discusses, *units of recovery* and *rollbacks*.

#### Units of recovery

A *unit of recovery* is the work, done by a single DB2 DBMS for an application, that changes DB2 data from one point of consistency to another. A *point of consistency* (also, *sync point* or *commit point*) is a time when all recoverable data that an application program accesses is consistent with other data. (For an explanation of maintaining consistency between DB2 and another subsystem such as IMS or CICS, see “Multiple system consistency” on page 459.)

A unit of recovery begins with the first change to the data after the beginning of the job or following the last point of consistency and ends at a later point of consistency. An example of units of recovery within an application program is shown in Figure 49 on page 428.

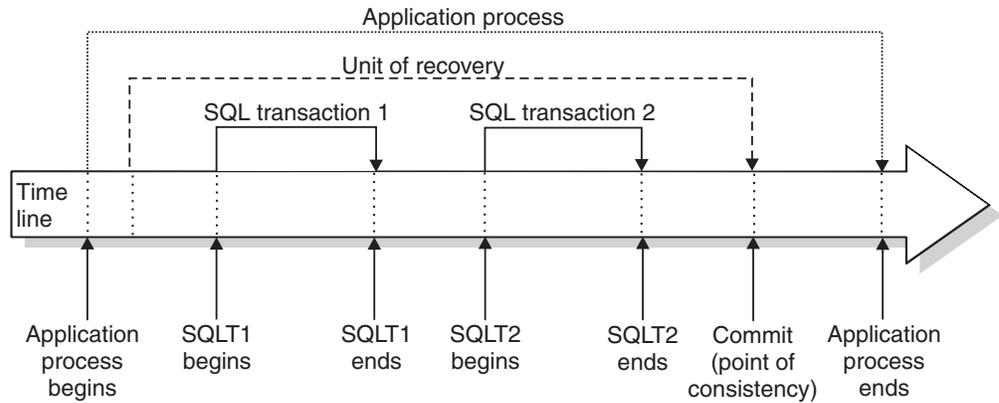

Figure 49. A unit of recovery within an application process

In this example, the application process makes changes to databases at SQL transaction 1 and 2. The application process can include a number of units of recovery or just one, but any complete unit of recovery ends with a commit point.

For example, a bank transaction might transfer funds from account A to account B. First, the program subtracts the amount from account A. Next, it adds the amount to account B. After subtracting the amount from account A, the two accounts are inconsistent. These accounts are inconsistent until the amount is added to account B. When both steps are complete, the program can announce a point of consistency and thereby make the changes visible to other application programs.

Normal termination of an application program automatically causes a point of consistency. The SQL COMMIT statement causes a point of consistency during program execution under TSO. A sync point causes a point of consistency in CICS and IMS programs.

## Rolling back work

If failure occurs within a unit of recovery, DB2 backs out any changes to data, returning the data to its state at the start of the unit of recovery; that is, DB2 *undoes* the work. The events are shown in Figure 50. The SQL ROLLBACK statement, and deadlocks and timeouts (reported as SQLCODE -911, SQLSTATE 40001), cause the same events.

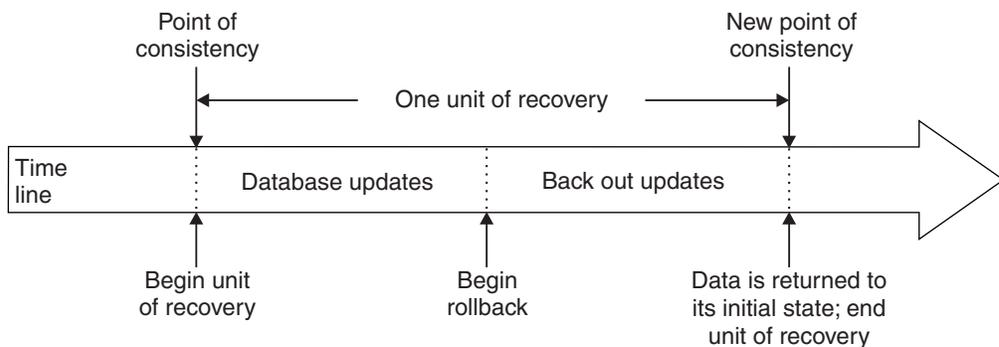

Figure 50. Unit of recovery (rollback)

The effects of inserts, updates, and deletes to large object (LOB) values are backed out along with all the other changes made during the unit of work being rolled back, even if the LOB values that were changed reside in a LOB table space with the LOG NO attribute.

An operator or an application can issue the CANCEL THREAD command with the NOBACKOUT option to cancel long running threads without backing out data changes. DB2 backs out changes to catalog and directory tables regardless of the NOBACKOUT option. As a result, DB2 does not read the log records and does not write or apply the compensation log records. After CANCEL THREAD NOBACKOUT processing, DB2 marks all objects associated with the thread as refresh pending (REFP) and puts the objects in a logical page list (LPL). For information about how to reset the REFP status, see *DB2 Utility Guide and Reference*.

The NOBACKOUT request might fail for either of the following two reasons:

- DB2 does not completely back out updates of the catalog or directory (message DSNIO32I with reason 00C900CC).
- The thread is part of a global transaction (message DSNV439I).

---

## Establishing the logging environment

The DB2 logging environment is established by using installation panels to specify options, such as whether to have dual active logs (strongly recommended), what media to use for archive log volumes, and how many log buffers to have. For details of the installation process, see Part 2 of *DB2 Installation Guide*.

### Creation of log records

Log records typically go through the following cycle:

1. DB2 registers changes to data and significant events in recovery log records.
2. DB2 processes recovery log records and breaks them into segments if necessary.
3. Log records are placed sequentially in *output log buffers*, which are formatted as VSAM control intervals (CIs). Each log record is identified by a continuously increasing RBA in the range 0 to  $2^{48}-1$ , where  $2^{48}$  represents 2 to the 48th power. (In a data sharing environment, a log record sequence number (LRSN) is used to identify log records. See *DB2 Data Sharing: Planning and Administration* for more information.)
4. The CIs are written to a set of predefined disk *active log data sets*, which are used sequentially and recycled.
5. As each active log data set becomes full, its contents are automatically *offloaded* to a new *archive log data set*.

If you change or create data that is compressed, the data logged is also compressed. Changes to compressed rows like inserts, updates, and deletes are also logged as compressed data.

### Retrieval of log records

Log records are retrieved through the following events:

1. A log record is requested using its RBA.
2. DB2 searches for the log record in the following locations in the order they are presented:
  - a. The log buffers.

- b. The active logs. The bootstrap data set registers which log RBAs apply to each active or archive log data set. If the record is in an active log, DB2 dynamically acquires a buffer, reads one or more CIs, and returns one record for each request.
- c. The archive logs. DB2 determines which archive volume contains the CIs, dynamically allocates the archive volume, acquires a buffer, and reads the CIs.

## Writing the active log

# The log buffers are written to an active log data set when they become full, when  
 # the write threshold is reached (as specified on the DSNTIPL panel), or, more often,  
 # when the DB2 subsystem forces the log buffer to be written (such as at commit  
 # time). In the last case, the same control interval can be written several times to the  
 # same location.

# Be sure to set your ZPARMs are set so that there are enough log buffers to avoid  
 # the need to wait for a buffer to become available (DSN6LOGP OUTBUFF  
 # parameter). Switching log data sets may also cause a temporary performance  
 # impact when the switch takes place and the associated recovery checkpoint is  
 # taken. This can be minimized by ensuring that the active log data sets are large  
 # enough to avoid frequent switching. In addition, some events can cause log buffers  
 # to be written before the ZPARM-defined threshold has been reached. These events  
 # include, but are not limited to:

- # • Phase 1 commit
- # • Abort processing
- # • GBP-dependent index split
- # • Mass delete in a data-sharing environment
- # • Use of GBPCACHE NO
- # • All log buffers being filled

# Consider the probable frequency of these events when you determine how often to  
 # commit changes.

# When DB2 is initialized, the active log data sets named in the BSDS are  
 # dynamically allocated for *exclusive* use by DB2 and remain allocated exclusively to  
 # DB2 (the data sets were allocated as DISP=OLD) until DB2 terminates. Those active  
 # log data sets cannot be replaced, nor can new ones be added, without terminating  
 # and restarting DB2. The size and number of log data sets is indicated by what was  
 # specified by installation panel DSNTIPL. The use of dual active logs increases  
 # availability as well as the reliability of recovery by eliminating a single point of  
 # failure.

## Writing the archive log (offloading)

The process of copying active logs to archive logs is called *offloading*. The relation of offloading to other logging events is shown schematically in Figure 51 on page 431.

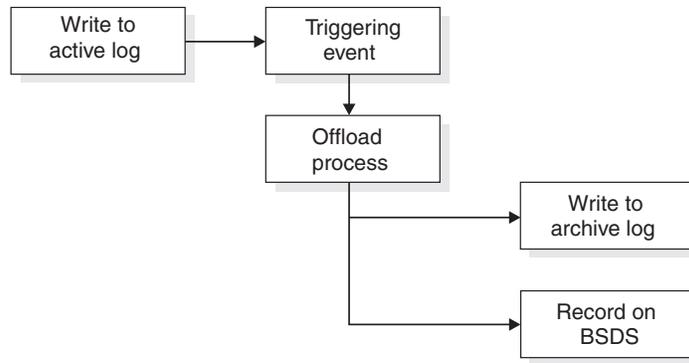

Figure 51. The offloading process

### Triggering offload

An offload of an active log to an archive log can be triggered by several events. The most common are when:

- An active log data set is full
- Starting DB2 and an active log data set is full
- The command ARCHIVE LOG is issued

An offload is also triggered by two uncommon events:

- An error occurring while writing to an active log data set. The data set is truncated before the point of failure, and the record that failed to write becomes the first record of the next data set. An offload is triggered for the truncated data set as in normal end-of-file. If there are dual active logs, both copies are truncated so the two copies remain synchronized.
- Filling of the last unarchived active log data set. Message DSNJ110E is issued, stating the percentage of its capacity in use; IFCID trace record 0330 is also issued if statistics class 3 is active. If all active logs become full, DB2 stops processing until offloading occurs and issues this message:

DSNJ111E - OUT OF SPACE IN ACTIVE LOG DATA SETS

### The offloading process

During the process, DB2 determines which data set to offload. Using the last log RBA offloaded, as registered in the BSDS, DB2 calculates the log RBA at which to start. DB2 also determines the log RBA at which to end, from the RBA of the last log record in the data set, and registers that RBA in the BSDS.

When all active logs become full, the DB2 subsystem runs an offload and halts processing until the offload is completed. If the offload processing fails when the active logs are full, then DB2 cannot continue doing any work that requires writing to the log. For additional information, see “Active log failure recovery” on page 535.

**Offload operator request:** When an active log is ready to be offloaded, a request can be sent to the z/OS console operator to mount a tape or prepare a disk unit. The value of the field WRITE TO OPER of the DSNTIPA installation panel determines whether the request is received. If the value is YES, the request is preceded by a WTOR (message number DSNJ008E) informing the operator to prepare an archive log data set for allocating.

The operator need not respond to message DSNJ008E immediately. However, delaying the response delays the offload process. It does not affect DB2 performance unless the operator delays response for so long that DB2 runs out of active logs.

The operator can respond by canceling the offload. In that case, if the allocation is for the first copy of dual archive data sets, the offload is merely delayed until the next active log data set becomes full. If the allocation is for the second copy, the archive process switches to single copy mode, but for the one data set only.

**Delay of log offload task:** When DB2 switches active logs and finds that the offload task has been active since the last log switch, it issues the following message to notify the operator that there might be an outstanding tape mount or some other problem that prevents the offload of the previous active log data set.

```
DSNJ017E - csect-name WARNING - OFFLOAD TASK HAS BEEN ACTIVE SINCE
          date-time AND MAY HAVE STALLED
```

DB2 continues processing. Issue the ARCHIVE LOG CANCEL OFFLOAD command to cancel and restart the offload task. If the offload task remains stalled, the active logs eventually become full and DB2 stops database update activity. To view the status of the offload task, issue the DISPLAY LOG command.

**Messages returned during offloading:** The following messages are sent to the z/OS console by DB2 and the offload process. With the exception of the DSNJ139I message, these messages can be used to find the RBA ranges in the various log data sets.

- The following message appears during DB2 initialization when the current active log data set is found, and after a data set switch. During initialization, the STARTRBA value in the message does not refer to the beginning of the data set, but to the position in the log where logging will begin.

```
DSNJ001I - csect-name CURRENT COPY n ACTIVE LOG DATA SET IS
          DSNAME=..., STARTRBA=..., ENDRBA=...
```

- The following message appears when an active data set is full:

```
DSNJ002I - FULL ACTIVE LOG DATA SET DSNAME=...,
          STARTRBA=..., ENDRBA=...
```

- The following message appears when offload reaches end-of-volume or end-of-data-set in an archive log data set:

Non-data sharing version is:

```
DSNJ003I - FULL ARCHIVE LOG VOLUME DSNAME=..., STARTRBA=..., ENDRBA=...,
          STARTTIME=..., ENDTIME=..., UNIT=..., COPYnVOL=...,
          VOLSPAN=..., CATLG=...
```

Data sharing version is:

```
DSNJ003I - FULL ARCHIVE LOG VOLUME DSNAME=..., STARTRBA=..., ENDRBA=...,
          STARTLRSN=..., ENDLRSN=..., UNIT=..., COPYnVOL=...,
          VOLSPAN=..., CATLG=...
```

- The following message appears when one data set of the next pair of active logs is not available because of a delay in offloading, and logging continues on one copy only:

```
DSNJ004I - ACTIVE LOG COPY n INACTIVE, LOG IN SINGLE MODE,
          ENDRBA=...
```

- The following message appears when dual active logging resumes after logging has been carried on with one copy only:

```
DSNJ005I - ACTIVE LOG COPY n IS ACTIVE, LOG IN DUAL MODE,
          STARTRBA=...
```

- The following message indicates that the offload task has ended:

```
DSNJ139I LOG OFFLOAD TASK ENDED
```

**Interruptions and errors while offloading:** Here is how DB2 handles the following interruptions in the offloading process:

- The command STOP DB2 does not take effect until offloading is finished.
- A DB2 failure during offload causes offload to begin again from the previous start RBA when DB2 is restarted.
- Offload handling of read I/O errors on the active log is described under “Active log failure recovery” on page 535, or write I/O errors on the archive log, under “Archive log failure recovery” on page 539.
- An unknown problem that causes the offload task to *hang* means that DB2 cannot continue processing the log. This problem might be resolved by retrying the offload, which you can do by using the option CANCEL OFFLOAD of the command ARCHIVE LOG, described in “Canceling log off-loads” on page 437.

### Archive log data sets

Archive log data sets can be placed on standard label tapes or disks and can be managed by DFSMSHsm (Data Facility Hierarchical Storage Manager). They are always written by QSAM. Archive logs on tape are read by BSAM; those on disk are read by BDAM. Each z/OS logical record in an archive log data set is a VSAM CI from the active log data set. The block size is a multiple of 4 KB. (For more information, see installation panel DSNTIPA in Part 2 of *DB2 Installation Guide*.)

Output archive log data sets are dynamically allocated, with names chosen by DB2. The data set name prefix, block size, unit name, and disk sizes needed for allocation are specified when DB2 is installed, and recorded in the DSNZPxxx module. You can also choose, at installation time, to have DB2 add a date and time to the archive log data set name. See installation panel DSNTIPH in Part 2 of *DB2 Installation Guide* for more information.

**Restrictions:** Consider the following restrictions for archive log data sets and volumes:

- You cannot specify specific volumes for new archive logs. If allocation errors occur, offloading is postponed until the next time loading is triggered.
- Do not use partitioned data set extended (PDSE) for archive log data. PDSEs are not supported for archive logs.

**Using dual archive logging:** If you specify dual archive logs at installation time, each log CI retrieved from the active log is written to two archive log data sets. The log records that are contained on a pair of dual archive log data sets are identical, but end-of-volumes are not synchronized for multivolume data sets.

Archiving to disk offers faster recoverability but is more expensive than archiving to tape. If you use dual logging, you can specify on installation panel DSNTIPA that the primary copy of the archive log go to disk and the secondary copy go to tape.

This feature increases recovery speed without using as much disk. The second tape is intended as a backup or can be sent to a remote site in preparation for disaster recovery. To make recovering from the COPY2 archive tape faster at the remote site, use the new installation parameter, ARC2FRST, to specify that COPY2 archive log should be read first. Otherwise, DB2 always attempts to read the primary copy of the archive log data set first.

**Archiving to tape:** If the unit name reflects a tape device, DB2 can extend to a maximum of twenty volumes. DB2 passes a file sequence number of 1 on the

catalog request for the first file on the next volume. Though that might appear to be an error in the integrated catalog facility catalog, it causes no problems in DB2 processing.

If you choose to offload to tape, consider adjusting the size of your active log data sets such that each set contains the amount of space that can be stored on a nearly full tape volume. That adjustment minimizes tape handling and volume mounts and maximizes the use of tape resources. However, such an adjustment is not always necessary.

If you want the active log data set to fit on one tape volume, consider placing a copy of the BSDS on the same tape volume as the copy of the active log data set. Adjust the size of the active log data set downward to offset the space required for the BSDS.

**Archiving to disk volumes:** All archive log data sets allocated on disk must be cataloged. If you choose to archive to disk, then the field CATALOG DATA of installation panel DSNTIPA must contain YES. If this field contains NO, and you decide to place archive log data sets on disk, you receive message DSNJ072E each time an archive log data set is allocated, although the DB2 subsystem still catalogs the data set.

If you use disk storage, be sure that the primary and secondary space quantities and block size and allocation unit are large enough so that the disk archive log data set does not attempt to extend beyond 15 volumes. That minimizes the possibility of unwanted z/OS B37 or E37 abends during the offload process. Primary space allocation is set with the PRIMARY QUANTITY field of the DSNTIPA installation panel. The primary space quantity must be less than 64K tracks because of the DFSMS Direct Access Device Space Management limit of 64K tracks on a single volume when allocating a sequential disk data set.

| **Using SMS to manage archive log data sets:** You can use DFSMS (Data Facility Storage Management Subsystem) to manage archive log data sets. When archiving to disk, DB2 uses the number of online storage volumes for the specified unit to determine a count of candidate volumes, up to a maximum of 15 volumes. If you are using SMS to direct archive log data set allocation, you should override this candidate volume count by specifying YES for the field SINGLE VOLUME on installation panel DSNTIPA. This will allow SMS to manage the allocation volume count appropriately when creating multi-volume disk archive log data sets.

Because SMS requires disk data sets to be cataloged, you must make sure the field CATALOG DATA on installation panel DSNTIPA contains YES. Even if it does not, message DSNJ072E is returned and the data set is forced to be cataloged by DB2.

| DB2 uses the basic direct access method (BDAM) to read archive logs from disk. DFSMS does not support reading of compressed data sets using BDAM. You should not, therefore, use DFSMS hardware compression on your archive log data sets. Also, BDAM does not support extended sequential format data sets (which are used for striped or compressed data), so do not have DFSMS assign the extended sequential format to your archive log data sets.

| Ensure that DFSMS does not alter the LRECL, BLKSIZE, or RECFM of the archive log data sets. Altering these attributes could result in read errors when DB2 attempts to access the log data.

**Attention:** DB2 does not issue an error or a warning if you write or alter archive data to an unreadable format. For example, if DB2 successfully writes archive log data to an extended format data set, DB2 issues an error message only when you attempt to read that data.

---

## Controlling the log

You can control and monitor log activity through several commands and a utility as discussed in the following sections:

“Archiving the log”

“Dynamically changing the checkpoint frequency” on page 437

“Setting limits for archive log tape units” on page 438

“Displaying log information” on page 438

## Archiving the log

---

### General-use Programming Interface

---

A properly authorized operator can archive the current DB2 active log data sets, whenever required, by issuing the ARCHIVE LOG command. Using ARCHIVE LOG can help with diagnosis by allowing you to quickly offload the active log to the archive log where you can use DSN1LOGP to further analyze the problem.

To issue this command, you must have either SYSADM authority, or have been granted the ARCHIVE privilege.

```
-ARCHIVE LOG
```

When you issue the preceding command, DB2 truncates the current active log data sets, then runs an asynchronous offload, and updates the BSDS with a record of the offload. The RBA that is recorded in the BSDS is the beginning of the last complete log record written in the active log data set being truncated.

You could use the ARCHIVE LOG command as follows to capture a point of consistency for the MSTR01 and XUSR17 databases:

```
-STOP DATABASE (MSTR01,XUSR17)
-ARCHIVE LOG
-START DATABASE (MSTR01,XUSR17)
```

In this simple example, the STOP command stops activity for the databases before archiving the log.

**Quiescing activity before offloading:** Another method of ensuring that activity has stopped before the log is archived is the MODE(QUIESCE) option of ARCHIVE LOG. With this option, DB2 users are quiesced after a commit point, and the resulting point of consistency is captured in the current active log before it is offloaded. Unlike the QUIESCE utility, ARCHIVE LOG MODE(QUIESCE) does not force all changed buffers to be written to disk and does not record the log RBA in SYSIBM.SYSCOPY. It does record the log RBA in the bootstrap data set.

Consider using MODE(QUIESCE) when planning for offsite recovery. It creates a system-wide point of consistency, which can minimize the number of data inconsistencies when the archive log is used with the most current image copy during recovery.

In a data sharing group, ARCHIVE LOG MODE(QUIESCE) might result in a delay before activity on all members has stopped. If this delay is unacceptable to you,

consider using ARCHIVE LOG SCOPE(GROUP) instead. This command causes truncation and offload of the logs for each active member of a data sharing group. Although the resulting archive log data sets do not reflect a point of consistency, all the archive logs are made at nearly the same time and have similar LRSN values in their last log records. When you use this set of archive logs to recover the data sharing group, you can use the ENDLRSN option in the CRESTART statement of the change log inventory utility (DSNJU003) to truncate all the logs in the group to the same point in time. See *DB2 Data Sharing: Planning and Administration* for more information.

The MODE(QUIESCE) option suspends all new update activity on DB2 up to the maximum period of time specified on the installation panel DSNTIPA, described in Part 2 of *DB2 Installation Guide*. If the time needed to quiesce is less than the time specified, then the command completes successfully; otherwise, the command fails when the time period expires. This time amount can be overridden when you issue the command, by using the TIME option:

```
-ARCHIVE LOG MODE(QUIESCE) TIME(60)
```

The preceding command allows for a quiesce period of up to 60 seconds before archive log processing occurs.

**Important**

Use of this option during prime time, or when time is critical, can cause a significant disruption in DB2 availability for all jobs and users that use DB2 resources.

By default, the command is processed asynchronously from the time you submit the command. (To process the command synchronously with other DB2 commands, use the WAIT(YES) option with QUIESCE; the z/OS console is then locked from DB2 command input for the entire QUIESCE period.)

During the quiesce period:

- Jobs and users on DB2 are allowed to go through commit processing, but are suspended if they try to update any DB2 resource after the commit.
- Jobs and users that only read data can be affected, because they can be waiting for locks held by jobs or users that were suspended.
- New tasks can start, but they are not allowed to update data.

As shown in the following example, the DISPLAY THREAD output issues message DSNV400I to indicate that a quiesce is in effect:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -
DSNV400I - ARCHIVE LOG QUIESCE CURRENTLY ACTIVE
DSNV402I - ACTIVE THREADS -
NAME      ST A   REQ ID          AUTHID  PLAN   ASID   TOKEN
BATCH    T *    20 TEPJOB        SYSADM  DSNTPE3 0012   12
DISPLAY ACTIVE REPORT COMPLETE
DSN9022I - DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION
```

When all updates are quiesced, the quiesce history record in the BSDS is updated with the date and time that the active log data sets were truncated, and with the last-written RBA in the current active log data sets. DB2 truncates the current active log data sets, switches to the next available active log data sets, and issues message DSNJ311E, stating that offload started.

The CHKFREQ value that is altered by the SET LOG command persists only while DB2 is active. On restart, DB2 uses the CHKFREQ value in the DB2 subsystem parameter load module. See Chapter 2 of *DB2 Command Reference* for detailed information about this command.

## Monitoring the system checkpoint

DB2 schedules a system checkpoint every time it switches active log data sets, regardless of the currently defined checkpoint frequency. If DB2 switches active logs and finds that there has not been a system checkpoint since the last log switch, it issues the following message to notify the operator that the system checkpoint processor might not be functioning.

```
DSNJ016E - csect-name WARNING - SYSTEM CHECKPOINT PROCESSOR MAY
          HAVE STALLED. LAST CHECKPOINT WAS TAKEN date-time
```

DB2 continues processing. This situation can result in a very long restart if logging continues without a system checkpoint. If DB2 continues logging beyond the defined checkpoint frequency, you should quiesce activity and terminate DB2 to minimize the restart time.

You can issue the DISPLAY LOG command or run the Print Log Map utility (DSNJU004) to display the most recent checkpoint. For additional information, see "Displaying log information."

## Setting limits for archive log tape units

Use the DB2 command SET ARCHIVE to set the upper limit for the number of and the deallocation time of tape units for the archive log. This command overrules the values specified during installation or in a previous invocation of the SET ARCHIVE command. The changes initiated by SET ARCHIVE are temporary; at restart, DB2 uses the values that were set during installation. See Chapter 2 of *DB2 Command Reference* for detailed information about this command.

## Displaying log information

Use the DISPLAY LOG command to display the current checkpoint frequency (either the number of log records or the minutes between checkpoints). See Chapter 2 of *DB2 Command Reference* for more details about the DISPLAY LOG and SET LOG commands.

You can obtain additional information about log data sets and checkpoints from the Print Log Map utility (DSNJU004). See Part 3 of *DB2 Utility Guide and Reference* for more information about utility DSNJU004.

---

## Resetting the log RBA

Each DB2 subsystem writes its own recovery logs. The log records are sequenced with a Relative Byte Address (RBA), which you need to reset before the RBA reaches its maximum value.

To determine when to reset the log RBA, use one of the following two methods:

- Apply the PTF for APAR PK27611. After you apply this APAR, message DSNJ032I is issued at the active log switch when the RBA threshold is reached. If the RBA exceeds x'F00000000000', the message is issued with the keyword **WARNING** and processing continues. If the RBA exceeds x'FFFF00000000', the message is issued with the keyword **CRITICAL**, and DB2 is stopped. To resolve any outstanding units of work, DB2 will restart automatically in restart-light

#  
#

mode. Then, DB2 will stop again. In this situation, you need to restart DB2 in ACCESS(MAINT) mode, and you must reset the log RBA value.

- Calculate how much space is left in the log. You can use the print log map (DSNJU004) utility to obtain the highest written RBA value in the log. Subtract this RBA from x'FFFFFFFFFFFF' to determine how much space is left in the log. If APAR PK27611 is applied, you need to use the RBA value of x'FFFF00000000' for this calculation.

You can use the output for the print log map utility to determine how many archive logs are created on an average day. This number multiplied by the RBA range of the archive log data sets (ENDRBA minus STARTRBA) provides the average number of bytes that are logged per day. Divide this value into the space remaining in the log to determine approximately how much time is left before the end of the log RBA range is reached. If there is less than one year remaining before the end of the log RBA range is reached, start planning to reset the log RBA value. If less than three months remain before the end of the log RBA range is reached, you need to take immediate action to reset the log RBA value.

## Log RBA range

The log RBA is an ever-increasing 6 byte hex value that starts as 0 (zero) when the DB2 subsystem is first installed and increases to a maximum value of x'FFFFFFFFFFFF' (2 to the 48th).

The rate at which the log RBA value increases through this range depends on the logging rate of the DB2 subsystem. In cases where a heavy logging rate is sustained over a period of years, the log RBA value can begin to approach the end of the range.

Before the DB2 subsystem reaches the end of the log RBA range, you need to reset the log RBA value. The process that you complete to reset the log RBA value depends on whether the DB2 subsystem is the member of a data sharing group or in a non-data sharing environment.

## Resetting the log RBA value in a data sharing environment

Before the member of a data sharing group reaches the end of the log RBA range, you need to reset the log RBA value for that member.

To reset the log RBA value in a data sharing environment:

1. Issue the STOP DB2 command to quiesce the member that is approaching the end of the log RBA range.
2. Restart this member in ACCESS(MAINT) mode.
3. Issue the -DISPLAY THREAD command. Ensure that there are no INDOUBT or POSTPONED ABORT units of recovery.
4. Issue the -DISPLAY DATABASE(\*) SPACENAM(\*) RESTRICT command. Ensure that all restricted states are removed.
5. Quiesce the member again by issuing the -STOP DB2 command.
6. **Optional:** Start a new member to take over the work of the member that is quiesced. If this is an acceptable solution, you can leave the original member stopped indefinitely.
7. To bring the original member back into the data sharing group, you must cold start the member with a STARTRBA of 0 (zero). To cold start the member:
  - a. Before restarting the member, apply the PTF for APAR PK22872.

- #
- #
- #
- b. If you are running an application that reads the logs with IFI (for example, a data replication product), apply the PTF for APAR PK81566 before restarting this member.
  - c. Make a full image copy of all data. To make a full image copy, the member might need to remain quiesced for a period of time. The length of time depends on the size of the databases. After all of the data has been image copied, you no longer need the member logs for recovery.
  - d. Cold start this member back to the RBA value of 0 (zero). This step removes all log data from the BSDS, and you can use the member again. This step requires utility DSNJU003 with the following options:
 

```
CRESTART CREATE,STARTRBA=0,ENDRBA=0
```

## Resetting the log RBA value in a non-data sharing environment

Before the DB2 subsystem in a non-data sharing environment reaches the end of the log RBA range, you need to reset the log RBA value for that subsystem.

To reset the log RBA value in a non-data sharing environment:

1. Issue the STOP DB2 command to quiesce the subsystem that is approaching the end of the log RBA range.
2. Restart DB2 in ACCESS(MAINT) mode.
3. Issue the -DISPLAY THREAD command. Ensure that there are no INDOUBT or POSTPONED ABORT units of recovery.
4. Issue the -DISPLAY UTILITY command. Ensure there are no active or stopped utilities.
5. Issue the -DISPLAY DATABASE(\*) SPACENAM(\*) RESTRICT command. Ensure that all restricted states are removed.
6. Quiesce the DB2 subsystem again by issuing the -STOP DB2 command.
7. Use IDCAMS to delete and redefine the table spaces SYSUTILX, SYSCOPY, and SYSLGRNX and their corresponding indexes. Then, re-initialize these page sets. For information about how to re-initialize these page sets, see member DSNTIJID in library SDSNSAMP.
8. Determine whether you can use the COPY utility, and complete the appropriate task as follows:
  - If the PTF for APAR PK28576 is applied, or can be applied, and you can use the COPY utility to make copies of all data, apply the PTF for APAR PK28576. This APAR enables the COPY utility to reset the RBA values in pages as they are copied. See the documentation for the PTF for information about enabling the COPY utility function that is provided by this APAR.
  - If you cannot use the COPY utility, do the following:
    - a. Use DSN1COPY to copy every table space and partition to another data set. If indexes are not included in this process, you must rebuild the indexes after restarting DB2.
    - b. Use DSN1COPY with the RESET parameter to copy each table space or partition to its original data set. This process resets the RBA values in all of the page sets. If indexes are not included in this process, you must rebuild the indexes after restarting DB2.
9. Cold start this subsystem back to the RBA value of 0 (zero) by using ACCESS(MAINT). This step removes all log data from the BSDS. This step requires utility DSNJU003 with the following options:
 

```
CRESTART CREATE,STARTRBA=0,ENDRBA=0
```

- # 10. If you did not reset the indexes by using DSN1COPY as specified in step 8, rebuild all indexes. Start by rebuilding the catalog and directory indexes, and then rebuild the indexes on user data.
- # 11. Take new, full image copies of all data. If you applied the PTF for APAR PK28576, run the COPY utility with option SHRLEVEL REFERENCE to automatically reset the RBA values in all of the page sets. This step can be performed in parallel with the previous step after the catalog and directory indexes are rebuilt.
- # 12. Stop DB2. If applicable, disable the reset RBA function in the COPY utility, and restart DB2 for normal access.

---

## Managing the bootstrap data set (BSDS)

The BSDS is a VSAM key-sequenced data set that contains information about the log data sets and the records those data sets include. It also contains information about buffer pool attributes. The BSDS is defined with access method services when DB2 is installed and is allocated by a DD statement in the DB2 startup procedure. It is deallocated when DB2 terminates.

Normally, DB2 keeps duplicate copies of the BSDS. If an I/O error occurs, DB2 deallocates the failing copy and continues with a single BSDS. However, you can restore the dual mode as follows:

1. Use access method services to rename or delete the failing BSDS.
2. Define a new BSDS with the same name as the deleted BSDS.
3. Issue the DB2 command RECOVER BSDS to make a copy of the good BSDS in the newly allocated data set.

The active logs are first registered in the BSDS by job DSNTIJID, when DB2 is installed. They cannot be replaced, nor new ones added, without terminating and restarting DB2.

Archive log data sets are dynamically allocated. When one is allocated, the data set name is registered in the BSDS in separate entries for each volume on which the archive log resides. The list of archive log data sets expands as archives are added, and wraps around when a user-determined number of entries has been reached. The maximum number of archive log data sets depends on whether the BSDS conversion utility (DSNJCNVB) has been run. The maximum number of data sets is 10000 if the BSDS has been converted (20000 for dual logging); otherwise the limits are 1000 for single archive logging and 2000 for dual logging. For more information about the BSDS conversion utility, see Part 3 of *DB2 Utility Guide and Reference*.

The inventory of archive log data sets can be managed by use of the change log inventory utility (DSNJU003). For further information, see “Changing the BSDS log inventory” on page 442.

A wide variety of tape management systems exist, along with the opportunity for external manual overrides of retention periods. Because of that, DB2 does not have an automated method to delete the archive log data sets from the BSDS inventory of archive log data sets. Thus, the information about an archive log data set can be in the BSDS long after the archive log data set has been scratched by a tape management system following the expiration of the data set’s retention period.

Conversely, the maximum number of archive log data sets could have been exceeded, and the data from the BSDS dropped long before the data set has reached its expiration date. For additional information, refer to “Deleting archive logs automatically” on page 443.

If you specified at installation that archive log data sets are cataloged when allocated, the BSDS points to the integrated catalog facility catalog for the information needed for later allocations. Otherwise, the BSDS entries for each volume register the volume serial number and unit information that is needed for later allocation.

## **BSDS copies with archive log data sets**

Each time a new archive log data set is created, a copy of the BSDS is also created. If the archive log is on tape, the BSDS is the first file on the first output volume. If the archive log is on disk, the BSDS copy is a separate file which could reside on a separate volume.

For better offload performance and space utilization, it is recommended that you use the default archive block size of 28672. If required, this value can be changed in the BLOCK SIZE field on installation panel DSNTIPA. The PRIMARY QUANTITY and SECONDARY QUANTITY fields should also be adjusted to reflect any changes in block size.

The data set names of the BSDS copy and the archive log are the same, except that the first character of the last data set name qualifier in the BSDS name is B instead of A, as in the following example:

**Archive log name**  
DSNCAT.ARCHLOG1.A0000001

**BSDS copy name**  
DSNCAT.ARCHLOG1.B0000001

If a read error while copying the BSDS, the copy is not created. Message DSNJ125I is issued, and the offload to the new archive log data set continues without the BSDS copy.

The utility DSNJU004, print log map, lists the information that is stored in the BSDS. For instructions on using it, see Part 3 of *DB2 Utility Guide and Reference*.

## **Changing the BSDS log inventory**

You do not have to take special steps to keep the BSDS updated with records of logging events: DB2 does that automatically. However, you might want to change the BSDS if you:

- Add more active log data sets.
- Copy active log data sets to newly allocated data sets, as when providing larger active log allocations.
- Move log data sets to other devices.
- Recover a damaged BSDS.
- Discard outdated archive log data sets.
- Create or cancel control records for conditional restart.
- Add to or change the DDF communication record.

You can change the BSDS by running the DB2 batch change log inventory (DSNJU003) utility. This utility should not be run when DB2 is active. If it is run when DB2 is active, inconsistent results can be obtained. For instructions on how to use the change log inventory utility, see Part 3 of *DB2 Utility Guide and Reference*.

You can copy an active log data set using the access method services IDCAMS REPRO statement. The copy can only be performed when DB2 is down, because DB2 allocates the active log data sets as exclusive (DISP=OLD) at DB2 startup. For more information about the REPRO statement, see *DFSMS/MVS: Access Method Services for the Integrated Catalog* and *z/OS DFSMS Access Method Services for Catalogs*.

---

## Discarding archive log records

You must keep enough log records to recover units of work and databases.

To recover units of recovery, you need log records at least until all current actions are completed. If DB2 abends, restart requires all log records since the previous checkpoint or the beginning of the oldest UR that was active at the abend, whichever is first on the log.

To tell whether all units of recovery are complete, read the status counts in the DB2 restart messages (shown in “Starting DB2” on page 324). If all counts are zero, no unit of recovery actions are pending. If there are indoubt units of recovery remaining, identify and recover them by the methods described in Chapter 17, “Monitoring and controlling DB2 and its connections,” on page 367.

To recover databases, you need log records and image copies of table spaces. How long you keep log records depends, then, on how often you make those image copies. Chapter 21, “Backing up and recovering databases,” on page 475 gives suggestions about recovery cycles; the following sections assume that you know what records you want to keep and describe only how to delete the records you do not want.

## Deleting archive logs automatically

You can use a disk or tape management system to delete archive log data sets or tapes automatically. The length of the retention period (in days), which is passed to the management system in the JCL parameter RETPD, is determined by the RETENTION PERIOD field on the DSNTIPA installation panel, discussed further in Part 2 of *DB2 Installation Guide*.

The default for the retention period keeps archive logs forever. If you use any other retention period, it must be long enough to contain as many recovery cycles as you plan for. For example, if your operating procedures call for a full image copy every sixty days of the least-frequently-copied table space, and you want to keep two complete image copy cycles on hand at all times, then you need an archive log retention period of at least 120 days. For more than two cycles, you need a correspondingly longer retention period.

If archive log data sets or tapes are deleted automatically, the operation does not update the archive log data set inventory in the BSDS. If you wish, you can update the BSDS with the change log inventory utility, as described in “Changing the BSDS log inventory” on page 442. The update is not really necessary; it wastes space in the BSDS to record old archive logs, but does no other harm as the

archive log data set inventory *wraps* and automatically deletes the oldest entries. See “Managing the bootstrap data set (BSDS)” on page 441 for more details.

## Locating archive log data sets

You must keep all the logs since the most recent checkpoint of DB2, so that DB2 can restart. You also must keep all the logs for two or more complete image copy cycles of your least-frequently-copied table space. What, then, can you discard?

You need an answer in terms of the log RBA ranges of the archive data sets. The earliest log record you want is identified by a log RBA. You can discard any archive log data sets that contain only records with log RBAs less than that.

The procedure that follows locates those data sets:

**Step 1: Resolve indoubt units of recovery:** If DB2 is running with TSO, continue with “Find the startup log RBA.” If DB2 is running with IMS, CICS, or distributed data, the following procedure applies:

1. The period between one startup and the next must be free of any indoubt units of recovery. Ensure that no DB2 activity is going on until you finish this procedure. (You might plan this procedure for a non-prime shift, for minimum impact on users.) To find out whether indoubt units exist, issue the DB2 command `DISPLAY THREAD TYPE(INDOUBT)`. If there are none, skip to “Find the startup log RBA.”
2. If there are one or more indoubt units of recovery, take one of the following actions:
  - Start IMS or CICS, causing that subsystem to resolve the indoubt units of recovery. If the thread is a distributed indoubt unit of recovery, restart the distributed data facility (DDF) to resolve the unit of work. If DDF does not start or cannot resolve the unit of work, use the command `RECOVER INDOUBT` to resolve the unit of work.
  - Issue the DB2 command `RECOVER INDOUBT`.These topics, including making the proper commit or abort decision, are covered in greater detail in “Resolving indoubt units of recovery” on page 463.
3. Re-issue the command `DISPLAY THREAD TYPE(INDOUBT)` to ensure that the indoubt units have been recovered. When none remain, continue with “Find the startup log RBA.”

**Step 2: Find the startup log RBA:** Keep at least all log records with log RBAs greater than the one given in this message, issued at restart:

```
DSNR003I RESTART...PRIOR CHECKPOINT RBA=XXXXXXXXXXXX
```

If you suspended DB2 activity while performing step 1, you can restart it now.

**Step 3: Find the minimum log RBA needed:** Suppose that you have determined to keep some number of complete image copy cycles of your least-frequently-copied table space. You now need to find the log RBA of the earliest full image copy you want to keep.

1. If you have any table spaces so recently created that no full image copies of them have ever been taken, take full image copies of them. If you do not take image copies of them, and you discard the archive logs that log their creation,

DB2 can never recover them.

**General-use Programming Interface**

The following SQL statement lists table spaces that have no full image copy:

```
SELECT X.DBNAME, X.NAME, X.CREATOR, X.NTABLES, X.PARTITIONS
FROM SYSIBM.SYSTABLESPACE X
WHERE NOT EXISTS (SELECT * FROM SYSIBM.SYSCOPY Y
                  WHERE X.NAME = Y.TSNAME
                  AND X.DBNAME = Y.DBNAME
                  AND Y.ICTYPE = 'F')
ORDER BY 1, 3, 2;
```

**End of General-use Programming Interface**

2. Issue the following SQL statement to find START\_RBA values:

**General-use Programming Interface**

```
SELECT DBNAME, TSNAME, DSNUM, ICTYPE, ICDATE, HEX(START_RBA)
FROM SYSIBM.SYSCOPY
ORDER BY DBNAME, TSNAME, DSNUM, ICDATE;
```

**End of General-use Programming Interface**

The statement lists all databases and table spaces within them, in ascending order by date.

Find the START\_RBA for the earliest full image copy (ICTYPE=F) that you intend to keep. If your least-frequently-copied table space is partitioned, and you take full image copies by partition, use the earliest date for all the partitions.

If you are going to discard records from SYSIBM.SYSCOPY and SYSIBM.SYSLGRNX, note the date of the earliest image copy you want to keep.

**Step 4: Copy catalog and directory tables:** Take full image copies of the DB2 table spaces listed in Table 96 to ensure that copies of these table spaces are included in the range of log records you will keep.

*Table 96. Catalog and directory tables to copy*

Database name	Table space names	
DSNDB01	DBD01	SYSUTILX
	SCT02	SYSLGRNX
	SPT01	
DSNDB06	SYSCOPY	SYSPLAN
	SYSDBASE	SYSSTATS
	SYSDBAUT	SYSSTR
	SYSGPAUT	SYSUSER
	SYSGROUP	SYSVIEWS
	SYSPKAGE	

**Step 5: Locate and discard archive log volumes:** Now that you know the minimum LOGRBA, from step 3, suppose that you want to find archive log volumes that contain only log records earlier than that. Proceed as follows:

1. Execute the print log map utility to print the contents of the BSDS. For an example of the output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*.

2. Find the sections of the output titled "ARCHIVE LOG COPY n DATA SETS". (If you use dual logging, there are two sections.) The columns labelled STARTRBA and ENDRBA show the range of log RBAs contained in each volume. Find the volumes (two, for dual logging) whose ranges include the minimum log RBA you found in step 3; these are the earliest volumes you need to keep.

If no volumes have an appropriate range, one of these cases applies:

- The minimum LOGRBA has not yet been archived, and you can discard all archive log volumes.
- The list of archive log volumes in the BSDS wrapped around when the number of volumes exceeded the number allowed by the RECORDING MAX field of installation panel DSNTIPA. If the BSDS does not register an archive log volume, it can never be used for recovery. Therefore, you should consider adding information about existing volumes to the BSDS. For instructions, see Part 3 of *DB2 Utility Guide and Reference*.

You should also consider increasing the value of MAXARCH. For information, see information about installation panel DSNTIPA in Part 2 of *DB2 Installation Guide*.

3. Delete any archive log data set or volume (both copies, for dual logging) whose ENDRBA value is less than the STARTRBA value of the earliest volume you want to keep.

Because BSDS entries wrap around, the first few entries in the BSDS archive log section might be more recent than the entries at the bottom. Look at the combination of date and time to compare age. Do not assume you can discard all entries above the entry for the archive log containing the minimum LOGRBA.

Delete the data sets. If the archives are on tape, scratch the tapes; if they are on disks, run a z/OS utility to delete each data set. Then, if you want the BSDS to list only existing archive volumes, use the change log inventory utility to delete entries for the discarded volumes; for an example, see Part 3 of *DB2 Utility Guide and Reference*.

---

## Chapter 19. Restarting DB2 after termination

This chapter tells what to expect when DB2 terminates normally or abnormally, and how to start it again. The concepts are important background for Chapter 20, “Maintaining consistency across multiple systems,” on page 459 and Chapter 21, “Backing up and recovering databases,” on page 475. This chapter includes the following topics:

“Termination”

“Normal restart and recovery” on page 448

“Deferring restart processing” on page 454

“Restarting with conditions” on page 455

Chapter 20, “Maintaining consistency across multiple systems,” on page 459 describes additional considerations for a DB2 subsystem that must be kept consistent with some other system. The term *object*, used throughout this chapter, refers to any database, table space, or index space.

**Restarting in a data sharing environment:** In a data sharing environment, restart processing is expanded to handle the coordination of data recovery across more than one DB2 subsystem. When certain critical resources are lost, restart includes additional processing to recovery and rebuild those resources. This process is called *group restart*, which is described in Chapter 5 of *DB2 Data Sharing: Planning and Administration*.

---

### Termination

DB2 terminates normally in response to the command STOP DB2. If DB2 stops for any other reason, the termination is considered abnormal.

#### Normal termination

In a normal termination, DB2 stops all activity in an orderly way. You can use either STOP DB2 MODE (QUIESCE) or STOP DB2 MODE (FORCE). The effects are given in Table 97.

Table 97. Termination using QUIESCE and FORCE

Thread type	QUIESCE	FORCE
Active threads	Run to completion	Roll back
New threads	Permitted	Not permitted
New connections	Not permitted	Not permitted

You can use either command to prevent new applications from connecting to DB2.

When you issue the command STOP DB2 MODE(QUIESCE), current threads can run to completion, and new threads can be allocated to an application that is running.

With IMS and CICS, STOP DB2 MODE(QUIESCE) allows a current thread to run only to the end of the unit of recovery, unless either of the following conditions are true:

- There are open, held cursors.

- Special registers are not in their original state.

Before DB2 can come down, all held cursors must be closed and all special registers must be in their original state, or the transaction must complete.

With CICS, QUIESCE mode brings down the CICS attachment facility, so an active task will not necessarily run to completion.

For example, assume that a CICS transaction opens no cursors declared WITH HOLD and modifies no special registers as follows:

```
EXEC SQL
      ← -STOP DB2 MODE(QUIESCE) issued here
:
:
SYNCPPOINT
:
EXEC SQL ← This receives an AETA abend
```

The thread is allowed to run only through the first SYNCPPOINT.

When you issue the command STOP DB2 MODE(FORCE), no new threads are allocated, and work on existing threads is rolled back.

During shutdown, use the command DISPLAY THREAD to check its progress. If shutdown is taking too long, you can issue STOP DB2 MODE (FORCE), but rolling back work can take as much or more time as the completion of QUIESCE.

When stopping in either mode, the following steps occur:

1. Connections end.
2. DB2 ceases to accept commands.
3. DB2 disconnects from the IRLM.
4. The shutdown checkpoint is taken and the BSDS is updated.

A data object could be left in an inconsistent state, even after a shutdown with mode QUIESCE, if it was made unavailable by the command STOP DATABASE, or if DB2 recognized a problem with the object. MODE (QUIESCE) does not wait for asynchronous tasks that are not associated with any thread to complete, before it stops DB2. This can result in data commands such as STOP DATABASE and START DATABASE having outstanding units of recovery when DB2 stops. These will become inflight units of recovery when DB2 is restarted, then be returned to their original states.

## Abends

An abend can leave data in an inconsistent state for any of the following reasons:

- Units of recovery might be interrupted before reaching a point of consistency.
- Committed data might not be written to external media.
- Uncommitted data might be written to external media.

---

## Normal restart and recovery

DB2 uses its recovery log and the bootstrap data set (BSDS) to determine what to recover when restarting. The BSDS identifies the active and archive log data sets, the location of the most recent DB2 checkpoint on the log, and the high-level qualifier of the integrated catalog facility catalog name.

After DB2 is initialized, the restart process goes through four phases, which are described in the following sections:

- “Phase 1: Log initialization”
- “Phase 2: Current status rebuild” on page 450
- “Phase 3: Forward log recovery” on page 451
- “Phase 4: Backward log recovery” on page 452

In the descriptions that follow, the terms *inflight*, *indoubt*, *in-commit*, and *in-abort* refer to statuses of a unit of work that is coordinated between DB2 and another system, such as CICS, IMS, or a remote DBMS. For definitions of those terms, see “Maintaining consistency after termination or failure” on page 461.

At the end of the fourth phase recovery, a checkpoint is taken, and committed changes are reflected in the data.

Application programs that do not commit often enough cause long running units of recovery (URs). These long running URs might be *inflight* after a DB2 failure. *Inflight* URs can extend DB2 restart time. You can restart DB2 more quickly by postponing the backout of long running URs. Use installation options LIMIT BACKOUT and BACKOUT DURATION to establish what work to delay during restart.

If your DB2 subsystem has the UR checkpoint count option enabled, DB2 generates console message DSNR035I and trace records for IFCID 0313 to inform you about long running URs. The UR checkpoint count option is enabled at installation time, through field UR CHECK FREQ on panel DSNTIPL. See Part 2 of *DB2 Installation Guide* for more information about enabling this option.

#  
#  
#  
#  
#  
#  
#

If your DB2 subsystem has the UR log threshold option enabled, DB2 generates console message DSNB260I when an *inflight* UR writes more than the installation-defined number of log records. DB2 also generates trace records for IFCID 0313 to inform you about these long running URs. You can enable the UR log threshold option at installation time, through field UR LOG WRITE CHECK on panel DSNTIPL. See Part 2 of *DB2 Installation Guide* for more information about enabling this option.

You can restart a large object (LOB) table space like other table spaces. LOB table spaces defined with LOG NO do not log LOB data, but they log enough control information (and follow a force-at-commit policy) so that they can restart without loss of data integrity.

## Phase 1: Log initialization

During phase 1, DB2 attempts to locate the last log RBA written before termination. Logging continues at the next log RBA after that. In phase 1, DB2:

1. Compares the high-level qualifier of the integrated catalog facility catalog name, in the BSDS, with the corresponding qualifier of the name in the current subsystem parameter module (DSNZPxxx).
  - If they are equal, processing continues with step 2 on page 450.
  - If they are not equal, DB2 terminates with this message:

```
DSNJ130I ICF CATALOG NAME IN BSDS
        DOES NOT AGREE WITH DSNZPARM.
        BSDS CATALOG NAME=aaaaa,
        DSNZPARM CATALOG NAME=bbbbbb
```

Without the check, the next DB2 session could conceivably update an entirely different catalog and set of table spaces. If the check fails, you presumably have the wrong parameter module. Start DB2 with the command START DB2 PARM(*module-name*), and name the correct module.

2. Checks the consistency of the timestamps in the BSDS.
  - If both copies of the BSDS are current, DB2 tests whether the two timestamps are equal.
    - If they are equal, processing continues with step 3.
    - If they are not equal, DB2 issues message DSNJ120I and terminates. That can happen when the two copies of the BSDS are maintained on separate disk volumes (as recommended) and one of the volumes is restored while DB2 is stopped. DB2 detects the situation at restart.
 

To recover, copy the BSDS with the latest timestamp to the BSDS on the restored volume. Also recover any active log data sets on the restored volume, by copying the dual copy of the active log data sets onto the restored volume. For more detailed instructions, see “BSDS failure recovery” on page 542.
  - If one copy of the BSDS was deallocated, and logging continued with a single BSDS, a problem could arise. If both copies of the BSDS are maintained on a single volume, and the volume was restored, or if both BSDS copies were restored separately, DB2 might not detect the restoration. In that case, log records not noted in the BSDS would be unknown to the system.
3. Finds in the BSDS the log RBA of the last log record written before termination. The highest RBA field (as shown in the output of the print log map utility) is updated only when the following events occur:
  - When DB2 is stopped normally (STOP DB2).
  - When active log writing is switched from one data set to another.
  - When DB2 has reached the end of the log output buffer. The size of this buffer is determined by the OUTPUT BUFFER field of installation panel DSNTIPL described in Part 2 of *DB2 Installation Guide*.
4. Scans the log forward, beginning at the log RBA of the most recent log record, up to the last control interval (CI) written before termination.
5. Prepares to continue writing log records at the next CI on the log.
6. Issues message DSNJ099I, which identifies the log RBA at which logging continues for the current DB2 session. That message signals the end of the log initialization phase of restart.

## Phase 2: Current status rebuild

During phase 2, DB2 determines the statuses of objects at the time of termination. By the end of the phase, DB2 has determined whether any units of recovery were interrupted by the termination. In phase 2, DB2:

1. Checks the BSDS to find the log RBA of the last complete checkpoint before termination.
2. Processes the RESTART or DEFER option of the parameter module of the START DB2 command if any exist. The default is always RESTART ALL.
3. Reads every log record from that checkpoint up to the end of the log (which was located during phase 1), and identifies:
  - All exception conditions existing for each database and all image copy information related to the DSNDB01.SYSUTILX, DSNDB01.DBD01, and DSNDB06.SYSCOPY table spaces.
  - All objects open at the time of termination, and how far back in the log to go to reconstruct data pages that were not written to disk.

The number of log records written between one checkpoint and the next is set when DB2 is installed; see the field CHECKPOINT\_FREQ of installation panel DSNTIPL, described in Part 2 of *DB2 Installation Guide*.

You can temporarily modify the checkpoint frequency by using the command SET LOG. The value you specify persists while DB2 is active; on restart, DB2 uses the value that is specified in the CHECKPOINT\_FREQ field of installation panel DSNTIPL. See Chapter 2 of *DB2 Command Reference* for detailed information about this command.

4. Issues message DSNR004I, which summarizes the activity required at restart for outstanding units of recovery.
5. Issues message DSNR007I if any outstanding units of recovery are discovered. The message includes, for each outstanding unit of recovery, its connection type, connection ID, correlation ID, authorization ID, plan name, status, log RBA of the beginning of the unit of recovery (URID), and the date and time of its creation.

During phase 2, no database changes are made, nor are any units of recovery completed. DB2 determines what processing is required by phase 3 forward log recovery before access to databases is allowed.

### Phase 3: Forward log recovery

During phase 3, DB2 completes the processing for all committed changes and database write operations. This includes:

- Making all database changes for each indoubt unit of recovery and locking the data to prevent access to it after restart
- Making database changes for inflight and in-abort units of recovery, and in the case of group restarts in which locks have been lost, acquiring locks to prevent access to data in use by those units of recovery

DB2 can use the fast log apply process to enhance performance of the forward recovery phase. See the Log Apply Storage field on panel DSNTIPL in *DB2 Installation Guide*, for details on defining storage for the sort used in fast log apply processing. DB2 executes these steps:

1. Detects whether a page set being recovered is at the same level ID as it was when the page set was last closed. If it is not, DB2 issues message DSNB232I and places the pages for that object on the logical page list (LPL). DB2 does not restart that object. In this case, you must recover from the down level page set using one of the methods described in “Recovery from down-level page sets” on page 548.
2. Scans the log forward, beginning at the lowest (earliest) log RBA that is either required for completion of database writes or is associated with the “Begin Unit of Recovery” of units of recovery that require locks.  
That log RBA is determined during phase 2. REDO log records for all units of recovery are processed in this phase.
3. Uses the log RBA of the earliest potential redo log record for each object (determined during phase 2). All earlier changes to the object have been written to disk; therefore, DB2 ignores their log records.
4. Reads the data or index page for each remaining redo log record. The page header registers the log RBA of the record of the last change to the page.
  - If the log RBA of the page header is greater than or equal to that of the current log record, the logged change has already been made and written to disk, and the log record is ignored.

- If the log RBA in the page header is less than that of the current log record, the change has not been made; DB2 makes the change to the page in the buffer pool.
5. Writes pages to disk as the need for buffers demands it.
  6. Marks the completion of each unit of recovery processed. If restart processing terminates later, those units of recovery do not reappear in status lists.
  7. Stops scanning at the current end of the log.
  8. Writes to disk all modified buffers not yet written.
  9. Issues message DSNR005I, which summarizes the number of remaining in-commit or indoubt units of recovery. There should not be any in-commit units of recovery, because all processing for these should have completed. The number of indoubt units of recovery should be equal to the number specified in the previous DSNR004I restart message.
  10. Issues message DSNR007I (described in “Phase 2: Current status rebuild” on page 450), which identifies any outstanding unit of recovery that still must be processed.

If DB2 encounters a problem while applying log records to an object during phase 3, the affected pages are placed in the logical page list. Message DSNI001I is issued once per page set or partition, and message DSNB250E is issued once per page. Restart processing continues.

DB2 issues status message DSNR031I periodically during this phase.

## Phase 4: Backward log recovery

During phase 4, DB2 changes performed for inflight or in-abort units of recovery are reversed. In phase 4, DB2:

1. Scans the log backward, starting at the current end. The scan continues until the earliest “Begin Unit of Recovery” record for any outstanding inflight or in-abort unit of recovery.
 

If you specified limited backout processing, the scan might stop prematurely (however, DB2 guarantees that all catalog and directory changes are completely backed out). In this case, the scan completes after DB2 receives the RECOVER POSTPONED command. You can have DB2 automatically issue this command after restart by specifying the AUTO option for limited backout processing, or you can issue this command manually.
2. Reads the data or index page for each remaining undo log record. The page header registers the log RBA of the record of the last change to the page.
  - If the log RBA of the page header is greater than or equal to that of the current log record, the logged change has already been made and written to disk, therefore DB2 reverses it.
  - If the log RBA in the page header is less than that of the current log record, the change has not been made; DB2 ignores it.
3. Writes redo compensation information in the log for each undo log record, as it does when backing out a unit of recovery. The redo records describe the reversal of the change and facilitate media recovery. They are written under all circumstances, even when:
  - The disk version of the data did not need to be reversed.
  - The page set has pages on the LPL.
  - An I/O error occurred on the disk version of the data.
  - The disk version of the data could not be allocated or opened.
4. Writes pages to disk as the need for buffers demands it.

5. Finally, writes to disk all modified buffers that have not yet been written.
6. Issues message DSNR006I, which summarizes the number of remaining inflight, in-abort, and postponed-abort units of recovery. The number of inflight and in-abort units of recovery should be zero; the number of postponed-abort units of recovery might not be zero.
7. Marks the completion of each completed unit of recovery in the log so that, if restart processing terminates, the unit of recovery is not processed again at the next restart.
8. If necessary, reacquires write claims for the objects on behalf of the indoubt and postponed-abort units of recovery.
9. Takes a checkpoint, after all database writes have been completed.

If DB2 encounters a problem while applying a log record to an object during phase 4, the affected pages are placed in the logical page list. Message DSNI001I is issued once per page set or partition, and message DSNB250E is issued once per page. Restart processing continues.

DB2 issues status message DSNR031I periodically during this phase.

## Restarting automatically

If you are running DB2 in a Sysplex, you can have the automatic restart function of z/OS automatically restart DB2 or IRLM after a failure.

When DB2 or IRLM stops abnormally, z/OS determines whether z/OS failed too, and where DB2 or IRLM should be restarted. It then restarts DB2 or IRLM.

You must have DB2 installed with a command prefix scope of S to take advantage of automatic restart. See Part 2 of *DB2 Installation Guide* for instruction on specifying command scope.

**Using an automatic restart policy:** You control how automatic restart works by using automatic restart policies. When the automatic restart function is active, the default action is to restart the subsystems when they fail. If this default action is not what you want, then you must create a policy defining the action you want taken.

To create a policy, you need the element names of the DB2 and IRLM subsystems:

- For a non-data-sharing DB2, the element name is 'DB2\$' concatenated by the subsystem name (DB2\$DB2A, for example). To specify that a DB2 subsystem is not to be restarted after a failure, include RESTART\_ATTEMPTS(0) in the policy for that DB2 element.
- For local mode IRLM, the element name is a concatenation of the IRLM subsystem name and the IRLM ID. For global mode IRLM, the element name is a concatenation of the IRLM data sharing group name, IRLM subsystem name, and the IRLM ID.

For instructions on defining automatic restart policies, see *z/OS MVS Setting Up a Sysplex*.

---

## Deferring restart processing

Usually, restarting DB2 activates restart processing for objects that were available when DB2 terminated (in other words, not stopped with the command STOP DATABASE). Restart processing applies or backs out log records for objects that have unresolved work.

Restart processing is controlled by what you choose on installation panel DSNTIPS, and the default is RESTART ALL.

If some specific object is causing problems, you should consider deferring its restart processing by starting DB2 without allowing that object to go through restart processing. When you defer restart of an object, DB2 puts pages necessary for the object's restart in the logical page list (LPL). Only those pages are inaccessible; the rest of the object can still be accessed after restart.

# There are restrictions to DB2's activation of restart processing for available objects.  
# When you say DEFER ALL at a site that is designated as RECOVERYSITE in  
# DSNZPxxx, all pages are placed in the LPL (as a page range, not as a large list of  
# individual pages). All pages for the index are also placed in the LPL. The following  
# conditions apply:  
#  
# • If DB2 cannot open and read the DBD01 table space it will not put DB2 into  
# ACCESS(MAINT), and DSNX204I is not be issued. Instead either DSNT500I or  
# DSNT501I 'resource unavailable' are issued.  
#  
# • For a deferring restart scenario that needs to recover all DB2 objects after DB2 is  
# up, it is recommend that you set the ZPARM DEFER ALL and start DB2 with  
# the ACCESS(MAINT) option.  
#  
# • If DEFER ALL is specified, DSNX204I is not issued.  
#  
# • With DEFER ALL, DB2 will not open any data sets, including SYSLGRNX and  
# DSNRTSTS, during any phase of restart, and will not attempt to apply any log  
# records.

DB2 can also defer restart processing for particular objects. DB2 puts pages in the LPL for any object (or specific pages of an object) with certain problems, such as an open or I/O error during restart. Again, only pages that are affected by the error are placed on the LPL.

You can defer an object's restart processing with any of the following actions:

**VARY the device (or volume) on which the objects reside OFFLINE.** If the data sets containing an object are not available, and the object requires recovery during restart, DB2 flags it as stopped and requiring deferred restart. DB2 then restarts without it.

**Delay the backout of a long running UR.** On installation panel DSNTIPL, you can use the following options:

- LIMIT BACKOUT defined as YES or AUTO indicates that some backout processing will be postponed when restarting DB2. Users must issue the RECOVER POSTPONED command to complete the backout processing when the YES option is selected. DB2 does the backout work automatically after DB2 is running and receiving new work when the AUTO option is selected.
- BACKOUT DURATION indicates the number of log records, specified as a multiplier, to be read during restart's backward log scan.

The amount of backout processing to be postponed is determined by:

- The frequency of checkpoints
- The BACKOUT DURATION installation option
- The characteristics of the inflight and in-abort activity when the system went down

Selecting a limited backout affects log processing during restart. The backward processing of the log proceeds until the oldest inflight or in-abort UR with activity against the catalog or directory is backed out, and the requested number of log records have been processed.

**Name the object with DEFER when installing DB2.** On installation panel DSNNTIPS, you can use the following options:

- DEFER ALL defers restart log apply processing for all objects, including DB2 catalog and directory objects.
- DEFER *list\_of\_objects* defers restart processing only for objects in the list.

Alternatively, you can specify RESTART *list\_of\_objects*, which limits restart processing to the list of objects in the list.

DEFER does not affect processing of the log during restart. Therefore, even if you specify DEFER ALL, DB2 still processes the full range of the log for both the forward and backward log recovery phases of restart. However, logged operations are not applied to the data set.

---

## Restarting with conditions

If you want to skip some portion of the log processing during DB2 restart, you can use a conditional restart. However, if a conditional restart skips any database change log records, data in the associated objects becomes inconsistent and any attempt to process them for normal operations might cause unpredictable results. The only operations that can safely be performed on the objects are recovery to a prior point of consistency, total replacement, or dropping.

In unusual cases, you might choose to make inconsistent objects available for use without recovering them. For example, the only inconsistent object might be a table space that is dropped as soon as DB2 is restarted, or the DB2 subsystem might be used only for testing application programs still under development. In cases like those, where data consistency is not critical, normal recovery operations can be partially or fully bypassed by using conditional restart control records in the BSDS. The procedure is:

1. While DB2 is stopped, run the change log inventory utility using the CRESTART control statement to create a new conditional restart control record.
2. Restart DB2. The type of recovery operations that take place is governed by the current conditional restart control record.

When considering a conditional restart, it is often useful to run the DSN1LOGP utility and review a summary report of the information contained in the log.

For an example of the messages that are written to the DB2 console during restart processing, see “Messages at start” on page 324.

# In a data sharing environment, you can use the new LIGHT(YES) or  
# LIGHT(NOINDOUBTS) parameter on the START DB2 command to quickly recover  
# retained locks on a DB2 member. For more information, see *DB2 Data Sharing:  
# Planning and Administration*.

| **Restart considerations for identity columns:** Cold starts and conditional restarts  
| that skip forward recovery can cause additional data inconsistency within identity  
| columns and sequence objects. After such restarts, DB2 might assign duplicate  
| identity column values and create gaps in identity column sequences. For  
| information about how to correct this data inconsistency, see “Recovering catalog  
| and directory tables” on page 502.

This section gives an overview of the available options for conditional restart. For more detail, see information about the change log inventory utility (DSNJU003) in Part 3 of *DB2 Utility Guide and Reference*. For information about data sharing considerations, see Chapter 5 of *DB2 Data Sharing: Planning and Administration*.

## Resolving postponed units of recovery

You can postpone some of the backout work that is associated with long running units of work during system restart by using the LIMIT BACKOUT installation option. By delaying such backout work, the DB2 subsystem can be restarted more quickly. If you specify LIMIT BACKOUT = YES, then you must use the RECOVER POSTPONED command to resolve postponed units of recovery. See Part 2 of *DB2 Installation Guide* for more information about installation options.

Use the RECOVER POSTPONED command to complete postponed backout processing on *all* units of recovery; you cannot specify a single unit of work for resolution. This command might take several hours to complete depending on the content of the long-running job. In some circumstances, you can elect to use the CANCEL option of the RECOVER POSTPONED command. This option leaves the objects in an inconsistent state (REFP) that you must resolve before using the objects. However, you might choose the CANCEL option for the following reasons:

- You determine that the complete recovery of the postponed units of recovery will take more time to complete than you have available. You also determine it is faster to either recover the objects to a prior point in time or run the LOAD utility with the REPLACE option.
- You want to replace the existing data in the object with new data.
- You decide to drop the object. To drop the object successfully, complete the following steps:
  1. Issue the RECOVER POSTPONED command with the CANCEL option.
  2. Issue the DROP TABLESPACE statement.
- You do not have the DB2 logs to successfully recover the postponed units of recovery.

### Errors encountered during RECOVER POSTPONED processing

If a required page cannot be accessed during RECOVER POSTPONED processing, or if any other error is encountered while attempting to apply a log record, the page set or partition is deferred and processing continues. DB2 writes a compensation log record to reflect those deferrals and places the page in the logical page list. Some errors encountered while recovering indexes cause the entire page set to be placed in the logical page list. Some errors halt the construction of the compensation log and mark the page set as RECP.

When an error prevents logging of a compensation log record, DB2 abends. If DB2 abends:

1. Fix the error.
2. Restart DB2.
3. Re-issue the RECOVER POSTPONED command if automatic backout processing has not been specified.

### Output from RECOVER POSTPONED processing

Output from the RECOVER POSTPONED command consists of informational messages. In Figure 52, backout processing was performed against two table space partitions and two index partitions:

```

DSNV435I ! RESOLUTION OF POSTPONED ABORT URS HAS BEEN SCHEDULED
DSN9022I ! DSNVRP 'RECOVER POSTPONED' NORMAL COMPLETION
DSNR047I ! DSNRBMON POSTPONED ABORT BACKOUT
PROCESSING LOG RECORD AT RBA 000002055000 TO RBA 000001E6A20E
DSNR047I ! DSNRBMON POSTPONED ABORT BACKOUT
PROCESSING LOG RECORD AT RBA 000002049000 TO RBA 000001E6A20E
DSNI024I ! DSNIRPL BACKOUT PROCESSING HAS COMPLETED
FOR PAGESET DSND04 .I PART 00000004.
DSNI024I ! DSNIRPL BACKOUT PROCESSING HAS COMPLETED
FOR PAGESET DSND04 .PT PART 00000004.
DSNI024I ! DSNIRPL BACKOUT PROCESSING HAS COMPLETED
FOR PAGESET DSND04 .I PART 00000002.
DSNI024I ! DSNIRPL BACKOUT PROCESSING HAS COMPLETED

```

*Figure 52. Example of output from RECOVER POSTPONED processing*

If the RECOVER POSTPONED processing lasts for an extended period, the output includes DSNR047I messages, as shown in Figure 52, to help you monitor backout processing. These messages show the current RBA that is being processed and the target RBA.

## Choosing recovery operations for conditional restart

The recovery operations that take place during restart are controlled by the currently active conditional restart control record. An active control record is created or deactivated by running the change log inventory utility with the CRESTART control statement. You can choose:

- To retain a specific portion of the log for future DB2 processing
- To read the log forward to recover indoubt and uncommitted units of recovery
- To read the log backward to back out uncommitted and in-abort units of recovery
- To do a cold start, not processing any log records.

A conditional restart record that specifies left truncation of the log causes any postponed abort units of recovery that began earlier than the truncation RBA to end without resolution. The combination of unresolved postponed abort units of recovery can cause more records than requested by the BACKODUR system parameter to be processed. The left truncation RBA takes precedence over BACKODUR in this case.

Be careful about doing a conditional restart that discards log records. If the discarded log records contain information from an image copy of the DB2 directory, a future execution of the RECOVER utility on the directory will fail. For more information, see “Recovering the catalog and directory” on page 498.

## Conditional restart records

In addition to information describing the active and archive logs, the BSDS contains two queues of records associated with conditional restart.

- A wrap-around queue of conditional restart control records. Each element in the queue records the choices you made when you created the record and the progress of the restart operation it controls. When the operation is complete, the use count is set at 1 for the record and it is not used again.
- A queue of checkpoint descriptions. Because a conditional restart can specify use of a particular log record range, the recovery process cannot automatically use the most recent checkpoint. The recovery process must find the latest checkpoint within the specified range, and uses that checkpoint queue for that purpose.

Use the utility DSN1LOGP to read information about checkpoints and conditional restart control records. See Part 3 of *DB2 Utility Guide and Reference* for information about that utility.

---

## Chapter 20. Maintaining consistency across multiple systems

This chapter explains data consistency issues which arise when DB2 acts in conjunction with other systems, either IMS, CICS, or remote DBMSs.

The following sections are presented:

“Multiple system consistency”

“Resolving indoubt units of recovery” on page 463

“Resolution of remote DBMS indoubt units of recovery” on page 467

“Consistency across more than two systems” on page 471

“Resolution of RRS indoubt units of recovery” on page 470

---

### Multiple system consistency

DB2 can work with other database management systems, including IMS, CICS, and other types of remote DBMSs through DDF. DB2 can also work with other DB2 subsystems through the distributed data facility (DDF).

If data in more than one subsystem is to be consistent, then all update operations at all subsystems for a single logical unit of work must either be committed or backed out.

### The two-phase commit process

In a distributed system, the actions of a logical unit of work might occur at more than one system. When these actions update recoverable resources, the commit process insures that either all the effects of the logical unit of work persist or that none of the effects persist, despite component, system, or communications failures.

DB2 uses a two-phase commit process in communicating between subsystems. That process is under the control of one of the subsystems, called the *coordinator*. The other systems involved are the *participants*. IMS, CICS, or WebSphere Application Server are always the coordinator when they interact with DB2. In transactions that include IMS, CICS, or WebSphere Application Server, DB2 is always a participant. DB2 is always the coordinator when it interacts with TSO and DB2 completely controls the commit process in these interactions. In interactions with other DBMSs, including other DB2 subsystems, your local DB2 can be either the coordinator or a participant.

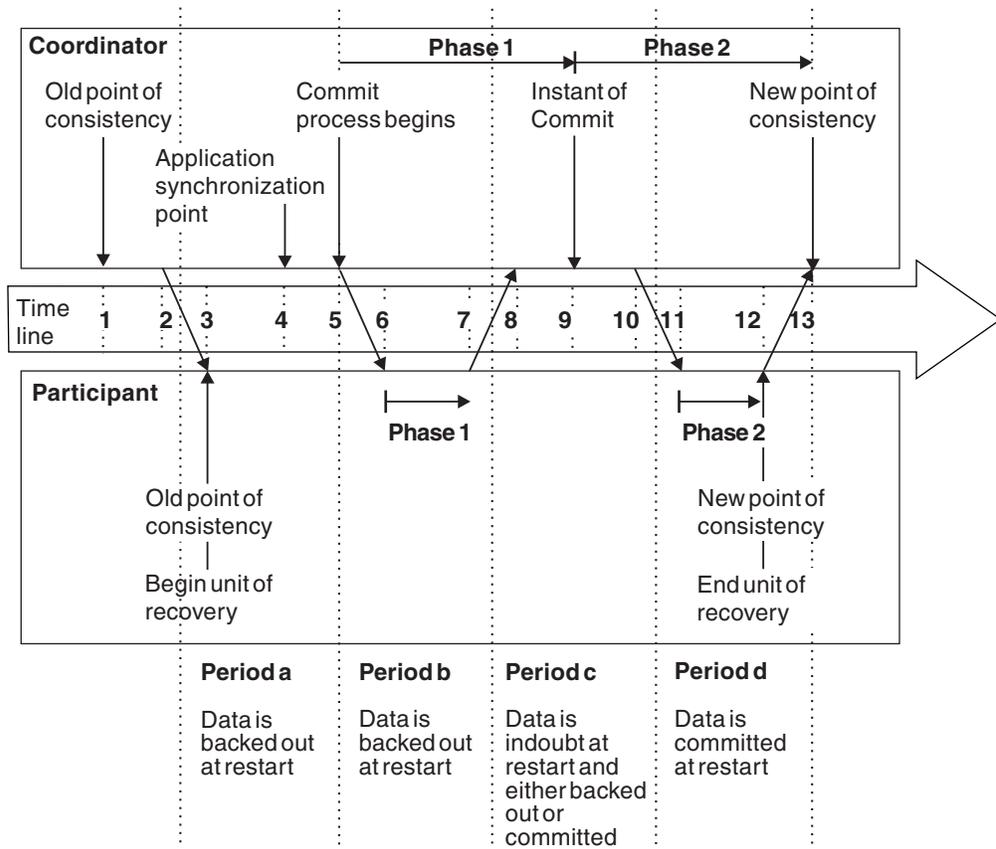

Figure 53. Time line illustrating a commit that is coordinated with another subsystem

## Illustration of two-phase commit

Figure 53 illustrates the two-phase commit process. Events in the coordinator (IMS, CICS, or DB2) are shown on the upper line, events in the participant on the lower line. The numbers in the following discussion are keyed to those in the figure. The resultant state of the update operations at the participant are shown between the two lines.

1. The data in the coordinator is at a point of consistency.
2. An application program in the coordinator calls the participant to update some data, by executing an SQL statement.
3. This starts a unit of recovery in the participant.
4. Processing continues in the coordinator until an application synchronization point is reached.
5. The coordinator then starts commit processing. IMS can do that by using a DL/I CHPK call, a fast path SYNC call, a GET UNIQUE call to the I/O PCB, or a normal application termination. CICS uses a SYNCPOINT command or a normal application termination. A DB2 application starts commit processing by an SQL COMMIT statement or by normal termination. Phase 1 of commit processing begins.
6. The coordinator informs the participant that it is to prepare for commit. The participant begins phase 1 processing.
7. The participant successfully completes phase 1, writes this fact in its log, and notifies the coordinator.

8. The coordinator receives the notification.
9. The coordinator successfully completes its phase 1 processing. Now both subsystems agree to commit the data changes, because both have completed phase 1 and could recover from any failure. The coordinator records on its log the instant of commit—the irrevocable decision of the two subsystems to make the changes.  
The coordinator now begins phase 2 of the processing—the actual commitment.
10. It notifies the participant to begin its phase 2.
11. The participant logs the start of phase 2.
12. Phase 2 is successfully completed, which establishes a new point of consistency for the participant. The participant then notifies the coordinator that it is finished with phase 2.
13. The coordinator finishes its phase 2 processing. The data controlled by both subsystems is now consistent and available to other applications.

There are occasions when the coordinator invokes the participant when no participant resource has been altered since the completion of the last commit process. This can happen, for example, when SYNCPOINT is issued after performance of a series of SELECT statements or when end-of-task is reached immediately after SYNCPOINT has been issued. When this occurs, the participant performs both phases of the two-phase commit during the first commit phase and records that the user or job is read-only at the participant.

## Maintaining consistency after termination or failure

If DB2 fails while acting as a coordinator, it has the appropriate information to determine commit or roll back decisions after restart. However, if DB2 fails while it acts as the participant, it must determine after restart whether to commit or to roll back units of recovery that were active at the time of the failure. For certain units of recovery, DB2 has enough information to make the decision. For others, it does not, and DB2 must get information from the coordinator when the connection is reestablished.

The status of a unit of recovery after a termination or failure depends upon the moment at which the incident occurred. Figure 53 on page 460 helps to illustrate the following possible statuses:

### Status Description and Processing

#### Inflight

The participant or coordinator failed before finishing phase 1 (period *a* or *b*); during restart, both systems back out the updates.

#### Indoubt

The participant failed after finishing phase 1 and before starting phase 2 (period *c*); only the coordinator knows whether the failure happened before or after the commit (point 9). If it happened before, the participant must back out its changes; if it happened afterward, it must make its changes and commit them. After restart, the participant waits for information from the coordinator before processing this unit of recovery.

#### In-commit

The participant failed after it began its own phase 2 processing (period *d*); it makes committed changes.

**In-abort**

The participant or coordinator failed after a unit of recovery began to be rolled back but before the process was complete (not shown in the figure). The operational system rolls back the changes; the failed system continues to back out the changes after restart.

**Postponed abort**

If LIMIT BACKOUT installation option is set to YES or AUTO, any backout not completed during restart is postponed. The status of the incomplete URs is changed from inflight or in-abort to postponed abort.

## Termination for multiple systems

Termination for multiple systems is like termination for single systems, but with the following additional considerations:

- Using STOP DB2 MODE(FORCE) could create indoubt units of recovery for threads that are between commit processing phases. These indoubt threads are resolved after you reconnect to the coordinator.
- Data updated by an indoubt unit of recovery is locked and unavailable for use by others. The unit could be indoubt when DB2 was stopped, or could be indoubt from an earlier termination and not yet resolved.
- A DB2 system failure can leave a unit of recovery in an indoubt state if the failure occurs between phase 1 and phase 2 of the commit process.

## Normal restart and recovery for multiple systems

When DB2 acts together with another system, the recovery log contains information about units of recovery that are inflight, indoubt, in-abort, postponed abort, or in-commit. The phases of restart and recovery deal with that information as follows:

**Phase 1: Log initialization**

This phase proceeds as described in “Phase 1: Log initialization” on page 449.

**Phase 2: Current status rebuild**

While reading the log, DB2 identifies:

- The coordinator and all participants for every unit of recovery.
- All units of recovery that are outstanding and their statuses (indoubt, in-commit, in-abort, or inflight, as described under “Maintaining consistency after termination or failure” on page 461).

**Phase 3: Forward log recovery**

DB2 makes all database changes for each indoubt unit of recovery, and locks the data to prevent access to it after restart. Later, when an indoubt unit of recovery is resolved, processing is completed in one of these ways:

- For the ABORT option of the RECOVER INDOUBT command, DB2 reads and processes the log, reversing all changes.
- For the COMMIT option of the RECOVER INDOUBT command, DB2 reads the log but does not process the records because all changes have been made.

At the end of this phase, indoubt activity is reflected in the database as though the decision was made to commit the activity, but the activity has not yet been committed. The data is locked and cannot be used until DB2 recognizes and acts upon the indoubt decision. (For a description of indoubt units of recovery, see “Resolving indoubt units of recovery” on page 463.)

## Phase 4: Backward log recovery

As described in “Phase 4: Backward log recovery” on page 452, this phase reverses changes performed for inflight or in-abort units of recovery. At the end of this phase, interrupted inflight and in-abort changes have been removed from the database (the data is consistent and can be used) or removal of the changes has been postponed (the data is inconsistent and unavailable).

If removal of the changes has been postponed, the units of recovery become known as *postponed abort* units of recovery. The data with pending backout work is in a restrictive state (restart pending) which makes the data unavailable. The data becomes available upon completion of backout work or upon cold or conditional restart of DB2.

If the LIMIT BACKOUT system parameter is AUTO, completion of the backout work begins automatically by DB2 when the system accepts new work. If the LIMIT BACKOUT system parameter is YES, completion of the backout work begins when you use the RECOVER POSTPONED command.

## Restarting multiple systems with conditions

If conditional restart is performed when DB2 is acting together with other systems, the following actions occur:

1. All information about another coordinator and other participants known to DB2 is displayed by messages DSNL438I and DSNL439I.
2. This information is purged. Therefore the RECOVER INDOUBT command must be used at the local DB2 when the local location is a participant, and at another DB2 when the local location is the coordinator.
3. Indoubt database access threads continue to appear as indoubt and no resynchronization with either a coordinator or a participant is allowed.

Methods for resolving inconsistencies caused by conditional restart and implications in a distributed environment are described in “Resolving inconsistencies resulting from a conditional restart” on page 622.

---

## Resolving indoubt units of recovery

If DB2 loses its connection to another system, it normally attempts to recover all inconsistent objects after restart. The information needed to resolve indoubt units of recovery must come from the coordinating system. This section describes the process of resolution for different types of other systems.

Check the console for message DSNR036I for unresolved units of recovery encountered during a checkpoint. This message might occur to remind operators of existing indoubt threads. See Part 2 of *DB2 Installation Guide* for details.

### Important

If the TCP/IP address that is associated with a DRDA server is subject to change, the domain name of each DRDA server must be defined in the CDB. This allows DB2 to recover from situations where the server’s IP address changes prior to successful resynchronization.

## Resolution of IMS indoubt units of recovery

The resolution of indoubt units in IMS has no effect on DL/I resources. Because IMS is in control of recovery coordination, DL/I resources are never indoubt. When IMS restarts, it automatically commits or backs out incomplete DL/I work, based on whether or not the commit decision was recorded on the IMS log. The existence of indoubt units does not imply that DL/I records are locked until DB2 connects.

During the current status rebuild phase of DB2 restart, the DB2 participant makes a list of indoubt units of recovery. IMS builds its own list of residual recovery entries (RREs). The RREs are logged at IMS checkpoints until all entries are resolved.

When indoubt units are recovered, the following steps occur:

1. IMS either passes an RRE to the IMS attachment facility to resolve the entry or informs the attachment facility of a cold start. The attachment facility passes the required information to DB2.
2. If DB2 recognizes that an entry has been marked by DB2 for commit and by IMS for roll back, it issues message DSNM005I. DB2 issues this message for inconsistencies of this type between DB2 and IMS.
3. The IMS attachment facility passes a return code to IMS, indicating that it should either destroy the RRE (if it was resolved) or keep it (if it was not resolved). The procedure is repeated for each RRE.
4. Finally, if DB2 has any remaining indoubt units, the attachment facility issues message DSNM004I.

The IMS attachment facility writes all the records involved in indoubt processing to the IMS log tape as type X'5501FE'.

For all resolved units, DB2 updates databases as necessary and releases the corresponding locks. For threads that access offline databases, the resolution is logged and acted on when the database is started.

DB2 maintains locks on indoubt work that was not resolved. This can create a backlog for the system if important locks are being held. Use the DISPLAY DATABASE LOCKS command to find out which tables and table spaces are locked by indoubt units of recovery. The connection remains active so you can clean up the IMS RREs. Recover the indoubt threads by the methods described in "Controlling IMS connections" on page 392.

All indoubt work should be resolved unless there are software or operating problems, such as with an IMS cold start. Resolution of indoubt units of recovery from IMS can cause delays in SQL processing. Indoubt resolution by the IMS control region takes place at two times:

- At the start of the connection to DB2, during which resolution is done synchronously
- When a program fails, during which the resolution is done asynchronously.

In the first case, SQL processing is prevented in all dependent regions until the indoubt resolution is completed. IMS does not allow connections between IMS dependent regions and DB2 before the indoubt units are resolved.

## Resolution of CICS indoubt units of recovery

The resolution of indoubt units has no effect on CICS resources. CICS is in control of recovery coordination and, when it restarts, CICS automatically commits or backs out each unit, depending on whether there was an end of unit of work log record. The existence of indoubt work does not lock CICS resources until DB2 connects.

A process to resolve indoubt units of recovery is initiated during start up of the attachment facility. During this process:

- The attachment facility receives a list of indoubt units of recovery for this connection ID from the DB2 participant and passes them to CICS for resolution.
- CICS compares entries from this list with entries in its own. CICS determines from its own list what action it took for the indoubt unit of recovery.
- For each entry in the list, CICS creates a task that drives the attachment facility, specifying the final commit or abort direction for the unit of recovery.
- If DB2 does not have any indoubt unit of recovery, a dummy list is passed. CICS then purges any unresolved units of recovery from previous connections, if any.

If the units of recovery cannot be resolved because of conditions described in messages DSN001I, DSN034I, DSN035I, or DSN036I, CICS enables the connection to DB2. For other conditions, it sends message DSN016I and terminates the connection.

For all resolved units, DB2 updates databases as necessary and releases the corresponding locks. For threads that access offline databases, the resolution is logged and acted on when the database is started. Unresolved units of work can remain after restart; resolve them by the methods described in “Manually recovering CICS indoubt units of recovery” on page 531.

## Resolution of WebSphere Application Server indoubt units of recovery

A *global transaction* is a unit of work that involves operations on multiple resource managers, such as DB2. All of the operations that comprise a global transaction are managed by a transaction manager, such as WebSphere Application Server. When the transaction manager receives transactionally demarcated requests from an application, it translates the requests into a series of transaction control commands, which it directs to the participating resource managers.

**Example:** An application requests updates to multiple databases. The transaction manager translates these update requests into transaction control commands that are passed to several resource managers. Each resource manager then performs its own set of operations on a database. When the application issues a COMMIT, the transaction manager coordinates the commit of the distributed transaction across all participating resource managers by using the two-phase commit protocol. If any resource manager is unable to complete its portion of the global transaction, the transaction manager directs all participating resource managers to roll back the operations that they performed on behalf of the global transaction.

If a communication failure occurs between the first phase (prepare) and the second phase (commit decision) of a commit, an indoubt transaction is created on the resource manager that experienced the failure. When an indoubt transaction is created, a message like this is displayed on the console of the resource manager:

```

00- 17.24.36 STC00051 DSNL405I = THREAD
- G91E1E35.GFA7.00F962CC4611.0001=217
- PLACED IN INDOUBT STATE BECAUSE OF
- COMMUNICATION FAILURE WITH COORDINATOR 9.30.30.53.
- INFORMATION RECORDED IN TRACE RECORD WITH IFCID=209
- AND IFCID SEQUENCE NUMBER=00000001

```

After a failure, WebSphere Application Server is responsible for resolving indoubt transactions and for driving any failure recovery. To perform these functions, the server must be restarted and the recovery process initiated by an operator. You can also manually resolve indoubt transactions with the RECOVER INDOUBT command.

**Recommendation:** Let WebSphere Application Server resolve the indoubt transactions. Manually recover indoubt transactions only as a last resort to get DB2 up and running, and to release locks.

To manually resolve indoubt transactions:

1. Display indoubt threads from the resource manager console:

```
-DISPLAY THD(*) T(I) DETAIL
```

This command produces output like this:

```

00- 17.01.03          =dis thd(*) t(i) detail
- 17.01.04 STC00051 DSNV401I = DISPLAY THREAD REPORT FOLLOWS -
- 17.01.04 STC00051 DSNV406I = INDOUBT THREADS -
- COORDINATOR          STATUS      RESET URID          AUTHID
- 9.30.30.53:4007      INDOUBT    0000111F049A      ADMF002
- V437-WORKSTATION=jaijeetsvl, USERID=admf002,
- APPLICATION NAME=db2jccmain
- V440-XID=7C7146CE 00000014 00000021 F6EF6F8B
- F36873BE A37AC6BC 256F295D 04BE7EE0
- 8DFEF680 D1A6EFD5 8C0E6343 67679239
- CC15A350 65BFB8EA 670CEBF4 E85938E0
- 06
- V467-HAS LUWID G91E1E35.GFA7.00F962CC4611.0001=217
- V466-THREAD HAS BEEN INDOUBT FOR 00:00:17
- DISPLAY INDOUBT REPORT COMPLETE

```

Note that in this example, only one indoubt thread exists.

A transaction is identified by a transaction identifier, called an XID. The first four bytes of the XID (in this case, 7C7146CE) identify the transaction manager. Each XID is associated with a logical unit of work ID (LUWID) at the DB2 server. Note the LUWID that is associated with each transaction, for use in the recovery step.

2. Query the transaction manager to determine whether a commit or abort decision was made for each transaction.
3. Based on the decision recorded by the transaction manager, recover each indoubt thread from the resource manager console by either committing or aborting the transaction. Specify the LUWID from the DISPLAY THREAD command.

```
-RECOVER INDOUBT ACTION(COMMIT) LUWID(217)
```

or:

```
-RECOVER INDOUBT ACTION(ABORT) LUWID(217)
```

This command produces output like this:

```

00- 17.30.21          =RECOVER INDOUBT ACTION(COMMIT) LUWID(217)
- 17.30.22 STC00051 DSNV414I = THREAD
- LUWID=G91E1E35.GFA7.00F962CC4611.0001=217 COMMIT
- SCHEDULED
- 17.30.22 STC00051 DSN9022I = DSNVRI '-RECOVER INDOUBT' NORMAL COMPLETION

```

4. Display indoubt threads again from the resource manager console:

```
-DISPLAY THD(*) T(I) DETAIL
```

This command produces output like this:

```

00- 17.03.37          =dis thd(*) t(i) detail
- 17.03.37 STC00051 DSNV401I = DISPLAY THREAD REPORT FOLLOWS -
- 17.03.37 STC00051 DSNV406I = INDOUBT THREADS -
- COORDINATOR          STATUS          RESET URID          AUTHID
- 9.30.30.53:4007      COMMITTED-H      0000111F049A ADMF002
- V437-WORKSTATION=jaijeetsv1, USERID=admf002,
- APPLICATION NAME=db2jccmain
- V440-XID=7C7146CE 00000014 00000021 F6EF6F8B
- F36873BE A37AC6BC 256F295D 04BE7EE0
- 8DFEF680 D1A6EFD5 8C0E6343 67679239
- CC15A350 65BFB8EA 670CEBF4 E85938E0
- 06
- V467-HAS LUWID G91E1E35.GFA7.00F962CC4611.0001=217
- DISPLAY INDOUBT REPORT COMPLETE

```

Notice that the transaction now appears as a heuristically committed transaction.

5. If the transaction manager does not recover the indoubt transactions in a timely manner, reset the transactions from the resource manager console to purge the indoubt thread information. Specify the IP address and port from the DISPLAY THREAD command.

```
-RESET INDOUBT IPADDR(9.30.30.53:4007)FORCE
```

This command produces output like this:

```

00- 17.37.13          =RESET INDOUBT IPADDR(9.30.30.53:4393)FORCE
- 17.37.13 STC00051 DSNL455I = DB2 HAS NO INFORMATION RELATED TO
- IPADDR 9.30.30.53:4007
- 17.37.13 STC00051 DSNL454I = QUALIFYING INDOUBT INFORMATION FOR
- IPADDR 9.30.30.53:4007 HAS BEEN PURGED

```

## Resolution of remote DBMS indoubt units of recovery

When communicating with a remote DBMS, indoubt units of recovery can result from failure with either the participant or coordinator or with the communication link between them even if the systems themselves have not failed.

Normally, if your subsystem fails while communicating with a remote system, you should wait until both systems and their communication link become operational. Your system then automatically recovers its indoubt units of recovery and continues normal operation. When DB2 restarts while any unit of recovery is indoubt, the data required for that unit remains locked until the unit of recovery is resolved.

If automatic recovery is not possible, DB2 alerts you to any indoubt units of recovery that you need to resolve. If it is imperative that you release locked resources and bypass the normal recovery process, you can resolve indoubt situations manually.

### **Important**

In a manual recovery situation, you must determine whether the coordinator decided to commit or abort and ensure that the same decision is made at the participant. In the recovery process, DB2 attempts to automatically resynchronize with its participants. If you decide incorrectly what the coordinator's recovery action is, data is inconsistent at the coordinator and participant.

If you choose to resolve units of recovery manually, you must:

- Commit changes made by logical units of work that were committed by the other system
- Roll back changes made by logical units of work that were rolled back by the other system

### **Making heuristic decisions**

From the DB2 point of view, a decision to commit or roll back an indoubt unit of recovery by any means but the normal resynchronization process is a *heuristic decision*. If you commit or roll back a unit of work and your decision is different from the other system's decision, data inconsistency occurs. This type of damage is called *heuristic damage*. If this situation should occur, and your system then updates any data involved with the previous unit of work, your data is corrupted and is extremely difficult to correct.

In order to make a correct decision, you must be absolutely sure that the action you take on indoubt units of recovery is the same as the action taken at the coordinator. Validate your decision with the administrator of the other systems involved with the logical unit of work.

### **Methods for determining the coordinator's commit or abort decision**

The first step is to communicate with the other system administrator. There are several ways to ascertain the status of indoubt units at other systems:

- Use a NetView program. Write a program that analyzes NetView alerts for each involved system, and returns the results through the NetView system.
- Use an automated z/OS console to ascertain the status of the indoubt threads at the other involved systems.
- Use the command `DISPLAY THREAD TYPE(INDOUBT) LUWID(luwid)`.

If the coordinator DB2 system is started and no DB2 cold start was performed, then `DISPLAY THREAD TYPE(INDOUBT)` can be used. If the decision was to commit, the display thread indoubt report includes the LUWID of the indoubt thread. If the decision was to abort, the thread is not displayed.

- Read the recovery log using `DSN1LOGP`.

If the coordinator DB2 cannot be started, then `DSN1LOGP` can determine the commit decision. If the coordinator DB2 performed a cold start (or any type of conditional restart), then the system log should contain messages `DSNL438I` or `DSNL439I`, which describe the status of the unit of recovery (LUWID).

### **Displaying information about indoubt threads**

Use `DISPLAY THREAD TYPE(INDOUBT)` to find information about allied and database access indoubt threads. The command provides information about threads where DB2 is a participant, a coordinator, or both. The `TYPE(INDOUBT)` option

tells you which systems still need indoubt resolution and provides the LUWIDs you need to recover indoubt threads. A thread that has completed phase 1 of commit and still has a connection with its coordinator is in the *prepared* state and is displayed as part of the display thread active report. If a prepared thread loses its connection with its coordinator, it enters the *indoubt* state and terminates its connections to any participants at that time. Any threads in the prepared or indoubt state when DB2 terminates are indoubt after DB2 restart. However, if the participant system is waiting for a commit or roll back decision from the coordinator, and the connection is still active, DB2 considers the thread active.

If a thread is indoubt at a participant, you can determine whether a commit or abort decision was made at the coordinator by issuing the DISPLAY THREAD command at the coordinator as described previously. If an indoubt thread appears at one system and does not appear at the other system, then the latter system backed out the thread, and the first system must therefore do the same. See “Monitoring threads” on page 383 for examples of output from the DISPLAY THREAD command.

### Recovering indoubt threads

After you determine whether you need to commit or roll back an indoubt thread, recover it with the RECOVER INDOUBT command. This command does not erase the thread’s indoubt status. It still appears as an indoubt thread until the systems go through the normal resynchronization process. An indoubt thread can be identified by its LUWID, LUNAME or IP address. You can also use the LUWID’s token with the command.

**Committing or rolling back:** Use the ACTION(ABORT|COMMIT) option of RECOVER INDOUBT to commit or roll back a logical unit of work. If your system is the coordinator of one or more other systems involved with the logical unit of work, your action propagates to the other system associated with the LUW.

For example, to recover two indoubt threads, the first with LUWID=DB2NET.LUNSITE0.A11A7D7B2057.0002 and the second with a token of 442, and commit the LUWs, enter:

```
-RECOVER INDOUBT ACTION(COMMIT) LUWID(DB2NET.LUNSITE0.A11A7D7B2057.0002,442)
```

Detailed scenarios describing indoubt thread resolution can be found in “Resolving indoubt threads” on page 588.

### Resetting the status of an indoubt thread

After manual recovery of an indoubt thread, allow the systems to resynchronize automatically; this resets the status of the indoubt thread. However, if heuristic damage or a protocol error occurs, you must use the RESET INDOUBT command to delete indoubt thread information for a thread whose *reset* status is *yes*. DB2 maintains this information until normal automatic recovery. You can purge information about threads where DB2 is either the coordinator or participant. If the thread is an allied thread connected with IMS or CICS, the command only applies to coordinator information about downstream participants. Information that is purged does not appear in the next display thread report and is erased from DB2’s logs.

For example, to purge information on two indoubt threads, the first with an LUWID=DB2NET.LUNSITE0.A11A7D7B2057.0002 and a resync port number of 123; and the second with a token of 442, enter:

```
-RESET INDOUBT LUWID(DB2NET.LUNSITE0.A11A7D7B2057.0002:123,442)
```

You can also use a LUNAME or IP address with the RESET INDOUBT command. A new keyword (IPADDR) can be used in place of LUNAME or LUW keywords, when the partner uses TCP/IP instead of SNA. The partner's resync port number is required when using the IP address. The DISPLAY THREAD output lists the resync port number. This allows you to specify a location, instead of a particular thread. You can reset all the threads associated with that location with the (\*) option.

## Resolution of RRS indoubt units of recovery

Sometimes a DB2 unit of recovery (for a thread that uses RRSAF) or an RRS unit of recovery (for a stored procedure) enters the INDOUBT state. This is a state where a failure occurs when the participant (DB2 for a thread that uses RRSAF or RRS for a stored procedure) has completed phase 1 of commit processing and is waiting for the decision from the commit coordinator. This failure could be a DB2 abnormal termination, an RRS abnormal termination, or both.

Normally, automatic resolution of indoubt units of recovery occurs when DB2 and RRS reestablish communication with each other. If something prevents this, then you can manually resolve an indoubt unit of recovery. This process is not recommended because it might lead to inconsistencies in recoverable resources.

The following errors make manual recovery necessary:

- An RRS cold start where the RRS log is lost.  
If DB2 is a participant and has one or more indoubt threads, then these indoubt threads must be manually resolved in order to commit or abort the database changes and to release database locks. If DB2 is a coordinator for an RRS unit of recovery, then DB2 knows the commit/abort decision but cannot communicate this information to the RRS compliant resource manager that has an indoubt unit of recovery.
- If DB2 performs a conditional restart and loses information from its log, then there might be inconsistent DB2 managed data.
- In a Sysplex, if DB2 is restarted on an z/OS system where RRS is not installed, then DB2 might have indoubt threads.  
This is a user error because RRS must be started on all processors in a Sysplex on which RRS work is to be performed.

Both DB2 and RRS can display information about indoubt units of recovery. Both also provide techniques for manually resolving these indoubt units of recovery.

In DB2, the DISPLAY THREAD command provides information about indoubt DB2 thread. The display output includes RRS unit of recovery IDs for those DB2 threads that have RRS either as a coordinator or as a participant. If DB2 is a participant, the RRS unit of recovery ID displayed can be used to determine the outcome of the RRS unit of recovery. If DB2 is the coordinator, you can determine the outcome of the unit of recovery from the DISPLAY THREAD output.

In DB2, the RECOVER INDOUBT command lets you manually resolve a DB2 indoubt thread. You can use RECOVER INDOUBT to commit or roll back a unit of recovery after you determine what the correct decision is.

RRS provides an ISPF interface that provides a similar capability.

---

## Consistency across more than two systems

The principles and methods for maintaining consistency across more than two systems are similar to those used to ensure consistency across two systems. The main difference involves a system's role as coordinator or participant when a unit of work spans multiple systems.

### Commit coordinator and multiple participants

The coordinator of a unit of work that involves two or more other DBMSs must ensure that all systems remain consistent. After the first phase of the two-phase commit process, the DB2 coordinator waits for the other participants to indicate that they can commit the unit of work. If all systems are able, the DB2 coordinator sends the commit decision and each system commits the unit of work.

If even one system indicates that it cannot commit, then the DB2 coordinator sends out the decision to roll back the unit of work at all systems. This process ensures that data among multiple DBMSs remains consistent. When DB2 is the participant, it follows the decision of the coordinator, whether the coordinator is another DB2 or another DBMS.

DB2 is always the participant when interacting with IMS or CICS systems, or WebSphere Application Server. However, DB2 can also serve as the coordinator for other DBMSs or DB2 subsystems in the same unit of work. For example, if DB2 receives a request from a coordinating system that also requires data manipulation on another system, DB2 propagates the unit of work to the other system and serves as the coordinator for that system.

In Figure 54, DB2A is the participant for an IMS transaction, but becomes the coordinator for the two database servers (AS1 and AS2), DB2B, and its respective DB2 servers (DB2C, DB2D, and DB2E).

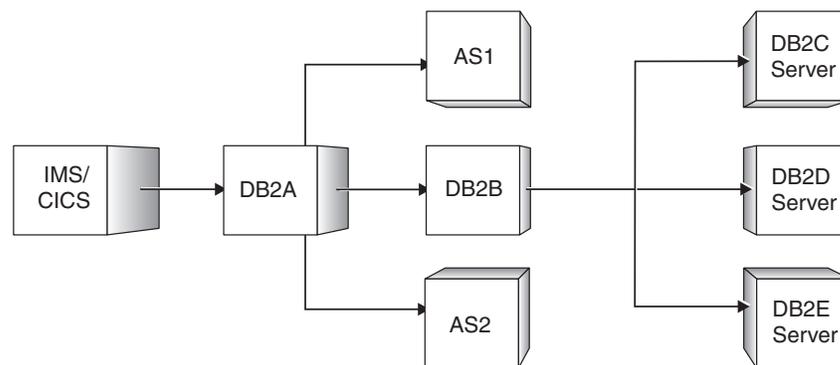

Figure 54. Illustration of multi-site unit of work

If the connection goes down between DB2A and the coordinating IMS system, the connection becomes an indoubt thread. However, DB2A's connections to the other systems are still waiting and are not considered indoubt. Wait for automatic recovery to occur to resolve the indoubt thread. When the thread is recovered, the unit of work commits or rolls back and this action is propagated to the other systems involved in the unit of work.

## Illustration of multi-site update

Figure 55 illustrates a multi-site update involving one coordinator and two participants.

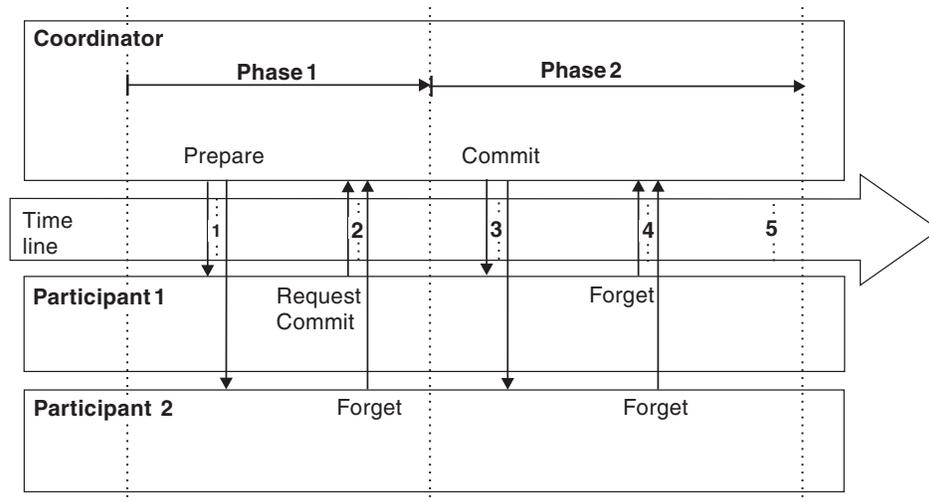

Figure 55. Illustration of multi-site update. C is the coordinator; P1 and P2 are the participants.

The following process describes each action that Figure 55 illustrates.

### Phase 1:

1. When an application commits a logical unit of work, it signals the DB2 coordinator. The coordinator starts the commit process by sending messages to the participants to determine whether they can commit.
2. A participant (*Participant 1*) that is willing to let the logical unit of work be committed, and which has updated recoverable resources, writes a log record. It then sends a request commit message to the coordinator and waits for the final decision (commit or roll back) from the coordinator. The logical unit of work at the participant is now in the prepared state.

If a participant (*Participant 2*) has not updated recoverable resources, it sends a forget message to the coordinator, releases its locks and forgets about the logical unit of work. A read-only participant writes no log records. As far as this participant is concerned, it does not matter whether the logical unit of work ultimately gets rolled back or committed.

If a participant wants to have the logical unit of work rolled back, it writes a log record and sends a message to the coordinator. Because a message to roll back acts like a veto, the participant in this case knows that the logical unit of work will be rolled back by the coordinator. The participant does not need any more information from the coordinator and therefore rolls back the logical unit of work, releases its locks, and forgets about the logical unit of work. (This case is not illustrated in the figure.)

### Phase 2:

3. After the coordinator receives request commit or forget messages from all its participants, it starts the second phase of the commit process. If at least one of the responses is request commit, the coordinator writes a log record and sends committed messages to all the participants who responded to the prepare

message with request commit. If neither the participants nor the coordinator have updated any recoverable resources, there is no second phase and no log records are written by the coordinator.

4. Each participant, after receiving a committed message, writes a log record, sends a response to the coordinator, and then commits the logical unit of work. If any participant responds with a roll back message, the coordinator writes a log record and sends a roll back message to all participants. Each participant, after receiving a roll back message writes a log record, sends an acknowledgment to the coordinator, and then rolls back the logical unit of work. (This case is not illustrated in the figure.)
5. The coordinator, after receiving the responses from all the participants that were sent a message in the second phase, writes an 'end' record and forgets the logical unit of work.

**Important:** If you try to resolve any indoubt threads manually, you need to know whether the participants committed or rolled back their units of work. With this information, you can make an appropriate decision regarding processing at your site.

---

## Chapter 21. Backing up and recovering databases

DB2 provides means for recovering data to its current state or to an earlier state. The units of data that can be recovered are table spaces, indexes, index spaces, partitions, and data sets.

This chapter explains the following topics:

- “Planning for backup and recovery”
- “Copying page sets and data sets” on page 493
- “Recovering page sets and data sets” on page 495
- “Recovering the catalog and directory” on page 498
- “Recovering data to a prior point of consistency” on page 499
- “Recovery of dropped objects” on page 509
- “Discarding SYSCOPY and SYSLGRNX records” on page 514
- “System-level point-in-time recovery” on page 515

For all commands and utility statements, the complete syntax and parameter descriptions can be found in *DB2 Command Reference* and *DB2 Utility Guide and Reference*.

---

### Planning for backup and recovery

Development at your site of backup and recovery procedures is critical in order to avoid costly and time-consuming losses of data. You should develop procedures to:

- Create a point of consistency
- Restore system and data objects to a point of consistency
- Back up the DB2 catalog and directory and your data
- Recover the DB2 catalog and directory and your data
- Recover from out-of-space conditions
- Recover from a hardware or power failure
- Recover from an z/OS component failure

In addition, you should consider a procedure for offsite recovery in case of a disaster.

To improve recovery capability in the event of a disk failure, it is advisable to use dual active logging and to place the copies of the active log data sets and the bootstrap data sets on different disk volumes. These concepts are described in “Establishing the logging environment” on page 429.

The principal tools for recovery are the utilities QUIESCE, REPORT, COPY, RECOVER, and MERGECOPY. This section also gives an overview of these utilities to help you with your backup and recovery planning.

This section covers the following topics, which you should consider when you plan for backup and recovery:

- “Considerations for recovering distributed data” on page 476
- “Considerations for recovering indexes” on page 477
- “Preparing for recovery” on page 477
- “Maximizing data availability during backup and recovery” on page 481
- “Events that occur during recovery” on page 478
- “How to find recovery information” on page 484
- “Preparing to recover to a prior point of consistency” on page 485

- “Preparing to recover the entire DB2 subsystem to a prior point-in-time” on page 486
- “Preparing for disaster recovery” on page 487
- “Ensuring more effective recovery from inconsistency” on page 490
- “Running the RECOVER utility in parallel” on page 492
- “Reading the log without RECOVER” on page 493

## Considerations for recovering distributed data

Using distributed data, no matter where a unit of work originates, the unit is processed as a whole at the target systems. At a DB2 server, the entire unit is either committed or rolled back. It is not processed if it violates referential constraints defined within the target system. Whatever changes it makes to data are logged. A set of related table spaces can be quiesced at the same point in the log, and image copies can be made of them simultaneously. If that is done, and if the log is intact, any data can be recovered after a failure and be internally consistent.

However, DB2 provides no special means to coordinate recovery between different subsystems even if an application accesses data in several systems. To guarantee consistency of data between systems, write your applications, as usual, to do all related updates within one unit of work.

Point in time recovery (to the last image copy or to an RBA) presents other problems. You cannot control a utility in one subsystem from another subsystem. In practice, you cannot quiesce two sets of table spaces, or make image copies of them, in two different subsystems at exactly the same instant. Neither can you recover them to exactly the same instant, because there are two different logs, and a relative byte address (RBA) does not mean the same thing for both of them.

In planning, then, the best approach is to consider carefully what the QUIESCE, COPY, and RECOVER utilities do for you and then plan not to place data that must be closely coordinated on separate subsystems. After that, recovery planning is a matter of agreement among database administrators at separate locations.

Because DB2 is responsible for recovering DB2 data only, it does not recover non-DB2 data. Non-DB2 systems do not always provide equivalent recovery capabilities.

## Extended recovery facility (XRF) toleration

DB2 can be used in an XRF recovery environment with CICS or IMS. All DB2-owned data sets (executable code, the DB2 catalog, user databases) must be on disk shared between the primary and alternate XRF processors. In the event of an XRF recovery, DB2 must be stopped on the primary processor and started on the alternate. For CICS that can be done automatically, by using the facilities provided by CICS, or manually, by the system operator. For IMS, that is a manual operation and must be done after the coordinating IMS system has completed the processor switch. In that way, any work that includes SQL can be moved to the alternate processor with the remaining non-SQL work. Other DB2 work (interactive or batch SQL and DB2 utilities) must be completed or terminated before DB2 can be switched to the alternate processor. Consider the effect of this potential interruption carefully when planning your XRF recovery scenarios.

Care must be taken to prevent DB2 from being started on the alternate processor until the DB2 system on the active, failing processor terminates. A premature start can cause severe integrity problems in data, the catalog, and the log. The use of global resource serialization (GRS) helps avoid the integrity problems by

preventing simultaneous use of DB2 on the two systems. The bootstrap data set (BSDS) must be included as a protected resource, and the primary and alternate XRF processors must be included in the GRS ring.

## Considerations for recovering indexes

To recover DB2 indexes to currency, you can use the REBUILD INDEX utility or the RECOVER utility. The REBUILD INDEX utility reconstructs the indexes by reading the appropriate rows in the table space, extracting the index keys, sorting the keys, and then loading the index keys into the index. The RECOVER utility recovers indexes by restoring an image copy of the index and then applying the log.

You can use the REBUILD INDEX utility to recover any index and you not need to prepare image copies of those indexes.

To use the RECOVER utility to recover indexes, you must include the following actions in your normal database operation:

- Create or alter indexes using the SQL statement ALTER INDEX with the option COPY YES before you can copy and recover them.
- Create image copies of all indexes that you plan to recover using the RECOVER utility. The COPY utility makes full image copies or concurrent copies of indexes. Incremental copies of indexes is not supported. If full image copies of the index are taken at timely intervals, recovering a large index might be faster than rebuilding the index.

**Tip:** You can recover indexes and table spaces in a single list when you use the RECOVER utility. If you use a single list of objects in one RECOVER utility control statement, the logs for all of the indexes and table spaces are processed in one pass.

## Preparing for recovery

The RECOVER utility supports the recovery of table spaces or index spaces. In the discussions about recovery in this chapter, the term page set can be a table space, index space, or any combination of these.

DB2 can recover a page set by using a backup copy or the recovery log or both. The DB2 recovery log contains a record of all changes made to the page set. If DB2 fails, it can recover the page set by restoring the backup copy and applying the log changes to it from the point of the backup copy.

The DB2 catalog and directory page sets must be copied at least as frequently as the most critical user page sets. Moreover, it is your responsibility to periodically copy the tables in the communications database (CDB), the application registration table, the object registration table, and the resource limit facility (governor), or to maintain the information necessary to re-create them. Plan your backup strategy accordingly.

**A recovery preparation scenario:** The following backup scenario suggests how DB2 utilities might be used:

Imagine that you are the database administrator for DBASE1. Table space TSPACE1 in DBASE1 has been available all week. On Friday, a disk write operation for TSPACE1 fails. You need to recover the table space to the last consistent point

before the failure occurred. You can do that because you have regularly followed a cycle of preparations for recovery. The most recent cycle began on Monday morning.

**Monday morning:** You start the DBASE1 database and make a *full image copy* of TSPACE1 and all indexes immediately. That gives you a starting point from which to recover. Use the COPY utility with the SHRLEVEL CHANGE option to improve availability. See Part 2 of *DB2 Utility Guide and Reference* for more information about the COPY utility.

**Tuesday morning:** You run COPY again. This time you make an incremental image copy to record only the changes made since the last full image copy that you took on Monday. You also make a full index copy.

TSPACE1 can be accessed and updated while the image copy is being made. For maximum efficiency, however, you schedule the image copies when online use is minimal.

**Wednesday morning:** You make another incremental image copy, and then create a full image copy by using the MERGECOPY utility to merge the incremental image copy with the full image copy.

**Thursday and Friday mornings:** You make another incremental image copy and a full index copy each morning.

**Friday afternoon:** An unsuccessful write operation occurs and you need to recover the table space. Run the RECOVER utility, as described in Part 2 of *DB2 Utility Guide and Reference*. The utility restores the table space from the full image copy made by MERGECOPY on Wednesday and the incremental image copies made on Thursday and Friday, and includes all changes made to the recovery log since Friday morning.

**Later Friday afternoon:** The RECOVER utility issues a message announcing that it has successfully recovered TSPACE1 to current point-in-time.

This imaginary scenario is somewhat simplistic. You might not have taken daily incremental image copies on just the table space that failed. You might not ordinarily recover an entire table space. However, it illustrates this important point: with proper preparation, recovery from a failure is greatly simplified.

## Events that occur during recovery

Figure 56 on page 479 shows an overview of the recovery process. To recover a page set, the RECOVER utility typically uses these items:

- A full image copy; that is, a complete copy of the page set
- For table spaces only, any later incremental image copies; each summarizes all the changes made to the table space from the time the previous image copy was made
- All log records for the page set that were created since the most recent image copy.

The RECOVER utility uses information in the SYSIBM.SYSCOPY catalog table to:

- Restore the page set with the data in the most recent full image copy (appearing, in Figure 56 on page 479, at X'40000').
- For table spaces only, apply all the changes summarized in any later incremental image copies. (There are two in Figure 56: X'80020' and X'C0040'.)

- Apply all changes to the page set that are registered in the log, beginning at the log RBA of the most recent image copy. (In Figure 56, X'C0040', that address is also stored in the SYSIBM.SYSCOPY catalog table.)

If the log has been damaged or discarded, or if data has been changed erroneously and then committed, you can recover to a particular point-in-time by limiting the range of log records to be applied by the RECOVER utility.

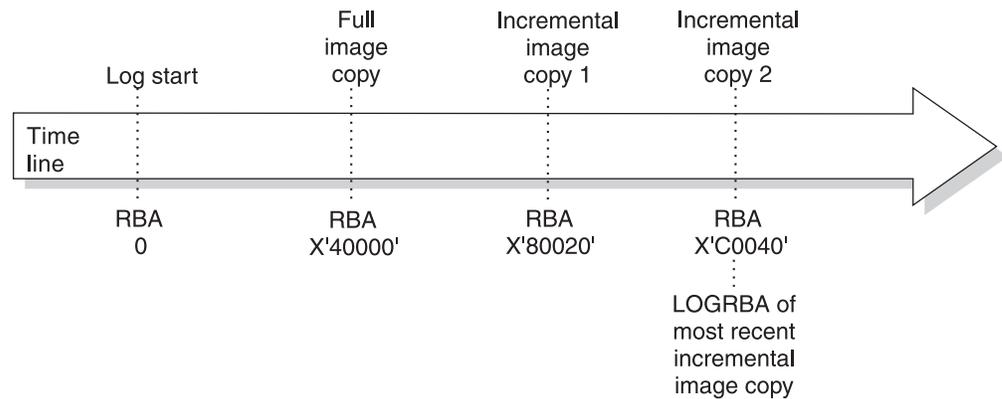

Figure 56. Overview of DB2 recovery. The figure shows one complete cycle of image copies; the SYSIBM.SYSCOPY catalog table can record many complete cycles.

### Complete recovery cycles

In planning for recovery, you determine how often to take image copies and how many complete cycles to keep. Those values tell how long you must keep log records and image copies for database recovery.

In deciding how often to take image copies, consider the time needed to recover a table space. It is determined by all of the following factors:

- The amount of log to traverse
- The time it takes an operator to mount and remove archive tape volumes
- The time it takes to read the part of the log needed for recovery
- The time needed to reprocess changed pages

In general, the more often you make image copies, the less time recovery takes; but, of course, the more time is spent making copies. If you use LOG NO without the COPYDDN keyword when you run the LOAD or REORG utilities, DB2 places the table space in copy pending status. You must remove the copy pending status of the table space by making an image copy before making further changes to the data. However, if you run REORG or LOAD REPLACE with the COPYDDN keyword, DB2 creates a full image copy of a table space during execution of the utility, so DB2 does not place the table space in copy pending status. Inline copies of indexes during LOAD and REORG are not supported.

If you use LOG YES and log all updates for table spaces, then an image copy of the table space is not required for data integrity. However, taking an image copy makes the recovery process more efficient. The process is even more efficient if you use MERGECOPY to merge incremental image copies with the latest full image copy. You can schedule the MERGECOPY operation at your own convenience, whereas the need for a recovery can come upon you unexpectedly. The MERGECOPY operation does not apply to indexes.

**Recommendation:** Copy your indexes after the associated utility has run. Indexes are placed in informational copy pending (ICOPY) status after running LOAD

TABLESPACE, REORG TABLESPACE, REBUILD INDEX, or REORG INDEX utilities. Only structural modifications of the index are logged when these utilities are run, so there is not enough information in the log to recover the index.

Use the CHANGELIMIT option of the COPY utility to let DB2 determine when an image copy should be performed on a table space and whether a full or incremental copy should be taken. Use the CHANGELIMIT and REPORTONLY options together to let DB2 recommend what types of image copies to make. When you specify both CHANGELIMIT and REPORTONLY, DB2 makes no image copies. The CHANGELIMIT option does not apply to indexes.

In determining how many complete copy and log cycles to keep, you are guarding against damage to a volume containing an important image copy or a log data set. A retention period of at least two full cycles is recommended. For further security, keep records for three or more copy cycles.

### A recovery cycle example

Table 98 suggests how often a user group with 10 locally defined table spaces (one table per table space) might take image copies, based on frequency of updating. Their least-frequently copied table is EMP\_SALS, containing employee salary data. If they choose to keep two complete image copy cycles on hand, then each time they copy EMP\_SALS they can delete records prior to its previous copy or copies, made two months ago. They will always have on hand between two months and four months of log records.

In the example, the user's most critical tables are copied daily. Hence, the DB2 catalog and directory are also copied daily.

*Table 98. DB2 log management example*

Table space name	Content	Update activity	Full image copy period
ORDERINF	Invoice line: part and quantity ordered	Heavy	Daily
SALESINF	Invoice description	Heavy	Daily
SALESQTA	Quota information for each sales person	Moderate	Weekly
SALES_DSC	Customer descriptions	Moderate	Weekly
PARTSINV	Parts inventory	Moderate	Weekly
PARTSINF	Parts suppliers	Light	Monthly
PARTS	Parts descriptions	Light	Monthly
SALESCOM	Commission rates	Light	Monthly
EMPLOYEE	Employee descriptive data	Light	Monthly
EMP_SALS	Employee salaries	Light	Bimonthly

If you do a full recovery, you do not need to recover the indexes unless they are damaged. If you recover to a prior point-in-time, you do need to recover the indexes. See "Considerations for recovering indexes" on page 477 for information about indexes.

## How DFSMSHsm affects your recovery environment

The Data Facility Hierarchical Storage Manager (DFSMSHsm) can automatically manage space and data availability among storage devices in your system. If you use it, you need to know that it automatically moves data to and from the DB2 databases.

DFSMSHsm manages your disk space efficiently by moving data sets that have not been used recently to less expensive storage. It also makes your data available for recovery by automatically copying new or changed data sets to tape or disk. It can delete data sets, or move them to another device. Its operations occur daily, at a specified time, and allow for keeping a data set for a predetermined period before deleting or moving it.

All DFSMSHsm operations can also be performed manually. *z/OS DFSMSHsm Managing Your Own Data* tells how to use the DFSMSHsm commands.

DFSMSHsm:

- Uses cataloged data sets
- Operates on user tables, image copies, and logs
- Supports VSAM data sets

If a volume has a DB2 storage group specified, the volume should only be recalled to like devices of the same VOLSER defined by CREATE or ALTER STOGROUP.

DB2 can recall user page sets that have been migrated. Whether DFSMSHsm recall occurs automatically is determined by the values of the RECALL DATABASE and RECALL DELAY fields of installation panel DSNTIPO. If the value of the RECALL DATABASE field is NO, automatic recall is not performed and the page set is considered an unavailable resource. It must be recalled explicitly before it can be used by DB2. If the value of the RECALL DATABASE field is YES, DFSMSHsm is invoked to recall the page sets automatically. The program waits for the recall for the amount of time specified by the RECALL DELAY parameter. If the recall is not completed within that time, the program receives an error message indicating the page set is unavailable but that recall was initiated.

The deletion of DFSMSHsm migrated data sets and the DB2 log retention period must be coordinated with use of the MODIFY utility. If not, you could need recovery image copies or logs that have been deleted. See “Discarding archive log records” on page 443 for suggestions.

## Maximizing data availability during backup and recovery

You need to develop a plan for backup and recovery, and you need to become familiar enough with that plan so that when an outage occurs, you can get back in operation as quickly as possible. This topic contains some factors to consider when you develop and implement your plan.

**Decide on the level of availability you need:** To do this, start by determining the primary types of outages you are likely to experience. Then, for each of those types of outages, decide on the maximum amount of time that you can spend on recovery. Consider the trade-off between cost and availability. Recovery plans for continuous availability are very costly, so you need to think about what percentage of the time your systems really need to be available.

**Practice for recovery:** You cannot know whether a backup and recovery plan is workable unless you practice it. In addition, the pressure of a recovery situation

can cause mistakes. The best way to minimize mistakes is to practice your recovery scenario until you know it well. The best time to practice is outside of regular working hours, when fewer key applications are running.

**Minimize preventable outages:** One aspect of your backup and recovery plan should be eliminating the need to recover whenever possible. One way to do that is to prevent outages caused by errors in DB2. Be sure to check available maintenance often and apply fixes for problems that are likely to cause outages.

**Determine the required backup frequency:** Use your recovery criteria to decide how often to make copies of your databases. For example, if the maximum acceptable recovery time after you lose a volume of data is two hours, your volumes typically hold about 4 GB of data, and you can read about 2 GB of data per hour, then you should make copies after every 4 GB of data written. You can use the COPY option SHRLEVEL CHANGE or DFSMSdss concurrent copy to make copies while transactions and batch jobs are running. You should also make a copy after running jobs that make large numbers of changes. In addition to copying your table spaces, you should also consider copying your indexes.

You can make additional backup image copies from a primary image copy by using the COPYTOCOPY utility. This capability is especially useful when the backup image is copied to a remote site that is to be used as a disaster recovery site for the local site. Applications can run concurrently with the COPYTOCOPY utility. Only utilities that write to the SYSCOPY catalog table cannot run concurrently with COPYTOCOPY.

**Minimize the elapsed time of RECOVER jobs:** The RECOVER utility supports the recovery of a list of objects in parallel. For those objects in the list that can be processed independently, multiple subtasks are created to restore the image copies for the objects. The parallel function can be used for either disk or tape.

**Minimize the elapsed time for copy jobs:** You can use the COPY utility to make image copies of a list of objects in parallel. Image copies can be made to either disk or tape.

**Determine the right characteristics for your logs:**

- If you have enough disk space, use more and larger active logs. Recovery from active logs is quicker than from archive logs.
- To speed recovery from archive logs, consider archiving to disk.
- If you archive to tape, be sure you have enough tape drives that DB2 does not have to wait for an available drive on which to mount an archive tape during recovery.
- Make the buffer pools and the log buffers large enough to be efficient.

**Minimize DB2 restart time:** Many recovery processes involve restart of DB2. You need to minimize the time that DB2 shutdown and startup take.

For non-data-sharing systems, you can limit the backout activity during DB2 system restart. You can postpone the backout of long running URs until after the DB2 system is operational. See “Deferring restart processing” on page 454 for an explanation of how to use the installation options LIMIT BACKOUT and BACKOUT DURATION to determine what backout work will be delayed during restart processing.

These are some major factors that influence the speed of DB2 shutdown:

- Number of open DB2 data sets  
During shutdown, DB2 must close and deallocate all data sets it uses if the fast shutdown feature has been disabled. The default is to use the fast shutdown feature. Contact your IBM software support representative for information about enabling and disabling the fast shutdown feature. The maximum number of concurrently open data sets is determined by the DB2 subsystem parameter DSMAX. Closing and deallocation of data sets generally takes .1 to .3 seconds per data set. See Part 5 (Volume 2) of *DB2 Administration Guide* for information about how to choose an appropriate value for DSMAX.  
Be aware that z/OS global resource serialization (GRS) can increase the time to close DB2 data sets. If your DB2 data sets are not shared among more than one z/OS system, set the GRS RESMIL parameter value to OFF or place the DB2 data sets in the SYSTEMS exclusion RNL. See *z/OS MVS Planning: Global Resource Serialization* for details.
- Active threads  
DB2 cannot shut down until all threads have terminated. Issue the DB2 command DISPLAY THREAD to determine if there are any active threads while DB2 is shutting down. If possible, cancel those threads.
- Processing of SMF data  
At DB2 shutdown, z/OS does SMF processing for all DB2 data sets opened since DB2 startup. You can reduce the time that this processing takes by setting the z/OS parameter DDCONS(NO).

These major factors influence the speed of DB2 startup:

- DB2 checkpoint interval  
The DB2 checkpoint interval creates a number of log records that DB2 writes between successive checkpoints. This value is controlled by the DB2 subsystem parameter CHKFREQ. The default of 50000 results in the fastest DB2 startup time in most cases.  
You can use the LOGLOAD or CHKTIME option of the SET LOG command to modify the CHKFREQ value dynamically without recycling DB2. The value you specify depends on your restart requirements. See “Dynamically changing the checkpoint frequency” on page 437 for examples of how you might use these command options. See Chapter 2 of *DB2 Command Reference* for detailed information about the SET LOG command.
- Long running units of work  
DB2 rolls back uncommitted work during startup. The amount of time for this activity is roughly double the time that the unit of work was running before DB2 shut down. For example, if a unit of work runs for two hours before a DB2 abend, it will take at least four hours to restart DB2. Decide how long you can afford for startup, and avoid units of work that run for more than half that long.  
You can use accounting traces to detect long running units of work. For tasks that modify tables, divide the elapsed time by the number of commit operations to get the average time between commit operations. Add commit operations to applications for which this time is unacceptable.  
**Recommendation:** To detect long running units of recovery, enable the UR CHECK FREQ option of installation panel DSNTIPL. If long running units of recovery are unavoidable, consider enabling the LIMIT BACKOUT option on installation panel DSNTIPL.
- Size of active logs  
If you archive to tape, you can avoid unnecessary startup delays by making each active log big enough to hold the log records for a typical unit of work. This

lessens the probability that DB2 will have to wait for tape mounts during startup. See Part 5 (Volume 2) of *DB2 Administration Guide* for more information about choosing the size of the active logs.

## How to find recovery information

This section contains guidance on locating and reporting information needed for recovery.

### Where recovery information resides

Information needed for recovery is contained in these locations:

- **SYSIBM.SYSCOPY**, a catalog table, contains information about full and incremental image copies. If concurrent updates were allowed when making the copy, the log RBA corresponds to the image copy start time; otherwise, it corresponds to the end time. The RECOVER utility uses the log RBA to look for log information after restoring the image copy. The SYSCOPY catalog table also contains information recorded by the COPYTOCOPY utility.

SYSCOPY also contains entries with the same kinds of log RBAs recorded by the utilities QUIESCE, REORG, LOAD, REBUILD INDEX, RECOVER TOCOPY, and RECOVER TOLOGPOINT. For a summary of the information contained in the DB2 catalog tables, see Appendix F of *DB2 SQL Reference*.

When the REORG utility is used, the time at which DB2 writes the log RBA to SYSIBM.SYSCOPY depends on the value of the SHRLEVEL parameter:

- For SHRLEVEL NONE, the log RBA is written at the end of the reload phase. If a failure occurs before the end of the reload phase, the RBA is not written to SYSCOPY.

If a failure occurs after the reload phase is complete (and thus, after the log RBA is written to SYSCOPY), the RBA is not backed out of SYSCOPY.

- For SHRLEVEL REFERENCE and SHRLEVEL CHANGE, the log RBA is written at the end of the switch phase.

If a failure occurs before the end of the switch phase, the RBA is not written to SYSCOPY.

If a failure occurs after the switch phase is complete (and thus, after the log RBA is written to SYSCOPY), the RBA is not backed out of SYSCOPY.

The log RBA is put in SYSCOPY whether the LOG option is YES or NO, or whether the UNLOAD PAUSE option is indicated.

When DSNDB01.DBD01, DSNDB01.SYSUTILX, and DSNDB06.SYSCOPY are quiesced or copied, a SYSCOPY record is created for each table space and any associated index that has the COPY YES attribute. For recovery reasons, the SYSCOPY records for these three objects are placed in the log.

- **SYSIBM.SYSLGRNX**, a directory table, contains records of the log RBA ranges used during each period of time that any recoverable page set is open for update. Those records speed recovery by limiting the scan of the log for changes that must be applied.

If you discard obsolete image copies, you should consider removing their records from SYSIBM.SYSCOPY and the obsolete log ranges from SYSIBM.SYSLGRNX. “Discarding SYSCOPY and SYSLGRNX records” on page 514 describes the process.

### Reporting recovery information

You can use the REPORT utility in planning for recovery. REPORT provides information necessary for recovering a page set. REPORT displays:

- Recovery information from the SYSIBM.SYSCOPY catalog table

- Log ranges of the table space from the SYSIBM.SYSLGRNX directory
- Archive log data sets from the bootstrap data set
- The names of all members of a table space set

You can also use REPORT to obtain recovery information about the catalog and directory.

Details about the REPORT utility and examples showing the results obtained when using the RECOVERY option are contained in Part 2 of *DB2 Utility Guide and Reference*.

## Preparing to recover to a prior point of consistency

The major steps in preparing to recover to a particular point-in-time are:

1. Release the data from any exception status.
2. Copy the data, taking appropriate precautions about concurrent activity.
3. Immediately after, establish a point when the data is consistent and no unit of work is changing it.

With that preparation, recovery to the point of consistency is as quick and simple as possible. DB2 begins recovery with the copy you made and reads the log only up to the point of consistency. At that point, there are no indoubt units of recovery to hinder restarting.

### Step 1: Resetting exception status

You can use the DISPLAY DATABASE RESTRICT command to determine whether the data is in an exception status. See Appendix C of *DB2 Utility Guide and Reference* for instructions on resetting those states.

For indexes that have been set to REBUILD-pending status at any time before the point of consistency, see “Recovering indexes on altered tables” on page 501.

### Step 2: Copying the data

You can copy the data and also establish a point of consistency for a list of objects, in one operation, by using the COPY utility with the option SHRLEVEL REFERENCE. That operation allows only read access to the data while it is copied. The data is consistent at the moment when copying starts and remains consistent until copying ends. The advantage of the method is that the data can be restarted at a point of consistency by restoring the copy only, with no need to read log records. The disadvantage is that updates cannot be made throughout the entire time that the data is being copied.

You can use the CONCURRENT option of the COPY utility to make a backup, with DFSMSdss concurrent copy, that is recorded in the DB2 catalog. For more information about using this option, see *DB2 Utility Guide and Reference*.

**Copying data while updates occur is not recommended.** However, to allow updates while the data is being copied, you can:

- Use the COPY utility with the option SHRLEVEL CHANGE.
- Use an offline program to copy the data, such as DSN1COPY, DFSMSHsm, or disk dump.

**If you allow updates while copying,** then step 3 is essential. With concurrent updates, the copy can include uncommitted changes. Those might be backed out after copying ends. Thus, the copy is not necessarily consistent data, and recovery

cannot rely on the copy only. Recovery requires reading the log up to a point of consistency, so you want to establish such a point as soon as possible.

### Step 3: Establishing a point of consistency

Use the QUIESCE utility also to establish a single point of consistency (a *quiesce point*) for one or more page sets. Typically, you name all the table spaces in a table space set that you want recovered to the same point-in-time to avoid referential integrity violations. Or you can use the QUIESCE utility with the TABLESPACESET keyword for RI-related tables. The following statement quiesces two table spaces in database DSN8D81A:

```
QUIESCE TABLESPACE DSN8D81A.DSN8S81E
        TABLESPACE DSN8D81A.DSN8S81D
```

QUIESCE writes changed pages from the page set to disk. The catalog table SYSIBM.SYSCOPY records the current RBA and the timestamp of the quiesce point. At that point, neither page set contains any uncommitted data. A row with ICTYPE Q is inserted into SYSCOPY for each table space quiesced. Page sets DSNDB06.SYSCOPY, DSNDB01.DBD01, and DSNDB01.SYSUTILX, are an exception: their information is written to the log. Indexes are quiesced automatically when you specify WRITE(YES) on the QUIESCE statement. A SYSIBM.SYSCOPY row with ICTYPE Q is inserted for indexes that have the COPY YES attribute.

QUIESCE allows concurrency with many other utilities; however, it does not allow concurrent updates until it has quiesced all specified page sets. Depending upon the amount of activity, that can take considerable time. Try to run QUIESCE when system activity is low.

Also, consider using the MODE(QUIESCE) option of the ARCHIVE LOG command when planning for offsite recovery. It creates a system-wide point of consistency, which can minimize the number of data inconsistencies when the archive log is used with the most current image copy during recovery. See “Archiving the log” on page 435 for more information about using the MODE(QUIESCE) option of the ARCHIVE LOG command.

## Preparing to recover the entire DB2 subsystem to a prior point-in-time

Under certain circumstances, you might want to reset the entire DB2 subsystem to a point of consistency. You can prepare a point of consistency by using the following procedure:

1. Display and resolve any indoubt units of recovery.
2. Use COPY to make image copies of all data, both user data and DB2 catalog and directory table spaces and optionally indexes. Copy SYSLGRNX and SYSCOPY last. Install job DSNTIJIC creates image copies of the DB2 catalog and directory table spaces. If you decide to copy your directory and catalog indexes, modify job DSNTIJIC to include those indexes. See Part 2 of *DB2 Installation Guide* for a description of job DSNTIJIC.

Alternatively, you can use an offline method to copy the data. In that case, stop DB2 first; that is, do step 3 before step 2. If you do not stop DB2 before copying, you might have trouble restarting after restoring the system. If you do a volume restore, verify that the restored data is cataloged in the integrated catalog facility catalog. Use the access method services LISTCAT command to get a listing of the integrated catalog.

3. Stop DB2 with the command STOP DB2 MODE (QUIESCE). DB2 does not actually stop until all currently executing programs have completed processing. Be sure to use MODE (QUIESCE); otherwise, I/O errors can occur when the steps listed in “Performing fall back to a prior shutdown point” on page 617 are used to restart DB2.
4. When DB2 has stopped, use access method services EXPORT to copy all BSDS and active log data sets. If you have dual BSDSs or dual active log data sets, export both copies of the BSDS and the logs.
5. Save all the data that has been copied or dumped, and protect it and the archive log data sets from damage.

## Preparing for disaster recovery

In the case of a total loss of a DB2 computing center, you can recover on another DB2 system at a recovery site. To do this, you must regularly back up the data sets and the log for recovery. As with all data recovery operations, the objectives of disaster recovery are to lose as little data, workload processing (updates), and time as possible.

You can provide shorter restart times after system failures by using the installation options LIMIT BACKOUT and BACKOUT DURATION. These options postpone the backout processing of long running URs during DB2 restart. See Part 2 of *DB2 Installation Guide* for the details on how to use these parameters.

### Data sharing

In a data sharing environment, you can use the LIGHT(YES) or LIGHT(NOINDOUBTS) parameter to quickly bring up a DB2 member to recover retained locks. Restart light is not recommended for a restart in place and is intended only for a cross-system restart for a system that does not have adequate capacity to sustain the DB2 IRLM pair. Restart light can be used for normal restart and recovery. See Chapter 5 of *DB2 Data Sharing: Planning and Administration* for more details.

For data sharing, you need to consider whether you want the DB2 group to use light mode at the recovery site. A light start might be desirable if you have configured only minimal resources at the remote site. If this is the case, you might run a subset of the members *permanently* at the remote site. The other members are restarted and then directly shutdown. The procedure for a light start at the remote site is:

1. Start the members that run *permanently* with the LIGHT(NO) option. This is the default.
2. Start other members in light mode. The members started in light mode use a smaller storage footprint. After their restart processing completes, they automatically shutdown. If ARM is in use, ARM does not automatically restart the members in light mode again.
3. Members started with LIGHT(NO) remain active and are available to run new work.

Several levels of preparation for disaster recovery exist:

- Prepare the recovery site to recover to a fixed point-in-time. For example, you could copy everything weekly with a DFSMSdss volume dump (logical) and manually send it to the recovery site, then restore the data there.

- For recovery through the last archive, copy and send the following objects to the recovery site as you produce them:
  - Image copies of all catalog, directory, and user page sets
  - Archive logs
  - Integrated catalog facility catalog EXPORT and list
  - BSDS lists

With this approach you can determine how often you want to make copies of essential recovery elements and send them to the recovery site.

After you establish your copy procedure and have it operating, you must prepare to recover your data at the recovery site. See “Remote site recovery from a disaster at the local site” on page 563 for step-by-step instructions on the disaster recovery process.

- Use the log capture exit to capture log data in real time and send it to the recovery site. See “Reading log records with the log capture exit routine” on page 1138 and “Log capture routines” on page 1105.

### System-wide points of consistency

In any disaster recovery scenario, system-wide points of consistency are necessary for maintaining data integrity and preventing a loss of data. A direct relationship exists between the frequency at which you make and send copies to the recovery site and the amount of data that you can potentially lose.

Figure 57 is an overview of the process of preparing to bring DB2 up at a recovery site.

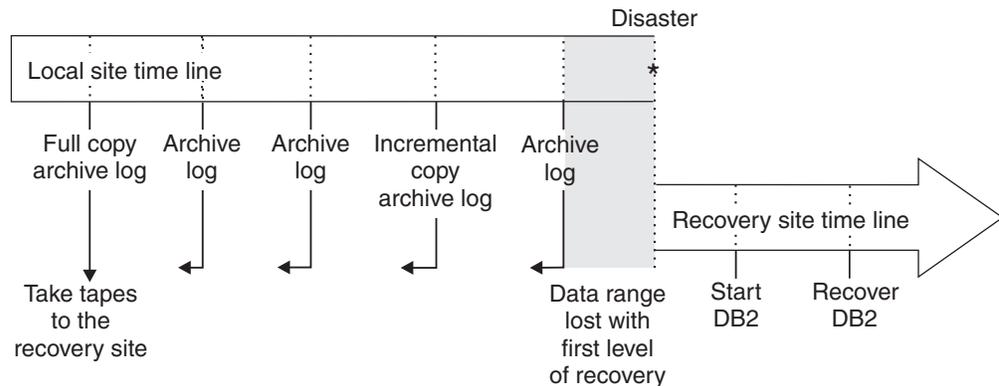

Figure 57. Preparing for disaster recovery. The information you need to recover is contained in the copies of data (including the DB2 catalog and directory) and the archive log data sets.

### Essential disaster recovery elements

A list of essential disaster recovery elements and the steps you need to take to create them follows. You must determine how often to make copies and send them to the recovery site.

- Image copies
  1. Make copies of your data sets and DB2 catalogs and directories.
 

Use the COPY utility to make copies for the local subsystem and additional copies for disaster recovery. You can also use the COPYTOCOPY utility to make additional image copies from the primary image copy made by the COPY utility. Install your local subsystem with the LOCALSITE option of the SITE TYPE field on installation panel DSNTIPO. Use the RECOVERYDDN

option when you run COPY to make additional copies for disaster recovery. You can use those copies on any DB2 subsystem that you have installed using the RECOVERYSITE option.<sup>5</sup>

For information about making multiple image copies, see COPY and COPYTOCOPY in Part 2 of *DB2 Utility Guide and Reference*. Do not produce the copies by invoking COPY twice.

2. Catalog the image copies if you want to track them.
3. Create a QMF report or use SPUFI to issue a SELECT statement to list the contents of SYSCOPY.
4. Send the image copies and report to the recovery site.
5. Record this activity at the recovery site when the image copies and the report are received.

All table spaces should have valid image copies. Indexes can have valid image copies or they can be rebuilt from the table spaces.

- Archive logs

1. Make copies of the archive logs for the recovery site.
  - a. Use the ARCHIVE LOG command to archive all current DB2 active log data sets. For more ARCHIVE LOG command information see “Archiving the log” on page 435.

**Recommendation:** When using dual logging, keep both copies of the archive log at the local site in case the first copy becomes unreadable. If the first copy is unreadable, DB2 requests the second copy. If the second copy is not available, the read fails.

However, if you take precautions when using dual logging, such as making another copy of the first archive log, you can send the second copy to the recovery site. If recovery is necessary at the recovery site, specify YES for the READ COPY2 ARCHIVE field on installation panel DSNTIPO. Using this option causes DB2 to request the second archive log first.

- b. Catalog the archive logs if you want to track them.

You will probably need some way to track the volume serial numbers and data set names. One way of doing this is to catalog the archive logs to create a record of the necessary information. You could also create your own tracking method and do it manually.
2. Use the print log map utility to create a BSDS report.
3. Send the archive copy, the BSDS report, and any additional information about the archive log to the recovery site.
4. Record this activity at the recovery site when the archive copy and the report are received.

- Consistent system time

1. Choose a consistent system time for all DB2 subsystems.

DB2 utilities, including the RECOVER utility, require system clocks that are consistent across all members of a DB2 data-sharing group. To prevent inconsistencies during data recovery, ensure that all system times are consistent with the system time at the failing site.
2. Ensure that the system clock remains consistent.

---

5. You can also use these copies on a subsystem installed with the LOCALSITE option if you run RECOVER with the RECOVERYSITE option. Or you can use copies prepared for the local site on a recovery site, if you run RECOVER with the option LOCALSITE.

Once you establish a consistent system time, do not alter the system clock. Any manual change in the system time (forward or backward) can affect how DB2 writes and processes image copies and log records.

- Integrated catalog facility catalog backups
  1. Back up all DB2-related integrated catalog facility catalogs with the VSAM EXPORT command on a daily basis.
  2. Synchronize the backups with the cataloging of image copies and archives.
  3. Use the VSAM LISTCAT command to create a list of the DB2 entries.
  4. Send the EXPORT backup and list to the recovery site.
  5. Record this activity at the recovery site when the EXPORT backup and list are received.
- DB2 libraries
  1. Back up DB2 libraries to tape when they are changed. Include the SMP/E, load, distribution, and target libraries, as well as the most recent user applications and DBRMs.
  2. Back up the DSNTIJUZ job that builds the ZPARM and DECP modules.
  3. Back up the data set allocations for the BSDS, logs, directory, and catalogs.
  4. Document your backups.
  5. Send backups and corresponding documentation to the recovery site.
  6. Record activity at the recovery site when the library backup and documentation are received.

For disaster recovery to be successful, all copies and reports must be updated and sent to the recovery site regularly. Data will be up to date through the last archive sent. For disaster recovery start up procedures, see “Remote site recovery from a disaster at the local site” on page 563.

## Ensuring more effective recovery from inconsistency

The DB2 RECOVER utility is often the quickest and easiest method of resolving data inconsistency problems. However, these problems can involve data that the RECOVER utility needs to use, such as the recovery log or image copy data sets. If the data needed by the RECOVER utility is damaged or unavailable, you might have to resolve the problem manually.

### Actions to take

To aid in successful recovery of inconsistent data:

- **During the installation of, or migration to, Version 8, make a full image copy of the DB2 directory and catalog using installation job DSNTIJIC.**

See Part 2 of *DB2 Installation Guide* for DSNTIJIC information. If you did not do this during installation or migration, use the COPY utility, described in Part 2 of *DB2 Utility Guide and Reference*, to make a full image copy of the DB2 catalog and directory. If you do not do this and you subsequently have a problem with inconsistent data in the DB2 catalog or directory, you will not be able to use the RECOVER utility to resolve the problem.
- **Periodically make an image copy of the catalog, directory, and user databases.**

This minimizes the time the RECOVER utility requires to perform recovery. In addition, this increases the probability that the necessary archive log data sets will still be available. You should keep *two* copies of each level of image copy data set. This reduces the risk involved if one image copy data set is lost or damaged. See Part 2 of *DB2 Utility Guide and Reference* for more information about using the COPY utility.

- **Use dual logging for your active log, archive log, and bootstrap data sets.**

This increases the probability that you can recover from unexpected problems. It is especially useful in resolving data inconsistency problems. See “Establishing the logging environment” on page 429 for related dual logging information.

- **Before using RECOVER, rename your data sets.**

If the image copy or log data sets are damaged, you can compound your problem by using the RECOVER utility. Therefore, before using RECOVER, rename your data sets by using one of the following methods:

- rename the data sets that contain the page sets you want to recover, or
- copy your data sets using DSN1COPY, or
- for user-defined data sets, use access method services to define a new data set with the original name.

The RECOVER utility applies log records to the new data set with the old name. Then, if a problem occurs during RECOVER utility processing, you will have a copy (under a different name) of the data set you want to recover.

- **Keep back-level image copy data sets.**

If you make an image copy of a page set containing inconsistent data, the RECOVER utility cannot resolve the data inconsistency problem. However, you can use RECOVER TOCOPY or TOLOGPOINT to resolve the inconsistency if you have an older image copy of the page set that was taken before the problem occurred. You can also resolve the inconsistency problem by using a point-in-time recovery to avoid using the most recent image copy.

- **Maintain consistency between related objects.**

A referential structure is a set of tables including indexes and their relationships. It must include at least one table, and for every table in the set, include all of the relationships in which the table participates, as well as all the tables to which it is related. To help maintain referential consistency, keep the number of table spaces in a table space set to a minimum, and avoid tables of different referential structures in the same table space. The TABLESPACESET option of the REPORT utility reports all members of a table space set defined by referential constraints.

A referential structure must be kept consistent with respect to point-in-time recovery. Use the QUIESCE utility to establish a point of consistency for a table space set, to which the table space set can later be recovered without introducing referential constraint violations.

A base table space must be kept consistent with its associated LOB table spaces with respect to point-in-time recovery. Use the TABLESPACESET option of the REPORT utility to find all LOB table spaces associated with a base table space. Use the QUIESCE utility to establish a point of consistency, for a table space set, to which the table space set can later be recovered.

## **Actions to avoid**

- **Do not discard archive logs you might need.**

The RECOVER utility might need an archive log to recover from an inconsistent data problem. If you have discarded it, you cannot use the RECOVER utility and must resolve the problem manually. For information about determining when you can discard archive logs, see “Discarding archive log records” on page 443.

- **Do not make an image copy of a page set that contains inconsistent data.**

If you use the COPY utility to make an image copy of a page set containing inconsistent data, the RECOVER utility cannot recover a problem involving that page set unless you have an older image copy of that page set taken before the problem occurred. You can run DSN1COPY with the CHECK option to determine whether intra-page data inconsistency problems exist on page sets

before making image copies of them. If you are taking a copy of a catalog or directory page set, you can run DSN1CHKR which verifies the integrity of the links, and the CHECK DATA utility which checks the DB2 catalog (DSNDB06). For information, see *DB2 Utility Guide and Reference*.

- **Do not use the TERM UTILITY command on utility jobs you want to restart.**

If an error occurs while a utility is running, the data on which the utility was operating might continue to be written beyond the commit point. If the utility is restarted later, processing resumes at the commit point or at the beginning of the current phase, depending on the restart parameter that was specified. If the utility stops while it has exclusive access to data, other applications cannot access that data. In this case, you might want to issue the TERM UTILITY command to terminate the utility and make the data available to other applications. However, use the TERM UTILITY command only if you cannot restart or do not need to restart the utility job.

When you issue the TERM UTILITY command, two different situations can occur:

- If the utility is active, it terminates at its next commit point.
- If the utility is stopped, it terminates immediately.

If you use the TERM UTILITY command to terminate a utility, the objects on which the utility was operating are left in an indeterminate state. Often, the same utility job cannot be rerun. The specific considerations vary for each utility, depending on the phase in process when you issue the command. For details, see Part 2 of *DB2 Utility Guide and Reference*.

## Running the RECOVER utility in parallel

You can schedule jobs with the RECOVER utility in two ways:

- Use the PARALLEL keyword on the RECOVER utility to support the recovery of a list of objects in parallel. For those objects in the list that can be processed independently, multiple subtasks are created to restore the image copies for the objects. The parallel function can be used for either disk or tape.

If an image copy on tape was taken at the tablespace level and not on partition or dataset level, the PARALLEL keyword cannot enable RECOVER utility on different parts (*RECOVER TABLESPACE name DSNUM 1 TABLESPACE name DSNUM 2 etc.*) to restore the parts in parallel. RECOVER must read the appropriate part of the dataset for every DSNUM specification. This means that for a tablespace level copy on tape, the tape is always read from the beginning. You can also refer to the PARALLEL keyword description in *Utility Guide and Reference*. It is recommended for image copies to tape, that a partitioned tablespace should be copied at the partition level and if practical, to different tape stacks. You can use LISTDEF with PARTLEVEL to simplify your work.

When you use one utility statement to recover indexes and table spaces, the logs for all indexes and table spaces are processed in one pass. This approach results in a significant performance advantage, especially when the required archive log data is on tape or the fast log apply function is enabled, or both of these conditions occur.

This parallel log processing for fast log apply is not dependent whether you specify *RECOVER TABLESPACE name DSNUM 1 TABLESPACE name DSNUM 2 etc.* or only *RECOVER TABLESPACE name*, because the log apply is always done at the partition level. You should also note that if you have copies at the partition level, you cannot specify *RECOVER TABLESPACE dbname.tsname*, you must specify *RECOVER TABLESPACE dbname.tsname DSNUM 1 TABLESPACE*

*dbname.tsname DSNUM 2 etc.* (refer also to message DSNU512I). You can simplify this specification by using LISTDEF with PARTLEVEL if all parts must be recovered.

- Schedule concurrent RECOVER jobs that process different partitions. The degree of parallelism in this case is limited by contention for both the image copies and the required log data.

Log data is read by concurrent jobs as follows:

- Active logs and archive logs are read entirely in parallel.
- A data set controlled by DFSMSshm is first recalled. It then resides on disk and is read in parallel.

## Using fast log apply during RECOVER

The RECOVER utility automatically uses the fast log apply process during the LOGAPPLY phase if fast log apply has been enabled on the DB2 subsystem. For detailed information about defining storage for the sort used in fast log apply processing, see the Log Apply Storage field on panel DSNTIPL in *DB2 Installation Guide*.

## Reading the log without RECOVER

The DATA CAPTURE(CHANGES) clause of the SQL statements CREATE TABLE and ALTER TABLE captures all SQL data changes made to the table on the DB2 log. The captured data can be propagated to an IMS subsystem or remain in the DB2 log. This allows the creation of duplicate data for recovery purposes. Although SQL changes to tables defined for data capture are supported from any subsystem, propagation is permitted only to an IMS subsystem. For further information see Appendix C, “Reading log records,” on page 1115.

Data written to the log for propagation to IMS uses an expanded format that is much longer than the DB2 internal format. Using DATA CAPTURE(CHANGES) can greatly increase the size of your log.

---

## Copying page sets and data sets

You can use the COPY utility to copy data from a page set to an z/OS sequential data set on disk or tape. It makes a full or incremental image copy, as you choose, and it can be used to make copies that will be used for local or offsite recovery operations. Use the COPYTOCOPY utility to make additional image copies from a primary image copy that you made with the COPY utility.

A full image copy is required for indexes. For information about copying indexes, see “Considerations for recovering indexes” on page 477.

You can use the CONCURRENT option of the COPY utility to make a copy, with DFSMSdss concurrent copy, that is recorded in the DB2 catalog. For more information about using this option, see *DB2 Utility Guide and Reference*.

Use the MERGECOPY utility to merge several image copies. MERGECOPY does not apply to indexes.

The CHANGELIMIT option of the COPY utility causes DB2 to make an image copy automatically when a table space has changed past a default limit or a limit you specify. DB2 determines whether to make a full or incremental image copy. DB2 makes an incremental image copy if the percent of changed pages is greater than the low CHANGELIMIT value and less than the high CHANGELIMIT value.

DB2 makes a full image copy if the percent of changed pages is greater than or equal to the high CHANGELIMIT value. The CHANGELIMIT option does not apply to indexes.

If you want DB2 to recommend what image copies should be made but not make the image copies, use the CHANGELIMIT and REPORTONLY options of the COPY utility.

If you specify the parameter DSNUM ALL with CHANGELIMIT and REPORTONLY, DB2 reports information for each partition of a partitioned table space or each piece of a nonpartitioned table space.

You can add conditional code to your jobs so that an incremental or full image copy, or some other step is performed depending on how much the table space has changed. When you use the COPY utility with the CHANGELIMIT option to display image copy statistics, the COPY utility uses the following return codes to indicate the degree that a table space or list of table spaces has changed:

**Code    Meaning**

- |   |                                                                                                                                                                                    |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Successful and no CHANGELIMIT value is met. No image copy is recommended or taken.                                                                                                 |
| 2 | Successful and the percent of changed pages is greater than the low CHANGELIMIT value and less than the high CHANGELIMIT value. An incremental image copy is recommended or taken. |
| 3 | Successful and the percent of changed pages is greater than or equal to the high CHANGELIMIT value. A full image copy is recommended or taken.                                     |

When you use generation data groups (GDGs) and need to make an incremental image copy, there are new steps you can take to prevent an empty image copy output data set from being created if no pages have been changed. You can perform one of the following:

1. Make a copy of your image copy step, but add the REPORTONLY and CHANGELIMIT options to the new COPY utility statement. The REPORTONLY keyword specifies that you only want image copy information displayed. Change the SYSCOPY DD card to DD DUMMY so that no output data set is allocated. Run this step to visually determine the change status of your table space.
2. Add step 1 before your existing image copy step, and add a JCL conditional statement to examine the return code and execute the image copy step if the table space changes meet either of the CHANGELIMIT values.

You can also use the COPY utility with the CHANGELIMIT option to determine whether any space map pages are broken, or to identify any other problems that might prevent an image copy from being taken, such as the object being in recover pending status. You need to correct these problems before you run the image copy job.

You can also make a full image copy when you run the LOAD or REORG utility. This technique is better than running the COPY utility after the LOAD or REORG utility because it decreases the time that your table spaces are unavailable. However, only the COPY utility makes image copies of indexes.

**Related information:** For guidance in using COPY and MERGECOPY and making image copies during LOAD and REORG, see Part 2 of *DB2 Utility Guide and Reference*.

## Backing up with DFSMS

The concurrent copy function of Data Facility Storage Management Subsystem (DFSMS) can copy a data set concurrently with access by other processes, without significant impact on application performance. The function requires the 3990 Model 3 controller with the extended platform.

There are two ways to use the concurrent copy function of Data Facility Storage Management Subsystem (DFSMS):

- Run the COPY utility with the CONCURRENT option. DB2 records the resulting image copies in SYSIBM.SYSCOPY. To recover with these DFSMS copies, you can run the RECOVER utility to restore those image copies and apply the necessary log records to them to complete recovery.
- Make copies using DFSMS outside of DB2's control. To recover with these copies, you must manually restore the data sets, and then run RECOVER with the LOGONLY option to apply the necessary log records.

## Backing up with RVA storage control or Enterprise Storage Server

IBM's RAMAC<sup>®</sup> Virtual Array (RVA) storage control with the peer-to-peer remote copy (PPRC) function or Enterprise Storage Server<sup>®</sup> provides a faster method of recovering DB2 subsystems at a remote site in the event of a disaster at the local site. You can use RVAs, PPRC, and the RVA fast copy function, SnapShot, to create entire DB2 subsystem backups to a point-in-time on a *hot stand-by* remote site without interruption of any application process. Another option is to use the Enterprise Storage Server FlashCopy<sup>®</sup> function to create point-in-time backups of entire DB2 subsystems.

To use RVA SnapShot or Enterprise Storage Server FlashCopy for a DB2 backup requires a method of suspending all update activity for a DB2 subsystem to make a remote copy of the entire subsystem without quiescing the update activity at the primary site. Use the SUSPEND option on the SET LOG command to suspend all logging activity at the primary site which also prevents any database updates.

After the remote copy has been created, use the RESUME option on the SET LOG command to return to normal logging activities. See the *DB2 Command Reference* for more details on using the SET LOG command.

For more information about RVA, see *IBM RAMAC Virtual Array*. For more information about using PPRC, see *RAMAC Virtual Array: Implementing Peer-to-Peer Remote Copy*. For more information about Enterprise Storage Server and the FlashCopy function, see *Enterprise Storage Server Introduction and Planning*.

---

## Recovering page sets and data sets

You can recover objects in either of the following ways:

- If you made backup copies of table spaces using the COPY utility, the COPYTOCOPY utility, or the inline copy feature of the LOAD or REORG utility, use the RECOVER utility to restore the objects to the current or a previous state. Backup copies of indexes are made using the DB2 COPY utility.

- If you made backup copies using a method outside of DB2's control, such as with DSN1COPY or the DFSMSdss concurrent copy function, use the same method to restore the objects to a prior point-in-time. Then, if you wish to restore the objects to currency, run the RECOVER utility with the LOGONLY option.

The RECOVER utility performs these actions:

- Restores the most current full image copy
- Applies changes recorded in later incremental image copies of table spaces, if applicable, and applies later changes from the archive or active log

RECOVER can act on:

- A table space, or list of table spaces
- An index, or list of indexes
- A specific partition or data set within a table space
- A specific partition within an index space
- A mixed list of table spaces, indexes, partitions, and data sets
- A single page
- A page range within a table space that DB2 finds in error
- The catalog and directory

Typically, RECOVER restores an object to its current state by applying all image copies and log records. It can also restore to a prior state, which is one of the following points in time:

- A specified point on the log (use the TOLOGPOINT keyword)
- A particular image copy (use the TOCOPY, TOLASTCOPY, or TOLASTFULLCOPY keywords)

The RECOVER utility can use image copies for the local site or the recovery site, regardless of where you invoke the utility. The RECOVER utility locates all full and incremental image copies.

The RECOVER utility first attempts to use the primary image copy data set. If an error is encountered (allocation, open, or I/O), RECOVER attempts to use the backup image copy. If DB2 encounters an error in the backup image copy or no backup image copy exists, RECOVER falls back to an earlier full copy and attempts to apply incremental copies and log records. If an earlier full copy is not available, RECOVER attempts to apply log records only.

For guidance in using RECOVER and REBUILD INDEX, see Part 2 of *DB2 Utility Guide and Reference*.

Not every recovery operation requires RECOVER; see also

“Recovering error ranges for a work file table space” on page 497

“Recovering the work file database” on page 497

“Recovering data to a prior point of consistency” on page 499

**Important:** Be very careful when using disk dump and restore for recovering a data set. Disk dump and restore can make one data set inconsistent with DB2 subsystem tables in some other data set. Use disk dump and restore only to restore the entire subsystem to a previous point of consistency, and prepare that point as described in the alternative in step 2 under “Preparing to recover to a prior point of consistency” on page 485.

## Recovering the work file database

You *cannot* use RECOVER with the work file database (called DSNDB07, except in a data sharing environment). That database is used for temporary space for certain SQL operations, such as join and ORDER BY. If DSNDB01.DBD01 is stopped or otherwise inaccessible when DB2 is started, then the descriptor for the work file database is not loaded into main storage and the work file database is not allocated. In order to recover from this condition after DSNDB01.DBD01 has been made available, it is necessary to stop and then start the work file database again.

## Problems with the user-defined work file data set

If you have a problem on a volume of a user-defined data set for the work file database, then:

1. Issue the following DB2 command:  
-STOP DATABASE (DSNDB07)
2. Use the DELETE and DEFINE functions of access method services to redefine a user work file on a different volume and reconnect it to DB2.
3. Issue the following DB2 command:  
-START DATABASE (DSNDB07)

## Problems with DB2-managed work file data sets

If you have a problem on a volume in a DB2 storage group for the work file database, such as a system I/O problem, then:

1. Enter the following SQL statement to remove the problem volume from the DB2 storage group:  

```
ALTER STOGROUP stogroup-name
  REMOVE VOLUMES (xxxxxx);
```
2. Issue the following DB2 command:  
-STOP DATABASE (DSNDB07)
3. Enter the following SQL statement to drop the table space with the problem:  

```
DROP TABLESPACE DSNDB07.tsname;
```
4. Re-create the table space. You can use the same storage group, because the problem volume has been removed, or you can use an alternate.  

```
CREATE TABLESPACE tsname
  IN DSNDB07
  USING STOGROUP stogroup-name;
```
5. Issue the following command:  
-START DATABASE (DSNDB07)

## Recovering error ranges for a work file table space

Page error ranges operate for work file table spaces in the same way as for other DB2 table spaces, except for the process of recovering them. Error ranges in a work file table space cannot be reset by RECOVER ERROR RANGE. Instead, perform the following procedure:

1. Stop the work file table space.
2. Correct the disk error, using the ICKDSF service utility or access method services to delete and redefine the data set.
3. Start the work file table space. When the work file table space is started, DB2 automatically resets the error range.

Also, DB2 always resets any error ranges when the work file table space is initialized, regardless of whether the disk error has really been corrected. Work file table spaces are initialized when:

- The work file table space is stopped and then started
- The work file database is stopped and then started, and the work file table space was not previously stopped
- DB2 is started and the work file table space was not previously stopped

If the error range is reset while the disk error still exists, and if DB2 has an I/O error when using the work file table space again, then DB2 sets the error range again.

---

## Recovering the catalog and directory

Catalog and directory objects must be recovered in a particular order. Because the recovery of some catalog and directory objects depends on information that is derived from other catalog and directory objects, you must recover these objects in separate RECOVER utility control statements. You can, however, use the same RECOVER control statement to recover a catalog or directory table space along with its corresponding IBM-defined indexes. After these logically dependent objects are restored to an undamaged state, you can recover the remaining catalog and directory objects in a single RECOVER utility control statement. These restrictions apply regardless of the type of recovery you perform on the catalog. See the description of RECOVER in Part 2 of *DB2 Utility Guide and Reference* for more information about the RECOVER utility and for details about the order in which you must recover objects in the catalog and directory.

You can use the REPORT utility to report on recovery information about the catalog and directory.

To avoid restart processing of any page sets before attempts are made to recover any of the members of the list of catalog and directory objects, use the DEFER option when installing DB2 followed by the option ALL. For more information about DEFER, see “Deferring restart processing” on page 454.

**Point in time recovery:** Recovering the DB2 catalog and directory to a prior point-in-time is strongly discouraged. For more information about recovering the catalog and directory to a prior point-in-time see “Considerations for recovering to a prior point of consistency” on page 499.

**Recovery after a conditional restart of DB2:** After a DB2 conditional restart in which a log record range is specified, such as with a cold start, a portion of the DB2 recovery log is no longer available. If the unavailable portion includes information that is needed for internal DB2 processing, an attempt to use the RECOVER utility to restore directory table spaces DSNDBD01 or SYSUTILX, or catalog table space SYSCOPY, will fail with abend 00E40119. Instead of using the RECOVER utility, use this procedure to recover those table spaces and their indexes:

1. Run DSN1COPY to recover the table spaces from an image copy.
2. Run the RECOVER utility with the LOGONLY option to apply updates from the log records to the recovered table spaces.
3. Rebuild the indexes.
4. Make a full image copy of the table spaces and optionally the indexes to establish a new recovery point.

---

## Recovering data to a prior point of consistency

You can restore data to a state it was in at a prior point-in-time if you back up that data appropriately. To restore data to a prior point of consistency, use the methods described in the following sections:

- “Using RECOVER to restore data to a previous point-in-time” on page 504.
- “Restoring data by using DSN1COPY” on page 508
- “Backing up and restoring data with non-DB2 dump and restore” on page 508

You cannot recover to some points in time. See Part 2 of *DB2 Utility Guide and Reference* for more information about these restrictions.

The following terms are used throughout this discussion:

Term	Meaning
------	---------

DBID	Database identifier
------	---------------------

OBID	Data object identifier
------	------------------------

PSID	Table space identifier
------	------------------------

## Considerations for recovering to a prior point of consistency

When you restore data in any of the following DB2 objects to a prior point of consistency, be aware of the considerations this section describes:

- Table spaces
- Tables with identity columns
- Indexes
- Catalog and directory tables

### Recovering table spaces

When you recover table spaces to a prior point of consistency, you need to consider how partitioned table spaces, segmented table spaces, LOB tables spaces, and table space sets can restrict recovery.

**Recovering partitioned table spaces:** You cannot recover a table space to a point-in-time prior to rotating partitions. After you rotate a partition, you cannot recover the contents of that partition.

If you recover to a point-in-time prior to the addition of a partition, DB2 cannot roll back the definition of the partition. In such a recovery, DB2 clears all data from the partition, and the partition remains part of the database.

If you recover a table space partition to a point-in-time before the table space partitions were rebalanced, you must include all partitions that are affected by that rebalance in your recovery list.

**Recovering segmented table spaces:** When data is restored to a prior point-in-time on a segmented table space, information in the DBD for the table space might not match the restored table space.

If you use the DB2 RECOVER utility, the database descriptor (DBD) is updated dynamically to match the restored table space on the next non-index access of the table. The table space must be in write access mode.

If you use a method outside of DB2's control, such as DSN1COPY to restore a table space to a prior point-in-time, run the REPAIR utility with the LEVELID option to force DB2 to accept the down-level data. Then run the REORG utility on the table space to correct the DBD.

**Recovering LOB table spaces:** When you recover tables with LOB columns, recover the entire set of objects, including the base table space, the LOB table spaces, and index spaces for the auxiliary indexes.

If you use the RECOVER utility to recover a LOB table space to a prior point of consistency, RECOVER might place the table space in a pending state. For more details about the particular pending states that the RECOVER utility sets, see "Using RECOVER to restore data to a previous point-in-time" on page 504.

**Recovering table space sets:** If you restore a page set to a prior state, restore all related tables and indexes to the same point to avoid inconsistencies. The table spaces that contain referentially related tables are called a *table space set*. Similarly, a LOB table space and its associated base table space are also part of a table space set. For example, in the DB2 sample application, a column in the EMPLOYEE table identifies the department to which each employee belongs. The departments are described by records in the DEPARTMENT table, which is in a different table space. If only that table space is restored to a prior state, a row in the unrestored EMPLOYEE table might then identify a department that does not exist in the restored DEPARTMENT table.

You can use the REPORT TABLESPACESET utility to determine all the page sets that belong to a single table space set and then restore those page sets that are related. However, if page sets are logically related outside of DB2 in application programs, you are responsible for identifying all the page sets on your own.

To determine a valid quiesce point for the table space set, use the procedure for determining a RECOVER TOLOGPOINT value. See RECOVER in Part 2 of *DB2 Utility Guide and Reference* for more information.

## Recovering tables that contain identity columns

When you recover a table that contains an identity column, consider the point-in-time to which you recover. Your recovery procedure can depend on whether that identity column existed, or was not yet defined at the point-in-time to which you recover. The following considerations apply for each of these two cases:

- If you recover to a point-in-time at which the identity column existed, you might create a gap in the sequence of identity column values. When you insert a row after this recovery, DB2 produces an identity value for the row as if all previously added rows still exist.

**Example:** Assume that at time T1 an identity column that increments by 1 contains the identity column values 1 through 100. At T2, the same identity column contains the values 1 through 1000. Now, assume that the table space is recovered back to time T1. When you insert a row after the recovery, DB2 generates an identity value of 1001. This value leaves a gap from 101 to 1000 in the values of the identity column.

To prevent a gap in identity column values, use the following ALTER TABLE statement to modify the attributes of the identity column before you insert rows after the recovery:

```
ALTER TABLE table-name
ALTER COLUMN identity-column-name
RESTART WITH next-identity-value
```

**Tip:** To determine the last value in an identity column, issue the MAX column function for ascending sequences of identity column values, or the MIN column function for descending sequences of identity column values. This method works only if the identity column does not use CYCLE.

- If you recover to a point-in-time at which the identity column was not yet defined, that identity column remains part of the table. The resulting identity column no longer contains values.

To regenerate missing identity column values, perform the following steps:

1. Choose a starting value for the identity column with the following ALTER TABLE statement:

```
ALTER TABLE table-name
ALTER COLUMN identity-column-name
RESTART WITH starting-identity-value
```

2. Run the REORG utility to regenerate lost sequence values.

If you do not choose a starting value, the REORG utility generates a sequence of identity column values that starts with the next value that DB2 would have assigned before the recovery.

A table space that contains an identity column is set to REORG-pending (REORP) status if you recover the table space to a point-in-time before the identity column was defined. To access the recovered table, you need to remove this status. See “Ensuring consistency” on page 506 for information about how to remove REORP status from a table space.

## Recovering indexes

When you recover indexes to a prior point of consistency, the following general rules apply:

- If an image copies exists for an indexes, use the RECOVER utility.
- If indexes do not have image copies, you must use REBUILD INDEX to re-create the indexes after the data has been recovered.

More specifically, you must consider how indexes on altered tables and indexes on tables in partitioned table spaces can restrict recovery.

**Recovering indexes on altered tables:** You cannot use the RECOVER utility to recover an index to a point-in-time that existed before you issued any of the following ALTER statements on that index. These statements place the index in REBUILD-pending (RBDP) status:

- ALTER INDEX PADDED
- ALTER INDEX NOT PADDED
- ALTER TABLE SET DATA TYPE on an indexed column for numeric data type changes
- ALTER TABLE ADD COLUMN and ALTER INDEX ADD COLUMN that are not issued in the same commit scope

When you recover a table space to prior point-in-time and the table space uses indexes that were set to RBDP at any time after the recovery point, you must use the REBUILD INDEX utility to rebuild these indexes.

For more information about the RECOVER and REBUILD INDEX utilities, see Part 2 of *DB2 Utility Guide and Reference*.

The output from the DISPLAY DATABASE RESTRICT command shows the restrictive states for index spaces. See *DB2 Command Reference* for descriptions of status codes displayed by the DISPLAY DATABASE command.

**Recovering indexes on tables in partitioned table spaces:** The partitioning of secondary indexes allows you to copy and recover at the entire index or individual partition level. However, if you use COPY at the partition level, you need to use RECOVER at the partition level also. If you use COPY at the partition level and then try to RECOVER the index, an error occurs. If COPY is performed at the index level, you can use RECOVER at either the index level or the partition level.

You cannot recover an index space to a point-in-time prior to rotating partitions. After you rotate a partition, you cannot recover the contents of that partition to a point-in-time before the rotation.

If you recover to a point-in-time prior to the addition of a partition, DB2 cannot roll back the addition of that partition. In such a recovery, DB2 clears all data from the partition, and it remains part of the database.

### Recovering catalog and directory tables

Recovering catalog and directory tables to a prior point-in-time is strongly discouraged for the following reasons:

- You must recover all table spaces that are associated with the catalog tables that you recover to the same point-in-time. For example, if you recover any table space in the DB2 catalog (DSNDB06) and directory (DSNDB01), all table spaces (except SYSUTILX) must be recovered.  
The catalog and directory contain definitions of all databases. When databases DSNDB01 and DSNDB06 are restored to a prior point, information about later definitions, authorizations, binds, and recoveries is lost. If you restore the catalog and directory, you might have to restore user databases; if you restore user databases, you might have to restore the catalog and directory.
- You might create catalog definitions that are inconsistent with your data. These catalog and data inconsistencies are usually the result of one of the following actions:
  - A catalog table space was restored.
  - SYSSEQ and SYSSEQ2 were recovered to a prior point-in-time.
  - The definition of a table, table space, index, or index space was changed after the data was last backed up.
- You can cause problems for user table spaces or index spaces that have been reorganized with FASTSWITCH.
- You can cause a populated VSAM data set that was defined with DEFINE NO option to revert back to the undefined state. To avoid errors, you must delete the existing VSAM data sets before the table space or index can be accessed.

Avoiding point-in-time recovery of the catalog is easier than attempting to correct the inconsistencies that the recovery causes. If you choose to recover catalog and directory tables to a prior point-in-time, you need to first shut down the DB2 system cleanly and then restart in ACCESS(MAINT) mode before the recovery. If you recover catalog tables to a prior point-in-time, you must perform the following actions to make catalog definitions consistent with your data.

1. Run the DSN1PRNT utility with the PARM=(FORMAT, NODATA) option on all data sets that might contain user table spaces. The NODATA option suppresses all row data, which reduces the output volume that you receive. Data sets that contain user tables are of the following form, where *y* can be either I or J:  
*catname.DSNDBC.dbname.tsname.y0001.A00n*

2. Execute the following SELECT statements to find a list of table space and table definitions in the DB2 catalog:

**Product-sensitive Programming Interface**

```
SELECT NAME, DBID, PSID FROM SYSIBM.SYSTABLESPACE;  
SELECT NAME, TSNAME, DBID, OBID FROM SYSIBM.SYSTABLES;
```

**End of Product-sensitive Programming Interface**

3. For each table space name in the catalog, look for a data set with a corresponding name. If a data set exists, take the following additional actions:
  - a. Find the field HPGOBID in the header page section of the DSN1PRNT output. This field contains the DBID and PSID for the table space. See if the corresponding table space name in the DB2 catalog has the same DBID and PSID.
  - b. If the DBID and PSID do not match, execute DROP TABLESPACE and CREATE TABLESPACE to replace the incorrect table space entry in the DB2 catalog with a new entry. Be sure to make the new table space definition exactly like the old one. If the table space is segmented, SEGSIZE must be identical for the old and new definitions.

A LOB table space can be dropped only if it is empty (that is, it does not contain auxiliary tables). If a LOB table space is not empty, you must first drop the auxiliary table before you drop the LOB table space. To drop auxiliary tables, you can perform one of the following actions:

    - Drop the base table.
    - Delete all rows that reference LOBs from the base table, and then drop the auxiliary table.
  - c. Find the PGSOBD fields in the data page sections of the DSN1PRNT output. These fields contain the OBIDs for the tables in the table space. For each OBID that you find in the DSN1PRNT output, search the DB2 catalog for a table definition with the same OBID.
  - d. If any of the OBIDs in the table space do not have matching table definitions, examine the DSN1PRNT output to determine the structure of the tables that are associated with these OBIDs. If you find a table whose structure matches a definition in the catalog, but the OBIDs differ, proceed to the next step. The OBIDXLAT option of DSN1COPY corrects the mismatch. If you find a table for which no table definition exists in the catalog, re-create the table definition using the CREATE TABLE statement. To re-create a table definition for a table that has had columns added, first use the **original** CREATE TABLE statement, and then use ALTER TABLE to add columns, which makes the table definition match the current structure of the table.
  - e. Use the utility DSN1COPY with the OBIDXLAT option to copy the existing data to the new tables in the table space, and translate the DBID, PSID, and OBIDs.

If a table space name in the DB2 catalog does not have a data set with a corresponding name, one of the following events has probably occurred:

- The table space was dropped after the point-in-time to which you recovered. In this case, you cannot recover the table space. Execute DROP TABLESPACE to delete the entry from the DB2 catalog.
- The table space was defined with the DEFINE(NO) option. In this case, the data set will be allocated when you insert data into the table space.

4. For each data set in the DSN1PRNT output, look for a corresponding DB2 catalog entry. If no entry exists, follow the instructions in “Recovery of an accidentally dropped table space” on page 511 to re-create the entry in the DB2 catalog.
5. If you recover the catalog tables SYSSEQ and SYSSEQ2, identity columns and sequence objects are inconsistent. To avoid duplicate identity column values, recover all table spaces that contain tables that use identity columns to the point-in-time to which you recovered SYSSEQ and SYSSEQ2. To eliminate gaps between identity column values, use the ALTER TABLE statement. For sequence objects, use the ALTER SEQUENCE statement to eliminate these gaps. See “Recovering tables that contain identity columns” on page 500 for more information.
6. Ensure that the IPREFIX values of user table spaces and index spaces that were reorganized with the FASTSWITCH option match the IPREFIX value in the VSAM data set names that are associated with each table space or partition. If the IPREFIX recorded in the DB2 catalog and directory is different from the VSAM cluster names, you cannot access your data. To ensure that these IPREFIX values match, complete the following procedure:
  - a. Query the SYSIBM.SYSTABLEPART and SYSIBM.SYSINDEXPART catalog tables to determine the IPREFIX value that is recorded in the catalog for objects that were reorganized with the FASTSWITCH option.
  - b. Compare this IPREFIX value to the IPREFIX value in the VSAM data set name that is associated with the table space or index space.
  - c. When IPREFIX values do not match for an object, rename the VSAM data set to specify the correct IPREFIX.
 

**Example:** If the catalog specifies an IPREFIX of J for an object but the VSAM data set that corresponds to this object is `catname.DSNDBC.dbname.spname.I0001.A001`, you must rename this data set to `catname.DSNDBC.dbname.spname.J0001.A001`.
7. Delete the VSAM data sets that are associated with table spaces that were created with the DEFINE NO option and that reverted to an unallocated state. After you delete the VSAM data sets, you can insert or load rows into these unallocated table spaces to allocate new VSAM data sets. For more information about the DEFINE NO option of the CREATE TABLESPACE and CREATE INDEX SQL statements, see *DB2 SQL Reference*.

See Part 3 of *DB2 Utility Guide and Reference* for more information about DSN1COPY and DSN1PRNT.

## Using RECOVER to restore data to a previous point-in-time

TOCOPY, TOLOGPOINT, TOLASTCOPY, and TOLASTFULLCOPY are options of the RECOVER utility. All of these options terminate recovery at a specified point. Because they recover data to a prior time, and not to the present, they are referred to as point-in-time recoveries.

### Using the TOCOPY, TOLASTCOPY, and TOLASTFULLCOPY options

The TOCOPY, TOLASTCOPY, and TOLASTFULLCOPY options identify an image copy as the point-in-time to which to recover. With these options, the RECOVER utility restores objects to the value of a specified image copy and does not apply subsequent changes from the log. If the image copy that is specified in one of these options cannot be applied, the RECOVER utility uses an earlier full image copy and applies the changes in the log up to the point-in-time at which the specified image copy was taken.

If the image copy data set is cataloged when the image copy is made, the entry for that copy in SYSIBM.SYSCOPY does not record the volume serial numbers of the data set. You can identify that copy by its name by using TOCOPY *data set name*. If the image copy data set was not cataloged when it was created, you can identify the copy by its volume serial identifier by using TOVOLUME *volser*.

### Using the TOLOGPOINT option

With TOLOGPOINT, the RECOVER utility restores the most recent full image copy and the most recent set of incremental copies that occur before the specified log point. The log and logged changes are applied up to, and including, the record that contains the log point. If no full image copy exists before the chosen log point, recovery is attempted entirely from the log. The log is applied from the log point at which the page set was created or the last LOAD or REORG TABLESPACE utility was run to a log point that you specify. You can apply the log only if you have **not** used the MODIFY RECOVERY utility to delete the SYSIBM.SYSLGRNX records for the log range your recovery requires.

You can use the TOLOGPOINT option in both data sharing and non-data-sharing environments. In a non-data-sharing environment, TOLOGPOINT and TORBA are interchangeable keywords that identify an RBA on the log at which recovery stops. TORBA can be used in a data sharing environment only if the TORBA value is before the point at which data sharing was enabled.

**Recommendation:** Use the TOLOGPOINT keyword instead of the TORBA keyword. Although DB2 still supports the TORBA option, the TOLOGPOINT option supports both data sharing and non-data-sharing environments and is used for both of these environments throughout this publication.

### Planning for point-in-time recovery

TOCOPY and TOLOGPOINT are viable alternatives in many situations in which recovery to the current point-in-time is not possible or is not desirable. To make these options work best, take periodic quiesce points at points of consistency that are appropriate to your applications.

When making copies of a single object, use SHRLEVEL REFERENCE to establish consistent points for TOCOPY recovery. Copies that are made with SHRLEVEL CHANGE do not copy data at a single instant, because changes can occur as the copy is made. A subsequent RECOVER TOCOPY operation can produce inconsistent data.

When copying a list of objects, use SHRLEVEL REFERENCE. If a subsequent recovery to a point-in-time is necessary, you can use a single RECOVER utility statement to list all of the objects, along with TOLOGPOINT to identify the common RBA or LRSN value. If you use SHRLEVEL CHANGE to copy a list of objects, you should follow it with a QUIESCE of the objects.

An inline copy that is made during LOAD REPLACE can produce unpredictable results if that copy is used later in a RECOVER TOCOPY operation. DB2 makes the copy during the RELOAD phase of the LOAD operation. Therefore, the copy does not contain corrections for unique index violations and referential constraint violations because those corrections occur during the INDEXVAL and ENFORCE phases.

To improve the performance of the recovery, take a full image copy of the page sets, and then quiesce them using the QUIESCE utility. This allows RECOVER TOLOGPOINT to recover the page sets to the quiesce point with minimal use of the log.

If you are working with partitioned table spaces, image copies that were taken prior to resetting the REORG-pending status of any partition of a partitioned table space cannot be used for recovery to a current point-in-time. Avoid performing a point-in-time recovery for a partitioned table space to a point-in-time that is after the REORG-pending status was set, but before a rebalancing REORG was performed. See information about RECOVER in Part 2 of *DB2 Utility Guide and Reference* for details on determining an appropriate point-in-time and creating a new recovery point.

If you use the REORG TABLESPACE utility with the FASTSWITCH YES option on only some partitions of a table space, you must recover that table space at the partition level. When you take an image copy of such a table space, the COPY utility issues the informational message DSNU429I. For a complete description of DSNU429I, see *DB2 Messages*.

**Authorization:** Restrict the use of the TOCOPY, TOLOGPOINT, TOLASTCOPY, and TOLASTFULLCOPY options of the RECOVER utility to personnel with a thorough knowledge of the DB2 recovery environment.

### Ensuring consistency

RECOVER TOLOGPOINT and RECOVER TOCOPY can be used on a single:

- Partition of a partitioned table space
- Partition of a partitioning index space
- Data set of a simple table space

All page sets must be restored to the same level; otherwise the data is inconsistent.

A table space and all of its indexes (or a table space set and all related indexes) should be recovered in a single RECOVER utility statement that specifies TOLOGPOINT. The log point should identify a quiesce point or a common SHRLEVEL REFERENCE copy point. This action avoids placing indexes in the CHECK-pending or RECOVER-pending status. If the log point is not a common quiesce point or SHRLEVEL REFERENCE copy point for all objects, use the following procedure:

1. RECOVER table spaces to the log point.
2. Use concurrent REBUILD INDEX jobs to rebuild the indexes for each table space.

This procedure ensures that the table spaces and indexes are synchronized and eliminates the need to run the CHECK INDEX utility.

Point in time recovery can cause table spaces to be placed in CHECK-pending status if they have table check constraints or referential constraints defined on them. When recovering tables that are involved in a referential constraint, you should recover all the table spaces that are involved in a constraint. This is the *table space set*. To avoid setting CHECK-pending status, you must perform both of the following tasks:

- Recover the table space set to a quiesce point.

If you do not recover each table space of the table space set to the same quiesce point, and if any of the table spaces are part of a referential integrity structure:

- All dependent table spaces that are recovered are placed in CHECK-pending status with the scope of the whole table space.
- All table spaces that are dependent on the table spaces that are recovered are placed in CHECK-pending status with the scope of the specific dependent tables.
- Establish a quiesce point or take an image copy after you add check constraints or referential constraints to a table.
 

If you recover each table space of a table space set to the same quiesce point, but referential constraints were defined after the quiesce point, the CHECK-pending status is set for the table space containing the table with the referential constraint.

For information about resetting the CHECK-pending status, see “Violation of referential constraint recovery” on page 558.

The RECOVER utility sets various states on table spaces. The following point-in-time recoveries set such states on table spaces:

- When the RECOVER utility finds an invalid column during the LOGAPPLY phase on a LOB table space, it sets the table space to auxiliary-warning (AUXW) status.
- When you recover a LOB table space to a point-in-time that is not a quiesce point or to an image copy that is produced with SHRLEVEL CHANGE, the LOB table space is placed in CHECK-pending (CHKP) status.
- When you recover only the LOB table space to any previous point-in-time, the base table space is placed in auxiliary CHECK-pending (ACHKP) status, and the index space containing an index on the auxiliary table is placed in REBUILD-pending (RBDP) status.
- When you recover only the base table space to a point-in-time, the base table space is placed in CHECK-pending (CHKP) status.
- When you recover only the index space containing an index on the auxiliary table to a point-in-time, the index space is placed in CHECK-pending (CHKP) status.
- When you recover partitioned table spaces with the RECOVER utility to a point-in-time that is prior to a partition rebalance, all partitions that were rebalanced are placed in REORG-pending (REORP) status.
- When you recover a table space to point-in-time prior to when an identity column was defined with the RECOVER utility, the table space is placed in REORG-pending (REORP) status.
- If you do not recover all objects that are members of a referential set to a prior point-in-time with the RECOVER utility, or if you recover a referential set to a point-in-time that is not a point of consistency with the RECOVER utility, all dependent table spaces are placed in CHECK-pending (CHKP) status.

See Part 2 of *DB2 Utility Guide and Reference* for detailed information about recovering a table space that contains LOB data.

To remove various pending states from a table space, run the following utilities in this order:

1. Use the REORG TABLESPACE utility to remove the REORP status.
2. If the table space status is auxiliary CHECK-pending status:
  - Use CHECK LOB for all associated LOB table spaces.
  - Use CHECK INDEX for all indexes on the LOB table spaces.
3. Use the CHECK DATA utility to remove the CHECK-pending status.

**Compressed data:** Use caution when recovering a single data set of a non-partitioned page set to a prior point-in-time. If the data set that is recovered was compressed with a different dictionary from the rest of the page set, you can no longer read the data. For important information about loading and compressing data, see the description of LOAD in Part 2 of *DB2 Utility Guide and Reference*.

The RECOVER utility does not reset the values that DB2 generates for identity columns.

**Important:** The RECOVER utility does not back out CREATE or ALTER statements. After a recovery to a previous point-in-time, all previous alterations to identity column attributes remain unchanged. Because these alterations are not backed out, a recovery to a point-in-time might put identity column tables out of sync with the SYSIBM.SYSSEQUENCES catalog table. You might need to modify identity column attributes after a recovery to resynchronize identity columns with the catalog table.

### **Restoring data by using DSN1COPY**

You can use DSN1COPY to restore data that was previously backed up by DSN1COPY or by COPY. If you use DSN1COPY to restore data or move data, the data definitions for the target object must be exactly the same as when the copy was created. You cannot use DSN1COPY to restore data that was backed up with the DFSMSdss concurrent copy facility.

Be careful when creating backups with DSN1COPY. You must ensure that the data is consistent, or you might produce faulty backup copies. One advantage of using COPY to create backups is that it does not allow you to copy data that is in CHECK-pending or RECOVER-pending status. You can use COPY to prepare an up-to-date image copy of a table space, either by making a full image copy or by making an incremental image copy and merging that incremental copy with the most recent full image copy.

Keep access method services LISTCAT listings of table space data sets that correspond to each level of retained backup data.

For more information about using DSN1COPY, see Part 3 of *DB2 Utility Guide and Reference*.

### **Backing up and restoring data with non-DB2 dump and restore**

You can use certain non-DB2 facilities to dump and restore data sets and volumes. But note carefully the limitations described in this section.

Even though DB2 data sets are defined as VSAM data sets, DB2 data cannot be read or written by VSAM record processing because it has a different internal format. The data can be accessed by VSAM control interval (CI) processing. If you manage your own data sets, you can define them as VSAM linear data sets (LDSs), and access them through services that support data sets of that type.

Access method services for CI and LDS processing are available in z/OS. IMPORT and EXPORT use CI processing; PRINT and REPRO do not, but they do support LDSs.

DFSMS Data Set Services (DFSMSdss) is available on z/OS and provides dump and restore services that can be used on DB2 data sets. Those services use VSAM CI processing.

## Recovery of dropped objects

The procedures described in this section can be used if a table or table space is inadvertently dropped.

### Avoiding accidentally dropping objects

To avoid the problem of accidentally dropping tables, you can create a table with the clause `WITH RESTRICT ON DROP`. No one can drop the table, nor the table space or database containing the table, until the restriction on the table is removed. The `ALTER TABLE` statement includes a clause to remove the restriction, as well as one to impose it.

### Procedures for recovery

The following terms are used throughout this discussion:

Term	Meaning
------	---------

<b>DBID</b>	Database identifier
-------------	---------------------

<b>OBID</b>	Data object identifier
-------------	------------------------

<b>PSID</b>	Table space identifier
-------------	------------------------

**Recommendation:** To prepare for this procedure, **run regular catalog reports** that include a list of all OBIDs in the subsystem. In addition create catalog reports that list dependencies on the table (such as referential constraints, indexes, and so on). After a table is dropped, this information disappears from the catalog.

If an OBID has been reused by DB2, you must run `DSN1COPY` to translate the OBIDs of the objects in the data set. However, this event is unlikely; DB2 reuses OBIDs only when no image copies exist that contain data from that table.

**Important:** When you recover a dropped object, you essentially recover a table space to a point-in-time. If you want to use log records to perform forward recovery on the table space, you need the IBM DB2 UDB Log Analysis Tool for z/OS.

### Recovery of an accidentally dropped table

Tables in a partitioned table space cannot be dropped without dropping the table space. If you accidentally drop a table space, see “Recovery of an accidentally dropped table space” on page 511.

To perform this procedure, you need a full image copy or a `DSN1COPY` file that contains the data from the dropped table.

For segmented table spaces, the image copy or `DSN1COPY` file must contain the table when it was active (that is, created). Because of the way space is reused for segmented table spaces, this procedure cannot be used if the table was not active when the image copy or `DSN1COPY` was made. For nonsegmented table spaces, the image copy or `DSN1COPY` file can contain the table when it was active or not active.

The following procedure recovers a dropped table:

1. If you know the DBID, the PSID, the original OBID of the dropped table, and the OBIDs of all other tables in the table space, go to step 2.

If you do not know all of the preceding items, use the following steps to find them. For later use with `DSN1COPY`, record the DBID, the PSID, and the OBIDs of all the tables in the table space, not just the dropped table.

- a. For the data set that contains the dropped table, run DSN1PRNT with the FORMAT and NODATA options. Record the HPGOBID field in the header page and the PGSOBD field from the data records in the data pages.  
For the auxiliary table of a LOB table space, record the HPGROID field in the header page instead of PGSOBD field in the data pages.
    - Field HPGOBID is 4 bytes long and contains the DBID in the first 2 bytes and the PSID in the last 2 bytes.
    - Field HPGROID (for LOB table spaces) contains the OBID of the table. A LOB table space can contain only one table.
    - Field PGSOBD (for non-LOB table spaces) is 2 bytes long and contains the OBID of the table. If your table space contains more than one table, check for all OBIDs. In other words, search for all different PGSOBD fields. You need to specify all OBIDs from the data set as input for the DSN1COPY utility.
  - b. Convert the hex values in the identifier fields to decimal so that they can be used as input for the DSN1COPY utility.
2. Use the SQL CREATE statement to re-create the table and any indexes on the table.
  3. To allow DSN1COPY to access the DB2 data set, stop the table space using the following command:  
-STOP DATABASE(*database-name*) SPACENAM(*tablespace-name*)  
Stopping the table space is necessary to ensure that all changes are written out and that no data updates occur during this procedure.
  4. Find the OBID for the table you created in step 2 by querying the SYSIBM.SYSTABLES catalog table. The following statement returns the object ID (OBID) for the table:

**Product-sensitive Programming Interface**

```
SELECT NAME, OBID FROM SYSIBM.SYSTABLES
WHERE NAME='table_name'
AND CREATOR='creator_name';
```

**End of Product-sensitive Programming Interface**

This value is returned in decimal format, which is the format you need for DSN1COPY.

5. Run DSN1COPY with the OBIDXLAT and RESET options to perform the OBID translation and to copy data from the dropped table into the original data set. You must specify a previous full image copy data set, inline copy data set, or DSN1COPY file as the input data set SYSUT1 in the control statement. Specify each of the input records in the following order in the SYSXLAT file to perform OBID translations:
  - a. The DBID that you recorded in step 1 as both the translation source and the translation target
  - b. The PSID that you recorded in step 1 as both the translation source and the translation target
  - c. The original OBID that you recorded in step 1 for the dropped table as the translation source and the OBID that you recorded in step 4 as the translation target
  - d. OBIDs of all other tables in the table space that you recorded in step 2 as both the translation sources and translation targets

Be sure that you have named the VSAM data sets correctly by checking messages DSN1998I and DSN1997I after DSN1COPY completes.

For more information about DSN1COPY, see Part 3 of *DB2 Utility Guide and Reference*.

6. Use DSN1COPY with the OBIDXLAT and RESET options to apply any incremental image copies. You must apply these incremental copies in sequence, and specify the same SYSXLAT records that step 5 specifies.

**Important:** After you complete this step, you have essentially recovered the table space to the point-in-time of the last image copy. If you want to use log records to perform forward recovery on the table space, you must use the IBM DB2 UDB Log Analysis Tool for z/OS at this point in the recovery procedure.

For more information about point-in-time recovery, see “Recovering data to a prior point of consistency” on page 499.

7. Start the table space for normal use by using the following command:  
`-START DATABASE(database-name) SPACENAM(tablespace-name)`
8. Rebuild all indexes on the table space.
9. Execute SELECT statements on the previously dropped table to verify that you can access the table. Include all LOB columns in these queries.
10. Make a full image copy of the table space. See “Copying page sets and data sets” on page 493 for more information about the COPY utility.
11. Re-create the objects that are dependent on the recovered table.

As explained in “Implications of dropping a table” on page 89, when a table is dropped, objects that are dependent on that table (synonyms, views, indexes, referential constraints, and so on) are dropped. (Aliases are not dropped.)

Privileges that are granted for that table are also dropped. Catalog reports or a copy of the catalog taken prior to the DROP TABLE can make this task easier.

## Recovery of an accidentally dropped table space

These procedures are for table spaces, including LOB table spaces, that were dropped accidentally. You might accidentally drop a table space, for example, when all tables in an implicitly created table space are dropped, or if someone unintentionally executes a DROP TABLESPACE statement for a particular table space.

When a table space is dropped, DB2 loses all information about the image copies of that table space. Although the image copy data set is not lost, locating it might require examination of image copy job listings or manually recorded information about the image copies.

This section provides two separate procedures: one for user-managed data sets and one for DB2-managed data sets.

**User-managed data sets:** The following procedure recovers dropped table spaces that are not part of the catalog. In this procedure, you copy the data sets containing data from the dropped table space to redefined data sets using the OBID-translate function of DSN1COPY.

1. Find the DBID for the database, the PSID for the dropped table space, and the OBIDs for the tables contained in the dropped table space. For information about how to do this, see step 1 of “Recovery of an accidentally dropped table” on page 509.

2. Rename the data set containing the dropped table space by using the IDCAMS ALTER command. Rename both the CLUSTER and DATA portion of the data set with a name that begins with the integrated catalog facility catalog name or alias.
3. Redefine the original DB2 VSAM data sets.  
Use the access method services LISTCAT command to obtain a list of data set attributes. The data set attributes on the redefined data sets must be the same as they were on the original data sets.
4. Use SQL CREATE statements to re-create the table space, tables, and any indexes on the tables.
5. To allow DSN1COPY to access the DB2 data sets, stop the table space using the following command:  
-STOP DATABASE(*database-name*) SPACENAM(*tablespace-name*)

This step is necessary to prevent updates to the table space during this procedure in the event that the table space has been left open.

6. Find the target identifiers of the objects you created in step 4 (which consist of a PSID for the table space and the OBIDs for the tables within that table space) by querying the SYSIBM.SYSTABLESPACE and SYSIBM.SYSTABLES catalog tables.

#### Product-sensitive Programming Interface

The following statement returns the object ID for a table space; this is the PSID.

```
SELECT DBID, PSID FROM SYSIBM.SYSTABLESPACE
WHERE NAME='tablespace_name' and DBNAME='database_name'
AND CREATOR='creator_name';
```

The following statement returns the object ID for a table:

```
SELECT NAME, OBID FROM SYSIBM.SYSTABLES
WHERE NAME='table_name'
AND CREATOR='creator_name';
```

#### End of Product-sensitive Programming Interface

These values are returned in decimal format, which is the format that you need for DSN1COPY.

7. Run DSN1COPY with the OBIDXLAT and RESET options to perform the OBID translation and to copy the data from the renamed VSAM data set that contains the dropped table space to the newly defined VSAM data set. Specify the VSAM data set that contains data from the dropped table space as the input data set SYSUT1 in the control statement. Specify each of the input records in the following order in the SYSXLAT file to perform OBID translations:
  - a. The DBID that you recorded in step 1 on page 511 as both the translation source and the translation target
  - b. The PSID that you recorded in step 1 on page 511 as the translation source and the PSID that you recorded in step 6 as the translation target
  - c. The original OBIDs that you recorded in step 1 on page 511 as the translation sources and the OBIDs that you recorded in step 6 as the translation targets

Be sure that you have named the VSAM data sets correctly by checking messages DSN1998I and DSN1997I after DSN1COPY completes.

For more information about DSN1COPY, see Part 3 of *DB2 Utility Guide and Reference*.

8. Use DSN1COPY with the OBIDXLAT and RESET options to apply any incremental image copies to the recovered table space. You must apply these incremental copies in sequence, and specify the same SYSXLAT records that step 7 specifies.

**Important:** After you complete this step, you have essentially recovered the table space to the point-in-time of the last image copy. If you want to use log records to perform forward recovery on the table space, you must now use the IBM DB2 UDB Log Analysis Tool for z/OS.

For more information about point-in-time recovery, see “Recovering data to a prior point of consistency” on page 499.

9. Start the table space for normal use by using the following command:  
`-START DATABASE(database-name) SPACENAM(tablespace-name)`
10. Rebuild all indexes on the table space.
11. Execute SELECT statements on each table in the recovered table space to verify the recovery. Include all LOB columns in these queries.
12. Make a full image copy of the table space.  
See “Copying page sets and data sets” on page 493 for more information about the COPY utility.
13. Re-create the objects that are dependent on the table.  
See step 11 of “Recovery of an accidentally dropped table” on page 509 for more information.

**DB2-managed data sets:** The following procedure recovers dropped table spaces that are part of the catalog. If a consistent full image copy or DSN1COPY file is available, you can use DSN1COPY to recover a dropped table space. To recover a dropped table space, complete the following procedure:

1. Find the original DBID for the database, the PSID for the table space, and the OBIDs of all tables contained in the dropped table space. For information about how to do this, see step 1 of “Recovery of an accidentally dropped table” on page 509.
2. Re-create the table space and all tables. This re-creation can be difficult when any of the following conditions are true:
  - A table definition is not available
  - A table is no longer required

If you cannot re-create a table, you must use a dummy table to take its place. A *dummy table* is a table with an arbitrary structure of columns that you delete after you recover the dropped table space.

**Attention:** When you use a dummy table, you lose all data from the dropped table that you do not re-create.

3. Re-create auxiliary tables and indexes if a LOB table space has been dropped.
4. To allow DSN1COPY to access the DB2 data set, stop the table space with the following command:  
`-STOP DATABASE(database-name) SPACENAM(tablespace-name)`
5. Find the new PSID, and OBIDs by querying the DB2 catalog as described in step 6 of “User-managed data sets” on page 511. (Find the OBID of the dummy table that you created in step 2 if you could not re-create a table.)
6. Run DSN1COPY with the OBIDXLAT and RESET options to translate the OBID and to copy data from a previous full image copy data set, inline copy data set, or DSN1COPY file. Use one of these copies as the input data set

SYSUT1 in the control statement. Specify each of the input records in the following order in the SYSXLAT file to perform OBID translations:

- a. The DBID that you recorded in step 1 as both the translation source and the translation target
- b. The PSID that you recorded in step 1 as the translation source and the PSID that you recorded in step 5 as the translation target
- c. The OBIDs that you recorded in step 1 as the translation sources and the OBIDs that you recorded in step 5 as the translation targets

Be sure that you name the VSAM data sets correctly by checking messages DSN1998I and DSN1997I after DSN1COPY completes.

For more information about DSN1COPY, see Part 3 of *DB2 Utility Guide and Reference*.

7. Use DSN1COPY with the OBIDLAT and RESET options to apply any incremental image copies to the recovered table space. You must apply these incremental copies in sequence, and specify the same SYSXLAT records that step 7 specifies.

**Important:** After you complete this step, you have essentially recovered the table space to the point-in-time of the last image copy. If you want to use log records to perform forward recovery on the table space, you must use the IBM DB2 UDB Log Analysis Tool for z/OS at this point in the recovery procedure.

For more information about point-in-time recovery, see “Recovering data to a prior point of consistency” on page 499.

8. Start the table space for normal by using the following command:  
`-START DATABASE(database-name) SPACENAM(tablespace-name)`
9. Drop all dummy tables. The row structure does not match the table definition. This mismatch makes the data in these tables unusable.
10. Reorganize the table space to remove all rows from dropped tables.
11. Rebuild all indexes on the table space.
12. Execute SELECT statements on each table in the recovered table space to verify the recovery. Include all LOB columns in these queries.
13. Make a full image copy of the table space.  
See “Copying page sets and data sets” on page 493 for more information about the COPY utility.
14. Re-create the objects that are dependent on the table.  
See step 11 on page 511 of “Recovery of an accidentally dropped table” on page 509 for more information.

## Discarding SYSCOPY and SYSLGRNX records

Use the MODIFY utility to delete obsolete records from SYSIBM.SYSCOPY and SYSIBM.SYSLGRNX. To keep a table space and its indexes synchronized, the MODIFY utility deletes the SYSCOPY and SYSLGRNX records for the table space and its indexes that are defined with the COPY YES option.

1. Follow the following steps of the procedure that is presented in “Locating archive log data sets” on page 444:
  - a. “Resolve indoubt units of recovery” on page 444.
  - b. “Find the startup log RBA” on page 444.
  - c. “Find the minimum log RBA needed” on page 444. In that step, note the date of the earliest image copy that you intend to keep.

**What copies to keep:** The earliest image copies and log data sets that you need for recovery to the present date are not necessarily the earliest ones that you

want to keep. If you foresee resetting the DB2 subsystem to its status at any earlier date, you also need the image copies and log data sets that allow you to recover to that date.

If the most recent image copy of an object is damaged, the RECOVER utility seeks a backup copy. If no backup copy is available, or if the backup is lost or damaged, RECOVER uses a previous image copy. It continues searching until it finds an undamaged image copy or no more image copies exist. The process has important implications for keeping archive log data sets. At the very least, you need all log records since the most recent image copy; to protect against loss of data from damage to that copy, you need log records as far back as the earliest image copy that you keep.

2. Run the MODIFY utility for each table space whose old image copies that you want to discard, using the date of the earliest image copy that you will keep. For example, you could enter:

```
MODIFY RECOVERY TABLESPACE dbname.tsname
      DELETE DATE date
```

The DELETE DATE option removes records that were written earlier than the given date. You can also use DELETE AGE to remove records that are older than a specified number of days.

You can delete SYSCOPY records for a single partition by naming it with the DSNUM keyword. That option does not delete SYSLGRNX records and does not delete SYSCOPY records that are later than the earliest point to which you can recover the entire table space. Thus, you can still recover by partition after that point.

You cannot run the MODIFY utility on a table space that is in RECOVER-pending status.

## System-level point-in-time recovery

DB2 provides the following solutions for system-level recovery:

- “Recovery to a given point-in-time” on page 517. The point-in-time is either between two backup times or between the last backup time and the current time. In recovery to a given point-in-time, after the appropriate volume copies have been restored, the outstanding logs are applied to the databases to recover the data to the designated point-in-time.
- “Recovery to the point-in-time of a backup” on page 518. In recovery to the point-in-time of a backup, the recovery involves restoring the appropriate volume copies of the data and logs. The logs are used only to back out inflight transactions on restart.
- “Remote site recovery from a disaster at a local site” on page 519. In remote site recovery, the recovery is determined by what you keep at the remote site. For example, in addition to offsite tapes of backups, current logs might have been transmitted electronically. If so, the current logs can be applied to the databases after the data and logs are restored from the offsite tapes.

In this section, a DB2 system is either a single non-data sharing DB2 subsystem or a DB2 data sharing group.

## System-level backup and restore

The DB2 solutions described in this section use the BACKUP SYSTEM and RESTORE SYSTEM online utilities. For system-level backup and recovery procedures that do not use these utilities, see “Backing up with RVA storage control or Enterprise Storage Server” on page 495 and “Remote site recovery from a disaster at the local site” on page 563.

| The online utilities BACKUP SYSTEM and RESTORE SYSTEM are described in  
| Part 2 of *DB2 Utility Guide and Reference*, and the stand-alone utility DSNJU003 is  
| described in Part 3 of *DB2 Utility Guide and Reference*.

# **BACKUP SYSTEM online utility:** This utility invokes z/OS Version 1 Release 5  
# DFSMSHsm services to take volume copies of the data. All DB2 data sets that are  
# to be copied (and then recovered) must be managed by SMS. This utility works in  
# both data-sharing and non-data sharing DB2 systems.

# The BACKUP SYSTEM utility requires z/OS Version 1 Release 5 or later data  
# structures called copy pools. Because these data structures are implemented in  
# z/OS, DB2 cannot generate copy pools automatically. Before you invoke the  
# BACKUP SYSTEM utility, copy pools must be allocated in z/OS. For a more  
# detailed description of how DB2 uses copy pools, see “Using DFSMSHsm with the  
# BACKUP SYSTEM utility” on page 37. For information about how to allocate a  
# copy pool in z/OS, see *z/OS DFSMSdfp Storage Administration Reference*.

# The BACKUP SYSTEM utility invokes the DFSMSHsm fast replication function to  
# take volume level backups using FlashCopy.

# You can use the BACKUP SYSTEM utility to ease the task of managing data  
# recovery. Choose either DATA ONLY or FULL, depending on your recovery needs.  
# Choose FULL if you want to backup both your DB2 data and your DB2 logs.

# Because the BACKUP SYSTEM utility does not quiesce transactions, the  
# system-level backup is a fuzzy copy, which might not contain committed data and  
# might contain uncommitted data. The RESTORE SYSTEM utility uses these  
# backups to restore databases to a given point-in-time. The DB2 data is made  
# consistent by DB2 restart processing and the RESTORE SYSTEM utility. DB2 restart  
# processing determines which transactions were active at the given recovery point,  
# and writes the compensation log records for any uncommitted work that needs to  
# be backed out. The RESTORE SYSTEM utility restores the database copy pool, and  
# then applies the log records to bring the DB2 data to consistency. During the  
# LOGAPPLY phase of the RESTORE SYSTEM utility, log records are applied to redo  
# the committed work that is missing from the system-level backup, and log records  
# are applied to undo the uncommitted work that might have been contained in the  
# system-level backup.

# *Using data-only system backups:* The BACKUP SYSTEM DATA ONLY utility control  
# statement creates system-level backups that contain only databases.

# The RESTORE SYSTEM utility uses these backups to restore databases to a given  
# point-in-time. In this type of recovery, you lose only a few seconds of data, or  
# none, based on the given recovery point. However, recovery time varies and might  
# be extended due to the processing of the DB2 logs during DB2 restart and during  
# the LOGAPPLY phase of the RESTORE SYSTEM utility. The number of logs to  
# process depends on the amount of activity on your DB2 system between the time  
# of the system-level backup and the given recovery point.

| For more information about recovering the DB2 system to a given point-in-time,  
| see “Recovery to a given point-in-time” on page 517.

| *Using full system backups:* The BACKUP SYSTEM FULL utility control statement  
| creates system-level backups that contain both logs and databases. With these

| copies, you can recover your DB2 system to the point-in-time of a backup using  
| normal DB2 restart recovery, or to a given point-in-time by using the RECOVER  
| SYSTEM utility.

# To recover your DB2 system to the point-in-time of a backup by using normal DB2  
# restart recovery, stop DB2, and then restore both the database and log copy pools  
# outside of DB2 by using DFSMSHsm FRRECOV COPYPOOL (cpname)  
# GENERATION (gen). After you successfully restart DB2, your DB2 system has  
# been recovered to a point of consistency based on the time of the backup. For more  
# information about this type of recovery, see “Recovery to the point-in-time of a  
# backup” on page 518.

# The RESTORE SYSTEM utility uses full system backup copies as input, but the  
# utility does not restore the volumes in the log copy pool. If your situation requires  
# that the volumes in the log copy pool be restored, you must restore the log copy  
# pool before restarting DB2. For example, you should restore the log copy pool  
# when you are using a full system-level backup at your remote site for disaster  
# recovery.

| When you recover your DB2 system to the point-in-time of a full system backup,  
| you could lose a few hours of data, because you are restoring your DB2 data and  
| logs to the time of the backup. However, recovery time is brief, because DB2  
| restart processing and the RESTORE SYSTEM utility need to process a minimal  
| number of logs.

# If you choose not to restore the log copy pool prior to running the RESTORE  
# SYSTEM utility, the recovery is equivalent to the recovery of a system with  
# data-only backups. In this type of recovery, you lose only a few seconds of data, or  
# none, based on the given recovery point. However, recovery time varies and might  
# be extended due to the processing of the DB2 logs during DB2 restart and during  
# the LOGAPPLY phase of the RESTORE SYSTEM utility. The number of logs to  
# process depends on the amount of activity on your DB2 system between the time  
# of the system-level backup and the given recovery point.

| For more information about recovering the DB2 system to a given point-in-time,  
| see “Recovery to a given point-in-time.”

| **RESTORE SYSTEM online utility:** This utility invokes z/OS Version 1 Release 5  
| or later DFSMSHsm services to recover a DB2 system to a prior point-in-time by  
| restoring the databases in the volume copies that have been provided by the  
| BACKUP SYSTEM utility. After restoring the data, this utility can then recover to a  
| given point-in-time.

| The SYSPITR option of DSNJU003 CRESTART allows you to create a conditional  
| restart control record (CRCR) to truncate logs for system point-in-time recovery in  
| preparation for running the RESTORE SYSTEM utility.

| If you restore the system data by some other means, use the RESTORE SYSTEM  
| utility with the LOGONLY option to skip the restore phase, and use the CRCR to  
| apply the logs to the restored databases.

### | **Recovery to a given point-in-time**

# To minimize the amount of data that you lose when you recover, recover to a  
# given point-in-time. You can recover your DB2 system to a given point-in-time by

# using the RESTORE SYSTEM utility. The RESTORE SYSTEM utility uses  
# system-level backups that contain only DB2 objects to restore your DB2 system to a  
# given point-in-time.

| **Backup:** You must perform the following procedure before an event occurs that  
| creates a need to recover your DB2 system:

- | 1. Use the BACKUP SYSTEM utility to create system-level backups. Choose either  
| DATA ONLY or FULL, depending on your recovery needs. Choose FULL if you  
| want to backup both your DB2 data and your DB2 logs.

| **Recovery:** If you have performed the appropriate backup procedures, you can  
| recover your DB2 system to a given point-in-time by using the RESTORE SYSTEM  
| utility:

- | 1. Issue the STOP DB2 command to stop the DB2 subsystem. If your system is a  
| data sharing group, stop all members of the group.
- # 2. If the backup is a full system backup, you might need to restore the log copy  
# pool outside of DB2 by using DFSMSHsm FRRECOV COPYPOOL (cpname)  
# GENERATION (gen). For data-only system backups, skip this step.
- | 3. Run DSNJU003 (the change log inventory utility) with the CRESTART SYSPITR  
| option specifying the log truncation point that corresponds to the point-in-time  
| to which you want to recover the system. For data sharing systems, run  
| DSNJU003 on all active members of the data-sharing group, and specify the  
| same LRSN truncation point for each member. If the point-in-time that you  
| specify for recovery is prior to the oldest system backup, you must manually  
| restore the volume backup from tape.
- | 4. For data sharing systems, delete all CF structures that the data sharing group  
| owns.
- | 5. Issue the Start DB2 command to restart your DB2 system. For data sharing  
| systems, start all active members.
- | 6. Run the RESTORE SYSTEM utility. If you manually restored the backup, use  
| the LOGONLY option of the RESTORE SYSTEM utility to apply the current  
| logs.
- # 7. Stop and restart DB2 again to remove ACCESS(MAINT) status.

| After the RESTORE SYSTEM utility completes successfully, your DB2 system has  
| been recovered to the given point-in-time with consistency.

### | **Recovery to the point-in-time of a backup**

| Recovery to the point-in-time of a backup minimizes the amount of time that is  
| required for recovery. You can recover using backups that either the BACKUP  
| SYSTEM utility or FlashCopy create.

| **Using backups from BACKUP SYSTEM:** To recover a DB2 system to the  
| point-in-time of a backup that the BACKUP SYSTEM utility creates, you must  
| perform the following backup and recovery procedures. For more information  
| about the BACKUP SYSTEM utility, see “BACKUP SYSTEM online utility” on page  
| 516.

| **Backup:** You must perform the following procedure before an event occurs that  
| creates a need to recover your DB2 system.

- | 1. Use BACKUP SYSTEM FULL to take the system backup. DFSMSHsm maintains  
| up to 85 versions of system backups on disk at any given time.

**Recovery:** If you have performed the appropriate backup procedures, you can use the following procedure to recover your DB2 system to the point-in-time of a backup:

1. Stop the DB2 subsystem. For data sharing systems, stop all members of the group.
2. Use the DFSMSHsm command `FRRECOV * COPYPOOL(cpname) GENERATION(gen)` to restore the database and log copy pools that the BACKUP SYSTEM utility creates. In this command, *cpname* specifies the name of the copy pool, and *gen* specifies which version of the copy pool is restored.
3. For data sharing systems, delete all CF structures that are owned by this group.
4. Start DB2. For data sharing systems, start all active members.
5. For data sharing systems, execute the GRECP and LPL recovery, which recovers the changed data that was stored in the coupling facility at the time of the backup.

**Using backups from FlashCopy:** To recover a DB2 system to the point-in-time of a backup that FlashCopy creates, you must perform the following backup and recovery procedures. For more information about the FlashCopy function, see *z/OS DFSMS Advanced Copy Services*.

**Backup:** You must perform the following procedure before an event occurs that creates a need to recover your DB2 system:

1. Issue the DB2 command `SET LOG SUSPEND` to suspend logging and update activity, and to quiesce 32K page writes and data set extensions. For data sharing systems, issue the command to each member of the group.
2. Use the FlashCopy function to copy all DB2 volumes. Include any ICF catalogs that are used by DB2, as well as active logs and BSDSs.
3. Issue the DB2 command `SET LOG RESUME` to resume normal DB2 update activity. To save disk space, you can use DFSMSdss to dump the disk copies you just created to a lower-cost medium, such as tape.

**Recovery:** If you have performed the appropriate backup procedures, you can use the following procedure to recover your DB2 system to the point-in-time of a backup:

1. Stop the DB2 subsystem. For data sharing systems, stop all members of the group.
2. Use DFSMSdss `RESTORE` to restore the FlashCopy data sets to disk. See *z/OS DFSMSdss Storage Administration Reference* for more information.
3. For data sharing systems, delete all CF structures that are owned by this group.
4. Start DB2. For data sharing systems, start all active members.
5. For data sharing systems, execute the GRECP and LPL recovery, which recovers the changed data that was stored in the coupling facility at the time of the backup.

### **Remote site recovery from a disaster at a local site**

After a disaster at your local site, you can recover at a remote site by using the `RESTORE SYSTEM` utility. You can use `RESTORE SYSTEM` to recover DB2 from the backups that the BACKUP SYSTEM utility produces, or you can use `RESTORE SYSTEM LOGONLY` to recover from backups you produce in some other way. For DB2 remote-site recovery procedures that do not use the `RESTORE SYSTEM` utility, see "Remote site recovery from a disaster at the local site" on page 563.

| **Recovering with BACKUP SYSTEM:** The following procedures use the BACKUP  
| SYSTEM and RESTORE SYSTEM utilities to recover your DB2 system:

| **Preparation:**

- | 1. Use BACKUP SYSTEM FULL to take the system backup.
- | 2. Transport the system backups to the remote site.

| **Recovery:**

- | 1. Run the DSNJU003 utility using the control statement CRESTART CREATE,  
| SYSPITR=*log-truncation-point*, where *log-truncation-point* is the RBA or LRSN  
| of the point to which you want to recover.
- | 2. Start DB2.
- | 3. Run the RESTORE SYSTEM utility using the control statement RESTORE SYSTEM  
| to recover to the current time (or to the time of the last log transmission from  
| the local site).

| **Recovering without BACKUP SYSTEM:** Use the following procedures to recover  
| your DB2 system if you **do not** use the BACKUP SYSTEM utility to produce  
| backups:

| **Preparation:**

- | 1. Issue the DB2 command SET LOG SUSPEND to suspend logging and update  
| activity, and to quiesce 32K page writes and data set extensions. For data  
| sharing systems, issue the command to each member of the data sharing group.
- | 2. Use the FlashCopy function to copy all DB2 volumes. Include any ICF catalogs  
| that are used by DB2, as well as active logs and BSDSs.
- | 3. Issue the DB2 command SET LOG RESUME to resume normal DB2 update  
| activity.
- | 4. Use DFSMSdss to dump the disk copies that you just created to tape, and then  
| transport this tape to the remote site. You can also use other methods to  
| transmit the copies you make to the remote site.

| **Recovery:**

- | 1. Use DFSMSdss to restore the FlashCopy data sets to disk.
- | 2. Run the DSNJU003 utility using the control statement CRESTART CREATE,  
| SYSPITR=*log-truncation-point*, where *log-truncation-point* is the RBA or LRSN  
| of the point to which you want to recover.
- | 3. Start DB2.
- | 4. Run the RESTORE SYSTEM utility using the control statement RESTORE SYSTEM  
| LOGONLY to recover to the current time (or to the time of the last log  
| transmission from the local site).

---

## Chapter 22. Recovery scenarios

This chapter contains problem scenarios and the recommended procedures for restarting and recovering DB2. The following situations are described:

- “IRLM failure recovery”
- “z/OS or power failure recovery” on page 522
- “Disk failure recovery” on page 522
- “Application error recovery” on page 524
- “IMS-related failure recovery” on page 525
- “CICS-related failure recovery” on page 529
- “Subsystem termination recovery” on page 534
- “Resource failure recovery” on page 535
  - “Active log failure recovery” on page 535
  - “Archive log failure recovery” on page 539
  - “BSDS failure recovery” on page 542
  - “Recovering the BSDS from a backup copy” on page 543
- # “DB2 database failures” on page 546
- “Recovering a DB2 subsystem to a prior point in time” on page 547
- “Recovery from down-level page sets” on page 548
- “Table space input/output error recovery” on page 550
- “DB2 catalog or directory input/output errors” on page 551
- “Integrated catalog facility failure recovery” on page 552
  - “Recovery when the VSAM volume data set (VVDS) is destroyed” on page 552
  - “Out of disk space or extent limit recovery” on page 554
- “Violation of referential constraint recovery” on page 558
- “Distributed data facility failure recovery” on page 558
- “Remote site recovery from a disaster at the local site” on page 563
- “Using a tracker site for disaster recovery” on page 574
- “Resolving indoubt threads” on page 588
  - “Communication failure recovery” on page 590
  - “Making a heuristic decision” on page 591
  - “Recovery from an IMS outage that results in an IMS cold start” on page 592
  - “Recovery from a DB2 outage at a requester that results in a DB2 cold start” on page 593
  - “Recovery from a DB2 outage at a server that results in a DB2 cold start” on page 596
  - “Correcting a heuristic decision” on page 596

---

### IRLM failure recovery

**Problem:** The IRLM fails in a wait, loop, or abend.

**Symptom:** The IRLM abends and the following message appears:

```
DXR122E irllmm ABEND UNDER IRLM TCB/SRB IN MODULE xxxxxxxx  
ABEND CODE zzzz
```

**System action:** If the IRLM abends, DB2 terminates. If the IRLM waits or loops, then terminate the IRLM, and DB2 terminates automatically.

**System programmer action:** None.

*Operator action:*

- Start the IRLM if you did not set it for automatic start when you installed DB2. (For instructions on starting the IRLM, see “Starting the IRLM” on page 381.)
- Start DB2. (For instructions, see “Starting DB2” on page 324.)
- Issue the command /START SUBSYS *ssid* to connect IMS to DB2.
- Issue the command DSNCL STRT to connect CICS to DB2. (See “Connecting from CICS” on page 388.)

---

## **z/OS or power failure recovery**

*Problem:* z/OS or processor power fails.

*Symptom:* No processing is occurring.

*System action:* None.

*System programmer action:* None.

*Operator action:*

1. IPL z/OS and initialize the job entry subsystem.
2. If you normally run VTAM with DB2, start VTAM at this point.
3. Start the IRLM if you did not set it for automatic start when you installed DB2. (See “Starting the IRLM” on page 381.)
4. Start DB2. (See “Starting DB2” on page 324.)
5. Use the RECOVER POSTPONED command if postponed-abort units of recovery were reported after restarting DB2, and the AUTO option of the LIMIT BACKOUT field on installation panel DSNTIPL was not specified.
6. Restart IMS or CICS.
  - a. IMS automatically connects and resynchronizes when it is restarted. (See “Connecting to the IMS control region” on page 392.)
  - b. CICS automatically connects to DB2 if the CICS PLT contains an entry for the attach module DSNCCOM0. Alternatively, use the command DSNCL STRT to connect the CICS attachment facility to DB2. (See “Connecting from CICS” on page 388.)

If you know that a power failure is imminent, it is a good idea to issue STOP DB2 MODE(FORCE) to allow DB2 to come down cleanly before the power is interrupted. If DB2 is unable to stop completely before the power failure, the situation is no worse than if DB2 were still up.

---

## **Disk failure recovery**

*Problem:* A disk hardware failure occurs, resulting in the loss of an entire unit.

*Symptom:* No I/O activity for the affected disk address. Databases and tables residing on the affected unit are unavailable.

*System action:* None

*System programmer action:* None

*Operator action:* Attempt recovery with the following procedure:

1. Assure that there are no incomplete I/O requests against the failing device. One way to do this is to force the volume off line by issuing the following z/OS command:

```
VARY xxx,OFFLINE,FORCE
```

where *xxx* is the unit address.

To check disk status you can issue:

```
D U,DASD,ONLINE
```

The following console message is displayed after you have forced a volume offline:

```
UNIT TYPE STATUS VOLSER VOLSTATE
4B1 3390 0-BOX XTRA02 PRIV/RSDNT
```

The disk unit is now available for service.

If you have previously set the I/O timing interval for the device class, the I/O timing facility should terminate all incomplete requests at the end of the specified time interval, and you can proceed to the next step without varying the volume off line. You can set the I/O timing interval either through the IECIOSxx z/OS parameter library member or by issuing the z/OS command SETIOS MIH,DEV=*devnum*,IOTIMING=*mm:ss*.

For more information about the I/O timing facility, see *z/OS MVS Initialization and Tuning Reference* and *z/OS MVS System Commands*.

2. An authorized operator issues the following command to stop all databases and table spaces residing on the affected volume:

```
-STOP DATABASE(database-name) SPACENAM(space-name)
```

If the disk unit must be disconnected for repair, all databases and table spaces on all volumes in the disk unit must be stopped.

3. Select a spare disk pack and use ICKDSF to initialize from scratch a disk unit with a different unit address (*yyy*) and the same volser.

```
// Job
//ICKDSF EXEC PGM=ICKDSF
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
REVAL UNITADDRESS(yyy) VERIFY(volser)
```

If you are initializing a 3380 or 3390 volume, use REVAL with the VERIFY parameter to ensure you are initializing the volume you want, or to revalidate the volume's home address and record 0. Details are provided in *Device Support Facilities User's Guide and Reference*. Alternatively, use ISMF to initialize the disk unit.

4. Issue this z/OS console command. *yyy* is the new unit address.

```
VARY yyy,ONLINE
```

5. To check disk status you can issue:

```
D U,DASD,ONLINE
```

The following console message is displayed:

```
UNIT TYPE STATUS VOLSER VOLSTATE
7D4 3390 0 XTRA02 PRIV/RSDNT
```

6. Issue the following command to start all the appropriate databases and table spaces that had been stopped previously:

```
-START DATABASE(database-name) SPACENAM(space-name)
```

7. Delete all table spaces (VSAM linear data sets) from the ICF catalog by issuing the following access method services command for each one of them:

```
DELETE catnam.DSNDBC.dbname.tsname.y0001.A00x CLUSTER NOSCRATCH
```

where *y* can be either I or J.

Access method services commands are described in detail in *z/OS DFSMS Access Method Services for Catalogs*.

8. For user-managed table spaces, the VSAM cluster and data components must be defined for the new volume by issuing the access method services DEFINE CLUSTER command with the data set name:

```
catnam.DSNDBC.dbname.tname.y0001.A00x
```

where *y* can be either I or J, and *x* is C (for VSAM clusters) or D (for VSAM data components).

This data set is the same as defined in Step 7. Detailed requirements for user-managed data sets are described in “Requirements for your own data sets” on page 38.

For a user-defined table space, the new data set must be defined before an attempt to recover it. Table spaces defined in storage groups can be recovered without prior definition.

9. Recover the table spaces using the RECOVER utility. Additional information and procedures for recovering data can be found in “Recovering page sets and data sets” on page 495.

---

## Application error recovery

**Problem:** An application program placed a logically incorrect value in a table.

**Symptom:** SQL SELECT returns unexpected data.

**System action:** The system returns SQLCODE 0 for the SELECT statement, because the error was not in SQL or DB2, but in the application program. That error can be identified and corrected, but the data in the table is now inaccurate.

**System programmer action:** You might be able to use RECOVER TOLOGPOINT to restore the database to a point before the error occurred, but there are many circumstances under which you must manually back out the changes introduced by the application. Among those are:

- Other applications changed the database after the error occurred. If you recover the table spaces modified by the bad application, you would lose all subsequent changes made by the other applications.
- DB2 checkpoints were taken after the error occurred. In this case, you can use RECOVER TOLOGPOINT to restore the data up to the last checkpoint before the error occurred, but all subsequent changes to the database are lost.

If you have a situation for which using RECOVER TOLOGPOINT is appropriate, you can use procedures similar to those that follow to back out the changes made by the bad application. For a discussion of RECOVER TOLOGPOINT, see “Using RECOVER to restore data to a previous point-in-time” on page 504.

### Procedure 1: If you have established a quiesce point

1. Run the REPORT utility twice, once using the RECOVERY option and once using the TABLESPACESET option. On each run, specify the table space containing the inaccurate data. If you want to recover to the last quiesce point, specify the option CURRENT when running REPORT RECOVERY.
2. Examine the REPORT output to determine the RBA of the quiesce point.

3. Execute RECOVER TOLOGPOINT with the RBA that you found, specifying the names of all related table spaces. Recovering all related table spaces to the same quiesce point prevents violations of referential constraints.

**Procedure 2: If you have not established a quiesce point**

If you use this procedure, you will lose any updates to the database that occurred after the last checkpoint before the application error occurred.

1. Run the DSN1LOGP stand-alone utility on the log scope available at DB2 restart, using the SUMMARY(ONLY) option. For instructions on running DSN1LOGP, see Part 3 of *DB2 Utility Guide and Reference*.
2. Determine the RBA of the most recent checkpoint before the first bad update occurred, from one of the following sources:

- Message DSNR003I on the operator's console. It looks (in part) like this:  
DSNR003I RESTART ..... PRIOR CHECKPOINT  
RBA=000007425468

The required RBA in this example is X'7425468'.

This technique works only if there have been no checkpoints since the application introduced the bad updates.

- Output from the print log map utility. You must know the time that the first bad update occurred. Find the last BEGIN CHECKPOINT RBA before that time.
3. Run DSN1LOGP again, using SUMMARY(ONLY) and specify the checkpoint RBA as the value of RBASTART. The output lists the work in the recovery log, including information about the most recent complete checkpoint, a summary of all processing occurring, and an identification of the databases affected by each active user. Sample output is shown in Figure 66 on page 606.
  4. One of the messages in the output (identified as DSN1151I or DSN1162I) describes the unit of recovery in which the error was made. To find the unit of recovery, use your knowledge of the time the program was run (START DATE= and TIME=), the connection ID (CONNID=), authorization ID (AUTHID=), and plan name (PLAN=). In that message, find the starting RBA as the value of START=.
  5. Execute RECOVER TOLOGPOINT with the starting RBA you found in the previous step.
  6. Recover any related table spaces or indexes to the same point in time.

*Operator action:* None.

---

## IMS-related failure recovery

This section includes scenarios for problems that can be encountered in the IMS environment:

“IMS control region (CTL) failure recovery” on page 526

“Resolution of indoubt units of recovery” on page 526

“IMS application failure recovery” on page 528

DB2 can be used in an XRF (Extended Recovery Facility) recovery environment with IMS. See “Extended recovery facility (XRF) toleration” on page 476 for more information about using XRF with IMS.

## IMS control region (CTL) failure recovery

*Problem:* The IMS control region fails.

*Symptom:*

- IMS waits, loops, or abends.
- DB2 attempts to send the following message to the IMS master terminal during an abend:

```
DSNM002I  IMS/TM xxxx DISCONNECTED FROM SUBSYSTEM  
          yyyy  RC=RC
```

This message cannot be sent if the failure prevents messages from being displayed.

- DB2 does not send any messages related to this problem to the z/OS console.

*System action:*

- DB2 detects that IMS has failed.
- DB2 either backs out or commits work in process.
- DB2 saves indoubt units of recovery. (These must be resolved at reconnection time.)

*System programmer action:* None.

*Operator action:*

1. Use normal IMS restart procedures, which include starting IMS by issuing the z/OS START IMS command.
2. The following results occur:
  - All DL/I and DB2 updates that have not been committed are backed out.
  - IMS is automatically reconnected to DB2.
  - IMS passes the recovery information for each entry to DB2 through the IMS attachment facility. (IMS indicates whether to commit or roll back.)
  - DB2 resolves the entries according to IMS instructions.

## Resolution of indoubt units of recovery

This section describes two different problems.

### Problem 1

There are unresolved indoubt units of recovery. When IMS connects to DB2, DB2 has one or more indoubt units of recovery that have not been resolved.

*Symptom:* If DB2 has indoubt units of recovery that IMS did not resolve, the following message is issued at the IMS master terminal:

```
DSNM004I  RESOLVE INDOUBT ENTRY(S) ARE OUTSTANDING FOR  
          SUBSYSTEM xxxx
```

When this message is issued, IMS was either cold started or it was started with an incomplete log tape. This message could also be issued if DB2 or IMS had an abend due to a software error or other subsystem failure.

*System action:*

- The connection remains active.
- IMS applications can still access DB2 databases.
- Some DB2 resources remain locked out.

If the indoubt thread is not resolved, the IMS message queues can start to back up. If the IMS queues fill to capacity, IMS terminates. Therefore, users must be aware of this potential difficulty and must monitor IMS until the indoubt units of work are fully resolved.

**System programmer action:**

1. Force the IMS log closed using /DBR FEOV, and then archive the IMS log. Use the command DFSERA10 to print the records from the previous IMS log tape for the last transaction processed in each dependent region. Record the PSB and the commit status from the X'37' log containing the recovery ID.
2. Run the DL/I batch job to back out each PSB involved that has not reached a commit point. The process might take some time because transactions are still being processed. It might also lock up a number of records, which could impact the rest of the processing and the rest of the message queues.
3. Enter the DB2 command DISPLAY THREAD (*imsid*) TYPE (INDOUBT).
4. Compare the NIDs (IMSID + OASN in hexadecimal) displayed in the DISPLAY THREAD messages with the OASNs (4 bytes decimal) shown in the DFSERA10 output. Decide whether to commit or roll back.
5. Use DFSERA10 to print the X'5501FE' records from the current IMS log tape. Every unit of recovery that undergoes indoubt resolution processing is recorded; each record with an 'IDBT' code is still indoubt. Note the correlation ID and the recovery ID, because they will be used during step 6.
6. Enter the following DB2 command, choosing to commit or roll back, and specifying the correlation ID:  
`-RECOVER INDOUBT (imsid) ACTION(COMMIT|ABORT) NID (nid)`

If the command is rejected because there are more network IDs associated, use the same command again, substituting the recovery ID for the network ID.

(For a description of the OASN and the NID, see "Duplicate correlation IDs" on page 396.)

**Operator action:** Contact the system programmer.

## Problem 2

Committed units of recovery should be aborted. At the time IMS connects to DB2, DB2 has committed one or more indoubt units of recovery that IMS says should be rolled back.

**Symptom:** By DB2 restart time, DB2 has committed and rolled back those units of recovery about which DB2 was not indoubt. DB2 records those decisions, and at connect time, verifies that they are consistent with the IMS/TM decisions.

An inconsistency can occur when the DB2 RECOVER INDOUBT command is used before IMS attempted to reconnect. If this happens, the following message is issued at the IMS master terminal:

```
DSNM005I  IMS/TM RESOLVE INDOUBT PROBLEM WITH  
          SUBSYSTEM xxxx
```

Because DB2 tells IMS to retain the inconsistent entries, the following message is issued when the resolution attempt ends:

```
DFS3602I  xxxx SUBSYSTEM RESOLVE-INDOUBT FAILURE,  
          RC=yyyy
```

**System action:**

- The connection between DB2 and IMS remains active.
- DB2 and IMS continue processing.
- No DB2 locks are held.
- No units of work are in an incomplete state.

**System programmer action:** Do not use the DB2 command RECOVER INDOUBT. The problem is that DB2 was *not* indoubt but should have been.

Database updates have most likely been committed on one side (IMS or DB2) and rolled back on the other side. (For a description of the OASN and the NID, see “Duplicate correlation IDs” on page 396.)

1. Enter the IMS command /DISPLAY OASN SUBSYS DB2 to display the IMS list of units of recovery that need to be resolved. The /DISPLAY OASN SUBSYS DB2 command produces the OASNs in a decimal format, not a hexadecimal format.
2. Issue the IMS command /CHANGE SUBSYS DB2 RESET to reset all the entries in the list. (No entries are passed to DB2.)
3. Use DFSERA10 to print the log records recorded at the time of failure and during restart. Look at the X'37', X'56', and X'5501FE' records at reconnect time. Notify the IBM support center about the problem.
4. Determine what the inconsistent unit of recovery was doing by using the log information, and manually make the DL/I and DB2 databases consistent.

**Operator action:** None.

## IMS application failure recovery

This section describes two different problems.

### Problem 1

An IMS application abends.

**Symptom:** The following messages appear at the IMS master terminal and at the LTERM that entered the transaction involved:

```
DFS555 - TRAN ttttttt ABEND (SYSIDssss);  
          MSG IN PROCESS: xxxx (up to 78 bytes of data) timestamp  
DFS555A - SUBSYSTEM xxxx OASN yyyyyyyyyyyyyyy STATUS COMMIT|ABORT
```

**System action:**

The failing unit of recovery is backed out by both DL/I and DB2.  
The connection between IMS and DB2 remains active.

**System programmer action:** None.

**Operator action:** If you think the problem was caused by a user error, refer to Part 2 of *DB2 Application Programming and SQL Guide*. For procedures to diagnose DB2 problems, rather than user errors, refer to Part 3 of *DB2 Diagnosis Guide and Reference*. If necessary, contact the IBM support center for assistance.

### Problem 2

DB2 has failed or is not running.

**Symptom:** One of the following status situations exists:

- If you specified error option Q, the program terminates with a U3051 user abend completion code.

- If you specified error option A, the program terminates with a U3047 user abend completion code.

In both cases, the master terminal receives a message (IMS message number DFS554), and the terminal involved also receives a message (DFS555).

*System action:* None.

*System programmer action:* None.

*Operator action:*

1. Restart DB2.
2. Follow the standard IMS procedures for handling application abends.

---

## CICS-related failure recovery

This section includes scenarios for problems that can be encountered in the CICS environment:

“CICS application failure recovery”

“Recovery when CICS is not operational”

“Recovery when CICS cannot connect to DB2” on page 530

“Manually recovering CICS indoubt units of recovery” on page 531

“CICS attachment facility failure recovery” on page 534

DB2 can be used in an XRF (Extended Recovery Facility) recovery environment with CICS. See “Extended recovery facility (XRF) toleration” on page 476 for more information about using XRF with CICS.

## CICS application failure recovery

*Problem:* A CICS application abends.

*Symptom:* The following message is sent to the user’s terminal.

```
DFH2206 TRANSACTION transid ABEND abcode BACKOUT SUCCESSFUL
```

*transid* can represent any abending CICS transaction and *abcode* is the abend code.

*System action:*

The failing unit of recovery is backed out in both CICS and DB2.  
The connection remains.

*System programmer action:* None.

*Operator action:*

1. For information about the CICS attachment facility abend, refer to Part 2 of *DB2 Messages*.
2. For an *AEY9* abend, start the CICS attachment facility.
3. For an *ASP7* abend, determine why the CICS SYNCPOINT was unsuccessful.
4. For other abends, see *DB2 Diagnosis Guide and Reference* or *CICS Transaction Server for z/OS Problem Determination Guide* for diagnostic procedures.

## Recovery when CICS is not operational

*Problem:* CICS is not operational.

*Symptom:* More than one symptom is possible.

- CICS waits or loops.  
Because DB2 cannot detect a wait or loop in CICS, you must find the origin of the wait or the loop. The origin can be in CICS, CICS applications, or in the CICS attachment facility. For diagnostic procedures for waits and loops, see Part 2 of *DB2 Diagnosis Guide and Reference*.
- CICS abends.
  - CICS issues messages indicating an abend occurred and requests abend dumps of the CICS region. See *CICS Transaction Server for z/OS Problem Determination Guide* for more information.
  - If threads are connected to DB2 when CICS terminates, DB2 issues message DSN3201I. The message indicates that DB2 end-of-task (EOT) routines have been run to clean up and disconnect any connected threads.

**System action:** DB2 performs each of the following actions:

- Detects the CICS failure.
- Backs out inflight work.
- Saves indoubt units of recovery to be resolved when CICS is reconnected.

**Operator action:**

1. Correct the problem that caused CICS to terminate abnormally.
2. Do an emergency restart of CICS. The emergency restart performs each of the following actions:
  - Backs out inflight transactions that changed CICS resources
  - Remembers the transactions with access to DB2 that might be indoubt.
3. Start the CICS attachment facility by entering the appropriate command for your release of CICS. See “Connecting from CICS” on page 388. The CICS attachment facility performs the following actions:
  - Initializes and reconnects to DB2.
  - Requests information from DB2 about the indoubt units of recovery and passes the information to CICS.
  - Allows CICS to resolve the indoubt units of recovery.

## Recovery when CICS cannot connect to DB2

**Problem:** The CICS attachment facility cannot connect to DB2.

**Symptom:**

- CICS remains operative, but the CICS attachment facility abends.
- The CICS attachment facility issues a message giving the reason for the connection failure, or it requests an X'04E' dump.
- The reason code in the X'04E' dump gives the reason for failure.
- CICS issues message DFH2206 indicating that the CICS attach facility has terminated abnormally with the DSNB abend code.
- CICS application programs trying to access DB2 while the CICS attachment facility is inactive are abnormally terminated. The code AEY9 is issued.

**System Action:** CICS backs out the abnormally terminated transaction and treats it like an application abend.

**Operator action:**

1. Start the CICS attachment facility by entering the appropriate command for your release of CICS. See “Connecting from CICS” on page 388.

2. The CICS attachment facility initializes and reconnects to DB2.
3. The CICS attachment facility requests information about the indoubt units of recovery and passes the information to CICS.
4. CICS resolves the indoubt units of recovery.

## Manually recovering CICS indoubt units of recovery

When the attachment facility abends, CICS and DB2 build indoubt lists either dynamically or during restart, depending on the failing subsystem.

For CICS, a DB2 unit of recovery could be indoubt if the forget entry (X'FD59') of the task-related installation exit is absent from the CICS system journal. The indoubt condition applies only to the DB2 UR, because CICS will have already committed or backed out any changes to its resources.

A DB2 unit of recovery is indoubt for DB2 if an End Phase 1 is present and the Begin Phase 2 is absent.

**Problem:** When CICS connects to DB2, there are one or more indoubt units of recovery that have not been resolved.

**Symptom:** One of the following messages is sent to the user-named CICS destination specified in the ERRDEST field in the resource control table (RCT): DSN2001I, DSN2034I, DSN2035I, or DSN2036I.

**System action:** The system action is summarized in Table 99:

Table 99. CICS abnormal indoubt unit of recovery situations

Message ID	Meaning
DSN2001I	The named unit of recovery cannot be resolved by CICS because CICS was cold started. The CICS attachment facility continues the startup process.
DSN2034I	The named unit of recovery is not indoubt for DB2, but is indoubt according to CICS log information. The reason is probably a CICS restart with the wrong tape. It could also be caused by a DB2 restart to a prior point in time.
DSN2035I	The named unit of recovery is indoubt for DB2, but is not in the CICS indoubt list. This is most likely due to an incorrect CICS restart. The CICS attachment facility continues the startup process and provides a transaction dump. It could also be caused by a DB2 restart to a prior point in time.
DSN2036I	CICS indicates roll back for the named unit of recovery, but DB2 has already committed the unit of recovery. The CICS attachment facility continues the startup process.

CICS retains details of indoubt units of recovery that were not resolved during connection start up. An entry is purged when it no longer appears on the list presented by DB2 or, when present, DB2 solves it.

**System programmer action:** Any indoubt unit of recovery that CICS cannot resolve must be resolved manually by using DB2 commands. This manual procedure should be used rarely within an installation, because it is required only where operational errors or software problems have prevented automatic resolution. *Any inconsistencies found during indoubt resolution must be investigated.*

To recover an indoubt unit, follow these steps:

**Step 1: Obtain a list of the indoubt units of recovery from DB2:**

Issue the following command:

```
-DISPLAY THREAD (connection-name) TYPE (INDOUBT)
```

You will receive the following messages:

```
DSNV401I - DISPLAY THREAD REPORT FOLLOWS -  
DSNV406I - INDOUBT THREADS -  
COORDINATOR      STATUS      RESET  URID          AUTHID  
coordinator-name status      yes/no urid          authid  
DISPLAY INDOUBT REPORT COMPLETE  
DSN9022I - DSNVDT '-DISPLAY THREAD' NORMAL COMPLETION
```

The *corr\_id* (correlation ID) for CICS Transaction Server for z/OS 1.1 and previous releases of CICS consists of:

**Byte 1** Connection type: G = group, P = pool

**Byte 2** Thread type: T = transaction (TYPE=ENTRY), G = group, C = command (TYPE=COMD)

**Bytes 3, 4**  
Thread number

**Bytes 5 - 8**  
Transaction ID

The *corr\_id* (correlation ID) for CICS Transaction Server for z/OS 1.2 and subsequent releases of CICS consists of:

**Bytes 1 - 4**  
Thread type: COMD, POOL, or ENTR

**Bytes 5 - 8**  
Transaction ID

**Bytes 9 - 12**  
Unique thread number

Two threads can sometimes have the same correlation ID when the connection has been broken several times and the indoubt units of recovery have not been resolved. In this case, the network ID (NID) must be used instead of the correlation ID to uniquely identify indoubt units of recovery.

The network ID consists of the CICS connection name and a unique number provided by CICS at the time the syncpoint log entries are written. This unique number is an 8-byte store clock value that is stored in records written to both the CICS system log and to the DB2 log at syncpoint processing time. This value is referred to in CICS as the *recovery token*.

**Step 2: Scan the CICS log for entries related to a particular unit of recovery:** To do this, search the CICS log, looking for a PREPARE record (JCRSTRIDX'F959'), for the task-related installation where the recovery token field (JCSRMTKN) equals the value obtained from the network-ID. The network ID is supplied by DB2 in the DISPLAY THREAD command output.

Locating the prepare log record in the CICS log for the indoubt unit of recovery provides the CICS task number. All other entries on the log for this CICS task can be located using this number.

CICS journal print utility DFHJUP can be used when scanning the log. See *CICS Transaction Server for z/OS Operations and Utilities Guide* for details on how to use this program.

**Step 3: Scan the DB2 log for entries related to a particular unit of recovery:** To do this, scan the DB2 log to locate the End Phase 1 record with the network ID required. Then use the URID from this record to obtain the rest of the log records for this unit of recovery.

When scanning the DB2 log, note that the DB2 start up message DSNJ099I provides the start log RBA for this session.

The DSN1LOGP utility can be used for that purpose. See Part 3 of *DB2 Utility Guide and Reference* for details on how to use this program.

**Step 4: If needed, do indoubt resolution in DB2:** DB2 can be directed to take the recovery action for an indoubt unit of recovery using a DB2 RECOVER INDOUBT command. Where the correlation ID is unique, use the following command:

```
DSNC -RECOVER INDOUBT (connection-name)
          ACTION (COMMIT/ABORT)
          ID (correlation-id)
```

If the transaction is a pool thread, use the value of the correlation ID (*corr\_id*) returned by DISPLAY THREAD for *thread#.tranid* in the command RECOVER INDOUBT. In this case, the first letter of the correlation ID is P. The transaction ID is in characters five through eight of the correlation ID.

If the transaction is assigned to a group (group is a result of using an entry thread), use *thread#.groupname* instead of *thread#.tranid*. In this case, the first letter of the correlation ID is a G and the group name is in characters five through eight of the correlation ID. *groupname* is the first transaction listed in a group.

Where the correlation ID is not unique, use the following command:

```
DSNC -RECOVER INDOUBT (connection-name)
          ACTION (COMMIT/ABORT)
          NID (network-id)
```

When two threads have the same correlation ID, use the NID keyword instead of the ID keyword. The NID value uniquely identifies the work unit.

To recover all threads associated with *connection-name*, omit the ID option.

The command results that are in either of the following messages to indicate whether the thread is committed or rolled back:

```
DSNV414I - THREAD thread#.tranid COMMIT SCHEDULED
DSNV415I - THREAD thread#.tranid ABORT SCHEDULED
```

When performing indoubt resolution, note that CICS and the attachment facility are not aware of the commands to DB2 to commit or abort indoubt units of recovery, because only DB2 resources are affected. However, CICS keeps details

about the indoubt threads that could not be resolved by DB2. This information is purged either when the list presented is empty, or when the list does not include a unit of recovery that CICS remembers.

*Operator action:* Contact the system programmer.

## CICS attachment facility failure recovery

*Problem:* The CICS attachment facility abends, or a CICS attachment thread subtask abends. CICS and DB2 remain active.

*Symptom:*

- If the main subtask abends, an abend dump is requested. The contents of the dump indicate the cause of the abend. When the dump is issued, shutdown of the CICS attachment facility begins.
- If a thread subtask terminates abnormally, an X'04E' dump is issued and the CICS application abends with a DSNB dump code. The X'04E' dump should show the cause of the abend. The CICS attachment facility remains active.

*System action:*

- The CICS attachment facility shuts down if there is a main subtask abend.
- The matching CICS application abends with a DSNB dump code if a thread subtask abends.

*System programmer action:* None.

*Operator action:* Correct the problem that caused the abend by analyzing the CICS formatted transaction dump or subtask SNAP dump. For more information about analyzing these dumps, see Part 2 of *DB2 Messages*. If the CICS attachment facility shuts down, use CICS commands to stop the execution of any CICS-DB2 applications.

---

## Subsystem termination recovery

*Problem:* Subsystem termination has been started by DB2 or by an operator cancel.

*Symptom:* Subsystem termination occurs. Usually some specific failure is identified by DB2 messages, and the following messages appear.

On the z/OS console:

```
DSNV086E - DB2 ABNORMAL TERMINATION REASON=XXXXXXXXX
DSN3104I - DSN3EC00 - TERMINATION COMPLETE
DSN3100I - DSN3EC00 - SUBSYSTEM ssnm READY FOR -START COMMAND
```

On the IMS master terminal:

```
DSNM002I  IMS/TM xxxx DISCONNECTED FROM SUBSYSTEM
          yyyy RC=rc
```

On the CICS transient data error destination defined in the RCT:

```
DSNC2025I - THE ATTACHMENT FACILITY IS INACTIVE
```

*System action:*

- IMS and CICS continue.
- In-process CICS and IMS applications receive SQLCODE -923 (SQLSTATE '57015') when accessing DB2.

In most cases, if an IMS or CICS application program is running when a -923 SQLCODE is returned, an abend occurs. This is because the application program generally terminates when it receives a -923 SQLCODE. To terminate, some synchronization processing occurs (such as a commit). If DB2 is not operational when synchronization processing is attempted by an application program, the application program abends. In-process applications can abend with an abend code X'04F'.

- New IMS applications are handled according to the error options.
  - For option R, SQL return code -923 is sent to the application, and IMS pseudo abends.
  - For option Q, the message is enqueued again and the transaction abends.
  - For option A, the message is discarded and the transaction abends.
- New CICS applications are handled as follows:
  - If the CICS attachment facility has not terminated, the application receives a -923 SQLCODE.
  - If the CICS attachment facility has terminated, the application abends (code AEY9).

***Operator action:***

1. Restart DB2 by issuing the command START DB2.
2. Reestablish the IMS connection by issuing the IMS command /START SUBSYS DB2.
3. Reestablish the CICS connection by issuing the CICS attachment facility command DSNCLSTR.

***System programmer action:***

1. Use the IFCEREP1 service aid to obtain a listing of the SYS1.LOGREC data set containing the SYS1.LOGREC entries. (For more information about this service aid, refer to the z/OS diagnostic techniques publication about SYS1.LOGREC.)
2. If the subsystem termination was due to a failure, collect material to determine the reason for failure (console log, dump, and SYS1.LOGREC).

---

## Resource failure recovery

This section includes scenarios for problems that can be encountered in the DB2 environment:

- “Active log failure recovery”
- “Archive log failure recovery” on page 539
- “BSDS failure recovery” on page 542
- “Recovering the BSDS from a backup copy” on page 543

### Active log failure recovery

This section covers some of the more likely active log problems. The following problems are not covered in this section:

- Active log dynamic allocation problems are indicated by message DSNJ103I at startup time.
- Active log open/close problems are indicated by message DSNJ104I.

See Chapter 23, “Recovery from BSDS or log failure during restart,” on page 597 for more information about correcting problems that result in a DSNJ103I or a DSNJ104I message.

## Problem 1 - Out of space in active logs

The available space in the active log is finite and can be exhausted. It can fill to capacity for one of several reasons, such as delays in offloading and excessive logging.

**Symptom:** An out of space condition on the active log has very serious consequences. When the active log becomes full, the DB2 subsystem cannot do any work that requires writing to the log until an offload is completed.

Due to the serious implications of this event, the DB2 subsystem issues the following warning message when the last available active log data set is 5% full and reissues the message after each additional 5% of the data set space is filled. Each time the message is issued, the offload process is started. IFCID trace record 0330 is also issued if statistics class 3 is active.

```
DSNJ110E - LAST COPYn ACTIVE LOG DATA SET IS nnn PERCENT FULL
```

If the active log fills to capacity, after having switched to single logging, the following message is issued, and an offload is started. The DB2 subsystem then halts processing until an offload has completed.

```
DSNJ111E - OUT OF SPACE IN ACTIVE LOG DATA SETS
```

Corrective action is required before DB2 can continue processing.

**System action:** DB2 waits for an available active log data set before resuming normal DB2 processing. Normal shutdown, with either QUIESCE or FORCE, is not possible because the shutdown sequence requires log space to record system events related to shutdown (for example, checkpoint records).

**Operator action:** Make sure offload is not waiting for a tape drive. If it is, mount a tape and DB2 will process the offload command.

If you are uncertain about what is causing the problem, enter the following command:

```
-ARCHIVE LOG CANCEL OFFLOAD
```

This command causes DB2 to restart the offload task. This might solve the problem.

If this command does not solve the problem, you must determine the cause of the problem and then reissue the command again. If the problem cannot be solved quickly, have the system programmer define additional active logs.

**System programmer action:** Additional active log data sets can permit DB2 to continue its normal operation while the problem causing the offload failures is corrected.

1. Use the z/OS command CANCEL command to bring DB2 down.
2. Use the access method services DEFINE command to define new active log data sets. Run utility DSNJLOGF to initialize the new active log data sets.  
To minimize the number of offloads taken per day in your installation, consider increasing the size of the active log data sets.
3. Define the new active log data sets in the BSDS by using the change log inventory utility (DSNJU003). For additional details, see Part 3 of *DB2 Utility Guide and Reference*.

- Restart DB2. Offload is started automatically during startup, and restart processing occurs.

### **Problem 2 - Write I/O error on active log data set**

*Symptom:* The following message appears:

```
DSNJ105I - csect-name LOG WRITE ERROR DSNAME=..., LOGRBA=...,  
          ERROR STATUS=ccccffss
```

*System action:*

- Marks the failing log data set TRUNCATED in the BSDS.
- Goes on to the next available data set.
- If dual active logging is used, truncates the other copy at the same point.
- The data in the truncated data set is offloaded later, as usual.
- The data set is not stopped. It is reused on the next cycle. However, if there is a DSNJ104 message indicating that there is a CATUPDT failure, then the data set is marked “stopped”.

*System programmer action:* If you get the DSNJ104 message indicating CATUPDT failure, you must use access method services and the change log inventory utility (DSNJU003) to add a replacement data set. This requires that you bring DB2 down. When you do this depends on how widespread the problem is.

- If the problem is localized and does not affect your ability to recover from any further problems, you can wait until the earliest convenient time.
- If the problem is widespread (perhaps affecting an entire set of active log data sets), take DB2 down after the next offload.

For instructions on using the change log inventory utility, see Part 3 of *DB2 Utility Guide and Reference*.

### **Problem 3 - Dual logging is lost**

*Symptom:* The following message appears:

```
DSNJ004I - ACTIVE LOG COPYn INACTIVE, LOG IN SINGLE MODE,  
          ENDRBA=...
```

Having completed one active log data set, DB2 found that the subsequent (COPY n) data sets were not offloaded or were marked “stopped”.

*System action:* Continues in single mode until offloading completes, then returns to dual mode. If the data set is marked “stopped”, however, then intervention is required.

*System programmer action:* Check that offload is proceeding and is not waiting for a tape mount. It might be necessary to run the print log map utility to determine the status of all data sets.

If there are “stopped” data sets, you must use IDCAMS to delete the data sets, and then re-add them using the change log inventory utility (DSNJU003). See Part 3 of *DB2 Utility Guide and Reference* for information about using the change log inventory utility.

### **Problem 4 - I/O errors while reading the active log**

*Symptom:* The following message appears:

```
DSNJ106I - LOG READ ERROR DSNAME=..., LOGRBA=...,  
          ERROR STATUS=ccccffss
```

*System action:*

- If the error occurs during offload, offload tries to pick the RBA range from a second copy.
  - If no second copy exists, the data set is stopped.
  - If the second copy also has an error, only the original data set that triggered the offload is stopped. Then the archive log data set is terminated, leaving a discontinuity in the archived log RBA range.
  - The following message is issued.
 

```
DSNJ124I - OFFLOAD OF ACTIVE LOG SUSPENDED FROM RBA xxxxxx
          TO RBA xxxxxx DUE TO I/O ERROR
```
  - If the second copy is satisfactory, the first copy is not stopped.
- If the error occurs during recovery, DB2 provides data from specific log RBAs requested from another copy or archive. If this is unsuccessful, recovery fails and the transaction cannot complete, but no log data sets are stopped. However, the table space being recovered is not accessible.

**System programmer action:** If the problem occurred during offload, determine which databases are affected by the active log problem and take image copies of those. Then proceed with a new log data set.

Also, you can use IDCAMS REPRO to archive as much of the stopped active log data set as possible. Then run the change log inventory utility to notify the BSDS of the new archive log and its log RBA range. Repairing the active log does not solve the problem, because offload does not go back to unload it.

If the active log data set has been stopped, it is not used for logging. The data set is not deallocated; it is still used for reading.

If the data set is not stopped, an active log data set should nevertheless be replaced if persistent errors occur. The operator is not told explicitly whether the data set has been stopped. To determine the status of the active log data set, run the print log map utility (DSNJU004). For more information about the print log map utility, see Part 3 of *DB2 Utility Guide and Reference*.

To replace the data set, take the following steps:

1. Be sure the data is saved.
  - If you have dual active logs, the data is saved on the other active log and it becomes your *new data set*. Skip to step 4 on page 539.
  - If you have not been using dual active logs, take the following steps to determine whether the data set with the error has been offloaded:
    - a. Use the print log map to list information about the archive log data sets from the BSDS.
    - b. Search the list for a data set whose RBA range includes the range of the data set with the error.
2. If the data set with the error has been offloaded (that is, if the value for High RBA offloaded in the print log map output is greater than the RBA range of the data set with the error), you need to manually add a new archive log to the BSDS using the change log inventory utility (DSNJU003). Use IDCAMS to define a new log having the same LRECL and BLKSIZE values as that defined in DSNZPxxx. You can use the access method services REPRO command to copy a data set with the error to the new archive log. If the archive log is not cataloged, DB2 can locate it from the UNIT and VOLSER values in the BSDS.
3. If an active log data set has been stopped, an RBA range has not been offloaded; copy from the data set with the error to a new data set. If additional

I/O errors prevent you from copying the entire data set, a gap occurs in the log and restart might fail, though the data still exists and is not overlaid. If this occurs, see Chapter 23, “Recovery from BSDS or log failure during restart,” on page 597.

4. Stop DB2, and use change log inventory to update information in the BSDS about the data set with the error.
  - a. Use DELETE to remove information about the bad data set.
  - b. Use NEWLOG to name the new data set as the new active log data set and to give it the RBA range that was successfully copied.

The DELETE and NEWLOG operations can be performed by the same job step; put the DELETE statement before the NEWLOG statement in the SYSIN input data set. This step will clear the stopped status and DB2 will eventually archive it.
5. Delete the data set in error by using access method services.
6. Redefine the data set so you can write to it. Use access method services DEFINE command to define the active log data sets. Run utility DSNJLOGF to initialize the active log data sets. If using dual logs, use access method services REPRO to copy the good log into the redefined data set so that you have two consistent, correct logs again.

## Archive log failure recovery

This section covers some of the more likely archive log problems. Problems not covered here include archive log open/close problems that are indicated by the message DSNJ104I. Most archive log problems are described in Chapter 23, “Recovery from BSDS or log failure during restart,” on page 597.

### Problem 1 - Allocation problems

*Symptom:* The following message appears:

```
DSNJ103I - csect-name LOG ALLOCATION ERROR DSNAME=dsname,  
ERROR STATUS=eeeeiii, SMS REASON CODE=sssssss
```

z/OS dynamic allocation provides the ERROR STATUS. If the allocation was for offload processing, the message is also displayed:

```
DSNJ115I - OFFLOAD FAILED, COULD NOT ALLOCATE AN ARCHIVE DATA SET
```

*System action:* One of the system actions occurs:

- The RECOVER utility is executing and requires an archive log. If neither log can be found or used, recovery fails.
- The active log became full and an offload was scheduled. Offload tries again the next time it is triggered. The active log does not wrap around; therefore, if there are no more active logs, data is not going to be lost.
- The input is needed for restart, which fails; refer to Chapter 23, “Recovery from BSDS or log failure during restart,” on page 597.

*Operator action:* Check the allocation error code for the cause of the problem and correct it. Ensure that drives are available and run the recovery job again. Caution must be exercised if a DFSMSdfp ACS user-exit filter has been written for an archive log data set, because this can cause the DB2 subsystem to fail on a device allocation error attempting to read the archive log data set.

## Problem 2 - Write I/O errors during archive log offload

**Symptom:** No specific DB2 message is issued for write I/O errors. Only a z/OS error recovery program message appears. If you get DB2 message DSNJ128I, the offload task has abended and you should consult Part 2 of *DB2 Messages*.

**System action:**

- Offload abandons that output data set (no entry in BSDS).
- Offload dynamically allocates a new archive and restarts offloading from the point at which it was previously triggered. If there is dual archiving, the second copy waits.
- If an error occurs on the new data set, the additional actions occur:
  - If in dual archive mode, message DSNJ114I is generated and the offload processing changes to single mode.  
DSNJ114I - ERROR ON ARCHIVE DATA SET, OFFLOAD CONTINUING  
WITH ONLY ONE ARCHIVE DATA SET BEING GENERATED
  - If in single mode, it abandons the output data set. Another attempt to offload this RBA range is made the next time offload is triggered.
  - The active log does not wrap around; if there are no more active logs, data is not lost.

**Operator action:** Ensure that offload is allocated on a good drive and control unit.

## Problem 3 - Read I/O errors on archive data set during recover

**Symptom:** No specific DB2 message is issued, only the z/OS error recovery program message appears.

**System action:**

- If a second copy exists, it is allocated and used.
- If a second copy does not exist, recovery fails.

**Operator action:** If you are recovering from tape, try recovering using a different drive. If this does not work, contact the system programmer.

**System programmer action:** The only option is to recover to the last image copy or the last quiesce point RBA. See Part 2 of *DB2 Utility Guide and Reference* for more information about using the RECOVER utility.

## Problem 4 - Insufficient disk space for offload processing

**Symptom:** While offloading the active log data sets to disk, DB2 offload processing terminates unexpectedly. DB2 does not issue any specific message other than:

DSNJ128I - LOG OFFLOAD TASK FAILED FOR ACTIVE LOG nnnnn

The failure is preceded by z/OS ABEND messages IEC030I, IEC031I, or IEC032I.

**System action:** DB2 deallocates the data set on which the error occurred. If in dual archive mode, DB2 changes to single archive mode and continues the offload. If the offload cannot complete in single archive mode, the active log data sets cannot be offloaded, and the status of the active log data sets remains NOTREUSEABLE. Another attempt to offload the RBA range of the active log data sets is made the next time offload is invoked.

**System programmer action:** If DB2 is operating with restricted active log resources (see message DSNJ110E), quiesce the DB2 subsystem to restrict logging activity until the z/OS ABEND is resolved.

This message is generated for a variety of reasons. When accompanied by the preceding z/OS abends, the most likely failures are as follows:

- The size of the archive log data set is too small to contain the data from the active log data sets during offload processing. All secondary space allocations have been used. This condition is normally accompanied by z/OS ABEND message IEC030I.

To solve the problem, increase the primary or secondary allocations (or both) for the archive log data set in DSNZPxxx. Another option is to reduce the size of the active log data set. If the data to be offloaded is particularly large, you can mount another online storage volume or make one available to DB2. Modifications to DSNZPxxx require that you stop and start DB2 to take effect.

- All available space on the disk volumes to which the archive data set is being written has been exhausted. This condition is normally accompanied by z/OS ABEND message IEC032I.

To solve the problem, make space available on the disk volumes, or make available another online storage volume for DB2. Then issue the DB2 command ARCHIVE LOG CANCEL OFFLOAD to get DB2 to retry the offload.

- The primary space allocation for the archive log data set (as specified in the load module for subsystem parameters) is too large to allocate to any available online disk device. This condition is normally accompanied by z/OS ABEND message IEC032I.

To solve the problem, make space available on the disk volumes, or make available another online storage volume for DB2. If this is not possible, an adjustment to the value of PRIQTY in the DSNZPxxx module is required to reduce the primary allocation. (For instructions, see Part 2 of *DB2 Installation Guide*. If the primary allocation is reduced, the size of the secondary space allocation might have to be increased to avoid future IEC030I abends.

## Temporary resource failure recovery

DB2 sometimes experiences a temporary problem when it accesses log data sets. For example, DB2 might experience a problem when it attempts to allocate or open archive log data sets during the rollback of a long-running unit of recovery. These temporary failures can be caused by:

- A temporary problem with DFHSM recall
- A temporary problem with the tape subsystem
- Uncataloged archive logs
- Archive tape mount requests being canceled

In these cases, DB2 issues messages for the access failure for each log data set. These messages provide information needed to resolve the access error. For example:

```
DSNJ104I ( DSNJR206 RECEIVED ERROR STATUS 00000004
          FROM DSNPCLOC FOR DSNAME=DSNC710.ARCHLOG1.A0000049
DSNJ104I ( DSNJR206 RECEIVED ERROR STATUS 00000004
          FROM DSNPCLOC FOR DSNAME=DSNC710.ARCHLOG2.A0000049
*DSNJ153E ( DSNJR006 CRITICAL LOG READ ERROR
          CONNECTION-ID = TEST0001
          CORRELATION-ID = CTHDCORID001
          LUWID = V71A.SYEC1DB2.B3943707629D=10
          REASON-CODE = 00D10345
```

You can attempt to recover from temporary failures by issuing a positive reply to message:

```
*26 DSNJ154I ( DSNJR126 REPLY Y TO RETRY LOG READ REQUEST, N TO ABEND
```

If the problem persists, quiesce other work in the system before replying N, which terminates DB2.

## BSDS failure recovery

For information about the BSDS, see “Managing the bootstrap data set (BSDS)” on page 441. Normally, there are two copies of the BSDS; but if one is damaged, DB2 immediately falls into single BSDS mode processing. The damaged copy of the BSDS must be recovered prior to the next restart. If you are in single mode and damage the only copy of the BSDS, or if you are in dual mode and damage both copies, DB2 stops until the BSDS is recovered. To proceed under these conditions, see “Recovering the BSDS from a backup copy” on page 543.

This section covers some of the BSDS problems that can occur. Problems not covered here include:

- RECOVER BSDS command failure (messages DSNJ301I through DSNJ307I)
- Change log inventory utility failure (message DSNJ123E)
- Errors in the BSDS backup being dumped by offload (message DSNJ125I).

See Part 2 of *DB2 Messages* for information about those problems.

### Problem 1 - An I/O error occurs

*Symptom:* The message appears:

```
DSNJ126I - BSDS ERROR FORCED SINGLE BSDS MODE
```

It is followed by one of these messages:

```
DSNJ107I - READ ERROR ON BSDS  
          DSNAME=... ERROR STATUS=...
```

```
DSNJ108I - WRITE ERROR ON BSDS  
          DSNAME=... ERROR STATUS=...
```

*System action:* The BSDS mode changes from dual to single.

*System programmer action:*

1. Use access method services to rename or delete the damaged BSDS and to define a new BSDS with the same name as the failing BSDS. Control statements can be found in job DSNTIJIN.
2. Issue the DB2 command RECOVER BSDS to make a copy of the good BSDS in the newly allocated data set and to reinstate dual BSDS mode.

### Problem 2 - An error occurs while opening

*Symptom:* The message appears:

```
DSNJ100I - ERROR OPENING BSDSn DSNAME=..., ERROR STATUS=eeii
```

The error status is VSAM return code/feedback. For information about VSAM codes, refer to *z/OS DFSMS: Macro Instructions for Data Sets*.

*System action:* None.

*System programmer action:*

1. Use access method services to delete or rename the damaged data set, to define a replacement data set, and to copy the remaining BSDS to the replacement with the REPRO command.
2. Use the command START DB2 to start the DB2 subsystem.

### Problem 3 - Unequal timestamps exist

*Symptom:* The following message appears:

```
DSNJ120I - DUAL BSDS DATA SETS HAVE UNEQUAL TIMESTAMPS,  
          BSDS1 SYSTEM=..., UTILITY=..., BSDS2 SYSTEM=..., UTILITY=...
```

Unequal timestamps can occur for the following reasons:

- One of the volumes containing the BSDS has been restored. All information of the restored volume is down-level. If the volume contains any active log data sets or DB2 data, their contents are also down-level. The down-level volume has the lower timestamp.

For information about resolving this problem, see “Failure during a log RBA read request” on page 615.

- Dual BSDS mode has degraded to single BSDS mode, and you are trying to start without recovering the bad BSDS.
- The DB2 subsystem abended after updating one copy of the BSDS, but prior to updating the second copy.

*System action:* DB2 attempts to resynchronize the BSDS data sets and restore dual BSDS mode. If this attempt succeeds, DB2 restart continues automatically.

*Operator action:* If DB2 restart fails, notify the system programmer.

*System programmer action:* If DB2 fails to automatically resynchronize the BSDS data sets, perform the following procedure:

1. Run the print log map utility (DSNJU004) on both copies of the BSDS; compare the lists to determine which copy is accurate or current.
2. Rename the down-level data set and define a replacement for it.
3. Copy the good data set to the replacement data set, using the REPRO command of access method services.
4. Use access method services REPRO to copy the current version of the active log to the down-level data set if all the following conditions are true:
  - The problem was caused by a restored down-level BSDS volume.
  - The restored volume contains active log data.
  - You were using dual active logs on separate volumes.

If you were not using dual active logs, you must cold start the subsystem. (For this procedure, see “Failure resulting from total or excessive loss of log data” on page 619).

If the restored volume contains database data, use the RECOVER utility to recover that data after successful restart.

## Recovering the BSDS from a backup copy

If DB2 is operating in single BSDS mode and the BSDS is damaged, or if DB2 is operating in dual BSDS mode and both BSDSs are damaged, DB2 stops and does not restart until dual BSDS is restored. In this case, take the following steps:

1. Locate the BSDS associated with the most recent archive log data set. The data set name of the most recent archive log appears on the z/OS console in the last occurrence of message DSNJ003I, which indicates that offloading has successfully completed. In preparation for the rest of this procedure, it is a good practice to keep a log of all successful archives noted by that message.
  - If archive logs are on disk, the BSDS is allocated on any available disk. The BSDS name is like the corresponding archive log data set name; change only the first letter of the last qualifier, from A to B, as in the following example:

**Archive log name**

DSN.ARCHLOG1.A0000001

**BSDS copy name**

DSN.ARCHLOG1.B0000001

- If archive logs are on tape, the BSDS is the first data set of the first archive log volume. The BSDS is not repeated on later volumes.
- 2. If the most recent archive log data set has no copy of the BSDS (presumably because an error occurred when offloading it), then locate an earlier copy of the BSDS from an earlier offload.
- 3. Rename any *damaged* BSDS by using the access method services ALTER command with the NEWNAME option. If the decision is made to delete any damaged BSDS, use the access method services DELETE command. For each damaged BSDS, use access method services to define a new BSDS as a replacement data set. Job DSNTIJIN contains access method services control statements to define a new BSDS.

The BSDS is a VSAM key-sequenced data set that has three components: cluster, index, and data. You must rename *all* components of the data set. Avoid changing the high-level qualifier. See *z/OS DFSMS Access Method Services for Catalogs* for detailed information about using the access method services ALTER command.

4. Use the access method services REPRO command to copy the BSDS from the archive log to one of the replacement BSDSs you defined in step 3. Do not copy any data to the second replacement BSDS; data is placed in the second replacement BSDS in a later step in this procedure.
  - a. Print the contents of the replacement BSDS.

Use the print log map utility (DSNJU004) to print the contents of the replacement BSDS. This enables you to review the contents of the replacement BSDS before continuing your recovery work.
  - b. Update the archive log data set inventory in the replacement BSDS.

Examine the print log map output and note that the replacement BSDS does not obtain a record of the archive log from which the BSDS was copied. If the replacement BSDS is a particularly old copy, it is missing all archive log data sets that were created later than the BSDS backup copy. Thus, the BSDS inventory of the archive log data sets must be updated to reflect the current subsystem inventory.

Use the change log inventory utility (DSNJU003) NEWLOG statement to update the replacement BSDS, adding a record of the archive log from which the BSDS was copied. Make certain the CATALOG option of the NEWLOG statement is properly set to CATALOG = YES if the archive log data set is cataloged. Also, use the NEWLOG statement to add any additional archive log data sets that were created later than the BSDS copy.
  - c. Update DDF information in the replacement BSDS.

If your installation's DB2 is part of a distributed network, the BSDS contains the DDF control record. You must review the contents of this record in the output of the print log map utility. If changes are required, use the change log inventory DDF statement to update the BSDS DDF record.
  - d. Update the active log data set inventory in the replacement BSDS.

In unusual circumstances, your installation could have added, deleted, or renamed active log data sets since the BSDS was copied. In this case, the replacement BSDS does not reflect the actual number or names of the active log data sets your installation has currently in use.

If you must delete an active log data set from the replacement BSDS log inventory, use the change log inventory utility DELETE statement.

If you need to add an active log data set to the replacement BSDS log inventory, use the change log inventory utility NEWLOG statement. Be certain that the RBA range is specified correctly on the NEWLOG statement.

If you must rename an active log data set in the replacement BSDS log inventory, use the change log inventory utility DELETE statement, followed by the NEWLOG statement. Be certain that the RBA range is specified correctly on the NEWLOG statement.

- e. Update the active log RBA ranges in the replacement BSDS.

Later, when a restart is performed, DB2 compares the RBAs of the active log data sets listed in the BSDS with the RBAs found in the actual active log data sets. If the RBAs do not agree, DB2 does not restart. The problem is magnified when a particularly old copy of the BSDS is used. To resolve this problem, you can use the change log inventory utility to change the RBAs found in the BSDS to the RBAs in the actual active log data sets. Use the following procedure to change RBAs in the BSDS:

- If you are not certain of the RBA range of a particular active log data set, use DSN1LOGP to print the contents of the active log data set. Obtain the logical starting and ending RBA values for the active log data set from the DSN1LOGP output. The STARTRBA value you use in the change log inventory utility must be at the beginning of a control interval. Similarly, the ENDRBA value you use must be at the end of a control interval. To get these values, round the starting RBA value from the DSN1LOGP output down so that it ends in X'000'. Round the ending RBA value up so that it ends in X'FFF'.
- When the RBAs of all active log data sets are known, compare the actual RBA ranges with the RBA ranges found in the BSDS (listed in the print log map utility output).

If the RBA ranges are equal for all active log data sets, you can proceed to the next recovery step without any additional work.

If the RBA ranges are not equal, then the values in the BSDS must be adjusted to reflect the actual values. For each active log data set that needs to have the RBA range adjusted, use the change log inventory utility DELETE statement to delete the active log data set from the inventory in the replacement BSDS. Then use the NEWLOG statement to redefine the active log data set to the BSDS.

- f. If only two active log data sets are specified in the replacement BSDS, add a new active log data set for each copy of the active log and define each new active log data set of the replacement BSDS log inventory.

If only two active log data sets are specified for each copy of the active log, DB2 can have difficulty during restart. The difficulty can arise when one of the active log data sets is full and has not been offloaded, while the second active log data set is close to filling. Adding a new active log data set for each copy of the active log can alleviate difficulties on restart in this scenario.

To add a new active log data set for each copy of the active log, use the access method services DEFINE command to define a new active log data set for each copy of the active log. The control statements to accomplish this task can be found in job DSNTIJIN. Once the active log data sets are physically defined and allocated, use the change log inventory utility

NEWLOG statement to define the new active log data sets of the replacement BSDS. The RBA ranges need not be specified on the NEWLOG statement.

5. Copy the updated BSDS copy to the second new BSDS data set. The dual bootstrap data sets are now identical.  
You should consider using the print log map utility (DSNJU004) to print the contents of the second replacement BSDS at this point.
6. See Chapter 23, "Recovery from BSDS or log failure during restart," on page 597 for information about what to do if you have lost your current active log data set. For a discussion of how to construct a conditional restart record, see "Step 4: Truncate the log at the point of error" on page 607.
7. Restart DB2, using the newly constructed BSDS. DB2 determines the current RBA and what active logs need to be archived.

---

## DB2 database failures

**Problem:** Allocation or open problems occur.

**Symptom 1:** The following message indicates an allocation problem:

```
DSNB207I - DYNAMIC ALLOCATION OF DATA SET FAILED.  
          REASON=rrrr DSNAME=dsn
```

where *rrrr* is an z/OS dynamic allocation reason code. For information about these reason codes, see *z/OS MVS Programming: Authorized Assembler Services Guide*.

**Symptom 2:** The following messages indicate a problem at open:

```
IEC161I rc[(sfi)] - ccc, iii, sss, ddn,  
          ddd, ser, xxx, dsn, cat
```

where:

<i>rc</i>	Is a return code
<i>sfi</i>	Is subfunction information ( <i>sfi</i> only appears with certain return codes)
<i>ccc</i>	Is a function code
<i>iii</i>	Is a job name
<i>sss</i>	Is a step name
<i>ddn</i>	Is a <i>ddname</i>
<i>ddd</i>	Is a device number (if the error is related to a specific device)
<i>ser</i>	Is a volume serial number (if the error is related to a specific volume)
<i>xxx</i>	Is a VSAM cluster name
<i>dsn</i>	Is a data set name
<i>cat</i>	Is a catalog name.

For information about these codes, see *z/OS MVS System Messages Volumes 1-10*.

```
DSNB204I - OPEN OF DATA SET FAILED. DSNAME = dsn
```

**System action:**

- The table space is automatically stopped.
- Programs receive an -904 SQLCODE (SQLSTATE '57011').
- If the problem occurs during restart, the table space is marked for deferred restart, and restart continues. The changes are applied later when the table space is started.

**System programmer action:** None.

**Operator action:**

1. Check reason codes and correct.
2. Ensure that drives are available for allocation.
3. Enter the command START DATABASE.

---

## # Recovering a DB2 subsystem to a prior point in time

# You can recover a DB2 subsystem and data sharing group to a prior point in time  
# by using the BACKUP SYSTEM and RESTORE SYSTEM utilities.

# In this recovery procedure, you create and populate a table that contains data that  
# is both valid and invalid. You need to restore your DB2 subsystem to a point in  
# time before the invalid data was inserted into the table, but after the point in time  
# when the valid data was inserted. Also, you create an additional table space and  
# table that DB2 will re-create during the log-apply phase of the restore process.

# To insert data into a table, determine the point in time that you want to recover to,  
# and then recover the DB2 subsystem to a prior point in time:

- # 1. Issue the START DB2 command to start DB2 and all quiesced members of the  
# data sharing group. Quiesced members are ones that you removed from the  
# data sharing group either temporarily or permanently. Quiesced members  
# remain dormant until you restart them.
- # 2. Issue SQL statements to create a database, a table space, and two tables with  
# one index for each table.
- # 3. Issue the BACKUP SYSTEM DATA ONLY utility control statement to create a  
# backup copy of only the database copy pool for a DB2 subsystem or data  
# sharing group.
- # 4. Issue an SQL statement to first insert rows into one of the tables, and then  
# update some of the rows.
- # 5. Use the LOAD utility with the LOG NO attribute to load the second table.
- # 6. Issue SQL statements to create another table space, table, and index in an  
# existing database. DB2 will re-create the additional table space and table  
# during the log-apply phase of the restore process.
- # 7. Issue the SET LOG SUSPEND command or the SET LOG RESUME command  
# to obtain a log truncation point, *logpoint1*, which is the point you want to  
# recover to. For a non-data sharing group, use the RBA value. For a data  
# sharing group, use the lowest log record sequence number (LRSN) among the  
# active members.

# The following example shows sample output for the SET LOG SUSPEND  
# command:

```
# 09.47.52 @set log suspend
# 09.47.52 STC00066 DSN9022I @ DSNJC001 '-SET LOG' NORMAL COMPLETION
# *09.47.55 STC00066 *DSNJ372I @ DSNJC09A UPDATE ACTIVITY HAS BEEN
# *SUSPENDED FOR VA1A AT RBA 00004777B710, LRSN C31E5141E0C4, PRIOR
# *CHECKPOINT RBA 000047778090
```

- # 8. Issue an SQL statement to first insert rows into one of the tables and then to  
# update and delete some rows.
- # 9. Issue the STOP DB2 command to stop DB2 and all active members of the data  
# sharing group.
- # 10. Run the DSNJU003 change log inventory utility to create a SYSPITR CRCR  
# record (CRESTART CREATE SYSPITR=*logpoint1*). The log truncation point is the  
# value that you obtained from issuing either the SET LOG SUSPEND  
# command, or the SET LOG RESUME command.
- # 11. For a data sharing group, delete all of the coupling facility structures.

DSNB232I *csect-name* - UNEXPECTED DATA SET LEVEL ID ENCOUNTERED

The message contains also the level ID of the data set, the level ID that DB2 expects, and the name of the data set.

**System action:**

- If the error was reported during mainline processing, DB2 sends back a "resource unavailable" SQLCODE to the application and a reason code explaining the error.
- If the error was detected while a utility was processing, the utility gives a return code 8.

**System programmer action:** You can recover by using any of the following methods:

If the message occurs during restart:

- Replace the data set with one at the proper level, using DSN1COPY, DFSMSHsm, or some equivalent method. To check the level ID of the new data set, run the stand-alone utility DSN1PRNT on it, with the options PRINT(0) (to print only the header page) and FORMAT. The formatted print identifies the level ID.
- Recover the data set to the current time, or to a prior time, using the RECOVER utility.
- Replace the contents of the data set, using LOAD REPLACE.

If the message occurs during normal operation, use any of the preceding methods in addition to one of the following action:

- Accept the down-level data set by changing its level ID.  
The REPAIR utility contains a statement for that purpose. Run a utility job with the statement REPAIR LEVELID. The LEVELID statement cannot be used in the same job step with any other REPAIR statement.

**Important**

If you accept a down-level data set or disable down-level detection, your data might be inconsistent.

For more information about using the utilities, see *DB2 Utility Guide and Reference*.

You can control down-level detection. Use the LEVELID UPDATE FREQ field of panel DSNTIPL to either disable down-level detection or control how often the level ID of a page set or partition is updated. DB2 accepts any value between 0 and 32767.

To disable down-level detection, specify 0 in the LEVELID UPDATE FREQ field of panel DSNTIPL.

To control how often level ID updates are taken, specify a value between 1 and 32767. See Part 2 of *DB2 Installation Guide* for more information about choosing the frequency of level ID updates.

---

## Procedure for recovering invalid LOBs

Unless your LOBs are fairly small, specifying LOG NO for LOB objects is recommended. The performance cost of logging exceeds the benefits you can receive from logging such large amounts of data. If no changes are made to LOB data, this is not an issue. However, you should make image copies of the LOB table space to prepare for failures. The frequency with which you make image copies is based on how often you update LOB data.

If you need to recover LOB data that changed after your last image copy, follow this procedure:

1. Run the RECOVER utility as you do for other table spaces:

```
RECOVER TABLESPACE dbname.lobts
```

If changes were made after the image copy, DB2 puts the table space in *Aux Warning* status. The purpose of this status is let you know that some of your LOBs are invalid. Applications that try to retrieve the values of those LOBs will receive SQLCODE -904. Applications can still access other LOBs in the LOB table space.

2. Get a report of the invalid LOBs by running CHECK LOB on the LOB table space:

```
CHECK LOB TABLESPACE dbname.lobts
```

DB2 generates the following messages:

```
LOB WITH ROWID = 'xxxxxxx' VERSION = n IS INVALID
```

3. Fix the invalid LOBs, by updating the LOBs or setting them to the null value. For example, suppose you determine from the CHECK LOB utility that the row of the EMP\_PHOTO\_RESUME table with ROWID X'C1BDC4652940D40A81C201AA0A28' has an invalid value for column RESUME. If host variable hvlob contains the correct value for RESUME, you can use this statement to correct the value:

```
UPDATE DSN8810.EMP_PHOTO_RESUME  
  SET RESUME = :hvlob  
 WHERE EMP_ROWID = ROWID(X'C1BDC4652940D40A81C201AA0A28');
```

---

## Table space input/output error recovery

**Problem:** A table space failed.

**Symptom:** The following message is issued:

```
DSNU086I  DSNUCDA1 READ I/O ERRORS ON SPACE= ddddddd.  
          DATA SET NUMBER= nnn.  
          I/O ERROR PAGE RANGE= aaaaa, bbbbbb.
```

where *ddddddd* is a table space name.

Any table spaces identified in DSNU086I messages must be recovered using one of the procedures in this section listed under "Operator Action".

**System action:** DB2 remains active.

**Operator action:** Fix the error range.

1. Use the command STOP DATABASE to stop the failing table space.

2. Use the command START DATABASE ACCESS (UT) to start the table space for utility-only access.
3. Start a RECOVER utility step to recover the error range by using the DB2 RECOVER (ddddddd) ERROR RANGE statement.  
If you receive message DSNU086I again, indicating the error range recovery cannot be performed, use the recovery procedure that follows this procedure.
4. Issue the command START DATABASE to start the table space for RO or RW access, whichever is appropriate. If the table space is recovered, you do not need to continue with the following procedure.

**If error range recovery fails:** If the error range recovery of the table space failed because of a hardware problem, proceed as follows:

1. Use the command STOP DATABASE to stop the table space or table space partition that contains the error range. This causes all the in-storage data buffers associated with the data set to be externalized to ensure data consistency during the subsequent steps.
2. Use the INSPECT function of the IBM Device Support Facility, ICKDSF, to check for track defects and to assign alternate tracks as necessary. The physical location of the defects can be determined by analyzing the output of messages DSNB224I, DSNU086I, IOS000I, which were displayed on the system operator's console at the time the error range was created. If damaged storage media is suspected, then request assistance from hardware support personnel before proceeding. Refer to *Device Support Facilities User's Guide and Reference* for information about using ICKDSF.
3. Use the command START DATABASE to start the table space with ACCESS(UT) or ACCESS(RW).
4. Run the utility RECOVER ERROR RANGE that, from image copies, locates, allocates, and applies the pages within the tracks affected by the error ranges.

---

## DB2 catalog or directory input/output errors

**Problem:** The DB2 catalog or directory failed.

**Symptom:** The following message is issued:

```
DSNU086I  DSNUCDA1 READ I/O ERRORS ON SPACE= dddddddd.
          DATA SET NUMBER= nnn.
          I/O ERROR PAGE RANGE= aaaaaa, bbbbbb.
```

where *ddddddd* is a table space name from the catalog or directory. *ddddddd* is the table space that failed (for example, SYSCOPY, abbreviation for SYSIBM.SYSCOPY, or SYSLGRNX, abbreviation for DSNDB01.SYSLGRNX). This message can indicate either read or write errors. You can also get a DSNB224I or DSNB225I message, which could indicate an input or output error for the catalog or directory.

Any catalog or directory table spaces that are identified in DSNU086I messages must be recovered with this procedure.

**System action:** DB2 remains active.

If the DB2 directory or any catalog table is damaged, only user IDs with the RECOVERDB privilege in DSNDB06, or an authority that includes that privilege, can do the recovery. Furthermore, until the recovery takes place, only those IDs can do anything with the subsystem. If an ID without proper authorization

attempts to recover the catalog or directory, message DSNU060I is displayed. If the authorization tables are unavailable, message DSNT500I is displayed indicating the resource is unavailable.

*System programmer action:* None.

*Operator action:* Take the following steps for each table space in the DB2 catalog and directory that has failed. If there is more than one, refer to the description of RECOVER in Part 2 of *DB2 Utility Guide and Reference* for more information about the specific order of recovery.

1. Stop the failing table spaces.
  2. Determine the name of the data set that failed. There are two ways to do this:
    - Check *prefix*.SDSNSAMP (DSNTIJIN), which contains the JCL for installing DB2. Find the fully qualified name of the data set that failed by searching for the name of the table space that failed (the one identified in the message as SPACE = *ddddddd*).
    - Construct the data set name by performing one of the following actions:
      - If the table space is in the DB2 catalog, the data set name format is:  
DSNC810.DSNDBC.DSNDB06.*ddddddd*.I0001.A001  
where *ddddddd* is the name of the table space that failed.
      - If the table space is in the DB2 directory, the data set name format is:  
DSNC810.DSNDBC.DSNDB01.*ddddddd*.I0001.A001  
where *ddddddd* is the name of the table space that failed.
- If you do not use the default (IBM-supplied) formats, the formats for data set names can be different.
3. Use access method services DELETE to delete the data set, specifying the fully qualified data set name.
  4. After the data set has been deleted, use access method services DEFINE to redefine the same data set, again specifying the same fully qualified data set name. Use the JCL for installing DB2 to determine the appropriate parameters.  
**Important:** The REUSE parameter must be coded in the DEFINE statements.
  5. Issue the command START DATABASE ACCESS(UT), naming the table space involved.
  6. Use the RECOVER utility to recover the table space that failed.
  7. Issue the command START DATABASE, specifying the table space name and RO or RW access, whichever is appropriate.

---

## Integrated catalog facility failure recovery

This section includes information regarding volume data set failures. The following topics are described:

- “Recovery when the VSAM volume data set (VVDS) is destroyed”
- “Out of disk space or extent limit recovery” on page 554

### Recovery when the VSAM volume data set (VVDS) is destroyed

*Problem:* A VSAM volume data set (VVDS) is either out of space or destroyed.

*Symptom:* DB2 sends the following message to the master console:

```
DSNP012I - DSNPSC0 - ERROR IN VSAM CATALOG LOCATE FUNCTION
          FOR data_set_name
          CTLGRC=50
          CTLGRSN=zzzzRRRR
          CONNECTION-ID=xxxxxxx,
          CORRELATION-ID=yyyyyyyyyyyyy
          LUW-ID=logical-unit-of-work-id=token
```

For a detailed explanation of this message, see Part 2 of *DB2 Messages*.

VSAM can also issue the following message:

```
IDC3009I VSAM CATALOG RETURN CODE IS 50, REASON CODE IS
          IGGCLaa - yy
```

In this VSAM message, *yy* is 28, 30, or 32 for an out-of-space condition. Any other values for *yy* indicate a damaged VVDS.

**System action:** Your program is terminated abnormally and one or more messages are issued.

**System programmer action:** None.

**Operator action:** For information about recovering the VVDS, consult *z/OS DFSMS: Managing Catalogs*.

The procedures given in these books describe three basic recovery scenarios. First determine which scenario exists for the specific VVDS in error. Then, before beginning the appropriate procedure, take the following steps:

1. Determine the names of all table spaces residing on the same volume as the VVDS. To determine the table space names, look at the VTOC entries list for that volume, which indicates the names of all the data sets on that volume. For information about how to determine the table space name from the data set name, refer to Part 2, "Designing a database: advanced topics," on page 23.
2. Use the DB2 COPY utility to take image copies of all table spaces of the volume. Taking image copies minimizes reliance on the DB2 recovery log and can speed up the processing of the DB2 RECOVER utility (to be mentioned in a subsequent step).

If the COPY utility cannot be used, continue with this procedure. Be aware that processing time increases because more information is obtained from the DB2 recovery log.

3. Use the command STOP DATABASE for all the table spaces that reside on the volume, or use the command STOP DB2 to stop the entire DB2 subsystem if an unusually large number or critical set of table spaces are involved.
4. If possible, use access method services to export all non-DB2 data sets residing on that volume. For more information, see *DFSMS/MVS: Access Method Services for the Integrated Catalog* and *z/OS DFSMS: Managing Catalogs*.
5. To recover all non-DB2 data sets on the volume, see *DFSMS/MVS: Access Method Services for the Integrated Catalog* and *z/OS DFSMS: Managing Catalogs*.
6. Use access method services DELETE and DEFINE commands to delete and redefine the data sets for all user-defined table spaces and DB2-defined data sets when the physical data set has been destroyed. DB2 automatically deletes and redefines all other STOGROUP defined table spaces.

You do not need to do this for those table spaces that are STOGROUP defined; DB2 takes care of them automatically.

7. Issue the DB2 START DATABASE command to restart all the table spaces stopped in step 3 on page 553. If the entire DB2 subsystem was stopped, issue the START DB2 command.
8. Use the DB2 RECOVER utility to recover any table spaces and indexes. For information about recovering table spaces, refer to Chapter 21, "Backing up and recovering databases," on page 475.

## Out of disk space or extent limit recovery

**Problem:** There is no more space on the volume on which the data set is stored or the data set might have reached its maximum DB2 size or its maximum number of VSAM extents.

**Symptom:** One of the following messages:

1. Extend request failure

When an insert or update requires additional space, but the space is not available in the current table or index space, DB2 issues the following message:

```
DSNP007I - DSNPmmmm - EXTEND FAILED FOR
           data-set-name. RC=rrrrrrrr
           CONNECTION-ID=xxxxxxx,
           CORRELATION-ID=yyyyyyyyyyy
           LUWID-ID=logical-unit-of-work-id=token
```

2. Look ahead warning

A look ahead warning occurs when there is enough space for a few inserts and updates, but the index space or table space is almost full. On an insert or update at the end of a page set, DB2 determines whether the data set has enough available space. DB2 uses the following values in this space calculation:

- The primary space quantity from the integrated catalog facility (ICF) catalog
- The secondary space quantity from the ICF catalog
- The allocation unit size

If enough space does not exist, DB2 tries to extend the data set. If the extend request fails, then DB2 issues the following message:

```
DSNP001I - DSNPmmmm - data-set-name IS WITHIN
           nK BYTES OF AVAILABLE SPACE.
           RC=rrrrrrrr
           CONNECTION-ID=xxxxxxx,
           CORRELATION-ID=yyyyyyyyyyy
           LUW-ID=logical-unit-of-work-id=token
```

**System action:** For a demand request failure during restart, the object supported by the data set (an index space or a table space) is stopped with deferred restart pending. Otherwise, the state of the object remains unchanged. Programs receive a -904 SQL return code (SQLSTATE '57011').

**System programmer action:** None.

**Operator action:** The appropriate choice of action depends on particular circumstances. The following topics are described in this section; the text following the list describes how to choose which action to take:

- "Procedure 1. Extend a data set" on page 555
- "Procedure 2. Enlarge a fully extended data set (user-managed)" on page 555
- "Procedure 3. Enlarge a fully extended data set (in a DB2 storage group)" on page 556
- "Procedure 4. Add a data set" on page 557
- "Procedure 5. Redefine a partition (index-based partitioning)" on page 557

- “Procedure 6. Redefine a partition (table-based partitioning)” on page 557
- “Procedure 7. Enlarge a fully extended data set for the work file database” on page 557

If the database qualifier of the data set name is DSNDB07, then the condition is on your work file database. Use “Procedure 7. Enlarge a fully extended data set for the work file database” on page 557.

In all other cases, if the data set has *not* reached its maximum DB2 size, then you can enlarge it. (The maximum size is 2 GB for a data set of a simple space, and 1, 2, or 4 GB for a data set containing a partition. Large partitioned table spaces and indexes on large partitioned table spaces have a maximum data set size of 4 GB.)

- If the data set has *not* reached the maximum number of VSAM extents, use “Procedure 1. Extend a data set.”
- If the data set *has* reached the maximum number of VSAM extents, use either “Procedure 2. Enlarge a fully extended data set (user-managed)” or “Procedure 3. Enlarge a fully extended data set (in a DB2 storage group)” on page 556, depending on whether the data set is user-managed or DB2-managed. User-managed data sets include essential data sets such as the catalog and the directory.

If the data set *has* reached its maximum DB2 size, then your action depends on the type of object it supports.

- If the object is a simple space, add a data set, using “Procedure 4. Add a data set” on page 557.
- If the object is partitioned, each partition is restricted to a single data set. You must redefine the partitions; use either “Procedure 5. Redefine a partition (index-based partitioning)” on page 557 or “Procedure 6. Redefine a partition (table-based partitioning)” on page 557.

**Procedure 1. Extend a data set:** If the data set is user-defined, provide more VSAM space. You can add volumes with the access method services command ALTER ADDVOLUMES or make room on the current volume.

If the data set is defined in a DB2 storage group, add more volumes to the storage group by using the SQL ALTER STOGROUP statement.

For more information about DB2 data set extension, refer to “Extending DB2-managed data sets” on page 31.

**Procedure 2. Enlarge a fully extended data set (user-managed):**

1. To allow for recovery in case of failure during this procedure, be sure that you have a recent full image copy (for table spaces or if you copy your indexes). Use the DSNUM option to identify the data set for table spaces or partitioning indexes.
2. Issue the command STOP DATABASE SPACENAM for the last data set of the object supported.
3. Depending on which version of z/OS you have and how many extents you need, complete one of the following tasks:

**You do not have z/OS V1.7 or later:**

(You can use this option with any version of z/OS, but you are limited to 255 extents.)

# Delete the last data set by using access method services. Then redefine  
# it and enlarge it as necessary, by giving new values for PRIQTY and  
# SECQTY.

| The object must be user-defined and a linear data set, and should not  
| have reached the maximum number of 32 data sets for a nonpartitioned  
| table space (or 254 data sets for LOB table spaces). For a partitioned  
| table space, a partitioning index, or a nonpartitioning index on a  
| partitioned table space, the maximum is 4096 data sets.

# **You have z/OS V1.7 or later:**

# If the DB2 subsystem is running on z/OS V1.7 or later, and the data set  
# will not be shared with any z/OS systems at an earlier level, convert  
# the data set to SMS-managed with the Extent Constraint Removal  
# option set to YES in the SMS data class. If you do this, the maximum  
# number of extents is 7257.

# If you have z/OS V1.7 and an older version coexisting in a  
# data-sharing environment, a DB2 data set extended over 255 extents in  
# V1.7 is not accessible by the lower release.

4. Issue the command START DATABASE ACCESS (UT) to start the object for utility-only access.
5. To recover the data set that was redefined, use RECOVER on the table space or index, and identify the data set by the DSNUM option (specify this DSNUM option for table spaces or partitioning indexes only).

RECOVER lets you specify a single data set number for a table space. Thus, only the last data set (the one that needs extension) must be redefined and recovered. This can be better than using REORG if the table space is very large and contains multiple data sets, and if the extension must be done quickly.

If you do not copy your indexes, then use the REBUILD INDEX utility.

6. Issue the command START DATABASE to start the object for either RO or RW access, whichever is appropriate.

**Procedure 3. Enlarge a fully extended data set (in a DB2 storage group):**

- #
1. Depending on which version of z/OS you have and how many extents you need, complete one of the following tasks:

# **You do not have z/OS V1.7 or later:**

# (You can use this option with any version of z/OS, but you are limited  
# to 255 extents.)

# Use ALTER TABLESPACE or ALTER INDEX with a USING clause. (You  
# do not have to stop the table space before you use ALTER  
# TABLESPACE.) You can give new values for PRIQTY and SECQTY in  
# the storage group.

# **You have z/OS V1.7 or later:**

# If the DB2 subsystem is running on z/OS V1.7 or later, and the data set  
# will not be shared with any z/OS systems at an earlier level, convert  
# the data set to SMS-managed with the Extent Constraint Removal  
# option set to YES in the SMS data class. If you do this, the maximum  
# number of extents is 7257.

# If you have z/OS V1.7 and an older version coexisting in a  
# data-sharing environment, a DB2 data set extended over 255 extents in  
# V1.7 is not accessible by the lower release.

2. Use one of the following procedures. Keep in mind that no movement of data occurs until this step is completed.

- For indexes:  
If you have taken full image copies of the index, run the RECOVER INDEX utility. Otherwise, run the REBUILD INDEX utility.
- For table spaces other than LOB table space:  
Run one of the following utilities on the table space: REORG, RECOVER, or LOAD REPLACE.
- For LOB table spaces defined with LOG YES:  
Run the RECOVER utility on the table space.
- For LOB table spaces defined with LOG NO, follow these steps:
  - a. Start the table space in read-only (RO) mode to ensure that no updates are made during this process.
  - b. Make an image copy of the table space.
  - c. Run the RECOVER utility on the table space.
  - d. Start the table space in read-write (RW) mode.

**Procedure 4. Add a data set:** If the object supported is user-defined, use the access method services to define another data set. The name of the new data set must continue the sequence begun by the names of the existing data sets that support the object. The last four characters of each name are a relative data set number: If the last name ended with A001, the next must end with A002, and so on. Also, be sure to add either I or J in the name of the data set.

If the object is defined in a DB2 storage group, DB2 automatically tries to create an additional data set. If that fails, access method services messages are sent to an operator indicating the cause of the problem. Correcting that problem allows DB2 to get the additional space.

**Procedure 5. Redefine a partition (index-controlled partitioning):**

1. Use ALTER INDEX ALTER PARTITION to alter the key range values of the partitioning index.
2. Use REORG with inline statistics on the partitions that are affected by the change in key range.
3. Use RUNSTATS on the nonpartitioned indexes.
4. Rebind the dependent packages and plans.

**Procedure 6. Redefine a partition (table-controlled partitioning):**

1. Use ALTER TABLE ALTER PARTITION to alter the partition boundaries.
2. Use REORG with inline statistics on the partitions that are affected by the change in partition boundaries.
3. Use RUNSTATS on the indexes.
4. Rebind the dependent packages and plans.

**Procedure 7. Enlarge a fully extended data set for the work file database:**

Use one of the following methods to add space for extension to the DB2 storage group:

- Use SQL to create more table spaces in database DSNDB07.

Or,

- Execute these steps:

1. Use the command STOP DATABASE(DSNDB07) to ensure that no users are accessing the database.
2. Use SQL to alter the storage group, adding volumes as necessary.
3. Use the command START DATABASE(DSNDB07) to allow access to the database.

---

## Violation of referential constraint recovery

**Problem:** A table space can contain violations of referential constraints.

**Symptom:** One of the following messages is issued at the end of utility processing, depending upon whether or not the table space is partitioned.

```
DSNU561I csect-name - TABLESPACE= tablespace-name PARTITION= partnum
          IS IN CHECK PENDING
DSNU563I csect-name - TABLESPACE= tablespace-name IS IN CHECK PENDING
```

**System action:** None. The table space is still available; however, it is not available to the COPY, REORG, and QUIESCE utilities, or to SQL select, insert, delete, or update operations that involve tables in the table space.

**System programmer action:** None.

**Operator action:**

1. Use the START DATABASE ACCESS (UT) command to start the table space for utility-only access.
2. Run the CHECK DATA utility on the table space. Take the following recommendations into consideration:
  - If you do not believe that violations exist, specify DELETE NO. If, indeed, violations do not exist, this resets the check-pending status; however, if violations do exist, the status is not going to be reset.
  - If you believe that violations exist, specify the DELETE YES option and an appropriate exception table (see Part 2 of *DB2 Utility Guide and Reference* for the syntax of this utility). This deletes all rows in violation, copies them to an exception table, and resets the check-pending status.
  - If the check-pending status was set during execution of the LOAD utility, specify the SCOPE PENDING option. This checks only those rows added to the table space by LOAD, rather than every row in the table space.
3. Correct the rows in the exception table, if necessary, and use the SQL INSERT statement to insert them into the original table.
4. Issue the command START DATABASE to start the table space for RO or RW access, whichever is appropriate. The table space is no longer in check-pending status and is available for use. If you use the ACCESS (FORCE) option of this command, the check-pending status is reset. However, this is not recommended because it does not correct violations of referential constraints.

---

## Distributed data facility failure recovery

The following failures related to the DDF are discussed in this section:

“Conversation failure recovery” on page 559

“Communications database failure recovery” on page 559

“Database access thread failure recovery” on page 560

“VTAM failure recovery” on page 561

“TCP/IP failure recovery” on page 561

“Remote logical unit failure recovery” on page 561

“Indefinite wait condition recovery” on page 562

“Security failure recovery for database access threads” on page 562

## Conversation failure recovery

**Problem:** A VTAM APPC or TCP/IP conversation failed during or after allocation and is unavailable for use.

**Symptom:** VTAM or TCP/IP returns a resource unavailable condition along with the appropriate diagnostic reason code and message. A DSNL500 or DSNL511 (conversation failed) message is sent to the console for the first failure to a location for a specific logical unit (LU) mode or TCP/IP address. All other threads detecting a failure from that LU mode or IP address are suppressed until communications to that LU using that mode are successful.

DB2 returns messages DSNL501I and DSNL502I. Message DSNL501I usually means that the other subsystem is not up.

**System action:** When the error is detected, it is reported by a console message and the application receives an SQL return code. For DB2 private protocol access, SQLCODE -904 (SQLSTATE '57011') is returned with resource type 1001, 1002, or 1003. The resource name in the SQLCA contains VTAM return codes such as RTNCD, FDBK2, RCPRI, and RCSEC, and any SNA SENSE information. See *VTAM for MVS/ESA Messages and Codes* for more information.

If you use application directed access or DRDA as the database protocols, SQLCODE -30080 is returned to the application. The SQLCA contains the VTAM diagnostic information, which contains only the RCPRI and RCSEC codes. For SNA communications errors, SQLCODE -30080 is returned. For TCP/IP connections, SQLCODE -30081 is returned. See *DB2 Codes* for more information about those SQL return codes.

The application can choose to request rollback or commit. Commit or rollback processing deallocates all but the first conversation between the allied thread and the remote database access thread. A commit or rollback message is sent over this remaining conversation.

Errors during the conversation's deallocation process are reported through messages, but do not stop the commit or rollback processing. If the conversation used for the commit or roll back message fails, the error is reported. If the error occurred during a commit process, the commit process continues, provided the remote database access was read only; otherwise the commit process is rolled back.

**System programmer action:** The system programmer needs to review the VTAM or TCP/IP return codes and might need to discuss the problem with a communications expert. Many VTAM or TCP/IP errors, besides the error of an inactive remote LU or TCP/IP errors, require a person who has a knowledge of VTAM or TCP/IP and the network configuration to diagnose them.

**Operator action:** Correct the cause of the unavailable resource condition by taking action required by the diagnostic messages appearing on the console.

## Communications database failure recovery

This section describes two different problems.

## Problem 1

A failure occurs during an attempt to access the DB2 CDB (after DDF is started).

*Symptom:* A DSNL700I message, indicating that a resource unavailable condition exists, is sent to the console. Other messages describing the cause of the failure are also sent to the console.

*System action:* The distributed data facility (DDF) does not terminate if it has already started and an individual CDB table becomes unavailable. Depending on the severity of the failure, threads will either receive a -904 SQL return code (SQLSTATE '57011') with resource type 1004 (CDB), or continue using VTAM defaults. Only the threads that access locations that have not had any prior threads will receive a -904 SQL return code. DB2 and DDF remain up.

*Operator action:* Correct the error based on the messages received, then stop and restart DDF.

## Problem 2

The DB2 CDB is not defined correctly. This occurs when DDF is started and the DB2 catalog is accessed to verify the CDB definitions.

*Symptom:* A DSNL701I, 702I, 703I, 704I, or 705I message is issued to identify the problem. Other messages describing the cause of the failure are also sent to the console.

*System action:* DDF fails to start. DB2 continues to run.

*Operator action:* Correct the error based on the messages received and restart DDF.

## Database access thread failure recovery

*Problem:* A database access thread has been deallocated and a conversation failure occurs.

*Symptom:* In the event of a failure of a database access thread, the DB2 server terminates the database access thread only if a unit of recovery exists. The server deallocates the database access thread and then deallocates the conversation with an abnormal indication (a negative SQL code), which is subsequently returned to the requesting application. The returned SQL code depends on the type of remote access:

- DB2 private protocol access

The application program receives a -904 SQL return code (SQLSTATE '57011') with a resource type 1005 at the requesting site. The SNA sense in the resource name contains the DB2 reason code describing the failure.

- DRDA access

For a database access thread or non-DB2 server, a DDM error message is sent to the requesting site and the conversation is deallocated normally. The SQL error status code is a -30020 with a resource type '1232' (agent permanent error received from the server).

*System action:* Normal DB2 error recovery mechanisms apply with the following exceptions:

- Errors caught in the functional recovery routine are automatically converted to rollback situations. The allied thread sees conversation failures.

- Errors occurring during commit, roll back, and deallocate *within the DDF function* do not normally cause DB2 to abend. Conversations are deallocated and the database access thread is terminated. The allied thread sees conversation failures.

**System programmer action:** All diagnostic information related to the failure must be collected at the serving site. For a DB2 DBAT, a dump is produced at the server.

**Operator action:** Communicate with the operator at the other site to take the appropriate corrective action, regarding the messages appearing on consoles at both the requesting and responding sites. Operators at both sites should gather the appropriate diagnostic information and give it to the programmer for diagnosis.

## VTAM failure recovery

**Problem:** VTAM terminates or fails.

**Symptom:** VTAM messages and DB2 messages are issued indicating that DDF is terminating and explaining why.

**System action:** DDF terminates.

An abnormal VTAM failure or termination causes DDF to issue a STOP DDF MODE(FORCE) command. The VTAM commands Z NET,QUICK or Z NET,CANCEL causes an abnormal VTAM termination. A Z NET,HALT causes a STOP DDF MODE(QUIESCE) to be issued by DDF.

**System programmer action:** None.

**Operator action:** Correct the condition described in the messages received at the console, and restart VTAM and DDF.

## TCP/IP failure recovery

**Problem:** TCP/IP terminates or fails.

**Symptom:** TCP/IP messages and DB2 messages are issued indicating that TCP/IP is unavailable.

**System action:** DDF periodically attempts to reconnect to TCP/IP. If the TCP/IP listener fails, DDF automatically tries to reestablish the TCP/IP listener for the SQL port or the resync port every three minutes. TCP/IP connections cannot be established until the TCP/IP listener is reestablished.

**System programmer action:** None.

**Operator action:** Correct the condition described in the messages received at the console, restart TCP/IP. You do not need to restart DDF after a TCP/IP failure.

## Remote logical unit failure recovery

**Problem:** A series of conversation or change number of sessions (CNOS) failures occur from a remote LU.

**Symptom:** Message DSNL501I is issued when a CNOS request to a remote LU fails. The CNOS request is the first attempt to connect to the remote site and must be negotiated before any conversations can be allocated. Consequently, if the remote LU is not active, message DSNL500I is displayed indicating that the CNOS request

cannot be negotiated. Message DSNL500I is issued only once for all the SQL conversations that fail because of a remote LU failure.

Message DSNL502I is issued for system conversations that are active to the remote LU at the time of the failure. This message contains the VTAM diagnostic information about the cause of the failure.

**System action:** Any application communications with a failed LU receives a message indicating a resource unavailable condition. The application programs receive SQL return code -904 (SQLSTATE '57011') for DB2 private protocol access and SQL return code -30080 for DRDA access. Any attempt to establish communication with such an LU fails.

**Operator action:** Communicate with the other sites involved regarding the unavailable resource condition, and request that appropriate corrective action be taken. If a DSNL502 message is received, the operator should activate the remote LU.

## Indefinite wait condition recovery

**Problem:** An allied thread is waiting indefinitely for a response from a remote subsystem or a database access thread is waiting for a response from the local subsystem.

**Symptom:** An application is in an indefinitely long wait condition. This can cause other DB2 threads to fail due to resources held by the waiting thread. DB2 sends an error message to the console and the application program receives an SQL return code.

**System action:** None.

**System programmer action:** None.

**Operator action:** Use the DISPLAY THREAD command with the LOCATION and DETAIL options to identify the LUWID and the session's allocation for the waiting thread. Then use the CANCEL DDF THREAD command to cancel the waiting thread. If the CANCEL DDF THREAD command fails to break the wait (because the thread is not suspended in DB2), try using VTAM commands such as VARY TERM,SID=xxx. For additional information concerning canceling DDF threads, see "The command CANCEL THREAD" on page 415 and "Using VTAM commands to cancel threads" on page 416.

To check for very long waits, look to see if the conversation timestamp is changing from the last time used. If it is changing, the conversation thread is not hung, but is taking more time for a long query. Also, look for conversation state changes and determine what they mean.

## Security failure recovery for database access threads

**Problem:** During database access thread allocation, the remote user does not have the proper security to access DB2 through the DDF.

**Symptom:** Message DSNL500I is issued at the requester for VTAM conversations (if it is a DB2 subsystem) with return codes RTNCD=0, FDBK2=B, RCPRI=4, RCSEC=5 meaning "Security Not Valid." The server has deallocated the conversation because the user is not allowed to access the server. For conversations using DRDA access, LU 6.2 communications protocols present specific reasons for

why the user failed, to be returned to the application. If the server is a DB2 database access thread, message DSNL030I is issued to describe what caused the user to be denied access into DB2 through DDF. No message is issued for TCP/IP connections.

**System action:** If the server is a DB2 subsystem, message DSNL030I is issued. Otherwise, the system programmer needs to refer to the documentation of the server. If the application uses DB2 private protocol access, it receives SQLCODE -904 (SQLSTATE '57011') with a reason code 00D3103D, indicating that a resource is unavailable. For DRDA access, SQLCODE -30082 is returned. See *DB2 Codes* for more information about those messages.

**System programmer action:** Refer to the description of 00D3103D in Part 3 of *DB2 Codes*.

**Operator action:** If it is a DB2 database access thread, the operator should provide the DSNL030I message to the system programmer. If it is not a DB2 server, the operator needs to work with the operator or programmer at the server to get diagnostic information needed by the system programmer.

---

## Remote site recovery from a disaster at the local site

**Problem:** Your local system experiences damage or disruption that prevents recovery from that site.

**Symptom:** Your local system hardware has suffered physical damage and is not operational.

**System programmer action:** Coordinate the activities detailed in “Restoring data from image copies and archive logs.”

**Operator action (at the recovery site):** The procedures in this scenario differ from other recovery procedures because you cannot use the hardware at your local DB2 site to recover data. You use hardware at a remote site to recover after a disaster using one of the following three methods:

- “Restoring data from image copies and archive logs”
- “Using a tracker site for disaster recovery” on page 574
- “Using data mirroring” on page 582

## Restoring data from image copies and archive logs

This scenario bases recovery on the latest available archive log and assumes that all copies and reports have arrived at the recovery site as specified in “Preparing for disaster recovery” on page 487. For data sharing, see Chapter 5 of *DB2 Data Sharing: Planning and Administration* for recovery procedures that are specific to data sharing.

1. For scenarios other than data sharing, continue with the next step.

### Data sharing

Remove old information from the coupling facility, if you have information in your coupling facility from practice startups. If you do not have old information in the coupling facility, you can omit this step.

- a. Enter the following z/OS command to display the structures for this data sharing group:

```
D XCF,STRUCTURE,STRNAME=grpname*
```

- b. For group buffer pools and the lock structure, enter the following command to force the connections off those structures:

```
SETXCF FORCE,CONNECTION,STRNAME=strname,CONNNAME=ALL
```

Connections for the SCA are not held at termination, so you do not need to force off any SCA connections.

- c. Delete all the DB2 coupling facility structures by using the following command for each structure:

```
SETXCF FORCE,STRUCTURE,STRNAME=strname
```

This step is necessary to remove old information that exists in the coupling facility from your practice startup when you installed the group.

2. If an integrated catalog facility catalog does not already exist, run job DSNTIJCA to create a user catalog.
3. Use the access method services IMPORT command to import the integrated catalog facility catalog.
4. Restore DB2 libraries, such as DB2 reslibs, SMP libraries, user program libraries, user DBRM libraries, CLISTS, SDSNSAMP, or where the installation jobs are, JCL for user-defined table spaces, and so on.
5. Use IDCAMS DELETE NOSCRATCH to delete all catalog and user objects. (Because step 3 imports a user ICF catalog, the catalog reflects data sets that do not exist on disk.)

```
# Obtain a copy of installation job DSNTIJIN. This job creates DB2 VSAM and
# non-VSAM data sets. Change the volume serial numbers in the job to volume
# serial numbers that exist at the recovery site. Comment out the steps that
# create DB2 non-VSAM data sets, if these data sets already exist. Run
# DSNTIJIN. However, do not run DSNTIJID.
```

### Data sharing

Obtain a copy of the installation job DSNTIJIN for the first data sharing member to be migrated. Run DSNTIJIN on the first data sharing member. For subsequent members of the data sharing group, run the DSNTIJIN that defines the BSDS and logs.

6. Recover the BSDS:
  - a. Use the access method services REPRO command to restore the contents of one BSDS data set (allocated in the previous step). The most recent BSDS image can be found in the last file (archive log with the highest number) on the latest archive log tape.

**Data sharing**

The BSDS data sets on each data sharing member need to be restored.

- b. To determine the RBA range for this archive log, use the print log map utility (DSNJU004) to list the current BSDS contents. Find the most recent archive log in the BSDS listing and add 1 to its ENDRBA value. Use this as the STARTRBA. Find the active log in the BSDS listing that starts with this RBA and use its ENDRBA as the ENDRBA.

**Data Sharing**

The LRSNs are also required.

- c. Delete the oldest archive log from the BSDS.
- d. Use the change log inventory utility (DSNJU003) to register this latest archive log tape data set in the archive log inventory of the BSDS just restored. This is necessary because the BSDS image on an archive log tape does not reflect the archive log data set residing on that tape.

**Data sharing**

Running DSNJU003 is critical for data sharing groups. Group buffer pool checkpoint information is stored in the BSDS and needs to be included from the most recent archive log.

After these archive logs are registered, use the print log map utility (DSNJU004) with the GROUP option to list the contents of all the BSDSs. You receive output that includes the start and end LRSN and RBA values for the latest active log data sets (shown as NOTREUSABLE). If you did not save the values from the DSNJ003I message, you can get those values by running DSNJU004, which creates output similar the output that is shown in Figure 58 and Figure 59 on page 566.

Figure 58 shows a partial example of output from the DSNJU004 utility. This output contains the BSDS information for the archive log member DB1G.

ACTIVE LOG COPY 1 DATA SETS		START RBA/LRSN/TIME	END RBA/LRSN/TIME	DATE	LTIME	DATA SET INFORMATION
000001C20000	ADFA0FB26C6D	1996.361 23:37:48.4	000001C67FFF ADFA208AA36B	1996.358	17:25	DSN=DSNDB0G.DB1G.LOGCOPY1.DS03 STATUS=TRUNCATED, REUSABLE
000001C68000	ADFA208AA36C	1996.362 00:53:10.1	000001D4FFFF <b>AE3C45273A77</b>	1996.358	17:25	DSN=DSNDB0G.DB1G.LOGCOPY1.DS01 STATUS=TRUNCATED, NOTREUSABLE
000001D50000	AE3C45273A78	1996.362 00:53:10.1	0000020D3FFF	1996.358	17:25	DSN=DSNDB0G.DB1G.LOGCOPY1.DS02 STATUS=NOTREUSABLE
1997.048 15:28:23.5	.....	.....	.....			

Figure 58. BSDS contents (partial) of member DB1G

Figure 59 on page 566 shows a partial example of output from the DSNJU004 utility. This output contains the BSDS information for the

archive log member DB2G.

ACTIVE LOG COPY 1 DATA SETS		END RBA/LRSN/TIME	DATE	LTIME	DATA SET INFORMATION
START RBA/LRSN/TIME	EMPTY DATA SET				
0000.000 00:00:00.0	000000000000	0000.000 00:00:00.0	1996.361	14:14	DSN=DSNDB0G.DB2G.LOGCOPY1.DS03 STATUS=NEW, REUSABLE

1997.048 15:28:23.7	.....	.....			

Figure 59. BSDS contents (partial) of member DB2G

**Data sharing**

Do all other preparatory activities as you would for a single system. Do these activities for *each* member of the data sharing group.

- e. Use the change log inventory utility to adjust the active logs:
    - 1) Use the DELETE option of the change log inventory utility (DSNJU003) to delete all active logs in the BSDS. Use the BSDS listing produced in step 6d on page 565 to determine the active log data set names.
    - 2) Use the NEWLOG statement of the change log inventory utility (DSNJU003) to add the active log data sets to the BSDS. Do not specify a STARTRBA or ENDRBA value in the NEWLOG statement. This indicates to DB2 that the new active logs are empty.
  - f. If you are using the DB2 distributed data facility, run the change log inventory utility with the DDF statement to update the LOCATION and the LUNAME values in the BSDS.
  - g. Use the print log map utility (DSNJU004) to list the new BSDS contents and ensure that the BSDS correctly reflects the active and archive log data set inventories. In particular, ensure that:
    - All active logs show a status of NEW and REUSABLE
    - The archive log inventory is complete and correct (for example, the start and end RBAs should be correct).
  - h. If you are using dual BSDSs, make a copy of the newly restored BSDS data set to the second BSDS dataset.
7. Optionally, you can restore archive logs to disk. Archive logs are typically stored on tape, but restoring them to disk could speed later steps. If you elect this option, and the archive log data sets are not cataloged in the primary integrated catalog facility catalog, use the change log inventory utility to update the BSDS. If the archive logs are listed as cataloged in the BSDS, DB2 allocates them using the integrated catalog and not the unit or volser specified in the BSDS. If you are using dual BSDSs, remember to update both copies.
  8. Use the DSN1LOGP utility to determine which transactions were in process at the end of the last archive log. Use the following job control language where *yyyyyyyyyyyy* is the STARTRBA of the last complete checkpoint within the RBA range on the last archive log from the previous print log map:

```
//SAMP EXEC PGM=DSN1LOGP
//SYSPRINT DD SYSOUT=*
//SYSSUMRY DD SYSOUT=*
//ARCHIVE DD DSN=last-archive,DISP=(OLD,KEEP),UNIT=TAPE,
```

```

                                LABEL=(2,SL),VOL=SER=volser1
                                (NOTE FILE 1 is BSDS COPY)
//SYSIN      DD *
              STARTRBA(yyyyyyyyyyyy) SUMMARY(ONLY)
/*

```

DSN1LOGP gives a report. For sample output and information about how to read it, see Part 3 of *DB2 Utility Guide and Reference*.

Note whether any utilities were executing at the end of the last archive log. You will have to determine the appropriate recovery action to take on each table space involved in a utility job.

If DSN1LOGP showed that utilities are inflight (PLAN=DSNUTIL), you need SYSUTILX to identify the utility status and determine the recovery approach. See “What to do about utilities in progress” on page 571.

9. Modify DSNZPxxx parameters:

- a. Run the DSNTINST CLIST in UPDATE mode. See Part 2 of *DB2 Installation Guide*.
- b. To defer processing of all databases, select “Databases to Start Automatically” from panel DSNTIPB. You are presented with panel DSNTIPS. Type DEFER in the first field, ALL in the second, and press Enter. You are returned to DSNTIPB.
- c. To specify where you are recovering, select “Operator Functions” from panel DSNTIPB. You are presented with panel DSNTIPO. Type RECOVERYSITE in the SITE TYPE field. Press Enter to continue.
- d. To optionally specify which archive log to use, select “Operator Functions” from panel DSNTIPB. You are presented with panel DSNTIPO. Type YES in the READ ARCHIVE COPY2 field if you are using dual archive logging and want to use the second copy of the archive logs. Press Enter to continue.
- e. Reassemble DSNZPxxx using job DSNTIJUZ (produced by the CLIST started in the first step).

At this point, you have the log, but the table spaces have not been recovered. With DEFER ALL, DB2 assumes that the table spaces are unavailable, but does the necessary processing to the log. This step also handles the units of recovery in process.

10. Use the change log inventory utility to create a conditional restart control record. In most cases, you can use this form of the CRESTART statement:

```

CRESTART CREATE, ENDRBA=nnnnnnnn000, FORWARD=YES,
          BACKOUT=YES

```

where *nnnnnnnn000* equals a value one more than the ENDRBA of the latest archive log.

### Data sharing

If you are recovering a data sharing group, and your logs are not at a single point of consistency, use this form of the CRESTART statement:

```
CRESTART CREATE,ENDLRSN=nnnnnnnnnnnn, FORWARD=YES, BACKOUT=YES
```

where *nnnnnnnnnnnn* is the LRSN of the last log record to be used during restart. Use the same LRSN for **all** members in a data sharing group. Determine the ENDLRSN value using one of the following methods:

- Use the DSN1LOGP summary utility to obtain the ENDLRSN value. In the 'Summary of Completed Events' section, find the lowest LRSN value listed in the DSN1213I message, for the data sharing group. Use this value for the ENDLRSN in the CRESTART statement.
- Use the print log map utility (DSNJU004) to list the BSDS contents. Find the ENDLRSN of the last log record available for each active member of the data sharing group. Subtract 1 from the **lowest** ENDLRSN in the data sharing group. Use this value for the ENDLRSN in the CRESTART statement. (In our example in Figure 58 on page 565, that is AE3C45273A77 - 1, which is AE3C45273A76.)
- If only the console logs are available, use the archive offload message, DSNJ003I to obtain the ENDLRSN. Compare the ending LRSN values for all members' archive logs. Subtract 1 from the **lowest** LRSN in the data sharing group. Use this value for the ENDLRSN in the CRESTART statement. (In our example in Figure 58 on page 565, that is AE3C45273A77 - 1, which is AE3C45273A76.)

DB2 discards any log information in the bootstrap data set and the active logs with an RBA greater than or equal to *nnnnnnnnnn000* or an LRSN greater than *nnnnnnnnnnnn* as listed in the preceding CRESTART statements.

Use the print log map utility to verify that the conditional restart control record that you created in the previous step is active.

- #
- #
- #
- #
11. Enter the command START DB2 ACCESS(MAINT). You must enter this command if real-time statistics are active and enabled; otherwise, errors or abends could occur during DB2 restart processing and recovery processing (for example, GRECP recovery, LPL recovery, or the RECOVER utility).

RECOVER INDEX. If you do not have an image copy of an index, use REBUILD INDEX to reconstruct the index from the recovered table space.

- a. Recover DSNDB01.SYSUTILX. This must be a separate job step.
- b. Recover all indexes on SYSUTILX. This must be a separate job step.
- c. Your recovery strategy for an object depends on whether a utility was running against it at the time the latest archive log was created. To identify the utilities that were running, you must recover SYSUTILX.

You cannot restart a utility at the recovery site that was interrupted at the disaster site. You must use the TERM command to terminate it. The TERM UTILITY command can be used on any object except DSNDB01.SYSUTILX.

Determine which utilities were executing and the table spaces involved by performing the following procedure:

- 1) Enter the DISPLAY UTILITY(\*) command and record the utility and the current phase.
  - 2) Run the DIAGNOSE utility with the DISPLAY SYSUTIL statement. The output consists of information about each active utility, including the table space name (in most instances). It is the only way to correlate the object name with the utility. Message DSNU866I gives information about the utility, while DSNU867I gives the database and table space name in USUDBNAM and USUSPNAM respectively.
- d. Use the command TERM UTILITY to terminate any utilities in progress on catalog or directory table spaces.  
See “What to do about utilities in progress” on page 571 for information about how to recover catalog and directory table spaces on which utilities were running.
  - e. Recover the rest of the catalog and directory objects starting with DBD01, in the order shown in the description of the RECOVER utility in Part 2 of *DB2 Utility Guide and Reference*.
14. Use any method desired to verify the integrity of the DB2 catalog and directory. Migration step 1 in Chapter 1 of *DB2 Installation Guide* lists one option for verification. The catalog queries in member DSNTESSQ of data set DSN810.SDSNSAMP can be used after the work file database is defined and initialized.
  15. Define and initialize the work file database.
    - a. Define temporary work files. Use installation job DSNTIJTM as a model.
    - b. Issue the command START DATABASE(*work-file-database*) to start the work file database.
  16. If you use data definition control support, recover the objects in the data definition control support database.
  17. If you use the resource limit facility, recover the objects in the resource limit control facility database.
  18. Modify DSNZPxxx to restart all databases:
    - a. Run the DSNTINST CLIST in UPDATE mode. See Part 2 of *DB2 Installation Guide*.
    - b. From panel DSNTIPB select “Databases to Start Automatically”. You are presented with panel DSNTIPS. Type RESTART in the first field, ALL in the second and press Enter. You are returned to DSNTIPB.
    - c. Reassemble DSNZPxxx using job DSNTIJUZ (produced by the CLIST started in the first step).
  19. Stop and start DB2.
  20. Make a full image copy of the catalog and directory.

21. Recover user table spaces and index spaces. See “What to do about utilities in progress” for information about how to recover table spaces or index spaces on which utilities were running. You cannot restart a utility at the recovery site that was interrupted at the disaster site. Use the TERM command to terminate any utilities running against user table spaces or index spaces.

- a. To determine which, if any, of your table spaces or index spaces are user-managed, perform the following queries for table spaces and index spaces.

Table spaces:

```
SELECT * FROM SYSIBM.SYSTABLEPART WHERE STORTYPE='E';
```

Index spaces:

```
SELECT * FROM SYSIBM.SYSINDEXPART WHERE STORTYPE='E';
```

To allocate user-managed table spaces or index spaces, use the access method services DEFINE CLUSTER command. To find the correct IPREFIX for the DEFINE CLUSTER command, perform the following queries for table spaces and index spaces.

Table spaces:

```
SELECT DBNAME, TSNAME, PARTITION, IPREFIX FROM SYSIBM.SYSTABLEPART  
WHERE DBNAME=dbname AND TSNAME=tsname  
ORDER BY PARTITION;
```

Index spaces:

```
SELECT IXNAME, PARTITION, IPREFIX FROM SYSIBM.SYSINDEXPART  
WHERE IXCREATOR=ixcreator AND IXNAME=ixname  
ORDER BY PARTITION;
```

Now you can perform the DEFINE CLUSTER command with the correct IPREFIX (I or J) in the data set name:

```
catname.DSNDBC.dbname.sname.y0001.A00x
```

where *y* can be either I or J, *x* is C (for VSAM clusters) or D (for VSAM data components), and *sname* is either the table space or index space name.

Access method services commands are described in detail in *z/OS DFSMS Access Method Services for Catalogs*.

- b. If your user table spaces or index spaces are STOGROUP-defined, and if the volume serial numbers at the recovery site are different from those at the local site, use ALTER STOGROUP to change them in the DB2 catalog.
  - c. Recover all user table spaces and index spaces from the appropriate image copies. If you do not copy your indexes, use the REBUILD INDEX utility to reconstruct the indexes.
  - d. Start all user table spaces and index spaces for read or write processing by issuing the command START DATABASE with the ACCESS(RW) option.
  - e. Resolve any remaining check pending states that would prevent COPY execution.
  - f. Run select queries with known results.
22. Make full image copies of all table spaces and indexes with the COPY YES attribute.
23. Finally, compensate for lost work since the last archive was created by rerunning online transactions and batch jobs.

**What to do about utilities in progress:** If any utility jobs were running after the last time that the log was offloaded before the disaster, you might need to take

some additional steps. After restarting DB2, the following utilities only need to be terminated with the TERM UTILITY command:

- CHECK INDEX
- MERGECOPY
- MODIFY
- QUIESCE
- RECOVER
- RUNSTATS
- STOSPACE

It is preferable to allow the RECOVER utility to reset pending states. However, it is occasionally necessary to use the REPAIR utility to reset them. Do not start the table space with ACCESS(FORCE) because FORCE resets any page set exception conditions described in “Database page set control records” on page 1120.

For the following utility jobs, perform the actions indicated:

#### CHECK DATA

Terminate the utility and run it again after recovery is complete.

**COPY** After you enter the TERM command, DB2 places a record in the SYSCOPY catalog table indicating that the COPY utility was terminated. This makes it necessary for you to make a full image copy. When you copy your environment at the completion of the disaster recovery scenario, you fulfill that requirement.

#### LOAD

Find the options you specified in Table 100, and perform the specified actions.

Table 100. Actions when LOAD is interrupted

LOAD options specified	What to do
LOG YES	If the RELOAD phase completed, recover to the current time. Recover the indexes.  If the RELOAD phase did not complete, recover to a prior point in time. The SYSCOPY record inserted at the beginning of the RELOAD phase contains the RBA or LRSN.
LOG NO and <i>copy-spec</i>	If the RELOAD phase completed, the table space is complete after you recover it to the current time. Recover the indexes.  If the RELOAD phase did not complete, then recover the table space to a prior point in time. Recover the indexes.
LOG NO, <i>copy-spec</i> , and SORTKEYS <i>integer</i> <sup>1</sup>	If the BUILD or SORTBLD phase completed, recover to the current time, and recover the indexes.  If the BUILD or SORTBLD phase did not complete, recover to a prior point in time. Recover the indexes.
LOG NO	Recover the table space to a prior point in time. You can use TOCOPY to do this.

**Note:** <sup>1</sup>You must specify a value that is greater than zero for *integer*. If you specify zero for *integer* the SORTKEYS option does not apply.

To avoid extra loss of data in a future disaster situation, run QUIESCE on table spaces before invoking LOAD. This enables you to recover a table space using TOLOGPOINT instead of TOCOPY.

## REORG

For a **user** table space, find the options you specified in Table 101, and perform the specified actions.

Table 101. Actions when REORG is interrupted

REORG options specified	What to do
LOG YES	<p>If the RELOAD phase completed, recover to the current time. Recover the indexes.</p> <p>If the RELOAD phase did not complete, recover to the current time to restore the table space to the point before REORG began. Recover the indexes.</p>
LOG NO	<p>If the build or SORTBLD phase completed, recover to the current time, and recover the indexes.</p> <p>If the build or SORTBLD phase did not complete, recover to the current time to restore the table space to the point before REORG began. Recover the indexes.</p>
SHRLEVEL CHANGE	<p>If the SWITCH phase completed, terminate the utility. Recover the table space to the current time. Recover the indexes.</p> <p>If the SWITCH phase did not complete, recover the table space to the current time. Recover the indexes.</p>
SHRLEVEL REFERENCE	Same as for SHRLEVEL CHANGE.

For a **catalog or directory** table space, follow these instructions:

For those table spaces that were using online REORG, find the options you specified in Table 101, and perform the specified actions.

If you have no image copies from immediately before REORG failed, use this procedure:

1. From your DISPLAY UTILITY and DIAGNOSE output, determine what phase REORG was in and which table space it was reorganizing when the disaster occurred.
2. Run RECOVER on the catalog and directory in the order shown in Part 2 of *DB2 Utility Guide and Reference*. Recover all table spaces to the current time, *except* the table space that was being reorganized. If the RELOAD phase of the REORG on that table space had not completed when the disaster occurred, recover the table space to the current time. Because REORG does not generate any log records prior to the RELOAD phase for catalog and directory objects, the RECOVER to current restores the data to the state it was in before the REORG. If the RELOAD phase completed, perform the following actions:
  - a. Run DSN1LOGP against the archive log data sets from the disaster site.
  - b. Find the begin-UR log record for the REORG that failed in the DSN1LOGP output.
  - c. Run RECOVER with the TOLOGPOINT option on the table space that was being reorganized. Use the URID of the begin-UR record as the TOLOGPOINT value.
3. Recover or rebuild all indexes.

If you have image copies from immediately before REORG failed, run RECOVER with the option TOCOPY to recover the catalog and directory, in the order shown in Part 2 of *DB2 Utility Guide and Reference*.

**Recommendation:** Make full image copies of the catalog and directory before you run REORG on them.

## Using a tracker site for disaster recovery

This section describes a different method for disaster recovery from that described in “Remote site recovery from a disaster at the local site” on page 563. Many steps are similar to a regular disaster recovery, so these steps are not described in detail here.

**Recommendation:** Test and document a disaster procedure that is customized for your location.

**Overview:** A DB2 *tracker* site is a separate DB2 subsystem or data sharing group that exists solely for the purpose of keeping shadow copies of your primary site’s data. No independent work can be run on the tracker site.

From the primary site, you transfer the BSDS and the archive logs, and that tracker site runs periodic LOGONLY recoveries to keep the shadow data up-to-date. If a disaster occurs at the primary site, the tracker site becomes the *takeover* site. Because the tracker site has been shadowing the activity on the primary site, you do not have to constantly ship image copies; the takeover time for the tracker site might be faster because DB2 recovery does not have to use image copies.

The following topics are described in this section:

“Characteristics of a tracker site”

“Setting up a tracker site” on page 575

“Using RESTORE SYSTEM LOGONLY to establish a recovery cycle” on page 575

“Using the RECOVER utility to establish a recovery cycle” on page 577

“Media failures during LOGONLY recovery” on page 580

“Maintaining the tracker site” on page 580

“Making the tracker site the takeover site” on page 580

### Characteristics of a tracker site

Because the tracker site must use only the primary site’s logs for recovery, you must not update the catalog and directory or the data at the tracker site. The DB2 subsystem at the tracker site disallows updates. In summary:

- The following SQL statements are not allowed at a tracker site:
  - GRANT or REVOKE
  - DROP, ALTER, or CREATE
  - UPDATE, INSERT, or DELETE

Dynamic read-only SELECT statements are also allowed, but not recommended. At the end of each tracker site recovery cycle, databases might contain uncommitted data and indexes might be inconsistent with the data at the tracker site.

- The only online utilities that are allowed are REPORT, DIAGNOSE, RECOVER, REBUILD, and RESTORE SYSTEM LOGONLY. Recovery to a prior point in time is not allowed.
- BIND is not allowed.
- TERM UTIL is not allowed for LOAD, REORG, REPAIR, and COPY.

- The START DATABASE command is not allowed when LPL or GRECP status exists for the object of the command. It is not necessary to use START DATABASE to clear LPL or GRECP conditions, because you are going to be running RECOVERY jobs that clear the conditions.
- The START DATABASE command with ACCESS(FORCE) is not allowed.
- Down-level detection is disabled.
- Log archiving is disabled.
- Real-time statistics are disabled.

### Setting up a tracker site

To set up the tracker site:

1. Create a mirror image of your primary DB2 subsystem or data sharing group. This process is described in steps 1 through 4 of the normal disaster recovery procedure, which includes such creating catalogs and restoring DB2 libraries.
2. Modify the subsystem parameters as follows:
  - Set the TRKSITE subsystem parameter to YES.
  - Optionally, set the SITETYP parameter to RECOVERYSITE if the full image copies this site will be receiving are created as remote site copies.
3. Use the access method services DEFINE CLUSTER command to allocate data sets for all user-managed table spaces that you will be sending over from the primary site.
4. Optionally, you can allocate data sets for user-managed indexes that you want to rebuild during recovery cycles. The main reason you rebuild indexes during recovery cycles is for running efficient queries on the tracker site. If you do not require indexes, you do not have to rebuild them for recovery cycles. For nonpartitioning indexes on very large tables, you can include indexes for LOGONLY recovery during the recovery cycle, which can reduce the amount of time it takes to bring up the disaster site. Be sure you define data sets with the proper I or J prefix for both indexes and table spaces. See REORG INDEX and REORG TABLESPACE in *DB2 Utility Guide and Reference* for more information about index and table space prefixes.
5. Send full image copies of all the primary site's DB2 data to the tracker site. Optionally, you can use the BACKUP SYSTEM utility with the DATA ONLY option and send copies of the database copy pool to the tracker site. If you send copies that the BACKUP SYSTEM utility creates, this step completes the tracker site setup procedure.
6. If you did not use the BACKUP SYSTEM utility in step 5, tailor installation job DSNTIJJN to create DB2 catalog data sets.

**Important:** Do not attempt to start the tracker site when you are setting it up. You must follow the procedure described in "Using the RECOVER utility to establish a recovery cycle" on page 577.

### Using RESTORE SYSTEM LOGONLY to establish a recovery cycle

When full image copies of all the data at the primary site are available to your tracker site, you can use the LOGONLY option of the RESTORE SYSTEM utility to periodically apply the active log, archive logs, and the BSDS from the primary site at the tracker site. Each time you restore the logs and the BSDS from the primary site at your tracker site, you establish a new recovery cycle.

Complete the following procedure to use the RESTORE SYSTEM utility to establish a recovery cycle at your tracker site:

1. While your primary site continues its usual workload, send a copy of the primary site's active log, archive logs, and BSDS to the tracker site.

Send full image copies for the following objects:

- Table spaces or partitions that are reorganized, loaded, or repaired with the LOG NO option after the latest recovery cycle.
- Objects that, after the latest recovery cycle, have been recovered to a point in time

**Recommendation:** If you are taking incremental image copies, run the MERGECOPY utility at the primary site before sending the copy to the tracker site.

2. At the tracker site, restore the BSDS that was received from the primary site.
  - Locate the BSDS in the latest archive log that is now at the tracker site.
  - Use the change log inventory utility (DSNJU003) to register this archive log in the archive log inventory of the new BSDS.
  - Use the change log inventory utility (DSNJU003) to register the primary site's active log in the new BSDS.

For more details about restoring the BSDS, see step 6 of "Remote site recovery from a disaster at the local site" on page 563.

3. Use the change log inventory utility (DSNJU003) with the following CRESTART control statement:

```
CRESTART CREATE, ENDRBA=nnnnnnnnn000, FORWARD=NO, BACKOUT=NO
```

In this control statement, *nnnnnnnnnn000* equals the RBA at which the latest archive log record ends plus one. You must not specify the RBA at which the an archive log begins because you cannot cold start or skip logs in tracker mode.

#### Data sharing

If you are recovering a data sharing group, you **must** use the following CRESTART control statement on all members of the data sharing group. The ENDLRSN value must be the same for all members.

```
CRESTART CREATE, ENDLRSN=nnnnnnnnnnnn, FORWARD=NO, BACKOUT=NO
```

In this control statement, *nnnnnnnnnnnnnn* is the lowest LRSN of all the members to be read during restart. You must specify one of the following values for the ENDLRSN:

- If you receive the ENDLRSN from the output of the print log map utility (DSNJU004) or from the console logs using message DSNJ003I, you must use ENDLRSN-1 as the input to the conditional restart.
- If you receive the ENDLRSN from the output of the DSN1LOGP utility (DSN1213I message), you can use the value that is displayed.

The ENDLRSN or ENDRBA value indicates the end log point for data recovery and for truncating the archive log. With ENDLRSN, the *missing* log records between the lowest and highest ENDLRSN values for all the members are applied during the next recovery cycle.

4. If the tracker site is a data sharing group, delete all DB2 coupling facility structures before restarting the tracker members.
5. If you used DSN1COPY to create a copy of SYSUTILX during the last tracker cycle, restore this copy with DSN1COPY.

6. At the tracker site, restart DB2 to begin a **tracker site recovery cycle**.

<p><b>Data sharing</b> For data sharing, restart <b>every</b> member of the data sharing group.</p>
---------------------------------------------------------------------------------------------------------

7. At the tracker site, run the RESTORE SYSTEM utility with the LOGONLY option to apply the logs (both archive and active) to the data at the tracker site. See “Media failures during LOGONLY recovery” on page 580 for information about what to do if a media failure occurs during LOGONLY recovery.
8. If the RESTORE SYSTEM utility issues a return code of 4, use DSN1COPY to make a copy of SYSUTILX and indexes that are associated with SYSUTILX before you recover or rebuild those objects. DSN1COPY issues a return code of 4 if applying the log marks one or more DB2 objects as RECP or RBDP.
9. Restart DB2 at the tracker site.
10. Issue the DISPLAY DATABASE RESTRICT command to display objects that are marked RECP, RBDP, or LPL and identify which objects are in a utility progress state (such as UTUT or UTRO). Run the RECOVER or REBUILD INDEX utility on these objects, or record which objects are in an exception state so that you can recover them at a later time. The exception states of these objects will be lost in the next recovery cycle.
11. After all recovery has completed at the tracker site, shut down the tracker site DB2. This is the end of the tracker site recovery cycle.  
If you choose to, you can stop and start the tracker DB2 several times before completing a recovery cycle.

### Using the RECOVER utility to establish a recovery cycle

When full image copies of all the data at the primary site are available to your tracker site, you can use the RECOVER utility to periodically apply the active log, archive logs, and BSDS from the primary site to the tracker site.

The following procedure establishes a recovery cycle at your tracker site:

1. While your primary site continues its usual workload, send a copy of the primary site’s active log, archive logs, and BSDS to the tracker site.

Send full image copies for the following objects:

- Table spaces or partitions that are reorganized, loaded, or repaired with the LOG NO option after the latest recovery cycle.
- Objects that, after the latest recovery cycle, have been recovered to a point in time.
- SYSUTILX. Send a full image copy to DSNDB01.SYSUTILX for normal (full image copy and log) recoveries. For LOGONLY recoveries, create a DSN1COPY of DSNDB01.SYSUTILX.

DB2 does not write SYSLGRNX entries for DSNDB01.SYSUTILX, which can lead to long recovery times at the tracker site. In addition, SYSUTILX and its indexes are updated during the tracker cycle when you run your recoveries. Because SYSUTILX must remain consistent with the SYSUTILX at the primary site, the tracker cycle updates must be discarded before the next tracker cycle.

**Recommendation:** If you are taking incremental image copies, run the MERGECOPY utility at the primary site before sending the copy to the tracker site.

2. At the tracker site, restore the BSDS that was received from the primary site.

- Locate the BSDS in the latest archive log that is now at the tracker site.
- Use the change log inventory utility (DSNJU003) to register this archive log in the archive log inventory of the new BSDS.
- Use the change log inventory utility (DSNJU003) to register the primary site's active log in the new BSDS.

For more details about restoring the BSDS, see step 6 of "Remote site recovery from a disaster at the local site" on page 563.

3. Use the change log inventory utility (DSNJU003) with the following CRESTART control statement:

```
CRESTART CREATE, ENDRBA=nnnnnnnn000, FORWARD=NO, BACKOUT=NO
```

In this control statement, *nnnnnnnn000* equals ENDRBA + 1 of the latest archive log. You must not specify STARTRBA, because you cannot cold start or skip logs in a tracker system.

#### Data sharing

If you are recovering a data sharing group, you **must** use the following CRESTART control statement on all members of the data sharing group. The ENDLRSN value must be the same for all members.

```
CRESTART CREATE, ENDLRSN=nnnnnnnnnnnn, FORWARD=NO, BACKOUT=NO
```

In this control statement, *nnnnnnnnnnnn* is the lowest ENDLRSN of all the members to be read during restart. You must specify one of the following values for the ENDLRSN:

- If you receive the ENDLRSN from the output of the print log map utility (DSNJU004) or from the console logs using message DSNJ003I, you must use ENDLRSN-1 as the input to the conditional restart.
- If you receive the ENDLRSN from the output of the DSN1LOGP utility (DSN1213I message), you can use the value that is displayed.

The ENDLRSN or ENDRBA value indicates the end log point for data recovery and for truncating the archive log. With ENDLRSN, the *missing* log records between the lowest and highest ENDLRSN values for all the members are applied during the next recovery cycle.

4. If the tracker site is a data sharing group, delete all DB2 coupling facility structures before restarting the tracker members.
5. At the tracker site, restart DB2 to begin a **tracker site recovery cycle**.

#### Data sharing

For data sharing, restart **every** member of the data sharing group.

6. At the tracker site, submit RECOVER jobs to recover database objects. Run the RECOVER utility with the LOGONLY option on all database objects that do not require recovery from an image copy. See "Media failures during LOGONLY recovery" on page 580 for information about what to do if a media failure occurs during LOGONLY recovery.

You must recover database objects as the following procedure specifies:

- a. Restore the full image copy or DSN1COPY of SYSUTILX.

**Recovering SYSUTILX:** If you are doing a LOGONLY recovery on SYSUTILX from a previous DSN1COPY backup, make another DSN1COPY

copy of that table space after the LOGONLY recovery is complete and before recovering any other catalog or directory objects.

After you recover SYSUTILX and either recover or rebuild its indexes, and before recovering other system and user table spaces, find out what utilities were running at the primary site.

- b. Recover the catalog and directory.

See *DB2 Utility Guide and Reference* for information about the order of recovery for the catalog and directory objects.

**User-defined catalog indexes:** Unless you require them for catalog query performance, it is not necessary to rebuild user-defined catalog indexes until the tracker DB2 becomes the takeover DB2. However, if you are recovering user-defined catalog indexes, do the recover in this step.

- c. If needed, recover other system data such as the data definition control support table spaces and the resource limit facility table spaces.
- d. Recover user data and, optionally, rebuild your indexes.

It is not necessary to rebuild indexes unless you intend to run dynamic queries on the data at the tracker site.

Because this is a tracker site, DB2 stores the conditional restart ENDRBA or ENDLRSN in the page set after each recovery completes successfully. By storing the log truncation value in the page set, DB2 ensures that it does not skip any log records between recovery cycles.

7. Enter DISPLAY UTIL(\*) for a list of currently running utilities.
8. Run the DIAGNOSE utility with the DISPLAY SYSUTIL statement to find out the names of the object on which the utilities are running. Installation SYSOPR authority is required.
9. Perform the following actions for objects at the tracker site on which utilities are pending. Restrictions apply to these objects with because DB2 prevents you from using the TERM UTIL command to remove pending statuses at a tracker site.
  - If a LOAD, REORG, REPAIR, or COPY is in progress on any catalog or directory object at the primary site, shut down DB2. You cannot continue recovering through the list of catalog and directory objects. Therefore, you cannot recover any user data. At the next recovery cycle, send a full image copy of the object from the primary site. At the tracker site, use the RECOVER utility to restore the object.
  - If a LOAD, REORG, REPAIR, or COPY utility is in progress on any user data, at the next recovery cycle, send a full image copy of the object from the primary site. At the tracker site, use the RECOVER utility to restore the object.
  - If an object is in the restart pending state, use LOGONLY recovery to recover the object when that object is no longer in restart pending state.

#### **Data sharing**

If read/write shared data (GPB-dependent data) is in the advisory recovery pending state, the tracker DB2 performs recovery processing. Because the tracker DB2 always performs a conditional restart, the postponed indoubt units of recovery are not recognized after the tracker DB2 restarts.

10. After all recovery has completed at the tracker site, shut down the tracker site DB2. This is the end of the tracker site recovery cycle. If you choose to, you can stop and start the tracker DB2 several times before completing a recovery cycle.

### Media failures during LOGONLY recovery

As documented in *DB2 Utility Guide and Reference*, if there is an I/O error during a LOGONLY recovery, recover the object using the image copies and logs after you correct the media failure.

If an entire volume is corrupted and you are using DB2 storage groups, you cannot use the ALTER STOGROUP statement to remove the corrupted volume and add another as is documented for a non-tracker system. Instead, you must remove the corrupted volume and reinitialize another volume with the same volume serial number before you invoke the RECOVER utility for all table spaces and indexes on that volume.

### Maintaining the tracker site

It is recommended that the tracker site and primary site be at the same maintenance level to avoid unexpected problems. Between recovery cycles, you can apply maintenance as you normally do, by stopping and restarting the DB2 subsystem or DB2 member.

If a tracker site fails, you can restart it normally.

Because bringing up your tracker site as the takeover site destroys the tracker site environment, you should save your complete tracker site prior to takeover site testing. The tracker site can then be restored after the takeover site testing, and the tracker site recovery cycles can be resumed.

#### Data sharing group restarts

During recovery cycles, the first member that comes up puts the ENDLRSN value in the shared communications area (SCA) of the coupling facility. If an SCA failure occurs during a recovery cycle, you must go through the recovery cycle again, using the same ENDLRSN value for your conditional restart.

### Making the tracker site the takeover site

If a disaster occurs at the primary site, the tracker site must become the *takeover* site. After the takeover site is restarted, you must apply log data or image copies that were enroute when the disaster occurred. The procedure to make the tracker site the takeover depends on whether you use RESTORE SYSTEM LOGONLY or the RECOVER utility in your tracker site recovery cycles.

**Recovering at a tracker site that uses RESTORE SYSTEM LOGONLY:** If you use RESTORE SYSTEM LOGONLY in the recovery cycles at the tracker site, use the following procedure after a disaster to make the tracker site the takeover site:

1. If log data for a recovery cycle is enroute or is available but has not yet been used in a recovery cycle perform the procedure in "Using RESTORE SYSTEM LOGONLY to establish a recovery cycle" on page 575.
2. Ensure that the TRKSITE NO subsystem parameter is specified.
3. For scenarios other than data sharing, continue with the next step.

**Data sharing**

If this is a data sharing system, delete the coupling facility structures.

4. Start DB2 at the same RBA or ENDLRSN that you used in the most recent tracker site recovery cycle. Specify FORWARD=YES and BACKOUT=YES in the CRESTART statement (this takes care of uncommitted work).
5. Restart the objects that are in GRECP or LPL status using the following START DATABASE command:  
START DATABASE(\*) SPACENAM(\*)
6. If you used to DSN1COPY to create a copy of SYSUTILX in the last recovery cycle, use DSN1COPY to restore that copy.
7. Terminate any in-progress utilities by using the following procedure:
  - a. Enter the command DISPLAY UTIL(\*).
  - b. Run the DIAGNOSE utility with DISPLAY SYSUTIL to get the names of objects on which utilities are being run.
  - c. Terminate in-progress utilities using the command TERM UTIL(\*).  
See “What to do about utilities in progress” on page 571 for more information about how to terminate in-progress utilities and how to recover an object on which a utility was running.
8. Rebuild indexes, including IBM and user-defined indexes on the DB2 catalog and user-defined indexes on table spaces.

**Recovering at a tracker site that uses the RECOVER utility:** If you use the RECOVER utility in the recovery cycles at your tracker site, use the following procedure after a disaster to make the tracker site the takeover site:

1. Restore the BSDS and register the archive log from the last archive you received from the primary site.
2. For scenarios other than data sharing, continue with the next step.

**Data sharing**

If this is a data sharing system, delete the coupling facility structures.

3. Ensure that the DEFER ALL and TRKSITE NO subsystem parameters are specified.
4. If this is a non-data-sharing DB2, the log truncation point varies depending on whether you have received more logs from the primary site since the last recovery cycle:
  - If you received no more logs from the primary site:  
Start DB2 using the same ENDRBA that you used on the last tracker cycle. Specify FORWARD=YES and BACKOUT=YES (this takes care of uncommitted work). If you have fully recovered the objects during the previous cycle, then they are current except for any objects that had outstanding units of recovery during restart. Because the previous cycle specified NO for FORWARD and BACKOUT and you have now specified YES, affected data sets are placed in LPL. Restart the objects that are in LPL status using the following START DATABASE command:  
START DATABASE(\*) SPACENAM(\*)

After you issue the command, all table spaces and indexes that were previously recovered are now current. Remember to rebuild any indexes that were not recovered during the previous tracker cycle, including user-defined indexes on the DB2 catalog.

- If you received more logs from the primary site:  
Start DB2 using the truncated RBA `nnnnnnnnnn000`, which is the `ENDRBA + 1` of the latest archive log. Specify `FORWARD=YES` and `BACKOUT=YES`. Run your recoveries as you did during recovery cycles.

#### Data sharing

You must restart **every** member of the data sharing group, the following CRESTART statement:

```
CRESTART CREATE, ENDLRSN=nnnnnnnnnnnn, FORWARD=YES, BACKOUT=YES
```

In this statement, `nnnnnnnnnnnn` is the LRSN of the last log record to be used during restart. See step 3 of “Using the RECOVER utility to establish a recovery cycle” on page 577 for more information about determining this value. The takeover DB2s must specify conditional restart with a common ENDLRSN value to allow all remote members to logically truncate the logs at a consistent point.

5. As described for a tracker recovery cycle, recover SYSUTILX from an image copy from the primary site, or from a previous DSN1COPY taken at the tracker site.
6. Terminate any in-progress utilities by using the following procedure:
  - a. Enter the command `DISPLAY UTIL(*)`.
  - b. Run the DIAGNOSE utility with `DISPLAY SYSUTIL` to get the names of objects on which utilities are being run.
  - c. Terminate in-progress utilities using the command `TERM UTIL(*)`.  
See “What to do about utilities in progress” on page 571 for more information about how to terminate in-progress utilities and how to recover an object on which a utility was running.
7. Continue with your recoveries either with the LOGONLY option or image copies. Do not forget to rebuild indexes, including IBM and user-defined indexes on the DB2 catalog and user-defined indexes on table spaces.

## Using data mirroring

Data mirroring is the automatic replication of current data from your primary site to a secondary site. You can use this secondary site for your recovery site to recover after a disaster without the need to restore DB2 image copies or apply DB2 logs to bring DB2 data to the current point in time.

**Important:** The scenarios and procedures for data mirroring are intended for environments that mirror an entire DB2 subsystem or data sharing group, which includes the catalog, directory, user data, BSDS, and active logs. You must mirror all volumes in such a way that they terminate at exactly the same point. You can achieve this final condition using consistency groups, which are described in “Consistency groups” on page 584.

### The rolling disaster

In a real disaster, your local site gradually and intermittently fails over a number of seconds. This kind of DB2 failure is known as a *rolling disaster*.

To use data mirroring for disaster recovery, you must mirror data from your local site with a method that does not reproduce a rolling disaster at your recovery site. To recover DB2 with data integrity, you must use volumes that end at a consistent point in time for each DB2 subsystem or data sharing group. Mirroring a rolling disaster causes volumes at your recovery site to end over a span of time rather than at one single point.

Figure 60 shows how a rolling can cause data to become inconsistent between two subsystems.

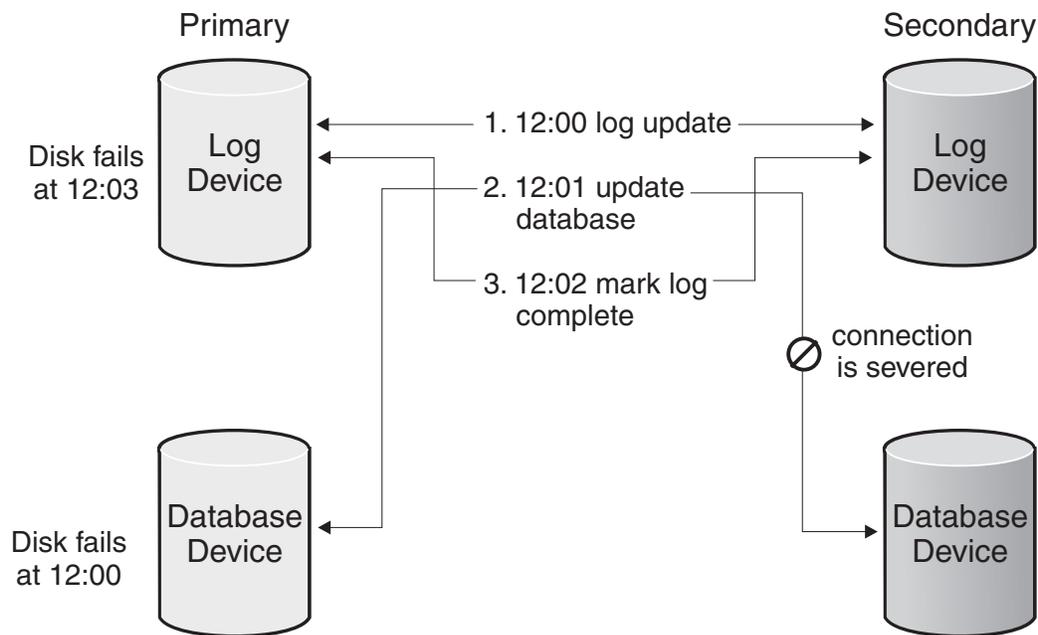

Figure 60. Data inconsistency caused by a rolling disaster

**Example:** In a rolling disaster, the following events at the primary site cause data inconsistency at your recovery site. This data inconsistency example follows the same scenario that Figure 60 depicts.

1. A table space is updated in the buffer pool (11:58).
2. The log record is written to disk on logical storage subsystem 1 (12:00).
3. Logical storage subsystem 2 fails (12:01).
4. The update to the table space is externalized to logical storage subsystem 2 but is not written because subsystem 2 failed (12:02).
5. The log record that table space update was made is written to disk on logical storage subsystem 1 (12:03).
6. Logical storage subsystem 1 fails (12:04).

Because the logical storage subsystems do not fail at the same point in time, they contain inconsistent data. In this scenario, the log indicates that the update is applied to the table space, but the update is not applied to the data volume that holds this table space.

**Attention:** Any disaster recovery solution that uses data mirroring must guarantee that all volumes at the recovery site contain data for the same point in time.

## Consistency groups

Generally, a *consistency group* is a collection of volumes that contain consistent, related data. This data can span logical storage subsystems and disk subsystems. For DB2 specifically, a consistency group contains an entire DB2 subsystem or a DB2 data sharing group. The following DB2 elements comprise a consistency group:

- Catalog tables
- Directory tables
- BSDS
- Logs
- All user data
- ICF catalogs

Additionally, all objects within a consistency group must represent the same point in time in at least one of the following situations:

- At the time of a backup
- After a normal DB2 restart

You can use various methods to create consistency groups. The following DB2 services enable you to create consistency groups:

- XRC I/O timestamping and system data mover
- FlashCopy consistency groups
- GDPSfreeze policies
- The DB2 SET LOG SUSPEND command
- The DB2 BACKUP SYSTEM utility

When a rolling disaster strikes your primary site, consistency groups guarantee that all volumes at the recovery site contain data for the same point in time. In a data mirroring environment, you must perform both of the following actions for each consistency group that you maintain:

- Mirror data to the secondary volumes in the same sequence that DB2 writes data to the primary volumes.

In many processing situations, DB2 must complete one write operation before it begins another write operation on a different disk group or a different storage server. A write operation that depends on a previous write operation is called a *dependent write*. Do not mirror a dependent write if you have not mirrored the write operation on which the dependent write depends. If you mirror data out of sequence, your recovery site will contain inconsistent data that you cannot use for disaster recovery.

- Temporarily suspend and queue write operations to create a group point of consistency when an error occurs between any pair of primary and secondary volumes.

When an error occurs that prevents the update of a secondary volume in a single-volume pair, this error might mark the beginning of a rolling disaster. To prevent your secondary site from mirroring a rolling disaster, you must suspend and queue data mirroring with the following steps after a write error between any pairs:

1. Suspend and queue all write operations in the volume pair that experiences a write error.
2. Invoke automation that temporarily suspends and queues data mirroring to all your secondary volumes.
3. Save data at the secondary site at a point of consistency.
4. If a rolling disaster does not strike your primary site, resume normal data mirroring after some amount of time that you have defined. If a rolling

disaster does strike your primary site, follow the recovery procedure in “Recovering in a data mirroring environment.”

## Recovering in a data mirroring environment

In a data mirroring environment, you can use a general procedure to recover at your secondary site from a disaster at your primary site. This procedure applies to all DB2 data mirroring scenarios except those that use Extended Remote Copy (XRC). This general procedure is valid only if you have established and maintained consistency groups before the disaster struck the primary site. If you use data mirroring to recover, you must recover your entire DB2 subsystem or data sharing group with data mirroring.

You do not need to restore DB2 image copies or apply DB2 logs to bring DB2 data to the current point in time when you use data mirroring. However, you might need image copies at the recovery site if the LOAD or RECOVER utilities were active at the time of the disaster.

To recover at the secondary site after a disaster, use the following procedure:

1. IPL all z/OS images at your recovery site that correspond to the z/OS images that you lost at your primary site.
2. For scenarios other than data sharing, continue with the next step.

### Data sharing

For data sharing groups, you must remove old information from the coupling facility.

- a. Enter the following z/OS command to display the structures for this data sharing group:

```
D XCF,STRUCTURE,STRNAME=grpname*
```

- b. For group buffer pools and the lock structure, enter the following command to force off the connections in those structures:

```
SETXCF FORCE,CONNECTION,STRNAME=strname,CONNAME=ALL
```

- c. Delete all the DB2 coupling facility structures by using the following command for each structure:

```
SETXCF FORCE,STRUCTURE,STRNAME=strname
```

3. If you are using the distributed data facility, set LOCATION and LUNAME in the BSDS to values that are specific to your new primary site. To set LOCATION and LUNAME run the stand-alone utility DSNJU003 (change log inventory) with the following control statement:

```
DDF LOCATION=locname, LUNAME=luname
```

4. Start all DB2 members using local DSNZPARM data sets and perform a normal restart.

### Data sharing

For data sharing groups, DB2 performs group restart. Shared data sets are set to GRECP (group buffer pool RECOVER-pending) status, and pages are added to the LPL (logical page list).

5. For scenarios other than data sharing, continue to the next step.

### Data sharing

For data sharing groups, perform the following procedure:

- a. Display all data sets with GRECP or LPL (logical page list) status with the following DB2 command:

```
-DISPLAY DATABASE(*) SPACENAM(*) RESTRICT(GRECP, LPL) LIMIT(*)
```

Record the output that this command generates.

- b. Start the DB2 directory with the following DB2 command:

```
-START DATABASE(DSNDB01) SPACENAM(*)
```

- c. Start the DB2 catalog with the following DB2 command:

```
-START DATABASE(DSNDB06) SPACENAM(*)
```

6. Use the following DB2 command to display all utilities that the failure interrupted:

```
-DISPLAY UTILITY(*)
```

If utilities are pending, record the output that this command and continue to step 7. You cannot restart utilities at a recovery site. You will terminate these utilities in step number 8. If no utilities are pending, continue to step number 9.

7. Use the DIAGNOSE utility to access the SYSUTILX directory table. This directory table is not listed in the *DB2 SQL Reference* because you can access it only when you use the DIAGNOSE utility. (The DIAGNOSE utility is normally intended to be used under the direction of IBM Software Support.)

Use the following control statement when you run the DIAGNOSE utility:

```
DIAGNOSE DISPLAY SYSUTILX  
END DIAGNOSE
```

Record the phase in which each pending utility was interrupted, and record the object on which each utility was operating.

8. Terminate all pending utilities with the following command:

```
-TERM UTILITY(*)
```

9. For scenarios other than data sharing, continue to the next step.

### Data sharing

For data sharing groups, use the following START DATABASE command on each database that contains objects in GRECP or LPL status:

```
-START DATABASE(database) SPACENAM(*)
```

When you use the START DATABASE command to recover objects, you do not need to provide DB2 with image copies.

**Tip:** Use up to 10 START DATABASE commands for each DB2 subsystem to increase the speed at which DB2 completes this operation. Multiple commands that run in parallel complete faster than a single command that specifies the same databases.

10. Start all remaining database objects with the following START DATABASE command:

START DATABASE(\*) SPACENAM(\*)

11. For each object that the LOAD utility has placed in a restrictive status, take one of the following actions:
  - If the object was a target of a LOAD utility control statement that specified SHRLEVEL CHANGE, restart the LOAD utility on this object at your convenience. This object contains valid data.
  - If the object was a target of a LOAD utility control statement that specified SHRLEVEL REFERENCE and the LOAD job was interrupted before the RELOAD phase, rebuild the indexes on this object.
  - If the object was a target of a LOAD utility control statement that specified SHRLEVEL REFERENCE and the LOAD job was interrupted during or after the RELOAD phase, you must recover this object to a point in time before this utility was run.
  - Otherwise, recover the object to a point in time before the LOAD job was run.
12. For each object that the REORG utility has placed in a restrictive status, take one of the following actions:
  - When the object was a target of a REORG utility control statement that specified SHERLEVEL NONE:
    - If the REORG job was interrupted before the RELOAD phase, no further action is required. This object contains valid data, and the indexes on this object are valid.
    - If the REORG job was interrupted during the RELOAD phase, you must recover this object to a point in time before this utility was run.
    - If the REORG job was interrupted after the RELOAD phase, rebuild the indexes on the object.
  - When the object was a target of a REORG utility control statement that does not specify SHERLEVEL NONE:
    - If the REORG job was interrupted before the SWITCH phase, no further action is required. This object contains valid data, and the indexes on this object are valid.
    - If the REORG job was interrupted during the SWITCH phase, no further action is required. This object contains valid data, and the indexes on this object are valid.
    - If the REORG job was interrupted after the SWITCH phase, you might need to rebuild non-partitioned secondary indexes.

### **Managing DFSMSHsm default settings when using the BACKUP SYSTEM and RESTORE SYSTEM utilities**

In some data mirroring situations, you might need to set or override the DFSMSHsm default settings for the BACKUP SYSTEM and RESTORE SYSTEM utilities.

For example, consider that the source volumes in the SMS storage groups for your database or log copy pools are mirrored, or that the target volumes in the SMS backup storage groups for your copy pools are mirrored. You can use IBM Remote Pair FlashCopy (Preserve Mirror) for Peer-to-Peer Remote Copy (PPRC). Also, you can allow FlashCopy to PPRC primary volumes. However, you might need to set or override the DFSMSHsm default settings for the BACKUP SYSTEM and RESTORE SYSTEM utilities.

The following prerequisites apply:

```

#           • You must be running on z/OS Version 1 Release 8 or later.
#           • You must apply APAR OA23849 to enable the DFSMSHsm FRBACKUP and
#           FRRECOV functions to support PPRC primary volumes.
#           • You must apply APAR OA24814 so that DFSMSHsm supports IBM Remote Pair
#           FlashCopy in FRBACKUP and FRRECOV operations in an SMS copy pool
#           environment.

#           To manage the DFSMSHsm default settings for these utilities, issue the DFSMSHsm
#           FRBACKUP PREPARE command:
#           • To set the DFSMSHsm defaults for the BACKUP SYSTEM utility and the
#           RESTORE SYSTEM utility, issue the following command:
#           FRBACKUP CP cp-name PREPARE ALLOWPPRC (FRBACKUP (x) FRRECOV (x))
#           • To override the DFSMSHsm defaults for the RESTORE SYSTEM utility, issue the
#           following command:
#           FRBACKUP CP cp-name PREPARE ALLOWPPRC (FRRECOV (x))

#           For more information about the FRBACKUP command, see z/OS DFSMS Storage
#           Administration Reference.

```

### Recovering with Extended Remote Copy

One method that ensures that data volumes remain consistent at your recovery site is by using Extended Remote Copy (XRC). In XRC remote mirroring, the DFSMS Advanced Copy services function automatically replicates current data from your primary site to a secondary site and establishes consistency groups. For specific information about extended remote copy or the extended remote copy environment, see *DFSMSdfp Advanced Services, SC26-7400*.

To recover at an XRC secondary site after a disaster, use the following procedure:

1. Issue the XEND XRC TSO command to end the XRC session.
2. Issue the XRECOVER XRC TSO command. This command changes your secondary site to your primary site and applies the XRC journals to recover data that was in transit when your primary site failed.
3. Complete the procedure in “Recovering in a data mirroring environment” on page 585.

---

## Resolving indoubt threads

This section describes problem scenarios involving indoubt threads resulting from the following types of error conditions:

“Communication failure recovery” on page 590

“Making a heuristic decision” on page 591

“Recovery from an IMS outage that results in an IMS cold start” on page 592

“Recovery from a DB2 outage at a requester that results in a DB2 cold start” on page 593

“Recovery from a DB2 outage at a server that results in a DB2 cold start” on page 596

“Correcting a heuristic decision” on page 596

All scenarios are developed in the context presented in “Description of the recovery environment” on page 589. System programmer, operator, and database administrator actions are indicated for the examples as appropriate. In these descriptions, the term *administrator* refers to the database administrator (DBA) if not otherwise specified.

## Description of the recovery environment

### Configuration

The configuration is composed of four systems at three geographic locations: Seattle (SEA), San Jose (SJ) and Los Angeles (LA). The system descriptions are as follows:

- DB2 subsystem at Seattle, Location name = IBMSEADB20001, Network name = IBM.SEADB21
- DB2 subsystem at San Jose, Location name = IBMSJ0DB20001 Network name = IBM.SJDB21
- DB2 subsystem at Los Angeles, Location name = IBMLA0DB20001 Network name = IBM.LADB21
- IMS subsystem at Seattle, Connection name = SEAIMS01

### Applications

The following IMS and TSO applications are running at Seattle and accessing both local and remote data.

- IMS application, IMSAPP01, at Seattle, accessing local data and remote data by DRDA access at San Jose, which is accessing remote data on behalf of Seattle by DB2 private protocol access at Los Angeles.
- TSO application, TSOAPP01, at Seattle, accessing data by DRDA access at San Jose and at Los Angeles.

### Threads

The following threads are described and keyed to Figure 61 on page 590. Data base access threads (DBAT) access data on behalf of a thread (either allied or DBAT) at a remote requester.

- Allied IMS thread **A** at Seattle accessing data at San Jose by DRDA access.
  - DBAT at San Jose accessing data for Seattle by DRDA access **1** and requesting data at Los Angeles by DB2 private protocol access **2**.
  - DBAT at Los Angeles accessing data for San Jose by DB2 private protocol access **2**.
- Allied TSO thread **B** at Seattle accessing local data and remote data at San Jose and Los Angeles, by DRDA access.
  - DBAT at San Jose accessing data for Seattle by DRDA access **3**.
  - DBAT at Los Angeles accessing data for Seattle by DRDA access **4**.

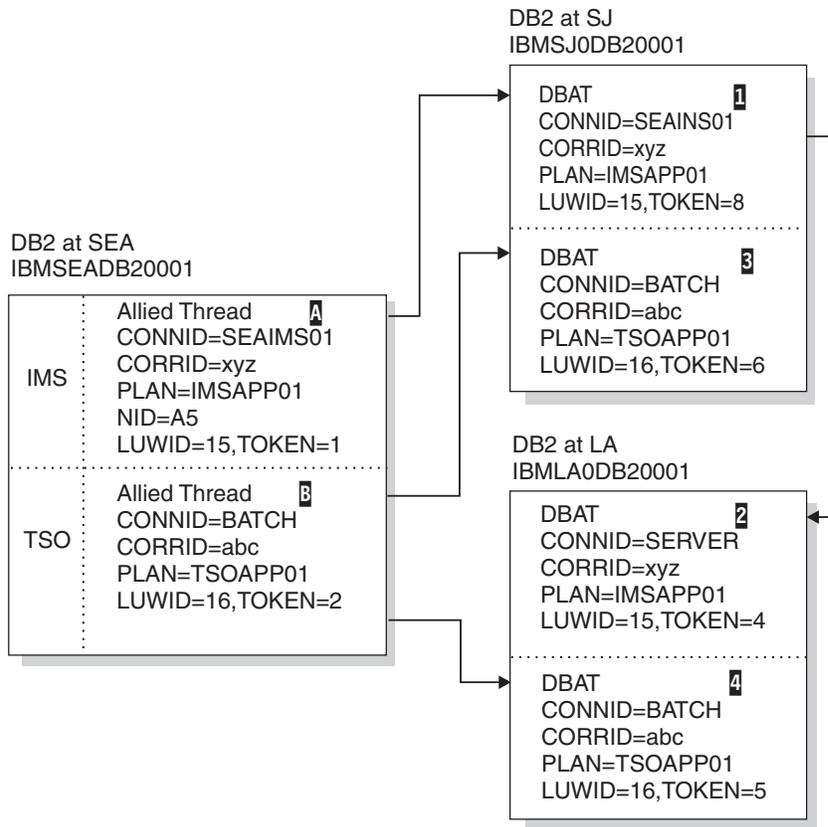

Figure 61. Resolving indoubt threads. Results of issuing DIS THD TYPE(ACTIVE) at each DB2 system.

The results of issuing the DISPLAY THREAD TYPE(ACTIVE) command to display the status of threads at all DB2 locations are summarized in the boxes of Figure 61. The logical unit of work IDs (LUWIDs) have been shortened for readability:

- LUWID=15 would be IBM.SEADB21.15A86A876789.0010
- LUWID=16 would be IBM.SEADB21.16B57B954427.0003

For the purposes of this section, assume that both applications have updated data at all DB2 locations. In the following problem scenarios, the error occurs after the coordinator has recorded the commit decision, but before the affected participants have recorded the commit decision. These participants are therefore indoubt.

## Communication failure recovery

**Problem:** A communication failure occurred between Seattle and Los Angeles after the DBAT at LA completed phase 1 of commit processing. At SEA, the TSO thread, LUWID=16 and TOKEN=2 **B**, cannot complete the commit with the DBAT at LA **4**.

**Symptom:** At SEA, NetView alert A006 is generated and message DSNL406 is displayed, indicating an indoubt thread at LA because of communication failure. At LA, alert A006 is generated and message DSNL405 is displayed, indicating a thread has entered indoubt state because of communication failure with SEA.

**System action:** At SEA, an IFCID 209 trace record is written. After the alert has been generated, and after the message has been displayed, the thread completes the commit, which includes the DBAT at SJ **3**. Concurrently, the thread is added

to the list of threads for which the SEA DB2 has an indoubt resolution responsibility. The thread appears in a display thread report for indoubt threads. The thread also appears in a display thread report for active threads until the application terminates.

The TSO application is told that the commit succeeded. If the application continues and processes another SQL request, it is rejected with an SQL code indicating it must roll back before any more SQL requests can be processed. This is to insure that the application does not proceed with an assumption based upon data retrieved from LA, or with the expectation that cursor positioning at LA is still intact.

At LA, an IFCID 209 trace record is written. After the alert is generated and the message displayed, the DBAT **4** is placed into the indoubt state. All locks remain held until resolution occurs. The thread appears in a display thread report for indoubt threads.

The DB2 systems, at both SEA and LA, periodically attempt reconnecting and automatically resolving the indoubt thread. If the communication failure only affects the session being used by the TSO application, and other sessions are available, automatic resolution occurs in a relatively short time. At this time, message DSNL407 is displayed by both DB2 subsystems.

*Operator action:* If message DSNL407 or DSNL415 for the thread identified in message DSNL405 does not appear in a reasonable period of time, call the system programmer. A communication failure is making database resources unavailable.

*System programmer action:* Determine and correct the cause of the communication failure. When corrected, automatic resolution of the indoubt thread occurs within a short time. If the failure cannot be corrected for a long time, call the database administrator. The database administrator might want to make a heuristic decision to release the database resources held for the indoubt thread. See “Making a heuristic decision.”

## Making a heuristic decision

*Problem:* The indoubt thread at LA is holding database resources that are needed by other applications.

*Symptom:* Many symptoms can be present, including:

- Message DSNL405 indicating a thread in the indoubt state.
- A display thread report of active threads showing a larger than normal number of threads.
- A display thread report of indoubt threads continuing to show the same thread.
- A display database report with the LOCKS option showing a large number of threads waiting for the locks held by the indoubt thread.
- Some threads terminating due to time out.
- IMS and CICS transactions not completing.

*Database administrator action:* Determine whether to commit or abort the indoubt thread. First, determine the name of the commit coordinator for the indoubt thread. This is the location name of the DB2 subsystem at SEA, and is included in the DB2 indoubt thread display report at LA. Then, have an authorized person at SEA perform one of the following actions:

- If the coordinator DB2 subsystem is active, or can be started, request a display thread report for indoubt threads, specifying the LUWID of the thread. (Remember that the token used at LA is different than the token used at SEA). *If there is no report entry for the LUWID, then the proper action is to abort. If there is an entry for the LUWID, it shows the proper action to take.*
- If the coordinator DB2 subsystem is not active and cannot be started, and if statistics class 4 was active when DB2 was active, search the SEA SMF data for an IFCID 209 event entry containing the indoubt LUWID. This entry indicates whether the commit decision was commit or abort.
- If statistics class 4 is not available, then run, at SEA, the DSN1LOGP utility requesting a summary report. The volume of log data to be searched can be restricted if you can determine the approximate SEA log RBA value in effect at the time of the communication failure. A DSN1LOGP entry in the summary report for the indoubt LUWID indicates whether the decision was commit or abort.

After determining the correct action to take, issue the RECOVER INDOUBT command at the LA DB2 subsystem, specifying the LUWID and the correct action.

**System action:** Issuing the RECOVER INDOUBT command at LA results in committing or aborting the indoubt thread. Locks are released. The thread does not disappear from the indoubt thread display until resolution with SEA is completed. The recover indoubt report shows that the thread is either committed or aborted by a heuristic decision. An IFCID 203 trace record is written, recording the heuristic action.

## Recovery from an IMS outage that results in an IMS cold start

**Problem:** The abnormal termination of IMS has left one allied thread **A** at the SEA DB2 subsystem indoubt. This is the thread having LUWID=15. Because the SEA DB2 still has effective communication with the DB2 subsystem at SJ, the LUWID=15 DBAT **1** at this system is waiting for the SEA DB2 to communicate the final decision and is not aware that IMS has failed. Also, the LUWID=15 DBAT at LA **2** which is connected to SJ is also waiting for SJ to communicate the final decision. This cannot be done until SEA communicates the decision to SJ.

**Symptom:** When IMS is cold started, and later reconnects with the SEA DB2 subsystem, IMS is not able to resolve the indoubt thread with DB2. Message DSNM004I is displayed at the IMS master terminal. This is the same process as described in “Resolution of indoubt units of recovery” on page 526.

**System action:** This is the same process as described in “Resolution of indoubt units of recovery” on page 526.

**System programmer action:** This is the same process as described in “Resolution of indoubt units of recovery” on page 526.

When the indoubt thread at the SEA DB2 subsystem is resolved by issuing the RECOVER INDOUBT command, completion of the two-phase commit process with the DB2 subsystems at SJ and LA occurs, and the unit of work commits or aborts.

**Operator action:** This is the same process as described in “Resolution of indoubt units of recovery” on page 526.

## Recovery from a DB2 outage at a requester that results in a DB2 cold start

**Problem:** The abnormal termination of the SEA DB2 has left the two DBATs at SJ **1**, **3** and the LUWID=16 DBAT at LA **4** indoubt. The LUWID=15 DBAT at LA **2**, connected to SJ, is waiting for the SJ DB2 to communicate the final decision.

The IMS subsystem at SEA is operational and has the responsibility of resolving indoubt units with the SEA DB2.

**Symptom:** The DB2 subsystem at SEA is started with a conditional restart record in the BSDS indicating a cold start:

- When the IMS subsystem reconnects, it attempts to resolve the indoubt thread identified in IMS as NID=A5. IMS has a resource recovery element (RRE) for this thread. The SEA DB2 informs IMS that it has no knowledge of this thread. IMS does not delete the RRE and it can be displayed by using the IMS DISPLAY OASN command. The SEA DB2 also:
  - Generates message DSN3005 for each IMS RRE for which DB2 has no knowledge.
  - Generates an IFCID 234 trace event.
- When the DB2 subsystems at SJ and LA reconnect with SEA, each detects that the SEA DB2 has cold started. Both the SJ DB2 and the LA DB2:
  - Display message DSNL411.
  - Generate alert A001.
  - Generate an IFCID 204 trace event.
- A display thread report of indoubt threads at both the SJ and LA DB2 subsystems shows the indoubt threads and indicates that the coordinator has cold started.

**System action:** The DB2 subsystem at both SJ and LA accept the cold start connection from SEA. Processing continues, waiting for a heuristic decision to resolve the indoubt threads.

**System programmer action:** Call the database administrator.

**Operator action:** Call the database administrator.

**Database administrator action:** At this point, neither the SJ nor the LA administrator know if the SEA coordinator was a participant of another coordinator. In this scenario, the SEA DB2 subsystem originated LUWID=16. However, it was a participant for LUWID=15, being coordinated by IMS.

Also not known to the administrator at LA is the fact that SEA distributed the LUWID=16 thread to SJ where it is also indoubt. Likewise, the administrator at SJ does not know that LA has an indoubt thread for the LUWID=16 thread. It is important that both SJ and LA make the same heuristic decision. It is also important that the administrators at SJ and LA determine the originator of the two-phase commit.

The recovery log of the originator indicates whether the decision was commit or abort. The originator might have more accessible functions to determine the decision. Even though the SEA DB2 cold started, you might be able to determine the decision from its recovery log. Or, if the failure occurred before the decision was recorded, you might be able to determine the name of the coordinator, if the

SEA DB2 was a participant. A summary report of the SEA DB2 recovery log can be provided by execution of the DSN1LOGP utility.

The LUWID contains the name of the logical unit (LU) where the distributed logical unit of work originated. This logical unit is most likely in the system that originated the two-phase commit.

If an application is distributed, any distributed piece of the application can initiate the two-phase commit. In this type of application, the originator of two-phase commit can be at a different system than that identified by the LUWID. With DB2 private protocol access, the two-phase commit can flow only from the system containing the application that initiates distributed SQL processing. In most cases, this is where the application originates.

The administrator must determine if the LU name contained in the LUWID is the same as the LU name of the SEA DB2 subsystem. If this is not the case (it is the case in this example), then the SEA DB2 is a participant in the logical unit of work, and is being coordinated by a remote system. You must communicate with that system and request that facilities of that system be used to determine if the logical unit of work is to be committed or aborted.

If the LUWID contains the LU name of the SEA DB2 subsystem, then the logical unit of work originated at SEA and is either an IMS, CICS, TSO, or BATCH allied thread of the SEA DB2. The display thread report for indoubt threads at a DB2 participant includes message DSNV458 if the coordinator is remote. This line provides external information provided by the coordinator to assist in identifying the thread. A DB2 coordinator provides the following identifier:

*connection-name.correlation-id*

where *connection-name* is:

- SERVER: the thread represents a remote application to the DB2 coordinator and uses DRDA access.
- BATCH: the thread represents a local batch application to the DB2 coordinator.

Anything else represents an IMS or CICS connection name. The thread represents a local application and the commit coordinator is the IMS or CICS system using this connection name.

In our example, the administrator at SJ sees that both indoubt threads have a LUWID with the LU name the same as the SEA DB2 LU name, and furthermore, that one thread (LUWID=15) is an IMS thread and the other thread (LUWID=16) is a batch thread. The LA administrator sees that the LA indoubt thread (LUWID=16) originates at SEA DB2 and is a batch thread.

The originator of a DB2 batch thread is DB2. To determine the commit or abort decision for the LUWID=16 indoubt threads, the SEA DB2 recovery log must be analyzed, if it can be. The DSN1LOGP utility must be executed against the SEA DB2 recovery log, looking for the LUWID=16 entry. There are three possibilities:

1. No entry is found. That portion of the DB2 recovery log was not available.
2. An entry is found but incomplete.
3. An entry is found and the status is committed or aborted.

In the third case, the heuristic decision at SJ and LA for indoubt thread LUWID=16 is indicated by the status indicated in the SEA DB2 recovery log. In the other two cases, the recovery procedure used when cold starting DB2 is important. If

recovery was to a previous point in time, the correct action is to abort. If recovery included repairing the SEA DB2 database, the SEA administrator might know what decision to make.

The recovery logs at SJ and LA can help determine what activity took place. If it can be determined that updates were performed at either SJ, LA, or both (but not SEA), then if both SJ and LA make the same heuristic action, there should be no data inconsistency. If updates were also performed at SEA, then looking at the SEA data might help determine what action to take. In any case, both SJ and LA should make the same decision.

For the indoubt thread with LUWID=15 (the IMS coordinator), there are several alternative paths to recovery. The SEA DB2 has been restarted. When it reconnects with IMS, message DSN3005 is issued for each thread that IMS is trying to resolve with DB2. The message indicates that DB2 has no knowledge of the thread that is identified by the IMS assigned NID. The outcome for the thread, commit or abort, is included in the message. Trace event IFCID=234 is also written to statistics class 4 containing the same information.

If there is only one such message, or one such entry in statistics class 4, then the decision for indoubt thread LUWID=15 is known and can be communicated to the administrator at SJ. If there are multiple such messages, or multiple such trace events, you must match the IMS NID with the network LUWID. Again, DSN1LOGP should be used to analyze the SEA DB2 recovery log if possible. There are now four possibilities:

1. No entry is found. That portion of the DB2 recovery log was not available.
2. An entry is found but incomplete because of lost recovery log.
3. An entry is found and the status is indoubt.
4. An entry is found and the status is committed or aborted.

In the fourth case, the heuristic decision at SJ for the indoubt thread LUWID=15 is determined by the status indicated in the SEA DB2 recovery log. If an entry is found whose status is indoubt, DSN1LOGP also reports the IMS NID value. The NID is the unique identifier for the logical unit of work in IMS and CICS. Knowing the NID allows correlation to the DSN3005 message, or to the 234 trace event, which provides the correct decision.

If an incomplete entry is found, the NID may or may not have been reported by DSN1LOGP. If it was, use it as previously discussed. If no NID is found, or the SEA DB2 has not been started, or reconnecting to IMS has not occurred, then the *correlation-id* used by IMS to correlate the IMS logical unit of work to the DB2 thread must be used in a search of the IMS recovery log. The SEA DB2 provided this value to the SJ DB2 when distributing the thread to SJ. The SJ DB2 displays this value in the report generated by DISPLAY THREAD TYPE(INDOUBT).

For IMS, the *correlation-id* is:

pst#.psbname

In CICS, the *correlation-id* consists of four parts:

Byte 1 - Connection Type - G=Group, P=Pool  
Byte 2 - Thread Type - T=transaction, G=Group, C=Command  
Bytes 3-4 - Thread Number  
Bytes 5-8 - Transaction-id

## Recovery from a DB2 outage at a server that results in a DB2 cold start

**Problem:** This problem is similar to “Recovery from a DB2 outage at a requester that results in a DB2 cold start” on page 593. If the DB2 subsystem at SJ is cold started instead of the DB2 at SEA, then the LA DB2 has the LUWID=15 **2** thread indoubt. The administrator would see that this thread did not originate at SJ, but did originate at SEA. To determine the commit or abort action, the LA administrator would request that DISPLAY THREAD TYPE(INDOUBT) be issued at the SEA DB2, specifying LUWID=15. IMS would not have any indoubt status for this thread, because it would complete the two-phase commit process with the SEA DB2.

As described in “Communication failure recovery” on page 590, the DB2 at SEA tells the application that the commit succeeded.

When a participant cold starts, a DB2 coordinator continues to include in the display of indoubt threads all committed threads where the cold starting participant was believed to be indoubt. These entries must be explicitly purged by issuing the RESET INDOUBT command. If a participant has an indoubt thread that cannot be resolved because of coordinator cold start, it can request a display of indoubt threads at the DB2 coordinator to determine the correct action.

## Correcting a heuristic decision

**Problem:** Assume the conditions of “Communication failure recovery” on page 590. The LA administrator is called to make a heuristic decision and decides to abort the indoubt thread with LUWID=16. The decision is made without communicating with SEA to determine the proper action. The thread at LA is aborted, while the threads at SEA and SJ are committed. Processing continues at all systems. DB2 at SEA has indoubt resolution responsibility with LA for LUWID=16.

**Symptom:** When the DB2 at SEA reconnects with the DB2 at LA, indoubt resolution occurs for LUWID=16. Both systems detect heuristic damage and both generate alert A004; each writes an IFCID 207 trace record. Message DSNL400 is displayed at LA and message DSNL403 is displayed at SEA..

**System action:** Processing continues. Indoubt thread resolution responsibilities have been fulfilled and the thread completes at both SJ and LA.

**System programmer action:** Call the database administrator.

**Operator action:** Call the database administrator.

**Database administrator action:** Correct the damage.

This is not an easy task. Since the time of the heuristic action, the data at LA might have been read or written by many applications. Correcting the damage can involve reversing the effects of these applications as well. The tools available are:

- DSN1LOGP. The summary report of this utility identifies the table spaces modified by the LUWID=16 thread.
- The statistics trace class 4 contains an IFCID 207. entry. This entry identifies the recovery log RBA for the LUWID=16 thread.

Notify the IBM Software Support about the problem.

---

## Chapter 23. Recovery from BSDS or log failure during restart

Use this chapter when you have reason to believe that the bootstrap data set (BSDS) or part of the recovery log for DB2 is damaged or lost and that damage is preventing restart. If the problem is discovered at restart, begin with one of these recovery procedures:

“Active log failure recovery” on page 535

“Archive log failure recovery” on page 539

“BSDS failure recovery” on page 542

If the problem persists, return to the procedures in this chapter.

When DB2 recovery log damage terminates restart processing, DB2 issues messages to the console identifying the damage and giving an abend reason code. (The SVC dump title includes a more specific abend reason code to assist in problem diagnosis.) If the explanations in Part 2 of *DB2 Messages* indicate that restart failed because of some problem not related to a log error, refer to Part 2 of *DB2 Diagnosis Guide and Reference* and contact the IBM support center.

To minimize log problems during restart, the system requires two copies of the BSDS. Dual logging is also recommended.

**Basic approaches to recovery:** There are two basic approaches to recovery from problems with the log:

- Restart DB2, bypassing the inaccessible portion of the log and rendering some data inconsistent. Then recover the inconsistent objects by using the RECOVER utility, or re-create the data using REPAIR. Use the methods that are described following this procedure to recover the inconsistent data.
- Restore the entire DB2 subsystem to a prior point of consistency. The method requires that you have first prepared such a point; for suggestions, see “Preparing to recover to a prior point of consistency” on page 485. Methods of recovery are described under “Unresolvable BSDS or log data set problem during restart” on page 616.

**Bypassing the damaged log:** Even if the log is damaged, and DB2 is started by circumventing the damaged portion, the log is the most important source for determining what work was lost and what data is inconsistent. For information about data sharing considerations, see Chapter 5 of *DB2 Data Sharing: Planning and Administration*.

Bypassing a damaged portion of the log generally proceeds with the following steps:

1. DB2 restart fails. A problem exists on the log, and a message identifies the location of the error. The following abend reason codes, which appear only in the dump title, can be issued for this type of problem. This is not an exhaustive list; other codes might occur.

---

00D10261	00D10264	00D10267	00D1032A	00D1032C
00D10262	00D10265	00D10268	00D1032B	00E80084
00D10263	00D10266	00D10329		

---

Figure 62 on page 598 illustrates the general problem:

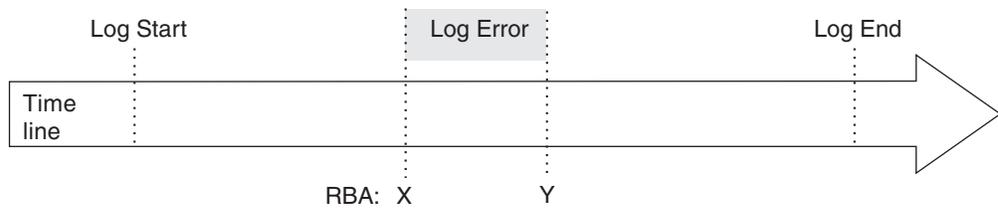

Figure 62. General problem of damaged DB2 log information

2. DB2 cannot skip over the damaged portion of the log and continue restart processing. Instead, you restrict processing to only a part of the log that is error free. For example, the damage shown in Figure 62 occurs in the log RBA range from X to Y. You can restrict restart to all of the log before X; then changes later than X are not made. Or you can restrict restart to all of the log after Y; then changes between X and Y are not made. In either case, some amount of data is inconsistent.
3. You identify the data that is made inconsistent by your restart decision. With the SUMMARY option, the DSN1LOGP utility scans the accessible portion of the log and identifies work that must be done at restart, namely, the units of recovery to be completed and the page sets that they modified. (For instructions on using DSN1LOGP, see Part 3 of *DB2 Utility Guide and Reference*.) Because a portion of the log is inaccessible, the summary information might not be complete. In some circumstances, your knowledge of work in progress is needed to identify potential inconsistencies.
4. You use the CHANGE LOG INVENTORY utility to identify the portion of the log to be used at restart, and to tell whether to bypass any phase of recovery. You can choose to do a cold start and bypass the entire log.
5. You restart DB2. Data that is unaffected by omitted portions of the log is available for immediate access.
6. Before you allow access to any data that is affected by the log damage, you resolve all data inconsistencies. That process is described under “Resolving inconsistencies resulting from a conditional restart” on page 622.

**Where to start:** The specific procedure depends on the phase of restart that was in control when the log problem was detected. On completion, each phase of restart writes a message to the console. You must find the last of those messages in the console log. The next phase after the one identified is the one that was in control when the log problem was detected. Accordingly, start at:

- “Log initialization or current status rebuild failure recovery” on page 599
- “Failure during forward log recovery” on page 608
- “Failure during backward log recovery” on page 613

As an alternative, determine which, if any, of the following messages was last received and follow the procedure for that message. Other DSN messages can be issued as well.

Message ID	Procedure to use
DSNJ001I	“Log initialization or current status rebuild failure recovery” on page 599
DSNJ100I	“Unresolvable BSDS or log data set problem during restart” on page 616
DSNJ107I	“Unresolvable BSDS or log data set problem during restart” on page 616
DSNJ119I	“Unresolvable BSDS or log data set problem during restart” on page 616
DSNR002I	None. Normal restart processing can be expected.

Message ID	Procedure to use
DSNR004I	"Failure during forward log recovery" on page 608
DSNR005I	"Failure during backward log recovery" on page 613
DSNR006I	None. Normal restart processing can be expected.
Other	"Log initialization or current status rebuild failure recovery"

Another scenario ( "Failure resulting from total or excessive loss of log data" on page 619) provides information to use if you determine (by using Log initialization or current status rebuild failure recovery) that an excessive amount (or all) of DB2 log information (BSDS, active, and archive logs) has been lost.

The last scenario in this chapter ("Resolving inconsistencies resulting from a conditional restart" on page 622) can be used to resolve inconsistencies introduced while using one of the restart scenarios in this chapter. If you decide to use "Unresolvable BSDS or log data set problem during restart" on page 616, it is not necessary to use "Resolving inconsistencies resulting from a conditional restart" on page 622.

Because of the severity of the situations described, the scenarios identify "Operations management action", rather than "Operator action". Operations management might not be performing all the steps in the procedures, but they must be involved in making the decisions about the steps to be performed.

---

## Log initialization or current status rebuild failure recovery

**Problem:** A failure occurred during the log initialization or current status rebuild phase of restart.

**Symptom:** An abend was issued indicating that restart failed. In addition, the last restart message received was a DSNJ001I message indicating a failure during current status rebuild, or none of the following messages was issued:

DSNJ001I  
 DSNR004I  
 DSNR005I

If none of the preceding messages were issued, the failure occurred during the log initialization phase of restart.

**System action:** The action depends on whether the failure occurred during log initialization or during current status rebuild.

- **Failure during log initialization:** DB2 terminates because a portion of the log is inaccessible, and DB2 cannot locate the end of the log during restart.
- **Failure during current status rebuild:** DB2 terminates because a portion of the log is inaccessible, and DB2 cannot determine the state of the subsystem (such as outstanding units of recovery, outstanding database writes, or exception database conditions) that existed at the prior DB2 termination.

**Operations management action:** To correct the problem, choose one of the following approaches:

- Correct the problem that has made the log inaccessible and start DB2 again. To determine if this approach is possible, refer to *DB2 Codes* for an explanation of

the messages and codes received. The explanation will identify the corrective action that can be taken to resolve the problem. In this case, it is not necessary to read the scenarios in this chapter.

- Restore the DB2 log and all data to a prior consistent point and start DB2. This procedure is described in “Unresolvable BSDS or log data set problem during restart” on page 616.
- Start DB2 without completing some database changes. Using a combination of DB2 services and your own knowledge, determine what work will be lost by truncating the log. The procedure for determining the page sets that contain incomplete changes is described in “Restart by truncating the log” on page 601. In order to obtain a better idea of what the problem is, read one of the following sections, depending on when the failure occurred.

## Description of failure during log initialization

Figure 63 illustrates the problem on the log.

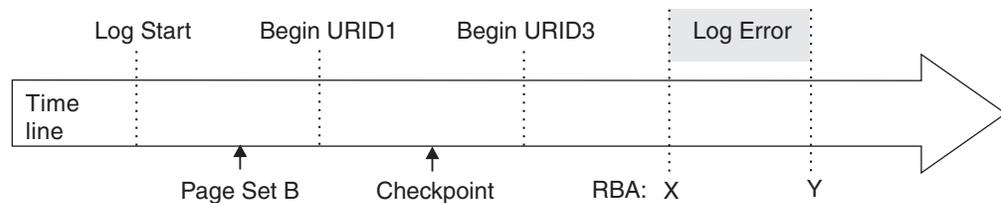

Figure 63. Failure during log initialization

The portion of the log between log RBAs X and Y is inaccessible. For failures that occur during the log initialization phase, the following activities occur:

1. DB2 allocates and opens each active log data set that is not in a stopped state.
2. DB2 reads the log until the last log record is located.
3. During this process, a problem with the log is encountered, preventing DB2 from locating the end of the log. DB2 terminates and issues one of the abend reason codes listed in Table 102 on page 602.

During its operations, DB2 periodically records in the BSDS the RBA of the last log record written. This value is displayed in the print log map report as follows:

```
HIGHEST RBA WRITTEN: 00000742989E
```

Because this field is updated frequently in the BSDS, the *highest RBA written* can be interpreted as an approximation of the end of the log. The field is updated in the BSDS when any one of a variety of internal events occurs. In the absence of these internal events, the field is updated each time a complete cycle of log buffers is written. A complete cycle of log buffers occurs when the number of log buffers written equals the value of the OUTPUT BUFFER field of installation panel DSNTIPL. The value in the BSDS is, therefore, relatively close to the end of the log.

To find the actual end of the log at restart, DB2 reads the log forward sequentially, starting at the log RBA that approximates the end of the log and continuing until the actual end of the log is located.

Because the end of the log is inaccessible in this case, some information has been lost. Units of recovery might have successfully committed or modified additional page sets past point X. Additional data might have been written, including those that are identified with writes pending in the accessible portion of the log. New

units of recovery might have been created, and these might have modified data. Because of the log error, DB2 cannot perceive these events.

How to restart DB2 is described under “Restart by truncating the log.”

## Description of failure during current status rebuild

Figure 64 illustrates the problem on the log.

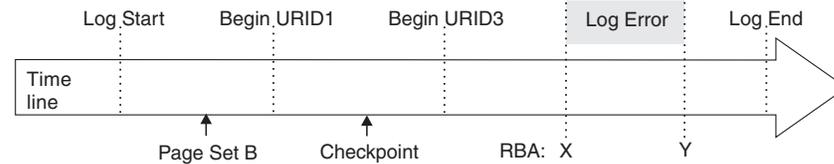

Figure 64. Failure during current status rebuild

The portion of the log between log RBAs X and Y is inaccessible. For failures that occur during the current status rebuild phase, the following activities occur:

1. Log initialization completes successfully.
2. DB2 locates the last checkpoint. (The BSDS contains a record of its location on the log.)
3. DB2 reads the log, beginning at the checkpoint and continuing to the end of the log.
4. DB2 reconstructs the subsystem’s state as it existed at the prior termination of DB2.
5. During this process, a problem with the log is encountered, preventing DB2 from reading all required log information. DB2 terminates with one of the abend reason codes listed in Table 102 on page 602.

Because the end of the log is inaccessible in this case, some information has been lost. Units of recovery might have successfully committed or modified additional page sets past point X. Additional data might have been written, including those that are identified with writes pending in the accessible portion of the log. New units of recovery might have been created, and these might have modified data. Because of the log error, DB2 cannot perceive these events.

How to restart DB2 is described under “Restart by truncating the log.”

## Restart by truncating the log

When a portion of the log is inaccessible, during the log initialization or current status rebuild phases of restart, DB2 cannot identify precisely what units of recovery failed to complete, what page sets those modified, and what page sets have writes pending. This procedure tells how to gather that information and restart.

### Step 1: Find the log RBA after the inaccessible part of the log

The log damage is illustrated in Figure 63 on page 600 and in Figure 64. The range of the log between RBAs X and Y is inaccessible to all DB2 processes.

Use the abend reason code accompanying the X'04E' abend and the message on the title of the accompanying dump at the operator’s console, to find the name and location of a procedure in Table 102 on page 602. Use that procedure to find X and Y.

Table 102. Abend reason codes and messages

Abend reason code	Message	Procedure	General error description
00D10261 00D10262 00D10263 00D10264 00D10265 00D10266 00D10267 00D10268	DSNJ012I	"RBA 1"	Log record is logically damaged
00D10329	DSNJ106I	"RBA 2"	I/O error occurred while log record was being read
00D1032A	DSNJ113E	"RBA 3" on page 603	Log RBA could not be found in BSDS
00D1032B	DSNJ103I	"RBA 4" on page 603	Allocation error occurred for an archive log data set
00D1032B	DSNJ007I	"RBA 5" on page 604	The operator canceled a request for archive mount
00D1032C	DSNJ104I	"RBA 4" on page 603	Open error occurred for an archive and active log data set
00E80084	DSNJ103I	"RBA 4" on page 603	Active log data set named in the BSDS could not be allocated during log initialization

**Procedure RBA 1:** The message accompanying the abend identifies the log RBA of the first inaccessible log record that DB2 detects. For example, the following message indicates a logical error in the log record at log RBA X'7429ABA'.

```
DSNJ012I ERROR D10265 READING RBA 000007429ABA
          IN DATA SET DSNCAT.LOGCOPY2.DS01
          CONNECTION-ID=DSN,
          CORRELATION-ID=DSN
```

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the log control interval definition (LCID). DB2 stores logical records in blocks of physical records to improve efficiency. When this type of an error on the log occurs during log initialization or current status rebuild, all log records within the physical log record are inaccessible. Therefore, the value of X is the log RBA that was reported in the message rounded down to a 4 KB boundary (X'7429000').

Continue with "Step 2: Identify lost work and inconsistent data" on page 604.

**Procedure RBA 2:** The message accompanying the abend identifies the log RBA of the first inaccessible log record that DB2 detects. For example, the following message indicates an I/O error in the log at RBA X'7429ABA'.

```
DSNJ106I LOG READ ERROR DSNAME=DSNCAT.LOGCOPY2.DS01,
          LOGRBA=000007429ABA,ERROR STATUS=0108320C
```

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the LCID. When this type of an error on the log occurs during log initialization or current status rebuild, all log records within the physical log record and beyond it to the end of the log data set are inaccessible to the log initialization or current status rebuild phase of

restart. Therefore, the value of X is the log RBA that was reported in the message, rounded down to a 4 KB boundary (X'7429000').

Continue with “Step 2: Identify lost work and inconsistent data” on page 604.

**Procedure RBA 3:** The message accompanying the abend identifies the log RBA of the inaccessible log record. This log RBA is not registered in the BSDS.

For example, the following message indicates that the log RBA X'7429ABA' is not registered in the BSDS:

```
DSNJ113E RBA 000007429ABA NOT IN ANY ACTIVE OR ARCHIVE
        LOG DATA SET. CONNECTION-ID=DSN, CORRELATION-ID=DSN
```

The print log map utility can be used to list the contents of the BSDS. For an example of the output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*.

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the LCID. When this type of an error on the log occurs during log initialization or current status rebuild, all log records within the physical log record are inaccessible.

Using the print log map output, locate the RBA closest to, but less than, X'7429ABA' for the value of X. If there is not an RBA that is less than X'7429ABA', a considerable amount of log information has been lost. If this is the case, continue with “Failure resulting from total or excessive loss of log data” on page 619.

If X has a value, continue with “Step 2: Identify lost work and inconsistent data” on page 604.

**Procedure RBA 4:** The message accompanying the abend identifies an entire data set that is inaccessible. For example, the following message indicates that the archive log data set DSNCAT.ARCHLOG1.A0000009 is not accessible, and the STATUS field identifies the code that is associated with the reason for the data set being inaccessible. For an explanation of the STATUS codes, see the explanation for the message in Part 2 of *DB2 Messages*.

```
DSNJ103I - csect-name LOG ALLOCATION ERROR
        DSNNAME=DSNCAT.ARCHLOG1.A0000009,ERROR
        STATUS=04980004
        SMS REASON CODE=00000000
```

To determine the value of X, run the print log map utility to list the log inventory information. For an example of the output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*. The output provides each log data set name and its associated log RBA range—the values of X and Y.

Verify the accuracy of the information in the print log map utility output for the active log data set with the lowest RBA range. For this active log data set only, the information in the BSDS is potentially inaccurate for the following reasons:

- When an active log data set is full, archiving is started. DB2 then selects another active log data set, usually the data set with the lowest RBA. This selection is made so that units of recovery do not have to wait for the archive operation to complete before logging can continue. However, if a data set has not been archived, nothing beyond it has been archived, and the procedure is ended.
- When logging has begun on a reusable data set, DB2 updates the BSDS with the new log RBA range for the active log data set, and marks it as *Not Reusable*. The

process of writing the new information to the BSDS can be delayed by other processing. It is therefore possible for a failure to occur between the time that logging to a new active log data set begins and the time that the BSDS is updated. In this case, the BSDS information is not correct.

The log RBA that appears for the active log data set with the lowest RBA range in the print log map utility output is valid, provided that the data set is marked *Not Reusable*. If the data set is marked *Reusable*, it can be assumed for the purposes of this restart that the starting log RBA (X) for this data set is one greater than the highest log RBA listed in the BSDS for all other active log data sets.

Continue with “Step 2: Identify lost work and inconsistent data.”

**Procedure RBA 5:** The message accompanying the abend identifies an entire data set that is inaccessible. For example, the following message indicates that the archive log data set DSNCAT.ARCHLOG1.A0000009 is not accessible. The operator canceled a request for archive mount, resulting in the following message:

```
DSNJ007I OPERATOR CANCELED MOUNT OF ARCHIVE
          DSNCAT.ARCHLOG1.A0000009 VOLSER=5B225.
```

To determine the value of X, run the print log map utility to list the log inventory information. For an example of the output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*. The output provides each log data set name and its associated log RBA range: the values of X and Y.

Continue with “Step 2: Identify lost work and inconsistent data.”

## Step 2: Identify lost work and inconsistent data

1. Obtain available information to help you determine the extent of the loss.

It is impossible for DB2 to determine what units of recovery are not completed, what database state information is lost, or what data is inconsistent in this situation. The log contains all such information, but the information is not available. The following steps explain what to do to obtain the information that is available within DB2 to help determine the extent of the loss. The steps also explain how to start DB2 in this situation.

After restart, data is inconsistent. Results of queries and any other operations on such data vary from incorrect results to abends. Abends that occur either identify an inconsistency in the data or incorrectly assume the existence of a problem in the DB2 internal algorithms. **If the inconsistent page sets cannot be identified and the problems in them cannot be resolved after starting DB2, there is a risk in following this procedure and allowing access to inconsistent data.**

- a. Execute the print log map utility. The report it produces includes a description of the last 100 checkpoints and provides, for each checkpoint:
  - The location in the log of the checkpoint (begin and end RBA)
  - The date and time of day that the checkpoint was performed.
- b. Locate the checkpoint on the log prior to the point of failure (X). Do that by finding the first checkpoint with an end RBA that is less than X.

If you cannot find such a checkpoint, this means that a considerable amount of log has been lost. In this case, either follow the procedure under “Failure resulting from total or excessive loss of log data” on page 619 or the procedure under “Unresolvable BSDS or log data set problem during restart” on page 616.

If the checkpoint is found, look at the date and time that it was created. If the checkpoint is several days old (and DB2 was operational during the interim), either follow the procedure under “Failure resulting from total or excessive loss of log data” on page 619 or the procedure under “Unresolvable BSDS or log data set problem during restart” on page 616.

Otherwise, continue with the next step.

2. Determine what work is lost and what data is inconsistent.

The portion of the log representing activity that occurred before the failure provides information about work that was in progress at that point. From this information, it might be possible to deduce the work that was in progress within the inaccessible portion of the log. If use of DB2 was limited at the time or if DB2 was dedicated to a small number of activities (such as batch jobs performing database loads or image copies), it might be possible to accurately identify the page sets that were made inconsistent. To make the identification, extract a summary of the log activity up to the point of damage in the log by using the DSN1LOGP utility described in Part 3 of *DB2 Utility Guide and Reference*.

Use the DSN1LOGP utility to specify the “BEGIN CHECKPOINT” RBA prior to the point of failure, which was determined in the previous step as the RBASTART. End the DSN1LOGP scan prior to the point of failure on the log (X - 1) by using the RBAEND specification.

Specifying the last complete checkpoint is very important for ensuring that complete information is obtained from DSN1LOGP.

Specify the SUMMARY(ONLY) option to produce a summary report.

Figure 65 is an example of a DSN1LOGP job to obtain summary information for the checkpoint discussed previously.

```
//ONE EXEC PGM=DSN1LOGP
//STEPLIB DD DSN=prefix.SDSNLOAD,DISP=SHR
//SYSABEND DD SYSOUT=A
//SYSPRINT DD SYSOUT=A
//SYSSUMRY DD SYSOUT=A
//BSDS DD DSN=DSNCAT.BSDS01,DISP=SHR
//SYSIN DD *
        RBASTART (7425468) RBAEND (7428FFF) SUMMARY (ONLY)
/*
```

Figure 65. Sample JCL for obtaining DSN1LOGP summary output for restart

3. Analyze the DSN1LOGP utility output.

The summary report that is placed in the SYSSUMRY file includes two sections of information: a summary of completed events (not shown here) and a restart summary shown in Figure 66 on page 606. A description of the sample output appears after the figure.

```

Figure 66. Partial sample of DSN1LOGP summary output

The following heading message is followed by messages that identify the units of recovery that have not yet completed and the page sets that they modified:

DSN1157I RESTART SUMMARY

Following the summary of outstanding units of recovery is a summary of page sets with database writes pending.

In each case (units of recovery or databases with pending writes), the earliest required log record is identified by the START information. In this context, START information is the log RBA of the earliest log record required in order to complete outstanding writes for this page set.

Those units of recovery with a START log RBA equal to, or prior to, the point Y cannot be completed at restart. All page sets modified by such units of recovery are inconsistent after completion of restart using this procedure.

All page sets identified in message DSN1160I with a START log RBA value equal to, or prior to, the point Y have database changes that cannot be written to disk. As in the case previously described, all such page sets are inconsistent after completion of restart using this procedure.

At this point, it is only necessary to identify the page sets in preparation for restart. After restart, the problems in the page sets that are inconsistent must be resolved.

Because the end of the log is inaccessible, some information has been lost, therefore, the information is inaccurate. Some of the units of recovery that appear to be inflight might have successfully committed, or they could have modified additional page sets beyond point X. Additional data could have been

written, including those page sets that are identified as having writes pending in the accessible portion of the log. New units of recovery could have been created, and these can have modified data. DB2 cannot detect that these events occurred.

From this and other information (such as system accounting information and console messages), it could be possible to determine what work was actually outstanding and which page sets will be inconsistent after starting DB2, because the record of each event contains the date and time to help determine how recent the information is. In addition, the information is displayed in chronological sequence.

### **Step 3: Determine what status information has been lost**

Some amount of system status information might have been lost. In some cases, you will know what information has been lost (such as the case in which utilities are in progress). In other cases, messages about the loss of status information (such as in the cases of deferred restart pending or write error ranges) might be received. If system status information has been lost, you might be able to reconstruct this information from recent console displays, messages, and abends that alerted you to these conditions. These page sets contain inconsistencies that you must resolve.

### **Step 4: Truncate the log at the point of error**

No DB2 process, including RECOVER, allows a gap in the log RBA sequence. You cannot process up to point X, skip over points X through Y, and continue after Y.

Use the change log inventory utility to create a conditional restart control record (CRCR) in the BSDS, identifying the end of the log (X) to use on a subsequent restart. The value is the RBA at which DB2 begins writing new log records. If point X is X'7429000', on the CRESTART control statement, specify ENDRBA=7429000.

At restart, DB2 discards the portion of the log beyond X'7429000' before processing the log for completing work (such as units of recovery and database writes). Unless otherwise directed, normal restart processing is performed within the scope of the log. Because log information has been lost, DB2 errors can occur. For example, a unit of recovery that has actually been committed can be rolled back. Also, some changes made by that unit of recovery might not be rolled back because information about data changes has been lost.

To minimize such errors, use this change log inventory control statement:

```
CRESTART CREATE,ENDRBA=7429000,FORWARD=NO,BACKOUT=NO
```

Recovering and backing out units of recovery with lost information can introduce more inconsistencies than the incomplete units of recovery.

When you start DB2 after you run DSNJU003 with the FORWARD=NO and the BACKOUT=NO change log inventory options, DB2 performs the following actions (in "Step 5: Start DB2" on page 608):

1. Discards from the checkpoint queue any entries with RBAs beyond the ENDRBA value in the CRCR (which is X'7429000' in the previous example).
2. Reconstructs the system status up to the point of log truncation.
3. Performs pending database writes that the truncated log specifies that have not already applied to the data. You can use the DSN1LOGP utility to identify these writes. No forward recovery processing occurs for units of work in a FORWARD=NO conditional restart. All pending writes for in-commit and

indoubt units of recovery are applied to the data. The processing for the different unit of work states that is described in “Phase 3: Forward log recovery” on page 462 does not occur.

4. Marks all units of recovery that have committed or are indoubt as complete on the log.
5. Leaves inflight and in-abort units of recovery incomplete. Inconsistent data is left in tables modified by inflight or indoubt URs. When you specify a BACKOUT=NO conditional restart, inflight and in-abort units of recovery are not backed out.

In a conditional restart that truncates the log, BACKOUT=NO minimizes DB2 errors for the following reasons:

- Inflight units of recovery might have been committed in the portion of the log that the conditional restart discarded. If these units of recovery are backed out as “Phase 4: Backward log recovery” on page 463 describes, DB2 can back out database changes incompletely, which introduces additional errors.
- Data modified by in-abort units of recovery could have been modified again after the point of damage on the log. For in-abort units of recovery DB2 could have written backout processing to disk after the point of log truncation. If these units of recovery are backed out as “Phase 4: Backward log recovery” on page 463 describes, DB2 can introduce additional data inconsistencies by backing out units of recovery that are already partially or fully backed out.

### Step 5: Start DB2

At the end of restart, the conditional restart control record (CRCR) is marked *DEACTIVATED* to prevent its use on a later restart. Until the restart has completed successfully, the CRCR is in effect. Start DB2 with ACCESS (MAINT) until data is consistent or page sets are stopped.

### Step 6: Resolve data inconsistency problems

After successfully restarting DB2, resolve all data inconsistency problems as described in “Resolving inconsistencies resulting from a conditional restart” on page 622.

---

## Failure during forward log recovery

**Problem:** A failure occurred during the forward log recovery phase of restart.

**Symptom:** An abend was issued, indicating that restart had failed. In addition, the last restart message received was a DSNR004I message indicating that log initialization had completed and thus the failure occurred during forward log recovery.

**System action:** DB2 terminates because a portion of the log is inaccessible, and DB2 is therefore unable to guarantee the consistency of the data after restart.

**Operations management action:** To start DB2 successfully, choose one of the following approaches:

- Correct the problem that has made the log inaccessible and start DB2 again. To determine if this approach is possible, refer to *DB2 Codes* for an explanation of the messages and codes received. The explanation will identify any corrective action that can be taken to resolve the problem. In this case, it is not necessary to read the scenarios in this chapter.

- Restore the DB2 log and all data to a prior consistent point and start DB2. This procedure is described in “Unresolvable BSDS or log data set problem during restart” on page 616.
- Start DB2 without completing some database changes. The exact changes cannot be identified; all that can be determined is which page sets might have incomplete changes. The procedure for determining which page sets contain incomplete changes is described in “Starting DB2 by limiting restart processing.” Continue reading this chapter to obtain a better idea of what the problem is.

## Understanding forward log recovery failure

Figure 67 illustrates the problem on the log.

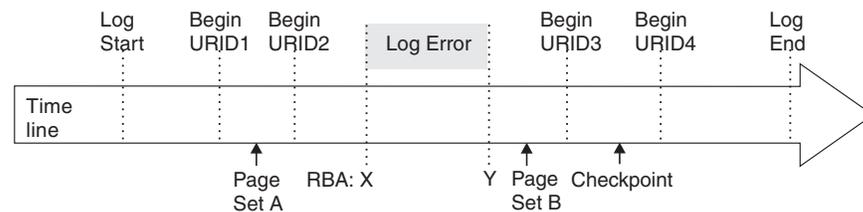

Figure 67. Illustration of failure during forward log recovery

The portion of the log between log RBA X and Y is inaccessible. The log initialization and current status rebuild phases of restart completed successfully. Restart processing was reading the log in a forward direction beginning at some point prior to X and continuing to the end of the log. Because of the inaccessibility of log data (between points X and Y), restart processing cannot guarantee the completion of any work that was outstanding at restart prior to point Y.

For purposes of discussion, assume the following work was outstanding at restart:

- The unit of recovery identified as URID1 was in-commit.
- The unit of recovery identified as URID2 was in-flight.
- The unit of recovery identified as URID3 was in-commit.
- The unit of recovery identified as URID4 was in-flight.
- Page set A had writes pending prior to the error on the log, continuing to the end of the log.
- Page set B had writes pending after the error on the log, continuing to the end of the log.

The earliest log record for each unit of recovery is identified on the log line in Figure 67. In order for DB2 to complete each unit of recovery, DB2 requires access to all log records from the beginning point for each unit of recovery to the end of the log.

The error on the log prevents DB2 from guaranteeing the completion of any outstanding work that began prior to point Y on the log. Consequently, database changes made by URID1 and URID2 might not be fully committed or backed out. Writes pending for page set A (from points in the log prior to Y) will be lost.

## Starting DB2 by limiting restart processing

This procedure describes how to start DB2 when a portion of the log is inaccessible during forward recovery. It also describes how to identify the units of recovery for which database changes cannot be fully guaranteed (either committed or backed

out) and the page sets that these units of recovery changed. You must determine which page sets are involved because after this procedure is used, the page sets will contain inconsistencies that must be resolved. In addition, using this procedure results in the completion of all database writes that are pending. For a description of this process of writing database pages to disk, see "Tuning database buffer pools" on page 671.

### Step 1: Find the log RBA after the inaccessible part of the log

The log damage is shown in Figure 67 on page 609. The range of the log between RBA X and RBA Y is inaccessible to all DB2 processes.

Use the abend reason code accompanying the X'04E' abend, and the message on the title of the accompanying dump at the operator's console, to find the name and the location of a procedure in Table 103. Use that procedure to find X and Y.

Table 103. Abend reason codes and messages

Abend reason code	Message	Procedure	General error description
00D10261 00D10262 00D10263 00D10264 00D10265 00D10266 00D10267 00D10268	DSNJ012I	"RBA 1"	Log record is logically damaged
00D10329	DSNJ106I	"RBA 2" on page 611	I/O error occurred while log record was being read
00D1032A	DSNJ113E	"RBA 3" on page 611	Log RBA could not be found in BSDS
00D1032B	DSNJ103I	"RBA 4" on page 612	Allocation error occurred for an archive log data set
00D1032B	DSN007I	"RBA 5" on page 612	The operator canceled a request for archive mount
00D1032C	DSNJ104E	"RBA 4" on page 612	Open error occurred for an archive log data set
00E80084	DSNJ103I	"RBA 4" on page 612	Active log data set named in the BSDS could not be allocated during log initialization.

**Procedure RBA 1:** The message accompanying the abend identifies the log RBA of the first inaccessible log record that DB2 detects. For example, the following message indicates a logical error in the log record at log RBA X'7429ABA':

```
DSNJ012I ERROR D10265 READING RBA 000007429ABA
          IN DATA SET DSNCAT.LOGCOPY2.DS01
          CONNECTION-ID=DSN
          CORRELATION-ID=DSN
```

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the log control interval definition (LCID). When this type of an error on the log occurs during forward log recovery, all log records within the physical log record, as described, are inaccessible. Therefore, the value of X is the log RBA that was reported in the message, rounded down to a 4K boundary (that is, X'7429000').

For purposes of following the steps in this procedure, assume that the extent of damage is limited to the single physical log record. Therefore, calculate the value of Y as the log RBA that was reported in the message, rounded up to the end of the 4K boundary (that is, X'7429FFF').

Continue with “Step 2: Identify incomplete units of recovery and inconsistent page sets” on page 612.

**Procedure RBA 2:** The message accompanying the abend identifies the log RBA of the first inaccessible log record that DB2 detects. For example, the following message indicates an I/O error in the log at RBA X'7429ABA':

```
DSNJ106I LOG READ ERROR DSNAME=DSNCAT.LOGCOPY2.DS01,  
        LOGRBA=000007429ABA, ERROR STATUS=0108320C
```

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the LCID. When this type of an error on the log occurs during forward log recovery, all log records within the physical log record and beyond it to the end of the log data set are inaccessible to the forward recovery phase of restart. Therefore, the value of X is the log RBA that was reported in the message, rounded down to a 4K boundary (that is, X'7429000').

To determine the value of Y, run the print log map utility to list the log inventory information. For an example of this output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*. Locate the data set name and its associated log RBA range. The RBA of the end of the range is the value Y.

Continue with “Step 2: Identify incomplete units of recovery and inconsistent page sets” on page 612.

**Procedure RBA 3:** The message accompanying the abend identifies the log RBA of the inaccessible log record. This log RBA is not registered in the BSDS.

For example, the following message indicates that the log RBA X'7429ABA' is not registered in the BSDS:

```
DSNJ113E RBA 000007429ABA NOT IN ANY ACTIVE OR ARCHIVE  
        LOG DATA SET. CONNECTION-ID=DSN, CORRELATION-ID=DSN
```

Use the print log map utility to list the contents of the BSDS. For an example of this output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*.

Figure 156 on page 1121 shows that a given physical log record is actually a set of logical log records (the log records generally spoken of) and the LCID. When this type of error on the log occurs during forward log recovery, all log records within the physical log record are inaccessible.

Using the print log map output, locate the RBA closest to, but less than, X'7429ABA'. This is the value of X. If an RBA less than X'7429ABA' cannot be found, the value of X is zero. Locate the RBA closest to, but greater than, X'7429ABA'. This is the value of Y.

Continue with “Step 2: Identify incomplete units of recovery and inconsistent page sets” on page 612.

**Procedure RBA 4:** The message accompanying the abend identifies an entire data set that is inaccessible. For example, the following message indicates that the archive log data set DSNCAT.ARCHLOG1.A0000009 is not accessible. The STATUS field identifies the code that is associated with the reason for the data set being inaccessible. For an explanation of the STATUS codes, see the explanation for the message in *DB2 Messages*.

```
DSNJ103I LOG ALLOCATION ERROR
          DSNNAME=DSNCAT.ARCHLOG1.A0000009, ERROR
          STATUS=04980004
          SMS REASON CODE=00000000
```

To determine the values of X and Y, run the print log map utility to list the log inventory information. For an example of this output, see the description of print log map (DSNJU004) in Part 2 of *DB2 Utility Guide and Reference*. The output provides each log data set name and its associated log RBA range: the values of X and Y.

Continue with “Step 2: Identify incomplete units of recovery and inconsistent page sets.”

**Procedure RBA 5:** The message accompanying the abend identifies an entire data set that is inaccessible. For example, the following message indicates that the archive log data set DSNCAT.ARCHLOG1.A0000009 is not accessible. The operator canceled a request for archive mount resulting in the following message:

```
DSNJ007I OPERATOR CANCELED MOUNT OF ARCHIVE
          DSNCAT.ARCHLOG1.A0000009 VOLSER=5B225.
```

To determine the values of X and Y, run the print log map utility to list the log inventory information. For an example of the output, see the description of print log map (DSNJU004) in Part 3 of *DB2 Utility Guide and Reference*. The output provides each log data set name and its associated log RBA range: the values of X and Y. Continue with “Step 2: Identify incomplete units of recovery and inconsistent page sets.”

## Step 2: Identify incomplete units of recovery and inconsistent page sets

Units of recovery that cannot be fully processed are considered *incomplete units of recovery*. Page sets that will be inconsistent after completion of restart are considered *inconsistent page sets*. Take the following steps to identify them:

1. Determine the location of the latest checkpoint on the log. Determine this by looking at one of the following sources, whichever is more convenient:
  - The operator’s console contains the following message, identifying the location of the start of the last checkpoint on the log at log RBA X'876B355'.

```
DSNR003I RESTART ... PRIOR CHECKPOINT
          RBA=00007425468
```
  - The print log map utility output identifies the last checkpoint, including its BEGIN CHECKPOINT RBA.
2. Run the DSN1LOGP utility to obtain a report of the outstanding work that is to be completed at the next restart of DB2. When you run the DSN1LOGP utility, specify the checkpoint RBA as the STARTRBA and the SUMMARY(ONLY) option. It is very important that you include the last complete checkpoint from running DSN1LOGP in order to obtain complete information.

Figure 65 on page 605 shows an example of the DSN1LOGP job submitted for the checkpoint that was reported in the DSNR003I message.

Analyze the output of the DSN1LOGP utility. The summary report that is placed in the SYSSUMRY file contains two sections of information. For an example of SUMMARY output, see Figure 66 on page 606; and for an example of the program that results in the output, see Figure 65 on page 605.

### **Step 3: Restrict restart processing to the part of the log after the damage**

Use the change log inventory utility to create a conditional restart control record (CRCR) in the BSDS. Identify the accessible portion of the log beyond the damage by using the STARTRBA specification, which will be used at the next restart. Specify the value Y+1 (that is, if Y is X'7429FFF', specify STARTRBA=742A000). Restart will restrict its processing to the portion of the log beginning with the specified STARTRBA and continuing to the end of the log. A sample change log inventory utility control statement is:

```
CRESTART CREATE,STARTRBA=742A000
```

### **Step 4: Start DB2**

At the end of restart, the CRCR is marked DEACTIVATED to prevent its use on a subsequent restart. Until the restart is complete, the CRCR will be in effect. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped.

### **Step 5: Resolve inconsistent data problems**

After the successful start of DB2, all data inconsistency problems must be resolved. "Resolving inconsistencies resulting from a conditional restart" on page 622 describes how to do this. At this time, all other data can be made available for use.

---

## **Failure during backward log recovery**

*Problem:* A failure occurred during the backward log recovery phase of restart.

*Symptom:* An abend was issued that indicated that restart failed because of a log problem. In addition, the last restart message received was a DSNR005I message, indicating that forward log recovery completed and thus the failure occurred during backward log recovery.

*System action:* DB2 terminates because a portion of the log that it needs is inaccessible, and DB2 is therefore unable to rollback some database changes during restart.

*Operations management action:* To start DB2, choose one of the following approaches:

- Correct the problem that has made the log inaccessible and start DB2 again. To determine whether this approach is possible, refer to *DB2 Codes* for an explanation of the messages and codes received. The explanation identifies the corrective action to take to resolve the problem. In this case, it is not necessary to read the scenarios in this chapter.
- Restore the DB2 log and all data to a prior consistent point and start DB2. This procedure is described in "Unresolvable BSDS or log data set problem during restart" on page 616.
- Start DB2 without rolling back some database changes. The exact database changes cannot be identified. All that can be determined is which page sets contain incomplete changes and which units of recovery made modifications to those page sets. The procedure for determining which page sets contain incomplete changes and which units of recovery made the modifications is

described in “Bypassing backout before restarting.” Continue reading this chapter to obtain a better idea of how to fix the problem.

## Understanding backward log recovery failure

Figure 68 illustrates the problem on the log.

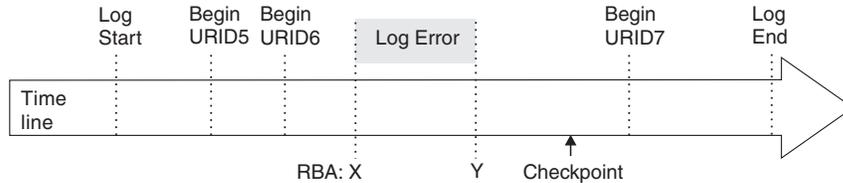

Figure 68. Illustration of failure during backward log recovery

The portion of the log between log RBA X and Y is inaccessible. Restart was reading the log in a backward direction beginning at the end of the log and continuing backward to the point marked by Begin URID5 in order to back out the changes made by URID5, URID6, and URID7. You can assume that DB2 determined that these units of recovery were inflight or in-abort. The portion of the log from point Y to the end has been processed. However, the portion of the log from Begin URID5 to point Y has not been processed and cannot be processed by restart. Consequently, database changes made by URID5 and URID6 might not be fully backed out. All database changes made by URID7 have been fully backed out, but these database changes might not have been written to disk. A subsequent restart of DB2 causes these changes to be written to disk during forward recovery.

## Bypassing backout before restarting

This procedure describes how to start DB2 when a portion of the log is inaccessible during backward recovery. It also describes how to identify the units of recovery that cannot be fully backed out and the page sets that are inconsistent because they were changed by the units of recovery that did not complete.

1. Determine the units of recovery that cannot be backed out and the page sets that will be inconsistent after the completion of restart. To do this, take the following steps:
  - a. Determine the location of the latest checkpoint on the log. This can be determined by looking at one of the following sources, whichever is more convenient:
    - The operator’s console contains message DSNR003I, which identifies the location of the start of the last checkpoint on the log at log RBA X'7425468'.
 

```
DSNR003I RESTART ... PRIOR CHECKPOINT
                    RBA=00007425468
```
    - Print log map utility output identifies the last checkpoint, including its BEGIN CHECKPOINT RBA.
  - b. Execute the DSN1LOGP utility to obtain a report of the outstanding work that is to be completed at the next restart of DB2. When you run DSN1LOGP, specify the checkpoint RBA as the RBASTART and the SUMMARY(ONLY) option. Include the last complete checkpoint in the execution of DSN1LOGP in order to obtain complete information.

Figure 66 on page 606 shows an example of the DSN1LOGP job submitted for the checkpoint that was reported in the DSNR003I message.

Analyze the output of the DSN1LOGP utility. The summary report that is placed in the SYSSUMRY file contains two sections of information. The sample report output shown in Figure 66 on page 606 resulted from the invocation shown in Figure 65 on page 605. The following description refers to that sample output.

The first section is headed by the following message:

```
DSN1150I SUMMARY OF COMPLETED EVENTS
```

That message is followed by others that identify completed events, such as completed units of recovery. That section does not apply to this procedure.

The second section is headed by this message:

```
DSN1157I RESTART SUMMARY
```

That message is followed by others that identify units of recovery that are not yet completed and the page sets that they modified. An example of the DSN1162I messages is shown in Figure 66 on page 606.

After the summary of outstanding units of recovery is a summary of page sets with database writes pending. An example of the DSN1160I message is shown in Figure 66 on page 606.

The restart processing that failed was able to complete all units of recovery processing within the accessible scope of the log after point Y. Database writes for these units of recovery are completed during the forward recovery phase of restart on the next restart. Therefore, do not bypass the forward recovery phase. All units of recovery that can be backed out have been backed out.

All remaining units of recovery to be backed out (DISP=INFLIGHT or DISP=IN-ABORT) are bypassed on the next restart because their STARTRBA values are less than the RBA of point Y. Therefore, all page sets modified by those units of recovery are inconsistent after restart. This means that some changes to data might not be backed out. At this point, it is only necessary to identify the page sets in preparation for restart.

2. Direct restart to bypass backward recovery processing. Use the change log inventory utility to create a conditional restart control record (CRCR) in the BSDS. Direct restart to bypass backward recovery processing during the subsequent restart by using the BACKOUT specification. At restart, all units of recovery requiring backout are declared complete by DB2, and log records are generated to note the end of the unit of recovery. The change log inventory utility control statement is:

```
CRESTART CREATE,BACKOUT=NO
```

3. Start DB2. At the end of restart, the CRCR is marked DEACTIVATED to prevent its use on a subsequent restart. Until the restart is complete, the CRCR is in effect. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped.
4. Resolve all inconsistent data problems. After the successful start of DB2, all data inconsistency problems must be resolved. "Resolving inconsistencies resulting from a conditional restart" on page 622 describes how to do this. At this time, all other data can be made available for use.

---

## Failure during a log RBA read request

*Problem:* The BSDS is wrapping around too frequently when log RBA read requests are submitted; when the last archive log data sets were added to the BSDS, the maximum allowable number of log data sets in the BSDS was exceeded. This caused the earliest data sets in the BSDS to be displaced by the new entry. Subsequently, the requested RBA containing the dropped log data set cannot be read after the wrap occurs.

**Symptom:** Abend code 00D1032A and message DSNJ113E are displayed:

```
DSNJ113E RBA log-rba NOT IN ANY ACTIVE OR ARCHIVE  
LOG DATA SET. CONNECTION-ID=aaaaaaaa, CORRELATION-ID=aaaaaaaa
```

**System programmer action:**

1. Stop DB2 with the STOP DB2 command, if it has not already been stopped automatically as a result of the problem.
2. Check any other messages and reason codes displayed and correct the errors indicated. Locate the output from an old print log map run, and identify the data set that contains the missing RBA. If the data set has not been reused, run the change log inventory utility to add this data set back into the inventory of log data sets.
3. Increase the maximum number of archive log volumes that can be recorded in the BSDS. To do this, update the MAXARCH system parameter value as follows:
  - a. Start the installation CLIST.
  - b. On panel DSNTIPA1, select UPDATE mode.
  - c. On panel DSNTIPT, change any data set names that are not correct.
  - d. On panel DSNTIPB, select the ARCHIVE LOG DATA SET PARAMETERS option.
  - e. On panel DSNTIPA, increase the value of RECORDING MAX.
  - f. When the installation CLIST editing completes, rerun job DSNTIJUZ to recompile the system parameters.
4. Start DB2 with the START DB2 command.

For more information about updating DB2 system parameters, see Part 2 of *DB2 Installation Guide*.

For instructions about adding an old archive data set, refer to “Changing the BSDS log inventory” on page 442. Also, see Part 3 of *DB2 Utility Guide and Reference* for additional information about the change log inventory utility.

---

## Unresolvable BSDS or log data set problem during restart

Use dual logging (active logs, archive logs, and bootstrap data sets) to reduce your efforts in resolving the problem described in this section.

**Problem:** During restart of DB2, serious problems with the BSDS or log data sets were detected and cannot be resolved.

**Symptom:** The following messages are issued:

```
DSNJ100I  
DSNJ107I  
DSNJ119I
```

Any of the following problems could be involved:

- A log data set is physically damaged.
- Both copies of a log data set could be physically damaged in the case of dual logging mode.
- A log data set could be lost.
- An archive log volume could have been reused even though it was still needed.
- A log data set could contain records that are not recognized by DB2 because they are logically broken.

*System action:* DB2 cannot be restarted unless the following procedure is used:

*Operations management action:* In serious cases such as this, it can be necessary to fall back to a prior shutdown level. If this procedure is used, all database changes between the shutdown point and the present will be lost, but all the data retained will be consistent within DB2.

If it is necessary to fall back, read “Preparing to recover to a prior point of consistency” on page 485.

If too much log information has been lost, use the alternative approach described in “Failure resulting from total or excessive loss of log data” on page 619.

## Preparing for recovery or restart

See “Preparing to recover to a prior point of consistency” on page 485 for preparation procedures.

## Performing fall back to a prior shutdown point

1. When a failure occurs and you decide to fall back, use the print log map utility against the most current copy of the BSDS. Even if you are not able to do this, continue with the next step. (If you are unable to do this, an error message will be issued.)
2. Use access method services IMPORT to restore the backed-up versions of the BSDS and active log data sets.
3. Use the print log map utility against the copy of the BSDS with which DB2 is to be restarted.
4. Determine whether any archive log data sets must be deleted.
  - If you have a copy of the most current BSDS, compare it to the BSDS with which DB2 is to be restarted. Delete and uncatalog any archive log data sets that are listed in the most current BSDS but are not listed in the previous one. These archive log data sets are normal physical sequential (SAM) data sets. If you are able to do this step, continue with step 5.
  - If you were not able to print a copy of the most current BSDS and the archive logs are cataloged, use access method services LISTCAT to check for archive logs with a higher sequence number than the last archive log shown in the BSDS being used to restart DB2.
    - If no archive log data sets with a higher sequence number exist, you do not have to delete or uncatalog any data sets, and you can continue with step 5.
    - Delete and uncatalog all archive log data sets that have a higher sequence number than the last archive log data set in the BSDS being used to restart DB2. These archive log data sets are SAM data sets. Continue with the next step.

If the archive logs are not cataloged, you do not need to uncatalog them.
5. Issue the command START DB2. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped. If DDL is required, the creator might not be the same.
6. Now, determine what data needs to be recovered, what data needs to be dropped, what data can remain unchanged, and what data needs to be recovered to the prior shutdown point.

- For table spaces and indexes that might have been changed after the shutdown point, use the DB2 RECOVER utility to recover these table spaces and indexes. They must be recovered in the order indicated in Part 2 of *DB2 Utility Guide and Reference*.
- For data that has not been changed after the shutdown point (data used with RO access), it is not necessary to use RECOVER or DROP.
- For table spaces that were deleted after the shutdown point, issue the DROP statement. These table spaces will not be recovered.
- Any objects created after the shutdown point should be re-created.

**You must recover all data that has potentially been modified after the shutdown point.** If the RECOVER utility is not used to recover modified data, serious problems can occur because of data inconsistency.

If an attempt is made to access data that is inconsistent, any of the following events can occur (and the list is not comprehensive):

- It is possible to successfully access the correct data.
  - Data can be accessed without DB2 recognizing any problem, but it might not be the data you want (the index might be pointing to the wrong data).
  - DB2 might recognize that a page is logically incorrect and, as a result, abend the subsystem with an X'04E' abend completion code and an abend reason code of X'00C90102'.
  - DB2 might notice that a page was updated after the shutdown point and, as a result, abend the requester with an X'04E' abend completion code and an abend reason code of X'00C200C1'.
7. Analyze the CICS log and the IMS log to determine the work that must be redone (work that was lost because of shutdown at the previous point). Inform all TSO users, QMF users, and batch users for which no transaction log tracking has been performed, about the decision to fall back to a previous point.
  8. When DB2 is started after being shut down, indoubt units of recovery can exist. This occurs if transactions are indoubt when the command STOP DB2 MODE (QUIESCE) is given. When DB2 is started again, these transactions will still be indoubt to DB2. IMS and CICS cannot know the disposition of these units of recovery.  
To resolve these indoubt units of recovery, use the command RECOVER INDOUBT.
  9. If a table space was dropped and re-created after the shutdown point, it should be dropped and re-created again after DB2 is restarted. To do this, use SQL DROP and SQL CREATE statements.  
Do not use the RECOVER utility to accomplish this, because it will result in the old version (which can contain inconsistent data) being recovered.
  10. If any table spaces and indexes were created after the shutdown point, these must be re-created after DB2 is restarted. There are two ways to accomplish this:
    - For data sets defined in DB2 storage groups, use the CREATE TABLESPACE statement and specify the appropriate storage group names. DB2 automatically deletes the old data set and redefines a new one.
    - For user-defined data sets, use access method services DELETE to delete the old data sets. After these data sets have been deleted, use access method services DEFINE to redefine them; then use the CREATE TABLESPACE statement.

---

## Failure resulting from total or excessive loss of log data

*Problem:* Either all copies of the BSDS and logs have been destroyed or lost, or an excessive amount of the active log has been destroyed or lost.

*Symptom:* Any messages or abends indicating that all or an excessive amount of log information has been lost.

*System action:* None.

*Operations management action:* Restart DB2 without any log data by using either the procedure in “Total loss of the log” or “Excessive loss of data in the active log” on page 620.

### Total loss of the log

Even if all copies of the BSDS and either the active or archive log or both have been destroyed or lost, DB2 can still be restarted, and data that belongs to that DB2 subsystem can still be accessed, provided that all system and user table spaces have remained intact and you have a recent copy of the BSDS. However, you must rely on your own sources to determine what data is inconsistent, because DB2 cannot provide any hints of inconsistencies. Other VSAM clusters on disk, such as the system databases DSNDB01, DSNDB04, and DSNB06, as well as user databases are assumed to exist.

For example, you might know that DB2 was dedicated to a few processes (such as utilities) during the DB2 session, and you might be able to identify the page sets they modified. If you cannot identify the page sets that are inconsistent, you must decide whether you are willing to assume the risk involved in restarting DB2 under those conditions. If you decide to restart, take the following steps:

1. Define and initialize the BSDSs. See “Recovering the BSDS from a backup copy” on page 543.
2. Define the active log data sets using the access method services DEFINE function. Run utility DSNJLOGF to initialize the new active log data sets.
3. Prepare to restart DB2 using no log data. See “Deferring restart processing” on page 454.

Each data and index page contains the log RBA of the last log record applied against the page. Safeguards within DB2 disallow a modification to a page that contains a log RBA that is higher than the current end of the log. There are two choices.

- a. Run the DSN1COPY utility specifying the RESET option to reset the log RBA in every data and index page. Depending on the amount of data in the subsystem, this process can take quite a long time. Because the BSDS has been redefined and reinitialized, logging begins at log RBA 0 when DB2 starts.

If the BSDS is not reinitialized, logging can be forced to begin at log RBA 0 by constructing a conditional restart control record (CRCR) that specifies a STARTRBA and ENDRBA that are both equal to 0, as the following command shows:

```
CRESTART CREATE,STARTRBA=0,ENDRBA=0
```

Continue with step 4.

- b. Determine the highest possible log RBA of the prior log. From previous console logs written when DB2 was operational, locate the last DSNJ001I message. When DB2 switches to a new active log data set, this message is

written to the console, identifying the data set name and the highest potential log RBA that can be written for that data set. Assume that this is the value X'8BFFF'. Add one to this value (X'8C000'), and create a conditional restart control record specifying the following change log inventory control statement:

```
CRESTART CREATE,STARTRBA=8C000,ENDRBA=8C000
```

When DB2 starts, all phases of restart are bypassed and logging begins at log RBA X'8C000'. If this method is chosen, it is not necessary to use the DSN1COPY RESET option and a lot of time is saved.

4. Start DB2. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped.
5. After restart, resolve all inconsistent data as described in "Resolving inconsistencies resulting from a conditional restart" on page 622.

## Excessive loss of data in the active log

By studying "Total loss of the log" on page 619, a procedure can be developed for restarting that meets the requirements of the situation. Specifically, when an excessive amount of the active log has been lost, the procedure can be adapted to fit the situation, as described in "Total loss of the log" on page 619. *Do not delete and redefine the BSDS.* Instead, proceed as follows:

1. Use the print log map utility (DSNJU004) against the copy of the BSDS with which DB2 is to be restarted.
2. Use the print log map output to obtain the data set names of all active log data sets. Use access method services LISTCAT to determine which active log data sets are no longer available or usable.
3. Use access method services DELETE to delete all active log data sets that are no longer usable.
4. Use access method services DEFINE to define new active log data sets. Run utility DSNJLOGF to initialize the new active log data sets. One active log data set must be defined for each one found to be no longer available or usable in step 2. Use the active log data set name found in the BSDS as the data set name for the access method services DEFINE statement.
5. Use the print log map utility (DSNJU004) output, and note whether an archive log data set exists that contains the RBA range of the redefined active log data set. To do this, note the starting and ending RBA values for the active log data set that was newly redefined, and look for an archive log data set with the same starting and ending RBA values.

If no such archive log data sets exist:

- a. Use the change log inventory utility (DSNJU003) DELETE statement to delete the newly redefined active log data sets from the BSDS active log data set inventory.
- b. Use the change log inventory utility (DSNJU003) NEWLOG statement to add the active log data set back into the BSDS active log data set inventory. Do not specify RBA ranges on the NEWLOG statement.

If the corresponding archive log data sets exist, then there are two courses of action:

- If you want to minimize the number of potential read operations against the archive log data sets, then use access method services REPRO to copy the data from each archive log data set into the corresponding active log data set. Make certain you copy the proper RBA range into the active log data set. Be sure that the active log data set is big enough to hold all the data from the archive log data set. When DB2 does an archive operation, it copies the

log data from the active log data set to the archive log data set, then pads the archive log data set with binary zeroes to fill a block. In order for the access method services REPRO command to be able to copy all of the data from the archive log data set to a newly defined active log data set, the new active log data set might need to be bigger than the original one.

For example, if the block size of the archive log data set is 28 KB, and the active log data set contains 80 KB of data, DB2 copies the 80 KB and pads the archive log data set with 4 KB of nulls to fill the last block. Thus, the archive log data set now contains 84 KB of data instead of 80 KB. In order for the access method services REPRO command to complete successfully, the active log data set must be able to hold 84 KB, rather than just 80 KB of data.

- If you are not concerned about read operations against the archive log data sets, complete the two steps that appear in the preceding list (as though the archive data sets did not exist).
6. Choose the appropriate point for DB2 to start logging (X'8C000') as described in "Total loss of the log" on page 619.
  7. To restart DB2 without using any log data, create a CRCR, as described for the change log inventory utility (DSNJU003) in Part 3 of *DB2 Utility Guide and Reference*.
  8. Start DB2. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped.
  9. After restart, resolve all inconsistent data as described in "Resolving inconsistencies resulting from a conditional restart" on page 622.

This procedure will cause all phases of restart to be bypassed and logging to begin at log RBA X'8C000'. It will create a gap in the log between the highest RBA kept in the BSDS and X'8C000', and that portion of the log will be inaccessible.

No DB2 process can tolerate a gap, including RECOVER. Therefore, all data must be image copied after a cold start. Even data that is known to be consistent must be image copied again when a gap is created in the log.

There is another approach to doing a cold start that does not create a gap in the log. This is only a method for eliminating the gap in the physical record. It does not mean that you can use a cold start to resolve the logical inconsistencies. The procedure is as follows:

1. Locate the last valid log record by using DSN1LOGP to scan the log. (Message DSN1213I identifies the last valid log RBA.)
2. Begin at an RBA that is known to be valid. If message DSN1213I indicated that the last valid log RBA is at X'89158', round this value up to the next 4K boundary (X'8A000').
3. Create a CRCR similar to the CRCR that the following command specifies:  
CRESTART CREATE, STARTRBA=8A000, ENDRBA=8A000
4. Use START DB2 ACCESS(MAINT) until data is consistent or page sets are stopped.
5. Now, take image copies of all data for which data modifications were recorded beyond log RBA X'8A000'. If you do not know what data was modified, take image copies of all data.

If image copies are not taken of data that has been modified beyond the log RBA used in the CRESTART statement, future RECOVER operations can fail or result in inconsistent data.

After restart, resolve all inconsistent data as described in Resolving inconsistencies resulting from a conditional restart.

---

## Resolving inconsistencies resulting from a conditional restart

When a conditional restart of the DB2 subsystem is done, the following problems can occur:

- Some amount of work is left incomplete.
- Some data is left inconsistent.
- Information about the status of the DB2 subsystem is made unusable.

### Inconsistencies in a distributed environment

In a distributed environment, when a DB2 system restarts, it indicates its restart status and the name of its recovery log to the systems with which it communicates. There are two possible conditions for restart status, *warm* and *cold*.

A cold status for restart means that the DB2 system has no memory of previous connections with its partner, and therefore has no memory of indoubt logical units of work. This includes all postponed aborted URs that end without resolution and any restart pending page sets and partitions are removed from restart pending state.

The partner accepts the cold start connection and remembers the recovery log name of the cold starting DB2. If the partner has indoubt thread resolution requirements with the cold starting DB2, those requirements cannot be achieved. The partner terminates its indoubt resolution responsibility with the cold starting DB2. However, as a participant, the partner has indoubt logical units of work that must be resolved manually.

The DB2 system has an incomplete record of resolution responsibilities. It attempts to reconstruct as much resynchronization information as possible and displays the information in one or more DSNL438 or DSNL439 messages. The displayed information is then forgotten.

A warm status for restart means the DB2 system does have memory of previous connections with the partner and therefore does have memory of indoubt logical units of work. The exchange of recovery log names validates that the correct recovery logs are being used for indoubt resolution. Each partner indicates its recovery log name and the recovery log name it believes to be the one the other partner is using. A warm start connection where one system specifies a recovery log name that is different than the name remembered by the other system is rejected if indoubt resolution is required between the two partners.

### Procedures for resolving inconsistencies

The following section explains what must be done to resolve any inconsistencies that exist. Before reading this section, the procedures in the other sections in this chapter must be considered. Each one provides important steps that must be followed before using the information in this section.

The following three methods describe one or more steps that must be taken to resolve inconsistencies in the DB2 subsystem. Before using these methods, however, complete the following procedure:

1. Obtain image copies of all DB2 table spaces. You will need these image copies if any of the following conditions apply:
  - You did a cold start.

- You did a conditional restart that altered or truncated the log.
- The log is damaged.
- Part of the log is no longer accessible.

The first thing to do after a conditional restart is to take image copies of all DB2 table spaces, except those that are inconsistent. For those table spaces suspected of being inconsistent, resolve the inconsistencies and then obtain image copies of them.

A cold start might cause down-level page set errors. Some of these errors cause message DSNB232I to be displayed during DB2 restart. After you restart DB2, check the console log for down-level page set messages. If any of those messages exist, correct the errors before you take image copies of the affected data sets. Other down-level page set errors are not detected by DB2 during restart. If you use the COPY utility with the SHRLEVEL REFERENCE option to make image copies, the COPY utility will issue message DSNB232I when it encounters down-level page sets. Correct those errors and continue making image copies. If you use some other method to make image copies, you will find out about down-level errors during normal DB2 operation. “Recovery from down-level page sets” on page 548 describes methods for correcting down-level page set errors.

Pay particular attention to DB2 subsystem table spaces. If any are inconsistent, recover all of them in the order shown in the discussion on recovering catalog and directory objects in Part 2 of *DB2 Utility Guide and Reference*.

When a portion of the DB2 recovery log becomes inaccessible, all DB2 recovery processes have difficulty operating successfully, including restart, RECOVER, and deferred restart processing. Conditional restart allowed circumvention of the problem during the restart process. To ensure that RECOVER does not attempt to access the inaccessible portions of the log, secure a copy (either full or incremental) that does not require such access. A failure occurs any time a DB2 process (such as the RECOVER utility) attempts to access an inaccessible portion of the log. You cannot be sure which DB2 processes must use that portion of the recovery log, and, therefore, you must assume that all data recovery requires that portion of the log.

2. Resolve database inconsistencies. If you determine that the existing inconsistencies involve indexes only (not data), use the utility RECOVER INDEX. If the inconsistencies involve data (either user data or DB2 subsystem data), continue reading this section.

Inconsistencies in DB2 subsystem databases DSNDB01 and DSNDB06 must be resolved before inconsistencies in other databases can be resolved. This is necessary because the subsystem databases describe all other databases, and access to other databases requires information from DSNDB01 and DSNDB06.

If the table space that cannot be recovered (and is thus inconsistent) is being dropped, either all rows are being deleted or the table is not necessary. In either case, drop the table when DB2 is restarted, and do not bother to resolve the inconsistencies before restarting DB2.

Any one of the following three procedures can be used to resolve data inconsistencies. However, using one of the first two procedures is advisable because of the complexity of the third procedure.

## Method 1. Recover to a prior point of consistency

See “Recovering data to a prior point of consistency” on page 499 for a description of how to successfully prepare for and do data recovery to a prior point of consistency.

## Method 2. Re-create the table space

Take the following steps to drop the table space and reconstruct the data using the CREATE statement. This procedure is simple relative to “Method 3. Use the REPAIR utility on the data.” However, if you want to use this procedure, you need to plan ahead, because, when a table space is dropped, all tables in that table space, as well as related indexes, authorities, and views, are implicitly dropped. Be prepared to reestablish indexes, views, and authorizations, as well as the data content itself.

DB2 subsystem tables, such as the catalog and directory, cannot be dropped. Follow either “Method 1. Recover to a prior point of consistency” on page 623 or “Method 3. Use the REPAIR utility on the data” for these tables.

1. Issue an SQL DROP TABLESPACE statement for all table spaces that are suspected of being involved in the problem.
2. Re-create the table spaces, tables, indexes, synonyms, and views using SQL CREATE statements.
3. Grant access to these objects as it was granted prior to the time of the error.
4. Reconstruct the data in the tables.
5. Run the RUNSTATS utility on the data.
6. Use COPY to acquire a full image copy of all data.
7. Use the REBIND process on all plans that use the tables or views involved in this activity.

## Method 3. Use the REPAIR utility on the data

The third method for resolving data inconsistencies involves the use of the REPAIR utility. This method of resolving inconsistencies is not recommended unless the inconsistency is limited to a small number of data or index pages for the following reasons.

- For extensive data inconsistency, this method can be fairly time consuming and complex, making the procedure more error prone than the two methods described previously.
- DSN1LOGP can identify page sets that contain inconsistencies, but it cannot identify the specific data modifications involved in the inconsistencies within a given page set.
- DB2 provides no mechanism to tell users whether data is physically consistent or damaged. If the data is damaged physically, you might learn this when you attempt to use SQL to access the data and find that the data is inaccessible.

If you decide to use this method to resolve data inconsistencies, be sure to read the following section carefully, because it contains information that is important to the successful resolution of the inconsistencies.

### *Considerations for using the REPAIR method:*

- Any pages that are on the logical page list (perhaps caused by this restart) cannot be accessed via the REPAIR utility. Because you have decided to use the REPAIR utility to resolve the inconsistency, issue the command START DATABASE (*dbase*) SPACENAM (*space*) ACCESS(FORCE), where *space* names the table space involved. That allows access to the data.
- As noted in “Recovering data to a prior point of consistency” on page 499, DB2 subsystem data (in the catalog and directory) exists in interrelated tables and table spaces. Data in DB2 subsystem databases cannot be modified via SQL, so the REPAIR utility must be used to resolve the inconsistencies that are identified.

- For a description of stored data and index formats, refer to Part 6 of *DB2 Diagnosis Guide and Reference*.
- DB2 stores data in data pages. The structure of data in a data page must conform to a set of rules for DB2 to be able to process the data accurately. Using a conditional restart process does not cause violations to this set of rules; but, if violations existed prior to conditional restart, they will continue to exist after conditional restart. Therefore, use DSN1COPY with the CHECK option.
- DB2 uses several types of pointers in accessing data. Each type (indexes, hashes, and links) is described in Part 6 of *DB2 Diagnosis Guide and Reference*. Look for these pointers and manually ensure their consistency.

Hash and link pointers exist in the DB2 directory database; link pointers also exist in the catalog database. DB2 uses these pointers to access data. During a conditional restart, it is possible for data pages to be modified without update of the corresponding pointers. When this occurs, one of the following actions can occur:

- If a pointer addresses data that is nonexistent or incorrect, DB2 abends the request. If SQL is used to access the data, a message identifying the condition and the page in question is issued.
- If data exists but no pointer addresses it, that data is virtually invisible to all functions that attempt to access it via the damaged hash or link pointer. The data might, however, be visible and accessible by some functions, such as SQL functions that use some other pointer that was not damaged. As might be expected, this situation can result in inconsistencies.

If a row containing a varying-length field is updated, it can increase in size. If the page in which the row is stored does not contain enough available space to store the additional data, the row is placed in another data page, and a pointer to the new data page is stored in the original data page. After a conditional restart, one of the following conditions can exist.

- The row of data exists, but the pointer to that row does not exist. In this case, the row is invisible and the data cannot be accessed.
- The pointer to the row exists, but the row itself no longer exists. DB2 abends the requester when any operation (for instance, a SELECT) attempts to access the data. If termination occurs, one or more messages will be received that identify the condition and the page containing the pointer.

When these inconsistencies are encountered, use the REPAIR utility to resolve them, as described in Part 2 of *DB2 Utility Guide and Reference*.

- If the log has been truncated, there can be problems changing data via the REPAIR utility. Each data and index page contains the log RBA of the last recovery log record that was applied against the page. DB2 does not allow modification of a page containing a log RBA that is higher than the current end of the log. If the log has been truncated and you choose to use the REPAIR utility rather than recovering to a prior point of consistency, the DSN1COPY RESET option must be used to reset the log RBA in every data and index page set to be corrected with this procedure.
- **This last step is imperative.** When all known inconsistencies have been resolved, full image copies of all modified table spaces must be taken, in order to use the RECOVER utility to recover from any future problems.

## Part 5. Performance monitoring and tuning

<b>Chapter 24. Planning your performance strategy</b>	633
Managing performance in general	633
Setting reasonable performance objectives	634
Defining the workload	634
Initial performance planning	635
Translating resource requirements into objectives	636
External design	636
Internal design	636
Coding and testing	637
Post-development review	637
Planning for performance monitoring	637
Continuous performance monitoring	638
Periodic performance monitoring	639

## Chapter 24. Planning your performance strategy

The first step toward improving performance is planning, which is the subject of this chapter.

For the elements of planning a strategy, see the following sections:

- “Managing performance in general”
- “Setting reasonable performance objectives” on page 634
- “Planning for performance monitoring” on page 637
- “Reviewing performance data” on page 640

Throughout the information about performance monitoring and tuning, remember the following information:

- DB2 is only a part of your overall system. Any change to zSeries hardware, disk subsystems, z/OS, IMS, CICS, TCP/IP, VTAM, the network, WebSphere, or distributed application platforms (such as Windows, UNIX, or Linux<sup>®</sup>) that share your enterprise IT infrastructure can affect how DB2 and its applications run.
- The recommendations for performance monitoring and tuning are based on current knowledge of DB2 performance for “normal” circumstances and “typical” systems. Therefore, that this book provides the best or most appropriate advice for any specific site cannot be guaranteed. In particular, the advice in this section on performance often approaches situations from a performance viewpoint only. At some sites, other factors of higher priority may make some performance recommendations in this section inappropriate.
- The recommendations are general. Performance measurements are highly dependent on workload and system characteristics external to DB2.

Information on performance monitoring and tuning in a data sharing environment is presented in *DB2 Data Sharing: Planning and Administration*.

---

### Managing performance in general

Managing the performance of any system involves the following steps:

1. Establish performance objectives.
2. Plan how to monitor performance.
3. Carry out the plan.
4. Analyze performance reports to decide whether the objectives have been met.
5. If performance is thoroughly satisfactory, use one of the following options:
  - Monitor less, because monitoring itself uses resources.
  - Continue monitoring to generate a history of performance to compare with future results.
6. If performance has not been satisfactory, take the following actions:
  - a. Determine the major constraints in the system.
  - b. Decide where you can afford to make trade-offs and which resources can bear an additional load. Nearly all tuning involves trade-offs among system resources.
  - c. Tune your system by adjusting its characteristics to improve performance.
  - d. Return to step 3 and continue to monitor the system.

Periodically, or after significant changes to your system or workload, return to step 1, reexamine your objectives, and refine your monitoring and tuning strategy accordingly.

---

## Setting reasonable performance objectives

How you define good performance for your DB2 subsystem depends on your particular data processing needs and their priority. Performance objectives should be realistic, in line with your budget, understandable, and measurable.

Common objectives include values for:

- Acceptable response time (a duration within which some percentage of all applications have completed)
- Average throughput (the total number of transactions or queries that complete within a given time)
- System availability, including mean time to failure and the durations of down times

Objectives such as these define the workload for the system and determine the requirements for resources, such as processor speed, amount of storage, additional software, and so on. Often, however, available resources limit the maximum acceptable workload, which requires revising the objectives.

**Service-level agreements:** Presumably, your users have a say in your performance objectives. A mutual agreement on acceptable performance, between the data processing and user groups in an organization, is often formalized and called a *service-level agreement*. Service-level agreements can include expectations of query response time, the workload throughput per day, hour, or minute, and windows provided for batch jobs (including utilities). These agreements list criteria for determining whether or not the system is performing adequately.

**Example:** A service-level agreement might require that 90% of all response times sampled on a local network in the prime shift be under 2 seconds, or that the average response time not exceed 6 seconds even during peak periods. (For a network of remote terminals, consider substantially higher response times.)

Performance objectives must reflect not only elapsed time, but also the amount of processing expected. Consider whether to define your criteria in terms of the average, the ninetieth percentile, or even the worst-case response time. Your choice can depend on your site's audit controls and the nature of the workloads.

z/OS workload management (WLM) can manage to the performance objectives in the service-level agreement and provide performance reporting analysis. The terms used in the service-level agreement and the WLM service policy are similar.

## Defining the workload

To define the workload of the system, begin by determining the type of workload. For each type, describe a preliminary workload profile that includes the following information:

- A definition of the workload type in terms of its function and its volume. You are likely to have many workloads that perform the same general function (for example, order entry through CICS or IMS transaction managers) and have an identifiable workload profile. Other workload types include SPUIFI and QMF

queries, transactions, utilities, and batch jobs. For the volume of a workload that is already processed by DB2, use the summary of its volumes from the DB2 statistics trace.

- The relative priority of the type, including periods during which the priorities change.
- The resources that are required to do the work, including physical resources that are managed by the operating system (such as real storage, disk I/O, and terminal I/O) and logical resources managed by the subsystem (such as control blocks and buffers).

Before installing DB2, gather design data during the phases of initial planning, external design, internal design, and coding and testing. Keep reevaluating your performance objectives with that information.

## Initial performance planning

Begin establishing resource requirements by estimating the following quantities. Make an estimate even if these quantities are uncertain at this stage.

### *For transactions:*

- Availability of transaction managers, such as IMS, CICS, or WebSphere
- Number of message pairs for each user function, either to and from a terminal or to and from a distributed application
- Network bandwidth and network device latencies
- Average and maximum number of concurrent users, either terminal operators or distributed application requesters
- Maximum rate of workloads per second, minute, hour, day, or week
- Number of disk I/O operations per user workload
- Average and maximum processor usage per workload type and total workload
- Size of tables
- Effects of objectives on operations and system programming

### *For query use:*

- Time required to key in user data
- Online query processing load
- Limits to be set for the query environment or preformatted queries
- Size of tables
- Effects of objectives on operations and system programming

### *For batch processing:*

- Batch windows for data reorganization, utilities, data definition activities, and BIND processing
- Batch processing load
- Length of batch window
- Number of records to process, data reorganization activity, use of utilities, and data definition activity
- Size of tables and complexity of the queries
- Effects of objectives on operations and system programming

Look at the base estimate to find ways to reduce the workload. Changes in design at this stage, before contention with other programs, are likely to be the most effective. Later, you can compare the actual production profile against the base.

## Translating resource requirements into objectives

For each workload type, convert the estimates of resource requirements into measurable objectives. Include statements about the throughput rates to be supported (including any peak periods) and the internal response time profiles to be achieved. Make assumptions about I/O rates, paging rates, and workloads. Include the following factors:

- System response time. You cannot guarantee requested response times before any of the design has been done. Therefore, plan to review your performance targets when you design and implement the system.  
Response times can vary for many reasons. Therefore, include acceptable tolerances in your descriptions of targets. Remember that distributed data processing adds overhead at both the local and remote locations.  
Exclude from the targets any unusual applications that have exceptionally heavy requirements for processing or database access, or establish individual targets for those applications.
- Network response time. Responses in the processor are likely to be in microseconds, whereas responses in the network with appropriate facilities can be about a millisecond. This difference in response times means that an overloaded network can impact the delivery of server responses to user terminals or distributed applications regardless of the speed of the processor.
- Disk response time. I/O operations are generally responsible for much internal processing time. Consider all I/O operations that affect a workload.
- Existing workload. Consider the effects of additional work on existing applications. In planning the capacity of the system, consider the total load on each major resource, not just the load for the new application.
- Business factors. When calculating performance estimates, concentrate on the expected peak throughput rate. Allow for daily peaks (for example, after receipt of mail), weekly peaks (for example, a Monday peak after weekend mail), and seasonal peaks as appropriate to the business. Also allow for peaks of work after planned interruptions, such as preventive maintenance periods and public holidays. Remember that the availability of input data is one of the constraints on throughput.

## External design

During the external design phase, you must:

1. Estimate the network, Web server, application server, processor, and disk subsystem workload.
2. Refine your estimates of logical disk accesses. Ignore physical accesses at this stage; one of the major difficulties will be determining the number of I/Os per statement.

## Internal design

During the internal design phase, you must:

1. Refine your estimated workload against the actual workload.
2. Refine disk access estimates against database design. After internal design, you can define physical data accesses for application-oriented processes and estimate buffer hit ratios.
3. Add the accesses for DB2 work file database, DB2 log, program library, and DB2 sorts.
4. Consider whether additional processor loads will cause a significant constraint.
5. Refine estimates of processor usage.

6. Estimate the internal response time as the sum of processor time and synchronous I/O time or as asynchronous I/O time, whichever is larger.
7. Prototype your DB2 system. Before committing resources to writing code, you can create a small database, update the statistics stored in the DB2 catalog tables, run SQL statements and examine the results.
8. Use DB2 estimation formulas to develop estimates for processor resource consumption and I/O costs for application processes that are high volume or complex.

### **Coding and testing**

During this phase:

1. Refine the internal design estimates of disk and processing resources.
2. Run the monitoring tools you have selected and check the results against the estimates. You might use a terminal network simulator such as TeleProcessing Network Simulator (TPNS) or other tools to test the system and simulate load conditions.

### **Post-development review**

When you are ready to test the complete system, review its performance in detail. Take the following steps to complete your performance review:

1. Validate system performance and response times against the objectives.
2. Identify resources whose usage requires regular monitoring.
3. Incorporate the observed figures into future estimates. This step requires:
  - a. Identifying discrepancies from the estimated resource usage
  - b. Identifying the cause of the discrepancies
  - c. Assigning priorities to remedial actions
  - d. Identifying resources that are consistently heavily used
  - e. Setting up utilities to provide graphic representation of those resources
  - f. Projecting the processor usage against the planned future system growth to ensure that adequate capacity will be available
  - g. Updating the design document with the observed performance figures
  - h. Modifying the estimation procedures to reflect what you have learned

You need feedback from users and might have to solicit it. Establish reporting procedures and teach your users how to use them. Consider logging incidents such as these:

- System, line and transaction or query failures
- System unavailable time
- Response times that are outside the specified limits
- Incidents that imply performance constraints, such as deadlocks, deadlock abends, and insufficient storage
- Situations, such as recoveries, that use additional system resources

The data logged should include the time, date, location, duration, cause (if it can be determined), and the action taken to resolve the problem.

---

## **Planning for performance monitoring**

Your plan for monitoring DB2 performance should include:

- A master schedule of monitoring. Large batch jobs or utility runs can cause activity peaks. Coordinate monitoring with other operations so that it need not conflict with unusual peaks, unless that is what you want to monitor.
- The kinds of analysis to be performed and the tools to be used. Document the data that is extracted from the monitoring output.

Some of the performance reports are derived from the products that are described in Appendix F, “Using tools to monitor performance,” on page 1191. These reports can be produced using Tivoli® Decision Support for OS/390, OMEGAMON® XE for DB2 Performance Monitor (DB2 PM), OMEGAMON (which includes the function of DB2 PM), other reporting tools, manual reduction, or a program of your own that extracts information from standard reports.

- A list of people who should review the results. The results of monitoring and the conclusions based on them should be available to the user support group and to system performance specialists.
- A strategy for tuning DB2. Describe how often changes are permitted and standards for testing their effects. Include the tuning strategy in regular system management procedures.

Tuning recommendations could include generic database and application design changes. You should update development standards and guidelines to reflect your experience and to avoid repeating mistakes.

Typically, your plan provides for four levels of monitoring:

- “Continuous performance monitoring”
- “Periodic performance monitoring” on page 639
- “Detailed performance monitoring” on page 639
- “Exception performance monitoring” on page 640

“A performance monitoring strategy” on page 640 describes a plan that includes all of these levels.

## Continuous performance monitoring

For monitoring the basic load of the system, try continually running classes 1, 3, 4, and 6 of the DB2 statistics trace and classes 1 and 3 of the DB2 accounting trace. In the data you collect, look for statistics or counts that differ from past records. Pay special attention to peak periods of activity, both of any new application and of the system as a whole.

Running accounting class 2 as well as class 1 allows you to separate DB2 times from application times.

Running with CICS without the open transaction environment (OTE), entails less need to run with accounting class 2. Application and non-DB2 processing take place under the CICS main TCB. Because SQL activity takes place under the SQL TCB, the class 1 and class 2 times are generally close. The CICS attachment work is spread across class 1, class 2, and time spent processing outside of DB2. Class 1 time thus reports on the SQL TCB time and some of the CICS attachment. If you are concerned about class 2 overhead and you use CICS, you can generally run without turning on accounting class 2.

Statistics and accounting information can be very helpful for application and database designers. Consider putting this information into a performance warehouse so that the data can be analyzed more easily by all the personnel who

need the information. OMEGAMON includes a performance warehouse that allows you to define, schedule, and run processes that:

- Automate the creation of reports
- Automate the conversion and loading of these reports and other data into a performance warehouse
- Analyze the data that is loaded into the performance warehouse using suggested rules or rules that you define yourself

The data in the performance warehouse can be accessed by any member of the DB2 Universal Database family or by any product that supports Distributed Relational Database Architecture (DRDA).

## Periodic performance monitoring

A typical periodic monitoring interval of about ten minutes provides information on the workload achieved, resources used, and significant changes to the system. In effect, you are taking “snapshots” at peak loads and under normal conditions.

**Recommendation:** Monitor peak periods when constraints and response-time problems are more pronounced.

The current peak is also a good indicator of the future average. You might have to monitor more frequently at first to confirm that expected peaks correspond with actual ones. Do not base conclusions on one or two monitoring periods, but on data from several days representing different periods.

Both continuous and periodic monitoring serve to check system throughput, utilized resources (processor, I/Os, and storage), changes to the system, and significant exceptions that might affect system performance. You might notice that subsystem response is becoming increasingly sluggish, or that more applications fail from lack of resources (such as from locking contention or concurrency limits). You also might notice an increase in the processor time DB2 is using, even though subsystem responses seem normal. In any case, if the subsystem continues to perform acceptably and you are not having any problems, DB2 might not need additional tuning.

For periodic monitoring, gather information from z/OS, the transaction manager (IMS, CICS, or WebSphere), the network, the distributed application platforms (such as Windows, UNIX, or Linux), and DB2 itself. To compare the different results from each source, monitor each for the same period of time. Because the monitoring tools require resources, you need to consider the overhead for using these tools. See “Minimizing the use of DB2 traces” on page 666 for information on DB2 trace overhead.

## Detailed performance monitoring

Add detailed monitoring to periodic monitoring when you discover or suspect a problem. Use it also to investigate areas not covered periodically. To keep the cost of the detailed monitoring low, limit the information to the specific application and data as much as possible.

If you have a performance problem, first verify that it is not caused by faulty design of an application or database. If you suspect a problem in application design, consult Part 4 of *DB2 Application Programming and SQL Guide*; for information about database design, see Part 2, “Designing a database: advanced topics,” on page 23.

If you believe that the problem is caused by the choice of system parameters, I/O device assignments, or other factors, begin monitoring DB2 to collect data about its internal activity. Appendix F, “Using tools to monitor performance,” on page 1191 suggests various techniques and methods.

If you have access path problems, refer to Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 for information.

## Exception performance monitoring

Exception monitoring looks for specific exceptional values or events, such as very high response times or deadlocks. Perform exception monitoring for response-time and concurrency problems. For an example, see “Scenario for analyzing concurrency” on page 876.

With OMEGAMON, exception monitoring is available in both batch reporting and Online Monitor. For information on how to use exception processing, set exception threshold limits in the threshold limit data set, and use the exception profiling function of OMEGAMON, see:

- *Using IBM Tivoli OMEGAMON XE on z/OS*
- *OMEGAMON Report Reference*
- *OMEGAMON Monitoring Performance from ISPF*
- *OMEGAMON Monitoring Performance from Performance Expert Client*

## A performance monitoring strategy

Consider the following cost factors when planning for performance monitoring and tuning:

- Trace overhead
- Trace data reduction and reporting times
- Time spent on report analysis and tuning action

“Minimizing the use of DB2 traces” on page 666 discusses overhead for global, accounting, statistics, audit, and performance traces.

---

## Reviewing performance data

Inspect your performance data to determine whether performance has been satisfactory, to identify problems, and to evaluate the monitoring process. When establishing requirements and planning to monitor performance, also plan how to review the results of monitoring.

Plan to review the performance data systematically. Review daily data weekly and weekly data monthly; review data more often if a report raises questions that require checking. Depending on your system, the weekly review might require about an hour, particularly after you have had some experience with the process and are able to locate quickly any items that require special attention. The monthly review might take half a day at first, less time later on. But when new applications are installed, workload volumes increased, or terminals added, allow more time for review.

Review the data on a gross level, looking for problem areas. Review details only if a problem arises or if you need to verify measurements.

When reviewing performance data, try to identify the basic pattern in the workload, and then identify variations of the pattern. After a certain period, discard most of the data you have collected, but keep a representative sample. For

example, save the report from the last week of a month for three months; at the end of the year, discard all but the last week of each quarter. Similarly, keep a representative selection of daily and monthly figures. Because of the potential volume of data, consider using Tivoli Decision Support for OS/390, Application Monitor for z/OS and OS/390, or a similar tool to track historical data in a manageable form.

## Typical review questions

Use the following questions as a basis for your own checklist. They are not limited strictly to performance items, but your historical data can provide most of their answers. If the performance data is for modeled workloads or changed workloads, the first question to ask for each category is "What changed?" Pointers to more information are also listed.

### How often was each transaction and SQL statement used?

1. Considering variations in the workload mix over time, are the monitoring times appropriate?
2. Should monitoring be done more frequently during the day, week, or month to verify this?
3. How many SELECT, INSERT, UPDATE, DELETE, PREPARE, DESCRIBE, DESCRIBE TABLE, PREPARE, OPEN, FETCH, and CLOSE statements are issued per second and per commit?
4. How many IRLM and buffer pool requests are issued per second and per commit?

See "Accounting trace" on page 1196.

### How were processor and I/O resources used?

1. Has usage increased for functions that run at a higher priority than DB2 tasks? Examine CICS, IMS, z/OS, JES, TCP/IP, VTAM, WebSphere Application Server, WebSphere MQ (formerly called MQSeries), other subsystems, and key applications.
2. Is the report of processor usage consistent with previous observations?
3. Are scheduled batch jobs able to run successfully?
4. Do any incident reports show that the first invocation of a function takes much longer than later ones? This increased time can happen when programs have to open data sets.
5. What is the CPU time and where is it accumulated? Separate CPU time into accounting TCB and SRB time, and distinguish non-nested, stored procedure, user-defined function, and trigger CPU times. Note the times for DB2 address spaces, DBM1, MSTR, IRLM, and DDF.
6. In a data sharing environment, how are the coupling facility (CF) lock, group buffer pool, and SCA structures performing? What is the peak CF CPU utilization?

See "Monitoring system resources" on page 1194, "Using z/OS, CICS, and IMS tools" on page 1193, and "Statistics trace" on page 1196.

### How much real storage was used, and how effective is storage?

1. Is the paging rate increasing? Adequate real storage is very important for DB2 performance.
2. What are the hit ratios for the buffer pools, the EDM pool (the cursor tables and package tables), the EDM DBD cache (the DBDs), and the dynamic statement cache?

See "Monitoring system resources" on page 1194.

### **To what degree was disk used?**

Is the number of I/O requests increasing? DB2 records both physical and logical requests. The number of physical I/Os depend on the configuration of indexes, the data records per control interval, and the buffer allocations.

See “Monitoring system resources” on page 1194 and “Statistics trace” on page 1196.

### **To what extent were DB2 log resources used?**

1. Is the log subject to undue contention from other data sets? In particular, is the log on the same drive as any resource whose updates are logged?

**Recommendation:** Do not put a recoverable (updated) resource and a log on the same drive. If that drive fails, you lose both the resource and the log, and you are unable to carry out forward recovery.

2. What is the I/O rate for requests and physical blocks on the log? What is the logging rate for one log in MB per second?

See “Statistics trace” on page 1196.

### **Do any figures indicate design, coding, or operational errors?**

1. Are disk, I/O, log, or processor resources heavily used? If so, was that heavy use expected at design time? If not, can the heavy use be explained in terms of heavier use of workloads?
2. Is the heavy usage associated with a particular application? If so, is there evidence of planned growth or peak periods?
3. What are your needs for concurrent read/write and query activity?
4. How often do locking contentions occur?
5. Are there any disk, channel, or path problems?
6. Are there any abends or dumps?

See “Monitoring system resources” on page 1194, “Statistics trace” on page 1196, and “Accounting trace” on page 1196.

### **What are the effects of DB2 locks?**

1. What are the incidents of deadlocks and timeouts?
2. What percentage of elapsed time is due to lock suspensions? How much lock or latch contention was encountered? Check the contention rate per second by class.
3. How effective is lock avoidance?

See “Monitoring of DB2 locking” on page 873

### **Were there any bottlenecks?**

1. Were any critical thresholds reached?
2. Are any resources approaching high utilization?

See “Monitoring system resources” on page 1194 and “Accounting trace” on page 1196.

## **Are your performance objectives reasonable?**

After beginning to monitor, you need to find out if the objectives themselves are reasonable. Are they achievable, given the hardware available? Are they based upon actual measurements of the workload?

When you measure performance against initial objectives and report the results to users, identify any systematic differences between the measured data and what the user sees. This means investigating the differences between internal response time (seen by DB2) and external response time (seen by the end user). If the measurements differ greatly from the estimates, revise response-time objectives for

the application, upgrade your system, or plan a reduced application workload. If the difference is not too large, however, you can begin tuning the entire system.

---

## Chapter 25. Analyzing performance data

This chapter includes the following topics:

- “Investigating the problem overall”
- “Reading accounting reports from OMEGAMON” on page 646
- “A general approach to problem analysis in DB2” on page 652

---

### Investigating the problem overall

When analyzing performance data, keep in mind that almost all symptoms of poor performance are magnified when contention occurs. For example, if there is a slowdown in disk operations:

- Transactions can pile up, waiting for data set activity.
- Transactions can wait for I/O and locks.
- Paging can be delayed.

In addition, more transactions in the system means greater processor overhead, greater real-storage demand, greater I/O demand, and greater locking demand. This increased overhead and demand can have a large impact.

In such situations, the system shows heavy use of **all** its resources. However, it is actually experiencing typical system stress, with a constraint that is yet to be found.

### Looking at the entire system

Start by looking at the overall system before you decide that you have a problem in DB2. In general, look in some detail to see why application processes are progressing slowly, or why a given resource is being heavily used. The best tool for that is the resource measurement facility (RMF™) of z/OS. If the application processes are running on distributed platforms, you must look at the performance on those platforms and the network connecting them with z/OS.

### Beginning to look at DB2

Before you analyze DB2 for performance problems, look at the overall system. If your initial analysis suggests that the performance problem is within DB2, the problem might be poor response time, an unexpected and unexplained high use of resources, or locking conflicts. Check factors such as total processor usage, disk activity, and paging.

First, turn on classes 1, 2, and 3 of the accounting trace to get a picture of task activity and determine whether the performance problem is within DB2. Although accounting trace class 2 has a high overhead cost for fetch-intensive applications, it is generally recommended that you keep it on in all cases. For other applications, accounting trace class 2 has an overhead of less than 5%. Accounting trace class 3 can help you determine which resources DB2 is waiting on.

Next, focus on particular activities, such as specific application processes or a specific time interval. You might see problems such as these:

- Slow response time. You could look at detailed traces of one slow task, a problem for which there could be several reasons. For instance, the users could be trying to do too much work with certain applications, work that clearly takes time, and the system simply cannot do all the work that they want done.

- Real storage constraints. Applications progress more slowly than expected because of paging interrupts. The constraints show as delays between successive requests recorded in the DB2 trace.
- Contention for a particular function. For example, there might be a wait on a particular data set, or a certain application might cause many application processes to put the same item in their queues. Use the DB2 performance trace to distinguish most of these cases.

For information about packages or DBRMs, run accounting trace classes 7 and 8. To determine which packages are consuming excessive resources, compare accounting trace classes 7 and 8 to the elapsed time for the whole plan on accounting classes 1 and 2.

A number greater than 1 in the QXMAXDEG field of the accounting trace indicates that parallelism was used. There are special considerations for interpreting such records, as described in “Monitoring parallel operations” on page 1001.

The easiest way to read and interpret the trace data is through the reports produced by OMEGAMON. If you do not have OMEGAMON or an equivalent program, refer to Appendix D, “Interpreting DB2 trace output,” on page 1139 for information about the format of data from DB2 traces.

You can also use the tools for performance measurement described in Appendix F, “Using tools to monitor performance,” on page 1191 to diagnose system problems. Also see Appendix F, “Using tools to monitor performance,” on page 1191 for information on analyzing the DB2 catalog and directory.

---

## Reading accounting reports from OMEGAMON

You can obtain OMEGAMON reports of accounting data in long or short format and in various levels of detail. The examples of OMEGAMON reports in this book are based on the default formats, which might have been modified for your installation. Furthermore, the OMEGAMON reports have been reformatted or modified for this publication. Refer to *OMEGAMON Report Reference* for an exact description of each report. See “Accounting for nested activities” on page 1028 for information on time results for triggers, stored procedures, and user-defined functions.

Although this section talks about OMEGAMON reports, you can also use DB2 PM to obtain the same reports.

### The accounting report (short format)

**General capabilities:** The OMEGAMON accounting report, short format, allows you to monitor application distribution, resources used by each major group of applications, and the average DB2 elapsed time for each major group. The report summarizes application-related performance data and orders the data by selected DB2 identifiers.

Monitoring application distribution helps you to identify the most frequently used transactions or queries, and is intended to cover the 20% of the transactions or queries that represent about 80% of the total work load. The TOP list function of OMEGAMON lets you identify the report entries that represent the largest user of a given resource.

To get an overall picture of the system work load, you can use the OMEGAMON GROUP command to group several DB2 plans together.

You can use the accounting report, short format, to:

- Monitor the effect of each application or group on the total work load
- Monitor, in each application or group:
  - DB2 response time (elapsed time)
  - Resources used (processor, I/Os)
  - Lock suspensions
  - Application changes (SQL used)
  - Usage of packages and DBRMs
  - Processor, I/O wait, and lock wait time for each package

An accounting report in the short format can list results in order by package. Thus you can summarize package or DBRM activity independently of the plan under which the package or DBRM executed.

Only class 1 of the accounting trace is needed for a report of information by plan. Classes 2 and 3 are recommended for additional information. Classes 7 and 8 are needed to give information by package or DBRM.

## **The accounting report (long format)**

Use the OMEGAMON accounting report, short format, to monitor your applications. Use the OMEGAMON accounting report, long format, when an application seems to have a problem, and you need a more detailed analysis. For a partial example of an accounting report, long format, see Figure 69 on page 648.

Figure 69. Partial accounting report (long format)

In analyzing a detailed accounting report, consider the following components of response time. (Fields of the report that are referred to are labeled in Figure 69.)

**Class 1 elapsed time:** Compare this with the CICS, IMS, WebSphere, or distributed application transit times:

- In CICS, you can use CICS Performance Analyzer to find the attach and detach times; use this time as the transit time.
- In IMS, use the PROGRAM EXECUTION time reported in IMS Performance Analyzer.

Differences between the CICS, IMS, WebSphere, or distributed application times and the DB2 accounting times arise mainly because the DB2 times do not include:

- Time before the first SQL statement, which for a distributed application includes the inbound network delivery time
- DB2 create thread
- DB2 terminate thread

- For a distributed application, the time to deliver the response to a commit if database access thread pooling is used

Differences can also arise from thread reuse in CICS, IMS, WebSphere, or distributed application processing or through multiple commits in CICS. If the class 1 elapsed time is significantly less than the CICS or IMS time, check the report from Tivoli Decision Support for OS/390, IMS Performance Analyzer, or an equivalent reporting tool to find out why. Elapsed time can occur:

- In DB2, during sign-on, create, or terminate thread
- Outside DB2, during CICS or IMS processing

**Not-in-DB2 time:** This is time calculated as the difference between the class 1 and the class 2 elapsed time. It is time spent outside of DB2, but within the DB2 accounting interval. A lengthy time can be caused by thread reuse, which can increase class 1 elapsed time, or a problem in the application program, CICS, IMS, or the overall system.

For a distributed application, not-in-DB2 time is calculated with this formula:

$$\text{Not\_in\_DB2 time} = A - (B + C + (D - E))$$

Where the variables have the following values:

- A** Class 1 elapsed time
- B** Class 2 non-tested elapsed time
- C** Class 1 non-tested time of any stored procedures, user-defined functions, or triggers
- D** Class 1 non-tested CPU time
- E** Class 2 non-tested CPU time

The calculated not-in-DB2 time might be zero. Furthermore, this time calculation is only an estimate. A primary factor that is not included in the equation is the amount of time that requests wait for CPU resources while executing within the DDF address space. To determine how long requests wait for CPU resources, look at the NOT ACCOUNT field. The NOT ACCOUNT field shows the time that requests wait for CPU resources while a distributed task is inside DB2.

**Lock/latch suspension time:** This shows contention for DB2 and IRLM resources. If contention is high, check the locking summary section of the report, and then proceed with the locking reports. For more information, see “Scenario for analyzing concurrency” on page 876.

In the OMEGAMON accounting report, see the field LOCK/LATCH(DB2+IRLM) (**A**).

**Synchronous I/O suspension time:** This is the total application wait time for synchronous I/Os. It is the total of database I/O and log write I/O. In the OMEGAMON accounting report, check the number reported for SYNCHRON. I/O (**B**).

If the number of synchronous read or write I/Os is higher than expected, check for:

- A change in the access path to data. If you have data from accounting trace class 8, the number of synchronous and asynchronous read I/Os is available for individual packages. Determine which package or packages have unacceptable

counts for synchronous and asynchronous read I/Os. Activate the necessary performance trace classes for the OMEGAMON SQL activity reports to identify the SQL statement or cursor that is causing the problem. If you suspect that your application has an access path problem, see Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931.

- A lower than expected buffer pool hit ratio. You can improve the ratio by tuning the buffer pool. Look at the number of synchronous reads in the buffer pool that are associated with the plan, and look at the related buffer pool hit ratio. If the buffer pool size and the buffer pool hit ratio for random reads is small, consider increasing the buffer pool size. By increasing the buffer pool size, you might reduce the amount of synchronous database I/O and reduce the synchronous I/O suspension time.
- A change to the catalog statistics, or statistics that no longer match the data.
- Changes in the application. Check the “SQL ACTIVITY” section and compare with previous data. There might have been some inserts that changed the amount of data. Also, check the names of the packages or DBRMs being executed to determine if the pattern of programs being executed has changed.
- Pages might be out of order so that sequential detection is not used, or data might have been moved to other pages. Run the REORG utility in these situations.
- A system-wide problem in the database buffer pool. Refer to “Using OMEGAMON to monitor buffer pool statistics” on page 683. You can also use OMEGAMON Buffer Pool Analyzer User's Guide or OMEGAMON, which contains the function of DB2 BPA, to manage and optimize buffer pool activity.
- A RID pool failure. Refer to “Increasing RID pool size” on page 689.
- A system-wide problem in the EDM pool. Refer to “Tuning EDM storage” on page 685.

If I/O time is greater than expected, and not caused by more read I/Os, check for:

- Synchronous write I/Os. See “Using OMEGAMON to monitor buffer pool statistics” on page 683. (You can also use OMEGAMON, which contains the function of DB2 BPA, to manage and buffer pool activity.)
- I/O contention. In general, each synchronous read I/O typically takes from 5 to 20 milliseconds, depending on the disk device. This estimate assumes that there are no prefetch or deferred write I/Os on the same device as the synchronous I/Os. Refer to “Monitoring I/O activity of data sets” on page 699.
- An increase in the number of users, or an increase in the amount of data. Also, drastic changes to the distribution of the data can cause the problem.

**Processor resource consumption:** The problem might be caused by DB2 or IRLM traces, a change in access paths, or an increase in the number of users. In the OMEGAMON accounting report, DB2 processor resource consumption is indicated in the field for class 2 CPU TIME ( **C** ).

**Other read suspensions:** The accumulated wait time for read I/O done under a thread other than this one. It includes time for:

- Sequential prefetch
- List prefetch
- Sequential detection
- Synchronous read I/O performed by a thread other than the one being reported

Generally, an asynchronous read I/O for sequential prefetch or sequential detection takes about 0.1 to 1 milliseconds per page. List prefetch takes about 0.2 to 2 milliseconds per page.

In the OMEGAMON accounting report, other read suspensions are reported in the field OTHER READ I/O ( **D** ).

*Other write suspensions:* The accumulated wait time for write I/O done under a thread other than this one. It includes time for:

- Asynchronous write I/O
- Synchronous write I/O performed by a thread other than the one being reported

As a guideline, an asynchronous write I/O takes 0.1 to 2 milliseconds per page.

In the OMEGAMON accounting report, other write suspensions are reported in the field OTHER WRTE I/O ( **E** ).

*Service task suspensions:* The accumulated wait time from switching synchronous execution units, by which DB2 switches from one execution unit to another. The most common contributors to service task suspensions are:

- Wait for phase 2 commit processing for updates, inserts, and deletes (UPDATE COMMIT). You can reduce this wait time by allocating the DB2 primary log on a faster disk. You can also help to reduce the wait time by reducing the number of commits per unit of work.
- Wait for OPEN/CLOSE service task (including HSM recall). You can minimize this wait time by using two strategies. If DSMAX is frequently reached, increase DSMAX. If DSMAX is not frequently reached, change CLOSE YES to CLOSE NO on data sets that are used by critical applications.
- Wait for SYSLGRNG recording service task.
- Wait for data set extend/delete/define service task (EXT/DEL/DEF). You can minimize this wait time by defining larger primary and secondary disk space allocation for the table space.
- Wait for other service tasks (OTHER SERVICE).

In the OMEGAMON accounting report, the total of this information is reported in the field SER.TASK SWTCH ( **F** ). The field is the total of the five fields that follow it. If several types of suspensions overlap, the sum of their wait times can exceed the total clock time that DB2 spends waiting. Therefore, when service task suspensions overlap other types, the wait time for the other types of suspensions is not counted.

*Archive log mode (QUIESCE):* The accumulated time the thread was suspended while processing ARCHIVE LOG MODE(QUIESCE). In the OMEGAMON accounting report, this information is reported in the field ARCH.LOG (QUIES) ( **G** ).

*Archive log read suspension:* This is the accumulated wait time the thread was suspended while waiting for a read from an archive log on tape. In the OMEGAMON accounting report, this information is reported in the field ARCHIVE LOG READ ( **H** ).

*Drain lock suspension:* The accumulated wait time the thread was suspended while waiting for a drain lock. If this value is high, see "Installation options for

wait times” on page 837, and consider running the OMEGAMON locking reports for additional detail. In the OMEGAMON accounting report, this information is reported in the field DRAIN LOCK ( **I** ).

*Claim release suspension:* The accumulated wait time the drainer was suspended while waiting for all claim holders to release the object. If this value is high, see “Installation options for wait times” on page 837, and consider running the OMEGAMON locking reports for additional details.

In the OMEGAMON accounting report, this information is reported in the field CLAIM RELEASE ( **J** ).

*Page latch suspension:* This field shows the accumulated wait time because of page latch contention. As an example, when the RUNSTATS and COPY utilities are run with the SHRLEVEL(CHANGE) option, they use a page latch to serialize the collection of statistics or the copying of a page. The page latch is a short duration “lock”. If this value is high, the OMEGAMON locking reports can provide additional data to help you determine which object is the source of the contention.

In a data sharing environment, high page latch contention could occur in a multithreaded application that runs on multiple members and requires many inserts. The OMEGAMON lock suspension report shows this suspension for page latch contention in the “other” category. If the suspension is on the index leaf page, use one of the following strategies:

- Make the inserts random
- Drop the index
- Perform the inserts from a single member

If the page latch suspension is on a space map page, use the member cluster option for the table space.

In the OMEGAMON accounting report, this information is reported in the field PAGE LATCH ( **K** ).

*Not-accounted-for DB2 time:* The DB2 accounting class 2 elapsed time that is not recorded as class 2 CPU time or class 3 suspensions. The most common contributors to this category are:

- z/OS paging
- Processor wait time
- On DB2 requester systems, the amount of time waiting for requests to be returned from either VTAM or TCP/IP, including time spent on the network and time spent handling the request in the target or server systems
- Time spent waiting for parallel tasks to complete (when query parallelism is used for the query)
- Some online performance monitoring

In the OMEGAMON accounting report, this information is reported in the field NOT ACCOUNT ( **L** ).

---

## A general approach to problem analysis in DB2

The following is a suggested sequence for investigating a response-time problem:

1. If the problem is inside DB2, determine which plan has the longest response time. If the plan can potentially allocate many different packages or DBRMs, determine which packages or DBRMs have the longest response time. Or, if you have a record of past history, determine which transactions show the largest increases.

Compare class 2 CPU time, class 3 time, and not accounted time. If your performance monitoring tool does not specify times other than class 2 and class 3, then you can determine the not accounted for time with the following formula:

Not accounted time = Class 2 elapsed time - Class 2 CPU time - Total class 3 time

2. If the class 2 CPU time is high, investigate by doing the following:
  - Check to see whether unnecessary trace options are enabled. Excessive performance tracing can be the reason for a large increase in class 2 CPU time.
  - Check the SQL statement count, the getpage count, and the buffer update count on the OMEGAMON accounting report. If the profile of the SQL statements has changed significantly, review the application. If the getpage counts or the buffer update counts change significantly, check for changes to the access path and significant increases in the number of rows in the tables that are accessed.
  - Use the statistics report to check buffer pool activity, including the buffer pool thresholds. If buffer pool activity has increased, be sure that your buffer pools are properly tuned. For more information on buffer pools, see “Tuning database buffer pools” on page 671.
  - Use EXPLAIN to check the efficiency of the access paths for your application. Based on the EXPLAIN results:
    - Use package-level accounting reports to determine which package or DBRM has a long elapsed time. In addition, use the class 7 CPU time for packages to determine which package or DBRM has the largest CPU time or the greatest increase in CPU time.
    - Use the OMEGAMON SQL activity report to analyze specific SQL statements. You can also use OMEGAMON to analyze specific SQL statements, including the currently running SQL statement.
    - If you have a history of the performance of the affected application, compare current EXPLAIN output to previous access paths and costs.
    - Check that RUNSTATS statistics are current.
    - Check that databases have been reorganized using the REORG utility.
    - Check which indexes are used and how many columns are accessed. Has your application used an alternative access path because an index was dropped?
    - Examine joins and subqueries for efficiency.

See Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 for help in understanding access path selection and analyzing access path problems. DB2 Visual Explain can give you a graphic display on your workstation of your EXPLAIN output.

- Check the counts in the locking section of the OMEGAMON accounting report. If locking activity has increased, see Chapter 31, “Improving concurrency,” on page 813. For a more detailed analysis, use the deadlock or timeout traces from statistics trace class 3 and the lock suspension report or trace.

3. If class 3 time is high, check the individual types of suspensions in the “Class 3 Suspensions” section of the OMEGAMON accounting report. (The fields referred to here are in Figure 69 on page 648).

- If LOCK/LATCH ( **A** ), DRAIN LOCK ( **I** ), or CLAIM RELEASE ( **J** ) time is high, see Chapter 31, “Improving concurrency,” on page 813.
- If SYNCHRON. I/O ( **B** ) time is high, see “Synchronous I/O suspension time” on page 649.
- If OTHER READ I/O ( **D** ) time is high, check prefetch I/O operations, disk contention and the tuning of your buffer pools.
- If OTHER WRITE I/O ( **E** ) time is high, check the I/O path, disk contention, and the tuning of your buffer pools.
- If SER.TASK SWTCH ( **F** ) is high, check open and close activity, as well as commit activity. A high value could also be caused by:
  - SYSLGRNG recording service
  - Data set extend/delete/define service

Consider also, the possibility that DB2 is waiting for Hierarchical Storage Manager (HSM) to recall data sets that had been migrated to tape. The amount of time that DB2 waits during the recall is specified on the RECALL DELAY parameter on installation panel DSNTIPO.

If accounting class 8 trace was active, each of these suspension times is available on a per-package or per-DBRM basis in the package block of the OMEGAMON accounting report.

4. If NOT ACCOUNT. ( **L** ) time is high, check for paging activity, processor wait time, return wait time for requests to be returned from VTAM or TCP/IP, wait time for completion of parallel tasks, and the use of online performance monitors. Turn off or reduce the intensity of online monitoring to eliminate or significantly reduce a high NOT ACCOUNT time that is caused by some monitors. A high NOT ACCOUNT time is acceptable if it is caused by wait time for completion of parallel tasks.

- Use RMF reports to analyze paging, CPU utilization, and other workload activities.
- Check the SER.TASK SWTCH field in the “Class 3 Suspensions” section of the OMEGAMON accounting reports.

Figure 70 on page 655 shows which reports you might use, depending on the nature of the problem, and the order in which to look at them.

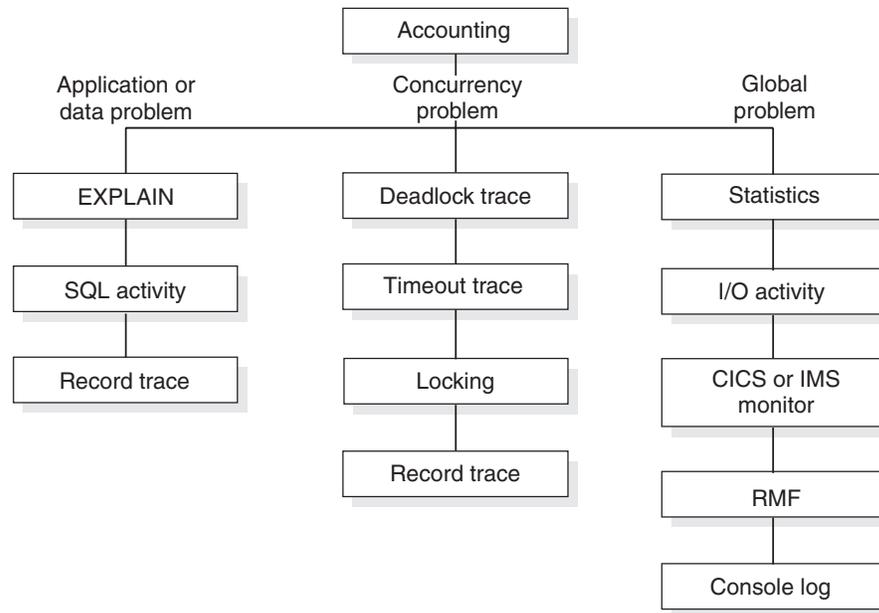

Figure 70. OMEGAMON reports used for problem analysis

If you suspect that the problem is in DB2, it is often possible to discover its general nature from the accounting reports. You can then analyze the problem in detail based on one of the branches shown in Figure 70:

- Follow the first branch, **Application or data problem**, when you suspect that the problem is in the application itself or in the related data. Also use this path for a further breakdown of the response time when no reason can be identified.
- The second branch, **Concurrency problem**, shows the reports required to investigate a lock contention problem. This is illustrated in “Scenario for analyzing concurrency” on page 876.
- Follow the third branch for a **Global problem**, such as an excessive average elapsed time per I/O. A wide variety of transactions could suffer similar problems.

Before starting the analysis in any of the branches, start the DB2 trace to support the corresponding reports. When starting the DB2 trace:

- Refer to *OMEGAMON Report Reference* for the types and classes needed for each report.
- To make the trace data available as soon as an experiment has been carried out, and to avoid flooding the SMF data sets with trace data, use a GTF data set as the destination for DB2 performance trace data.

Alternatively, use the Collect Report Data function in OMEGAMON to collect performance data. You specify only the report set, not the DB2 trace types or classes you need for a specific report. Collect Report Data lets you collect data in a TSO data set that is readily available for further processing. No SMF or GTF handling is required.

- To limit the amount of trace data collected, you can restrict the trace to particular plans or users in the reports for SQL activity or locking. However, you cannot so restrict the records for performance class 4, which traces asynchronous I/O for specific page sets. You might want to consider turning on selective traces and be aware of the added costs incurred by tracing.

If the problem is not in DB2, check the appropriate reports from a CICS or IMS reporting tool.

When CICS or IMS reports identify a commit, the timestamp can help you locate the corresponding OMEGAMON accounting trace report.

| You can match DB2 accounting records with CICS accounting records. If you  
| specify ACCOUNTREC(UOW) or ACCOUNTREC(TASK) on the DB2ENTRY RDO  
| definition, the CICS LU 6.2 token is included in the DB2 trace records, in field  
| QWHCTOKN of the correlation header. To help match CICS and DB2 accounting  
| records, specify ACCOUNTREC(UOW) or ACCOUNTREC(TASK) in the  
| DB2ENTRY definition. That writes a DB2 accounting record after every transaction.  
| As an alternative, you can produce OMEGAMON accounting reports that  
| summarize accounting records by CICS transaction ID. Use the OMEGAMON  
| function Correlation Translation to select the subfield containing the CICS  
| transaction ID for reporting.

| You can synchronize the statistics recording interval with the RMF reporting  
| interval, using the STATIME and SYNCVAL subsystem parameters. STATIME  
| specifies the length of the statistics interval, and SYNCVAL specifies that the  
| recording interval is synchronized with some part of the hour.

| **Example:** If the RMF reporting interval is 15 minutes, you can set the STATIME to  
| 15 minutes and SYNCVAL to 0 to synchronize with RMF at the beginning of the  
| hour. These values cause DB2 statistics to be recorded at 15, 30, 45, and 60 minutes  
# past the hour, matching the RMF report interval. To generate Statistics reports at  
# one minute interval, you can set STATIME to 1 and SYNCVAL 0 to synchronize  
# with RMF at the beginning of the hour. These settings will generate statistics  
# reports at a more granular level, simplifying the task of identifying short term  
# spikes issues.

| Synchronizing the statistics recording interval across data sharing members and  
| with the RMF reporting interval is helpful because having the DB2 statistics, RMF,  
| and CF data for identical time periods makes the problem analysis more accurate.

---

## Chapter 26. Improving response time and throughput

Response time consists of the following three components:

- Processor resource consumption, which is shown on Figure 69 on page 648 as “CPU TIME”.
- Wait time traced in accounting class 3, which includes:
  - I/O wait time (synchronous and asynchronous)
  - Lock and latch wait time
- Other time

In general, you can improve the response time and throughput of your DB2 applications and queries by:

- “Reducing I/O operations”
- “Reducing the time needed to perform I/O operations” on page 660
- “Reducing processor resource consumption” on page 665
- “Response time reporting” on page 667

The chapter concludes with an overview of how various DB2 response times are reported.

Parallel processing, which is described in Chapter 35, “Parallel operations and query performance,” on page 991, can also improve response times. And, DB2 data sharing is also a possible solution for increasing throughput in your system, as well as an opportunity for an improved price for performance ratio. For more information about data sharing, see *DB2 Data Sharing: Planning and Administration*.

---

### Reducing I/O operations

Reducing the number of I/O operations is one way to improve the response time of your applications and queries. This section describes the following ways you can minimize I/O operations:

- “Using RUNSTATS to keep access path statistics current”
- “Reserving free space in table spaces and indexes” on page 658
- “Making buffer pools large enough for the workload” on page 660
- “Formatting early and speed up formatting” on page 664

Using indexes can also minimize I/O operations. For information on indexes and access path selection see “Overview of index access” on page 952.

#### Using RUNSTATS to keep access path statistics current

The RUNSTATS utility collects statistics about DB2 objects. These statistics can be stored in the DB2 catalog and are used during the bind process to choose the path in accessing data. If you never use RUNSTATS and subsequently rebind your packages or plans, DB2 will not have the information it needs to choose the most efficient access path. This can result in unnecessary I/O operations and excessive processor consumption. See “Gathering monitor statistics and update statistics” on page 916 for more information on using RUNSTATS.

Run RUNSTATS at least once against each table and its associated indexes. How often you rerun the utility depends on how current you need the catalog data to

be. If data characteristics of the table vary significantly over time, you should keep the catalog current with those changes. RUNSTATS is most beneficial for the following:

- Table spaces that contain frequently accessed tables
- Tables involved in a sort
- Tables with many rows
- Tables against which SELECT statements having many search arguments are performed

For some tables, you will find no good time to run RUNSTATS. For example, you might use some tables for work that is in process. The tables might have only a few rows in the evening when it is convenient to run RUNSTATS, but they might have thousands or millions of rows in them during the day. For such tables, consider these possible approaches:

- Set the statistics to a relatively high number and hope your estimates are appropriate.
- Use volatile tables. For information about defining a table as volatile, see *DB2 SQL Reference*.

Whichever approach that you choose, monitor the tables because optimization is adversely affected by incorrect information.

## Reserving free space in table spaces and indexes

### General-use Programming Interface

You can use the PCTFREE and FREEPAGE clauses of the CREATE and ALTER TABLESPACE statements and CREATE and ALTER INDEX statements to improve the performance of INSERT and UPDATE operations. The table spaces and indexes for the DB2 catalog can also be altered to modify FREEPAGE and PCTFREE. These options are not applicable for LOB table spaces.

You can change the values of PCTFREE and FREEPAGE for existing indexes and table spaces using the ALTER INDEX and ALTER TABLESPACE statements, but the change has no effect until you load or reorganize the index or table space.

When you specify a sufficient amount of free space, the advantages during normal processing are:

- Better clustering of rows (giving faster access)
- Fewer overflows
- Less frequent reorganizations needed
- Less information locked by a page lock
- Fewer index page splits

The disadvantages are:

- More disk space occupied
- Less information transferred per I/O
- More pages to scan
- Possibly more index levels
- Less efficient use of buffer pools and storage controller cache

### Specifying free space on pages

The PCTFREE clause specifies what percentage of each page in a table space or index is left free when loading or reorganizing the data. DB2 uses the free space later on when you insert or update your data; when no free space is available, DB2

holds your additional data on another page. When several records are physically located out of sequence, performance suffers.

The default for PCTFREE for table spaces is 5 (5% of the page is free). If you have previously used a large PCTFREE to force one row per page, you should instead use MAXROWS 1 on the CREATE or ALTER TABLESPACE statement. MAXROWS has the advantage of maintaining the free space even when new data is inserted.

The default for indexes is 10. The maximum amount of space that is left free in index nonleaf pages is 10%, even if you specify a value higher than 10 for PCTFREE.

To determine the amount of free space currently on a page, run the RUNSTATS utility and examine the PERCACTIVE column of SYSIBM.SYSTABLEPART. See Part 2 of *DB2 Utility Guide and Reference* for information about using RUNSTATS.

### **Determining pages of free space**

The FREEPAGE clause specifies how often DB2 leaves a full page of free space when loading data or when reorganizing data or indexes. DB2 uses the free space later on when you insert or update your data. For example, if you specify 10 for FREEPAGE, DB2 leaves every 10th page free.

The maximum value you can specify for FREEPAGE is 255; however, in a segmented table space, the maximum value is 1 less than the number of pages specified for SEGSIZE.

### **Recommendations for allocating free space**

The goal for allocating free space is to maintain the physical clustering of the data and to reduce the need to frequently reorganize table spaces and indexes. However, you do not want to allocate too much disk space.

Use of PCTFREE or FREEPAGE depends on the type of SQL and the distribution of that activity across the table space or index. When deciding whether to allocate free space consider the data and each index separately and assess the insert and update activity on the data and indexes.

*When not to use free space:* Free space is not necessary if:

- The object is read-only.

If you do not plan to insert or update data in a table, there is no need to leave free space for either the table or its indexes.

- The object is not read-only, inserts are at the end, and updates that lengthen varying-length columns are few.

For example, if inserts are in ascending order by key of the clustering index or are caused by LOAD RESUME SHRLEVEL NONE and update activity is only on fixed-length columns with non-compressed data, the free space for both the table and clustering index should be zero. Generally, free space is beneficial for a non-clustering index because inserts are usually random. However, if the non-clustering index contains a column with a timestamp value that causes the inserts into the index to be in sequence, the free space should be zero.

*When to use PCTFREE:* When free space is needed, using PCTFREE is recommended over using FREEPAGE in most situations.

If update activity on compressed data, which often results in longer rows, is heavy or insert volume is heavy, use a PCTFREE value greater than the default.

|  
|  
|

*When to use FREEPAGE:* Use FREEPAGE rather than PCTFREE if MAXROWS is 1 or rows are larger than half a page because you cannot insert a second row on a page.

*Additional recommendations:*

- For concurrency, use MAXROWS or larger PCTFREE values for small tables and shared table spaces that use page locking. This reduces the number of rows per page, thus reducing the frequency that any given page is accessed.
- For the DB2 catalog table spaces and indexes, use the defaults for PCTFREE. If additional free space is needed, use FREEPAGE.

\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_

## Making buffer pools large enough for the workload

Make buffer pools as large as you can afford for the following reasons:

- Using larger buffer pools might mean fewer I/O operations and therefore faster access to your data.
- Using larger buffer pools can reduce I/O contention for the most frequently used tables and indexes.
- Using larger buffer pools can speed sorting by reducing I/O contention for work files.

However, many factors affect how you determine the number of buffer pools to have and how big they should be. See “Determining size and number of buffer pools” on page 677 for more information.

---

## Reducing the time needed to perform I/O operations

You can reduce the time needed to perform individual I/O operations in several ways:

- “Distributing data sets efficiently”
- “Creating additional work file table spaces” on page 663
- “Managing space for I/O performance” on page 664

For information on parallel operations, see Chapter 35, “Parallel operations and query performance,” on page 991.

For information on I/O scheduling priority, see “z/OS performance options for DB2” on page 717.

## Distributing data sets efficiently

Avoid I/O contention and increase throughput through the I/O subsystem by placing frequently used data sets on fast disk devices and by distributing I/O activity. Distributing I/O activity is less important when you use disk devices with parallel access volumes (PAV) support and multiple allegiance support. (For more information, see “Storage servers and advanced features” on page 716)

### Putting frequently used data sets on fast devices

Assign the most frequently used data sets to the faster disk devices at your disposal. For partitioned table spaces, you might choose to have some partitions on faster devices than other partitions. Placing frequently used data sets on fast disk

devices also improves performance for nonpartitioned table spaces. You might consider partitioning any nonpartitioned table spaces that have excessive I/O contention at the data set level.

### Distributing the I/O

Allocate frequently used data sets or partitions across your available disk volumes so that I/O operations are distributed. Even with RAID devices, in which the data set is spread across the physical disks in an array, it is important that is accessed at the same time on separate logical volumes to reduce the chance of an I/O request being queued in z/OS.

Consider isolating data sets with characteristics that do not complement other data sets. For example, do not put high volume transaction work that uses synchronous reads on the same volume as something of lower importance that uses list prefetch.

**Considering the partitioning scheme of partitioned tablespaces:** If the partitions of your partitioned table spaces must be of relatively the same size (which can be a great benefit for query parallelism), consider using a ROWID column as all or part of the partitioning key. For partitions that are of such unequal size that performance is negatively affected, alter the limit key values to set new partition boundaries and then reorganize the affected partitions to rebalance the data. Alternatively, you can use the REORG utility with the REBALANCE keyword to set new partition boundaries. REBALANCE causes DB2 to change the limit key values such that the rows in the range of partitions being reorganized will be distributed across those partitions as evenly as possible.

### Increasing the number of data sets for an index:

#### General-use Programming Interface

If you increase the number of data sets that are used for an index and spread those data sets across the available I/O paths, you can reduce the physical contention on the index. Using data-partitioned secondary indexes or making the piece size of a nonpartitioned index smaller increases the number of data sets that are used for the index.

**Using data-partitioned secondary indexes (DPSIs):** A secondary index on a partitioned table space can be partitioned. When you partition an index, the partitioning scheme is that of the data in the underlying table, and each index partition has its own data set. Although data-partitioned secondary indexes promote partition independence and can provide performance advantages, they do not always improve query performance. Before using a data-partitioned secondary index, understand their advantages and disadvantages as explained in “Data-partitioned secondary index (DPSI)” on page 56.

**Decreasing the piece size of nonpartitioned indexes:** If I/O contention on a nonpartitioned index has prevented you from running batch update jobs in parallel, use the PIECESIZE option of CREATE or ALTER INDEX to indicate how large DB2 should make the data sets that make up the nonpartitioned index. As the specification of the maximum addressability of a data set, the piece size of a nonpartitioned index limits how much data DB2 puts into a data set before it is broken into multiple pieces (data sets). By making the piece size smaller than the default value, for example, you can end up with many more data sets.

- *Choosing a value for PIECESIZE.* To choose a PIECESIZE value, divide the size of the nonpartitioned index by the number of data sets that you want. For

example, to ensure that you have 5 data sets for the nonpartitioned index, and your nonpartitioned index is 10 MB (and not likely to grow much), specify PIECESIZE 2M. If your nonpartitioned index is likely to grow, choose a larger value.

When choosing a value, remember that the maximum partition size of the table space determines the maximum number of data sets that the index can use. If the underlying table space is defined with a DSSIZE of 4G or greater (or with LARGE), the limit is 254 pieces for table spaces with 254 parts or less and 4096 pieces for table spaces with more than 254 parts; otherwise, the limit is 32 pieces. Nonpartitioned indexes that were created on LARGE table spaces in Version 5 can have only 128 pieces. If an attempt is made to allocate more data sets than the limit, an abend occurs.

Keep your PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, although PIECESIZE has no effect on primary and secondary space allocation, the value of your primary quantity and the secondary quantities should be evenly divisible into PIECESIZE to avoid wasting space. Because the underlying data sets are always allocated at the size of PRIQTY and extended, when possible, with the size of SECQTY, understand the implications of their values with the PIECESIZE value:

- If PRIQTY is larger than PIECESIZE, a new data set is allocated and used when the file size exceeds PIECESIZE. Thus, part of the allocated primary storage goes unused, and no secondary extents are created.
- If PRIQTY is smaller than PIECESIZE and SECQTY is not zero, secondary extents are created until the total file size equals or exceeds PIECESIZE. After the allocation of a secondary extent causes the total file size to meet or exceed PIECESIZE, a new data set is allocated and used. When the total file size exceeds PIECESIZE, the part of secondary storage that is allocated beyond PIECESIZE goes unused.
- If PRIQTY is smaller than PIECESIZE and SECQTY is zero, an "unavailable resource" message is returned when the data set fills up. No secondary extents are created nor are additional data sets allocated.

- *Identifying suitable nonpartitioned indexes.* If a nonpartitioned index that has a lot of I/O and a high IOS queue time, consider using the Parallel Access Volumes (PAV) feature and the multiple allegiance feature. For more information about these features, see "Storage servers and channel subsystems" on page 715. Also, consider breaking up the index into smaller pieces. Use the statistics trace to identify I/O intensive data sets. IFCID 199 contains information about every data set that averages more than one I/O per second during the statistics interval. IOS queue time that is 2 or 3 times higher than connect time is considered high. The RMF (Resource Measurement Facility) Device Activity report provides IOS time and CONN time.
- *Determining the number of pieces a nonpartitioned index is using.* You can use one of the following techniques to determine the number of pieces that a nonpartitioned index uses:
  - For DB2-managed data sets, use access method services LISTCAT to check the number of data sets that have been created.
  - For user-managed data sets, examine the high-used RBA (HURBA) for each data set.

End of General-use Programming Interface

## Creating additional work file table spaces

If your applications require any of the following, allocate additional work file table spaces on separate disk volumes in a work file database (database DSNDB07 in a non data-sharing environment) to help minimize I/O contention:

- Large concurrent sorts or a single large sort
- Created temporary tables
- Some merge, star, and outer joins
- Non-correlated subqueries
- Materialized views
- Materialized nested table expressions
- Triggers with transition variables

For a single query, the recommended number of work file disk volumes to have is one-fifth the maximum number of data partitions, with 5 as a minimum and 50 as a maximum. For concurrently running queries, multiply this value by the number of concurrent queries.

In addition, in a query parallelism environment, the number of work file disk volumes should be at least equal to the maximum number of parallel operations that is seen for queries in the given workload.

Place these volumes on different channel or control unit paths. Monitor the I/O activity for the work file table spaces, because you might need to further separate this work file activity to avoid contention. As the amount of work file activity increases, consider increasing the size of the buffer pool for work files to support concurrent activities more efficiently. The general recommendation for the work file buffer pool is to increase the size to minimize the following buffer pool statistics:

- MERGE PASSES DEGRADED, which should be less than 1% of MERGE PASS REQUESTED
- WORKFILE REQUESTS REJECTED, which should be less than 1% of WORKFILE REQUEST ALL MERGE PASSES
- Synchronous read I/O, which should be less than 1% of pages read by prefetch
- Prefetch quantity of 4 or less, which should be near 8

During the installation or migration process, you allocated table spaces for 4-KB, 8-KB, 16-KB, and 32-KB buffering.

**Steps to create an additional work file table space:** Use the following steps to create a new work file table space, *xyz*. (If you are using DB2-managed data sets, omit the step to create the data sets.)

1. Define the required data sets using the VSAM DEFINE CLUSTER statement. You might want to use the definitions in the edited, installation job DSNTIJTM as a model. For more information about job DSNTIJTM and the number of work files, see *DB2 Installation Guide*.
2. Create the work file table space by entering the following SQL statement:

```
CREATE TABLESPACE xyz IN DSNDB07
  BUFFERPOOL BP7
  CLOSE NO
  USING VCAT DSNCR810;
```

## Managing space for I/O performance

Managing space effectively, by speeding up preformatting and avoiding excessive extents, can improve I/O performance.

### Formatting early and speed up formatting

This section describes a general way to speed up preformatting of data by allocating in cylinders, and a more specific way you can preformat a table space before inserting data.

*Allocate space in cylinders or in large primary and secondary quantities:* Specify your space allocation amounts to ensure allocation by CYLINDER. If you use record allocation for more than a cylinder, cylinder allocation is used. Cylinder allocation can reduce the time required to do SQL mass inserts and to perform LOGONLY recovery; it does not affect the time required to recover a table space from an image copy or to run the REBUILD utility.

When inserting records, DB2 preformats space within a page set as needed. The allocation amount, which is either CYLINDER or TRACK, determines the amount of space that is preformatted at any one time. See “Formatting early and speed up formatting” for a way you can preformat data using LOAD or REORG.

Because less space is preformatted at one time for the TRACK allocation amount, a mass insert can take longer when the allocation amount is TRACK than the same insert when the allocation amount is CYLINDER. However, smart secondary space allocation minimizes the difference between TRACK and CYLINDER. Refer to “Secondary space allocation” on page 32 for information about smart secondary space allocation.

The allocation amount is dependent on device type and the number of bytes you specify for PRIQTY and SECQTY when you define table spaces and indexes. The default SECQTY is 10% of the PRIQTY, or 3 times the page size, whichever is larger. This default quantity is an efficient use of storage allocation. Choosing a SECQTY value that is too small in relation to the PRIQTY value results in track allocation.

For more information about how space allocation amounts are determined, see the description of the DEFINE CLUSTER command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

*Preformatting during LOAD or REORG:* When DB2’s preformatting delays impact the performance or execution time consistency of applications that do heavy insert processing, and if the table size can be predicted for a business processing cycle, consider using the PREFORMAT option of LOAD and REORG. If you preformat during LOAD or REORG, DB2 does not have to preformat new pages during execution. When the preformatted space is used and when DB2 has to extend the table space, normal data set extending and preformatting occurs.

Consider preformatting only if preformatting is causing a measurable delay with the insert processing or causing inconsistent elapsed times for insert applications. For more information about the PREFORMAT option, see Part 2 of *DB2 Utility Guide and Reference*.

**Recommendation:** Quantify® the results of preformatting in your environment by assessing the performance both before and after using preformatting.

## Avoiding excessive extents

Data set extent size affects performance because excessively small extents can degrade performance during a sequential database scan.

**Example:** Suppose that the sequential data transfer speed is 100 MB per second and that the extent size is 10 MB. The sequential scan must move to a new extent every 100 milliseconds.

**Recommendation:** You should maintain extent sizes that are large enough to avoid excessively frequent extent moving during scans.

A linear data set is limited to 123 extents on a volume and 251 total extents on all volumes. If a data set grows and extents are not monitored, jobs will eventually fail due to these extent limitations.

**Recommendation:** Monitor the number of extents to avoid reaching the maximum number of extents on a volume and the maximum number of extents on all volumes.

Specifying sufficient primary and secondary allocations for frequently used data sets minimizes I/O time, because the data is not located at different places on the disks. Listing the catalog or VTOC occasionally to determine the number of secondary allocations that have been made for your more frequently used data sets can also be helpful. Alternatively, you can use IFCID 0258 in the statistics class 3 trace to monitor data set extensions. OMEGAMON monitors IFCID 0258. You can define a threshold for the number of extents, and receive an alert when a data set exceeds that number of extents.

If you discover that the data sets backing frequently used table spaces or indexes have an excessive number of extents, and if the data sets are user-defined, you can use access method services to reallocate the affected data sets using a larger primary allocation quantity. If the data sets were created using STOGROUPs, you can use the procedure for modifying the definition of table spaces presented in “Altering table spaces” on page 69.

**Specify primary quantity for nonpartitioned indexes:** To prevent wasted space for nonpartitioned indexes, do one of the following things:

- Let DB2 use the default primary quantity and calculate the secondary quantities. Do this by specifying 0 for the IXQTY subsystem parameter, and by omitting a PRIQTY and SECQTY value in the CREATE INDEX statement or ALTER INDEX statement. If a primary and secondary quantity were previously specified for an index, you can specify PRIQTY -1 and SECQTY -1 to change to the default primary quantity and calculated secondary quantity.
- If the MGEXTSZ subsystem parameter is set to NO, so that you control secondary space allocations, make sure that the value of  $PRIQTY + (N \times SECQTY)$  is a value that evenly divides into PIECESIZE. For more information about PIECESIZE, see Chapter 5 of *DB2 SQL Reference*.

---

## Reducing processor resource consumption

Many factors affect the amount of processor resources that DB2 consumes. This section describes some ways to reduce DB2 consumption of these resources. It contains the following topics:

- “Reusing threads for your high-volume transactions” on page 666
- “Minimizing the use of DB2 traces” on page 666

- “Using fixed-length records” on page 667

Other ways to reduce DB2 consumption of processor resources include:

- Consider caching authorizations for plans, packages, and routines (user-defined functions and stored procedures). See “Caching authorization IDs for best performance” on page 151 for more information.
- Use an isolation level of cursor stability and CURRENTDATA(NO) to allow lock avoidance. See “The ISOLATION option” on page 851 for more information.
- Avoid using excess granularity for locking, such as row-level locking. See “LOCKSIZE clause of CREATE and ALTER TABLESPACE” on page 842.
- Reorganize indexes and table spaces. Reorganizing can improve the performance of access paths. Reorganizing indexes and table spaces is also important after table definition changes, such as changing the data type of a column, so that the data is converted to its new definition. Otherwise, DB2 must track the data and apply the changes as the data is accessed. See “When to reorganize indexes and table spaces” on page 924.
- Ensure that your access paths are effective. Have only the indexes that you need. Update statistics and rebind as necessary. See “Gathering monitor statistics and update statistics” on page 916 and “Whether to rebind after gathering statistics” on page 927.

## Reusing threads for your high-volume transactions

For high-volume transactions, reusing threads can help performance significantly.

- For IMS, process multiple input messages in one scheduling of the IMS processing program by setting PROCLIM to a value greater than 1 and using class priority scheduling. This shares the cost of thread creation and termination among more than one transaction. Alternatively, you can reuse threads with wait for input (WFI), or the IMS fast path and class scheduling. See Part 2 of *DB2 Installation Guide* for more information.
- For CICS, you can enhance thread reuse through specifications for pool and entry threads in the CICS resource definition online (RDO).
- If you are using the Resource Recovery Services attachment facility, see the RRSAP chapter of Part 6 of *DB2 Application Programming and SQL Guide* for more information about reusing threads.

## Minimizing the use of DB2 traces

Using the DB2 trace facility, particularly performance and global trace, can consume a large amount of processing resources. Suppressing these trace options significantly reduces additional processing costs.

### Global trace

Global trace requires 2% to 100% additional processor utilization. If conditions permit at your site, the DB2 global trace should be turned off. You can do this by specifying NO for the field TRACE AUTO START on panel DSNTIPN at installation. Then, if the global trace is needed for serviceability, you can start it using the START TRACE command.

### Accounting and statistics traces

Enabling accounting class 2 along with accounting classes 1 and 3 provides additional detail relating directly to the accounting record IFCID 0003, as well as recording thread level entry into and exit from DB2. This allows you to separate DB2 times from application times. Running accounting class 2 does add to the cost of processing. How much overhead occurs depends on how much SQL the

application issues. Typically, an online transaction incurs an additional 2.5% when running with accounting class 2. A typical batch query application, which accesses DB2 more often, incurs about 10% overhead when running with accounting class 2. If most of your work is through CICS, you most likely do not need to run with class 2, because the class 1 and class 2 times are very close.

**Exception:** If you are using CICS Transaction Server for z/OS 2.2 with the Open Transaction Environment (OTE), activate and run class 2.

If you have very light DB2 usage and you are using Measured Usage, then you need the SMF 89 records. In other situations, be sure that SMF 89 records are not recorded to avoid this overhead.

### **Audit trace**

The performance impact of auditing is directly dependent on the amount of audit data produced. When the audit trace is active, the more tables that are audited and the more transactions that access them, the greater the performance impact. The overhead of audit trace is typically less than 5%.

When estimating the performance impact of the audit trace, consider the frequency of certain events. For example, security violations are not as frequent as table accesses. The frequency of utility runs is likely to be measured in executions per day. Alternatively, authorization changes can be numerous in a transaction environment.

### **Performance trace**

The combined overhead of all performance classes runs from about 20% to 100%. The overhead for performance trace classes 1 through 3 is typically in the range of 5% to 30%. Therefore, turn on only the performance trace classes required to address a specific performance problem and qualify the trace as much as possible to limit the that is data gathered to only the data that you need. For example, qualify the trace by the plan name and IFCID.

Suppressing other trace options, such as TSO, IRLM, z/OS, IMS, CICS, and other trace options can also reduce overhead.

## **Using fixed-length records**

Use fixed-length columns rather than varying-length columns, particularly in tables that contain many short columns. This can reduce processor use, but is offset by the need for more disk space. If you must use varying-length columns, see Table 109 on page 707 for recommendations about where to place those columns for the best performance and to reduce logging.

If you use ALTER to add a fixed-length column to a table, that column is treated as variable-length until the table has been reorganized.

---

## **Response time reporting**

To correctly monitor response time, you must understand how it is reported. Response time can be measured in several different ways. Figure 71 on page 669 shows how some of the main measures relate to the flow of a transaction.

Figure 71 on page 669 shows the following times:

**End user response time**

This is the time from the moment the end user presses the enter key until he or she receives the first response back at the terminal.

**DB2 accounting elapsed times**

These times are collected in the records from the accounting trace and can be found in the OMEGAMON accounting reports. They are taken over the accounting interval between the point where DB2 starts to execute the first SQL statement, and the point preceding thread termination or reuse by a different user (sign-on).

This interval excludes the time spent creating a thread, and it includes a portion of the time spent terminating a thread.

For parallelism, there are special considerations for doing accounting. See "Monitoring parallel operations" on page 1001 for more information.

Elapsed times for stored procedures or user-defined functions separate the time spent in the allied address space and the time spent in the stored procedures address space.

There are two elapsed times:

- Class 1 elapsed time

This time is always presented in the accounting record and shows the duration of the accounting interval. It includes time spent in DB2 as well as time spent in the front end. In the accounting reports, it is referred to as "application time."

- Class 2 elapsed time

Class 2 elapsed time, produced only if the accounting class 2 is active, counts only the time spent in the DB2 address space during the accounting interval. It represents the sum of the times from any entry into DB2 until the corresponding exit from DB2. It is also referred to as the time spent in DB2. If class 2 is not active for the duration of the thread, the class 2 elapsed time does not reflect the entire DB2 time for the thread, but only the time when the class was active.

**DB2 total transit time**

In the particular case of an SQL transaction or query, the "total transit time" is the elapsed time from the beginning of create thread, or sign-on of another authorization ID when reusing the thread, until either the end of the thread termination, or the sign-on of another authorization ID.

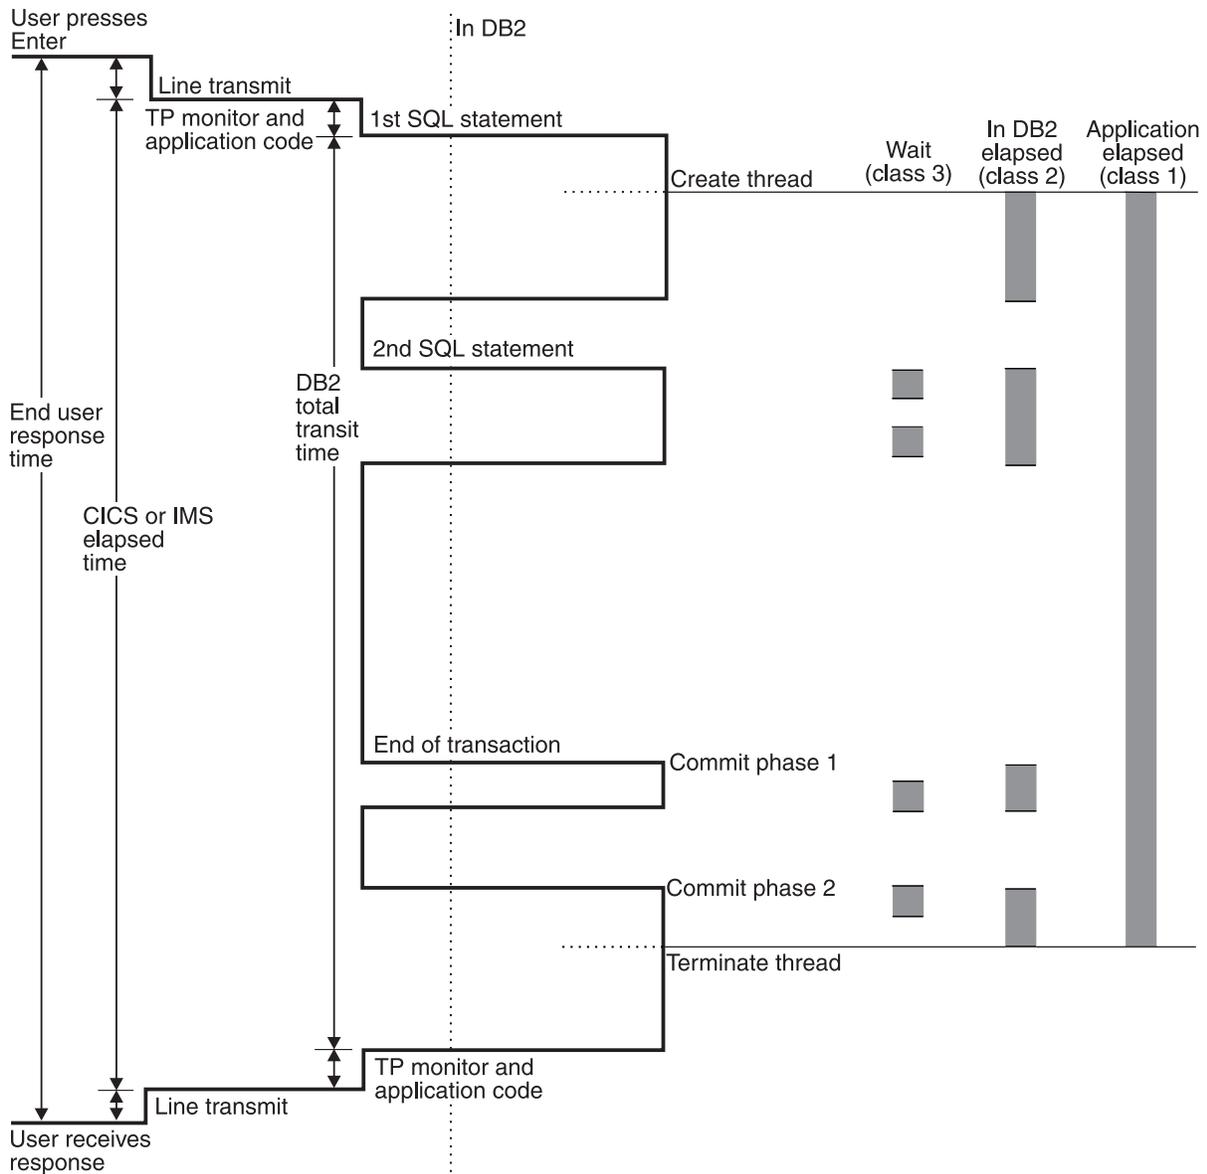

Figure 71. Transaction response times. Class 1 is standard accounting data. Class 2 is elapsed and processor time in DB2. Class 3 is elapsed wait time in DB2. Standard accounting data is provided in IFCID 0003, which is turned on with accounting class 1. When accounting classes 2 and 3 are turned on as well, IFCID 0003 contains additional information about DB2 times and wait times.

---

## Chapter 27. Tuning DB2 buffer, EDM, RID, and sort pools

Proper tuning of your buffer pools, EDM pools, RID pools, and sort pools can improve the response time and throughput for your applications and provide optimum resource utilization. Using data compression can also improve buffer-pool hit ratios and reduce table space I/O rates. For more information on compression, see “Compressing your data” on page 708. This chapter covers the following topics:

- “Tuning database buffer pools”
- “Tuning EDM storage” on page 685
- “Increasing RID pool size” on page 689
- “Controlling sort pool size and sort processing” on page 690

---

### Tuning database buffer pools

Buffer pools are areas of virtual storage that temporarily store pages of table spaces or indexes. When an application program accesses a row of a table, DB2 places the page that contains that row in a buffer. If the requested data is already in a buffer, the application program does not have to wait for it to be retrieved from disk. Avoiding the need to retrieve data from disk results in faster performance.

If the row is changed, the data in the buffer must be written back to disk eventually. But that write operation might be delayed until DB2 takes a checkpoint, or until one of the related write thresholds is reached. (In a data sharing environment, however, the writing mechanism is somewhat different. See Chapter 6 of *DB2 Data Sharing: Planning and Administration* for more information.)

The data remains in the buffer until DB2 decides to use the space for another page. Until that time, the data can be read or changed without a disk I/O operation.

DB2 allows you to use up to 50 buffer pools that contain 4-KB buffers and up to 10 buffer pools each for 8-KB, 16-KB, and 32-KB buffers. You can set the size of each of those buffer pools separately when installing DB2. You can change the sizes and other characteristics of a buffer pool at any time while DB2 is running, by using the ALTER BUFFERPOOL command.

This section includes the following information:

- “Terminology: Types of buffer pool pages” on page 672
- “Read operations” on page 672
- “Write operations” on page 672
- “Assigning a table space or index to a buffer pool” on page 673
- “Buffer pool thresholds” on page 673
- “Determining size and number of buffer pools” on page 677
- “Choosing a page-stealing algorithm” on page 680
- “Long-term page fix option for buffer pools” on page 681
- “Monitoring and tuning buffer pools using online commands” on page 681
- “Using OMEGAMON to monitor buffer pool statistics” on page 683

| **Buffer Pool Analyzer:** You can use the Buffer Pool Analyzer for z/OS to  
| recommend buffer pool allocation changes and to do “what if” analysis of your  
| buffer pools.

## Terminology: Types of buffer pool pages

At any moment, a database buffer pool can have three types of pages:

***In-use pages:*** These are pages that are currently being read or updated. The data they contain is available for use by other applications.

***Updated pages:*** These are pages whose data has been changed but have not yet been written to disk.

***Available pages:*** These pages can be considered for new use, to be overwritten by an incoming page of new data. Both in-use pages and updated pages are *unavailable* in this sense; they are not considered for new use.

## Read operations

DB2 uses three read mechanisms: *normal read*, *sequential prefetch*, and *list sequential prefetch*.

***Normal read:*** Normal read is used when just one or a few consecutive pages are retrieved. The unit of transfer for a normal read is one page.

***Sequential prefetch:*** Sequential prefetch is performed concurrently with other operations of the originating application program. It brings pages into the buffer pool before they are required and reads several pages with a single I/O operation.

Sequential prefetch can be used to read data pages, by table space scans or index scans with clustered data reference. It can also be used to read index pages in an index scan. Sequential prefetch allows CP and I/O operations to be overlapped.

See “Sequential prefetch (PREFETCH=S)” on page 973 for a complete description of sequential prefetch.

***List sequential prefetch:*** List sequential prefetch is used to prefetch data pages that are not contiguous (such as through non-clustered indexes). List prefetch can also be used by incremental image copy. For a complete description of the mechanism, see “List prefetch (PREFETCH=L)” on page 974.

## Write operations

Write operations are usually performed concurrently with user requests. Updated pages are queued by data set until they are written when:

- A checkpoint is taken.
- The percentage of updated pages in a buffer pool for a single data set exceeds a preset limit called the vertical deferred write threshold (VDWQT). For more information on this threshold, see “Buffer pool thresholds” on page 673.
- The percentage of unavailable pages in a buffer pool exceeds a preset limit called the deferred write threshold (DWQT). For more information on this threshold, see “Buffer pool thresholds” on page 673.

Table 104 lists how many pages DB2 can write in a single I/O operation.

*Table 104. Number of pages that DB2 can write in a single I/O operation*

Page size	Number of pages
2 KB	64

Table 104. Number of pages that DB2 can write in a single I/O operation (continued)

Page size	Number of pages
4 KB	32
8 KB	16
16 KB	8
32 KB	4

## Assigning a table space or index to a buffer pool

How you assign data to buffer pools can have a significant impact on performance. See “Reasons to choose more than one buffer pool” on page 680 for guidance in choosing a scheme for assigning data and indexes to buffer pools.

### Assigning data to default buffer pools

Installation panel DSNTIP1 lets you set one default buffer pool for user data and one for user indexes. Choosing a value other than the default value of BP0 for both of these options is a good idea, because BP0 must be used by the DB2 catalog and directory. BP0 is much more difficult to monitor and tune if user data and indexes also use that buffer pool.

### Assigning data to particular buffer pools

You assign a table space or an index to a particular buffer pool by a clause of the following SQL statements: CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, ALTER INDEX. The buffer pool is actually allocated the first time a table space or index assigned to it is opened.

You cannot use the ALTER statement to change the assignment of the catalog and the directory. BP0 is the default buffer pool for sorting, but you can change that by assigning the work file table spaces to another buffer pool. BP0 has a default size of 20000 and a minimum size of 2000. As with any other buffer pool, you can change the size using the ALTER BUFFERPOOL command.

## Buffer pool thresholds

The information under this heading, up to “Determining size and number of buffer pools” on page 677, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

DB2’s use of a buffer pool is governed by several preset values called *thresholds*. Each threshold is a level of use which, when exceeded, causes DB2 to take some action. Certain thresholds might indicate a buffer pool shortage problem, while other thresholds merely report normal buffer management by DB2. The level of use is usually expressed as a percentage of the total size of the buffer pool. For example, the “immediate write threshold” of a buffer pool (described in more detail later) is set at 97.5%. When the percentage of unavailable pages in a buffer pool exceeds that value, DB2 writes pages to disk when updates are completed.

**Thresholds for very small buffer pools:** This section describes fixed and variable thresholds that are in effect for buffer pools that are sized for the best performance; that is, for buffer pools of 1000 buffers or more. For very small buffer pools, some of the thresholds are lower to prevent “buffer pool full” conditions, but those thresholds are not described.

## Fixed thresholds

Some thresholds, like the immediate write threshold, you cannot change. Monitoring buffer pool usage includes noting how often those thresholds are reached. If they are reached too often, the remedy is to increase the size of the buffer pool, which you can do with the ALTER BUFFERPOOL command. Increasing the size, though, can affect other buffer pools, depending on the total amount of real storage available for your buffers.

The fixed thresholds are more critical for performance than the variable thresholds. Generally, you want to set buffer pool sizes large enough to avoid reaching any of these thresholds, except occasionally.

Each of the fixed thresholds is expressed as a percentage of the buffer pool that might be occupied by unavailable pages.

From the highest value to the lowest value, the fixed thresholds are:

- **Immediate write threshold (IWTH): 97.5%**

This threshold is checked whenever a page is to be updated. If the threshold has been exceeded, the updated page is written to disk as soon as the update completes. The write is synchronous with the SQL request; that is, the request waits until the write is completed. The two operations do not occur concurrently.

Reaching this threshold has a significant effect on processor usage and I/O resource consumption. For example, updating three rows per page in 10 sequential pages ordinarily requires one or two write operations. However, when IWTH has been exceeded, the updates require 30 synchronous writes.

Sometimes DB2 uses synchronous writes even when the IWTH has not been exceeded. For example, when more than two checkpoints pass without a page being written, DB2 uses synchronous writes. Situations such as these do not indicate a buffer shortage.

- **Data management threshold (DMTH): 95%**

This threshold is checked before a page is read or updated. If the threshold is not exceeded, DB2 accesses the page in the buffer pool once for each **page**, no matter how many rows are retrieved or updated in that page. If the threshold is exceeded, DB2 accesses the page in the buffer pool once for each **row** that is retrieved or updated in that page.

**Recommendation:** Avoid reaching the DMTH because it has a significant effect on processor usage.

The DMTH is maintained for each individual buffer pool. When the DMTH is reached in one buffer pool, DB2 does **not** release pages from other buffer pools.

- **Sequential prefetch threshold (SPTH): 90%**

This threshold is checked at two different times:

- Before scheduling a prefetch operation. If the threshold has been exceeded, the prefetch is not scheduled.
- During buffer allocation for an already-scheduled prefetch operation. If the threshold has been exceeded, the prefetch is canceled.

When the sequential prefetch threshold is reached, sequential prefetch is inhibited until more buffers become available. Operations that use sequential prefetch, such as those using large and frequent scans, are adversely affected.

## Thresholds you can change

You can change some thresholds directly by using the ALTER BUFFERPOOL command. Changing a threshold in one buffer pool has no effect on any other buffer pool.

From highest to lowest default value, the variable thresholds are:

- **Sequential steal threshold (VPSEQT)**

This threshold is a percentage of the buffer pool that might be occupied by sequentially accessed pages. These pages can be in any state: updated, in-use, or available. Hence, any page might or might not count toward exceeding any other buffer pool threshold.

The default value for this threshold is 80%. You can change that to any value from 0% to 100% by using the VPSEQT option of the ALTER BUFFERPOOL command.

This threshold is checked before stealing a buffer for a sequentially accessed page instead of accessing the page in the buffer pool. If the threshold has been exceeded, DB2 tries to steal a buffer holding a sequentially accessed page rather than one holding a randomly accessed page.

Setting the threshold to 0% would prevent any sequential pages from taking up space in the buffer pool. In this case, prefetch is disabled, and any sequentially accessed pages are discarded as soon as they are released.

Setting the threshold to 100% allows sequential pages to monopolize the entire buffer pool.

- **Virtual buffer pool parallel sequential threshold (VPPSEQT)**

This threshold is a portion of the buffer pool that might be used to support parallel operations. It is measured as a percentage of the sequential steal threshold (VPSEQT). Setting VPPSEQT to zero disables parallel operation.

The default value for this threshold is 50% of the sequential steal threshold (VPSEQT). You can change that to any value from 0% to 100% by using the VPPSEQT option on the ALTER BUFFERPOOL command.

- **Virtual buffer pool assisting parallel sequential threshold (VPXPSEQT)**

This threshold is a portion of the buffer pool that might be used to assist with parallel operations initiated from another DB2 in the data sharing group. It is measured as a percentage of VPPSEQT. Setting VPXPSEQT to zero disallows this DB2 from assisting with Sysplex query parallelism at run time for queries that use this buffer pool. For more information about Sysplex query parallelism, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*.

The default value for this threshold is 0% of the parallel sequential threshold (VPPSEQT). You can change that to any value from 0% to 100% by using the VPXPSEQT option on the ALTER BUFFERPOOL command.

- **Deferred write threshold (DWQT)**

This threshold is a percentage of the buffer pool that might be occupied by unavailable pages, including both updated pages and in-use pages.

The default value for this threshold is 30%. You can change that to any value from 0% to 90% by using the DWQT option on the ALTER BUFFERPOOL command.

DB2 checks this threshold when an update to a page is completed. If the percentage of unavailable pages in the buffer pool exceeds the threshold, write operations are scheduled for enough data sets (at up to 128 pages per data set) to decrease the number of unavailable buffers to 10% below the threshold. For example, if the threshold is 50%, the number of unavailable buffers is reduced to 40%.

When the deferred write threshold is reached, the data sets with the oldest updated pages are written asynchronously. DB2 continues writing pages until the ratio goes below the threshold.

- **Vertical deferred write threshold (VDWQT)**

#  
#  
#

This threshold is similar to the deferred write threshold, but it applies to the number of updated pages for a single page set in the buffer pool. If the percentage or number of updated pages for the data set exceeds the threshold, writes are scheduled for that data set, up to 128 pages.

You can specify this threshold in one of two ways:

- As a *percentage* of the buffer pool that might be occupied by updated pages from a single page set.

# The default value for this threshold is 5%. You can change the percentage to  
# any value from 0% to 90%.

- As the total *number of buffers* in the buffer pool that might be occupied by updated pages from a single page set.

You can specify the number of buffers from 0 to 9999. If you want to use the number of buffers as your threshold, you must set the percentage threshold to 0.

**Changing the threshold:** Change the percent or number of buffers by using the VDWQT keyword on the ALTER BUFFERPOOL command.

Because any buffers that count toward VDWQT also count toward DWQT, setting the VDWQT percentage higher than DWQT has no effect: DWQT is reached first, write operations are scheduled, and VDWQT is never reached. Therefore, the ALTER BUFFERPOOL command does not allow you to set the VDWQT percentage to a value greater than DWQT. You can specify a number of buffers for VDWQT that is higher than DWQT, but again, with no effect.

This threshold is overridden by certain DB2 utilities, which use a constant limit of 64 pages rather than a percentage of the buffer pool size. LOAD, REORG, and RECOVER use a constant limit of 128 pages.

**Setting VDWQT to 0:** If you set VDWQT to zero, DB2 implicitly uses the minimum value of 1% of the buffer pool (a specific number of pages) to avoid synchronous writes to disk. The number of pages is determined by the buffer pool page size, as shown in Table 105:

Table 105. Number of change pages based on buffer pool size

Buffer pool page size	Number of changed pages
4 KB	40
8 KB	24
16 KB	16
32 KB	12

## Guidelines for setting buffer pool thresholds

How you set buffer pools depends on your workload and the type and size of data being cached. But always think about the entire system when making buffer pool tuning decisions.

For help in tuning your buffer pools, try the Buffer Pool Analyzer for z/OS.

**Pages are frequently re-referenced and updated:** Suppose that you have a workload such as a branch table in a bank that contains a few hundred rows and is updated by every transaction. For such a workload, you want a high value for the deferred write and vertical deferred write threshold (90%). The result is that I/O is deferred until DB2 checkpoint and you have a lower I/O rate to disk.

However, if the set of pages updated exceeds the size of the buffer pool, setting both DWQT and VDWQT to 90% might cause the sequential prefetch threshold

(and possibly the data management threshold and the immediate write threshold) to be reached frequently. You might need to set DWQT and VDWQT lower in that case.

**Pages are rarely referenced:** Suppose that you have a customer table in a bank that has millions of rows that are accessed randomly or are updated sequentially in batch. In this case, lowering the DWQT or VDWQT thresholds (perhaps down to 0) can avoid a surge of write I/Os caused by DB2 checkpoint. Lowering those thresholds causes the write I/Os to be distributed more evenly over time. Secondly, this can improve performance for the storage controller cache by avoiding the problem of flooding the device at DB2 checkpoint.

**Query-only buffer pools:** For a buffer pool used exclusively for query processing, setting VPSEQT to 100% is reasonable. If parallel query processing is a large part of the workload, set VPPSEQT and, if applicable, VPPSEQT, to a very high value.

**Mixed workloads:** For a buffer pool used for both query and transaction processing, the value you set for VPSEQT should depend on the respective priority of the two types of processing. The higher you set VPSEQT, the better queries tend to perform, at the expense of transactions. If you are not sure what value to set for VPSEQT, use the default setting.

**Buffer pools containing LOBs:** Put LOB data in buffer pools that are not shared with other data. For both LOG YES and LOG NO LOBs, use a deferred write threshold (DWQT) of 0. LOBs specified with LOG NO have their changed pages written at commit time (*force-at-commit* processing). If you set DWQT to 0, those writes happen continuously in the background rather than in a large surge at commit.

LOBs defined with LOG YES can use deferred write, but by setting DWQT to 0, you can avoid massive writes at DB2 checkpoints.

## Determining size and number of buffer pools

The size and the number of buffer pools that you use in your DB2 subsystem can significantly affect the performance of that subsystem. This section helps to explain how to choose the best number of buffer pools for your subsystem, and the size of those buffer pools.

### Buffer pool sizes

Initially, you set the sizes (in number of pages) of your buffer pools on installation panels DSNTIP1 and DSNTIP2. Because you can modify the sizes of buffer pools using the ALTER BUFFERPOOL command, choosing an exact size initially is not important.

### The buffer-pool hit ratio

You can help some of your applications and queries by making the buffer pools large enough to increase the *buffer hit ratio*. Buffer hit ratio is a measure of how often a page access (a *getpage*) is satisfied without requiring an I/O operation.

Accounting reports, which are application related, show the hit ratio for specific applications. An accounting trace report shows the ratio for single threads. The OMEGAMON buffer pool statistics report shows the hit ratio for the subsystem as a whole. For example, the buffer-pool hit ratio is shown in field **A** in Figure 73 on page 683. The buffer hit ratio uses the following formula to determine how many *getpage* operations did not require an I/O operation:

Hit ratio = (getpages - pages\_read\_from\_disk) / getpages

where `pages_read_from_disk` is the sum of the following fields:

- Number of synchronous reads (field **B** in Figure 73 on page 683)
- Number of pages read via sequential prefetch (field **C**)
- Number of pages read via list prefetch (field **D**)
- Number of pages read via dynamic prefetch (field **E**)

*Example:* If you have 1000 getpages and 100 pages were read from disk, the equation would be as follows:

$$\text{Hit ratio} = (1000-100)/1000$$

The hit ratio in this case is 0.9.

**Highest hit ratio:** The highest possible value for the hit ratio is 1.0, which is achieved when every page requested is always in the buffer pool. Reading index non-leaf pages tend to have a very high hit ratio since they are frequently re-referenced and thus tend to stay in the buffer pool.

**Lowest hit ratio:** The lowest hit ratio occurs when the requested page is not in the buffer pool; in this case, the hit ratio is 0 or less. A negative hit ratio means that prefetch has brought pages into the buffer pool that are not subsequently referenced. The pages are not referenced because either the query stops before it reaches the end of the table space or DB2 must take the pages away to make room for newer ones before the query can access them.

**A low hit ratio is not always bad:** While it might seem desirable to make the buffer hit ratio as close to 1.0 as possible, do not automatically assume a low buffer-pool hit ratio is bad. The hit ratio is a relative value, based on the type of application. For example, an application that browses huge amounts of data using table space scans might very well have a buffer-pool hit ratio of 0. What you want to watch for is those cases where the hit ratio drops significantly for the same application. In those cases, it might be helpful to investigate further.

**Hit ratios for additional processes:** The hit ratio measurement becomes less meaningful if the buffer pool is being used by additional processes, such as work files or utilities. Some utilities and SQL statements use a special type of getpage request that reserve an empty buffer without requiring that the page be read from disk.

A getpage is issued for each empty work file page without read I/O during sort input processing. The hit ratio can be calculated if the work files are isolated in their own buffer pools. If they are, then the number of getpages used for the hit ratio formula is divided in half as follows:

$$\text{Hit ratio} = ((\text{getpages} / 2) - \text{pages\_read\_from\_disk}) / (\text{getpages} / 2)$$

### Buffer pool size guidelines

DB2 handles large buffer pools very efficiently. Searching in large buffer pools does not use any more of the processor's resources than searching in smaller pools.

If insufficient real storage exists to back the buffer pool storage, the resulting paging activity may cause performance degradation. If you see significant paging activity, increase the amount of real storage or decrease the size of the buffer pools.

**Important:** Sufficient real and auxiliary storage must exist to support the combined size of all the buffer pools that are defined. Insufficient storage might cause the system to enter into a wait state and to require an IPL.

**Problems with paging:** Paging occurs when the virtual storage requirements for a buffer pool exceeds the real storage capacity for the z/OS image. In this case, the least recently used data pages in the buffer pool are migrated to auxiliary storage. Subsequent access to these pages results in a page fault and the page must be brought into real storage from auxiliary storage. Paging of buffer pool storage can negatively affect DB2 performance. The statistics for PAGE-INS REQUIRED FOR WRITE and PAGE-INS REQUIRED FOR READ shown in Figure 73 on page 683 are useful in determining if the buffer pool size setting is too large for available real storage.

**Allocating buffer pool storage:** DB2 limits the total amount of storage that is allocated for virtual buffer pools to approximately twice the amount of real storage. However, to avoid paging, it is strongly recommended that you set the total buffer pool size to less than the real storage that is available to DB2.

**Recommendation:** The total buffer pool storage should not exceed the available real storage.

DB2 allocates the minimum buffer pool storage as shown in Table 106.

*Table 106. Buffer pool storage allocation*

Buffer pool page size	Minimum number of pages allocated
4 KB	2000
8 KB	1000
16 KB	500
32 KB	250

If the amount of virtual storage that is allocated to buffer pools is more than twice the amount of real storage, you cannot increase the buffer pool size.

### Advantages of large buffer pools

In general, larger buffer pool sizes can:

- Result in a higher buffer-pool hit ratio, which can reduce the number of I/O operations. Fewer I/O operations can reduce I/O contention, which can provide better response time and reduce the processor resource needed for I/O operations.
- Give an opportunity to achieve higher transaction rates with the same response time. For any given response time, the transaction rate depends greatly on buffer pool size.
- Prevent I/O contention for the most frequently used disks, particularly the catalog tables and frequently referenced user tables and indexes. In addition, a large buffer pool is beneficial when a DB2 sort is used during a query, because I/O contention on the disks containing the work file table spaces is reduced.

### Choosing one or many buffer pools

Whether you choose one or many 4-KB buffer pools, you must have at least 250 buffers in BP32K. Some SQL operations, such as joins, can create a result row that does not fit into a 4-KB page. You must also have 8-KB and 16-KB buffer pools.

**Buffer Pool Analyzer:** You can use the Buffer Pool Analyzer for z/OS to recommend buffer pool allocation changes and to do “what if” analysis of your buffer pools. Specifically, the “what if” analysis can help you compare the performance of a single buffer pool and multiple buffer pools. Additionally, the Buffer Pool Analyzer can recommend how to split buffer pools and where to place table space and index space objects.

**Reasons to choose a single buffer pool:** If your system has any or all of the following conditions, it is probably best to choose a single 4 KB buffer pool:

- It is already storage constrained.
- You have no one with the application knowledge necessary to do more specialized tuning.
- It is a test system.

**Reasons to choose more than one buffer pool:** You can benefit from the following advantages if you use more than one buffer pool:

- You can isolate data in separate buffer pools to favor certain applications, data, and indexes. This benefit is twofold:
  - You can favor certain data and indexes by assigning more buffers. For example, you might improve the performance of large buffer pools by putting indexes into separate pools from data.
  - You can customize buffer pool tuning parameters to match the characteristics of the data. For example, you might want to put tables and indexes that are updated frequently into a buffer pool with different characteristics from those that are frequently accessed but infrequently updated.
- You can put work files into a separate buffer pool. This can provide better performance for sort-intensive queries. Applications that use created temporary tables use work files for those tables. Keeping work files separate allows you to monitor temporary table activity more easily.
- This process of segregating different activities and data into separate buffer pools has the advantage of providing good and relatively inexpensive performance diagnosis data from statistics and accounting traces.

## Choosing a page-stealing algorithm

When DB2 must take away a page in the buffer pool to make room for a newer page, this action is called “stealing” the page from the buffer pool. DB2 usually uses a least-recently-used (LRU) algorithm for managing pages in storage. That is, it takes away older pages so that more recently used pages can remain in the buffer pool.

However, using the ALTER BUFFERPOOL command, you can also choose to have DB2 use a first-in, first-out (FIFO) algorithm. With this simple algorithm, DB2 does not keep track of how often a page is referenced—the pages that are oldest are moved out, no matter how frequently they are referenced. This simple approach to page stealing results in a small decrease in the cost of doing a getpage operation, and it can reduce internal DB2 latch contention in environments that require very high concurrency.

### Recommendations:

- In most cases, keep the default, LRU.
- Use FIFO for buffer pools that have no I/O; that is, the table space or index remains in the buffer pool. Because all the pages are there, the additional cost of a more complicated page management algorithm is not required. FIFO is also beneficial if buffer hit ratio is low, for example, less than 1%.
- Keep objects that can benefit from the FIFO algorithm in different buffer pools from those that benefit from the LRU algorithm. See options for PGSTEAL in ALTER BUFFERPOOL command in *DB2 Command Reference*.

## Long-term page fix option for buffer pools

You can use the PGFIX keyword with the ALTER BUFFERPOOL command to fix a buffer pool in real storage for an extended period of time. The PGFIX keyword has the following options:

**PGFIX(YES)** The buffer pool is fixed in real storage for the long term. Page buffers are fixed when they are first used and remain fixed.

**PGFIX(NO)** The buffer pool is not fixed in real storage for the long term. Page buffers are fixed and unfixed in real storage, allowing for paging to disk. PGFIX(NO) is the default option.

**Recommendation:** Use PGFIX(YES) for buffer pools with a high I/O rate, that is, a high number of pages read or written. For buffer pools with zero I/O, such as some read-only data or some indexes with a nearly 100% hit ratio, PGFIX(YES) is not recommended. In these cases, PGFIX(YES) does not provide a performance advantage.

To prevent PGFIX(YES) buffer pools from exceeding the real storage capacity, DB2 uses an 80% threshold when allocating PGFIX(YES) buffer pools. If the threshold is exceeded, DB2 overrides the PGFIX(YES) option with PGFIX(NO).

## Monitoring and tuning buffer pools using online commands

The information under this heading, up to “Using OMEGAMON to monitor buffer pool statistics” on page 683, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The DISPLAY BUFFERPOOL and ALTER BUFFERPOOL commands allow you to monitor and tune buffer pools on line, while DB2 is running, without the overhead of running traces.

You can use the ALTER BUFFERPOOL command to change the following attributes:

- Size
- Thresholds
- Page stealing algorithm

You can use the DISPLAY BUFFERPOOL command to display the current status of one or more active or inactive buffer pools. For example, the following command produces a detailed report of the status of BP0, as shown in Figure 72 on page 682.

```
DISPLAY BUFFERPOOL(BP0) DETAIL
```

```

+DISPLAY BPOOL(BPO) DETAIL
DSNB401I + BUFFERPOOL NAME BPO, BUFFERPOOL ID 0, USE COUNT 47
DSNB402I + BUFFERPOOL SIZE = 2000 BUFFERS
          ALLOCATED      = 2000   TO BE DELETED   = 0
          IN-USE/UPDATED = 0
DSNB406I + PAGE STEALING METHOD = LRU
DSNB404I + THRESHOLDS -

DSNB9022I + DSNB1CMD '+DISPLAY BPOOL' NORMAL COMPLETION

```

Figure 72. Sample output from the DISPLAY BUFFERPOOL command.

In Figure 72, find the following fields:

- SYNC READ I/O (R) (**A**) shows the number of random synchronous read I/O operations. SYNC READ I/O (S) (**B**) shows the number of sequential synchronous read I/O operations. Sequential synchronous read I/Os occur when prefetch is disabled.

To determine the total number of synchronous read I/Os, add SYNC READ I/O (S) and SYNC READ I/O (R).

- In message DSNB412I, REQUESTS (**C**) shows the number of times that sequential prefetch was triggered, and PREFETCH I/O (**D**) shows the number of times that sequential prefetch occurred. PAGES READ (**E**) shows the number of pages read using sequential prefetch.
- SYS PAGE UPDATES (**F**) corresponds to the number of buffer updates.
- SYS PAGES WRITTEN (**G**) is the number of pages written to disk.
- DWT HIT (**H**) is the number of times the deferred write threshold (DWQT) was reached. This number is workload dependent.
- VERTICAL DWT HIT (**I**) is the number of times the vertical deferred write threshold (VDWQT) was reached. This value is per data set, and it is related to the number of asynchronous writes.

Because the number of synchronous read I/Os (**A**) and the number of SYS PAGE UPDATES (**F**) are relatively high, you would want to tune the buffer pools by changing the buffer pool specifications. For example, you could increase the buffer

pool size to reduce the amount of unnecessary I/O, which would make buffer operations more efficient. To do that, enter the following command:

```
-ALTER BUFFERPOOL(BP0) VPSIZE(6000)
```

To obtain buffer pool information on a specific data set, you can use the LSTATS option of the DISPLAY BUFFERPOOL command. For example, you can use the LSTATS option to:

- Provide page count statistics for a certain index. With this information, you could determine whether a query used the index in question, and perhaps drop the index if it was not used.
- Monitor the response times on a particular data set. If you determine that I/O contention is occurring, you could redistribute the data sets across your available disks.

This same information is available with IFCID 0199 (statistics class 8).

For more information on the ALTER BUFFERPOOL or DISPLAY BUFFERPOOL commands, see Chapter 2 of *DB2 Command Reference*.

## Using OMEGAMON to monitor buffer pool statistics

You can find information about the database buffer pools in the statistics report produced by OMEGAMON, as Figure 73 shows.

TOT4K READ OPERATIONS	QUANTITY	TOT4K WRITE OPERATIONS	QUANTITY

Figure 73. OMEGAMON database buffer pool statistics (modified)

The formula for the buffer-pool hit ratio (fields **A** through **E**) is explained in “The buffer-pool hit ratio” on page 677

Increase the buffer pool size or reduce the workload if:

- Sequential prefetch is inhibited. PREF.DISABLED-NO BUFFER ( **F** ) shows how many times sequential prefetch is disabled because the sequential prefetch threshold (90% of the pages in the buffer pool are unavailable) has been reached.
- You detect poor update efficiency. You can determine update efficiency by checking the values in both of the following fields:
  - BUFF.UPDATES/PAGES WRITTEN ( **H** )
  - PAGES WRITTEN PER WRITE I/O ( **J** )

In evaluating the values you see in these fields, remember that no values are absolutely acceptable or absolutely unacceptable. Each installation's workload is a special case. To assess the update efficiency of your system, monitor for overall trends rather than for absolute high values for these ratios.

The following factors impact buffer updates per pages written and pages written per write I/O:

- Sequential nature of updates
- Number of rows per page
- Row update frequency

For example, a batch program that processes a table in skip sequential mode with a high row update frequency in a dedicated environment can achieve very good update efficiency. In contrast, update efficiency tends to be lower for transaction processing applications, because transaction processing tends to be random.

The following factors affect the ratio of pages written per write I/O:

- *Checkpoint frequency.* The CHECKPOINT FREQ field on installation panel DSNTIPN specifies either the number of consecutive log records written between DB2 system checkpoints or the number of minutes between DB2 system checkpoints. You can use a large value to specify CHECKPOINT FREQ in number of log records; the default value is 500 000. You can use a small value to specify CHECKPOINT FREQ in minutes. If you specify CHECKPOINT FREQ in minutes, the recommended setting is 2 to 5 minutes. At checkpoint time, I/Os are scheduled to write all updated pages on the deferred write queue to disk. If system checkpoints occur too frequently, the deferred write queue does not grow large enough to achieve a high ratio of pages written per write I/O.
- *Frequency of active log switch.* DB2 takes a system checkpoint each time the active log is switched. If the active log data sets are too small, checkpoints occur often, which prevents the deferred write queue from growing large enough to achieve a high ratio of pages written per write I/O. For recommendations on active log data set size, see "Log capacity" on page 703.
- *Buffer pool size.* The deferred write thresholds (VDWQT and DWQT) are a function of buffer pool size. If the buffer pool size is decreased, these thresholds are reached more frequently, causing I/Os to be scheduled more often to write some of the pages on the deferred write queue to disk. This prevents the deferred write queue from growing large enough to achieve a high ratio of pages written per write I/O.
- *Number of data sets, and the spread of updated pages across them.* The maximum number of pages written per write I/O is 32, subject to a limiting scope of 180 pages (roughly one cylinder).

**Example:** If your application updates page 2 and page 179 in a series of pages, the two changed pages could potentially be written with one write I/O. But if your application updates page 2 and page 185 within a series of pages, writing the two changed pages would require two write I/Os because of the 180-page limit. Updated pages are placed in a deferred write queue

based on the data set. For batch processing it is possible to achieve a high ratio of pages written per write I/O, but for transaction processing the ratio is typically lower.

For LOAD, REORG, and RECOVER, the maximum number of pages written per write I/O is 64, and there is typically no limiting scope. However, in some cases, such as loading a partitioned table space with nonpartitioned indexes, a 180-page limit scope exists.

- SYNCHRONOUS WRITES ( **I** ) is a high value. This field counts the number of immediate writes. However, immediate writes are not the only type of synchronous write. Therefore, providing a monitoring value for the number of immediate writes can be difficult.

Ignore SYNCHRONOUS WRITES when DM THRESHOLD is zero.

- DM THRESHOLD ( **K** ) is reached. This field shows how many times a page was immediately released because the data management threshold was reached. The quantity listed for this field should be zero.

Also note the following fields:

- WRITE ENGINE NOT AVAILABLE ( **L** )

This field records the number of times that asynchronous writes were deferred because DB2 reached its maximum number of concurrent writes. You cannot change this maximum value. This field has a nonzero value occasionally.

- PREF.DISABLED-NO READ ENG ( **G** )

This field records the number of times that a sequential prefetch was not performed because the maximum number of concurrent sequential prefetches was reached. Instead, normal reads were done. You cannot change this maximum value.

- PAGE-INS REQUIRED FOR WRITE ( **M** )

This field records the number of page-ins that are required for a read or write I/O. When the buffer pools are first allocated, the count might be high. After the first allocations are complete, the count should be close to zero.

---

## Tuning EDM storage

EDM storage is composed of these three components, each of which is in a separate storage area:

- The EDM pool, which contains:
  - Skeleton cursor tables (SKCTs)
  - Cursor tables (CTs), or copies of the SKCTs
  - Skeleton package tables (SKPTs)
  - Package tables (PTs), or copies of the SKPTs
  - An authorization cache block for each plan, excluding plans that are bound with CACHESIZE(0)
- The EDM DBD cache, which contains database descriptors (DBDs)
- The EDM statement cache, which contains the skeletons of dynamic SQL if your installation has YES for the CACHE DYNAMIC SQL field of installation panel DSNTIP8

In releases of DB2 prior to Version 8, these components were in a single storage pool. With Version 8, they are in three separate storage pools, and the option to have the dynamic SQL statement cache in a data space is removed.

During the installation process, DSNTINST CLIST calculates the size of the EDM pool and the EDM DBD cache. You can check the calculated sizes on installation panel DSNTIPC. For more information on estimating and specifying the sizes, see *DB2 Installation Guide*.

For data sharing, you might need to increase the EDM DBD cache storage estimate. For more information, see Chapter 2 of *DB2 Data Sharing: Planning and Administration*.

Because of an internal process that changes the size of plans initially bound in one release and then are rebound in a later release, you should carefully monitor the size of the EDM pool, the EDM DBD cache, and the EDM statement cache and increase their sizes, if necessary.

## EDM storage space handling

When pages are needed from the EDM pool, the EDM DBD cache, or the EDM statement cache, any pages that are available are allocated first. If the available pages do not provide enough space to satisfy the request, pages are “stolen” from an inactive SKCT, SKPT, DBD, or dynamic SQL skeleton. If enough space is still not available, an SQL error code is sent to the application program.

Table 107 shows how you should design EDM storage:

*Table 107. Designing the EDM storage pools*

Design...	To contain...
EDM pool	<ul style="list-style-type: none"> <li>• The CTs and PTs in use</li> <li>• The SKCTs for the most frequently used applications</li> <li>• The SKPTs for the most frequently used applications</li> <li>• The cache blocks for your plans that have caches</li> </ul>
EDM DBD cache	<ul style="list-style-type: none"> <li>• The DBDs in use</li> <li>• The DBDs referred to by the SKCTs and SKPTs for the most frequently used applications</li> </ul>
EDM statement cache	<ul style="list-style-type: none"> <li>• The skeletons of the most frequently used dynamic SQL statements, if your system has enabled the dynamic statement cache</li> </ul>

By designing the EDM storage pools this way, you can avoid allocation I/Os, which can represent a significant part of the total number of I/Os for a transaction. You can also reduce the processing time necessary to check whether users attempting to execute a plan are authorized to do so.

EDM storage pools that are too small cause:

- Increased I/O activity in DSNDB01.SCT02, DSNDB01.SPT01, and DSNDB01.DBD01
- Increased response times, due to loading the SKCTs, SKPTs, and DBDs
- Fewer threads used concurrently, due to a lack of storage

### Implications for database design

When you design your databases, be aware that a very large number of objects in your database means a larger DBD for that database. And when you drop objects, storage is not automatically reclaimed in that DBD, which can mean that DB2 must

take more locks for the DBD. To reclaim storage in the DBD, use the MODIFY utility, as described in Part 2 of *DB2 Utility Guide and Reference*.

Monitor and manage DBDs to prevent them from becoming too large. Very large DBDs can reduce concurrency and degrade the performance of SQL operations that create or alter objects because of increased I/O and logging. DBDs that are created or altered in DB2 Version 6 or later do not need contiguous storage, but can use pieces of approximately 32 KB. Older DBDs require contiguous storage.

### Monitoring and EDM storage

The DB2 statistics record provides information on the EDM pool, the EDM DBD cache, and the EDM statement cache. Figure 74 shows how OMEGAMON presents this information in the statistics report.

EDM POOL	QUANTITY
-----	-----
PAGES IN EDM POOL <b>A</b>	8192.00
HELD BY DBDS	55.00
HELD BY CTS	0.00
HELD BY SKCTS	6.00
HELD BY SKPTS	35.00

LOCAL CACHE HIT RATIO (%)	N/C

Figure 74. EDM storage utilization in the OMEGAMON statistics report

The important values to monitor are:

**Efficiency of the EDM pool:** You can measure the efficiency of the EDM pool by using the following ratios:

DBD HIT RATIO (%) **C**  
CT HIT RATIO (%) **D**  
PT HIT RATIO (%) **E**

These ratios for the EDM pool depend upon your location's work load. In most DB2 subsystems, a value of 80% or more is acceptable. This value means that at least 80% of the requests were satisfied without I/O.

The number of free pages is shown in FREE PAGES (**B**) in Figure 74. If this value is more than 20% of PAGES IN EDM STORAGE (**A**) during peak periods, the EDM pool size is probably too large. In this case, you can reduce its size without affecting the efficiency ratios significantly.

*EDM statement cache hit ratio:* If you have caching turned on for dynamic SQL, the EDM storage statistics have information that can help you determine how successful your applications are at finding statements in the cache. See mapping macro DSNDQISE for descriptions of these fields.

PREPARE REQUESTS (**F**) in Figure 74 records the number of requests to search the cache. FULL PREPARES (**G**) records the number of times that a statement was inserted into the cache, which can be interpreted as the number of times a statement was not found in the cache. To determine how often the dynamic statement was used from the cache, check the value in GLOBAL CACHE HIT RATIO (**H**). The value is calculated with the following formula:

$(\text{PREPARE REQUESTS} - \text{FULL PREPARES}) / \text{PREPARE REQUESTS} = \text{hit ratio}$

*EDM pool space utilization and performance:* For smaller EDM pools, space utilization or fragmentation is normally more critical than for larger EDM pools. For larger EDM pools, performance is normally more critical. DB2 emphasizes performance and uses less optimum EDM storage allocation when the EDM pool size exceeds 40 MB. For systems with large EDM pools that are greater than 40 MB to continue to use optimum EDM storage allocation at the cost of performance, you can set the keyword EDMBFIT in the DSNTIJUZ job to YES. The EDMBFIT keyword adjusts the search algorithm on systems with EDM pools that are larger than 40 MB. The default NO tells DB2 to use a first-fit algorithm while YES tells DB2 to use a better-fit algorithm.

**Recommendation:** Set EDMBFIT to NO in most cases. It is especially important to set EDMBFIT to NO when a high class 24 latch (EDM LRU latch) contention exists. For example, be sure to set EDMBFIT to NO when class 24 latch contention exceeds 500 contentions per second.

**Recommendation:** Set EDMBFIT to YES when EDMPOOL full conditions occur for an EDM pool size that exceeds 40 MB.

## Tips for managing EDM storage

Here are guidelines for helping keep EDM storage, especially the EDM pool, under control.

### Use packages

By using multiple packages you can increase the effectiveness of EDM pool storage management by having smaller objects in the pool.

## Use RELEASE(COMMIT) when appropriate

Using the bind option RELEASE(COMMIT) for infrequently used packages and plans can cause objects to be removed from the EDM pool sooner.

## Be aware of large DBDs

DBDs in new function mode can be larger than DBDs in previous releases. Therefore, the DBDs might contain additional expansion areas. DBDs that were created before Version 8 are expanded when they are read. When a DBD is expanded, DB2 requires storage for two copies while the DBD is loaded.

## Understand the impact of using DEGREE(ANY)

A plan or package that is bound with DEGREE(ANY) can require 50 to 70% more storage for the CTs and PTs in the EDM pool than one bound with DEGREE(1). If you change a plan or package to DEGREE(ANY), check the change in the column AVGSIZE in SYSPLAN or SYSPACKAGE to determine the increase required.

---

## Increasing RID pool size

The RID pool is used for all record identifier (RID) processing. It is used for enforcing unique keys while updating multiple rows and for sorting RIDs during the following operations:

- List prefetch, including single index list prefetch
- Access via multiple indexes
- Hybrid joins

To favor the selection and efficient completion of those access paths, increase the maximum RID pool size. However, if there is not enough RID pool storage, it is possible that the statement might revert to a table space scan.

A RID pool size of 0 disables those access paths. If you specify a RID pool size of 0, plans or packages that were previously bound with a non-zero RID pool size might experience significant performance degradation. Rebind any plans or packages that include SQL statements that use RID processing.

The default RID pool size is 8 MB. You can override this value on installation panel DSNTIPC.

To determine if a transaction used the RID pool, see the RID Pool Processing section of the OMEGAMON accounting trace record.

The RID pool, which all concurrent work shares, is limited to a maximum of 10 000 MB. The RID pool is created at system initialization, but no space is allocated until RID storage is needed. It is then allocated in 32-KB blocks as needed, until the maximum size that you specified on installation panel DSNTIPC is reached.

The general formula for computing RID pool size is:

Number of concurrent RID processing activities ×  
average number of RIDs × 2 × 5 bytes per RID

**Example:** Three concurrent RID processing activities, with an average of 4000 RIDs each, would require 120 KB of storage, because:

$$3 \times 4000 \times 2 \times 5 = 120\text{KB}$$

Whether your SQL statements that use RID processing complete efficiently or not depends on other concurrent work using the RID pool.

---

## Controlling sort pool size and sort processing

Sort is invoked when a cursor is opened for a SELECT statement that requires sorting. The maximum size of the sort work area allocated for each concurrent sort user depends on the value you specified for the SORT POOL SIZE field on installation panel DSNTIPC. The default value is 2 MB.

### Estimating the maximum size of the sort pool

You can change the maximum size of the sort pool by using the installation panels in UPDATE mode. A rough formula for determining the maximum size is as follows:

$$32000 \times (16 + \text{sort key length} + \text{sort data length})$$

For sort key length and sort data length, use values that represent the maximum values for the queries you run. To determine these values, refer to fields QW0096KL (key length) and QW0096DL (data length) in IFCID 0096, as mapped by macro DSNDQW01. You can also determine these values from an SQL activity trace.

If a column is in the ORDER BY clause that is not in the select clause, that column should be included in the sort data length and the sort key length as shown in the following example:

```
SELECT C1, C2, C3
   FROM tablex
   ORDER BY C1, C4;
```

If C1, C2, C3, and C4 are each 10 bytes in length, you could estimate the sort pool size as follows:

$$32000 \times (16 + 20 + (10 + 10 + 10 + 10)) = 2342000 \text{ bytes}$$

Where the values are determined in the following way:

- 32000 = maximum number of sort nodes
- 16 = size (in bytes) of each node
- 20 = sort key length (ORDER BY C1, C4)
- 10+10+10+10 = sort data length (each column is 10 bytes in length)

### How sort work files are allocated

The sort begins with the input phase when ordered sets of rows are written to work files. At the end of the input phase, when all the rows have been sorted and inserted into the work files, the work files are merged together, if necessary, into one work file containing the sorted data. The merge phase is skipped if there is only one work file at the end of the input phase. In some cases, intermediate merging might be needed if the maximum number of sort work files has been allocated.

The work files that are used in sort are logical work files, which reside in work file table spaces in your work file database (which is DSNDB07 in a non data-sharing environment). DB2 uses the buffer pool when writing to the logical work file. Only the buffer pool size limits the number of work files that can be used for sorting.

A sort can complete in the buffer pool without I/Os. This is the ideal situation, but it might be unlikely, especially if the amount of data being sorted is large. The sort row size is actually made up of the columns being sorted (the sort key length) and the columns the user selects (the sort data length). Having a very large buffer pool for sort activity can help avoid disk I/Os.

When your application needs to sort data, the work files are allocated on a least recently used basis for a particular sort. For example, if five logical work files (LWFs) are to be used in the sort, and the installation has three work file table spaces (WFTSs) allocated, then:

- LWF 1 would be on WFTS 1.
- LWF 2 would be on WFTS 2.
- LWF 3 would be on WFTS 3.
- LWF 4 would be on WFTS 1.
- LWF 5 would be on WFTS 2.

To support large sorts, DB2 can allocate a single logical work file to several physical work file table spaces.

## Improving the performance of sort processing

The following factors affect the performance of DB2 sort processing:

- The larger the sort pool, the more efficient the sort is.
- Minimize I/O contention on the I/O paths to the physical work files. Also, make sure that physical work files are allocated on different I/O paths and packs to minimize I/O contention. Using disk devices with Parallel Access Volumes (PAV) support is another way to significantly minimize I/O contention. (For more information, see “Parallel Access Volumes (PAV)” on page 716.)
- Allocate additional physical work files in excess of the defaults, and put those work files in their own buffer pool.

Segregating work file activity enables you to better monitor and tune sort performance. It also allows DB2 to handle sorts more efficiently because these buffers are available only for sort without interference from other DB2 work.

Applications using created temporary tables use work file space until a COMMIT or ROLLBACK occurs. (If a cursor is defined WITH HOLD, then the data is held past the COMMIT.) If sorts are happening concurrently with the temporary table’s existence, then you probably need more space to handle the additional use of the work files. Applications that require star join, materialized views, materialized nested table expressions, non-correlated subqueries or triggers also use work files.

For information about defining additional work file table spaces, refer to “Creating additional work file table spaces” on page 663.

- Applications should only sort those columns that need to be sorted, as these key fields appear twice in the sort row size. The smaller the sort row size, the more rows can fit it.
- Because varying-length columns are padded to their maximum length, do not select VARCHAR columns unless they are required.
- A buffer pool sequential steal threshold (VPSEQT) of 100% avoids wasting buffers, unless a sparse index is used to access the work files. The default value of 80% allows 20% of the buffers to go unused. A value of 99% prevents space map pages, which are randomly accessed, from being overwritten by massive prefetch. If sparse index access is used, the default of 80% is recommended.

Other factors that influence sort performance include the following:

- The better sorted the data is, the more efficient the sort is.
- If the buffer pool deferred write threshold (DWQT) or data set deferred write threshold (VDWQT) are reached, writes are scheduled. For a large sort using many logical work files, this is difficult to avoid, even if a very large buffer pool is specified.

- If I/Os occur in the sorting process, in the merge phase DB2 uses sequential prefetch to bring pages into the buffer pool with a prefetch quantity of eight pages. However, if the buffer pool is constrained, then DB2 uses a prefetch quantity of four pages or less, or disables prefetch entirely because of the unavailability of enough pages.

For any SQL statement that initiates sort activity, the OMEGAMON SQL activity reports provide information on the efficiency of the sort that is involved.

---

## Chapter 28. Improving resource utilization

When system resources are shared among transactions, end user queries, Web requests, distributed application requests, and batch programs, it is important to control how those resources are used. You need to separate data and set priorities carefully. You might choose to emphasize resource use, performance, concurrency, or data security.

Choose the controls that best match your goals. You may, for example, want to minimize resource usage, maximize throughput or response time, ensure a certain level of service to some users, or avoid conflicts between users. Your goal might be to favor a certain class of users or to achieve the best overall system performance.

Many of the things you currently do for a single DB2 to improve response time or reduce processor consumption also hold true in the data sharing environment. Thus, most of the information in this chapter holds true for data sharing as well.

This chapter covers the following topics:

- “Managing the opening and closing of data sets”
- “Planning the placement of DB2 data sets” on page 698
- “DB2 logging” on page 700
- “Improving disk utilization: space and device utilization” on page 707
- “Improving real storage utilization” on page 712
- “Performance and storage” on page 714
- “z/OS performance options for DB2” on page 717
- “Controlling resource usage” on page 720
- “Resource limit facility (governor)” on page 722

For more information about tuning in a data sharing environment, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*. For more information about reducing resource usage in distributed applications, see “Tuning distributed applications” on page 1008. For more information about setting thread limits, see Chapter 29, “Managing DB2 threads,” on page 735

---

### Managing the opening and closing of data sets

Having the needed data sets open and available for use is important for the performance of transactions. However, the number of open data sets affects the amount of available storage, and number of open data sets in read-write state affects restart time. This section describes how DB2 manages this open and close activity and gives some recommendations about how you can influence this processing.

This section includes the following topics:

- “Determining the maximum number of open data sets”
- “Understanding the CLOSE YES and CLOSE NO options” on page 696
- “Switching to read-only for infrequently updated and infrequently accessed page sets” on page 697

#### Determining the maximum number of open data sets

DB2 defers closing and deallocating the table spaces or indexes until the number of open data sets reaches 99% of the value that you specified for DSMAX.

When DSMAX is reached, DB2 closes 300 data sets or 3% of the value of DSMAX, whichever number of data sets is fewer. Thus, DSMAX controls not only the limit of open data sets, but in some cases also controls the number of data sets that are closed when that limit is reached.

### How DB2 determines DSMAX

Initially, DB2 calculates DSMAX as follows:

- Let *concdb* be the number of concurrent databases specified on installation panel DSNTIPE.
- Let *tables* be the number of tables per database specified on installation panel DSNTIPD.
- Let *indexes* be the number of indexes per table. The installation CLIST sets this variable to 2.
- Let *tblspaces* be the number of table spaces per database specified on installation panel DSNTIPD.

DB2 calculates the number of open data sets with the following formula:

$$\text{concdb} \times \{(\text{tables} \times \text{indexes}) + \text{tblspaces}\}$$

### Modifying DSMAX

The formula used by DB2 does not take partitioned or LOB table spaces into account. Those table spaces can have many data sets. If you have many partitioned table spaces or LOB table spaces, you might need to increase DSMAX. Don't forget to consider the data sets for nonpartitioned indexes defined on partitioned table spaces. If those indexes are defined with a small PIECESIZE, there could be many data sets. You can modify DSMAX by updating field DSMAX - MAXIMUM OPEN DATA SETS on installation panel DSNTIPC.

*Calculating the size of DSMAX:* DSMAX should be larger than the maximum number of data sets that are open and in use at one time. For the most accurate count of open data sets, refer to the OPEN/CLOSE ACTIVITY section of the OMEGAMON statistics report. Make sure the statistics trace was run at a peak period, so that you can obtain the most accurate maximum figure.

The best indicator of when to increase DSMAX is when the open and close activity of data sets is high, 1 per second as a general guideline. Refer to the OPEN/CLOSE value under the SER.TASK SWITCH section of the OMEGAMON accounting report. Consider increasing DSMAX when this value shows more than 1 event per second.

To calculate the total number of data sets (rather than the number that are open during peak periods), you can do the following:

1. To find the number of simple and segmented table spaces, use the following query. The calculation assumes that you have one data set for each simple, segmented, and LOB table space.

These catalog queries are included in DSNTESP in SDSNSAMP. You can use them as input to SPUFI.

#### General-use Programming Interface

##### Query 1

```
SELECT CLOSERULE, COUNT(*)
FROM SYSIBM.SYSTABLESPACE
WHERE PARTITIONS = 0
GROUP BY CLOSERULE;
```

|\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_|

2. To find the number of data sets for the partitioned table spaces, use the following query, which returns the number of partitioned table spaces and the total number of partitions. Partitioned table spaces can require up to 4096 data sets for the data, and a corresponding number of data sets for each partitioned index.

|\_\_\_\_\_ General-use Programming Interface \_\_\_\_\_|

**Query 2**

```
SELECT CLOSERULE, COUNT(*), SUM(PARTITIONS)
FROM SYSIBM.SYSTABLESPACE
WHERE PARTITIONS > 0
GROUP BY CLOSERULE;
```

|\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_|

3. To find the number of data sets required for each nonpartitioned index, use the following query. The calculation assumes that you have only one data set for each nonpartitioned index. If you use pieces, adjust accordingly.

|\_\_\_\_\_ General-use Programming Interface \_\_\_\_\_|

**Query 3**

```
SELECT CLOSERULE, COUNT(*)
FROM SYSIBM.SYSINDEXES T1, SYSIBM.SYSINDEXPART T2
WHERE T1.NAME = T2.IXNAME
AND T1.CREATOR = T2.IXCREATOR
AND T2.PARTITION = 0
GROUP BY CLOSERULE;
```

|\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_|

- |
- |
- |
4. To find the number of data sets for the partitioned indexes, use the following query, which returns the number of index partitions. You have one data set for each index partition.

|\_\_\_\_\_ General-use Programming Interface \_\_\_\_\_|

**Query 4**

```
SELECT CLOSERULE, COUNT(*)
FROM SYSIBM.SYSINDEXES T1, SYSIBM.SYSINDEXPART T2
WHERE T1.NAME = T2.IXNAME
AND T1.CREATOR = T2.IXCREATOR
AND T2.PARTITION > 0
GROUP BY CLOSERULE;
```

|\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_|

- |
- |
5. To find the total number of data sets, add the numbers that result from the four queries. (For Query 2, use the sum of the partitions that was obtained.)

## Recommendations

As with many recommendations in DB2, you must weigh the cost of performance versus availability when choosing a value for DSMAX. Consider the following factors:

- For best performance, you should leave enough margin in your specification of DSMAX so that frequently used data sets can remain open after they are no

longer referenced. If data sets are opened and closed frequently, such as every few seconds, you can improve performance by increasing DSMAX.

- The number of open data sets on your subsystem that are in read/write state affects checkpoint costs and log volumes. To control how long data sets stay open in a read/write state, specify values for the RO SWITCH CHKPTS and RO SWITCH TIME fields of installation panel DSNTIPN. See “Switching to read-only for infrequently updated and infrequently accessed page sets” on page 697 for more information.
- Consider segmented table spaces to reduce the number of data sets.  
To reduce open and close activity, you can try reducing the number of data sets by combining tables into segmented table spaces. This approach is most useful for development or end-user systems where there are a lot of smaller tables that can be combined into single table spaces.

## Understanding the CLOSE YES and CLOSE NO options

### General-use Programming Interface

This section describes how DB2 manages data set closing and how the CLOSE value for a table space or index affects the process of closing an object’s data sets. The term **page set** refers to a table space or index.

#### The process of closing

DB2 dynamically manages page sets using two levels of page set closure—logical close and physical close.

**Logical close:** This occurs when the application has been deallocated from that page set. This is at either commit or deallocation time, depending on the RELEASE(COMMIT/DEALLOCATE) option of the BIND command, and is driven by the use count. When a page set is logically closed, the page set use count is decremented. When the page set use count is zero, the page set is considered not in use; this makes it a candidate for physical close.

**Physical close:** This happens when DB2 closes and deallocates the data sets for the page set.

#### When the data sets are closed

As described in “Determining the maximum number of open data sets” on page 693, the number of open data sets determines when it is necessary to close data sets. When DB2 closes data sets, all data sets for a particular table space, index, or partition are closed.

The value you specify for CLOSE determines the *order* in which page sets that are not in use are closed. When the open data set count becomes greater than 99% of DSMAX, DB2 first closes page sets defined with CLOSE YES. The least recently used page sets are closed first.

If the number of open data sets cannot be limited by closing page sets or partitions defined with CLOSE YES, DB2 then must close page sets or partitions defined with CLOSE NO. The least recently used CLOSE NO data sets are closed first.

Delaying the physical closure of page sets or partitions until necessary is called *deferred close*. Deferred closing of a page set or partition that is no longer being used means that another application or user can access the table space and employ

the accompanying indexes without DB2 reopening the data sets. Thus, deferred closing of page sets or partitions can improve your applications' performance by avoiding I/O processing.

**Recommendation:** For a table space whose data is continually referenced, in most cases it does not matter whether it is defined with CLOSE YES or CLOSE NO; the data sets remain open. This is also true, but less so, for a table space whose data is not referenced for short periods of time; because DB2 uses deferred close to manage data sets, the data sets are likely to be open when they are used again.

You could find CLOSE NO appropriate for page sets that contain data you do not frequently use but is so performance-critical that you cannot afford the delay of opening the data sets.

If the number of open data sets is a concern, choose CLOSE YES for page sets with many partitions or data sets.

\_\_\_\_\_ End of General-use Programming Interface \_\_\_\_\_

## Switching to read-only for infrequently updated and infrequently accessed page sets

For both CLOSE YES and CLOSE NO page sets, DB2 automatically converts infrequently updated page sets or partitions from read-write to read-only state according to the values you specify in the RO SWITCH CHKPTS and RO SWITCH TIME fields of installation panel DSNTIPL.

#  
#  
#  
#  
#

With data sharing, DB2 uses the CLOSE YES or CLOSE NO attribute of the table space or index space to determine whether to physically close infrequently accessed page sets that have had global buffer pool dependencies. Infrequently accessed CLOSE YES page sets are physically closed. Infrequently accessed CLOSE NO page sets remain open.

RO SWITCH CHKPTS is the number of consecutive DB2 checkpoints since a page set or partition was last updated; the default is 5. RO SWITCH TIME is the amount of elapsed time since a page set or partition was last updated; the default is 10 minutes. If either condition is met, the page set or partition is converted from read-write to read-only state.

**Updating SYSLGRNX:** For both CLOSE YES and CLOSE NO page sets, SYSLGRNX entries are updated when the page set is converted from read-write state to read-only state. When this conversion occurs for table spaces, the SYSLGRNX entry is closed and any updated pages are externalized to disk. For indexes defined as COPY NO, there is no SYSLGRNX entry, but the updated pages are externalized to disk.

**Performance benefits of read-only switching:** An infrequently used page set's conversion from read-write to read-only state results in the following performance benefits:

- Improved data recovery performance because SYSLGRNX entries are more precise, closer to the last update transaction commit point. As a result, the RECOVER utility has fewer log records to process.
- Minimized logging activities. Log records for page set open, checkpoint, and close operations are only written for updated page sets or partitions. Log records are not written for read-only page sets or partitions.

*Recommendations for RO SWITCH TIME and RO SWITCH CHKPTS:* In most cases, the default values are adequate. However, if you find that the amount of R/O switching is causing a performance problem for the updates to SYSLGRNX, consider increasing the value of RO SWITCH TIME, perhaps to 30 minutes.

---

## Planning the placement of DB2 data sets

To improve performance, plan the placement of DB2 data sets carefully. Concentrate mainly on data sets for system files (especially the active logs), for the DB2 catalog and directory, and for user data and indexes. The objective is to balance I/O activity between different volumes, control units, and channels, which minimizes the I/O elapsed time and I/O queuing.

This section includes the following topics:

- “Estimating concurrent I/O requests”
- “Crucial DB2 data sets”
- “Changing catalog and directory size and location” on page 699
- “Monitoring I/O activity of data sets” on page 699
- “Work file data sets” on page 699

### Estimating concurrent I/O requests

DB2 has a multi-tasking structure in which each user’s request runs under a different task control block (TCB). In addition, the DB2 system itself has its own TCBs and SRBs for logging and database writes. When your DB2 system is loaded with data, you can estimate the maximum number of concurrent I/O requests as:

MAX USERS + 600 sequential prefetches + 600 asynchronous writes

This figure is important when you calculate the number of data paths for your DB2 subsystem.

### Crucial DB2 data sets

First, decide which data sets are crucial to DB2’s functioning. To gather this information, use the I/O reports from the DB2 performance trace. If these reports are not available, consider these the most important data sets:

For transactions:

- DSNDB01.SCT02 and its index
- DSNDB01.SPT01 and its index
- DSNDB01.DBD01
- DSNDB06.SYSPLAN table space and indexes on SYSPLANAUTH table
- DSNDB06.SYSPKAGE
- Active and archive logs
- Most frequently used user table spaces and indexes

For queries:

- DSNDB01.DBD01
- DSNDB06.SYSPLAN table space and indexes on SYSPLANAUTH
- DSNDB06.SYSPKAGE
- DSNDB06.SYSDBASE table space and its indexes
- DSNDB06.SYSVIEWS table space and the index on SYSVTREE
- Work file table spaces
- QMF system table data sets
- Most frequently used user table spaces and indexes

These lists do not include other data sets that are less crucial to DB2's performance, such as those that contain program libraries, control blocks, and formats. Those types of data sets have their own design recommendations.

## Changing catalog and directory size and location

Consider changing the size or location of your DB2 catalog or directory if necessary for your site. See Appendix F, "Using tools to monitor performance," on page 1191 for guidelines on when to do this.

To change the size or location of DB2 catalog or directory data sets, you must run the RECOVER utility on the appropriate database, or the REORG utility on the appropriate table space. A hierarchy of recovery dependencies determines the order in which you should try to recover data sets. This order is discussed in the description of the RECOVER utility in Part 2 of *DB2 Utility Guide and Reference*.

## Monitoring I/O activity of data sets

The best way to monitor your I/O activity against database data sets is through IFCID 0199 (statistics class 8). This IFCID can give you information such as the average write I/O delay or the maximum delay for a particular data set over the last statistics reporting interval. The same information is also reported in the DISPLAY BUFFERPOOL command with the LSTATS option. Furthermore, OMEGAMON reports IFCID 0199 in batch reports and in online monitoring.

More detailed information is available, with more overhead, with the I/O trace (performance class 4). If you want information about I/O activity to the log and BSDS data sets, use performance class 5.

You can also use RMF to monitor data set activity. SMF record type 42-6 provides activity information and response information for a data set over a time interval. These time intervals include the components of I/O time, such as IOS queue time. Using RMF incurs about the same overhead as statistics class 8.

For information on how to tune your environment to improve I/O performance, see "Reducing the time needed to perform I/O operations" on page 660 and "Synchronous I/O suspension time" on page 649.

## Work file data sets

Work file data sets are used for sorting, for materializing views and nested table expressions, for temporary tables, and for other activities. DB2 does not distinguish or place priorities on these uses of the work file data sets. Excessive activity from one type of use can interfere and detract from the performance of others. It is important to monitor how work files use devices, both in terms of space use and I/O response times.

*More about temporary work file result tables:* Part 2 of *DB2 Installation Guide* contains information about how to estimate the disk storage required for temporary work file result tables. The storage is similar to that required for regular tables. When a temporary work file result table is populated using an INSERT statement, it uses work file space.

No other process can use the same work file space as that temporary work file table until the table goes away. The space is reclaimed when the application process commits or rolls back, or when it is deallocated, depending which RELEASE option was used when the plan or package was bound.

To best monitor these result tables, keep work files in a separate buffer pool. Use IFCID 0311 in performance trace class 8 to distinguish these tables from other uses of the work file.

---

## DB2 logging

DB2 logs changes made to data, and other significant events, as they occur. You can find background information on the DB2 log in Chapter 18, “Managing the log and the bootstrap data set,” on page 427. When you focus on logging performance issues, remember that the characteristics of your workload have a direct effect on log write performance. Long-running tasks that commit infrequently have a lot more data to write at commit than a typical transaction. These tasks can cause subsystem impact because of the excess storage consumption, locking contention, and resources that are consumed for a rollback.

Don’t forget to consider the cost of reading the log as well. The cost of reading the log directly affects how long a restart or a recovery occurs because DB2 must read the log data before applying the log records back to the table space.

This section includes the following topics:

- “Logging performance issues and recommendations”
- “Log capacity” on page 703
- “Controlling the amount of log data” on page 705

### Logging performance issues and recommendations

This section provides background information on logging operations. By understanding the day-to-day activity on the log, you can more effectively pinpoint when problems occur and better understand how to tune for best performance.

#### Log writes

Log writes are divided into two categories: synchronous and asynchronous.

*Asynchronous writes:* Asynchronous writes are the most common. These asynchronous writes occur when data is updated. Before- and after-image records are usually moved to the log output buffer, and control is returned to the application. However, if no log buffer is available, the application must wait for one to become available.

*Synchronous writes:* Synchronous writes usually occur at commit time when an application has updated data. This write is called 'forcing' the log because the application must wait for DB2 to force the log buffers to disk before control is returned to the application. If the log data set is not busy, all log buffers are written to disk. If the log data set is busy, the requests are queued until it is freed.

*Writing to two logs:* Dual logging is shown in Figure 75 on page 701.

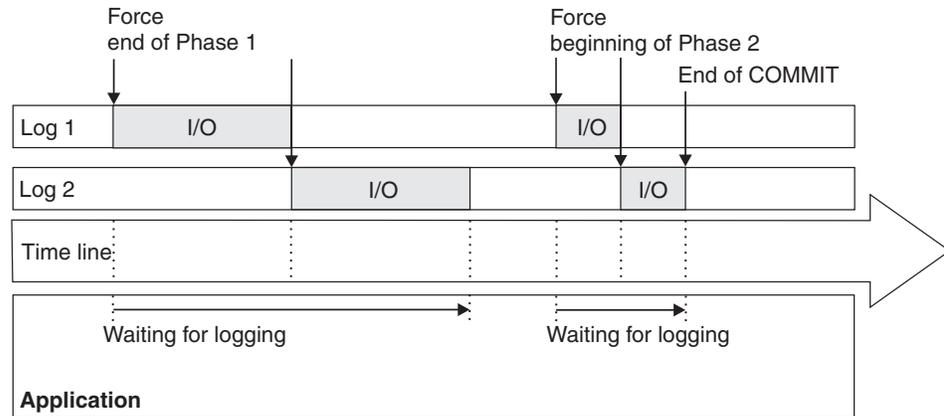

Figure 75. Dual logging during two-phase commit

If there are two logs (recommended for availability), the write to the first log, in general, must complete before the write to the second log begins. The first time a log control interval is written to disk, the write I/Os to the log data sets are performed in parallel. However, if the same 4 KB log control interval is again written to disk, then the write I/Os to the log data sets must be done serially to prevent any possibility of losing log data in case of I/O errors on both copies simultaneously.

**Two-phase commit log writes:** Because they use two-phase commit, applications that use the CICS, IMS, and RRS attachment facilities force writes to the log twice, as shown in Figure 75. The first write forces all the log records of changes to be written (if they have not been written previously because of the write threshold being reached). The second write writes a log record that takes the unit of recovery into an in-commit state.

**Recommendations:** To improve log write performance:

- **Choose a large size for OUTPUT BUFFER size:** The OUTPUT BUFFER field of installation panel DSNTIPL lets you specify the size of the output buffer used for writing active log data sets. The maximum size of this buffer (OUTBUFF) is 400 000 KB. Choose as large a size as your system can tolerate to decrease the number of forced I/O operations that occur because there are no more buffers. A large size can also reduce the number of wait conditions. A non-zero value for **A** in Figure 76 on page 702 is an indicator that your output buffer is too small. Ensure that the size you choose is backed up by real storage. A non-zero value for **B** in Figure 76 on page 702 is an indicator that your output buffer is too large for the amount of available real storage.

LOG ACTIVITY	QUANTITY	/SECOND	/THREAD	/COMMIT
READS SATISFIED-OUTPUT BUFF	211.00	0.12	N/C	0.00
READS SATISFIED-OUTP.BUF(%)	100.00			
READS SATISFIED-ACTIVE LOG	0.00	0.00	N/C	0.00
READS SATISFIED-ACTV.LOG(%)	0.00			
READS SATISFIED-ARCHIVE LOG	0.00	0.00	N/C	0.00
READS SATISFIED-ARCH.LOG(%)	0.00			
TAPE VOLUME CONTENTION WAIT	0.00	0.00	N/C	0.00
READ DELAYED-UNAVAIL.RESOUR	0.00	0.00	N/C	0.00
ARCHIVE LOG READ ALLOCATION	0.00	0.00	N/C	0.00
ARCHIVE LOG WRITE ALLOCAT.	0.00	0.00	N/C	0.00
CONTR.INTERV.OFFLOADED-ARCH	0.00	0.00	N/C	0.00
LOOK-AHEAD MOUNT ATTEMPTED	0.00	0.00	N/C	0.00
LOOK-AHEAD MOUNT SUCCESSFUL	0.00	0.00	N/C	0.00
UNAVAILABLE OUTPUT LOG BUFF <b>A</b>	0.00	0.00	N/C	0.00
OUTPUT LOG BUFFER PAGED IN <b>B</b>	8.00	0.00	N/C	0.10
LOG RECORDS CREATED <b>C</b>	234.00	0.13	N/C	2.85
LOG CI CREATED <b>D</b>	9.00	0.01	N/C	0.11
LOG WRITE I/O REQ (COPY1&2)	96.00	0.05	N/C	1.17
LOG CI WRITTEN (COPY1&2)	96.00	0.05	N/C	1.17
LOG RATE FOR 1 LOG (MB/Sec)	N/A	0.00	N/A	N/A
LOG WRITE SUSPENDED	39.00	0.02	N/C	0.48

Figure 76. Log statistics in the OMEGAMON statistics report

- **Choose fast devices for log data sets:** The devices assigned to the active log data sets must be fast ones. Because of its very high sequential performance, ESS is particularly recommended in environments in which the write activity is high to avoid logging bottlenecks.
- **Avoid device contention:** Place the copy of the bootstrap data set and, if using dual active logging, the copy of the active log data sets, on volumes that are accessible on a path different than that of their primary counterparts.
- **Preformat new active log data sets:** Whenever you allocate new active log data sets, preformat them using the DSNJLOGF utility described in Part 3 of *DB2 Utility Guide and Reference*. This action avoids the overhead of preformatting the log, which normally occurs at unpredictable times.

## Log reads

During a rollback, restart, and database recovery, the performance impact of log reads is evident. DB2 must read from the log and apply changes to the data on disk. Every process that requests a log read has an input buffer dedicated to that process. DB2 searches for log records in the following order:

1. Output buffer
2. Active log data set
3. Archive log data set

If the log records are in the output buffer, DB2 reads the records directly from that buffer. If the log records are in the active or archive log, DB2 moves those log records into the input buffer used by the reading process (such as a recovery job or a rollback).

It is always fastest for DB2 to read the log records from the active log rather than the archive log. Access to archived information can be delayed for a considerable length of time if a unit is unavailable or if a volume mount is required (for example, a tape mount).

**Recommendations:** To improve log read performance:

- **Archive to disk:** If the archive log data set resides on disk, it can be shared by many log readers. In contrast, an archive on tape cannot be shared among log readers. Although it is always best to avoid reading archives altogether, if a process must read the archive, that process is serialized with anyone else who must read the archive tape volume. For example, every rollback that accesses the archive log must wait for any previous rollback work that accesses the same archive tape volume to complete.
- **Avoid device contention on the log data sets:** Place your active log data sets on different volumes and I/O paths to avoid I/O contention in periods of high concurrent log read activity.

When there are multiple concurrent readers of the active log, DB2 can ease contention by assigning some readers to a second copy of the log. Therefore, for performance and error recovery, use dual logging and place the active log data sets on a number of different volumes and I/O paths. Whenever possible, put data sets within a copy or within different copies on different volumes and I/O paths. Ensure that no data sets for the first copy of the log are on the same volume as data sets for the second copy of the log.

- **Stripe active log data sets:** The active logs can be striped using DFSMS. *Striping* is a technique to improve the performance of data sets that are processed sequentially. Striping is achieved by splitting the data set into segments or stripes and spreading those stripes across multiple volumes. Striping can improve the maximum throughput log capacity and is most effective when there are many log records between commits. Striping is useful if you have a high I/O rate for the logs. Striping is needed more with ESCON<sup>®</sup> channels than with the faster FICON<sup>®</sup> channels.

## Log capacity

The capacity that you specify for the active log affects DB2 performance significantly. If you specify a capacity that is too small, DB2 might need to access data in the archive log during rollback, restart, and recovery. Accessing an archive takes a considerable amount of time.

The following subsystem parameters affect the capacity of the active log. In each case, increasing the value you specify for the parameter increases the capacity of the active log. See Part 2 of *DB2 Installation Guide* for more information on updating the active log parameters. The parameters are:

- The NUMBER OF LOGS field on installation panel DSNTIPL controls the number of active log data sets you create.
- The ARCHIVE LOG FREQ field on installation panel DSNTIPL is where you provide an estimate of how often active log data sets are copied to the archive log.
- The UPDATE RATE field on installation panel DSNTIPL is where you provide an estimate of how many database changes (inserts, update, and deletes) you expect per hour.

The DB2 installation CLIST uses UPDATE RATE and ARCHIVE LOG FREQ to calculate the data set size of each active log data set.

- The CHECKPOINT FREQ field on installation panel DSNTIPN specifies the number of log records that DB2 writes between checkpoints or the number of minutes between checkpoints.

Part 2 of *DB2 Installation Guide* goes into more detail on the relationships among these parameters and their effects on operations and performance.

## Total capacity and the number of logs

Determining the configuration of your active log data sets is challenging. That is, you need to have sufficient capacity in the active log to avoid reading the archives, and you need to consider how that total capacity should be divided. Having too many or too few active log data sets has ramifications. This information is summarized in Table 108.

Table 108. The effects of installation options on log data sets. You can modify the size of the data sets in installation job DSNTIJIN

Value for ARCHIVE LOG FREQ	Value for NUMBER OF LOGS	Result
Low	High	Many small data sets. Can cause operational problems when archiving to tape. Checkpoints occur too frequently.
High	Low	Few large data sets. Can result in a shortage of active log data sets.

## Choosing a checkpoint frequency

At least one checkpoint is taken each time DB2 switches to a new active log data set. If the data sets are too small, checkpoints occur too frequently. As a result, database writes are not efficient. As a guideline, provide enough active log space for at least 10 checkpoint intervals.

A checkpoint interval is defined by the number you specify for checkpoint frequency (the CHECKPOINT FREQ subsystem parameter). You can specify the interval in terms of the number of log records that are written between checkpoints or the number of minutes between checkpoints. Avoid taking more than one checkpoint per minute by raising the CHECKPOINT FREQ value so that the checkpoint interval becomes at least one minute during peak periods. You can change CHECKPOINT FREQ dynamically with the SET LOG or SET SYSPARM command.

## Calculating average log record size

One way to determine how much log volume you need is to consider the average size of a log record. As a general estimate, you can start with 200 bytes as the average size. To increase the accuracy of this estimate, get the real size of the log records that are written. To calculate the average size of log records that are written, you need values from the statistics report shown in Figure 76 on page 702: the LOG RECORDS CREATED counter (**C**) and the number of control intervals created in the active log counter (**D**). Use the following formula:

$$\mathbf{D} \times 4 \text{ KB} / \mathbf{C} = \text{avg size of log record}$$

## Increasing the number of active log data sets

You can use the change log inventory utility (DSNJU003) to add more active log data sets to the BSDS. If the BSDS conversion utility (DSNJCNVB) has been run, you can specify up to a maximum of 93 data sets per active log copy instead of 31.

For more information about the change log inventory utility, see *DB2 Utility Guide and Reference*. For more information about the BSDS conversion utility, see Part 2 of *DB2 Installation Guide*.

## Tips on setting the size of active log data sets

You can modify installation job DSNTIJIN to change the size of your active log data set. Some things to consider:

- When you calculate the size of the active log data set, identify the longest unit of work in your application programs. For example, if a batch application program commits only once every 20 minutes, the active log data set should be twice as large as the update information produced during this period by all of the application programs that are running.

Allow time for possible operator interventions, I/O errors, and tape drive shortages if off-loading to tape. DB2 supports up to 20 tape volumes for a single archive log data set. If your archive log data sets are under the control of DFSMSHsm, also consider the Hierarchical Storage Manager recall time, if the data set has been migrated by Hierarchical Storage Manager.

For more information on determining and setting the size of your active log data sets, refer to *DB2 Installation Guide*.

- When archiving to disk, set the primary space quantity and block size for the archive log data set so that you can offload the active log data set without forcing the use of secondary extents in the archive log data set. This action avoids space abends when writing the archive log data set.
- Make the number of records for the active log be divisible by the blocking factor of the archive log (disk or tape).

DB2 always writes complete blocks when it creates the archive log copy of the active log data set. If you make the archive log blocking factor evenly divisible into the number of active log records, DB2 does not have to pad the archive log data set with nulls to fill the block. This action can prevent REPRO errors if you should ever have to REPRO the archive log back into the active log data set, such as during disaster recovery.

To determine the blocking factor of the archive log, divide the value specified on the BLOCK SIZE field of installation panel DSNTIPA by 4096 (that is, BLOCK SIZE / 4096). Then modify the DSNTIJIN installation job so that the number of records in the DEFINE CLUSTER field for the active log data set is a multiple of the blocking factor.

- If you offload to tape, consider adjusting the size of each of your active log data sets to contain the same amount of space as can be stored on a nearly full tape volume. This minimizes tape handling and volume mounts and maximizes the use of the tape resource.

If you change the size of your active log data set to fit on one tape volume, remember that the bootstrap data set is copied to the tape volume along with the copy of the active log data set. Therefore, decrease the size of your active log data set to offset the space that is required on the archive tape for the bootstrap data set.

## Controlling the amount of log data

Certain processes cause a large amount of information to be logged, requiring a large amount of log space.

### Utilities

The utility operations REORG and LOAD LOG(YES) cause all reorganized or loaded data to be logged. For example, if a table space contains 200 million rows of data, this data, along with control information, is logged when this table space is the object of a REORG utility job. If you use REORG with the DELETE option to eliminate old data in a table and run CHECK DATA to delete rows that are no longer valid in dependent tables, you can use LOG(NO) to control log volume.

**Recommendation:** When populating a table with many records or reorganizing table spaces or indexes, specify LOG(NO) and take an inline copy or take a full image copy immediately after the LOAD or REORG.

Specify LOG(YES) when adding less than 1% of the total table space. This creates additional logging, but eliminates the need for a full image copy.

## SQL

The amount of logging performed for applications depends on how much data is changed. Certain SQL statements are quite powerful, making it easy to modify a large amount of data with a single statement. These statements include:

- INSERT with a fullselect
- Mass deletes and mass updates (except for deleting all rows for a table in a segmented table space)
- Data definition statements log an entire database descriptor for which the change was made. For very large DBDs, this can be a significant amount of logging.
- Modification to a row that contains a LOB column defined as LOG YES.

For nonsegmented table spaces, each of these statements results in the logging of all database data that change. For example, if a table contains 200 million rows of data, that data and control information are logged if all of the rows are deleted in a table using the SQL DELETE statement. No intermediate commit points are taken during this operation.

For segmented table spaces, a mass delete results in the logging of the data of the deleted records when any of the following conditions are true:

- The table is the parent table of a referential constraint.
- The table is defined as DATA CAPTURE(CHANGES), which causes additional information to be logged for certain SQL operations.
- A delete trigger is defined on the table.

### Recommendations:

- For **mass delete** operations, consider using segmented table spaces. If segmented table spaces are not an option, create one table per table space and use LOAD REPLACE with no rows in the input data set to empty the entire table space.
- For **inserting a large amount of data**, instead of using an SQL INSERT statement, use the LOAD utility with LOG(NO) and take an inline copy.
- For **updates**, consider your workload when defining a table's columns. The amount of data that is logged for update depends on whether the row contains all fixed-length columns or not. For fixed-length non-compressed rows, changes are logged only from the beginning of the first updated column to the end of the last updated column.

For varying-length rows, data is logged from the first changed byte to the end of the last updated column. (A varying-length row contains one or more varying-length columns.)

To determine your workload type, read-intensive or update-intensive, check the log data rate. Use the formula in "Calculating average log record size" on page 704 to determine the average log size and divide that by 60 to get the average number of log bytes written per second.

- If you log less than 5 MB per second, the workload is read-intensive.
- If you log more than 5 MB per second, the workload is update-intensive.

Table 109 on page 707 summarizes the recommendations for the type of row and type of workload you run.

Table 109. Recommendations for database design to reduce log quantities

	Read-intensive workload	Update-intensive workload
<b>Fixed-length non-compressed rows</b>		Keep frequently updated columns close to each other.
<b>Varying-length rows</b>	Keep varying-length columns at the end of the row to improve read performance.	Keep all frequently updated columns near the end of the row. However, if only fixed-length columns will be updated, keep those columns close to each other at the beginning of the row.

- If you have many data definition statements (CREATE, ALTER, DROP) for a single database, issue them within a single unit of work to avoid logging the changed DBD for each data definition statement. However, be aware that the DBD is locked until the COMMIT is issued.
- Use LOG NO for any LOBs that require frequent updating and for which the tradeoff of nonrecoverability of LOB data from the log is acceptable. (You can still use the RECOVER utility on LOB table spaces to recover control information that ensures physical consistency of the LOB table space.)  
Because LOB table spaces defined as LOG NO are nonrecoverable from the DB2 log, make a recovery plan for that data. For example, if you run batch updates, be sure to take an image copy after the updates are complete.

## Improving disk utilization: space and device utilization

To use disk space more efficiently, you can:

- Change your allocation of data sets to keep data sets within primary allocations. To understand how DB2 extends data sets, see “Allocating and extending data sets.”
- Manage them with the Hierarchical Storage Management functional component (DFSMSHsm) of DFSMS, as described in “Managing DB2 data sets with DFSMSHsm” on page 35.
- Compress your data, as described in “Compressing your data” on page 708.
- Choose a page size that gives you good disk use and I/O performance characteristics, as described in “Choosing a page size” on page 45.
- Evaluate the need for and characteristics of your indexes, as described in “Evaluating your indexes” on page 711.

To manage the use of disk, you can use RMF to monitor how your devices are used. Watch for usage rates that are higher than 30% to 35%, and for disk devices with high activity rates. Log devices can have more than 50% utilization without performance problems.

## Allocating and extending data sets

Primary and secondary allocation sizes are the main factors that affect the amount of disk space that DB2 uses.

In general, the primary allocation must be large enough to handle the storage needs that you anticipate. The secondary allocation must be large enough for your applications to continue operating until the data set is reorganized.

If the secondary allocation space is too small, the data set might have to be extended more times to satisfy those activities that need a large space.

IFCID 0258 allows you to monitor data set extension activities by providing information, such as the primary allocation quantity, maximum data set size, high allocated space before and after extension activity, number of extents before and after the extend, maximum volumes of a VSAM data set, and number of volumes before and after the extend. Access IFCID 0258 in Statistics Class 3 (SC03) through an IFI READA request.

See Chapter 3, “Creating storage groups and managing DB2 data sets,” on page 27 for more information about extending data sets.

## Compressing your data

You can compress data in a table space or partition by specifying `COMPRESS YES` on `CREATE TABLESPACE` or `ALTER TABLESPACE` and then running the `LOAD` or `REORG` utility. When you compress data, bit strings that occur frequently are replaced by shorter strings. Information about the mapping of bit strings to their replacements is stored in a *compression dictionary*. Computer processing is required to compress data before it is stored and to decompress the data when it is retrieved from storage. In many cases, using the `COMPRESS` clause can significantly reduce the amount of disk space needed to store data, but the compression ratio you achieve depends on the characteristics of your data.

With compressed data, you might see some of the following performance benefits, depending on the SQL work load and the amount of compression:

- Higher buffer pool hit ratios
- Fewer I/Os
- Fewer getpage operations

As described under “Determining the effectiveness of compression” on page 710, you can use the `DSN1COMP` utility to determine how well your data will compress. Data in a LOB table space or a table space that is defined in a `TEMP` database (a table space for declared temporary tables) cannot be compressed.

### Deciding whether to compress

Consider these points before compressing data:

- Data row size  
DB2 compresses the data of one record at a time. (The prefix of the record is not compressed.) As row lengths become shorter, compression yields diminishing returns because 8 bytes of overhead are required to store each record in a data page. On the other hand, when row lengths are very long, compression of the data portion of the row may yield little or no reduction in data set size because DB2 rows cannot span data pages. In the case of very long rows, using a larger page size can enhance the benefits of compression, especially if the data is accessed primarily in a sequential mode.  
If compressing the record produces a result that is no shorter than the original, DB2 does not compress the record.
- Table space size  
Compression can work very well for large table spaces. With small table spaces, the size of the compression dictionary (64 KB) can offset the space savings that compression provides.
- Processing costs

Compressing data can result in a higher processor cost, depending on the SQL work load. However, if you use IBM's synchronous data compression hardware, processor time is significantly less than if you use just the DB2-provided software simulation or an edit or field procedure to compress the data.

Decompressing a row of data costs significantly less than compressing that same row. This rule applies regardless of whether the compression uses the synchronous data compression hardware or the software simulation that is built into DB2.

The data access path that DB2 uses affects the processor cost for data compression. In general, the relative overhead of compression is higher for table space scans and is less costlier for index access.

- I/O costs

When rows are accessed sequentially, fewer I/Os might be required to access data that is stored in a compressed table space. However, there is a tradeoff between reduced I/O resource consumption and the extra processor cost for decoding the data.

- If random I/O is necessary to access the data, the number of I/Os will not decrease significantly, unless the associated buffer pool is larger than the table and the other applications require little concurrent buffer pool usage.
- Some types of data compress better than others. Data that contains hexadecimal characters or strings that occur with high frequency compresses quite well, while data that contains random byte frequencies might not compress at all. For example, textual and decimal data tends to compress well because certain byte strings occur frequently.

- Data patterns

The frequency of patterns in the data determines the compression savings. Data with many repeated strings (such as state and city names or numbers with sequences of zeros) results in good compression savings.

- Table space design

Each table space or partition that contains compressed data has a compression dictionary, which is built by using the LOAD utility with the REPLACE or RESUME NO options or the REORG TABLESPACE utility without the KEEPDICTIONARY option for either utility. A dictionary is also built for LOAD RESUME YES without KEEPDICTIONARY if the table space has no rows. The dictionary contains a fixed number of entries, usually 4096, and resides with the data. The dictionary content is based on the data at the time it was built, and does not change unless the dictionary is rebuilt or recovered, or compression is disabled with ALTER TABLESPACE.

If you use LOAD to build the compression dictionary, the first  $n$  rows loaded in the table space determine the contents of the dictionary. The value of  $n$  is determined by how much your data can be compressed.

If you have a table space with more than one table and the data used to build the dictionary comes from only one or a few of those tables, the data compression might not be optimal for the remaining tables. Therefore, put a table you want to compress into a table space by itself, or into a table space that only contains tables with similar kinds of data.

REORG uses a sampling technique to build the dictionary. This technique uses the first  $n$  rows from the table space and then continues to sample rows for the remainder of the UNLOAD phase. In most cases, this sampling technique produces a better dictionary than does LOAD, and using REORG might produce better results for table spaces that contain tables with dissimilar kinds of data.

For more information about using LOAD or REORG to create a compression dictionary, see Part 2 of *DB2 Utility Guide and Reference*.

- Existing exit routines

An exit routine is executed before compressing or after decompressing, so you can use DB2 data compression with your existing exit routines. However, do not use DB2 data compression in conjunction with DSN8HUFF. (DSN8HUFF is a sample edit routine that compresses data using the Huffman algorithm, which is provided with DB2). This adds little additional compression at the cost of significant extra CPU processing.

- Logging effects

If a data row is compressed, all data that is logged because of SQL changes to that data is compressed. Thus, you can expect less logging for insertions and deletions; the amount of logging for updates varies. Applications that are sensitive to log-related resources can experience some benefit with compressed data.

External routines that read the DB2 log cannot interpret compressed data without access to the compression dictionary that was in effect when the data was compressed. However, using IFCID 306, you can cause DB2 to write log records of compressed data in decompressed format. You can retrieve those decompressed records by using the IFI function READS.

- Distributed data

DB2 decompresses data before transmitting it to VTAM.

## Tuning recommendation

In some cases, using compressed data results in an increase in the number of getpages, lock requests, and synchronous read I/Os. Sometimes, updated compressed rows cannot fit in the home page, and they must be stored in the overflow page. This can cause additional getpage and lock requests. If a page contains compressed fixed-length rows with no free space, an updated row probably has to be stored in the overflow page.

To avoid the potential problem of more getpage and lock requests, add more free space within the page. Start with 10% additional free space and adjust further, as needed. If, for example, 10% free space was used without compression, then start with 20% free space with compression for most cases. This recommendation is especially important for data that is heavily updated.

## Determining the effectiveness of compression

Before compressing data, you can use the DSN1COMP stand-alone utility to estimate how well it will compress. After data is compressed, use compression reports and catalog statistics to determine how effectively it was compressed.

- DSN1COMP

Use stand-alone utility DSN1COMP to find out how much space it will save and how much processing it will require to compress your data. Run DSN1COMP on a data set that contains a table space, a table space partition, or an image copy. DSN1COMP generates a report of compression statistics but does not compress the data. For instructions on using DSN1COMP, see Part 3 of *DB2 Utility Guide and Reference*.

- Compression reports

Examine the compression reports after you use REORG or LOAD to build the compression dictionary and compress the data. Both utilities issue a report message (DSNU234I or DSNU244I). This report message gives information about

how well the data is compressed and how much space is saved. (REORG with the KEEPDICTIONARY option does not produce the report.)

- Catalog statistics

In addition to the compression reports, these columns in the catalog tables contain information about data compression:

- PAGESAVE column of the SYSIBM.SYSTABLEPART tells you the percentage of pages that are saved by compressing the data.
- PCTROWCOMP columns of SYSIBM.SYSTABLES and SYSIBM.SYSTABSTATS tells you the percentage of the rows that were compressed in the table or partition the last time RUNSTATS was run. Use the RUNSTATS utility to update these catalog columns.

## Evaluating your indexes

In many cases, you might be able to eliminate indexes that are no longer necessary or change the characteristics of an index to reduce disk usage. In addition to disk space savings, dropping unneeded indexes improves performance because of savings in index maintenance.

- “Eliminating unnecessary partitioning indexes”
- “Dropping indexes created to avoid sorts”
- “Using nonpadded indexes” on page 712

### Eliminating unnecessary partitioning indexes

Before DB2 Version 8, when you created a partitioned table space, you needed to define a partitioning index on the table to specify the partitioning keys and the limit key values. This is called index-controlled partitioning. The partitioning index required as many data sets as the partitioned table space. Dropping partitioning indexes that are used solely to partition the data and not to access it and converting to table-controlled partitioning eliminates the disk space that is required for the partitioning index data sets. Likewise, creating new table spaces with table-controlled partitioning, in which the partitioning key and limit keys are specified in the CREATE TABLESPACE statement and not the CREATE INDEX statement, eliminates the need for any partitioning index data sets.

For more information about table-controlled partitioning, see “Implementing table-controlled partitioning” on page 51.

### Dropping indexes created to avoid sorts

Drop any indexes that are defined only to avoid a sort for queries with an ORDER BY if DB2 can perform a backward scan of another index to avoid the sort. Prior to DB2 Version 8, you might have had an ascending index and created a descending version of the index for the sole purpose of avoiding a sort. For example, consider the following query:

```
SELECT C1, C2, C3 FROM T
   WHERE C1 > 1
   ORDER BY C1 DESC;
```

Having an ascending index on C1 would not have prevented a sort to order the data. To avoid the sort, you needed a descending index on C1. Beginning in Version 8, DB2 can scan an index either forwards or backwards, which can eliminate the need to have indexes with the same columns but with different ascending and descending characteristics.

For DB2 to be able to scan an index backwards, the index must be defined on the same columns as the ORDER BY and the ordering must be exactly opposite of what is requested in the ORDER BY. For example, if an index is defined as C1 DESC, C2 ASC, then DB2 can use:

- A forward scan of the index for ORDER BY C1 DESC, C2 ASC
- A backward scan of the index for ORDER BY C1 ASC, C2 DESC

However, DB2 would need to sort for either of these two ORDER BY clauses:

- ORDER BY C1 ASC, C2 ASC
- ORDER BY C1 DESC, C2 DESC

### Using nonpadded indexes

When you define an index as NOT PADDED, the varying-length columns in the index are not padded to their maximum length. If the index contains at least one varying-length column, the length information is stored with the key. Thus, you can save disk space by using nonpadded indexes instead of padded indexes. The amount of savings depends on the number of varying-length columns in the index and the actual length of the columns in those indexes versus their maximum lengths.

For example, assume that you have an index key that is defined on a VARCHAR(128) column and the actual length of the key is 8 bytes. An index that is defined as NOT PADDED would require approximately 9 times less storage than an index that is defined as PADDED, as shown by the following calculation:

$$(128 + 4) / (8 + 2 + 4) = 9$$

---

## Improving real storage utilization

This section provides specific information for both real and virtual storage tuning. With DB2, the amount of real storage often needs to be close to the amount of virtual storage. For a general overview of some factors relating to virtual storage planning, see Part 2 of *DB2 Installation Guide*.

Use the following techniques to reduce your use of real storage:

**Minimize storage needed for locks:** You can save real storage by using the LOCKSIZE TABLESPACE option on the CREATE TABLESPACE statements for large tables, which affects concurrency. This option is most practical when concurrent read activity without a write intent, or a single write process, is used.

You can use LOCKSIZE PAGE or LOCKSIZE ROW more efficiently when you commit your data more frequently or when you use cursor stability with CURRENTDATA NO. For more information on specifying LOCKSIZE TABLESPACE, see “Monitoring of DB2 locking” on page 873.

**Reduce the number of open data sets:** You can reduce the number of open data sets by:

- Including multiple tables in segmented table spaces
- Using fewer indexes
- Reducing the value you use for DSMAX

**Improve the performance for sorting:** The highest performance sort is the sort that is avoided. However, because some sorting cannot be avoided, make sorting as efficient as possible. For example, assign the buffer pool for your work file table spaces in database DSNDB07, which are used in sorting, to a buffer pool other than BP0, such as to BP07. For more information about how to:

- Make sorting more efficient, see “Improving the performance of sort processing” on page 691.
- Reduce the need to sort, see “Overview of index access” on page 952.
- Determine the amount of sort activity, see “Determining sort activity” on page 977.

#  
#  
#  
#  
#  
#  
#

**Release unused thread storage:** If you experience virtual storage constraints due to thread storage, consider having DB2 periodically free unused thread storage. To release unused storage threads, specify YES for the CONTRACT THREAD STG field on installation panel DSNTIPE. However, you should use this option only when your DB2 subsystem has many long-running threads and your virtual storage is constrained. To determine the level of thread storage on your subsystem, see IFCID 0225 or QW0225AL in statistics trace class 6.

### Recommendation:

**Provide for pooled threads:** As described in “Using threads in INACTIVE MODE for DRDA-only connections” on page 742, distributed threads that are allowed to be pooled use less storage than inactive database access threads. On a per connection basis, pooled threads use even less storage than inactive database access threads. Inactive database access threads require around 70 KB of storage in the *ssnmDBM1* address space per thread, and each thread must be paired with a connection. In contrast, pooled threads are not directly linked with connections. While each pooled thread requires 200 KB in the *ssnmDBM1* address space, each thread does not require a corresponding connection, and each connection uses only about 8 KB total in the DDF address space and the extended common storage area.

**Ensure ECSA size is adequate:** The extended common service area (ECSA) is a system area that DB2 shares with other programs. Shortage of ECSA at the system level leads to use of the common service area.

DB2 places some load modules and data into the common service area. These modules require primary addressability to any address space, including the application’s address space. Some control blocks are obtained from common storage and require global addressability. For more information, see *DB2 Installation Guide*.

**Ensure EDM pool space is being used efficiently:** Monitor your use of EDM pool storage using DB2 statistics and see “Tips for managing EDM storage” on page 688.

**Use less buffer pool storage:** Using fewer and smaller buffer pools reduces the amount of real storage space DB2 requires. Buffer pool size can also affect the number of I/O operations performed; the smaller the buffer pool, the more I/O operations needed. Also, some SQL operations, such as joins, can create a result row that will not fit on a 4-KB page. For information about this, see “Making buffer pools large enough for the workload” on page 660.

**Control maximum number of LE tokens:** When a function is executed and needs to access storage used by Language Environment, it obtains an LE token from the pool. Language Environment provides a common run-time environment for programming languages. A token is taken each time one of the following functions is executed:

- Log functions (LOG, LN, LOG10)

- Trigonometry functions (ACOS, ASIN, ATAN, ATANH, ATAN2, COS, COSH, SIN, SINH, TAN, and TANH)
- EXP
- POWER®
- RAND
- ADD\_MONTHS
- LAST\_DAY
- NEXT\_DAY
- ROUND\_TIMESTAMP
- TRUNC\_TIMESTAMP
- LOWER
- TRANSLATE
- UPPER

On completion of the call to LE, the token is returned to the pool. The MAXIMUM LE TOKENS (LEMAX) field on installation panel DSNTIP7 controls the maximum number of LE tokens that are active at any time. The LEMAX default value is 20 with a range of 0 to 50. If the value is zero, no tokens are available. If a large number of functions are executing at the same time, all the token may be used. Thus, if a statement needs a token and none is available, the statement is queued. If the statistics trace QLENTRDY is very large, indicating a delay for an application because an LE token is not immediately available, the LEMAX may be too small. If the statistics trace QLETIMEW for cumulative time spent is very large, the LEMAX may be too small. Increase the number of tokens for the MAXIMUM LE TOKENS field on installation panel DSNTIP7.

---

## Performance and storage

To meet the diverse needs of application data, a range of storage options is available, each with different access speeds, capacities, and costs per megabyte. This broad selection of storage alternatives supports requirements for enhanced performance and expanded online storage options, providing more options in terms of performance and price.

The levels in the DB2 storage hierarchy include real storage, storage controller cache, disk, and auxiliary storage. Increasing the I/O rate and decreasing the frequency of disk access to move data between real storage and storage devices is key to good performance.

### Real storage

Real storage refers to the processor storage where program instructions reside while they are executing. It also refers to where data is held, for example, data in DB2 buffer pools that has not been paged out to auxiliary storage, the EDM pools, and the sort pool. To be used, data must either reside or be brought into processor storage or processor special registers. The maximum amount of real storage that one DB2 subsystem can use is the real storage of the processor, although other limitations may be encountered first.

DB2's large capacity for buffers in real storage and its write avoidance and sequential access techniques allow applications to avoid a substantial amount of read and write I/O, combining single accesses into sequential access, so that the disk devices are used more effectively.

## Storage devices

A wide range of storage devices exist. This section presents information about newer storage servers, such as the IBM Enterprise Storage Server (ESS), and older storage devices types, such as RVA and 3390.

### Planning considerations for storage device types

Some storage device types are more optimal for certain types of applications. When choosing storage devices types, consider the following hardware characteristics that affect performance:

- The size of the cache
- The number of channels and type of channels that are attached and online to a group of logical volumes
- The size of non-volatile storage (NVS), if deferred write performance is a problem
- Disk arrays
- Advanced features such as Parallel Access Volumes (PAV), Multiple Allegiance, and Flashcopy

### Storage servers

An I/O subsystem typically consists of many storage disks, which are housed in storage servers, for example, the IBM Enterprise Storage Server (ESS). Storage servers provide increased functionality and performance over that of Just a Bunch of Disks (JBOD) technology.

Cache is one of the additional functions. Cache acts as a secondary buffer as data is moved between real storage and disk. Storing the same data in processor storage and the cache is not useful. To be useful, the cache must be significantly larger than the buffers in real storage, store different data, or provide another performance advantage. ESS and many other new storage servers use large caches and always prestage the data in the cache. You do not need to actively manage the cache in the newer storage servers as you must do with older storage device types.

With ESS and other new storage servers, disk performance does not generally affect sequential I/O performance. The measure of disk speed in terms of RPM (revolutions per minute) is relevant only if the cache hit ratio is low and the I/O rate is very high. If the I/O rate per disk is proportional to the disk size, small disks perform better than large disks. Large disks are very efficient for storing infrequently accessed data. As with cache, spreading the data across more disks is always better.

**Storage servers and channel subsystems:** The channels can be more of a bottleneck than any other component of the I/O subsystem with ESS and other newer storage servers. The degree of I/O parallelism that can be sustained efficiently is largely a function of the number of channels. In general, more channels mean better performance.

However, not all channels are alike. ESCON channels, which used to be the predominant channel type, have a maximum instantaneous data transfer rate of approximately 17 MB per second. FICON channels currently have a speed of 200 MB per second. FICON is the z/OS equivalent of Open Systems Fibre Channel Protocol (FCP). The FICON speed is bidirectional, theoretically allowing 200 MB per second to be sustained in both directions. Channel adaptors in the host processor and the storage server limit the actual speed. The FICON channels in the zSeries 900 servers are faster than those in the prior processors.

| **Storage servers and advanced features:** ESS offers many advanced features to  
# further boost performance. Other storage servers may offer similar function.

# *Extended Address Volumes (EAV):* With extended address volumes (EAV), you can  
# store more data that is in VSAM data sets on a single volume than you can store  
# on non-extended address volumes. However, the maximum amount of data that  
# you can store in a single DB2 table space or index space is the same for extended  
# and non-extended address volumes. The same DB2 data sets might use more space  
# on extended address volumes than on non-extended address volumes because  
# space allocations in the extended area are multiples of 21 cylinders on extended  
# address volumes.

| *Parallel Access Volumes (PAV):* The parallel access volumes (PAV) feature allows  
| multiple concurrent I/Os on a given device when the I/O requests originate from  
| the same system. PAVs make storing multiple partitions on the same volume with  
| almost no loss of performance possible. In older disk subsystems, if more than one  
| partition is placed on the same volume (intentionally or otherwise), attempts to  
| read the partitions result in contention, which shows up as I/O subsystem queue  
| (IOSQ) time. Without PAVs, poor placement of a single data set can almost double  
| the elapsed time of a parallel query.

| *Multiple Allegiance:* The multiple allegiance feature allows multiple active  
| concurrent I/Os on a given device when the I/O requests originate from different  
| systems. PAVs and multiple allegiance dramatically improve I/O performance for  
| parallel work on the same volume by nearly eliminating IOSQ or PEND time and  
| drastically lowering elapsed time for transactions and queries.

| *Flashcopy:* The Flashcopy feature provides for fast copying of full volumes. After  
| an initialization period is complete, the logical copy is considered complete but the  
| physical movement of the data is deferred.

| *Peer-to-Peer Remote Copy (PPRC):* The PPRC and PPRC XD (Extended Distance)  
| provides a faster method for recovering DB2 subsystems at a remote site in the  
| event of a disaster at the local site. For more information about using PPRC and  
| PPRC XD, see “Backing up with RVA storage control or Enterprise Storage Server”  
| on page 495.

## **Older storage device types**

| Unlike cache on the newer storage servers, older devices have much smaller  
| caches. The small caches require some user management. You can use DFSMS to  
| provide dynamic management of the cache storage.

**The amount of storage controller cache:** The amount of cache to use for DB2  
depends primarily on the relative importance of price and performance. It is not  
often effective to have large memory resources for both DB2 buffers and storage  
controller cache. If you decide to concentrate on the storage controller cache for  
performance gains, then use the maximum available cache size. If the cache is  
substantially larger than the DB2 buffer pools, DB2 can make effective use of the  
cache to reduce I/O times for random I/O. For sequential I/O, the improvement  
the cache provides is generally small.

**Sort work files:** Sort work files can have a large number of concurrent processes  
that can overload a storage controller with a small cache and thereby degrade  
system performance. For example, one large sort could use 100 sequential files,  
needing 60 MB of storage. Unless the cache sizes are large, you might need to

specify BYPASS on installation panel DSNTIPE or use DFSMS controls to prevent the use of the cache during sort processing. Separate units for sort work can give better performance.

---

## z/OS performance options for DB2

You can set z/OS performance options for DB2 using z/OS workload management (WLM). With workload management, you define performance goals and assign a business importance to each goal. You define the goals for work in business terms, and the system decides how much resource, such as CPU and storage, should be given to the work to meet its goal.

WLM controls the dispatching priority based on the goals you supply. WLM raises or lowers the priority as needed to meet the specified goal. Thus, you do not need to fine-tune the exact priorities of every piece of work in the system and can focus instead on business objectives.

The three kinds of goals are:

- *Response time.* How quickly you want the work to be processed.
- *Execution velocity.* How fast the work should be run when ready, without being delayed for processor, storage, I/O access, and queue delay.
- *Discretionary.* A category for low priority work for which there are no performance goals.

Response times are appropriate goals for “end user” applications, such as QMF users running under the TSO address space goals, or users of CICS using the CICS work load goals. You can also set response time goals for distributed users, as described in “Using z/OS workload management to set performance objectives” on page 745.

For DB2 address spaces, velocity goals are more appropriate. A small amount of the work done in DB2 is counted toward this velocity goal. Most of the work done in DB2 applies to the end user goal.

This section describes ways to set performance options for DB2 address spaces:

- “Determining z/OS workload management velocity goals”
- “How DB2 assigns I/O priorities” on page 718

For information about WLM and defining goals through the service definition, see *z/OS MVS Planning: Workload Management*.

## Determining z/OS workload management velocity goals

This section tells you how to set velocity goals when you are managing CICS, IMS, or DDF according to WLM response-time goals and you are set up to use WLM-established stored procedures address spaces. Use following service classes for velocity:

- The default SYSSTC service class for:
  - VTAM and TCP/IP address spaces
  - IRLM address space (IRLMPROC)

**Important:** The VTAM, TCP/IP, and IRLM address spaces must always have a higher dispatching priority than all of the DBMS address spaces, their attached address spaces, and their subordinate address spaces. Do not allow WLM to reduce the priority of VTAM, TCP/IP, or IRLM to or below that of the other DBMS address spaces.

- A high velocity goal for a service class whose name you define, such as PRODREGN, for the following:
  - DB2 (all address spaces, except for the DB2-established stored procedures address space)
  - Important:** The DB2-started address spaces, including *ssnmDBM1*, *ssnmMSTR*, and *ssnmDIST*, must have the same service class.
  - CICS (all region types)
  - IMS (all region types except BMPs)

The velocity goals for CICS and IMS regions are only important during startup or restart. After transactions begin running, WLM ignores the CICS or IMS velocity goals and assigns priorities based on the goals of the transactions that are running in the regions. A high velocity goal is good for ensuring that startups and restarts are performed as quickly as possible.

Similarly, when you set response time goals for DDF threads or for stored procedures in a WLM-established address space, the only work controlled by the DDF or stored procedure velocity goals are the DB2 service tasks (work performed for DB2 that cannot be attributed to a single user). The user work runs under separate goals for the enclave, as described in “Using z/OS workload management to set performance objectives” on page 745.

For the DB2-established stored procedures address space, use a velocity goal that reflects the requirements of the stored procedures in comparison to other application work. Depending on what type of distributed work you do, this might be equal to or lower than the goal for PRODREGN.

IMS BMPs can be treated along with other batch jobs or given a velocity goal, depending on what business and functional requirements you have at your site.

Consider the following other workload management considerations:

- IRLM must be eligible for the SYSSTC service class. To make IRLM eligible for SYSSTC, do not classify IRLM to one of your own service classes.
- If you need to change a goal, change the velocity between 5 and 10%. Velocity goals do not translate directly to priority. Higher velocity tends to have higher priority, but this is not always the case.
- WLM can assign I/O priority (based on I/O delays) separately from processor priority.  
See “How DB2 assigns I/O priorities” for information about how read and write I/O priorities are determined.
- z/OS workload management dynamically manages storage isolation to meet the goals you set.

## How DB2 assigns I/O priorities

DB2 informs z/OS about which address space’s priority is to be associated with a particular I/O request. Then WLM handles the management of the request from there. Table 110 describes to which enclave or address space DB2 associates I/O read requests.

Table 110. How read I/O priority is determined

Request type	Synchronous reads	Prefetch reads
Local	Application’s address space	Application’s address space

Table 110. How read I/O priority is determined (continued)

Request type	Synchronous reads	Prefetch reads
DDF or Sysplex query parallelism (assistant only)	Enclave priority	Enclave priority

Table 111 describes to which enclave or address space DB2 associates I/O write requests.

Table 111. How write I/O priority is determined

Request type	Synchronous writes	Deferred writes
Local	Application's address space	ssnmDBM1 address space
DDF	DDF address space	ssnmDBM1 address space

## IBM System z9 Integrated Information Processor usage monitoring

The System z9<sup>®</sup> Integrated Information Processor (IBM zIIP) is a specialty engine that runs eligible database workloads. The IBM zIIP is designed to help free-up general computing capacity and lower software costs for select DB2 workloads such as business intelligence (BI), enterprise resource planning (ERP), and customer relationship management (CRM) on the mainframe. The IBM zIIP is a high-speed engine that better enables you to centralize your data on the mainframe, breaking down traditional walls between transactional data stores on the mainframe and the BI, ERP, and CRM applications that run on distributed computers.

With the zIIP capability, the System z9 mainframe helps minimize the need to maintain duplicate copies of data and provides better security between applications and data. New accounting fields and improvements to RMF also permit you to project the amount of CPU time eligible to run on an IBM zIIP without installing any IBM zIIPs.

Portions of DDF server thread processing, utility processing, and star join parallel child processing can be directed to an IBM zIIP. The amount of general-purpose processor savings will vary based on the amount of workload executed by the zIIP, among other factors.

### *Processes that can use IBM zIIPs:*

- DDF server threads that process SQL requests from applications that access DB2 by TCP/IP.
- Parallel child processes. A portion of each child process executes under a dependent enclave SRB if it processes on behalf of an application that DB2 from an allied address space, or under an independent enclave SRB if the processing is performed on behalf of a remote application that accesses DB2 by TCP/IP. The enclave priority is inherited from the invoking allied address space for a dependent enclave or from the main DDF server thread enclave classification for an independent enclave.
- Utility index build and maintenance processes for the LOAD, REORG, and REBUILD INDEX utilities. A portion of the index build/maintenance runs under a dependent enclave SRB.

### *Processes that cannot use IBM zIIPs:*

# External stored procedures

# Triggers or functions that join the enclave SRB using a TCB

# DDF server threads that use SNA to connect to DB2

# *Using trace to monitor zIIP usage:* The DB2 accounting trace records provide information related to application programs including processor resources consumed by the application. Accumulated zIIP CPU time is not accumulated in the existing class 1, class 2, and class 7 accounting fields.

# *Using RMF to monitor zIIP usage:* The Resource Measurement Facility (RMF) provides information on zIIP usage to help you identify when to consider purchasing a zIIP or adding more zIIPs. Also, SMF Type 72 records contain information on zIIP usage and fields in SMF Type 30 records let you know how much time is spent on zIIPs, as well as how much time was spent executing zIIP eligible work on standard processors. For more details about the new RMF support for zIIPs, refer to the z/OS MVS Initialization and Tuning Reference.

# *Considerations for data sharing:* In a data sharing environment, where DB2 Version 8 is part of the data sharing group, DRDA work running in the Version 7 member cannot run on the zIIP. Work running on the Version 8 member will run on the zIIP. IBM zIIP capacity is not included in the sysplex routing information returned to DB2 Connect Server. Accordingly, members without zIIPs might be favored over members with zIIPs.

---

## Controlling resource usage

DB2 includes a resource limit facility (governor), which helps control the use of DB2 resources. Other facilities, such as z/OS workload management (WLM), and the QMF governor, complement the DB2 governor. Because DB2 is integrated with the operating system and transaction subsystems, control definitions are used in most cases. This integration simplifies the task of controlling resources for the user.

Each of the objectives presented in Table 112 is matched with a control facility that you can use to achieve the objective.

*Table 112. Controlling the use of resources*

Objective	How to accomplish it	Where it is described
Prioritizing resources	z/OS workload management	"Prioritizing resources" on page 721, "z/OS performance options for DB2" on page 717 and "Using z/OS workload management to set performance objectives" on page 745
Limiting resources for each job	Time limit on job or step (through z/OS system settings or JCL)	"Limiting resources for each job" on page 721
Limiting resources for TSO sessions	Time limit for TSO logon	"Limiting resources for TSO sessions" on page 721
Limiting resources for IMS and CICS	IMS and CICS controls	"Limiting resources for IMS and CICS" on page 722
Limiting resources for a stored procedure	ASUTIME column of SYSIBM.SYSROUTINES catalog table.	"Limiting resources for a stored procedure" on page 722

Table 112. Controlling the use of resources (continued)

Objective	How to accomplish it	Where it is described
Limiting dynamic statement execution time	QMF governor and DB2 resource limit facility	“Resource limit facility (governor)” on page 722
Reducing locking contention	DB2 locking parameters, DISPLAY DB LOCKS, lock trace data, database design	Chapter 31, “Improving concurrency,” on page 813
Evaluating long-term resource usage	Accounting trace data, OMEGAMON reports	“OMEGAMON” on page 1202
Predicting resource consumption	DB2 EXPLAIN statement, Visual Explain, DB2 Estimator, predictive governing capability	Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 and “Predictive governing” on page 730
Controlling use of parallelism	DB2 resource limit facility, SET CURRENT DEGREE statement	“Disabling query parallelism” on page 1005

## Prioritizing resources

z/OS workload management (WLM) controls the execution of DB2 work based on the priorities that you set. See *z/OS MVS Initialization and Tuning Guide* for more information about setting priorities on work.

In CICS environments without the Open Transaction Environment (OTE) function, DB2 work and application work is performed in different tasks. DB2 work is managed at the subtask level. With CICS OTE, DB2 work and application work can be performed in the same task. You can manage the DB2 subtasks through various settings in the CICS resource definition online (RDO). Without OTE, some overhead is incurred for each task switch. Therefore, depending on the SQL activity, CICS OTE can improve performance significantly because of the reduction of needing to switch tasks.

In other environments such as batch and TSO, which typically have a single task requesting DB2 services, the task-level processor dispatching priority is irrelevant. Access to processor and I/O resources for synchronous portions of the request is governed solely by WLM.

## Limiting resources for each job

Because most of the resource usage occurs within the standard job structure, you can control processor usage by changing the TIME parameter for the job or step. The time limit applies even when DB2 is sorting the result rows. If the time limit is exceeded, the job step abends, and any uncommitted work is rolled back. If you want to control the total amount of resources used, rather than the amount used by a single query, then use this control.

Refer to the *z/OS MVS JCL User's Guide* for more information on setting resource limits.

## Limiting resources for TSO sessions

Time limits can apply to either TSO sessions or to batch jobs. Your z/OS system programmer can provide a time parameter on the logon procedure or on a job statement in the logon preprompt exit. This time limit is for the session, rather

than for an individual query or a single program. If you want to control the amount of resources used for an entire TSO session, rather than the amount used by a single query, then use this control.

You can find more information about setting the resource limit for a TSO session in these manuals:

- *z/OS TSO/E Programming Guide*
- *z/OS TSO/E Customization*

## Limiting resources for IMS and CICS

You can use various IMS commands (including PROCLIM, or processing limit) to limit the resources used by a transaction, a class, a program, a database, or a subsystem. For more information, see *IMS Command Reference*.

For a detailed description of performance factors in a CICS system, see *CICS Transaction Server for z/OS Performance Guide*.

## Limiting resources for a stored procedure

DB2 stored procedures are especially designed for high volume online transactions. To establish limits for stored procedures, you can:

- Set a processor limit for each stored procedure, by updating the ASUTIME column of the SYSIBM.SYSROUTINES catalog table. This limit allows DB2 to cancel procedures that loop.
- Set a limit for the maximum number of times that a procedure can terminate abnormally, by specifying a value in the MAX ABEND COUNT field on installation panel DSNTIPX. This limit is a system limit that applies to all stored procedures and prevents a problem procedure from overwhelming the system with abend dump processing.
- Set a limit for the maximum number of times that a specific procedure can terminate abnormally, by specifying the STOP AFTER FAILURES option on the ALTER or CREATE PROCEDURE statement. This limit allows you to override the system limit specified in MAX ABEND COUNT and specify different limits for different procedures.

For information about controlling the amount of storage used by stored procedures address spaces, see “Controlling address space storage” on page 1023.

---

## Resource limit facility (governor)

The DB2 resource limit facility (governor) lets you perform the following activities:

- Set warning and error thresholds for dynamic SELECT, INSERT, UPDATE, or DELETE statements. The resource limit facility can inform users (via your application programs) that a processing limit might be exceeded for a particular dynamic SQL statement. This is called *predictive governing*.
- Stop dynamic SQL statements (SELECT, INSERT, UPDATE, or DELETE) that exceed the processor limit that you have specified. This is sometimes called *reactive governing*. The resource limit facility does not control static SQL statements whether or not they are executed locally or remotely.
- Restrict bind and rebind activities to avoid performance impacts on production data.
- Restrict particular parallelism modes for dynamic queries.

#  
#

**Note:** No limits apply to primary or secondary authorization IDs with installation SYSADM or installation SYSOPR authority.

**Data sharing:** See *DB2 Data Sharing: Planning and Administration* for information about special considerations for using the resource limit facility in a data sharing group.

This section includes the following topics:

- “Using resource limit tables (RLSTs)”
- “Governing dynamic queries” on page 728
- “Restricting bind operations” on page 733
- “Restricting parallelism modes” on page 733

## Using resource limit tables (RLSTs)

Use one or more *resource limit specification tables* (RLSTs) to give governing information to DB2.

If you are a system administrator, you must determine how your location intends to use the governor and create several local procedures. Establish a procedure for creating and maintaining your RLSTs, and for establishing limits for any newly written applications. Develop procedures for console operators, such as switching RLSTs every day at a certain time.

### Creating an RLST

Resource limit specification tables can reside in any database; however, because a database has some special attributes while the resource limit facility is active, it is best to put RLSTs in their own database.

When you install DB2, installation job DSNTIJSJG creates a database, table space, table, and descending index for the resource limit specification. You can tailor those statements. For more information about job DSNTIJSJG, see Part 2 of *DB2 Installation Guide*.

To create a new resource limit specification table, use the following statements, also included in installation job DSNTIJSJG. You must have sufficient authority to define objects in the DSNRLST database and to specify *authid*, which is the authorization ID specified on field RESOURCE AUTHID of installation panel DSNTIPP.

**Creating the table:** Use the following statement:

```
| CREATE TABLE authid.DSNRLSTxx
|         (AUTHID  VARCHAR(128)  NOT NULL WITH DEFAULT,
|          PLANNAM CHAR(8)      NOT NULL WITH DEFAULT,
|          ASUTIME INTEGER,
|          -----3-column format -----
|          LUNAME  CHAR(8)      NOT NULL WITH DEFAULT,
|          -----4-column format -----
|          RLFFUNC CHAR(1)     NOT NULL WITH DEFAULT,
|          RLFBIND CHAR(1)     NOT NULL WITH DEFAULT,
|          RLFCOLLN VARCHAR(128) NOT NULL WITH DEFAULT,
|          RLFPKG  VARCHAR(128) NOT NULL WITH DEFAULT),
|          -----8-column format -----
|          RLFASUERR INTEGER,
|          RLFASUWARN INTEGER,
|          RLF_CATEGORY_B CHAR(1) NOT NULL WITH DEFAULT)
|          -----11-column format -----
|          IN DSNRLST.DSNRLSxx;
```

The name of the table is *authid.DSNRLSTxx*, where *xx* is any two-character alphanumeric value, and *authid* is specified when DB2 is installed. Because the two characters *xx* must be entered as part of the START command, they must be alphanumeric—no special or DBCS characters.

All future column names defined by IBM will appear as RLFxxxxx. To avoid future naming conflicts, begin your own column names with characters other than RLF.

**Creating the index:** To create an index for the 11-column format, use the following SQL:

```
CREATE UNIQUE INDEX authid.DSNARLxx
  ON authid.DSNRLSTxx
  (RLFFUNC, AUTHID DESC, PLANNAME DESC,
   RLFCOLLN DESC, RLFPKG DESC, LUNAME DESC)
  CLUSTER CLOSE NO;
```

The *xx* in the index name (*DSNARLxx*) must match the *xx* in the table name (*DSNRLSTxx*) and it must be a descending index.

# **Populating the RLST:** Use INSERT, UPDATE, MERGE, and DELETE statements to populate the resource limit specification table. Changes to the resource limit specification table are immediately effective for all new threads, and for those that have not issued their first dynamic SELECT, INSERT, UPDATE, MERGE, TRUNCATE, or DELETE statement.

# However, if you change the resource limit specification table while a thread is executing, the limit that existed when the thread issued its first dynamic statement applies throughout the life of the thread until DB2 reads in the new limit. DB2 reads in a new limit in the following situations:

- # • When the application uses a different primary authorization ID.
- # • When the resource limit facility is stopped and started again.
- # • When a predictively governed package or DBRM is loaded for execution.

# To insert, update, or delete from the resource limit specification table, you need only the usual table privileges on the RLST. No higher authority is required.

**Starting and stopping the RLST:** Activate any particular RLST by using the DB2 command START RLIMIT ID=*xx* where *xx* is the two-character identifier that you specified on the name *DSNRLSTxx*. This command gives you the flexibility to use a different RLST at different times; however, only one RLST can be active at a time.

**Example:** You can use different RLSTs for the day shift and the evening shift, as shown in Table 113 and Table 114 on page 725.

*Table 113. Example of RLST for the day shift*

AUTHID	PLANNAME	ASUTIME	LUNAME
BADUSER		0	LUDBD1
ROBYN		100000	LUDBD1
	PLANA	300000	LUDBD1
		50000	LUDBD1

Table 114. Example of RLST for the night shift. During the night shift AUTHID, ROBYN, and all PLANA users from LUDBD1 run without limit.

AUTHID	PLANNAME	ASUTIME	LUNAME
BADUSER		0	LUDBD1
ROBYN		NULL	LUDBD1
	PLANA	NULL	LUDBD1
		50000	LUDBD1

At installation time, you can specify a default RLST to be used each time that DB2 is restarted. For more information on resource limit facility subsystem parameters, see Part 2 of *DB2 Installation Guide*.

If the governor is active and you restart it without stopping it, any jobs that are active continue to use their original limits, and all new jobs use the limits in the new table.

If you stop the governor while a job is executing, the job runs with *no limit*, but its processing time continues to accumulate. If you later restart the governor, the new limit takes effect for an active job only when the job passes one of several internal checkpoints. A typical dynamic statement, which builds a result table and fetches from it, passes those checkpoints at intervals that can range *from moments to hours*. As a result, your change to the governor might not stop an active job within the time you expect.

Use the DB2 command CANCEL THREAD to stop an active job that does not pick up the new limit when you restart the governor.

**Restricted activity on the RLST:** While the governor is active, you cannot execute the following SQL statements on the RLST, or the table space and database in which the RLST is contained:

- DROP DATABASE
- DROP INDEX
- DROP TABLE
- DROP TABLESPACE
- RENAME TABLE

You cannot stop a database or table space that contains an active RLST; nor can you start the database or table space with ACCESS(UT).

### Descriptions of the RLST columns

Here is a complete description for all RLST columns. In no case will all columns in a particular row be populated; the columns you must populate depend on what function is performed by that row (determined by the value in RLFFUNC) and how narrowly you want to qualify values. For example, you can qualify broadly by leaving the AUTHID column blank, which means that the row applies to all authorization IDs. Or, you can qualify very narrowly by specifying a different row for each authorization ID for which the function applies.

**Search order:** DB2 tries to find the most exact match when it determines which row to use for a particular function. The search order depends on which function is being requested (type of governing, bind operations, or parallelism restrictions). The search order is described under each of those functions.

## AUTHID

The resource specification limits apply to the primary authorization ID that you specify in this column. A blank means that the limit specifications in this row apply to all authorization IDs for the location that is specified in LUNAME. No limits apply to primary or secondary authorization IDs with installation SYSADM or installation SYSOPR authority.

#  
#

## PLANNAME

The resource specification limits apply to this plan. If you are specifying a function that applies to plans (RLFFUNC=blank or '6'), a blank means that the limit specifications in this row apply to all plans for the location that is specified in LUNAME. Qualify by plan name only if the dynamic statement is issued from a DBRM bound in a plan, not a package; otherwise, DB2 does not find this row. If the RLFFUNC column contains a function for packages ('1,' '2,' or '7'), this column must be blank; if it is not blank, the row is ignored.

## ASUTIME

The number of processor service units allowed for any single dynamic SELECT, INSERT, UPDATE, or DELETE statement. Use this column for reactive governing.

Other possible values and their meanings are:

**null** No limit

### 0 (zero) or a negative value

No dynamic SELECT, INSERT, UPDATE, or DELETE statements are permitted.

The governor samples the processing time in service units. Service units are independent of processor changes. The processing time for a particular SQL statement varies according to the processor on which it is executed, but the service units required remains roughly constant. The service units consumed are not exact between different processors because the calculations for service units are dependent on measurement averages performed before new processors are announced. A relative metric is used so that the RLST values do not need to be modified when processors are changed. However, in some cases, DB2 workloads can differ from the measurement averages. In these cases, RLST value changes may be necessary. For information about how to calculate service units, see "Calculating service units" on page 732.

## LUNAME

The LU name of the location where the request originated. A blank value in this column represents the local location, *not* all locations. The value PUBLIC represents all of the DBMS locations in the network; these locations do not need to be DB2 subsystems. PUBLIC is the only value for TCP/IP connections.

## RLFFUNC

Specifies how the row is used. The values that have an effect are:

**blank** The row reactively governs dynamic SELECT, INSERT, UPDATE, or DELETE statements by plan name.

**'1'** The row reactively governs bind operations.

**'2'** The row reactively governs dynamic SELECT, INSERT, UPDATE, or DELETE statements by package or collection name.

**'3'** The row disables query I/O parallelism.

- '4' The row disables query CP parallelism.
- '5' The row disables Sysplex query parallelism.
- '6' The row predictively governs dynamic SELECT, INSERT, UPDATE, or DELETE statements by plan name.
- '7' The row predictively governs dynamic SELECT, INSERT, UPDATE, or DELETE statements by package or collection name.

All other values are ignored.

#### **RLFBIND**

Shows whether bind operations are allowed. An 'N' implies that bind operations are not allowed. Any other value means that bind operations are allowed. This column is used only if RLFFUNC is set to '1'.

#### **RLFCOLLN**

Specifies a package collection. A blank value in this column means that the row applies to all package collections from the location that is specified in LUNAME. Qualify by collection name only if the dynamic statement is issued from a package; otherwise DB2 does not find this row. If RLFFUNC=blank, '1,' or '6', then RLFCOLLN must be blank.

#### **RLFPKG**

Specifies a package name. A blank value in this column means that the row applies to all packages from the location that is specified in LUNAME. Qualify by package name only if the dynamic statement is issued from a package; otherwise DB2 does not find this row. If RLFFUNC=blank, '1', or '6', then RLFPKG must be blank.

#### **RLFASUERR**

Used for predictive governing (RLFFUNC= '6' or '7'), and only for statements that are in cost category A. The error threshold number of system resource manager processor service units allowed for a single dynamic SELECT, INSERT, UPDATE, or DELETE statement. If the predicted processor cost (in service units) is greater than the error threshold, an SQLCODE -495 is returned to the application.

Other possible values and their effects are:

**null** No error threshold

#### **0 (zero) or a negative value**

All dynamic SELECT, INSERT, UPDATE, or DELETE statements receive SQLCODE -495.

#### **RLFASUWARN**

Used for predictive governing (RELFFUNC= '6' or '7'), and only for statements that are in cost category A. The warning threshold number of processor service units that are allowed for a single dynamic SELECT, INSERT, UPDATE, or DELETE statement. If the predicted processor cost (in service units) is greater than the warning threshold, an SQLCODE +495 is returned to the application.

Other possible values and their effects are:

**null** No warning threshold

#### **0 (zero) or a negative value**

All dynamic SELECT, INSERT, UPDATE, or DELETE statements receive SQLCODE +495.

**Important:** Make sure the value for RLFASUWARN is less than that for RLFASUERR. If the warning value is higher, the warning is never reported. The error takes precedence over the warning.

#### **RLF\_CATEGORY\_B**

Used for predictive governing (RLFFUNC='6' or '7'). Tells the governor the default action to take when the cost estimate for a given statement falls into cost category B, which means that the predicted cost is indeterminate and probably too low. You can tell if a statement is in cost category B by running EXPLAIN and checking the COST\_CATEGORY column of the DSN\_STATEMNT\_TABLE.

The acceptable values are:

- blank** By default, prepare and execute the SQL statement.
- Y** Prepare and execute the SQL statement.
- N** Do not prepare or execute the SQL statement. Return SQLCODE -495 to the application.
- W** Complete the prepare, return SQLCODE +495, and allow the application logic to decide whether to execute the SQL statement or not.

## **Governing dynamic queries**

You can use two modes of governing to control the amount of system resources that a dynamic SELECT, INSERT, UPDATE, or DELETE uses. These modes are called *reactive* and *predictive*. You can use either mode or both together.

**Specifying reactive governing:** Specify either of the following values in the RLFFUNC column of the RLST:

- blank** Govern by plan name
- '2'** Govern by package name

Any statement that exceeds a limit you set in the RLST terminates with a -905 SQLCODE and a corresponding '57014' SQLSTATE. You can establish a single limit for all users, different limits for individual users, or both. Limits do not apply to primary or secondary authorization IDs with installation SYSADM or installation SYSOPR authority. For queries entering DB2 from a remote site, the local site limits are used.

**Specifying predictive governing:** Specify either of the following values in the RLFFUNC column of the RLST:

- '6'** Govern by plan name
- '7'** Govern by package name

See “Qualifying rows in the RLST” on page 729 for more information about how to qualify rows in the RLST. See “Predictive governing” on page 730 for more information about using predictive governing.

This section includes the following topics:

- “Qualifying rows in the RLST” on page 729
- “Predictive governing” on page 730
- “Combining reactive and predictive governing” on page 731

- “Governing statements from a remote site” on page 732
- “Calculating service units” on page 732

### Qualifying rows in the RLST

DB2 tries to find the closest match when determining limits for a particular dynamic statement. In summary, the search order of matching is as follows:

1. Exact match
2. Authorization ID
3. Plan name, or collection name and package name
4. LU name
5. No row match

**Governing by plan or package name:** Governing by plan name and package name are mutually exclusive.

- Plan name

The RLF governs the DBRMs in the MEMBER list specified on the BIND PLAN command. The RLFFUNC, RLFCOLLN, and RLFPKG columns must contain blanks. Table 115 is an example of this:

Table 115. Qualifying rows by plan name

RLFFUNC	AUTHID	PLANNAME	LUNAME	ASUTIME
(blank)	JOE	PLANA	(blank)	(null)
(blank)	(blank)	WSPLAN	SAN_JOSE	15000
(blank)	(blank)	(blank)	PUBLIC	10000

The first row in Table 115 shows that when Joe runs PLANA at the local location, there are no limits for any dynamic statements in that plan.

The second row shows that if anyone runs WSPLAN from SAN\_JOSE, the dynamic statements in that plan are restricted to 15 000 SUs each.

The third row is entered as a cap for any unknown authorization IDs or plan names from any location in the network, including the local location. (An alternative would be to let the default values on installation panel DSNTIPR and DSNTIPO serve as caps.)

- Collection and package name

The resource limit facility governs the packages used during the execution of the SQL application program. PLANNAME must contain blank, and RLFFUNC must contain '2'. Table 116 is an example of this:

Table 116. Qualifying rows by collection or package name

	RLFFUNC	AUTHID	RLFCOLLN	RLFPKG	LUNAME	ASUTIME
#	2	JOE	DSNESPCS	(blank)	(blank)	40000
#	2	(blank)	(blank)	DSNESM68	PUBLIC	15000

# The first row in Table 116 shows that when Joe runs any package in collection DSNESPCS from the local location, dynamic statements are restricted to 40 000 SUs.

# The second row indicates that if anyone from any location (including the local location) runs SPUFI package DSNESM68, dynamic statements are limited to 15 000 SUs.

**Governing by LU name:** Specify an originating system’s LU name in the LUNAME column, or, specify PUBLIC for all remote LUs. An LUNAME with a

value other than PUBLIC takes precedence over PUBLIC. If you leave LUNAME blank, DB2 assumes that you mean the local location only and none of your incoming distributed requests will qualify. PUBLIC is the only value for TCP/IP connections.

**Setting a default for when no row matches:** If no row in the RLST matches the currently executing statement, then DB2 uses the default set on the RLST ACCESS ERROR field of installation panel DSNTIPO (for queries that originate locally) or DSNTIPR (for queries that originate remotely). This default applies to reactive governing only.

For predictive governing, if no row matches, then no predictive governing occurs.

### Predictive governing

DB2's predictive governing capability has an advantage over the reactive governor in that it avoids wasting processing resources by giving you the ability to prevent a query from running when it appears that it exceeds processing limits. With the reactive governor, those resources are already used before the query is stopped.

See Figure 77 for an overview of how predictive governing works.

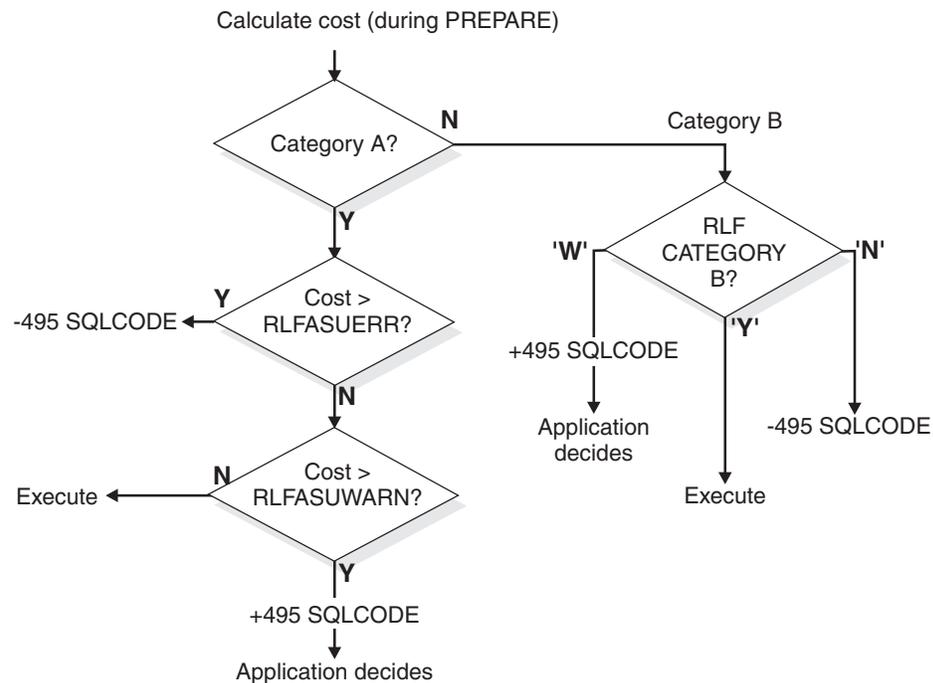

Figure 77. Processing for predictive governing

At prepare time for a dynamic SELECT, INSERT UPDATE, or DELETE statement, DB2 searches the active RLST to determine if the processor cost estimate exceeds the error or warning threshold that you set in RLFASUWARN and RLFASUERR columns for that statement. DB2 compares the cost estimate for a statement to the thresholds you set, and the following actions occur:

- If the cost estimate is in cost category A and the error threshold is exceeded, DB2 returns a -495 SQLCODE to the application, and the statement is not prepared or run.

- If the estimate is in cost category A and the warning threshold is exceeded, a +495 SQLCODE is returned at prepare time. The prepare is completed, and the application or user decides whether to run the statement.
- If the estimate is in cost category B, DB2 takes the action you specify in the RLF\_CATEGORY\_B column; that is, it either prepares and executes the statement, does not prepare or execute the statement, or returns a warning SQLCODE, which lets the application decide what to do.
- If the estimate is in cost category B and the warning threshold is exceeded, a +495 SQLCODE is returned at prepare time. The prepare is completed, and the application or user decides whether to run the statement.

**Example:** Table 117 is an RLST with two rows that use predictive governing.

Table 117. Predictive governing example

RLFFUNC	AUTHID	RLFCOLLN	RLFPKG	RLFASUWARN	RLFASUERR	RLF_CATEGORY_B
7	(blank)	COLL1	C1PKG1	900	1500	Y
7	(blank)	COLL2	C2PKG1	900	1500	W

The rows in the RLST for this example cause DB2 to act as follows for all dynamic INSERT, UPDATE, DELETE, and SELECT statements in the packages listed in this table (C1PKG1 and C2PKG1):

- Statements in cost category A that are predicted to be less than 900 SUs will execute.
- Statements in cost category A that are predicted to be between 900 and 1500 SUs receive a +495 SQLCODE.
- Statements in cost category A that are predicted to be greater than 1500 SUs receive SQLCODE -495, and the statement is not executed.

**Cost category B:** The two rows differ only in how statements in cost category B are treated. For C1PKG1, the statement will execute. For C2PKG2, the statements receive a +495 SQLCODE and the user or application must decide whether to execute the statement.

### Combining reactive and predictive governing

A dynamic statement can be governed both before and after the statement is executed. For example, if the processing cost estimate is in cost category B and you decide to run the statement, you can use the RLST to terminate the statement after a certain amount of processor time, the same as it does today. To use both modes of governing, you need two rows in the RLST as shown in Table 118.

Table 118. Combining reactive and predictive governing

RLFFUNC	AUTHID	PLANNAME	ASUTIME	RLFASUWARN	RLFASUERR	RLF_CATEGORY_B
6	USER1	PLANA	0	800	1000	W
(blank)	USER1	PLANA	1100	0	0	(blank)

The rows in the RLST for this example cause DB2 to act as follows for a dynamic SQL statement that runs under PLANA:

#### *Predictive mode:*

- If the statement is in COST\_CATEGORY A and the cost estimate is greater than 1000 SUs, USER1 receives SQLCODE -495 and the statement is not executed.

- If the statement is in COST\_CATEGORY A and the cost estimate is greater than 800 SUs but less than 1000 SUs, USER1 receives SQLCODE +495.
- If the statement is in COST\_CATEGORY B, USER1 receives SQLCODE +495.

**Reactive mode:** In either of the following cases, a statement is limited to 1100 SUs:

- The cost estimate for a statement in COST\_CATEGORY A is less than 800 SUs
- The cost estimate for a COST\_CATEGORY A is greater than 800 and less than 1000 or is in COST\_CATEGORY B and the user chooses to execute the statement

## Governing statements from a remote site

For distributed processing, keep in mind the following guidelines:

- For dynamic statements coming from requesters using DRDA protocols, you must govern by package name (RLFFUNC=2 or RLFFUNC=7), which means that PLANNAME must be blank. Specify the originating system's LU name in the LUNAME column, or specify PUBLIC for all remote LUs. If you leave LUNAME blank, DB2 assumes that you mean the local location only and none of your incoming distributed requests will qualify.
- For dynamic statements coming from requesters using DB2 private protocol, you must govern by plan name (RLFFUNC=(blank) or '6'), which means that RLFCOLLN and RLFPKG must be blank. Specify the originating system's LU name in the LU column, or specify PUBLIC for all remote LUs. Again, a value other than PUBLIC takes precedence over PUBLIC. PLANNAME can be blank or the name of the plan created at the requester's location. RLFPKG and RLFCOLLN must be blank.
- For dynamic statements coming from requesters using TCP/IP, you cannot specify the LU name. You must use PUBLIC.
- If no row is present in the RLST to govern access from a remote location, the limit is the default set on the RLST ACCESS ERROR field of installation panel DSNTIPR.

## Calculating service units

The easiest way to get SU times for the ASUTIME, RLFASUWARN, or RLFASUERR columns is to use the value in the PROCESU column of DSN\_STATEMNT\_TABLE as your starting point. You can also get the value from the IFCID 0022 record.

However, if you don't have statement table information or if there are adhoc queries for which you have no information, you can use the following formula to calculate SU time:

SU time = processor time × service units per second value

The value for service units per second depends on the processor model. You can find this value for your processor model in *z/OS MVS Initialization and Tuning Guide*, where SRM is discussed.

For example, if processor A is rated at 900 service units per second and you do not want any single dynamic SQL statement to use more than 10 seconds of processor time, you could set ASUTIME as follows:

ASUTIME time = 10 seconds × 900 service units/second = 9000 service units

Later, you could upgrade to processor B, which is rated at 1000 service units per second. If the value you set for ASUTIME remains the same (9000 service units), your dynamic SQL is only allowed 9 seconds for processing time but an equivalent number of processor service units:

ASUTIME = 9 seconds × 1000 service units/second = 9000 service units

As this example illustrates, after you establish an ASUTIME (or RLFASUWARN or RLFASUERR) for your current processor, there is no need to modify it when you change processors.

## Restricting bind operations

To restrict bind operations, use RLF function 1 (RLFFUNC='1') and qualify rows by authorization ID and LU name. The same precedence search order applies:

1. AUTHID and LUNAME match
2. AUTHID matches
3. LUNAME matches

A value of PUBLIC for LUNAME applies to all authorization IDs at all locations, while a blank LUNAME governs bind operations for IDs at the local location only.

4. If no entry matches, or if your RLST cannot be read, then the resource limit facility does not disable bind operations.

### Example

Table 119 is an example of an RLST that disables bind operations for all but three authorization IDs. Notice that BINDER from the local site is able to bind but that BINDER from San Francisco is not able to bind. Everyone else from all locations, including the local one, is disabled from doing binds.

Table 119. Restricting bind operations

RLFFUNC	AUTHID	LUNAME	RLFBIND
1	BINDGUY	PUBLIC	
1	NIGHTBND	PUBLIC	
1	(blank)	PUBLIC	N
1	BINDER	SANFRAN	N
1	BINDER	(blank)	

## Restricting parallelism modes

The RLST lets you disable parallelism for dynamic queries. You might want to do this if, for example, one mode of parallelism for a particular query performs better or one mode for a particular query does not perform well. For governing query parallelism, remember the following guidelines:

- The resource limit facility only governs query parallelism for dynamic queries when the value of the CURRENT DEGREE special register is 'ANY'.
- To disable all query parallelism for a dynamic query, you need rows in your RLST to cover all possible modes of parallelism for your system. You need one row with RLFFUNC='3' and one row with RLFFUNC='4', and, if Sysplex query parallelism is possible in your system, then you must add an additional row containing RLFFUNC='5'. If parallelism is disabled for a query, the query runs sequentially.
- Qualifying by plan or by package are not separate functions as they are for predictive and reactive governing. If you want to qualify by plan name, the query must be executed from a plan or DB2 will not find the row. If you want to qualify by package name, the query must be executed from a package or DB2 will not find the row.

If you want to qualify rows by authorization ID only, you can leave all three columns blank: RLFCOLLN, RLFPKG, and RLFPLAN.

- If no entry can be found in your RLST that applies to parallelism, or if your RLST cannot be read, then the resource limit facility does not disable query parallelism.

*Table 120. Example RLST to govern query parallelism*

RLFFUNC	AUTHID	LUNAME	RLFCOLLN	RLFPKG
3	(blank)	PUBLIC	blank	IOHOG
4	(blank)	PUBLIC	blank	CPUHOG
5	(blank)	PUBLIC	blank	CPUHOG

If the RLST in Table 120 is active, it causes the following effects:

- Disables I/O parallelism for all dynamic queries in IOHOG.
- Disables CP parallelism and Sysplex query parallelism for all dynamic queries in CPUHOG.

---

## Chapter 29. Managing DB2 threads

Threads are an important DB2 resource. A thread is a DB2 structure that describes an application's connection and traces its progress. When you install DB2, you choose a maximum number of active allied and database access threads that can be allocated concurrently. Choosing a good number for maximum threads is important to keep applications from queuing and to provide good response time.

When writing an application, you should know when threads are created and terminated and when they can be reused, because thread allocation can be a significant part of the cost in a short transaction.

This chapter provides a general introduction on how DB2 uses threads. It includes the following sections:

- A discussion of how to choose the maximum number of concurrent threads, in "Setting thread limits"
- A description of the steps in creating and terminating an allied thread, in "Allied thread allocation" on page 736
- An explanation of the differences between allied threads and database access threads (DBATs) and a description of how DBATs are created, including how they become active or pooled and how to set performance goals for individual DDF threads, under "Database access threads" on page 741
- Design options for reducing thread allocations and improving performance generally, under "CICS design options" on page 748, "IMS design options" on page 748, "TSO design options" on page 749, and "DB2 QMF design options" on page 750

---

### Setting thread limits

#  
#  
#  
#

You set the limit of the number of allied and database access threads that can be allocated concurrently using the MAX USERS and MAX REMOTE ACTIVE fields on installation panel DSNTIPE. The combined maximum allowed for MAX USERS and MAX REMOTE ACTIVE is 2000.

Set these values to provide good response time without wasting resources, such as virtual and real storage. The value you specify depends upon your machine size, your work load, and other factors. When specifying values for these fields, consider the following:

- Fewer threads than needed under utilize the processor and cause queuing for threads.
- More threads than needed do not improve the response time. They require more real storage for the additional threads and might cause more paging and, hence, performance degradation.

|

If virtual storage or real storage is the limiting factor, set MAX USERS and MAX REMOTE ACTIVE according to the available storage. For more information on storage, refer to Part 2 of *DB2 Installation Guide*.

**Thread limits for TSO and call attachment:** For the TSO and call attachment facilities, you limit the number of threads indirectly by choosing values for the MAX TSO CONNECT and MAX BATCH CONNECT fields of installation panel

DSNTIPE. These values limit the number of connections to DB2. The number of threads and connections allowed affects the amount of work that DB2 can process.

---

## Allied thread allocation

This section describes at a high level the steps in allocating an allied thread, and some of the factors related to the performance of those steps. This section does not explain how a database access thread is allocated. For more information on database access threads, see “Database access threads” on page 741.

### Step 1: Thread creation

During thread creation with ACQUIRE(ALLOCATE), the resources needed to execute the application are acquired. During thread creation with ACQUIRE(USE), only the thread is created.

The following list shows the main steps in thread creation.

1. Check the maximum number of threads.

DB2 checks whether the maximum number of active threads, specified as MAX USERS for local threads or MAX REMOTE ACTIVE for remote threads on the Storage Sizes panel (DSNTIPE) when DB2 was installed, has been exceeded. If it has been exceeded, the request waits. The wait for threads is not traced, but the number of requests queued is provided in the performance trace record with IFCID 0073.
2. Check the plan authorization.

The authorization ID for an application plan is checked in the SYSPLANAUTH catalog table (IFCID 0015). If this check fails, the table SYSUSERAUTH is checked for the SYSADM special privilege.
3. For an application plan, load the control structures associated with the plan.

The control block for an application plan is divided into sections. The header and directory contain control information; SQL sections contain SQL statements from the application. A copy of the plan's control structure is made for each thread executing the plan. Only the header and directory are loaded when the thread is created.
4. Load the descriptors necessary to process the plan.

Some of the control structures describe the DB2 table spaces, tables, and indexes used by the application. If ACQUIRE(ALLOCATE) is used, all the descriptors referred to in the plan are loaded now. If the plan is bound with ACQUIRE(USE), they are loaded when SQL statements are executed.

The most relevant factors from a system performance point of view are:

**Thread reuse:** Thread creation is a significant cost for small and medium transactions. When execution of a transaction is terminated, the thread can sometimes be reused by another transaction using the same plan. For more information on thread reuse, see “Providing for thread reuse” on page 739.

**ACQUIRE option of BIND:** ACQUIRE(ALLOCATE) causes all the resources referred to in the application to be allocated when the thread is created. ACQUIRE(USE) allocates the resources only when an SQL statement is about to be executed. In general, ACQUIRE(USE) is recommended. However, if most of the SQL is used in every execution of the transaction, ACQUIRE(ALLOCATE) is recommended.

*EDM pool size:* The size of the EDM pool influences the number of I/Os needed to load the control structures necessary to process the plan or package. To avoid a large number of allocation I/Os, the EDM pool must be large enough to contain the structures that are needed. See “Tuning EDM storage” on page 685 for more information.

## Step 2: Resource allocation

Some of the structures necessary to process the statement are stored in 4 KB pages. If they are not already present, those are read into database buffer pool BP0 and copied from there into the EDM pool. If the plan was bound with ACQUIRE(USE), it acquires resources when the statement is about to execute.

1. Load the control structures necessary to process the SQL section.  
If it is not already in the EDM pool, DB2 loads the control structure’s section corresponding to this SQL statement.
2. Load structures necessary to process statement.  
Load any structures referred to by this SQL statement that are not already in the EDM pool.
3. Allocate and open data sets.  
When the control structure is loaded, DB2 locks the resources used.

The most important performance factors for resource allocation are the same as the factors for thread creation.

## Step 3: SQL statement execution

If the statement resides in a package, the directory and header of the package’s control structure is loaded at the time of the first execution of a statement in the package. The control structure for the package is allocated at statement execution time. This is contrasted with the control structures for plans bound with ACQUIRE(ALLOCATE), which are allocated at thread creation time. The header of the plan’s control structures is allocated at thread creation time regardless of ACQUIRE(ALLOCATE) or ACQUIRE(USE).

When the package is allocated, DB2 checks authorization using the package authorization cache or the SYSPACKAUTH catalog table. DB2 checks to see that the plan owner has execute authority on the package. On the first execution, the information is not in the cache; therefore, the catalog is used. Thereafter, the cache is used. For more information about package authorization caching, see “Caching authorization IDs for best performance” on page 151.

For dynamic bind, authorization checking also occurs at statement execution time.

A summary record, produced at the end of the statement (IFCID 0058), contains information about each scan that is performed. Included in the record is the following information:

- The number of updated rows
- The number of processed rows
- The number of deleted rows
- The number of examined rows
- The number of pages that are requested through a getpage operation
- The number of rows that are evaluated during the first stage (stage 1) of processing

- The number of rows that are evaluated during the second stage (stage 2) of processing
- The number of getpage requests that are issued to enforce referential constraints
- The number of rows that are deleted or set null to enforce referential constraints
- The number of inserted rows

From a system performance perspective, the most important factor in the performance of SQL statement execution is the size of the database buffer pool. If the buffer pool is large enough, some index and data pages can remain there and can be accessed again without an additional I/O operation. For more information on buffer pools, see Chapter 27, “Tuning DB2 buffer, EDM, RID, and sort pools,” on page 671.

## Step 4: Commit and thread termination

Commit processing can occur many times while a thread is active. For example, an application program running under the control structure of the thread could issue an explicit COMMIT or SYNCPOINT several times during its execution. When the application program or the thread terminates, an implicit COMMIT or SYNCPOINT is issued.

When a COMMIT or SYNCPOINT is issued from an IMS application running with DB2, the two-phase commit process begins if DB2 resources have been changed since the last commit point. In a CICS or RRSAP application, the two-phase commit process begins only if DB2 resources have changed and a non-DB2 resource has changed within the same commit scope. For more information on the commit process for IMS and CICS applications, see “Multiple system consistency” on page 459.

The significant events that show up in a performance trace of a commit and thread termination operation are as follows:

### 1. Commit phase 1

In commit phase 1 (IFCID 0084), DB2 writes an end of phase 1 record to the log (IFCIDs 0032 and 0033). There are two I/Os, one to each active log data set (IFCIDs 0038 and 0039).

### 2. Commit phase 2

In commit phase 2 (IFCID 0070), DB2 writes a beginning of phase 2 record to the log. Again, the trace shows two I/Os. Page and row locks (except those protecting the current position of cursors declared with the WITH HOLD option), held to a commit point, are released. An unlock (IFCID 0021) with a requested token of zeros frees any lock for the specified duration. A summary lock record (IFCID 0020) is produced, which gives the maximum number of page locks held and the number of lock escalations. DB2 writes an end of phase 2 record to the log.

If RELEASE(COMMIT) is used, the following events also occur:

- Table space locks are released.
- All the storage used by the thread is freed, including storage for control blocks, CTs and PTs, and working areas.
- The use counts of the DBDs are decreased by one. If space is needed in the EDM DBD cache, a DBD can be freed when its use count reaches zero.
- Those table spaces and index spaces with no claimers are made candidates for deferred close. See “Understanding the CLOSE YES and CLOSE NO options” on page 696 for more information on deferred close.

### 3. Thread termination

When the thread is terminated, the accounting record is written. It does not report transaction activity that takes place before the thread is created.

If RELEASE(DEALLOCATE) is used to release table space locks, the DBD use count is decreased, and the thread storage is released.

## Variations on thread management

Minor differences exist in the transaction flow in different environments and for SQL statements originating dynamically.

### TSO and call attachment facility differences

The TSO attachment facility and call attachment facility (CAF) can be used to request that SQL statements from CICS, IMS, or RRSAF be executed in TSO foreground and batch. The processes differ from CICS or IMS transactions in that:

- There is no sign-on. The user is identified when the TSO address space is connected.
- Commit requires only a single phase and only one I/O operation to each log. Single phase commit records are IFCID 0088 and 0089.
- Threads cannot be reused because the thread is allocated to the user address space.

### Thread management for Resource Recovery Services attachment facility (RRSAF)

With RRSAF, you have sign-on capabilities, the ability to reuse threads, and the ability to coordinate commit processing across different resource managers. For more information, see Part 6 of *DB2 Application Programming and SQL Guide*.

### Differences for SQL under DB2 QMF

DB2 QMF uses CAF to create a thread when a request for work, such as a SELECT statement, is issued. A thread is maintained until the end of the session only if the requester and the server reside in different DB2 subsystems. If the requester and the server are both in the local DB2 subsystem, the thread is not maintained.

For more information about DB2 QMF connections, see *DB2 Query Management Facility: Installing and Managing DB2 QMF for TSO/CICS*.

## Providing for thread reuse

In general, you want transactions to reuse threads when transaction volume is high and the cost of creating threads is significant, but thread reuse is also useful for a lower volume of priority transactions. For a transaction of five to ten SQL statements (10 I/O operations), the cost of thread creation can be 10% of the processor cost. But the steps needed to reuse threads can incur costs of their own.

Later in this chapter, the following sections cover thread reuse for specific situations:

- “Reusing threads for remote connections” on page 745 provides information on the conditions for thread reuse for database access threads.
- “CICS design options” on page 748 tells how to write CICS transactions to reuse threads.
- “IMS design options” on page 748 tells how to write IMS transactions to reuse threads.

## Bind options for thread reuse

In DB2, you can prepare allied threads for reuse by binding the plan with the ACQUIRE(USE) and RELEASE(DEALLOCATE) options; otherwise, the allocation cost is not eliminated but only slightly reduced. Be aware of the following effects:

- ACQUIRE(ALLOCATE) acquires all resources needed by the plan, including locks, when the thread is created; ACQUIRE(USE) acquires resources only when they are needed to execute a particular SQL statement. If most of the SQL statements in the plan are executed whenever the plan is executed, ACQUIRE(ALLOCATE) costs less. If only a few of the SQL statements are likely to be executed, ACQUIRE(USE) costs less and improves concurrency. But with thread reuse, if most of your SQL statements eventually get issued, ACQUIRE(USE) might not be as much of an improvement.
- RELEASE(DEALLOCATE) does not free cursor tables (SKCTs) at a commit point; hence, the cursor table could grow as large as the plan. If you are using created temporary tables, the logical work file space is not released until the thread is deallocated. Thus, many uses of the same created temporary table do not cause reallocation of the logical work files, but be careful about holding onto this resource for long periods of time if you do not plan to use it.

## Using reports to tell when threads were reused

The NORMAL TERM., ABNORMAL TERM., and IN DOUBT sections of the OMEGAMON accounting report, shown in Figure 78, can help you identify, by plan, when threads were reused. In the figure:

- NEW USER ( **A** ) tells how many threads were not terminated at the end of the previous transaction or query, and hence reused.
- DEALLOCATION ( **B** ) tells how many threads were terminated at the end of the query or transaction.
- APPL. PROGR. END ( **C** ) groups all the other reasons for accounting. Since the agent did not abend, these are considered normal terminations.

This technique is accurate in IMS but not in CICS, where threads are reused frequently by the same user. For CICS, also consider looking at the number of commits and aborts per thread. For CICS:

- NEW USER ( **A** ) is thread reuse with a different authorization ID or transaction code.
- RESIGN-ON ( **D** ) is thread reuse with the same authorization ID.

NORMAL TERM.	TOTAL	ABNORMAL TERM.	TOTAL	IN DOUBT	TOTAL
NEW USER <b>A</b>	0	APPL.PROGR. ABEND	0	APPL.PGM. ABEND	0
DEALLOCATION <b>B</b>	0	END OF MEMORY	0	END OF MEMORY	0
APPL.PROGR. END <b>C</b>	0	RESOL.IN DOUBT	0	END OF TASK	0
RESIGNON <b>D</b>	0	CANCEL FORCE	0	CANCEL FORCE	0
DBAT INACTIVE	0				
IN2 INACTIVE	193				
RRS COMMIT	0				
END U. THRESH	0				
BLOCK STORAGE	0				
STALENESS	0

## Database access threads

This section describes the following topics:

- “Using allied threads and database access threads”
- “Setting thread limits for database access threads”
- “Using threads in INACTIVE MODE for DRDA-only connections” on page 742
- “Using threads with private-protocol connections” on page 744
- “Reusing threads for remote connections” on page 745
- “Using z/OS workload management to set performance objectives” on page 745

For information on performance considerations for distributed processing, see “Tuning distributed applications” on page 1008.

### Using allied threads and database access threads

Database access threads are created to access data at a DB2 server on behalf of a requester using either DRDA or DB2 private protocol. A database access thread is created when an SQL request is received from the requester. Allied threads perform work at a requesting DB2.

Database access threads differ from allied threads in the following ways:

- Database access threads have two modes of processing: ACTIVE MODE and INACTIVE MODE. These modes are controlled by setting the DDF THREADS field on the installation panel DSNTIPR.
  - ACTIVE MODE: When the value of DDF THREADS is ACTIVE, a database access thread is always active from initial creation to termination.
  - INACTIVE MODE: When the value of DDF THREADS is INACTIVE, a database access thread can be active or pooled. When a database access thread in INACTIVE MODE is active, it is processing requests from client connections within units of work. When a database access thread is pooled, it is waiting for the next request from a client to start a new unit of work.
- Database access threads run in enclave SRB mode.
- Only when in INACTIVE MODE, a database access thread is terminated after it has processed 200 units of work or after the database access thread has been idle in the pool for the amount of time specified in the POOL THREAD TIMEOUT field on the installation panel DSNTIP5. This termination does not prevent another database access thread from being created to meet processing demand, as long as the value of the MAX REMOTE ACTIVE field on panel DSNTIPE has not been reached.

**Recommendation:** Use INACTIVE MODE threads instead of ACTIVE MODE threads if you can.

### Setting thread limits for database access threads

When you install DB2, you choose a maximum number of active threads that can be allocated concurrently; the MAX USERS field on panel DSNTIPE represents the maximum number of allied threads, and the MAX REMOTE ACTIVE field on panel DSNTIPE represents the maximum number of database access threads. Together, the values you specify for these fields cannot exceed 1999.

In the MAX REMOTE CONNECTED field of panel DSNTIPE, you can specify up to 150 000 as the maximum number concurrent remote connections that can concurrently exist within DB2. This upper limit is only obtained if you specify the

recommended value INACTIVE for the DDF THREADS field of installation panel DSNTIPR. Figure 79 illustrates the relationship among the number of active threads in the system and the total number of connections.

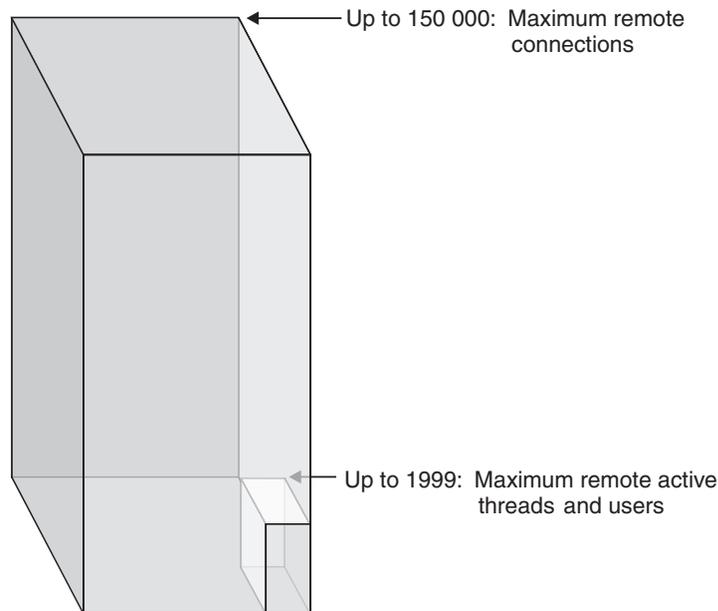

Figure 79. Relationship between active threads and maximum number of connections.

## Using threads in INACTIVE MODE for DRDA-only connections

When the value of DDF THREADS is INACTIVE, DRDA connections with a client cause a pooling behavior in database access threads. A different database access behavior is used when private-protocol connections are involved. For information about private-protocol connections and database access threads, see “Using threads with private-protocol connections” on page 744.

A database access thread that is not currently processing a unit of work is called a pooled thread, and it is disconnected. DB2 always tries to pool database access threads, but in some cases cannot do so. The conditions listed in Table 121 determine if a thread can be pooled.

Table 121. Requirements for pooled threads

If there is...	Thread can be pooled?
A DRDA hop to another location	Yes
A package that is bound with RELEASE(COMMIT)	Yes
A package that is bound with RELEASE(DEALLOCATE)	Yes
A held cursor, a held LOB locator, or a package bound with KEEP DYNAMIC(YES)	No
A declared temporary table that is active (the table was not explicitly dropped through the DROP TABLE statement or the ON COMMIT DROP TABLE clause on the DECLARE GLOBAL TEMPORARY TABLE statement)	No

When the conditions listed in Table 121 are true, the thread can be pooled when a COMMIT is issued. After a ROLLBACK, a thread can be pooled even if it had open cursors defined WITH HOLD or a held LOB locator because ROLLBACK

closes all cursors and LOB locators. ROLLBACK is also the only way to use the KEEP DYNAMIC(YES) bind option to clear information about a dynamic SQL statement.

## Understanding the advantages of database access threads in INACTIVE MODE

Letting threads be pooled has the following advantages:

- You can leave an application that is running on a workstation connected to DB2 from the time the application is first activated until the workstation is shut down and thus avoid the delay of repeated connections.
- DB2 can support a larger number of DDF connections (150 000 instead of 4999).
- Less storage is used for each DDF connection. (A connection uses significantly less storage than a database access thread.)
- You get an accounting trace record each time that a thread is pooled rather than once for the entire time that you are connected. When a pooled thread becomes active, the accounting fields for that thread are re-initialized. As a result, the accounting record contains information about active threads only, which makes it easier to study how distributed applications are performing. If a pooled mode thread remains active because of KeepDynamic sections, an accounting record is still written.

**Exception:** If you employ account record accumulation, an accounting trace is not produced each time that a thread becomes pooled. Accounting records can be rolled up by concatenated combinations of the following values:

- End user ID
  - End transaction name
  - End user workstation name
- Each time that a thread is pooled, workload manager resets the information that it maintains on that thread. The next time that thread is activated, workload manager begins managing to the goals that you have set for the transactions that run in that service class. If you use multiple performance periods, it is possible to favor short-running units of work that use fewer resources while giving fewer resources over time to long running units of work. See “Establishing performance periods for DDF threads” on page 747 for more information.
  - You can use response time goals, which is not recommended when using ACTIVE MODE threads.
  - INACTIVE MODE threads can better take advantage of the ability to time out idle active threads, as described in “Timing out idle active threads.”
  - Thread reuse lets DDF use a small pool of database access threads to support a large group of network clients.
  - The response times reported by RMF include periods between requests and within the same unit of work. These times are shown as idle delays.

## Enabling threads to be pooled

You must specify INACTIVE on the DDF THREADS field of installation panel DSNTIPR to allow threads to be pooled.

## Timing out idle active threads

Active server threads that have remained idle for a specified period of time (in seconds) can be canceled by DB2. When you install DB2, you choose a maximum IDLE THREAD TIMEOUT period, from 0 to 9999 seconds. The timeout period is an approximation. If a server thread has been waiting for a request from the requesting site for this period of time, it is canceled unless the thread is currently pooled or in doubt thread. A value of 0, the default, means that the server threads cannot be canceled because of an idle thread timeout.

**Recommendation:** Use the default option with the option ACTIVE for the DDF THREADS field on DSNTIPR. If you specify a timeout interval with ACTIVE, an application would have to start its next unit of work within the timeout period specification, or risk being canceled.

*TCP/IP keep\_alive interval for the DB2 subsystem:* For TCP/IP connections, it is a good idea to specify the IDLE THREAD TIMEOUT value in conjunction with a TCP/IP keep\_alive interval of 5 minutes or less to make sure that resources are not locked for a long time when a network outage occurs. It is recommended that you override the TCP/IP stack keep\_alive interval on a single DB2 subsystem by specifying a numeric value in the field TCP/IP KEEPALIVE on installation panel DSNTIPS.

## Using threads with private-protocol connections

Database access threads with private-protocol connections behave differently than threads with DRDA-only connections. When a database access thread is associated with a private-protocol connection, whether inbound, outbound, or both, the database access thread remains with the connection or connections. During periods of inactivity, DB2 reduces the memory footprint of threads until the next unit of work begins.

The MAX INACTIVE DBATS setting determines whether DB2 will reduce the memory footprint of a private-protocol connection that involves a database access thread. When a private-protocol connection ends a unit of work, DB2 first compares the number of current inactive database access threads to the value that is specified for your installation for MAX INACTIVE DBATS. Based on these values, DB2 either makes the thread inactive or allows it to remain active:

- If the current number of inactive database access threads is below the value in MAX INACTIVE DBATS, the thread becomes inactive. It cannot be used by another connection.
- If the current number of inactive database access threads meets or exceeds the value in MAX INACTIVE DBATS, the thread remains active. However, too many active threads (that is, more than MAX REMOTE ACTIVE) can cause the thread and its connection to be terminated.

To limit the number of inactive database access threads that can be created, specify a value in the MAX INACTIVE DBATS field of installation panel DSNTIPR. The default is 0, which means that any database access thread that involves a private-protocol-connection remains active.

While using a private-protocol connection, DB2 always tries to make threads inactive, but in some cases cannot do so. If MAX INACTIVE DBATS is greater than 0 and the value has not been exceeded, the conditions listed in Table 122 determine if a thread can be inactive.

*Table 122. Requirements for inactive threads*

If there is...	Thread can be inactive?
A hop to another location	Yes
A package that is bound with RELEASE(COMMIT)	Yes
A package that is bound with RELEASE(DEALLOCATE)	No
A held cursor, a held LOB locator, or a package bound with KEEP DYNAMIC(YES)	No

Table 122. Requirements for inactive threads (continued)

If there is...	Thread can be inactive?
A declared temporary table that is active (the table was not explicitly dropped through the DROP TABLE statement)	No

## Reusing threads for remote connections

The cost to create a thread can be significant and, as described in “Providing for thread reuse” on page 739, reusing threads is a way to avoid that cost. DB2 UDB for z/OS can reuse threads at the requester and at the server. At the requester, a thread can be reused for an application that uses the CICS, IMS, or RRS attachment facility as described later in this chapter. As a server, DB2 can assign that connection to a pooled database access thread. Those threads can be shared and reused by thousands of client connections, which lets DB2 support very large client networks at minimal cost. (Inactive threads are only eligible to be reused by the same connection.)

If your server is not DB2 UDB for z/OS, or some other server that can reuse threads, then reusing threads for your requesting CICS, IMS, or RRS applications is not a benefit for distributed access. Thread reuse occurs when sign-on occurs with a new authorization ID. If that request is bound for a server that does not support thread reuse, that change in the sign-on ID causes the connection between the requester and server to be released so that it can be rebuilt again for the new ID.

## Using z/OS workload management to set performance objectives

z/OS supports enclave system request blocks (SRBs). A z/OS enclave lets each thread have its own performance objective. Using z/OS workload management (WLM) support, you can establish z/OS performance objectives for individual DDF server threads. For details on using workload management, see *z/OS MVS Planning: Workload Management*.

The z/OS performance objective of the DDF address space does not govern the performance objective of the user thread. As described in “z/OS performance options for DB2” on page 717, you should assign the DDF address space to a z/OS performance objective that is similar to the DB2 database services address space (*ssnmDBM1*). The z/OS performance objective of the DDF address space determines how quickly DB2 is able to perform operations associated with managing the distributed DB2 work load, such as adding new users or removing users that have terminated their connections. This performance objective should be a service class with a single velocity goal. This performance objective is assigned by modifying the WLM Classification Rules for started tasks (STC).

### Classifying DDF threads

You can classify DDF threads by, among other things, authorization ID and stored procedure name. The stored procedure name is only used as a classification if the first statement issued by the client after the CONNECT is an SQL CALL statement. Use the WLM administrative application to define the service classes you want z/OS to manage. These service classes are associated with performance objectives. When a WLM-established stored procedure call originates locally, it inherits the performance objective of the caller, such as TSO or CICS.

**Important:** If you do not classify your DDF transactions into service classes, they are assigned to the default class, the *discretionary* class, which is at a very low priority.

**Classification attributes:** Each of the WLM classification attributes has a two or three character abbreviation that you can use when entering the attribute on the WLM menus. The following WLM classification attributes pertain to DB2 DDF threads:

- AI** Accounting information. The value of the DB2 accounting string associated with the DDF server thread, described by QMDAAINF in the DSNDQMDA mapping macro. WLM imposes a maximum length of 143 bytes for accounting information.
- CI** The DB2 correlation ID of the DDF server thread, described by QWHCCV in the DSNDQWHC mapping macro.
- CN** The DB2 collection name of the *first* SQL package accessed by the DRDA requester in the unit of work.
- LU** The VTAM LUNAME of the system that issued the SQL request.
- NET** The VTAM NETID of the system that issued the SQL request.
- PC** Process name. This attribute can be used to classify the application name or the transaction name. The value is defined by QWHCEUTX in the DSNDQWHC mapping macro.
- PK** The name of the **first** DB2 package accessed by the DRDA requester in the unit of work.
- PN** The DB2 plan name associated with the DDF server thread. For DB2 private protocol requesters and DB2 DRDA requesters that are at Version 3 or subsequent releases, this is the DB2 plan name of the requesting application. For other DRDA requesters, use 'DISTSERV' for PN.
- PR** Stored procedure name. This classification only applies if the first SQL statement from the client is a CALL statement.
- SI** Subsystem instance. The DB2 server's z/OS subsystem name.
- SPM** Subsystem parameter. This qualifier has a maximum length of 255 bytes. The first 16 bytes contain the client's user ID. The next 18 bytes contain the client's workstation name. The remaining 221 bytes are reserved.
