**Important:** If the length of the client's user ID is less than 16 bytes, uses blanks after the user ID to pad the length. If the length of the client's workstation name is less than 18 bytes, uses blanks after the workstation name to pad the length.
- SSC** Subsystem collection name. When the DB2 subsystem is a member of a DB2 data sharing group, this attribute can be used to classify the data sharing group name. The value is defined by QWHADSGN in the DSNDQWHA mapping macro.
- UI** User ID. The DDF server thread's primary authorization ID, after inbound name translation.

Figure 80 on page 747 shows how you can associate DDF threads with service classes.

```

Figure 80. Classifying DDF threads using z/OS workload management. You assign performance goals to service classes using the services classes menu of WLM.

In Figure 80, the following classifications are shown:

- All DB2P applications accessing their first SQL package in the collection ONLINE are in service class PRDONLIN.
- All DB2P applications that call stored procedure PAYPROC first are in service class PRDONLIN.
- All work performed by DB2P user SYSADM is in service class PRDONLIN.
- Users other than SYSADM that run the DB2P PACKAGE QMFOS2 are in the PRDQUERY class. (The QMFOS2 package is not in collection ONLINE.)
- All other work on the production system is in service class PRBBATCH.
- All users of the test DB2 system are assigned to the TESTUSER class except for work that first calls stored procedure PAYPROCT, which is in service class TESTPAYR.

**Establishing performance periods for DDF threads**

You can establish performance periods for DDF threads, including threads that run in the WLM-established stored procedures address space. By establishing multiple performance periods, you can cause the thread’s performance objectives to change based upon the thread’s processor consumption. Thus, a long-running unit of work can move down the priority order and let short-running transactions get in and out at a higher priority.

To design performance strategies for these threads, take into account the events that cause a DDF thread to reset its z/OS performance period. The z/OS performance period is reset by terminating the z/OS enclave for the thread and creating a new z/OS enclave for the thread, as described in “Monitoring distributed processing with RMF” on page 1021.

Because threads that are always active do not terminate the enclave and thus do not reset the performance period to period 1, a long-running thread always ends up in the last performance period. Any new business units of work that use that thread will suffer the performance consequences. This makes performance periods unattractive for long-running threads. For always active threads, therefore, use velocity goals and use a single-period service class.

## Basic procedure for establishing performance objectives

To establish performance objectives for DDF threads and the related address spaces, use the following steps:

1. Create a WLM service definition that assigns service classes to the DDF threads under subsystem type DDF and to the DDF address space under subsystem type STC.
2. Install the service definition using the WLM menus and activate a policy (VARY WLM,POLICY=*policy*).

Threads are assigned a service class by the classification rules in the active WLM service policy. Each service class period has a performance objective (goal), and WLM raises or lowers that period's access to system resources as needed to meet the specified goal. For example, the goal might be "application APPL8 should run in less than 3 seconds of elapsed time 90% of the time".

No matter what your service class goals are, a request to start an address space might time out, depending on the timeout value that is specified in the TIMEOUT VALUE field of installation DSNTIPX. If the timeout value is too small, you might need to increase it to account for a busy system.

---

## CICS design options

The CICS attachment facility provides a multithread connection to DB2 to allow you to operate DB2 with CICS. Threads allow each CICS application transaction or DB2 command to access DB2 resources. A thread runs under its own subtask task control block (TCB).

When a transaction needs a thread, an existing thread can be reused or a new thread can be created. If no existing thread is available, and if the maximum number of threads has not been reached, a thread is created. Use the CICS resource definition online (RDO) to tune the CICS attachment facility and define the characteristics of your threads. For more information, see:

- *CICS Transaction Server for OS/390 Resource Definition Guide* for information about RDO
- *CICS Transaction Server for z/OS DB2 Guide* for information about DB2 performance considerations and setup of the CICS attachment facility

---

## IMS design options

The IMS attachment facility gives you the following design options:

- Control the number of IMS regions connected to DB2. For IMS, this is also the maximum number of concurrent threads.
- Optimize the number of concurrent threads used by IMS.

A dependent region with a subsystem member (SSM) that is not empty is connected to DB2 at start up time. Regions with a null SSM cannot create a thread to DB2. A thread to DB2 is created at the first execution of an SQL statement in an IMS application schedule; it is terminated when the application terminates.

The maximum number of concurrent threads used by IMS can be controlled by the number of IMS regions that can connect to DB2 by transaction class assignments. You can control the number by doing the following:

- Minimize the number of regions needing a thread by the way in which you assign applications to regions.

- Provide an empty SSM member for regions that will not connect to DB2.
- Provide efficient thread reuse for high volume transactions.

Thread creation and termination is a significant cost in IMS transactions. IMS transactions identified as wait for input (WFI) can reuse threads: they create a thread at the first execution of an SQL statement and reuse it until the region is terminated. In general, though, use WFI only for transactions that reach a region utilization of at least 75%.

Some degree of thread reuse can also be achieved with IMS class scheduling, queuing, and a PROCLIM count greater than one. IMS Fast Path (IFP) dependent regions always reuse the DB2 thread.

---

## TSO design options

You can tune your TSO attachment facility by choosing values for the following parameters on the Storage Sizes installation panel (DSNTIPE):

<b>MAX TSO CONNECT</b>	The maximum number of TSO foreground connections (including DB2I, QMF, and foreground applications)
<b>MAX BATCH CONNECT</b>	The maximum number of TSO background connections (including batch jobs and utilities)

Because DB2 must be stopped to set new values, consider setting a higher MAX BATCH CONNECT for batch periods. The statistics record (IFCID 0001) provides information on the create thread queue. The OMEGAMON statistics report (in Figure 81 on page 750) shows that information under the SUBSYSTEM SERVICES section.

For TSO or batch environments, having 1% of the requests queued is probably a good number to aim for by adjusting the MAX USERS value of installation panel DSNTIPE. Queuing at create thread time is not desirable in the CICS and IMS environments. If you are running IMS or CICS in the same DB2 subsystem as TSO and batch, use MAX BATCH CONNECT and MAX TSO CONNECT to limit the number of threads taken by the TSO and batch environments. The goal is to allow enough threads for CICS and IMS so that their threads do not queue. To determine the number of allied threads queued, see the QUEUED AT CREATE THREAD field ( **A** ) of the OMEGAMON statistics report.

SUBSYSTEM SERVICES	QUANTITY

## DB2 QMF design options

DB2 QMF has the following significant performance options:

- The DSQSIROW parameter of the ISPSTART command
- SPACE parameter of the user QMF profile (Q.PROFILES)
- QMF region size and the spill file attributes
- TRACE parameter of the user QMF profile (Q.PROFILES)

For more information on these aspects of DB2 QMF and how they affect performance, see *DB2 Query Management Facility: Installing and Managing DB2 QMF for TSO/CICS*.

---

## Chapter 30. Tuning your queries

The information under this heading, up to the end of this chapter, is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

This chapter tells you how to improve the performance of your queries. It begins with “General tips and questions.”

For more detailed information and suggestions, see:

- “Writing efficient predicates” on page 755
- “General rules about predicate evaluation” on page 759
- “Using host variables efficiently” on page 779
- “Writing efficient subqueries” on page 785
- “Using scrollable cursors efficiently” on page 790
- “Writing efficient queries on tables with data-partitioned secondary indexes” on page 792

If you still have performance problems after you have tried the suggestions in these sections, you can use other, more risky techniques. See “Special techniques to influence access path selection” on page 794 for information.

---

### General tips and questions

**Recommendation:** If you have a query that is performing poorly, first go over the following checklist to see that you have not overlooked some of the basics:

- “Is the query coded as simply as possible?”
- “Are all predicates coded correctly?”
- “Are there subqueries in your query?” on page 752
- “Does your query involve aggregate functions?” on page 753
- “Do you have an input variable in the predicate of an SQL query?” on page 754
- “Do you have a problem with column correlation?” on page 754
- “Can your query be written to use a noncolumn expression?” on page 754
- “Can materialized query tables help your query performance?” on page 754
- “Does the query contain encrypted data?” on page 755

#### Is the query coded as simply as possible?

Make sure the SQL query is coded as simply and efficiently as possible. Make sure that no unused columns are selected and that there is no unneeded ORDER BY or GROUP BY.

#### Are all predicates coded correctly?

**Indexable predicates:** Make sure all the predicates that you think should be indexable are coded so that they can be indexable. Refer to Table 124 on page 760 to see which predicates are indexable and which are not.

**Unintentionally redundant or unnecessary predicates:** Try to remove any predicates that are unintentionally redundant or not needed; they can slow down performance.

*Declared lengths of host variables:* For string comparisons other than equal comparisons, ensure that the declared length of a host variable is less than or equal to the length attribute of the table column that it is compared to. For languages in which character strings are nul-terminated, the string length can be less than or equal to the column length plus 1. If the declared length of the host variable is greater than the column length, the predicate is stage 1 but cannot be a matching predicate for an index scan.

For example, assume that a host variable and an SQL column are defined as follows:

C language declaration	SQL definition
char string_hv[15]	STRING_COL CHAR(12)

A predicate such as WHERE STRING\_COL > :string\_hv is not a matching predicate for an index scan because the length of string\_hv is greater than the length of STRING\_COL. One way to avoid an inefficient predicate using character host variables is to declare the host variable with a length that is less than or equal to the column length:

```
char string_hv[12]
```

Because this is a C language example, the host variable length could be 1 byte greater than the column length:

```
char string_hv[13]
```

For numeric comparisons, a comparison between a DECIMAL column and a float or real host variable is stage 2 if the precision of the DECIMAL column is greater than 15. For example, assume that a host variable and an SQL column are defined as follows:

C language declaration	SQL definition
float float_hv	DECIMAL_COL DECIMAL(16,2)

A predicate such as WHERE DECIMAL\_COL = :float\_hv is not a matching predicate for an index scan because the length of DECIMAL\_COL is greater than 15. However, if DECIMAL\_COL is defined as DECIMAL(15,2), the predicate is stage 1 and indexable.

## Are there subqueries in your query?

If your query uses subqueries, see “Writing efficient subqueries” on page 785 to understand how DB2 executes subqueries. There are no absolute rules to follow when deciding how or whether to code a subquery. But these are general guidelines:

- If efficient indexes are available on the tables in the subquery, then a correlated subquery is likely to be the most efficient kind of subquery.
- If no efficient indexes are available on the tables in the subquery, then a noncorrelated subquery would be likely to perform better.
- If multiple subqueries are in any parent query, make sure that the subqueries are ordered in the most efficient manner.

**Example:** Assume that MAIN\_TABLE has 1000 rows:

```
SELECT * FROM MAIN_TABLE
  WHERE TYPE IN (subquery 1) AND
         PARTS IN (subquery 2);
```

Assuming that subquery 1 and subquery 2 are the same type of subquery (either correlated or noncorrelated) and the subqueries are stage 2, DB2 evaluates the subquery predicates in the order they appear in the WHERE clause. Subquery 1 rejects 10% of the total rows, and subquery 2 rejects 80% of the total rows.

The predicate in subquery 1 (which is referred to as P1) is evaluated 1000 times, and the predicate in subquery 2 (which is referred to as P2) is evaluated 900 times, for a total of 1900 predicate checks. However, if the order of the subquery predicates is reversed, P2 is evaluated 1000 times, but P1 is evaluated only 200 times, for a total of 1200 predicate checks.

Coding P2 before P1 appears to be more efficient if P1 and P2 take an equal amount of time to execute. However, if P1 is 100 times faster to evaluate than P2, then coding subquery 1 first might be advisable. If you notice a performance degradation, consider reordering the subqueries and monitoring the results. Consult “Writing efficient subqueries” on page 785 to help you understand what factors make one subquery run more slowly than another.

If you are unsure, run EXPLAIN on the query with both a correlated and a noncorrelated subquery. By examining the EXPLAIN output and understanding your data distribution and SQL statements, you should be able to determine which form is more efficient.

This general principle can apply to all types of predicates. However, because subquery predicates can potentially be thousands of times more processor- and I/O-intensive than all other predicates, the order of subquery predicates is particularly important.

Regardless of coding order, DB2 performs noncorrelated subquery predicates before correlated subquery predicates, unless the subquery is transformed into a join.

Refer to “DB2 predicate manipulation” on page 775 to see in what order DB2 will evaluate predicates and when you can control the evaluation order.

## Does your query involve aggregate functions?

If your query involves aggregate functions, make sure that they are coded as simply as possible; this increases the chances that they will be evaluated when the data is retrieved, rather than afterward. In general, an aggregate function performs best when evaluated during data access and next best when evaluated during DB2 sort. Least preferable is to have an aggregate function evaluated after the data has been retrieved. Refer to “When are aggregate functions evaluated? (COLUMN\_FN\_EVAL)” on page 950 for help in using EXPLAIN to get the information you need.

For aggregate functions to be evaluated during data retrieval, the following conditions must be met for all aggregate functions in the query:

- No sort is needed for GROUP BY. Check this in the EXPLAIN output.
- No stage 2 (residual) predicates exist. Check this in your application.
- No distinct set functions exist, such as COUNT(DISTINCT C1).
- If the query is a join, all set functions must be on the last table joined. Check this by looking at the EXPLAIN output.
- All aggregate functions must be on single columns with no arithmetic expressions.

- The aggregate function is not one of the following aggregate functions:
  - STDDEV
  - STDDEV\_SAMP
  - VAR
  - VAR\_SAMP

If your query involves the functions MAX or MIN, refer to “One-fetch access (ACCESSTYPE=I1)” on page 957 to see whether your query could take advantage of that method.

## Do you have an input variable in the predicate of an SQL query?

When host variables or parameter markers are used in a query, the actual values are not known when you bind the package or plan that contains the query. DB2 therefore uses a default filter factor to determine the best access path for an SQL statement. If that access path proves to be inefficient, you can do several things to obtain a better access path.

See “Using host variables efficiently” on page 779 for more information.

## Do you have a problem with column correlation?

Two columns in a table are said to be correlated if the values in the columns do not vary independently.

DB2 might not determine the best access path when your queries include correlated columns. If you think you have a problem with column correlation, see “Column correlation” on page 772 for ideas on what to do about it.

## Can your query be written to use a noncolumn expression?

The following predicate combines a column, SALARY, with values that are not from columns on one side of the operator:

```
WHERE SALARY + (:hv1 * SALARY) > 50000
```

If you rewrite the predicate in the following way, DB2 can evaluate it more efficiently:

```
WHERE SALARY > 50000/(1 + :hv1)
```

In the second form, the column is by itself on one side of the operator, and all the other values are on the other side of the operator. The expression on the right is called a *noncolumn expression*. DB2 can evaluate many predicates with noncolumn expressions at an earlier stage of processing called *stage 1*, so the queries take less time to run.

For more information on noncolumn expressions and stage 1 processing, see “Properties of predicates” on page 755.

## Can materialized query tables help your query performance?

Dynamic queries that operate on very large amounts of data and involve multiple joins might take a long time to run. One way to improve the performance of these queries is to generate the results of all or parts of the queries in advance, and store the results in *materialized query tables*.

Materialized query tables are user-created tables. Depending on how the tables are defined, they are user-maintained or system-maintained. If you have set subsystem parameters or an application sets special registers to tell DB2 to use materialized query tables, when DB2 executes a dynamic query, DB2 uses the contents of applicable materialized query tables if DB2 finds a performance advantage to doing so.

For information about materialized query tables, see Chapter 32, “Using materialized query tables,” on page 885.

## Does the query contain encrypted data?

Encryption and decryption can degrade the performance of some queries. However, you can lessen the performance impact of encryption and decryption by writing your queries carefully and designing your database with encrypted data in mind. For more information about avoiding performance degradation while using encrypted data, see “Performance recommendations for data encryption” on page 212.

---

## Writing efficient predicates

**Definition:** *Predicates* are found in the clauses WHERE, HAVING or ON of SQL statements; they describe attributes of data. They are usually based on the columns of a table and either qualify rows (through an index) or reject rows (returned by a scan) when the table is accessed. The resulting qualified or rejected rows are independent of the access path chosen for that table.

**Example:** The following query has three predicates: an equal predicate on C1, a BETWEEN predicate on C2, and a LIKE predicate on C3.

```
SELECT * FROM T1
  WHERE C1 = 10 AND
        C2 BETWEEN 10 AND 20 AND
        C3 NOT LIKE 'A%'
```

**Effect on access paths:** This section explains the effect of predicates on access paths. Because SQL allows you to express the same query in different ways, knowing how predicates affect path selection helps you write queries that access data efficiently.

This section describes:

- “Properties of predicates”
- “General rules about predicate evaluation” on page 759
- “Predicate filter factors” on page 766
- “DB2 predicate manipulation” on page 775
- “Column correlation” on page 772

## Properties of predicates

Predicates in a HAVING clause are not used when selecting access paths; hence, in this section the term ‘predicate’ means a predicate after WHERE or ON.

A predicate influences the selection of an access path because of:

- Its **type**, as described in “Predicate types” on page 756
- Whether it is **indexable**, as described in “Indexable and nonindexable predicates” on page 757
- Whether it is **stage 1** or **stage 2**

- Whether it contains a ROWID column, as described in “Is direct row access possible? (PRIMARY\_ACCESTYPE = D)” on page 946

There are special considerations for “Predicates in the ON clause” on page 758.

**Predicate definitions:** Predicates are identified as:

**Simple or compound**

A *compound* predicate is the result of two predicates, whether simple or compound, connected together by AND or OR Boolean operators. All others are *simple*.

**Local or join**

*Local predicates* reference only one table. They are local to the table and restrict the number of rows returned for that table. *Join predicates* involve more than one table or correlated reference. They determine the way rows are joined from two or more tables. For examples of their use, see “Interpreting access to two or more tables (join)” on page 959.

**Boolean term**

Any predicate that is not contained by a compound OR predicate structure is a *Boolean term*. If a Boolean term is evaluated false for a particular row, the whole WHERE clause is evaluated false for that row.

**Predicate types**

The type of a predicate depends on its operator or syntax. The type determines what type of processing and filtering occurs when the predicate is evaluated. Table 123 shows the different predicate types.

*Table 123. Definitions and examples of predicate types*

Type	Definition	Example
Subquery	Any predicate that includes another SELECT statement.	C1 IN (SELECT C10 FROM TABLE1)
Equal	Any predicate that is not a subquery predicate and has an equal operator and no NOT operator. Also included are predicates of the form C1 IS NULL and C1 IS NOT DISTINCT FROM.	C1=100
Range	Any predicate that is not a subquery predicate and has an operator in the following list: >, >=, <, <=, LIKE, or BETWEEN.	C1>100
IN-list	A predicate of the form column IN (list of values).	C1 IN (5,10,15)
NOT	Any predicate that is not a subquery predicate and contains a NOT operator. Also included are predicates of the form C1 IS DISTINCT FROM.	COL1 <> 5 or COL1 NOT BETWEEN 10 AND 20

**Example: Influence of type on access paths:** The following two examples show how the predicate type can influence DB2’s choice of an access path. In each one, assume that a unique index I1 (C1) exists on table T1 (C1, C2), and that all values of C1 are positive integers.

The following query has a range predicate:

```
SELECT C1, C2 FROM T1 WHERE C1 >= 0;
```

However, the predicate does not eliminate any rows of T1. Therefore, it could be determined during bind that a table space scan is more efficient than the index scan.

The following query has an equal predicate:

```
SELECT * FROM T1 WHERE C1 = 0;
```

DB2 chooses the index access in this case because the index is highly selective on column C1.

## Indexable and nonindexable predicates

**Definition:** *Indexable* predicate types can match index entries; other types cannot. Indexable predicates might not become matching predicates of an index; it depends on the indexes that are available and the access path chosen at bind time.

**Examples:** If the employee table has an index on the column LASTNAME, the following predicate can be a matching predicate:

```
SELECT * FROM DSN8810.EMP WHERE LASTNAME = 'SMITH';
```

The following predicate cannot be a matching predicate, because it is not indexable.

```
SELECT * FROM DSN8810.EMP WHERE SEX <> 'F';
```

**Recommendation:** To make your queries as efficient as possible, use indexable predicates in your queries and create suitable indexes on your tables. Indexable predicates allow the possible use of a matching index scan, which is often a very efficient access path.

## Stage 1 and stage 2 predicates

**Definition:** Rows retrieved for a query go through two stages of processing.

1. *Stage 1* predicates (sometimes called *sargable*) can be applied at the first stage.
2. *Stage 2* predicates (sometimes called *nonsargable* or *residual*) cannot be applied until the second stage.

The following items determine whether a predicate is stage 1:

- Predicate syntax

See Table 124 on page 760 for a list of simple predicates and their types. See Examples of predicate properties for information on compound predicate types.

- Type and length of constants or columns in the predicate

A simple predicate whose syntax classifies it as indexable and stage 1 might not be indexable or stage 1 because it contains constants and columns whose lengths are too long.

**Example:** The following predicate is not indexable:

```
CHARCOL<'ABCDEF'G', where CHARCOL is defined as CHAR(6)
```

The predicate is not indexable because the length of the column is shorter than the length of the constant.

**Example:** The following predicate is not stage 1:

```
DECCOL>34.5, where DECCOL is defined as DECIMAL(18,2)
```

The predicate is not stage 1 because the precision of the decimal column is greater than 15.

- Whether DB2 evaluates the predicate before or after a join operation. A predicate that is evaluated after a join operation is always a stage 2 predicate.

- Join sequence

The same predicate might be stage 1 or stage 2, depending on the join sequence. *Join sequence* is the order in which DB2 joins tables when it evaluates a query. The join sequence is not necessarily the same as the order in which the tables appear in the predicate.

**Example:** This predicate might be stage 1 or stage 2:

```
T1.C1=T2.C1+1
```

If T2 is the first table in the join sequence, the predicate is stage 1, but if T1 is the first table in the join sequence, the predicate is stage 2.

You can determine the join sequence by executing EXPLAIN on the query and examining the resulting plan table. See Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 for details.

All indexable predicates are stage 1. The predicate C1 LIKE %BC is stage 1, but is not indexable.

**Recommendation:** Use stage 1 predicates whenever possible.

### Boolean term (BT) predicates

*Definition:* A *Boolean term predicate*, or *BT predicate*, is a simple or compound predicate that, when it is evaluated false for a particular row, makes the entire WHERE clause false for that particular row.

**Examples:** In the following query P1, P2 and P3 are simple predicates:

```
SELECT * FROM T1 WHERE P1 AND (P2 OR P3);
```

- P1 is a simple BT predicate.
- P2 and P3 are simple non-BT predicates.
- P2 OR P3 is a compound BT predicate.
- P1 AND (P2 OR P3) is a compound BT predicate.

*Effect on access paths:* In single-index processing, only Boolean term predicates are chosen for matching predicates. Hence, only indexable Boolean term predicates are candidates for matching index scans. To match index columns by predicates that are not Boolean terms, DB2 considers multiple-index access.

In join operations, Boolean term predicates can reject rows at an earlier stage than can non-Boolean term predicates.

**Recommendation:** For join operations, choose Boolean term predicates over non-Boolean term predicates whenever possible.

## Predicates in the ON clause

The ON clause supplies the join condition in an outer join. For a full outer join, the clause can use only equal predicates. For other outer joins, the clause can use any predicates except predicates that contain subqueries.

For left and right outer joins, and for inner joins, join predicates in the ON clause are treated the same as other stage 1 and stage 2 predicates. A stage 2 predicate in the ON clause is treated as a stage 2 predicate of the inner table.

For full outer join, the ON clause is evaluated during the join operation like a stage 2 predicate.

In an outer join, predicates that are evaluated after the join are stage 2 predicates. Predicates in a table expression can be evaluated before the join and can therefore be stage 1 predicates.

**Example:** In the following statement, the predicate “EDLEVEL > 100” is evaluated before the full join and is a stage 1 predicate:

```
SELECT * FROM (SELECT * FROM DSN8810.EMP
WHERE EDLEVEL > 100) AS X FULL JOIN DSN8810.DEPT
ON X.WORKDEPT = DSN8810.DEPT.DEPTNO;
```

For more information about join methods, see “Interpreting access to two or more tables (join)” on page 959.

---

## General rules about predicate evaluation

### Recommendations:

1. In terms of resource usage, the earlier a predicate is evaluated, the better.
2. Stage 1 predicates are better than stage 2 predicates because they disqualify rows earlier and reduce the amount of processing needed at stage 2.
3. When possible, try to write queries that evaluate the most restrictive predicates first. When predicates with a high filter factor are processed first, unnecessary rows are screened as early as possible, which can reduce processing cost at a later stage. However, a predicate’s restrictiveness is only effective among predicates of the same type and the same evaluation stage. For information about filter factors, see “Predicate filter factors” on page 766.

This section contains the following topics:

- “Order of evaluating predicates”
- “Examples of predicate properties” on page 765
- “Predicate filter factors” on page 766
- “Column correlation” on page 772
- “DB2 predicate manipulation” on page 775
- “Predicates with encrypted data” on page 779

## Order of evaluating predicates

Two sets of rules determine the order of predicate evaluation.

The first set:

1. Indexable predicates are applied first. All matching predicates on index key columns are applied first and evaluated when the index is accessed.  
Next, stage 1 predicates that have not been picked as matching predicates but still refer to index columns are applied to the index. This is called *index screening*.
2. Other stage 1 predicates are applied next.  
After data page access, stage 1 predicates are applied to the data.
3. Finally, the stage 2 predicates are applied on the returned data rows.

The second set of rules describes the order of predicate evaluation within each of the stages:

1. All equal predicates (including column IN *list*, where *list* has only one element, or column BETWEEN *value1* AND *value1*) are evaluated.
2. All range predicates and predicates of the form *column* IS NOT NULL are evaluated.
3. All other predicate types are evaluated.

After both sets of rules are applied, predicates are evaluated in the order in which they appear in the query. Because you specify that order, you have some control over the order of evaluation.

**Exception:** Regardless of coding order, non-correlated subqueries are evaluated before correlated subqueries, unless DB2 transforms the subquery into a join.

## Summary of predicate processing

Table 124 lists many of the simple predicates and tells whether those predicates are indexable or stage 1. The following terms are used:

- *subq* means a correlated or noncorrelated subquery.
- *noncor subq* means a noncorrelated subquery.
- *cor subq* means a correlated subquery.
- *op* is any of the operators >, >=, <, <=, >, <.
- *value* is a constant, host variable, or special register.
- *pattern* is any character string that does *not* start with the special characters for percent (%) or underscore (\_).
- *char* is any character string that does *not* include the special characters for percent (%) or underscore (\_).
- *expression* is any expression that contains arithmetic operators, scalar functions, aggregate functions, concatenation operators, columns, constants, host variables, special registers, or date or time expressions.
- *noncol expr* is a noncolumn expression, which is any expression that does not contain a column. That expression can contain arithmetic operators, scalar functions, concatenation operators, constants, host variables, special registers, or date or time expressions.

An example of a noncolumn expression is

```
CURRENT DATE - 50 DAYS
```

- *Tn col expr* is an expression that contains a column in table *Tn*. The expression might be only that column.
- *predicate* is a predicate of any type.

In general, if you form a compound predicate by combining several simple predicates with OR operators, the result of the operation has the same characteristics as the simple predicate that is evaluated latest. For example, if two indexable predicates are combined with an OR operator, the result is indexable. If a stage 1 predicate and a stage 2 predicate are combined with an OR operator, the result is stage 2.

Table 124. Predicate types and processing

Predicate Type	Index-able?	Stage 1?	Notes

	<i>expression op (subq)</i>	N	N	

**Notes to Table 124 on page 760:**

1. Indexable only if an ESCAPE character is specified and used in the LIKE predicate. For example, COL LIKE '+%char' ESCAPE '+' is indexable.
2. Indexable only if the pattern in the host variable is an indexable constant (for example, host variable='char%').
3. If both COL1 and COL2 are from the same table, access through an index on either one is not considered for these predicates. However, the following query is an exception:

```
SELECT * FROM T1 A, T1 B WHERE A.C1 = B.C2;
```

By using correlation names, the query treats one table as if it were two separate tables. Therefore, indexes on columns C1 and C2 are considered for access.

4. If the subquery has already been evaluated for a given correlation value, then the subquery might not have to be reevaluated.
5. Not indexable or stage 1 if a field procedure exists on that column.
6. The column on the left side of the join sequence must be in a different table from any columns on the right side of the join sequence.
7. The tables that contain the columns in *expression1* or *expression2* must already have been accessed.
8. The processing for WHERE NOT COL = *value* is like that for WHERE COL <> *value*, and so on.
9. If *noncol expr*, *noncol expr1*, or *noncol expr2* is a noncolumn expression of one of these forms, then the predicate is not indexable:
  - *noncol expr* + 0
  - *noncol expr* - 0
  - *noncol expr* \* 1
  - *noncol expr* / 1
  - *noncol expr* CONCAT *empty string*
10. COL, COL1, and COL2 can be the same column or different columns. The columns are in the same table.
11. Any of the following sets of conditions make the predicate stage 2:
  - The first value obtained before the predicate is evaluated is DECIMAL(*p,s*), where *p*>15, and the second value obtained before the predicate is evaluated is REAL or FLOAT.
  - The first value obtained before the predicate is evaluated is CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC, and the second value obtained before the predicate is evaluated is DATE, TIME, or TIMESTAMP.
12. The predicate is stage 1 but not indexable if the first value obtained before the predicate is evaluated is CHAR or VARCHAR, the second value obtained before the predicate is evaluated is GRAPHIC or VARGRAPHIC, and the first value obtained before the predicate is evaluated is not Unicode mixed.
13. If both sides of the comparison are strings, any of the following sets of conditions makes the predicate stage 1 but not indexable:
  - The first value obtained before the predicate is evaluated is CHAR or VARCHAR, and the second value obtained before the predicate is evaluated is GRAPHIC or VARGRAPHIC.
  - Both of the following conditions are true:
    - Both sides of the comparison are CHAR or VARCHAR, or both sides of the comparison are BINARY or VARBINARY

#

- #                   – The length the first value obtained before the predicate is evaluated is
- #                   less than the length of the second value obtained before the predicate is
- #                   evaluated.
- #                   • Both of the following conditions are true:
- #                   – Both sides of the comparison are GRAPHIC or VARGRAPHIC.
- #                   – The length of the first value obtained before the predicate is evaluated is
- #                   less than the length of the second value obtained before the predicate is
- #                   evaluated.
- #                   • Both of the following conditions are true:
- #                   – The first value obtained before the predicate is evaluated is GRAPHIC or
- #                   VARGRAPHIC, and the second value obtained before the predicate is
- #                   evaluated is CHAR or VARCHAR.
- #                   – The length of the first value obtained before the predicate is evaluated is
- #                   less than the length of the second value obtained before the predicate is
- #                   evaluated.
- #                   14. If both sides of the comparison are strings, but the two sides have different
- #                   CCSIDs, the predicate is stage 1 and indexable only if the first value obtained
- #                   before the predicate is evaluated is Unicode and the comparison does not
- #                   meet any of the conditions in note 13 on page 763.
- |                   15. Under either of these circumstances, the predicate is stage 2:
- |                   • *noncol expr* is a case expression.
- |                   • All of the following conditions are true:
- |                   – *noncol expr* is the product or the quotient of two noncolumn expressions
- |                   – *noncol expr* is an integer value
- |                   – COL is a FLOAT or a DECIMAL column
- |                   16. If COL has the ROWID data type, DB2 tries to use direct row access instead of
- |                   index access or a table space scan.
- |                   17. If COL has the ROWID data type, and an index is defined on COL, DB2 tries
- |                   to use direct row access instead of index access.
- |                   18. IN-list predicates are indexable and stage 1 if the following conditions are
- |                   true:
- |                   • The IN list contains only simple items. For example, constants, host
- |                   variables, parameter markers, and special registers.
- |                   • The IN list does not contain any aggregate functions or scalar functions.
- |                   • The IN list is not contained in a trigger's WHEN clause.
- |                   • For numeric predicates where the left side column is DECIMAL with
- |                   precision greater than 15, none of the items in the IN list are FLOAT.
- |                   • For string predicates, the coded character set identifier is the same as the
- |                   identifier for the left side column.
- |                   • For DATE, TIME, and TIMESTAMP predicates, the left side column must be
- |                   DATE, TIME, or TIMESTAMP.
- |                   19. COL IN (*corr subq*) and EXISTS (*corr subq*) predicates might become indexable
- |                   and stage 1 if they are transformed to a join during processing.
- #                   20. The predicate types COL IS NULL and COL IS NOT NULL are stage 2
- #                   predicates when they query a column that is defined as NOT NULL.
- #                   21. If the predicate type is COL IS NULL and the column is defined as NOT
- #                   NULL, the table is not accessed because C1 cannot be NULL.
- #                   22. The ANY and SOME keywords behave similarly. If a predicate with the ANY
- #                   keyword is not indexable and not stage 1, a similar predicate with the SOME
- #                   keyword is not indexable and not stage 1.

- # 23. Under either of these circumstances, the predicate is stage 2:
  - # • *noncol expr* is a case expression.
  - # • *noncol expr* is the product or the quotient of two noncolumn expressions,
  - # that product or quotient is an integer value, and COL is a FLOAT or a
  - # DECIMAL column.
- # 24. COL IN (*noncor subq*) is stage 1 for type N access only. Otherwise, it is stage 2.
- # 25. If the inner table is as EBCDIC or ASCII column and the outer table is a
- # Unicode column, the predicate is stage 1 and indexable.
- # 26. This type of predicate is not stage 1 when a nullability mismatch is possible.

## Examples of predicate properties

Assume that predicate P1 and P2 are simple, stage 1, indexable predicates:

P1 AND P2 is a compound, stage 1, indexable predicate.

P1 OR P2 is a compound, stage 1 predicate, not indexable except by a union of RID lists from two indexes.

The following examples of predicates illustrate the general rules shown in Table 124 on page 760. In each case, assume that there is an index on columns (C1,C2,C3,C4) of the table and that 0 is the lowest value in each column.

- WHERE C1=5 AND C2=7

Both predicates are stage 1 and the compound predicate is indexable. A matching index scan could be used with C1 and C2 as matching columns.

- WHERE C1=5 AND C2>7

Both predicates are stage 1 and the compound predicate is indexable. A matching index scan could be used with C1 and C2 as matching columns.

- WHERE C1>5 AND C2=7

Both predicates are stage 1, but only the first matches the index. A matching index scan could be used with C1 as a matching column.

- WHERE C1=5 OR C2=7

Both predicates are stage 1 but not Boolean terms. The compound is indexable. Multiple-index access for the compound predicate is not possible because there is no index that has C2 as the leading column. For single-index access, C1 and C2 can be only index screening columns.

- WHERE C1=5 OR C2<>7

The first predicate is indexable and stage 1, and the second predicate is stage 1 but not indexable. The compound predicate is stage 1 and not indexable.

- WHERE C1>5 OR C2=7

Both predicates are stage 1 but not Boolean terms. The compound is indexable. Multiple-index access for the compound predicate is not possible because no index has C2 as the leading column. For single-index access, C1 and C2 can be only index screening columns.

- WHERE C1 IN (*cor subq*) AND C2=C1

Both predicates are stage 2 and not indexable. The index is not considered for matching-index access, and both predicates are evaluated at stage 2.

- WHERE C1=5 AND C2=7 AND (C3 + 5) IN (7,8)

The first two predicates only are stage 1 and indexable. The index is considered for matching-index access, and all rows satisfying those two predicates are passed to stage 2 to evaluate the third predicate.

- WHERE C1=5 OR C2=7 OR (C3 + 5) IN (7,8)

The third predicate is stage 2. The compound predicate is stage 2 and all three predicates are evaluated at stage 2. The simple predicates are not Boolean terms and the compound predicate is not indexable.

- WHERE C1=5 OR (C2=7 AND C3=C4)

The third predicate is stage 2. The two compound predicates (C2=7 AND C3=C4) and (C1=5 OR (C2=7 AND C3=C4)) are stage 2. All predicates are evaluated at stage 2.

- WHERE (C1>5 OR C2=7) AND C3 = C4

The compound predicate (C1>5 OR C2=7) is indexable and stage 1. The simple predicate C3=C4 is not stage1; so the index is not considered for matching-index access. Rows that satisfy the compound predicate (C1>5 OR C2=7) are passed to stage 2 for evaluation of the predicate C3=C4.

## Predicate filter factors

**Definition:** The *filter factor* of a predicate is a number between 0 and 1 that estimates the proportion of rows in a table for which the predicate is true. Those rows are said to *qualify* by that predicate.

**Example:** Suppose that DB2 can determine that column C1 of table T contains only five distinct values: A, D, Q, W and X. In the absence of other information, DB2 estimates that one-fifth of the rows have the value D in column C1. Then the predicate C1='D' has the filter factor 0.2 for table T.

**How DB2 uses filter factors:** Filter factors affect the choice of access paths by estimating the number of rows qualified by a set of predicates.

For simple predicates, the filter factor is a function of three variables:

1. The literal value in the predicate; for instance, 'D' in the previous example.
2. The operator in the predicate; for instance, '=' in the previous example and '<>' in the negation of the predicate.
3. Statistics on the column in the predicate. In the previous example, those include the information that column T.C1 contains only five values.

**Recommendation:** Control the first two of those variables when you write a predicate. Your understanding of how DB2 uses filter factors should help you write more efficient predicates.

Values of the third variable, statistics on the column, are kept in the DB2 catalog. You can update many of those values, either by running the utility RUNSTATS or by executing UPDATE for a catalog table. For information about using RUNSTATS, see "Gathering monitor statistics and update statistics" on page 916. For information on updating the catalog manually, see "Updating catalog statistics" on page 804.

If you intend to update the catalog with statistics of your own choice, you should understand how DB2 uses:

- "Default filter factors for simple predicates"
- "Filter factors for uniform distributions" on page 767
- "Interpolation formulas" on page 768
- "Filter factors for all distributions" on page 769

### Default filter factors for simple predicates

Table 125 on page 767 lists default filter factors for different types of predicates. DB2 uses those values when no other statistics exist.

**Example:** The default filter factor for the predicate C1 = 'D' is 1/25 (0.04). If D is actually not close to 0.04, the default probably does not lead to an optimal access path.

Table 125. DB2 default filter factors by predicate type

Predicate Type	Filter Factor
Col = literal	1/25
Col <> literal	1 - (1/25)
Col IS NULL	1/25
Col IS NOT DISTINCT FROM	1/25
Col IS DISTINCT FROM	1 - (1/25)
Col IN (literal list)	(number of literals)/25
Col Op literal	1/3
Col LIKE literal	1/10
Col BETWEEN literal1 and literal2	1/10

**Note:**

Op is one of these operators: <, <=, >, >=.

Literal is any constant value that is known at bind time.

### Filter factors for uniform distributions

DB2 uses the filter factors in Table 126 if:

- There is a positive value in column COLCARDF of catalog table SYSIBM.SYSCOLUMNS for the column "Col".
- There are no additional statistics for "Col" in SYSIBM.SYSCOLDIST.

**Example:** If D is one of only five values in column C1, using RUNSTATS puts the value 5 in column COLCARDF of SYSCOLUMNS. If there are no additional statistics available, the filter factor for the predicate C1 = 'D' is 1/5 (0.2).

Table 126. DB2 uniform filter factors by predicate type

Predicate type	Filter factor
Col = literal	1/COLCARDF
Col <> literal	1 - (1/COLCARDF)
Col IS NULL	1/COLCARDF
Col IS NOT DISTINCT FROM	1/COLCARDF
Col IS DISTINCT FROM	1 - (1/COLCARDF)
Col IN (literal list)	number of literals /COLCARDF
Col Op1 literal	interpolation formula
Col Op2 literal	interpolation formula
Col LIKE literal	interpolation formula
Col BETWEEN literal1 and literal2	interpolation formula

**Note:**

Op1 is < or <=, and the literal is not a host variable.

Op2 is > or >=, and the literal is not a host variable.

Literal is any constant value that is known at bind time.

**Filter factors for other predicate types:** The examples selected in Table 125 on page 767 and Table 126 on page 767 represent only the most common types of predicates. If P1 is a predicate and F is its filter factor, then the filter factor of the predicate NOT P1 is (1 - F). But, filter factor calculation is dependent on many things, so a specific filter factor cannot be given for all predicate types.

## Interpolation formulas

**Definition:** For a predicate that uses a range of values, DB2 calculates the filter factor by an *interpolation formula*. The formula is based on an estimate of the ratio of the number of values in the range to the number of values in the entire column of the table.

**The formulas:** The formulas that follow are rough estimates, subject to further modification by DB2. They apply to a predicate of the form *col op. literal*. The value of (Total Entries) in each formula is estimated from the values in columns HIGH2KEY and LOW2KEY in catalog table SYSIBM.SYSCOLUMNS for column *col*:  
Total Entries = (HIGH2KEY value - LOW2KEY value).

- For the operators < and <=, where the literal is not a host variable:  
(Literal value - LOW2KEY value) / (Total Entries)
- For the operators > and >=, where the literal is not a host variable:  
(HIGH2KEY value - Literal value) / (Total Entries)
- For LIKE or BETWEEN:  
(High literal value - Low literal value) / (Total Entries)

**Example:** For column C2 in a predicate, suppose that the value of HIGH2KEY is 1400 and the value of LOW2KEY is 200. For C2, DB2 calculates (Total Entries) = 1200.

For the predicate C1 BETWEEN 800 AND 1100, DB2 calculates the filter factor F as:  
F = (1100 - 800)/1200 = 1/4 = 0.25

**Interpolation for LIKE:** DB2 treats a LIKE predicate as a type of BETWEEN predicate. Two values that bound the range qualified by the predicate are generated from the literal string in the predicate. Only the leading characters found before the escape character ('%' or '\_' ) are used to generate the bounds. So if the escape character is the first character of the string, the filter factor is estimated as 1, and the predicate is estimated to reject no rows.

**Defaults for interpolation:** DB2 might not interpolate in some cases; instead, it can use a default filter factor. Defaults for interpolation are:

- Relevant only for ranges, including LIKE and BETWEEN predicates
- Used only when interpolation is not adequate
- Based on the value of COLCARDF
- Used whether uniform or additional distribution statistics exist on the column if either of the following conditions is met:
  - The predicate does not contain constants
  - COLCARDF < 4.

Table 127 on page 769 shows interpolation defaults for the operators <, <=, >, >= and for LIKE and BETWEEN.

Table 127. Default filter factors for interpolation

COLCARDF	Factor for Op	Factor for LIKE or BETWEEN
>=100000000	1/10,000	3/100000
>=10000000	1/3,000	1/10000
>=1000000	1/1,000	3/10000
>=100000	1/300	1/1000
>=10000	1/100	3/1000
>=1000	1/30	1/100
>=100	1/10	3/100
>=2	1/3	1/10
=1	1/1	1/1
<=0	1/3	1/10

**Note:** Op is one of these operators: <, <=, >, >=.

### Filter factors for all distributions

RUNSTATS can generate additional statistics for a column or set of columns. DB2 can use that information to calculate filter factors. DB2 collects two kinds of distribution statistics:

#### Frequency

The percentage of rows in the table that contain a value for a column or set of columns

#### Cardinality

The number of distinct values in a set of columns

*When they are used:* Table 128 lists the types of predicates on which these statistics are used.

Table 128. Predicates for which distribution statistics are used

Type of statistic	Single column or concatenated columns	Predicates
Frequency	Single	COL= <i>literal</i> COL IS NULL COL IN ( <i>literal-list</i> ) COL <i>op literal</i> COL BETWEEN <i>literal</i> AND <i>literal</i> COL= <i>host-variable</i> COL1=COL2 T1.COL=T2.COL COL IS NOT DISTINCT FROM
Frequency	Concatenated	COL= <i>literal</i> COL IS NOT DISTINCT FROM

Table 128. Predicates for which distribution statistics are used (continued)

Type of statistic	Single column or concatenated columns	Predicates
Cardinality	Single	COL= <i>literal</i> COL IS NULL COL IN ( <i>literal-list</i> ) COL <i>op</i> <i>literal</i> COL BETWEEN <i>literal</i> AND <i>literal</i> COL= <i>host-variable</i> COL1=COL2 T1.COL=T2.COL COL IS NOT DISTINCT FROM
Cardinality	Concatenated	COL= <i>literal</i> COL=: <i>host-variable</i> COL1=COL2 COL IS NOT DISTINCT FROM

**Note:** *op* is one of these operators: <, <=, >, >=.

**How they are used:** Columns COLVALUE and FREQUENCYF in table SYSCOLDIST contain distribution statistics. Regardless of the number of values in those columns, running RUNSTATS deletes the existing values and inserts rows for frequent values.

You can run RUNSTATS without the FREQVAL option, with the FREQVAL option in the *correl-spec*, with the FREQVAL option in the *colgroup-spec*, or in both, with the following effects:

- If you run RUNSTATS without the FREQVAL option, RUNSTATS inserts rows for the 10 most frequent values for the first column of the specified index.
- If you run RUNSTATS with the FREQVAL option in the *correl-spec*, RUNSTATS inserts rows for concatenated columns of an index. The NUMCOLS option specifies the number of concatenated index columns. The COUNT option specifies the number of frequent values. You can collect most-frequent values, least-frequent values, or both.
- If you run RUNSTATS with the FREQVAL option in the *colgroup-spec*, RUNSTATS inserts rows for the columns in the column group that you specify. The COUNT option specifies the number of frequent values. You can collect most-frequent values, least-frequent values, or both.
- If you specify the FREQVAL option, RUNSTATS inserts rows for columns of the specified index and for columns in a column group.

See Part 2 of *DB2 Utility Guide and Reference* for more information about RUNSTATS. DB2 uses the frequencies in column FREQUENCYF for predicates that use the values in column COLVALUE and assumes that the remaining data are uniformly distributed.

**Example: Filter factor for a single column**

Suppose that the predicate is C1 IN ('3','5') and that SYSCOLDIST contains these values for column C1:

COLVALUE	FREQUENCYF
'3'	.0153
'5'	.0859
'8'	.0627

The filter factor is  $.0153 + .0859 = .1012$ .

*Example: Filter factor for correlated columns*

Suppose that columns C1 and C2 are correlated. Suppose also that the predicate is C1='3' AND C2='5' and that SYSCOLDIST contains these values for columns C1 and C2:

COLVALUE	FREQUENCY
'1' '1'	.1176
'2' '2'	.0588
'3' '3'	.0588
'3' '5'	.1176
'4' '4'	.0588
'5' '3'	.1764
'5' '5'	.3529
'6' '6'	.0588

The filter factor is .1176.

**Using multiple filter factors to determine the cost of a query**

When DB2 estimates the cost of a query, it determines the filter factor repeatedly and at various levels. For example, suppose that you execute the following query:

```
SELECT COLS FROM T1
WHERE C1 = 'A'
AND C3 = 'B'
AND C4 = 'C';
```

Table T1 consists of columns C1, C2, C3, and C4. Index I1 is defined on table T1 and contains columns C1, C2, and C3.

Suppose that the simple predicates in the compound predicate have the following characteristics:

- C1='A'** Matching predicate
- C3='B'** Screening predicate
- C4='C'** Stage 1, nonindexable predicate

To determine the cost of accessing table T1 through index I1, DB2 performs these steps:

1. Estimates the matching index cost. DB2 determines the index matching filter factor by using single-column cardinality and single-column frequency statistics because only one column can be a matching column.
2. Estimates the total index filtering. This includes matching and screening filtering. If statistics exist on column group (C1,C3), DB2 uses those statistics. Otherwise DB2 uses the available single-column statistics for each of these columns.  
DB2 will also use FULLKEYCARD as a bound. Therefore, it can be critical to have column group statistics on column group (C1, C3) to get an accurate estimate.
3. Estimates the table-level filtering. If statistics are available on column group (C1,C3,C4), DB2 uses them. Otherwise, DB2 uses statistics that exist on subsets of those columns.

**Important:** If you supply appropriate statistics at each level of filtering, DB2 is more likely to choose the most efficient access path.

You can use RUNSTATS to collect any of the needed statistics.

## Column correlation

Two columns of data, A and B of a single table, are correlated if the values in column A do not vary independently of the values in column B.

**Example:** Table 129 is an excerpt from a large single table. Columns CITY and STATE are highly correlated, and columns DEPTNO and SEX are entirely independent.

Table 129. Data from the CREWINFO table

CITY	STATE	DEPTNO	SEX	EMPNO	ZIPCODE
Fresno	CA	A345	F	27375	93650
Fresno	CA	J123	M	12345	93710
Fresno	CA	J123	F	93875	93650
Fresno	CA	J123	F	52325	93792
New York	NY	J123	M	19823	09001
New York	NY	A345	M	15522	09530
Miami	FL	B499	M	83825	33116
Miami	FL	A345	F	35785	34099
Los Angeles	CA	X987	M	12131	90077
Los Angeles	CA	A345	M	38251	90091

In this simple example, for every value of column CITY that equals 'FRESNO', there is the same value in column STATE ('CA').

### How to detect column correlation

The first indication that column correlation is a problem is because of poor response times when DB2 has chosen an inappropriate access path. If you suspect two columns in a table (CITY and STATE in table CREWINFO) are correlated, then you can issue the following SQL queries that reflect the relationships between the columns:

```
SELECT COUNT (DISTINCT CITY) AS CITYCOUNT,  
       COUNT (DISTINCT STATE) AS STATECOUNT FROM CREWINFO;
```

The result of the count of each distinct column is the value of COLCARDF in the DB2 catalog table SYSCOLUMNS. Multiply the previous two values together to get a preliminary result:

```
CITYCOUNT x STATECOUNT = ANSWER1
```

Then issue the following SQL statement:

```
SELECT COUNT(*) FROM  
       (SELECT DISTINCT CITY, STATE  
        FROM CREWINFO) AS V1;           (ANSWER2)
```

Compare the result of the previous count (ANSWER2) with ANSWER1. If ANSWER2 is less than ANSWER1, then the suspected columns are correlated.

### Impacts of column correlation

DB2 might not determine the best access path, table order, or join method when your query uses columns that are highly correlated. Column correlation can make

the estimated cost of operations cheaper than they actually are. Column correlation affects both single table queries and join queries.

**Column correlation on the best matching columns of an index:** The following query selects rows with females in department A345 from Fresno, California. Two indexes are defined on the table, Index 1 (CITY,STATE,ZIPCODE) and Index 2 (DEPTNO,SEX).

**Query 1**

```
SELECT ... FROM CREWINFO WHERE
  CITY = 'FRESNO' AND STATE = 'CA'           (PREDICATE1)
  AND DEPTNO = 'A345' AND SEX = 'F';        (PREDICATE2)
```

Consider the two compound predicates (labeled PREDICATE1 and PREDICATE2), their actual filtering effects (the proportion of rows they select), and their DB2 filter factors. Unless the proper catalog statistics are gathered, the filter factors are calculated as if the columns of the predicate are entirely independent (not correlated).

When the columns in a predicate correlate but the correlation is not reflected in catalog statistics, the actual filtering effect to be significantly different from the DB2 filter factor. Table 130 shows how the actual filtering effect and the DB2 filter factor can differ, and how that difference can affect index choice and performance.

Table 130. Effects of column correlation on matching columns

	INDEX 1	INDEX 2
Matching predicates	Predicate1 CITY=FRESNO AND STATE=CA	Predicate2 DEPTNO=A345 AND SEX=F
Matching columns	2	2
DB2 estimate for matching columns (Filter Factor)	column=CITY, COLCARDF=4 Filter Factor=1/4 column=STATE, COLCARDF=3 Filter Factor=1/3	column=DEPTNO, COLCARDF=4 Filter Factor=1/4 column=SEX, COLCARDF=2 Filter Factor=1/2
Compound filter factor for matching columns	$1/4 \times 1/3 = 0.083$	$1/4 \times 1/2 = 0.125$
Qualified leaf pages based on DB2 estimations	$0.083 \times 10 = 0.83$ INDEX CHOSEN (.8 < 1.25)	$0.125 \times 10 = 1.25$
Actual filter factor based on data distribution	4/10	2/10
Actual number of qualified leaf pages based on compound predicate	$4/10 \times 10 = 4$	$2/10 \times 10 = 2$ BETTER INDEX CHOICE (2 < 4)

DB2 chooses an index that returns the fewest rows, partly determined by the smallest filter factor of the matching columns. Assume that filter factor is the only influence on the access path. The combined filtering of columns CITY and STATE seems very good, whereas the matching columns for the second index do not seem to filter as much. Based on those calculations, DB2 chooses Index 1 as an access path for Query 1.

The problem is that the filtering of columns CITY and STATE should not look good. Column STATE does almost no filtering. Since columns DEPTNO and SEX do a better job of filtering out rows, DB2 should favor Index 2 over Index 1.

**Column correlation on index screening columns of an index:** Correlation might also occur on nonmatching index columns, used for index screening. See “Nonmatching index scan (ACCESSTYPE=I and MATCHCOLS=0)” on page 955 for more information. Index screening predicates help reduce the number of data rows that qualify while scanning the index. However, if the index screening predicates are correlated, they do not filter as many data rows as their filter factors suggest. To illustrate this, use “Query 1” on page 773 with the following indexes on Table 129 on page 772:

Index 3 (EMPNO,CITY,STATE)  
 Index 4 (EMPNO,DEPTNO,SEX)

In the case of Index 3, because the columns CITY and STATE of Predicate 1 are correlated, the index access is not improved as much as estimated by the screening predicates and therefore Index 4 might be a better choice. (Note that index screening also occurs for indexes with matching columns greater than zero.)

**Multiple table joins:** In Query 2, Table 131 is added to the original query (see “Query 1” on page 773) to show the impact of column correlation on join queries.

Table 131. Data from the DEPTINFO table

CITY	STATE	MANAGER	DEPT	DEPTNAME
Fresno	CA	Smith	J123	ADMIN
Los Angeles	CA	Jones	A345	LEGAL

**Query 2**

```
SELECT ... FROM CREWINFO T1,DEPTINFO T2
  WHERE T1.CITY = 'FRESNO' AND T1.STATE='CA'           (PREDICATE 1)
  AND T1.DEPTNO = T2.DEPT AND T2.DEPTNAME = 'LEGAL';
```

The order that tables are accessed in a join statement affects performance. The estimated combined filtering of Predicate1 is lower than its actual filtering. So table CREWINFO might look better as the first table accessed than it should.

Also, due to the smaller estimated size for table CREWINFO, a nested loop join might be chosen for the join method. But, if many rows are selected from table CREWINFO because Predicate1 does not filter as many rows as estimated, then another join method or join sequence might be better.

**What to do about column correlation**

If column correlation is causing DB2 to choose an inappropriate access path, try one of these techniques to alter the access path:

- | • For leading indexed columns, run the RUNSTATS utility with the KEYCARD option determine the column correlation. For all other column groups, run the RUNSTATS utility with the COLGROUP option.
- | • Run the RUNSTATS utility to collect column correlation information for any column group with the COLGROUP option.
- | • Update the catalog statistics manually.
- | • Use SQL that forces access through a particular index.

The last two techniques are discussed in “Special techniques to influence access path selection” on page 794.

The RUNSTATS utility collects the statistics DB2 needs to make proper choices about queries. With RUNSTATS, you can collect statistics on the concatenated key columns of an index and the number of distinct values for those concatenated columns. This gives DB2 accurate information to calculate the filter factor for the query.

**Example:** RUNSTATS collects statistics that benefit queries like this:

```
SELECT * FROM T1
WHERE C1 = 'a' AND C2 = 'b' AND C3 = 'c' ;
```

where:

- The first three index keys are used (MATCHCOLS = 3).
- An index exists on C1, C2, C3, C4, C5.
- Some or all of the columns in the index are correlated in some way.

See “Using RUNSTATS to keep access path statistics current” on page 657 for information on using RUNSTATS to influence access path selection. See “Updating catalog statistics” on page 804 for information on updating catalog statistics manually.

## DB2 predicate manipulation

In some specific cases, DB2 either modifies some predicates, or generates extra predicates. Although these modifications are transparent to you, they have a direct impact on the access path selection and your PLAN\_TABLE results. This is because DB2 always uses an index access path when it is cost effective. Generating extra predicates provides more indexable predicates potentially, which creates more chances for an efficient index access path.

Therefore, to understand your PLAN\_TABLE results, you must understand how DB2 manipulates predicates. The information in Table 124 on page 760 is also helpful.

### Predicate modifications for IN-list predicates

If an IN-list predicate has only one item in its list, the predicate becomes an EQUAL predicate.

A set of simple, Boolean term, equal predicates on the same column that are connected by OR predicates can be converted into an IN-list predicate. For example: C1=5 or C1=10 or C1=15 converts to C1 IN (5,10,15).

### When DB2 simplifies join operations

Because full outer joins are less efficient than left or right joins, and left and right joins are less efficient than inner joins, you should always try to use the simplest type of join operation in your queries. However, if DB2 encounters a join operation that it can simplify, it attempts to do so. In general, DB2 can simplify a join operation when the query contains a predicate or an ON clause that eliminates the null values that are generated by the join operation.

**Example:** Consider this query:

```
SELECT * FROM T1 X FULL JOIN T2 Y
ON X.C1=Y.C1
WHERE X.C2 > 12;
```

The outer join operation gives you these result table rows:

- The rows with matching values of C1 in tables T1 and T2 (the inner join result)
- The rows from T1 where C1 has no corresponding value in T2
- The rows from T2 where C1 has no corresponding value in T1

However, when you apply the predicate, you remove all rows in the result table that came from T2 where C1 has no corresponding value in T1. DB2 transforms the full join into a left join, which is more efficient:

```
SELECT * FROM T1 X LEFT JOIN T2 Y
  ON X.C1=Y.C1
 WHERE X.C2 > 12;
```

**Example:** The predicate, X.C2>12, filters out all null values that result from the right join:

```
SELECT * FROM T1 X RIGHT JOIN T2 Y
  ON X.C1=Y.C1
 WHERE X.C2>12;
```

Therefore, DB2 can transform the right join into a more efficient inner join without changing the result:

```
SELECT * FROM T1 X INNER JOIN T2 Y
  ON X.C1=Y.C1
 WHERE X.C2>12;
```

The predicate that follows a join operation must have the following characteristics before DB2 transforms an outer join into a simpler outer join or into an inner join:

- The predicate is a Boolean term predicate.
- The predicate is false if one table in the join operation supplies a null value for all of its columns.

These predicates are examples of predicates that can cause DB2 to simplify join operations:

```
T1.C1 > 10
T1.C1 IS NOT NULL
T1.C1 > 10 OR T1.C2 > 15
T1.C1 > T2.C1
T1.C1 IN (1,2,4)
T1.C1 LIKE 'ABC%'
T1.C1 BETWEEN 10 AND 100
12 BETWEEN T1.C1 AND 100
```

**Example:** This examples shows how DB2 can simplify a join operation because the query contains an ON clause that eliminates rows with unmatched values:

```
SELECT * FROM T1 X LEFT JOIN T2 Y
  FULL JOIN T3 Z ON Y.C1=Z.C1
  ON X.C1=Y.C1;
```

Because the last ON clause eliminates any rows from the result table for which column values that come from T1 or T2 are null, DB2 can replace the full join with a more efficient left join to achieve the same result:

```
SELECT * FROM T1 X LEFT JOIN T2 Y
  LEFT JOIN T3 Z ON Y.C1=Z.C1
  ON X.C1=Y.C1;
```

In one case, DB2 transforms a full outer join into a left join when you cannot write code to do it. This is the case where a view specifies a full outer join, but a subsequent query on that view requires only a left outer join.

**Example:** Consider this view:

```
CREATE VIEW V1 (C1,T1C2,T2C2) AS
  SELECT COALESCE(T1.C1, T2.C1), T1.C2, T2.C2
  FROM T1 X FULL JOIN T2 Y
  ON T1.C1=T2.C1;
```

This view contains rows for which values of C2 that come from T1 are null. However, if you execute the following query, you eliminate the rows with null values for C2 that come from T1:

```
SELECT * FROM V1
  WHERE T1C2 > 10;
```

Therefore, for this query, a left join between T1 and T2 would have been adequate. DB2 can execute this query as if the view V1 was generated with a left outer join so that the query runs more efficiently.

### **Predicates generated through transitive closure**

When the set of predicates that belong to a query logically imply other predicates, DB2 can generate additional predicates to provide more information for access path selection.

**Rules for generating predicates:** For single-table or inner join queries, DB2 generates predicates for transitive closure if:

- The query has an equal type predicate: COL1=COL2. This could be:
  - A local predicate
  - A join predicate
- The query also has a Boolean term predicate on one of the columns in the first predicate with one of the following formats:
  - COL1 *op value*  
*op* is =, <>, >, >=, <, or <=.  
*value* is a constant, host variable, or special register.
  - COL1 (NOT) BETWEEN *value1* AND *value2*
  - COL1=COL3

For outer join queries, DB2 generates predicates for transitive closure if the query has an ON clause of the form COL1=COL2 and a before join predicate that has one of the following formats:

- COL1 *op value*  
*op* is =, <>, >, >=, <, or <=
- COL1 (NOT) BETWEEN *value1* AND *value2*

DB2 generates a transitive closure predicate for an outer join query only if the generated predicate does not reference the table with unmatched rows. That is, the generated predicate cannot reference the left table for a left outer join or the right table for a right outer join.

For a multiple-CCSID query, DB2 does not generate a transitive closure predicate if the predicate that would be generated has these characteristics:

- The generated predicate is a range predicate (*op* is >, >=, <, or <=).

- Evaluation of the query with the generated predicate results in different CCSID conversion from evaluation of the query without the predicate. See Chapter 4 of *DB2 SQL Reference* for information on CCSID conversion.

When a predicate meets the transitive closure conditions, DB2 generates a new predicate, whether or not it already exists in the WHERE clause.

The generated predicates have one of the following formats:

- COL *op* *value*  
*op* is =, <>, >, >=, <, or <=.  
*value* is a constant, host variable, or special register.
- COL (NOT) BETWEEN *value1* AND *value2*
- COL1=COL2 (for single-table or inner join queries only)

**Example of transitive closure for an inner join:** Suppose that you have written this query, which meets the conditions for transitive closure:

```
SELECT * FROM T1, T2
WHERE T1.C1=T2.C1 AND
T1.C1>10;
```

DB2 generates an additional predicate to produce this query, which is more efficient:

```
SELECT * FROM T1, T2
WHERE T1.C1=T2.C1 AND
T1.C1>10 AND
T2.C1>10;
```

**Example of transitive closure for an outer join:** Suppose that you have written this outer join query:

```
SELECT * FROM
(SELECT T1.C1 FROM T1 WHERE T1.C1>10) X
LEFT JOIN
(SELECT T2.C1 FROM T2) Y
ON X.C1 = Y.C1;
```

The before join predicate, T1.C1>10, meets the conditions for transitive closure, so DB2 generates a query that has the same result as this more-efficient query:

```
SELECT * FROM
(SELECT T1.C1 FROM T1 WHERE T1.C1>10) X
LEFT JOIN
(SELECT T2.C1 FROM T2 WHERE T2.C1>10) Y
ON X.C1 = Y.C1;
```

**Predicate redundancy:** A predicate is redundant if evaluation of other predicates in the query already determines the result that the predicate provides. You can specify redundant predicates or DB2 can generate them. DB2 does not determine that any of your query predicates are redundant. All predicates that you code are evaluated at execution time regardless of whether they are redundant. If DB2 generates a redundant predicate to help select access paths, that predicate is ignored at execution.

**Adding extra predicates:** DB2 performs predicate transitive closure only on equal and range predicates. However, you can help DB2 to choose a better access path by adding transitive closure predicates for other types of operators, such as IN or LIKE. For example, consider the following SELECT statement:

```

SELECT * FROM T1,T2
WHERE T1.C1=T2.C1
AND T1.C1 LIKE 'A%';

```

If T1.C1=T2.C1 is true, and T1.C1 LIKE 'A%' is true, then T2.C1 LIKE 'A%' must also be true. Therefore, you can give DB2 extra information for evaluating the query by adding T2.C1 LIKE 'A%':

```

SELECT * FROM T1,T2
WHERE T1.C1=T2.C1
AND T1.C1 LIKE 'A%'
AND T2.C1 LIKE 'A%';

```

## Predicates with encrypted data

DB2 provides built-in functions for data encryption and decryption. These functions can secure sensitive data, but they can also degrade the performance of some statements if they are not used carefully. If a predicate contains any operator other than = and <>, encrypted data must be decrypted before comparisons can be made. Decryption makes the predicates stage 2. For advice on avoiding unnecessary encryption and decryption for predicate evaluation, see “Performance recommendations for data encryption” on page 212.

---

## Using host variables efficiently

*Host variables require default filter factors:* When you bind a static SQL statement that contains host variables, DB2 uses a default filter factor to determine the best access path for the SQL statement. For more information on filter factors, including default values, see “Predicate filter factors” on page 766.

DB2 often chooses an access path that performs well for a query with several host variables. However, in a new release or after maintenance has been applied, DB2 might choose a new access path that does not perform as well as the old access path. In many cases, the change in access paths is due to the default filter factors, which might lead DB2 to optimize the query in a different way.

The two ways to change the access path for a query that contains host variables are:

- Bind the package or plan that contains the query with the option REOPT(ALWAYS) or the option REOPT(ONCE).
- Rewrite the query.

## Changing the access path at run time

You can use the following bind options to control how DB2 determines the access path for SQL statements with variable values:

### REOPT(ALWAYS)

DB2 determines the access path for any SQL statement with variable values each time the statement is run.

### REOPT(ONCE)

DB2 determines and caches the access path for any SQL statement with variable values only once at run time, using the first set of input variable values. If the statement is run multiple times, DB2 does not reoptimize each time unless the cached statement is invalidated or removed from the cache.

REOPT(NONE) DB2 determines the access path at bind time, and does not change the access path at run time.

### The REOPT(ALWAYS) bind option

Specify the REOPT(ALWAYS) bind option when you want DB2 to determine access paths at both bind time and run time for statements that contain host variables and special registers: At run time, DB2 uses the values in these variables to determine the access paths. If the statement runs multiple times, DB2 determines the access path each time that the statement runs.

Consider using the REOPT(ALWAYS) bind option in the following circumstances:

- The SQL statement does not perform well with the access path that is chosen at bind time.
- The SQL statement takes a relatively long time to execute. For long-running SQL statements, the performance gain from the better access path that is chosen based on the input variable values for each run can be greater than the performance cost of reoptimizing the access path each time that the statement runs.

To use the REOPT(ALWAYS) bind option most efficiently, first determine which SQL statements in your applications perform poorly with the REOPT(NONE) bind option and the REOPT(ONCE) bind option. Separate the code containing those statements into units that you bind into packages with the REOPT(ALWAYS) option. Bind the rest of the code into packages using the REOPT(NONE) bind option or the REOPT(ONCE) bind option, as appropriate. Then bind the plan with the REOPT(NONE) bind option. Statements in the packages bound with REOPT(ALWAYS) are candidates for repeated reoptimization at run time.

**Example:** To determine which queries in plans and packages that are bound with the REOPT(ALWAYS) bind option will be reoptimized at run time, execute the following SELECT statements:

```
SELECT PLNAME,
       CASE WHEN STMTNOI <> 0
            THEN STMTNOI
            ELSE STMTNO
       END AS STMTNUM,
       SEQNO, TEXT
FROM   SYSIBM.SYSSTMT
WHERE  STATUS IN ('B','F','G','J')
ORDER BY PLNAME, STMTNUM, SEQNO;

SELECT COLLID, NAME, VERSION,
       CASE WHEN STMTNOI <> 0
            THEN STMTNOI
            ELSE STMTNO
       END AS STMTNUM,
       SEQNO, STMT
FROM   SYSIBM.SYSPACKSTMT
WHERE  STATUS IN ('B','F','G','J')
ORDER BY COLLID, NAME, VERSION, STMTNUM, SEQNO;
```

If you specify the bind option VALIDATE(RUN), and a statement in the plan or package is not bound successfully, that statement is incrementally bound at run time. If you also specify the bind option REOPT(ALWAYS), DB2 reoptimizes the access path during the incremental bind.

**Example:** To determine which plans and packages have statements that will be incrementally bound, execute the following SELECT statements:

```

SELECT DISTINCT NAME
FROM SYSIBM.SYSSTMT
WHERE STATUS = 'F' OR STATUS = 'H';
SELECT DISTINCT COLLID, NAME, VERSION
FROM SYSIBM.SYSPACKSTMT
WHERE STATUS = 'F' OR STATUS = 'H';

```

### The REOPT(ONCE) bind option

You can use the REOPT(ONCE) bind option to determine the access path for an SQL statement at run time. The REOPT(ONCE) bind option determines the access path for an SQL statement only once at run time and works only with dynamic SQL statements. The REOPT(ONCE) bind option allows DB2 to store the access path for dynamic SQL statements in the dynamic statement cache.

Consider using the REOPT(ONCE) bind option in the following circumstances:

- The SQL statement is a dynamic SQL statement.
- The SQL statement does not perform well with the access path that is chosen at bind time.
- The SQL statement is relatively simple and takes a relatively short time to execute. For simple SQL statements, reoptimizing the access path each time that the statement runs can degrade performance more than using the access path from the first run for each subsequent run.
- The same SQL statement is repeated many times in a loop, or is run by many threads. Because of the dynamic statement cache, the access path that DB2 chooses for the first set of input variables will perform well for subsequent executions of the same SQL statement, even if the input variable values are different each time.

To use the REOPT(ONCE) bind option most efficiently, first determine which dynamic SQL statements in your applications perform poorly with the REOPT(NONE) bind option and the REOPT(ALWAYS) bind option. Separate the code containing those statements into units that you bind into packages with the REOPT(ONCE) option. Bind the rest of the code into packages using the REOPT(NONE) bind option or the REOPT(ALWAYS) bind option, as appropriate. Then bind the plan with the REOPT(ONCE) bind option. A dynamic statement in a package that is bound with REOPT(ONCE) is a candidate for reoptimization the first time that the statement is run.

**Example:** To determine which queries in plans and packages that are bound with the REOPT(ONCE) bind option will be reoptimized at run time, execute the following SELECT statements:

```

SELECT PLNAME,
CASE WHEN STMTNOI <> 0
THEN STMTNOI
ELSE STMTNO
END AS STMTNUM,
SEQNO, TEXT
FROM SYSIBM.SYSSTMT
WHERE STATUS IN ('J')
ORDER BY PLNAME, STMTNUM, SEQNO;
SELECT COLLID, NAME, VERSION,
CASE WHEN STMTNOI <> 0
THEN STMTNOI
ELSE STMTNO
END AS STMTNUM,
SEQNO, STMT

```

```

|         FROM SYSIBM.SYSPACKSTMT
|         WHERE STATUS IN ('J')
|         ORDER BY COLLID, NAME, VERSION, STMTNUM, SEQNO;

```

If you specify the bind option VALIDATE(RUN), and a statement in the plan or package is not bound successfully, that statement is incrementally bound at run time.

**Example:** To determine which plans and packages have statements that will be incrementally bound, execute the following SELECT statements:

```

| SELECT DISTINCT NAME
|     FROM SYSIBM.SYSSTMT
|     WHERE STATUS = 'F' OR STATUS = 'H';
|
| SELECT DISTINCT COLLID, NAME, VERSION
|     FROM SYSIBM.SYSPACKSTMT
|     WHERE STATUS = 'F' OR STATUS = 'H';

```

### The REOPT(NONE) bind option

You should use the REOPT(NONE) bind option when an SQL statement with variable values performs well with the access path that is chosen at bind time. Keep in mind that an SQL statement that performs well with the REOPT(NONE) bind option might perform even better with the bind options that change the access path at run time.

## Rewriting queries to influence access path selection

### Important

This section describes tactics for rewriting queries to influence how DB2 selects access paths. The access path selection "tricks" that are described in the section might cause significant performance degradation if they are not carefully implemented and monitored.

**Example:** The selection method might change in a later release of DB2, causing your changes to degrade performance.

Before and after you make any permanent changes, take performance measurements. When you migrate to a new release, evaluate the performance again. Be prepared to back out any changes that have degraded performance.

The examples that follow identify potential performance problems and offer suggestions for tuning the queries. However, before you rewrite any query, you should consider whether the REOPT(ALWAYS) or REOPT(ONCE) bind options can solve your access path problems. See "Changing the access path at run time" on page 779 for more information about REOPT(ALWAYS) and REOPT(ONCE).

### *Example 1: An equal predicate*

An equal predicate has a default filter factor of 1/COLCARDF. The actual filter factor might be quite different.

#### *Query:*

```

| SELECT * FROM DSN8810.EMP
|     WHERE SEX = :HV1;

```

**Assumptions:** Because the column SEX has only two different values, 'M' and 'F', the value COLCARDF for SEX is 2. If the numbers of male and female employees

are not equal, the actual filter factor of 1/2 is larger or smaller than the default, depending on whether :HV1 is set to 'M' or 'F'.

**Recommendation:** One of these two actions can improve the access path:

- Bind the package or plan that contains the query with the REOPT(ALWAYS) bind option. This action causes DB2 to reoptimize the query at run time, using the input values you provide. You might also consider binding the package or plan with the REOPT(ONCE) bind option.
- Write predicates to influence the DB2 selection of an access path, based on your knowledge of actual filter factors. For example, you can break the query into three different queries, two of which use constants. DB2 can then determine the exact filter factor for most cases when it binds the plan.

```
SELECT (HV1);
  WHEN ('M')
    DO;
      EXEC SQL SELECT * FROM DSN8810.EMP
        WHERE SEX = 'M';
    END;
  WHEN ('F')
    DO;
      EXEC SQL SELECT * FROM DSN8810.EMP
        WHERE SEX = 'F';
    END;
  OTHERWISE
    DO:
      EXEC SQL SELECT * FROM DSN8810.EMP
        WHERE SEX = :HV1;
    END;
END;
```

### *Example 2: Known ranges*

Table T1 has two indexes: T1X1 on column C1 and T1X2 on column C2.

#### *Query:*

```
SELECT * FROM T1
  WHERE C1 BETWEEN :HV1 AND :HV2
        AND C2 BETWEEN :HV3 AND :HV4;
```

**Assumptions:** You know that:

- The application always provides a narrow range on C1 and a wide range on C2.
- The desired access path is through index T1X1.

**Recommendation:** If DB2 does not choose T1X1, rewrite the query as follows, so that DB2 does not choose index T1X2 on C2:

```
SELECT * FROM T1
  WHERE C1 BETWEEN :HV1 AND :HV2
        AND (C2 BETWEEN :HV3 AND :HV4 OR 0=1);
```

### *Example 3: Variable ranges*

Table T1 has two indexes: T1X1 on column C1 and T1X2 on column C2.

#### *Query:*

```
SELECT * FROM T1
  WHERE C1 BETWEEN :HV1 AND :HV2
        AND C2 BETWEEN :HV3 AND :HV4;
```

**Assumptions:** You know that the application provides both narrow and wide ranges on C1 and C2. Hence, default filter factors do not allow DB2 to choose the best access path in all cases. For example, a small range on C1 favors index T1X1 on C1, a small range on C2 favors index T1X2 on C2, and wide ranges on both C1 and C2 favor a table space scan.

**Recommendation:** If DB2 does not choose the best access path, try either of the following changes to your application:

- Use a dynamic SQL statement and embed the ranges of C1 and C2 in the statement. With access to the actual range values, DB2 can estimate the actual filter factors for the query. Preparing the statement each time it is executed requires an extra step, but it can be worthwhile if the query accesses a large amount of data.
- Include some simple logic to check the ranges of C1 and C2, and then execute one of these static SQL statements, based on the ranges of C1 and C2:

```
SELECT * FROM T1 WHERE C1 BETWEEN :HV1 AND :HV2
AND (C2 BETWEEN :HV3 AND :HV4 OR 0=1);
```

```
SELECT * FROM T1 WHERE C2 BETWEEN :HV3 AND :HV4
AND (C1 BETWEEN :HV1 AND :HV2 OR 0=1);
```

```
SELECT * FROM T1 WHERE (C1 BETWEEN :HV1 AND :HV2 OR 0=1)
AND (C2 BETWEEN :HV3 AND :HV4 OR 0=1);
```

#### **Example 4: ORDER BY**

Table T1 has two indexes: T1X1 on column C1 and T1X2 on column C2.

#### **Query:**

```
SELECT * FROM T1
WHERE C1 BETWEEN :HV1 AND :HV2
ORDER BY C2;
```

In this example, DB2 could choose one of the following actions:

- Scan index T1X1 and then sort the results by column C2
- Scan the table space in which T1 resides and then sort the results by column C2
- Scan index T1X2 and then apply the predicate to each row of data, thereby avoiding the sort

Which choice is best depends on the following factors:

- The number of rows that satisfy the range predicate
- The cluster ratio of the indexes

If the actual number of rows that satisfy the range predicate is significantly different from the estimate, DB2 might not choose the best access path.

**Assumptions:** You disagree with the DB2 choice.

**Recommendation:** In your application, use a dynamic SQL statement and embed the range of C1 in the statement. That allows DB2 to use the actual filter factor rather than the default, but requires extra processing for the PREPARE statement.

#### **Example 5: A join operation**

Tables A, B, and C each have indexes on columns C1, C2, C3, and C4.

**Assumptions:** The actual filter factors on table A are much larger than the default factors. Hence, DB2 underestimates the number of rows selected from table A and wrongly chooses that as the first table in the join.

**Recommendations:** You can:

- Reduce the estimated size of Table A by adding predicates
- Disfavor any index on the join column by making the join predicate on table A nonindexable

**Example:** The following query illustrates the second of those choices.

```
SELECT * FROM T1 A, T1 B, T1 C
WHERE (A.C1 = B.C1 OR 0=1)
      AND A.C2 = C.C2
      AND A.C2 BETWEEN :HV1 AND :HV2
      AND A.C3 BETWEEN :HV3 AND :HV4
      AND A.C4 < :HV5
      AND B.C2 BETWEEN :HV6 AND :HV7
      AND B.C3 < :HV8
      AND C.C2 < :HV9;
```

The result of making the join predicate between A and B a nonindexable predicate (which cannot be used in single index access) disfavors the use of the index on column C1. This, in turn, might lead DB2 to access table A or B first. Or, it might lead DB2 to change the access type of table A or B, thereby influencing the join sequence of the other tables.

---

## Writing efficient subqueries

**Definitions:** A *subquery* is a SELECT statement within the WHERE or HAVING clause of another SQL statement.

**Decision needed:** You can often write two or more SQL statements that achieve identical results, particularly if you use subqueries. The statements have different access paths, however, and probably perform differently.

**Topic overview:** The topics that follow describe different methods to achieve the results intended by a subquery and tell what DB2 does for each method. The information should help you estimate what method performs best for your query.

The first two methods use different types of subqueries:

- “Correlated subqueries”
- “Noncorrelated subqueries” on page 786

A subquery can sometimes be transformed into a join operation. Sometimes DB2 does that to improve the access path, and sometimes you can get better results by doing it yourself. The third method is:

- “Conditions for DB2 to transform a subquery into a join” on page 788

Finally, for a comparison of the three methods as applied to a single task, see:

- “Subquery tuning” on page 790

## Correlated subqueries

**Definition:** A *correlated* subquery refers to at least one column of the outer query.

Any predicate that contains a correlated subquery is a stage 2 predicate unless it is transformed to a join.

**Example:** In the following query, the correlation name, X, illustrates the subquery's reference to the outer query block.

```
SELECT * FROM DSN8810.EMP X
WHERE JOB = 'DESIGNER'
AND EXISTS (SELECT 1
            FROM DSN8810.PROJ
            WHERE DEPTNO = X.WORKDEPT
            AND MAJPROJ = 'MA2100');
```

**What DB2 does:** A correlated subquery is evaluated for each qualified row of the outer query that is referred to. In executing the example, DB2:

1. Reads a row from table EMP where JOB='DESIGNER'.
2. Searches for the value of WORKDEPT from that row, in a table stored in memory.  
The in-memory table saves executions of the subquery. If the subquery has already been executed with the value of WORKDEPT, the result of the subquery is in the table and DB2 does not execute it again for the current row. Instead, DB2 can skip to step 5.
3. Executes the subquery, if the value of WORKDEPT is not in memory. That requires searching the PROJ table to check whether there is any project, where MAJPROJ is 'MA2100', for which the current WORKDEPT is responsible.
4. Stores the value of WORKDEPT and the result of the subquery in memory.
5. Returns the values of the current row of EMP to the application.

DB2 repeats this whole process for each qualified row of the EMP table.

**Notes on the in-memory table:** The in-memory table is applicable if the operator of the predicate that contains the subquery is one of the following operators:

<, <=, >, >=, =, <>, EXISTS, NOT EXISTS

The table is not used, however, if:

- There are more than 16 correlated columns in the subquery
- The sum of the lengths of the correlated columns is more than 256 bytes
- There is a unique index on a subset of the correlated columns of a table from the outer query

The in-memory table is a wrap-around table and does not guarantee saving the results of all possible duplicated executions of the subquery.

## Noncorrelated subqueries

**Definition:** A *noncorrelated* subquery makes no reference to outer queries.

**Example:**

```
SELECT * FROM DSN8810.EMP
WHERE JOB = 'DESIGNER'
AND WORKDEPT IN (SELECT DEPTNO
                 FROM DSN8810.PROJ
                 WHERE MAJPROJ = 'MA2100');
```

**What DB2 does:** A noncorrelated subquery is executed once when the cursor is opened for the query. What DB2 does to process it depends on whether it returns a single value or more than one value. The query in the preceding example can return more than one value.

## Single-value subqueries

When the subquery is contained in a predicate with a simple operator, the subquery is required to return 1 or 0 rows. The simple operator can be one of the following operators:

<, <=, >, >=, =, <>, NOT <, NOT <=, NOT >, NOT >=

The following noncorrelated subquery returns a single value:

```
SELECT *
FROM   DSN8810.EMP
WHERE  JOB = 'DESIGNER'
      AND WORKDEPT <= (SELECT MAX(DEPTNO)
                       FROM   DSN8810.PROJ);
```

**What DB2 does:** When the cursor is opened, the subquery executes. If it returns more than one row, DB2 issues an error. The predicate that contains the subquery is treated like a simple predicate with a constant specified, for example, `WORKDEPT <= 'value'`.

**Stage 1 and stage 2 processing:** The rules for determining whether a predicate with a noncorrelated subquery that returns a single value is stage 1 or stage 2 are generally the same as for the same predicate with a single variable.

## Multiple-value subqueries

A subquery can return more than one value if the operator is one of the following:  
*op* ANY, *op* ALL, *op* SOME, IN, EXISTS

where *op* is any of the operators >, >=, <, <=, NOT <, NOT <=, NOT >, NOT >=.

**What DB2 does:** If possible, DB2 reduces a subquery that returns more than one row to one that returns only a single row. That occurs when there is a range comparison along with ANY, ALL, or SOME. The following query is an example:

```
SELECT * FROM DSN8810.EMP
WHERE  JOB = 'DESIGNER'
      AND WORKDEPT <= ANY (SELECT DEPTNO
                          FROM   DSN8810.PROJ
                          WHERE  MAJPROJ = 'MA2100');
```

DB2 calculates the maximum value for DEPTNO from table DSN8810.PROJ and removes the ANY keyword from the query. After this transformation, the subquery is treated like a single-value subquery.

That transformation can be made with a *maximum value* if the range operator is:

- > or >= with the quantifier ALL
- < or <= with the quantifier ANY or SOME

The transformation can be made with a *minimum value* if the range operator is:

- < or <= with the quantifier ALL
- > or >= with the quantifier ANY or SOME

The resulting predicate is determined to be stage 1 or stage 2 by the same rules as for the same predicate with a single-valued subquery.

**When a subquery is sorted:** A noncorrelated subquery is sorted when the comparison operator is IN, NOT IN, = ANY, <> ANY, = ALL, or <> ALL. The sort enhances the predicate evaluation, reducing the amount of scanning on the

subquery result. When the value of the subquery becomes smaller or equal to the expression on the left side, the scanning can be stopped and the predicate can be determined to be true or false.

When the subquery result is a character data type and the left side of the predicate is a datetime data type, then the result is placed in a work file without sorting. For some noncorrelated subqueries that use IN, NOT IN, = ANY, <> ANY, = ALL, or <> ALL comparison operators, DB2 can more accurately pinpoint an entry point into the work file, thus further reducing the amount of scanning that is done.

**Results from EXPLAIN:** For information about the result in a plan table for a subquery that is sorted, see “When are aggregate functions evaluated? (COLUMN\_FN\_EVAL)” on page 950.

## Conditions for DB2 to transform a subquery into a join

For a SELECT, UPDATE, or DELETE statement, DB2 can sometimes transform a subquery into a join between the result table of a subquery and the result table of an outer query.

For a SELECT statement, DB2 does the transformation if the following conditions are true:

- The transformation does not introduce redundancy.
- The subquery appears in a WHERE clause.
- The subquery does not contain GROUP BY, HAVING, or aggregate functions.
- The subquery has only one table in the FROM clause.
- For a correlated subquery, the comparison operator of the predicate containing the subquery is IN, = ANY, or = SOME.
- For a noncorrelated subquery, the comparison operator of the predicate containing the subquery is IN, EXISTS, = ANY, or = SOME.
- For a noncorrelated subquery, the subquery select list has only one column, guaranteed by a unique index to have unique values.
- For a noncorrelated subquery, the left side of the predicate is a single column with the same data type and length as the subquery’s column. (For a correlated subquery, the left side can be any expression.)

For an UPDATE or DELETE statement, or a SELECT statement that does not meet the previous conditions for transformation, DB2 does the transformation of a correlated subquery into a join if the following conditions are true:

- The transformation does not introduce redundancy.
- The subquery is correlated to its immediate outer query.
- The FROM clause of the subquery contains only one table, and the outer query (for SELECT), UPDATE, or DELETE references only one table.
- If the outer predicate is a quantified predicate with an operator of =ANY or an IN predicate, the following conditions are true:
  - The left side of the outer predicate is a single column.
  - The right side of the outer predicate is a subquery that references a single column.
  - The two columns have the same data type and length.
- The subquery does not contain the GROUP BY or DISTINCT clauses.
- The subquery does not contain aggregate functions.

- The SELECT clause of the subquery does not contain a user-defined function with an external action or a user-defined function that modifies data.
- The subquery predicate is a Boolean term predicate.
- The predicates in the subquery that provide correlation are stage 1 predicates.
- The subquery does not contain nested subqueries.
- The subquery does not contain a self-referencing UPDATE or DELETE.
- For a SELECT statement, the query does not contain the FOR UPDATE OF clause.
- For an UPDATE or DELETE statement, the statement is a searched UPDATE or DELETE.
- For a SELECT statement, parallelism is not enabled.

For a statement with multiple subqueries, DB2 does the transformation only on the last subquery in the statement that qualifies for transformation.

**Example:** The following subquery can be transformed into a join because it meets the first set of conditions for transformation:

```
SELECT * FROM EMP
  WHERE DEPTNO IN
    (SELECT DEPTNO FROM DEPT
     WHERE LOCATION IN ('SAN JOSE', 'SAN FRANCISCO')
     AND DIVISION = 'MARKETING');
```

If there is a department in the marketing division which has branches in both San Jose and San Francisco, the result of the SQL statement is not the same as if a join were done. The join makes each employee in this department appear twice because it matches once for the department of location San Jose and again of location San Francisco, although it is the same department. Therefore, it is clear that to transform a subquery into a join, the uniqueness of the subquery select list must be guaranteed. For this example, a unique index on any of the following sets of columns would guarantee uniqueness:

- (DEPTNO)
- (DIVISION, DEPTNO)
- (DEPTNO, DIVISION).

The resultant query is:

```
SELECT EMP.* FROM EMP, DEPT
  WHERE EMP.DEPTNO = DEPT.DEPTNO AND
        DEPT.LOCATION IN ('SAN JOSE', 'SAN FRANCISCO') AND
        DEPT.DIVISION = 'MARKETING';
```

**Example:** The following subquery can be transformed into a join because it meets the second set of conditions for transformation:

```
UPDATE T1 SET T1.C1 = 1
  WHERE T1.C1 = ANY
    (SELECT T2.C1 FROM T2
     WHERE T2.C2 = T1.C2);
```

**Results from EXPLAIN:** For information about the result in a plan table for a subquery that is transformed into a join operation, see “Is a subquery transformed into a join?” on page 950.

## Subquery tuning

The following three queries all retrieve the same rows. All three retrieve data about all designers in departments that are responsible for projects that are part of major project MA2100. These three queries show that there are several ways to retrieve a desired result.

### Query A: A join of two tables

```
SELECT DSN8810.EMP.* FROM DSN8810.EMP, DSN8810.PROJ
WHERE JOB = 'DESIGNER'
AND WORKDEPT = DEPTNO
AND MAJPROJ = 'MA2100';
```

### Query B: A correlated subquery

```
SELECT * FROM DSN8810.EMP X
WHERE JOB = 'DESIGNER'
AND EXISTS (SELECT 1 FROM DSN8810.PROJ
            WHERE DEPTNO = X.WORKDEPT
            AND MAJPROJ = 'MA2100');
```

### Query C: A noncorrelated subquery

```
SELECT * FROM DSN8810.EMP
WHERE JOB = 'DESIGNER'
AND WORKDEPT IN (SELECT DEPTNO FROM DSN8810.PROJ
                 WHERE MAJPROJ = 'MA2100');
```

If you need columns from both tables EMP and PROJ in the output, you must use a join.

PROJ might contain duplicate values of DEPTNO in the subquery, so that an equivalent join cannot be written.

In general, query A might be the one that performs best. However, if there is no index on DEPTNO in table PROJ, then query C might perform best. The IN-subquery predicate in query C is indexable. Therefore, if an index on WORKDEPT exists, DB2 might do IN-list access on table EMP. If you decide that a join cannot be used and there is an available index on DEPTNO in table PROJ, then query B might perform best.

When looking at a problem subquery, see if the query can be rewritten into another format or see if there is an index that you can create to help improve the performance of the subquery.

Knowing the sequence of evaluation is important, for the different subquery predicates and for all other predicates in the query. If the subquery predicate is costly, perhaps another predicate could be evaluated before that predicate so that the rows would be rejected before even evaluating the problem subquery predicate.

---

## Using scrollable cursors efficiently

The following recommendations help you get the best performance from your scrollable cursors:

- Determine when scrollable cursors work best for you.

Scrollable cursors are a valuable tool for writing applications such as screen-based applications, in which the result table is small and you often move back and forth through the data. However, scrollable cursors require more DB2

processing than non-scrollable cursors. If your applications require large result tables or you only need to move sequentially forward through the data, use non-scrollable cursors.

- Declare scrollable cursors as SENSITIVE only if you need to see the latest data. If you do not need to see updates that are made by other cursors or application processes, using a cursor that you declare as INSENSITIVE requires less processing by DB2.

If you need to see only some of the latest updates, and you do not need to see the results of insert operations, declare scrollable cursors as SENSITIVE STATIC. See Chapter 5 of *DB2 SQL Reference* for information about which updates you can see with a scrollable cursor that is declared as SENSITIVE STATIC.

If you need to see all of the latest updates and inserts, declare scrollable cursors as SENSITIVE DYNAMIC.

- To ensure maximum concurrency when you use a scrollable cursor for positioned update and delete operations, specify ISOLATION(CS) and CURRENTDATA(NO) when you bind packages and plans that contain updatable scrollable cursors. See Chapter 31, “Improving concurrency,” on page 813 for more details.
- Use the FETCH FIRST *n* ROWS ONLY clause with scrollable cursors when it is appropriate.

In a distributed environment, when you need to retrieve a limited number of rows, FETCH FIRST *n* ROWS ONLY can improve your performance for distributed queries that use DRDA access by eliminating unneeded network traffic. See Part 4 of *DB2 Application Programming and SQL Guide* for more information.

In a local environment, if you need to scroll through a limited subset of rows in a table, you can use FETCH FIRST *n* ROWS ONLY to make the result table smaller.

- In a distributed environment, if you do not need to use your scrollable cursors to modify data, do your cursor processing in a stored procedure.

Using stored procedures can decrease the amount of network traffic that your application requires.

- In a TEMP database, create table spaces that are large enough for processing your scrollable cursors.

DB2 uses declared temporary tables for processing the following types of scrollable cursors:

- SENSITIVE STATIC SCROLL
- INSENSITIVE SCROLL
- ASENSITIVE SCROLL, if the cursor sensitivity is INSENSITIVE. A cursor that meets the criteria for a read-only cursor has an effective sensitivity of INSENSITIVE.

See the DECLARE CURSOR statement in *DB2 SQL Reference* for more information about cursor sensitivity. See *DB2 Installation Guide* for more information about calculating the appropriate size for declared temporary tables for cursors.

- Remember to commit changes often for the following reasons:
  - You frequently need to leave scrollable cursors open longer than non-scrollable cursors.
  - There is an increased chance of deadlocks with scrollable cursors because scrollable cursors allow rows to be accessed and updated in any order. Frequent commits can decrease the chances of deadlocks.

| Because the predicate is based only on values of a DPSI key (STATE), DB2 must  
| examine all partitions to find the matching rows.

| Now suppose that you modify the query in the following way:

```
| SELECT CUSTNO, PURCH_AMT  
| FROM Q1  
| WHERE DATE BETWEEN '2002-01-01' AND '2002-01-31' AND  
| STATE = 'CA';
```

| Because the predicate is now based on values of a partitioning index key (DATE)  
| and on values of a DPSI key (STATE), DB2 can eliminate the scanning of data  
| partitions 2 and 3, which do not satisfy the query for the partitioning key. This can  
| be determined at bind time because the columns of the predicate are compared to  
| constants.

| Now suppose that you use host variables instead of constants in the same query:

```
| SELECT CUSTNO, PURCH_AMT  
| FROM Q1  
| WHERE DATE BETWEEN :hv1 AND :hv2 AND  
| STATE = :hv3;
```

| DB2 can use the predicate on the partitioning column to eliminate the scanning of  
| unneeded partitions at run time.

| Writing queries to take advantage of limited partition scan is especially useful  
| when a correlation exists between columns that are in a partitioning index and  
| columns that are in a DPSI.

| For example, suppose that you create table Q2, with partitioning index DATE\_IX  
| and DPSI ORDERNO\_IX:

```
| CREATE TABLESPACE TS2 NUMPARTS 3;  
|  
| CREATE TABLE Q2 (DATE DATE,  
| ORDERNO CHAR(8),  
| STATE CHAR(2),  
| PURCH_AMT DECIMAL(9,2))  
| IN TS2  
| PARTITION BY (DATE)  
| (PARTITION 1 ENDING AT ('2000-12-31'),  
| PARTITION 2 ENDING AT ('2001-12-31'),  
| PARTITION 3 ENDING AT ('2002-12-31'));  
|  
| CREATE INDEX DATE_IX ON Q2 (DATE) PARTITIONED CLUSTER;  
|  
| CREATE INDEX ORDERNO_IX ON Q2 (ORDERNO) PARTITIONED;
```

| Also suppose that the first 4 bytes of each ORDERNO column value represent the  
| four-digit year in which the order is placed. This means that the DATE column and  
| the ORDERNO column are correlated.

| To take advantage of limited partition scan, when you write a query that has the  
| ORDERNO column in the predicate, also include the DATE column in the  
| predicate. The partitioning index on DATE lets DB2 eliminate the scanning of  
| partitions that are not needed to satisfy the query. For example:

```
| SELECT ORDERNO, PURCH_AMT  
| FROM Q2  
| WHERE ORDERNO BETWEEN '2002AAAA' AND '2002ZZZZ' AND  
| DATE BETWEEN '2002-01-01' AND '2002-12-31';
```

---

## Special techniques to influence access path selection

### Important

This section describes tactics for rewriting queries and modifying catalog statistics to influence how DB2 selects access paths. The access path selection "tricks" that are described in the section might cause significant performance degradation if they are not carefully implemented and monitored.

**Example:** The selection method might change in a later release of DB2, causing your changes to degrade performance.

Save the old catalog statistics or SQL before you consider making any changes to control the choice of access path. Before and after you make any changes, take performance measurements. When you migrate to a new release, evaluate the performance again. Be prepared to back out any changes that have degraded performance.

This section contains the following information about determining and changing access paths:

- Obtaining information about access paths
- "Minimizing overhead for retrieving few rows: OPTIMIZE FOR *n* ROWS" on page 795
- "Fetching a limited number of rows: FETCH FIRST *n* ROWS ONLY" on page 795
- "Using the CARDINALITY clause to improve the performance of queries with user-defined table function references" on page 798
- "Reducing the number of matching columns" on page 799
- "Rearranging the order of tables in a FROM clause" on page 803
- "Updating catalog statistics" on page 804
- "Using a subsystem parameter" on page 805
- "Giving optimization hints to DB2" on page 806

## Obtaining information about access paths

You can obtain information about DB2 access paths by using the following methods:

- Use Visual Explain.

The DB2 Visual Explain tool, which is invoked from a workstation client, can be used to display and analyze information on access paths chosen by DB2. Visual Explain displays the access path information in both graphic and text formats. The tool provides you with an easy-to-use interface to the PLAN\_TABLE output and allows you to invoke EXPLAIN for dynamic SQL statements. You can also access the catalog statistics for certain referenced objects of an access path. In addition, the tool allows you to archive EXPLAIN output from previous SQL statements to analyze changes in your SQL environment. See *DB2 Visual Explain online help* for more information.

- Run OMEGAMON DB2 Performance Monitor accounting reports.

Another way to track performance is with the OMEGAMON DB2 Performance Monitor accounting reports. The accounting report, short layout, ordered by PLANNAME, lists the primary performance figures. Check the plans that contain SQL statements whose access paths you tried to influence. If the elapsed

time, TCB time, or number of getpage requests increases sharply without a corresponding increase in the SQL activity, then there could be a problem. You can use OMEGAMON Online Monitor to track events after your changes have been implemented, providing immediate feedback on the effects of your changes.

- Specify the bind option EXPLAIN.

You can also use the EXPLAIN option when you bind or rebind a plan or package. Compare the new plan or package for the statement to the old one. If the new one has a table space scan or a nonmatching index space scan, but the old one did not, the problem is probably the statement. Investigate any changes in access path in the new plan or package; they could represent performance improvements or degradations. If neither the accounting report ordered by PLANNAME or PACKAGE nor the EXPLAIN statement suggest corrective action, use the OMEGAMON SQL activity reports for additional information. For more information on using EXPLAIN, see “Obtaining PLAN\_TABLE information from EXPLAIN” on page 932.

## Fetching a limited number of rows: FETCH FIRST *n* ROWS ONLY

In some applications, you execute queries that can return a large number of rows, but you need only a small subset of those rows. Retrieving the entire result table from the query can be inefficient. You can specify the FETCH FIRST *n* ROWS ONLY clause in a SELECT statement to limit the number of rows in the result table of a query to *n* rows. In addition, for a distributed query that uses DRDA access, FETCH FIRST *n* ROWS ONLY, DB2 prefetches only *n* rows.

**Example:** Suppose that you write an application that requires information on only the 20 employees with the highest salaries. To return only the rows of the employee table for those 20 employees, you can write a query like this:

```
SELECT LASTNAME, FIRSTNAME, EMPNO, SALARY
FROM EMP
ORDER BY SALARY DESC
FETCH FIRST 20 ROWS ONLY;
```

**Interaction between OPTIMIZE FOR *n* ROWS and FETCH FIRST *n* ROWS ONLY:** In general, if you specify FETCH FIRST *n* ROWS ONLY but not OPTIMIZE FOR *n* ROWS in a SELECT statement, DB2 optimizes the query as if you had specified OPTIMIZE FOR *n* ROWS.

| When both the FETCH FIRST *n* ROWS ONLY clause and the OPTIMIZE FOR *n* ROWS clause are specified, the value for the OPTIMIZE FOR *n* ROWS clause is used for access path selection.

| **Example:** Suppose that you submit the following SELECT statement:

```
| SELECT * FROM EMP
| FETCH FIRST 5 ROWS ONLY
| OPTIMIZE FOR 20 ROWS;
```

| The OPTIMIZE FOR value of 20 rows is used for access path selection.

## Minimizing overhead for retrieving few rows: OPTIMIZE FOR *n* ROWS

When an application executes a SELECT statement, DB2 assumes that the application will retrieve all the qualifying rows. This assumption is most

appropriate for batch environments. However, for interactive SQL applications, such as SPUFI, it is common for a query to define a very large potential result set but retrieve only the first few rows. The access path that DB2 chooses might not be optimal for those interactive applications.

This section discusses the use of `OPTIMIZE FOR n ROWS` to affect the performance of interactive SQL applications. Unless otherwise noted, this information pertains to local applications. For more information on using `OPTIMIZE FOR n ROWS` in distributed applications, see Part 4 of *DB2 Application Programming and SQL Guide*.

**What `OPTIMIZE FOR n ROWS` does:** The `OPTIMIZE FOR n ROWS` clause lets an application declare its intent to do either of these things:

- Retrieve only a subset of the result set
- Give priority to the retrieval of the first few rows

DB2 uses the `OPTIMIZE FOR n ROWS` clause to choose access paths that minimize the response time for retrieving the first few rows. For distributed queries, the value of *n* determines the number of rows that DB2 sends to the client on each DRDA network transmission. See Part 4 of *DB2 Application Programming and SQL Guide* for more information on using `OPTIMIZE FOR n ROWS` in the distributed environment.

**Use `OPTIMIZE FOR 1 ROW` to avoid sorts:** You can influence the access path most by using `OPTIMIZE FOR 1 ROW`. `OPTIMIZE FOR 1 ROW` tells DB2 to select an access path that returns the first qualifying row quickly. This means that whenever possible, DB2 avoids any access path that involves a sort. If you specify a value for *n* that is anything but 1, DB2 chooses an access path based on cost, and you won't necessarily avoid sorts.

**How to specify `OPTIMIZE FOR n ROWS` for a CLI application:** For a Call Level Interface (CLI) application, you can specify that DB2 uses `OPTIMIZE FOR n ROWS` for all queries. To do that, specify the keyword `OPTIMIZEFORNROWS` in the initialization file. For more information, see Chapter 3 of *DB2 ODBC Guide and Reference*.

**How many rows you can retrieve with `OPTIMIZE FOR n ROWS`:** The `OPTIMIZE FOR n ROWS` clause does not prevent you from retrieving all the qualifying rows. However, if you use `OPTIMIZE FOR n ROWS`, the total elapsed time to retrieve all the qualifying rows might be significantly greater than if DB2 had optimized for the entire result set.

**When `OPTIMIZE FOR n ROWS` is effective:** `OPTIMIZE FOR n ROWS` is effective only on queries that can be performed incrementally. If the query causes DB2 to gather the whole result set before returning the first row, DB2 ignores the `OPTIMIZE FOR n ROWS` clause, as in the following situations:

- The query uses `SELECT DISTINCT` or a set function distinct, such as `COUNT(DISTINCT C1)`.
- Either `GROUP BY` or `ORDER BY` is used, and no index can give the necessary ordering.
- A aggregate function and no `GROUP BY` clause is used.
- The query uses `UNION`.

**Example:** Suppose that you query the employee table regularly to determine the employees with the highest salaries. You might use a query like this:

```
SELECT LASTNAME, FIRSTNAME, EMPNO, SALARY
FROM EMP
ORDER BY SALARY DESC;
```

An index is defined on column EMPNO, so employee records are ordered by EMPNO. If you have also defined a descending index on column SALARY, that index is likely to be very poorly clustered. To avoid many random, synchronous I/O operations, DB2 would most likely use a table space scan, then sort the rows on SALARY. This technique can cause a delay before the first qualifying rows can be returned to the application.

If you add the OPTIMIZE FOR *n* ROWS clause to the statement, DB2 will probably use the SALARY index directly because you have indicated that you expect to retrieve the salaries of only the 20 most highly paid employees.

**Example:** The following statement uses that strategy to avoid a costly sort operation:

```
SELECT LASTNAME, FIRSTNAME, EMPNO, SALARY
FROM EMP
ORDER BY SALARY DESC
OPTIMIZE FOR 20 ROWS;
```

#### *Effects of using OPTIMIZE FOR *n* ROWS:*

- The join method could change. Nested loop join is the most likely choice, because it has low overhead cost and appears to be more efficient if you want to retrieve only one row.
- An index that matches the ORDER BY clause is more likely to be picked. This is because no sort would be needed for the ORDER BY.
- List prefetch is less likely to be picked.
- Sequential prefetch is less likely to be requested by DB2 because it infers that you only want to see a small number of rows.
- In a join query, the table with the columns in the ORDER BY clause is likely to be picked as the outer table if there is an index on that outer table that gives the ordering needed for the ORDER BY clause.

**Recommendation:** For a local query, specify OPTIMIZE FOR *n* ROWS only in applications that frequently fetch only a small percentage of the total rows in a query result set. For example, an application might read only enough rows to fill the end user's terminal screen. In cases like this, the application might read the remaining part of the query result set only rarely. For an application like this, OPTIMIZE FOR *n* ROWS can result in better performance by causing DB2 to favor SQL access paths that deliver the first *n* rows as fast as possible.

When you specify OPTIMIZE FOR *n* ROWS for a remote query, a small value of *n* can help limit the number of rows that flow across the network on any given transmission.

You can improve the performance for receiving a large result set through a remote query by specifying a large value of *n* in OPTIMIZE FOR *n* ROWS. When you specify a large value, DB2 attempts to send the *n* rows in multiple transmissions. For better performance when retrieving a large result set, in addition to specifying OPTIMIZE FOR *n* ROWS with a large value of *n* in your query, do not execute other SQL statements until the entire result set for the query is processed. If

retrieval of data for several queries overlaps, DB2 might need to buffer result set data in the DDF address space. See “Block fetching result sets” on page 1009 for more information.

For local or remote queries, to influence the access path most, specify OPTIMIZE for 1 ROW. This value does not have a detrimental effect on distributed queries.

## Favoring index access

One common database design involves tables that contain groups of rows that logically belong together. Within each group, the rows should be accessed in the same sequence every time. The sequence is determined by the primary key on the table. Lock contention can occur when DB2 chooses different access paths for different applications that operate on a table with this design.

To minimize contention among applications that access tables with this design, specify the VOLATILE keyword when you create or alter the tables. A table that is defined with the VOLATILE keyword is known as a *volatile table*. When DB2 executes queries that include volatile tables, DB2 uses index access whenever possible. One exception is for DELETE statements on a VOLATILE table in a segmented table space when no WHERE clause is specified. In this case, a table space scan is used. As well as minimizing contention, using index access preserves the access sequence that the primary key provides.

Defining a table as volatile has a similar effect on a query to setting the NPGTHRSH subsystem parameter to favor matching index access for all qualified tables. (See “Using a subsystem parameter” on page 805 for information on the settings for NPGTHRSH.) However, the effect of NPGTHRSH is subsystem-wide, and index access might not be appropriate for many queries. Defining tables as volatile lets you limit the set of queries that favor index access to queries that involve the volatile tables.

## Using a subsystem parameter to control outer join processing

Subsystem parameter OJPERFEH can improve outer join processing. In particular, when the value of OJPERFEH is YES, DB2 takes the following actions, which can improve outer join processing in most cases:

- Does not merge table expressions or views if the parent query block of a table expression or view contains an outer join, and the merge would cause a column in a predicate to become an expression.
- Does not attempt to reduce work file usage for outer joins.
- Uses transitive closure for the ON predicates in outer joins.

However, these actions might not improve performance for some outer joins.

*Recommendation:* If the performance of queries that contain outer joins is not adequate, set OJPERFEH to NO, restart DB2, and rerun those queries.

## Using the CARDINALITY clause to improve the performance of queries with user-defined table function references

The cardinality of a user-defined table function is the number of rows that are returned when the function is invoked. DB2 uses this number to estimate the cost of executing a query that invokes a user-defined table function. The cost of executing a query is one of the factors that DB2 uses when it calculates the access

| path. Therefore, if you give DB2 an accurate estimate of a user-defined table  
| function's cardinality, DB2 can better calculate the best access path.

| You can specify a cardinality value for a user-defined table function by using the  
| CARDINALITY clause of the SQL CREATE FUNCTION or ALTER FUNCTION  
| statement. However, this value applies to all invocations of the function, whereas a  
| user-defined table function might return different numbers of rows, depending on  
| the query in which it is referenced.

| To give DB2 a better estimate of the cardinality of a user-defined table function for  
| a particular query, you can use the CARDINALITY or CARDINALITY  
| MULTIPLIER clause in that query. DB2 uses those clauses at bind time when it  
| calculates the access cost of the user-defined table function. Using this clause is  
| recommended only for programs that run on DB2 UDB for z/OS because the  
| clause is not supported on earlier versions of DB2.

| *Example of using the CARDINALITY clause to specify the cardinality of a*  
| *user-defined table function invocation:* Suppose that when you created  
| user-defined table function TUDF1, you set a cardinality value of 5, but in the  
| following query, you expect TUDF1 to return 30 rows:

| SELECT \*  
| FROM TABLE(TUDF1(3)) AS X;

| Add the CARDINALITY 30 clause to tell DB2 that, for this query, TUDF1 should  
| return 30 rows:

| SELECT \*  
| FROM TABLE(TUDF1(3) CARDINALITY 30) AS X;

| *Example of using the CARDINALITY MULTIPLIER clause to specify the*  
| *cardinality of a user-defined table function invocation:* Suppose that when you  
| created user-defined table function TUDF2, you set a cardinality value of 5, but in  
| the following query, you expect TUDF2 to return 30 times that many rows:

| SELECT \*  
| FROM TABLE(TUDF2(10)) AS X;

| Add the CARDINALITY MULTIPLIER 30 clause to tell DB2 that, for this query,  
| TUDF1 should return 5\*30, or 150, rows:

| SELECT \*  
| FROM TABLE(TUDF2(10) CARDINALITY MULTIPLIER 30) AS X;

## Reducing the number of matching columns

Discourage the use of a poorer performing index by reducing the index's matching predicate on its leading column. Consider the example in Figure 82 on page 800, where the index that DB2 picks is less than optimal.

```

CREATE TABLE PART_HISTORY (
  PART_TYPE CHAR(2),      IDENTIFIES THE PART TYPE
  PART_SUFFIX CHAR(10),  IDENTIFIES THE PART
  W_NOW INTEGER,         TELLS WHERE THE PART IS
  W_FROM INTEGER,       TELLS WHERE THE PART CAME FROM
  DEVIATIONS INTEGER,   TELLS IF ANYTHING SPECIAL WITH THIS PART
  COMMENTS CHAR(254),
  DESCRIPTION CHAR(254),
  DATE1 DATE,
  DATE2 DATE,
  DATE3 DATE);

CREATE UNIQUE INDEX IX1 ON PART_HISTORY
(PART_TYPE,PART_SUFFIX,W_FROM,W_NOW);
CREATE UNIQUE INDEX IX2 ON PART_HISTORY
(W_FROM,W_NOW,DATE1);

```

Table statistics		Index statistics IX1 IX2		
CARDF	100,000	FIRSTKEYCARDF	1000	50
NPAGES	10,000	FULLKEYCARDF	100,000	100,000
		CLUSTERRATIO	99%	99%
		NLEAF	3000	2000
		NLEVELS	3	3
	column	cardinality	HIGH2KEY	LOW2KEY
	-----	-----	-----	-----
	Part_type	1000	'ZZ'	'AA'
	w_now	50	1000	1
	w_from	50	1000	1

```

Q1:
SELECT * FROM PART_HISTORY -- SELECT ALL PARTS
WHERE PART_TYPE = 'BB'    P1 -- THAT ARE 'BB' TYPES
AND W_FROM = 3           P2 -- THAT WERE MADE IN CENTER 3
AND W_NOW = 3           P3 -- AND ARE STILL IN CENTER 3

```

ESTIMATED VALUES					WHAT REALLY HAPPENS			
index	matchcols	filter factor	data rows		index	matchcols	filter factor	data rows
ix2	2	.02*.02	40		ix2	2	.02*.50	1000
ix1	1	.001	100		ix1	1	.001	100

Figure 82. Reducing the number of MATCHCOLS

DB2 picks IX2 to access the data, but IX1 would be roughly 10 times quicker. The problem is that 50% of all parts from center number 3 are still in Center 3; they have not moved. Assume that there are no statistics on the correlated columns in catalog table SYSCOLDIST. Therefore, DB2 assumes that the parts from center number 3 are evenly distributed among the 50 centers.

You can get the desired access path by changing the query. To discourage the use of IX2 for this particular query, you can change the third predicate to be nonindexable.

```

SELECT * FROM PART_HISTORY
WHERE PART_TYPE = 'BB'
AND W_FROM = 3
AND (W_NOW = 3 + 0)    <-- PREDICATE IS MADE NONINDEXABLE

```

Now index I2 is not picked, because it has only one match column. The preferred index, I1, is picked. The third predicate is a nonindexable predicate, so an index is not used for the compound predicate.

You can make a predicate nonindexable in many ways. The recommended way is to add 0 to a predicate that evaluates to a numeric value or to concatenate an empty string to a predicate that evaluates to a character value.

Indexable	Nonindexable
T1.C3=T2.C4	(T1.C3=T2.C4 CONCAT '')
T1.C1=5	T1.C1=5+0

These techniques do not affect the result of the query and cause only a small amount of overhead.

The preferred technique for improving the access path when a table has correlated columns is to generate catalog statistics on the correlated columns. You can do that either by running RUNSTATS or by updating catalog table SYSCOLDIST manually.

## Creating indexes for efficient star-join processing

A *star schema* is a database design that, in its simplest form, consists of a large table called a *fact table*, and two or more smaller tables, called *dimension tables*. More complex star schemas can be created by breaking one or more of the dimension tables into multiple tables.

To access the data in a star schema design, you often write SELECT statements that include join operations between the fact table and the dimension tables, but no join operations between dimension tables. These types of queries are known as *star-join queries*.

For a star-join query, DB2 uses a special join type called a *star join* if the following conditions are true:

- The tables meet the conditions that are specified in “Star join (JOIN\_TYPE='S’)” on page 967.
- The STARJOIN system parameter is set to ENABLE, and the number of tables in the query block is greater than or equal to the minimum number that is specified in the SJTABLES system parameter.  
See “Star join (JOIN\_TYPE='S’)” on page 967 for detailed discussions of these system parameters.

This section gives suggestions for choosing indexes might improve star-join query performance.

### Recommendations for creating indexes for star-join queries

Follow these recommendations to improve performance of star-join queries:

- Define a multi-column index on all key columns of the fact table. Key columns are fact table columns that have corresponding dimension tables.
- If you do not have information about the way that your data is used, first try a multi-column index on the fact table that is based on the correlation of the data. Put less highly correlated columns later in the index key than more highly correlated columns. See “Determining the order of columns in an index for a star schema design” on page 802 for information on deriving an index that follows this recommendation.

- As the correlation of columns in the fact table changes, reevaluate the index to determine if columns in the index should be reordered.
- Define indexes on dimension tables to improve access to those tables.
- When you have executed a number of queries and have more information about the way that the data is used, follow these recommendations:
  - Put more selective columns at the beginning of the index.
  - If a number of queries do not reference a dimension, put the column that corresponds to that dimension at the end of the index.

When a fact table has more than one multi-column index and none of those indexes contains all key columns, DB2 evaluates all of the indexes and uses the index that best exploits star join.

### Determining the order of columns in an index for a star schema design

You can use the following method to determine the order of columns in a multi-column index. The description of the method uses the following terminology:

**F** A fact table.

**D1...Dn**  
Dimension tables.

**C1...Cn**  
Key columns in the fact table. C1 is joined to dimension D1, C2 is joined to dimension D2, and so on.

**cardD1...cardDn**  
Cardinality of columns C1...Cn in dimension tables D1...Dn.

**cardC1...cardCn**  
Cardinality of key columns C1...Cn in fact table F.

**cardCij**  
Cardinality of pairs of column values from key columns Ci and Cj in fact table F.

**cardCijk**  
Cardinality of triplets of column values from key columns Ci, Cj, and Ck in fact table F.

**Density**  
A measure of the correlation of key columns in the fact table. The density is calculated as follows:

**For a single column**  
 $\text{card}C_i / \text{card}D_i$

**For pairs of columns**  
 $\text{card}C_{ij} / (\text{card}D_i * \text{card}D_j)$

**For triplets of columns**  
 $\text{card}C_{ijk} / (\text{card}D_i * \text{card}D_j * \text{card}D_k)$

**S** The current set of columns whose order in the index is not yet determined.

**S-{Cm}**  
The current set of columns, excluding column Cm

Follow these steps to derive a fact table index for a star-join query that joins n columns of fact table F to n dimension tables D1 through Dn:

1. Define the set of columns whose index key order is to be determined as the  $n$  columns of fact table  $F$  that correspond to dimension tables. That is,  $S=\{C_1, \dots, C_n\}$  and  $L=n$ .
2. Calculate the density of all sets of  $L-1$  columns in  $S$ .
3. Find the lowest density. Determine which column is not in the set of columns with the lowest density. That is, find column  $C_m$  in  $S$ , such that for every  $C_i$  in  $S$ ,  $\text{density}(S-\{C_m\}) < \text{density}(S-\{C_i\})$ .
4. Make  $C_m$  the  $L$ th column of the index.
5. Remove  $C_m$  from  $S$ .
6. Decrement  $L$  by 1.
7. Repeat steps 2 through 6  $n-2$  times. The remaining column after iteration  $n-2$  is the first column of the index.

*Example of determining column order for a fact table index:* Suppose that a star schema has three dimension tables with the following cardinalities:

```
cardD1=2000
cardD2=500
cardD3=100
```

Now suppose that the cardinalities of single columns and pairs of columns in the fact table are:

```
cardC1=2000
cardC2=433
cardC3=100
cardC12=625000
cardC13=196000
cardC23=994
```

Determine the best multi-column index for this star schema.

Step 1: Calculate the density of all pairs of columns in the fact table:

```
density(C1,C2)=625000/(2000*500)=0.625
density(C1,C3)=196000/(2000*100)=0.98
density(C2,C3)=994/(500*100)=0.01988
```

Step 2: Find the pair of columns with the lowest density. That pair is (C2,C3). Determine which column of the fact table is not in that pair. That column is C1.

Step 3: Make column C1 the third column of the index.

Step 4: Repeat steps 1 through 3 to determine the second and first columns of the index key:

```
density(C2)=433/500=0.866
density(C3)=100/100=1.0
```

The column with the lowest density is C2. Therefore, C3 is the second column of the index. The remaining column, C2, is the first column of the index. That is, the best order for the multi-column index is C2, C3, C1.

## Rearranging the order of tables in a FROM clause

The order of tables or views in the FROM CLAUSE can affect the access path. If your query performs poorly, it could be because the join sequence is inefficient. You can determine the join sequence within a query block from the PLANNO column in the PLAN\_TABLE. For information on using the PLAN\_TABLE, see Chapter 34, "Using EXPLAIN to improve SQL performance," on page 931. If you

think that the join sequence is inefficient, try rearranging the order of the tables and views in the FROM clause to match a join sequence that might perform better.

## Updating catalog statistics

If you have the proper authority, you can influence access path selection by using an SQL UPDATE or INSERT statement to change statistical values in the DB2 catalog. However, this is not generally recommended except as a last resort. Although updating catalog statistics can help a certain query, other queries can be affected adversely. Also, the UPDATE statements must be repeated after RUNSTATS resets the catalog values. You should be very careful if you attempt to update statistics. For a list of catalog statistics that you can update, see Table 162 on page 903.

If you update catalog statistics for a table space or index manually, and you are using dynamic statement caching, you need to invalidate statements in the cache that involve those table spaces or indexes. To invalidate statements in the dynamic statement cache without updating catalog statistics or generating reports, you can run the RUNSTATS utility with the REPORT NO and UPDATE NONE options on the table space or the index that the query is dependent on.

The example shown in Figure 82 on page 800, involves this query:

```
SELECT * FROM PART_HISTORY -- SELECT ALL PARTS
WHERE PART_TYPE = 'BB'    P1 -- THAT ARE 'BB' TYPES
      AND W_FROM = 3      P2 -- THAT WERE MADE IN CENTER 3
      AND W_NOW = 3       P3 -- AND ARE STILL IN CENTER 3
```

This query has a problem with data correlation. DB2 does not know that 50% of the parts that were made in Center 3 are still in Center 3. The problem was circumvented by making a predicate nonindexable. But suppose that hundreds of users are writing queries similar to that query. Having all users change their queries would be impossible. In this type of situation, the best solution is to change the catalog statistics.

For the query in Figure 82 on page 800, you can update the catalog statistics in one of two ways:

- Run the RUNSTATS utility, and request statistics on the correlated columns W\_FROM and W\_NOW. This is the preferred method. See “Gathering monitor statistics and update statistics” on page 916 and Part 2 of *DB2 Utility Guide and Reference* for more information.
- Update the catalog statistics manually.

**Updating the catalog to adjust for correlated columns:** One catalog table that you can update is SYSIBM.SYSCOLDIST, which gives information about a column or set of columns in a table. Assume that because columns W\_NOW and W\_FROM are correlated, only 100 distinct values exist for the combination of the two columns, rather than 2500 (50 for W\_FROM \* 50 for W\_NOW). Insert a row like this to indicate the new cardinality:

```
INSERT INTO SYSIBM.SYSCOLDIST
(FREQUENCY, FREQUENCYF, IBMREQD,
 TOWNER, TBNAME, NAME, COLVALUE,
 TYPE, CARDF, COLGROUPCOLNO, NUMCOLUMNS)
VALUES(0, -1, 'N',
 'USRTO01', 'PART_HISTORY', 'W_FROM', ' ',
 'C', 100, X'00040003', 2);
```

You can also use the RUNSTATS utility to put this information in SYSCOLDIST. See *DB2 Utility Guide and Reference* for more information.

You tell DB2 about the frequency of a certain combination of column values by updating SYSIBM.SYSCOLDIST. For example, you can indicate that 1% of the rows in PART\_HISTORY contain the values 3 for W\_FROM and 3 for W\_NOW by inserting this row into SYSCOLDIST:

```
INSERT INTO SYSIBM.SYSCOLDIST
(FREQUENCY, FREQUENCYF, STATSTIME, IBMREQD,
TOWNER, TBNAME, NAME, COLVALUE,
TYPE, CARDF, COLGROUPCOLNO, NUMCOLUMNS)
VALUES(0, .0100, '1996-12-01-12.00.00.000000', 'N',
'USRT001', 'PART_HISTORY', 'W_FROM', X'00800000030080000003',
'F', -1, X'00040003', 2);
```

**Updating the catalog for joins with table functions:** Updating catalog statistics **might cause extreme performance problems** if the statistics are not updated correctly. Monitor performance, and be prepared to reset the statistics to their original values if performance problems arise.

## Using a subsystem parameter

This section describes subsystem parameters that influence access path selection. To set subsystem parameters, modify and run installation job DSNTIJUZ. See Part 2 of *DB2 Installation Guide* for information about how to set subsystem parameters. This section contains the following topics:

- “Using a subsystem parameter to favor matching index access”
- “Using a subsystem parameter to optimize queries with IN-list predicates” on page 806

### Using a subsystem parameter to favor matching index access

DB2 often does a table space scan or nonmatching index scan when the data access statistics indicate that a table is small, even though matching index access is possible. This is a problem if the table is small or empty when statistics are collected, but the table is large when it is queried. In that case, the statistics are not accurate and can lead DB2 to pick an inefficient access path.

The best solution to the problem is to run RUNSTATS again after the table is populated. However, if you cannot do that, you can use subsystem parameter NPGTHRSH to cause DB2 to favor matching index access over a table space scan and over nonmatching index access.

The value of NPGTHRSH is an integer that indicates the tables for which DB2 favors matching index access. Values of NPGTHRSH and their meanings are:

- |            |                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -1         | DB2 favors matching index access for all tables.                                                                                                                                                            |
| 0          | DB2 selects the access path based on cost, and no tables qualify for special handling. This is the default.                                                                                                 |
| $n \geq 1$ | If data access statistics have been collected for all tables, DB2 favors matching index access for tables for which the total number of pages on which rows of the table appear (NPAGES) is less than $n$ . |

# Tables with default statistics for NPAGES (NPAGES =-1) are presumed to have 501  
# pages. For such tables, DB2 will favor matching index access only when  
# NPGTHRSH is set above 501.

**Recommendation:** Before you use NPGTHRSR, be aware that in some cases, matching index access can be more costly than a table space scan or nonmatching index access. Specify a small value for NPGTHRSR (10 or less), which limits the number of tables for which DB2 favors matching index access. If you need to use matching index access only for specific tables, create or alter those tables with the VOLATILE parameter, rather than using the system-wide NPGTHRSR parameter. See “Favoring index access” on page 798.

### Using a subsystem parameter to optimize queries with IN-list predicates

You can use the INLISTP parameter to control IN-list predicate optimization. If you set the INLISTP parameter to a number *n* that is between 1 and 5000, DB2 optimizes for an IN-list predicate with up to *n* values. If you set the INLISTP predicate to zero, the optimization is disabled. The default value for the INLISTP parameter is 50.

When you enable the INLISTP parameter, you enable two primary means of optimizing some queries that contain IN-list predicates:

- The IN-list predicate is pushed down from the parent query block into the materialized table expression.
- A correlated IN-list predicate in a subquery that is generated by transitive closure is moved up to the parent query block.

## Giving optimization hints to DB2

This section describes how experienced programmer analysts can tell DB2 how to process a query. You do this by giving DB2 *hints*. The process of giving hints to DB2 is relatively simple but determining what those hints should be is not. Always test and analyze the results of any query that uses optimization hints.

Giving optimization hints to DB2 is useful in the following situations:

- You want to ensure consistency of response times across rebinds and across release migrations. When a plan or package is rebound, the access path is reformulated. If the database or application has changed, or if DB2 has new function that causes it to choose a different access path, it is handy to have the ability to use an old access path if the new one does not perform as well.  
For this reason, it is a good idea to save the access paths of your critical queries before migrating to a new release of DB2.
- You want to temporarily bypass the access path chosen by DB2.

This section describes the following topics:

- “Planning to use optimization hints”
- “Enabling optimization hints for the subsystem” on page 807
- “Scenario: Preventing a change at rebind” on page 807
- “Scenario: Modifying an existing access path” on page 809
- “Reasons to use the QUERYNO clause” on page 810
- “How DB2 validates the hint” on page 810
- “Limitations on optimization hints” on page 812

### Planning to use optimization hints

Before you can give hints to DB2, make sure your PLAN\_TABLE is of the correct format. The steps are:

1. Migrate your existing authid.PLAN\_TABLE to the 49-column format described in Figure 107 on page 935.

2. For best performance, create an ascending index on the following columns of PLAN\_TABLE:
  - QUERYNO
  - APPLNAME
  - PROGNAME
  - VERSION
  - COLLID
  - OPTHINT

The DB2 sample library, in member DSNTEESC, contains an appropriate CREATE INDEX statement that you can modify.

### Enabling optimization hints for the subsystem

#  
#  
#

On the subsystem where the application is bound or where dynamic queries are prepared, specify YES in the OPTIMIZATION HINTS field of installation panel DSN TIP8. If you specify NO, DB2 ignores any hints.

### Scenario: Preventing a change at rebind

The following scenario assumes that DB2 is using an access path that you like for a particular query and that there is currently a row in the PLAN\_TABLE for that desired access path. By making that access path a hint, DB2 will use your hint when you rebind or migrate to a new release.

1. Determine the query number that currently exists for that query in the PLAN\_TABLE. To ensure that the query number is always correlated with that query in the application, modify the statement in the application to use the QUERYNO clause. (If you want to use some kind of numbering convention for queries that use access path hints, you can change the query number in PLAN\_TABLE. The important thing is to have the query in the application have a query number that is unique for that application and that matches the QUERYNO value in the PLAN\_TABLE.)

Here is an example of the QUERYNO clause:

```
SELECT * FROM T1
  WHERE C1 = 10 AND
         C2 BETWEEN 10 AND 20 AND
         C3 NOT LIKE 'A%'
  QUERYNO 100;
```

For more information about reasons to use the QUERYNO clause, see “Reasons to use the QUERYNO clause” on page 810.

2. Make the PLAN\_TABLE rows for that query (QUERYNO=100) into a hint by updating the OPTHINT column with the name you want to call the hint. In this case, the name is OLDPATH:

```
UPDATE PLAN_TABLE
  SET OPTHINT = 'OLDPATH' WHERE
  QUERYNO = 100 AND
  APPLNAME = ' ' AND
  PROGNAME = 'DSNTEP2' AND
  VERSION = ' ' AND
  COLLID = 'DSNTEP2';
```

3. Tell DB2 to use the hint, and indicate in the PLAN\_TABLE that DB2 used the hint.
  - For dynamic SQL statements in the program, follow these steps:
    - a. Execute the SET CURRENT OPTIMIZATION HINT statement in the program to tell DB2 to use OLDPATH. For example:
 

```
SET CURRENT OPTIMIZATION HINT = 'OLDPATH';
```

If you do not explicitly set the CURRENT OPTIMIZATION HINT special register, the value that you specify for the bind option OPTHINT is used. If you execute the SET CURRENT OPTIMIZATION HINT statement statically, rebind the plan or package to pick up the SET CURRENT OPTIMIZATION HINT statement.

- b. Execute the EXPLAIN statement on the SQL statements for which you have instructed DB2 to use OLDPATH. This step adds rows to the PLAN\_TABLE for those statements. The rows contain a value of OLDPATH in the HINT\_USED column.

# If DB2 uses all of the hints that you provided, it returns SQLCODE +394 from the PREPARE of the EXPLAIN statement and from the PREPARE of SQL statements that use the hints. If any of your hints are invalid, or if any duplicate hints were found, DB2 issues SQLCODE +395. If DB2 does not find an optimization hint, DB2 returns another SQLCODE. Usually, this SQLCODE is 0.

# If the dynamic statement cache is enabled, DB2 includes the value of the CURRENT OPTIMIZATION HINT special register when looking for a match in the dynamic statement cache. If the execution of the statement results in a cache hit, the query does not go through prepare and DB2 uses the cached plan. If no match is found for the statement in the dynamic statement cache, the query goes through prepare, and DB2 considers the optimization hints.

- For static SQL statements in the program, rebind the plan or package that contains the statements. Specify bind options EXPLAIN(YES) and OPTHINT('OLDPATH') to add rows for those statements in the PLAN\_TABLE that contain a value of OLDPATH in the HINT\_USED column.

| If DB2 uses the hint you provided, it returns SQLCODE +394 from the rebind. If your hints are invalid, DB2 issues SQLCODE +395. If DB2 does not find an optimization hint, it returns another SQLCODE. Usually, this SQLCODE is 0.

4. Select from PLAN\_TABLE to see what was used:

```
SELECT *
FROM PLAN_TABLE
WHERE QUERYNO = 100
ORDER BY TIMESTAMP, QUERYNO, QBLOCKNO, PLANNO, MIXOPSEQ;
```

The PLAN\_TABLE in Table 132 shows the OLDPATH hint, indicated by a value in OPTHINT and it also shows that DB2 used that hint, indicated by OLDPATH in the HINT\_USED column.

Table 132. PLAN\_TABLE that shows that the OLDPATH optimization hint is used.

QUERYNO	METHOD	TNAME	OPTHINT	HINT_USED
100	0	EMP	OLDPATH	
100	4	EMPPROJECT	OLDPATH	
100	3		OLDPATH	
100	0	EMP		OLDPATH
100	4	EMPPROJECT		OLDPATH
100	3			OLDPATH

## Scenario: Modifying an existing access path

The following scenario assumes that DB2 is using a hybrid join where you know it can perform better with a sort merge join. The example assumes that the query is dynamic.

1. Put the old access path in the PLAN\_TABLE and associate it with a query number.

```
EXPLAIN ALL SET QUERYNO=200 FOR
SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
FROM DSN8610.EMPPROJACT X, DSN8610.EMP Y
WHERE X.EMPNO = Y.EMPNO
AND X.EMPTIME > 0.5
AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
ORDER BY X.ACTNO, X.PROJNO;
```

2. Make the PLAN\_TABLE rows into a hint by updating the OPTHINT column with the name you want to call the hint. In this case, the name is NOHYB:

```
UPDATE PLAN_TABLE
SET OPTHINT = 'NOHYB' WHERE
QUERYNO = 200 AND
APPLNAME = ' ' AND
PROGNAME = 'DSNTEP2' AND
VERSION = '' AND
COLLID = 'DSNTEP2';
```

3. Change the access path so that merge scan join is used rather than hybrid join:

```
UPDATE PLAN_TABLE
SET METHOD = 2 WHERE
QUERYNO = 200 AND
APPLNAME = ' ' AND
PROGNAME = 'DSNTEP2' AND
VERSION = '' AND
COLLID = 'DSNTEP2' AND
OPTHINT = 'NOHYB' AND
METHOD = 4;
```

4. Tell DB2 to look for the NOHYB hint for this query:

```
SET CURRENT OPTIMIZATION HINT = 'NOHYB';
```

5. Explain the query again to check for the results:

```
EXPLAIN ALL SET QUERYNO=200 FOR
SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
FROM DSN8610.EMPPROJACT X, DSN8610.EMP Y
WHERE X.EMPNO = Y.EMPNO
AND X.EMPTIME > 0.5
AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
ORDER BY X.ACTNO, X.PROJNO;
```

6. Select from the PLAN\_TABLE to verify the results:

```
SELECT *
FROM PLAN_TABLE
WHERE QUERYNO = 200
ORDER BY TIMESTAMP, QUERYNO, QBLOCKNO, PLANNO, MIXOPSEQ;
```

The PLAN\_TABLE in Table 133 shows the NOHYB hint, indicated by a value in OPTHINT and it also shows that DB2 used that hint, indicated by NOHYB in the HINT\_USED column.

Table 133. PLAN\_TABLE that shows that the NOHYB optimization hint is used.

QUERYNO	METHOD	TNAME	OPTHINT	HINT_USED
200	0	EMP	NOHYB	
200	2	EMPPROJACT	NOHYB	
200	3		NOHYB	

Table 133. *PLAN\_TABLE* that shows that the *NOHYB* optimization hint is used. (continued)

QUERYNO	METHOD	TNAME	OPTHINT	HINT_USED
200	0	EMP		NOHYB
200	2	EMPPROJECT		NOHYB
200	3			NOHYB

7. Analyze the performance of the statement to see if it is acceptable.

### Reasons to use the QUERYNO clause

You do not need to assign a query number to use optimization hints. If you don't assign a query number, DB2 uses the statement number. However, assigning a query number is especially useful in the following cases:

- For dynamic statements

The query number for dynamic applications is the statement number in the application *where the prepare occurs*. For some applications, such as DSNTEP2, the same statement in the application prepares each dynamic statement, resulting in the same query number for each dynamic statement. Assigning a query number to each statement that uses optimization hints eliminates ambiguity as to which rows in the *PLAN\_TABLE* are associated with each query.

- For static statements

If you change an application that has static statements, the statement number might change, causing rows in the *PLAN\_TABLE* to be out of sync with the modified application. Statements that use the *QUERYNO* clause are not dependent on the statement number. You can move those statements around without affecting the relationship between rows in the *PLAN\_TABLE* and the statements that use those rows in the application.

### How DB2 locates the PLAN\_TABLE rows for a hint

DB2 uses the *QUERYNO*, *APPLNAME*, *PROGNAME*, *VERSION*, *COLLID*, and *OPTHINT* columns of the *PLAN\_TABLE* to determine the rows to use for a hint. For a *PLAN\_TABLE* row, the *QUERYNO*, *APPLNAME*, *PROGNAME*, *VERSION*, and *COLLID* values must match the corresponding values for an SQL statement before the SQL statement can use that row. In addition, the *OPTHINT* value for that row must match the value in the *CURRENT OPTIMIZATION HINT* special register if the SQL statement is executed dynamically. If the SQL statement is executed statically, the *OPTHINT* value for the row must match the value of bind option *OPTHINT* for the package or plan that contains the SQL statement. If no *PLAN\_TABLE* rows meet these conditions, DB2 determines the access path for the SQL statement without using hints.

### How DB2 validates the hint

When you specify an optimization hint by using the *OPTHINT* bind option for static statements, or the *CURRENT OPTIMIZATION HINT* special register for dynamic statements, DB2 ensures that you choose a valid access path. To ensure a valid access path, DB2 validates the *PLAN\_TABLE* rows in which the value in the *OPTHINT* column matches the specified hint. If the access path that you specify has major problems, DB2 invalidates all hints for that query block. In that event, DB2 determines the access path as it normally does.

DB2 validates the information in **only** the *PLAN\_TABLE* columns in Table 134 on page 811.

Table 134. *PLAN\_TABLE* columns that DB2 validates

Column	Correct values or other explanation
METHOD	Must be 0, 1, 2, 3, or 4. Any other value invalidates the hints. See “Interpreting access to two or more tables (join)” on page 959 for more information about join methods.
CREATOR and TNAME	Must be specified and must name a table, materialized view, materialized nested table expression. Blank if method is 3. If a table is named that does not exist or is not involved in the query, then the hints are invalid.
TABNO	Required only if CREATOR, TNAME, and CORRELATION_NAME do not uniquely identify the table. This situation might occur when the same table is used in multiple views (with the same CORRELATION_NAME).  This field is ignored if it is not needed.
ACCESSTYPE	Must contain I, I1, N, M, R, RW, T, or V. Any other value invalidates the hints.  Values of I, I1, and N all mean single index access. DB2 determines which of the three values to use based on the index specified in ACCESSNAME.  M indicates multiple index access. DB2 uses only the first row in the authid.PLAN_TABLE for multiple index access (MIXOPSEQ=0). The choice of indexes, and the AND and OR operations involved, is determined by DB2. If multiple index access isn’t possible, then the hints are invalidated.  See “Is access through an index? (ACCESSTYPE is I, I1, N or MX)” on page 944 and “Is access through more than one index? (ACCESSTYPE=M)” on page 944 for more information.
ACCESSCREATOR and ACCESSNAME	Ignored if ACCESSTYPE is R or M. If ACCESSTYPE is I, I1, or N, then these fields must identify an index on the specified table.  If the index doesn’t exist, or if the index is defined on a different table, then the hints are invalid. Also, if the specified index can’t be used, then the hints are invalid.
SORTN_JOIN and SORTC_JOIN	Must be Y, N or blank. Any other value invalidates the hints.  This value determines if DB2 should sort the new (SORTN_JOIN) or composite (SORTC_JOIN) table. This value is ignored if the specified join method, join sequence, access type and access name dictate whether a sort of the new or composite tables is required.  See “Are sorts performed?” on page 949 for more information.
PREFETCH	Must be S, L or blank. Any other value invalidates the hints.  This value determines whether DB2 should use sequential prefetch (S), list prefetch (L), or no prefetch (blank). (A blank does not prevent sequential detection at run time.) This value is ignored if the specified access type and access name dictates the type of prefetch required.

Table 134. PLAN\_TABLE columns that DB2 validates (continued)

Column	Correct values or other explanation
PAGE_RANGE	Must be Y, N or blank. Any other value invalidates the hints. See “Was a scan limited to certain partitions? (PAGE_RANGE=Y)” on page 948 for more information.
PARALLELISM_MODE	<p>This value is used only if it is possible to run the query in parallel; that is, the SET CURRENT DEGREE special register contains ANY, or the plan or package was bound with DEGREE(ANY).</p> <p>If parallelism is possible, this value must be I, C, X or null. All of the restrictions involving parallelism still apply when using access path hints. If the specified mode cannot be performed, the hints are either invalidated or the mode is modified by the optimizer, possibly resulting in the query being run sequentially. If the value is null then the optimizer determines the mode.</p> <p>See Chapter 35, “Parallel operations and query performance,” on page 991 for more information.</p>
ACCESS_DEGREE or JOIN_DEGREE	<p>If PARALLELISM_MODE is specified, use this field to specify the degree of parallelism. If you specify a degree of parallelism, this must be a number greater than zero, and DB2 might adjust the parallel degree from what you set here. If you want DB2 to determine the degree, do not enter a value in this field.</p> <p>If you specify a value for ACCESS_DEGREE or JOIN_DEGREE, you must also specify a corresponding ACCESS_PGROUP_ID and JOIN_PGROUP_ID.</p>
WHEN_OPTIMIZE	<p>Must be R, B, or blank. Any other value invalidates the hints.</p> <p>When a statement in a plan that is bound with REOPT(ALWAYS) qualifies for reoptimization at run time, and you have provided optimization hints for that statement, the value of WHEN_OPTIMIZE determines whether DB2 reoptimizes the statement at run time. If the value of WHEN_OPTIMIZE is blank or B, DB2 uses only the access path that is provided by the optimization hints at bind time. If the value of WHEN_OPTIMIZE is R, DB2 determines the access path at bind time using the optimization hints. At run time, DB2 searches the PLAN_TABLE for hints again, and if hints for the statement are still in the PLAN_TABLE and are still valid, DB2 optimizes the access path using those hints again.</p>
PRIMARY_ACCESSTYPE	Must be D or blank. Any other value invalidates the hints.

### Limitations on optimization hints

Optimization hints cannot force or undo query transformations, such as subquery transformation to join or materialization or merge of a view or table expression.

A query that is not transformed in one release of DB2 might be transformed in a later release of DB2. Therefore, if you include a hint in one release of DB2 for a query that is not transformed in that release, but in a later release of DB2, the query is transformed, DB2 does not use the hint in the later release.

---

## Chapter 31. Improving concurrency

This chapter begins with an overview of concurrency and locks in the following sections:

- “Definitions of concurrency and locks” on page 814
- “Effects of DB2 locks” on page 814
- “Basic recommendations to promote concurrency” on page 816

After the basic recommendations, the chapter covers some of the major techniques that DB2 uses to control concurrency:

- **Transaction locks** mainly control access by SQL statements. Those locks are the ones over which you have the most control.
  - “Aspects of transaction locks” on page 821 describes the various types of transaction locks that DB2 uses and how they interact.
  - “Options for tuning locks” on page 836 describes what you can change to control locking. Your choices include:
    - “IRLM startup procedure options” on page 836
    - “Installation options for wait times” on page 837
    - “Other options that affect locking” on page 841
    - “Bind options” on page 847
    - “Isolation overriding with SQL statements” on page 862
    - “The LOCK TABLE statement” on page 863

Under those headings, *lock* (with no qualifier) refers to *transaction lock*.

- **LOB locks** are described separately from transaction locks because the purpose of LOB locks is different than that of regular transition locks. See “LOB locks” on page 864.
- **Latches** are conceptually similar to locks in that they control serialization. They can improve concurrency because they are usually held for shorter duration than locks and they cannot “deadlatch”. However, latches can wait, and this wait time is reported in accounting trace class 3. Because latches are not under your control, they are not described in any detail.
- **Claims and drains** provide another mechanism to control serialization. SQL applications and some utilities make claims for objects when they first access them. Operations that drain can take control of an object by quiescing the existing claimers and preventing new claims. After a drainer completes its operations, claimers can resume theirs. DB2 utilities, commands, and some SQL statements can act as drainers.

“Claims and drains for concurrency control” on page 869 describes claims and drains in more detail and explains how to plan utility jobs and other activities to maximize efficiency.

The chapter also describes how you can monitor DB2’s use of locks and how you can analyze a sample problem in “Monitoring of DB2 locking” on page 873.

Finally, “Deadlock detection scenarios” on page 881 shows how to detect deadlock situations.

DB2 extends its concurrency controls to multiple subsystems for data sharing. For information about that, see *DB2 Data Sharing: Planning and Administration*.

---

## Definitions of concurrency and locks

**Definition:** *Concurrency* is the ability of more than one application process to access the same data at essentially the same time.

**Example:** An application for order entry is used by many transactions simultaneously. Each transaction makes inserts in tables of invoices and invoice items, reads a table of data about customers, and reads and updates data about items on hand. Two operations on the same data, by two simultaneous transactions, might be separated only by microseconds. To the users, the operations appear concurrent.

**Conceptual background:** Concurrency must be controlled to prevent lost updates and such possibly undesirable effects as unrepeatable reads and access to uncommitted data.

**Lost updates.** Without concurrency control, two processes, A and B, might both read the same row from the database, and both calculate new values for one of its columns, based on what they read. If A updates the row with its new value, and then B updates the same row, A's update is lost.

**Access to uncommitted data.** Also without concurrency control, process A might update a value in the database, and process B might read that value before it was committed. Then, if A's value is not later committed, but backed out, B's calculations are based on uncommitted (and presumably incorrect) data.

**Unrepeatable reads.** Some processes require the following sequence of events: A reads a row from the database and then goes on to process other SQL requests. Later, A reads the first row again and must find the same values it read the first time. Without control, process B could have changed the row between the two read operations.

To prevent those situations from occurring unless they are specifically allowed, DB2 might use *locks* to control concurrency.

**What do locks do?** A lock associates a DB2 resource with an application process in a way that affects how other processes can access the same resource. The process associated with the resource is said to "hold" or "own" the lock. DB2 uses locks to ensure that no process accesses data that has been changed, but not yet committed, by another process.

**What do you do about locks?** To preserve data integrity, your application process acquires locks implicitly, that is, under DB2 control. It is not necessary for a process to request a lock explicitly to conceal uncommitted data. Therefore, sometimes you need not do anything about DB2 locks. Nevertheless processes acquire, or avoid acquiring, locks based on certain general parameters. You can make better use of your resources and improve concurrency by understanding the effects of those parameters.

---

## Effects of DB2 locks

The effects of locks that you want to minimize are *suspension*, *timeout*, and *deadlock*.

### Suspension

**Definition:** An application process is *suspended* when it requests a lock that is already held by another application process and cannot be shared. The suspended process temporarily stops running.

**Order of precedence for lock requests:** Incoming lock requests are queued. Requests for lock promotion, and requests for a lock by an application process that already holds a lock on the same object, precede requests for locks by new applications. Within those groups, the request order is “first in, first out”.

**Example:** Using an application for inventory control, two users attempt to reduce the quantity on hand of the same item at the same time. The two lock requests are queued. The second request in the queue is suspended and waits until the first request releases its lock.

**Effects:** The suspended process resumes running when:

- All processes that hold the conflicting lock release it.
- The requesting process times out or deadlocks and the process resumes to deal with an error condition.

## Timeout

**Definition:** An application process is said to *time out* when it is terminated because it has been suspended for longer than a preset interval.

**Example:** An application process attempts to update a large table space that is being reorganized by the utility REORG TABLESPACE with SHRLEVEL NONE. It is likely that the utility job will not release control of the table space before the application process times out.

**Effects:** DB2 terminates the process, issues two messages to the console, and returns SQLCODE -911 or -913 to the process (SQLSTATES '40001' or '57033'). Reason code 00C9008E is returned in the SQLERRD(3) field of the SQLCA. Alternatively, you can use the GET DIAGNOSTICS statement to check the reason code. If statistics trace class 3 is active, DB2 writes a trace record with IFCID 0196.

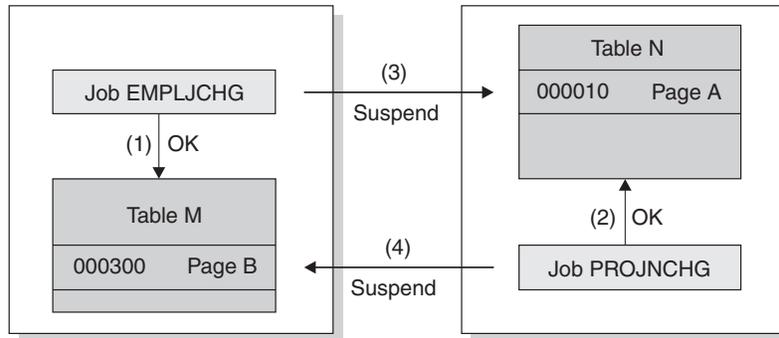

COMMIT and ROLLBACK operations do not time out. The command STOP DATABASE, however, may time out and send messages to the console, but it will retry up to 15 times.

For more information about setting the timeout interval, see “Installation options for wait times” on page 837.

## Deadlock

**Definition:** A *deadlock* occurs when two or more application processes each hold locks on resources that the others need and without which they cannot proceed.

**Example:** Figure 83 on page 816 illustrates a deadlock between two transactions.

**Notes:**

1. Jobs EMPLJCHG and PROJNCHG are two transactions. Job EMPLJCHG accesses table M, and acquires an exclusive lock for page B, which contains record 000300.
2. Job PROJNCHG accesses table N, and acquires an exclusive lock for page A, which contains record 000010.
3. Job EMPLJCHG requests a lock for page A of table N while still holding the lock on page B of table M. The job is suspended, because job PROJNCHG is holding an exclusive lock on page A.
4. Job PROJNCHG requests a lock for page B of table M while still holding the lock on page A of table N. The job is suspended, because job EMPLJCHG is holding an exclusive lock on page B. The situation is a deadlock.

*Figure 83. A deadlock example*

**Effects:** After a preset time interval (the value of DEADLOCK TIME), DB2 can roll back the current unit of work for one of the processes or request a process to terminate. That frees the locks and allows the remaining processes to continue. If statistics trace class 3 is active, DB2 writes a trace record with IFCID 0172. Reason code 00C90088 is returned in the SQLERRD(3) field of the SQLCA. Alternatively, you can use the GET DIAGNOSTICS statement to check the reason code. (The codes that describe DB2's exact response depend on the operating environment; for details, see Part 5 of *DB2 Application Programming and SQL Guide*.)

It is possible for two processes to be running on distributed DB2 subsystems, each trying to access a resource at the other location. In that case, neither subsystem can detect that the two processes are in deadlock; the situation resolves only when one process times out.

---

## Basic recommendations to promote concurrency

Recommendations are grouped by their scope:

- "Recommendations for system and subsystem options"
- "Recommendations for database design" on page 817
- "Recommendations for application design" on page 818

### Recommendations for system and subsystem options

*Optimize overall performance:* Some performance problems can appear to be locking problems although they are really problems somewhere else in the system. For example, a table space scan of a large table can result in timeouts. Resolve overall system, subsystem, and application performance problems to ensure that you not only eliminate locking symptoms but also correct other underlying performance problems.

*Eliminate swapping:* If a task is waiting or is swapped out and the unit of work has not been committed, then it still holds locks. When a system is heavily loaded, contention for processing, I/O, and storage can cause waiting. Consider reducing the number of threads or initiators, increasing the priority for the DB2 tasks, and providing more processing, I/O, and real memory.

## Recommendations for database design

*Keep like things together:* Put tables relevant to the same application into the same database. Give each application process that creates private tables a private database. Put tables together in a segmented table space if they are similar in size and can be recovered together.

*Keep unlike things apart:* Use an adequate number of databases, schema or authorization-ID qualifiers, and table spaces. Concurrency and performance is improved for SQL data definition statements, GRANT statements, REVOKE statements, and utilities. For example, a general guideline is a maximum of 50 tables per database. For more information about lock contention on the catalog, see “Locks on the DB2 catalog” on page 828 and “Utility locks on the catalog and directory” on page 871.

*Plan for batch inserts:* If your application does sequential batch insertions, excessive contention on the space map pages for the table space can occur. This problem is especially apparent in data sharing, where contention on the space map means the added overhead of page P-lock negotiation. For these types of applications, consider using the MEMBER CLUSTER option of CREATE TABLESPACE. This option causes DB2 to disregard the clustering index (or implicit clustering index) when assigning space for the SQL INSERT statement. For more information about using this option in data sharing, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*. For the syntax, see Chapter 5 of *DB2 SQL Reference*.

*Use LOCKSIZE ANY until you have reason not to:* LOCKSIZE ANY is the default for CREATE TABLESPACE. It allows DB2 to choose the lock size, and DB2 usually chooses LOCKSIZE PAGE and LOCKMAX SYSTEM for non-LOB table spaces. For LOB table spaces, it chooses LOCKSIZE LOB and LOCKMAX SYSTEM. You should use LOCKSIZE TABLESPACE or LOCKSIZE TABLE only for read-only table spaces or tables, or when concurrent access to the object is not needed. Before you choose LOCKSIZE ROW, you should estimate whether there will be an increase in overhead for locking and weigh that against the increase in concurrency.

*Examine small tables:* For small tables with high concurrency requirements, estimate the number of pages in the data and in the index. If the index entries are short or they have many duplicates, then the entire index can be one root page and a few leaf pages. In this case, spread out your data to improve concurrency, or consider it a reason to use row locks.

*Partition the data:* Large tables can be partitioned to take advantage of parallelism for online queries, batch jobs, and utilities. When batch jobs are run in parallel and each job goes after different partitions, lock contention is reduced. In addition, in a data sharing environment, data sharing overhead is reduced when applications that are running on different members go after different partitions.

*Partition secondary indexes:* The use of data-partitioned secondary indexes (DPSIs) promotes partition independence and, therefore, can reduce lock contention and

improve index availability, especially for utility processing, partition-level operations (such as dropping or rotating partitions), and recovery of indexes.

However, the use of data-partitioned secondary indexes does not always improve the performance of queries. For example, for a query with a predicate that references only the columns of a data-partitioned secondary index, DB2 must probe each partition of the index for values that satisfy the predicate if index access is chosen as the access path. Therefore, take into account data access patterns and maintenance practices when deciding to use a data-partitioned secondary index. Replace a nonpartitioned index with a partitioned index only if there are perceivable benefits such as improved data or index availability, easier data or index maintenance, or improved performance.

For examples of how query performance can be improved with data-partitioned secondary indexes, see “Writing efficient queries on tables with data-partitioned secondary indexes” on page 792.

**Fewer rows of data per page:** By using the MAXROWS clause of CREATE or ALTER TABLESPACE, you can specify the maximum number of rows that can be on a page. For example, if you use MAXROWS 1, each row occupies a whole page, and you confine a page lock to a single row. Consider this option if you have a reason to avoid using row locking, such as in a data sharing environment where row locking overhead can be greater.

**Consider volatile tables to ensure index access:** If multiple applications access the same table, consider defining the table as VOLATILE. DB2 uses index access whenever possible for volatile tables, even if index access does not appear to be the most efficient access method because of volatile statistics. Because each application generally accesses the rows in the table in the same order, lock contention can be reduced.

## Recommendations for application design

**Access data in a consistent order:** When different applications access the same data, try to make them do so in the same sequence. For example, make both access rows 1,2,3,5 in that order. In that case, the first application to access the data delays the second, but the two applications cannot deadlock. For the same reason, try to make different applications access the same tables in the same order.

**Commit work as soon as is practical:** To avoid unnecessary lock contention, issue a COMMIT statement as soon as possible after reaching a point of consistency, even in read-only applications. To prevent unsuccessful SQL statements (such as PREPARE) from holding locks, issue a ROLLBACK statement after a failure. Statements issued through SPUFI can be committed immediately by the SPUFI autocommit feature.

Taking commit points frequently in a long running unit of recovery (UR) has the following benefits at the possible cost of more CPU usage and log write I/Os:

- Reduces lock contention, especially in a data sharing environment
- Improves the effectiveness of lock avoidance, especially in a data sharing environment
- Reduces the elapsed time for DB2 system restart following a system failure
- Reduces the elapsed time for a unit of recovery to rollback following an application failure or an explicit rollback request by the application
- Provides more opportunity for utilities, such as online REORG, to break in

Consider using the UR CHECK FREQ field or the UR LOG WRITE CHECK field of installation panel DSNTIPN to help you identify those applications that are not committing frequently. UR CHECK FREQ, which identifies when too many checkpoints have occurred without a UR issuing a commit, is helpful in monitoring overall system activity. UR LOG WRITE CHECK enables you to detect applications that might write too many log records between commit points, potentially creating a lengthy recovery situation for critical tables.

Even though an application might conform to the commit frequency standards of the installation under normal operational conditions, variation can occur based on system workload fluctuations. For example, a low-priority application might issue a commit frequently on a system that is lightly loaded. However, under a heavy system load, the use of the CPU by the application may be pre-empted, and, as a result, the application may violate the rule set by the UR CHECK FREQ parameter. For this reason, add logic to your application to commit based on time elapsed since last commit, and not solely based on the amount of SQL processing performed. In addition, take frequent commit points in a long running unit of work that is read-only to reduce lock contention and to provide opportunities for utilities, such as online REORG, to access the data.

**Retry an application after deadlock or timeout:** Include logic in a batch program so that it retries an operation after a deadlock or timeout. Such a method could help you recover from the situation without assistance from operations personnel. Field SQLERRD(3) in the SQLCA returns a reason code that indicates whether a deadlock or timeout occurred. Alternatively, you can use the GET DIAGNOSTICS statement to check the reason code.

**Close cursors:** If you define a cursor using the WITH HOLD option, the locks it needs can be held past a commit point. Use the CLOSE CURSOR statement as soon as possible in your program to cause those locks to be released and the resources they hold to be freed at the first commit point that follows the CLOSE CURSOR statement. Whether page or row locks are held for WITH HOLD cursors is controlled by the RELEASE LOCKS parameter on installation panel DSNTIP8. Closing cursors is particularly important in a distributed environment.

**Free locators:** If you have executed the HOLD LOCATOR statement, the LOB locator holds locks on LOBs past commit points. Use the FREE LOCATOR statement to release these locks.

**Bind plans with ACQUIRE(USE):** ACQUIRE(USE), which indicates that DB2 will acquire table and table space locks when the objects are first used and not when the plan is allocated, is the best choice for concurrency. Packages are always bound with ACQUIRE(USE), by default. ACQUIRE(ALLOCATE) can provide better protection against timeouts. Consider ACQUIRE(ALLOCATE) for applications that need gross locks instead of intent locks or that run with other applications that may request gross locks instead of intent locks. Acquiring the locks at plan allocation also prevents any one transaction in the application from incurring the cost of acquiring the table and table space locks. If you need ACQUIRE(ALLOCATE), you might want to bind all DBRMs directly to the plan.

For information about intent and gross locks, see “The mode of a lock” on page 825.

**Bind with ISOLATION(CS) and CURRENTDATA(NO) typically:** ISOLATION(CS) lets DB2 release acquired row and page locks as soon as possible.

CURRENTDATA(NO) lets DB2 avoid acquiring row and page locks as often as possible. After that, in order of decreasing preference for concurrency, use these bind options:

1. ISOLATION(CS) with CURRENTDATA(YES), when data returned to the application must not be changed before your next FETCH operation.
2. ISOLATION(RS), when data returned to the application must not be changed before your application commits or rolls back. However, you do not care if other application processes insert additional rows.
3. ISOLATION(RR), when data evaluated as the result of a query must not be changed before your application commits or rolls back. New rows cannot be inserted into the answer set.

For more information about the ISOLATION option, see “The ISOLATION option” on page 851.

For updatable static scrollable cursors, ISOLATION(CS) provides the additional advantage of letting DB2 use *optimistic concurrency control* to further reduce the amount of time that locks are held. With optimistic concurrency control, DB2 releases the row or page locks on the base table after it materializes the result table in a temporary global table. DB2 also releases the row lock after each FETCH, taking a new lock on a row only for a positioned update or delete to ensure data integrity. For more information about optimistic concurrency control, see “Advantages and disadvantages of the isolation values” on page 852.

For updatable dynamic scrollable cursors and ISOLATION(CS), DB2 holds row or page locks on the base table (DB2 does not use a temporary global table). The most recently fetched row or page from the base table remains locked to maintain data integrity for a positioned update or delete.

**Use ISOLATION(UR) cautiously:** UR isolation acquires almost no locks on rows or pages. It is fast and causes little contention, but it reads uncommitted data. Do not use it unless you are sure that your applications and end users can accept the logical inconsistencies that can occur.

**Use sequence objects to generate unique, sequential numbers:** Using an identity column is one way to generate unique sequential numbers. However, as a column of a table, an identity column is associated with and tied to the table, and a table can have only one identity column. Your applications might need to use one sequence of unique numbers for many tables or several sequences for each table. As a user-defined object, sequences provide a way for applications to have DB2 generate unique numeric key values and to coordinate the keys across multiple rows and tables.

The use of sequences can avoid the lock contention problems that can result when applications implement their own sequences, such as in a one-row table that contains a sequence number that each transaction must increment. With DB2 sequences, many users can access and increment the sequence concurrently without waiting. DB2 does not wait for a transaction that has incremented a sequence to commit before allowing another transaction to increment the sequence again.

**Examine multi-row operations:** In an application, multi-row inserts, positioned updates, and positioned deletes have the potential of expanding the unit of work. This can affect the concurrency of other users accessing the data. Minimize

contention by adjusting the size of the host-variable-array, committing between inserts, updates, and preventing lock escalation.

**Use global transactions:** The Resource Recovery Services attachment facility (RRSAF) relies on an z/OS component called Resource Recovery Services (RRS). RRS provides system-wide services for coordinating two-phase commit operations across z/OS products. For RRSAF applications and IMS transactions that run under RRS, you can group together a number of DB2 agents into a single global transaction. A global transaction allows multiple DB2 agents to participate in a single global transaction and thus share the same locks and access the same data. When two agents that are in a global transaction access the same DB2 object within a unit of work, those agents will not deadlock with each other. The following restrictions apply:

- There is no Parallel Sysplex support for global transactions.
- Because each of the "branches" of a global transaction are sharing locks, uncommitted updates issued by one branch of the transaction are visible to other branches of the transaction.
- Claim/drain processing is not supported across the branches of a global transaction, which means that attempts to issue CREATE, DROP, ALTER, GRANT, or REVOKE may deadlock or timeout if they are requested from different branches of the same global transaction.
- LOCK TABLE may deadlock or timeout across the branches of a global transaction.

For information on how to make an agent part of a global transaction for RRSAF applications, see Section 7 of *DB2 Application Programming and SQL Guide*.

---

## Aspects of transaction locks

Transaction locks have the following four basic aspects:

- "The size of a lock"
- "The duration of a lock" on page 824
- "The mode of a lock" on page 825
- "The object of a lock" on page 827

Knowing the aspects helps you understand why a process suspends or times out or why two processes deadlock. To change the situation, you also need to know:

- "DB2 choices of lock types" on page 830

### The size of a lock

#### Definition

The *size* (sometimes *scope* or *level*) of a lock on data in a table describes the amount of data controlled. The possible sizes of locks are table space, table, partition, page, and row. This section contains information about locking for non-LOB data. See "LOB locks" on page 864 for information on locking for LOBs.

#### Hierarchy of lock sizes

The same piece of data can be controlled by locks of different sizes. A table space lock (the largest size) controls the most data, all the data in an entire table space. A page or row lock controls only the data in a single page or row.

As Figure 84 suggests, row locks and page locks occupy an equal place in the hierarchy of lock sizes.

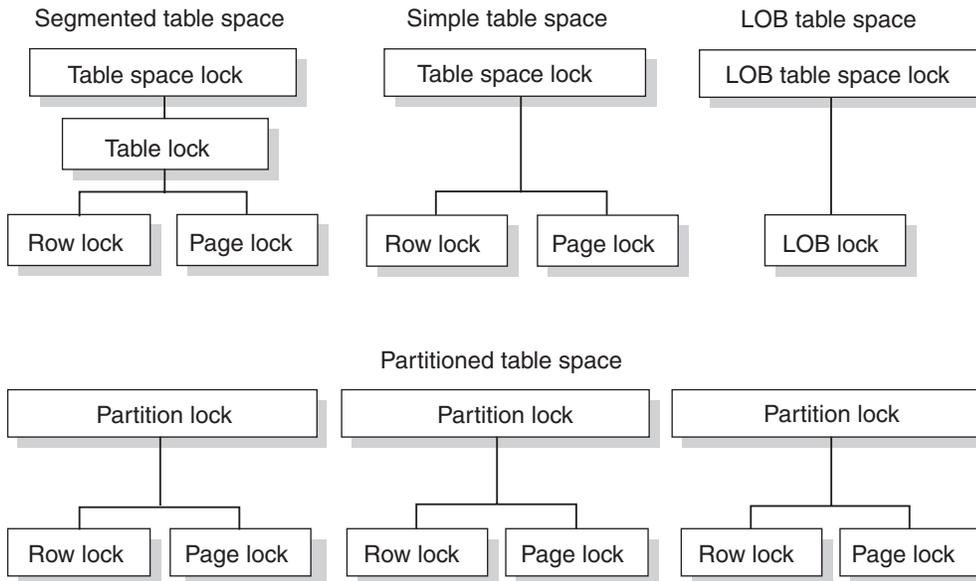

Figure 84. Sizes of objects locked

### General effects of size

Locking larger or smaller amounts of data allows you to trade performance for concurrency. Using page or row locks instead of table or table space locks has the following effects:

- Concurrency usually improves, meaning better response times and higher throughput rates for many users.
- Processing time and use of storage increases. That is especially evident in batch processes that scan or update a large number of rows.

Using only table or table space locks has the following effects:

- Processing time and storage usage is reduced.
- Concurrency can be reduced, meaning longer response times for some users but better throughput for one user.

### Effects of table spaces of different types

- In a **partitioned table space**, locks are obtained at the partition level. Individual partitions are locked as they are accessed. This locking behavior enables greater concurrency because gross locks (S, U, or X) can be obtained on individual partitions instead of on the entire partitioned table space. (Partition locks are always acquired, even if the table space was defined in a version of DB2 prior to Version 8 with the LOCKPART NO clause. For LOCKPART NO table spaces, DB2 no longer locks the entire table space with one lock when any partition of the table space is accessed.)

**Restrictions:** If any of the following conditions are true, DB2 must lock *all* partitions:

- The plan is bound with ACQUIRE(ALLOCATE).
- The table space is defined with LOCKSIZE TABLESPACE.
- The LOCK TABLE statement is used without the PART option.

- A **simple table space** can contain more than one table. A lock on the table space locks all the data in every table. A single page of the table space can contain

rows from every table. A lock on a page locks every row in the page, no matter what tables the data belongs to. Thus, a lock needed to access data from one table can make data from other tables temporarily unavailable. That effect can be partly undone by using row locks instead of page locks.

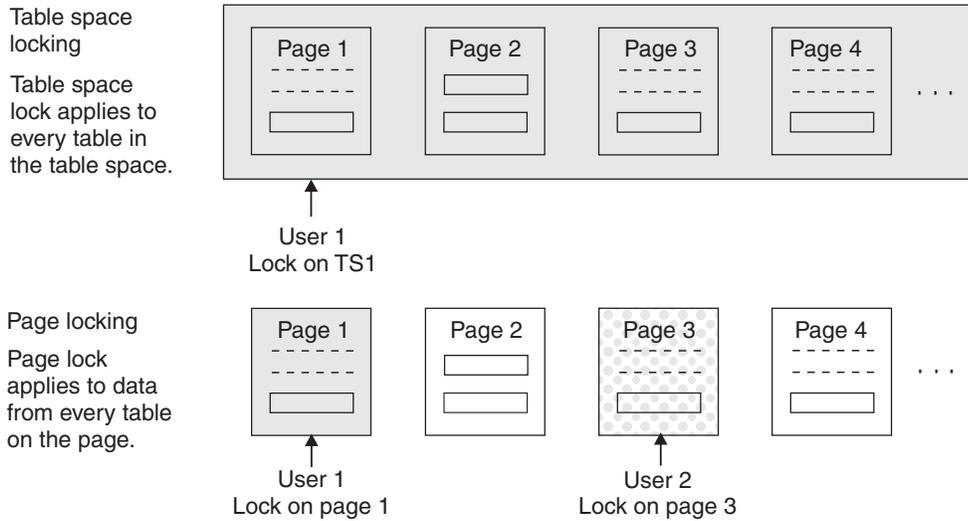

- In a **segmented table space**, rows from different tables are contained in different pages. Locking a page does not lock data from more than one table. Also, DB2 can acquire a table lock, which locks only the data from one specific table. Because a single row, of course, contains data from only one table, the effect of a row lock is the same as for a simple or partitioned table space: it locks one row of data from one table.
- In a **LOB table space**, pages are not locked. Because there is no concept of a row in a LOB table space, rows are not locked. Instead, LOBs are locked. See “LOB locks” on page 864 for more information.

### Differences between simple and segmented table spaces

Figure 85 on page 824 illustrates the difference between the effects of page locks on simple and segmented table spaces. Suppose that tables T1 and T2 reside in table space TS1. In a *simple* table space, a single page can contain rows from both T1 and T2. If User 1 and User 2 acquire incompatible locks on different pages, such as exclusive locks for updating data, neither can access all the rows in T1 and T2 until one of the locks is released. (User 1 and User 2 can both hold a page lock on the same page when the mode of the locks are compatible, such as locks for reading data.)

As the figure also shows, in a *segmented* table space, a table lock applies only to segments assigned to a single table. Thus, User 1 can lock all pages assigned to the segments of T1 while User 2 locks all pages assigned to segments of T2. Similarly, User 1 can lock a page of T1 without locking any data in T2.

**Simple table space:**

**Segmented table space:**

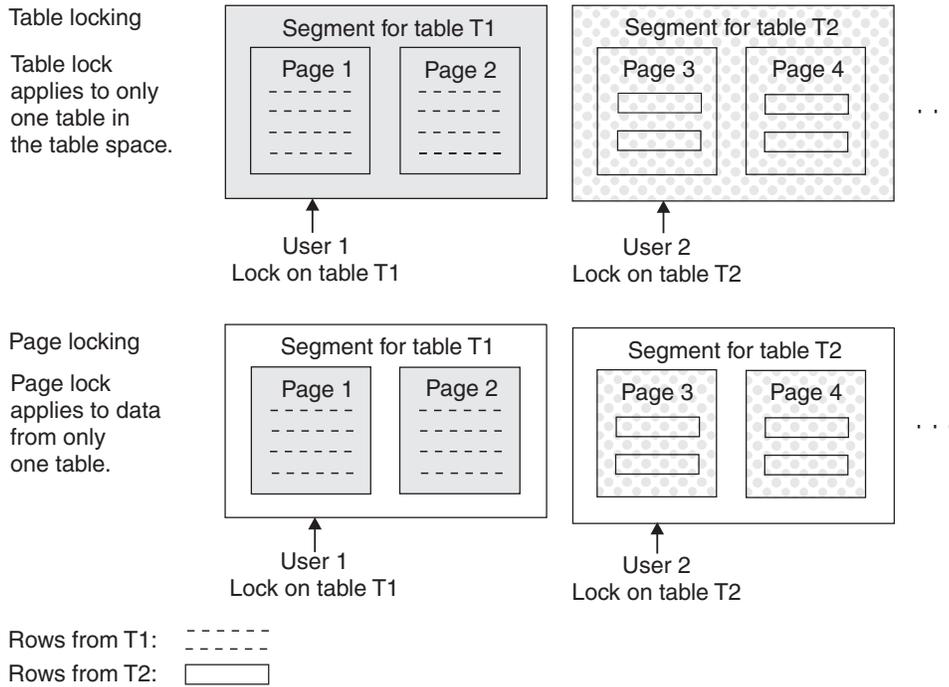

Figure 85. Page locking for simple and segmented table spaces

For information about controlling the size of locks, see:

- “LOCKSIZE clause of CREATE and ALTER TABLESPACE” on page 842
- “The LOCK TABLE statement” on page 863

**The duration of a lock**

*Definition:* The *duration* of a lock is the length of time the lock is held. It varies according to when the lock is acquired and when it is released.

**Effects**

For maximum concurrency, locks on a small amount of data held for a short duration are better than locks on a large amount of data held for a long duration.

However, acquiring a lock requires processor time, and holding a lock requires storage; thus, acquiring and holding one table space lock is more economical than acquiring and holding many page locks. Consider that trade-off to meet your performance and concurrency objectives.

**Duration of partition, table, and table space locks:** Partition, table, and table space locks can be acquired when a plan is first allocated, or you can delay acquiring them until the resource they lock is first used. They can be released at the next commit point or be held until the program terminates.

On the other hand, LOB table space locks are always acquired when needed and released at a commit or held until the program terminates. See “LOB locks” on page 864 for information about locking LOBs and LOB table spaces.

**Duration of page and row locks:** If a page or row is locked, DB2 acquires the lock only when it is needed. When the lock is released depends on many factors, but it is rarely held beyond the next commit point.

For information about controlling the duration of locks, see “Bind options” on page 847 for information about the ACQUIRE and RELEASE, ISOLATION, and CURRENTDATA bind options.

## The mode of a lock

**Definition:** The *mode* (sometimes *state*) of a lock tells what access to the locked object is permitted to the lock owner and to any concurrent processes.

The possible modes for page and row locks and the modes for partition, table, and table space locks are listed in “Modes of page and row locks” and “Modes of table, partition, and table space locks” on page 826. See “LOB locks” on page 864 for more information about modes for LOB locks and locks on LOB table spaces.

When a page or row is locked, the table, partition, or table space containing it is also locked. In that case, the table, partition, or table space lock has one of the *intent* modes: IS, IX, or SIX. The modes S, U, and X of table, partition, and table space locks are sometimes called *gross* modes. In the context of reading, SIX is a gross mode lock because you don’t get page or row locks; in this sense, it is like an S lock.

**Example:** An SQL statement locates John Smith in a table of customer data and changes his address. The statement locks the entire table space in mode IX and the specific row that it changes in mode X.

### Modes of page and row locks

Modes and their effects are listed in the order of increasing control over resources.

- S (SHARE)** The lock owner and any concurrent processes can read, but not change, the locked page or row. Concurrent processes can acquire S or U locks on the page or row or might read data without acquiring a page or row lock.
- U (UPDATE)** The lock owner can read, but not change, the locked page or row. Concurrent processes can acquire S locks or might read data without acquiring a page or row lock, but no concurrent process can acquire a U lock.

U locks reduce the chance of deadlocks when the lock owner is reading a page or row to determine whether to change it, because the owner can start with the U lock and then promote the lock to an X lock to change the page or row.

**X (EXCLUSIVE)**

The lock owner can read or change the locked page or row. A concurrent process cannot acquire S, U, or X locks on the page or row. However, a concurrent process, such as those bound with the CURRENTDATA(NO) or ISO(UR) options or running with YES specified for the EVALUNC subsystem parameter, can read the data without acquiring a page or row lock.

**Modes of table, partition, and table space locks**

Modes and their effects are listed in the order of increasing control over resources.

**IS (INTENT SHARE)**

The lock owner can read data in the table, partition, or table space, but not change it. Concurrent processes can both read and change the data. The lock owner might acquire a page or row lock on any data it reads.

**IX (INTENT EXCLUSIVE)**

The lock owner and concurrent processes can read and change data in the table, partition, or table space. The lock owner might acquire a page or row lock on any data it reads; it must acquire one on any data it changes.

**S (SHARE)**

The lock owner and any concurrent processes can read, but not change, data in the table, partition, or table space. The lock owner does not need page or row locks on data it reads.

**U (UPDATE)**

The lock owner can read, but not change, the locked data; however, the owner can promote the lock to an X lock and then can change the data. Processes concurrent with the U lock can acquire S locks and read the data, but no concurrent process can acquire a U lock. The lock owner does not need page or row locks.

U locks reduce the chance of deadlocks when the lock owner is reading data to determine whether to change it. U locks are acquired on a table space when locksize is TABLESPACE and the statement is a SELECT with a FOR UPDATE clause. Similarly, U locks are acquired on a table when lock size is TABLE and the statement is a SELECT with a FOR UPDATE clause.

**SIX (SHARE with INTENT EXCLUSIVE)**

The lock owner can read and change data in the table, partition, or table space. Concurrent processes can read data in the table, partition, or table space, but not change it. Only when the lock owner changes data does it acquire page or row locks.

**X (EXCLUSIVE)**

The lock owner can read or change data in the table, partition, or table space. A concurrent

process can access the data if the process runs with UR isolation or if data in a partitioned table space is running with CS isolation and CURRENTDATA((NO). The lock owner does not need page or row locks.

## Lock mode compatibility

The major effect of the lock mode is to determine whether one lock is compatible with another.

**Definition:** Locks of some modes do not shut out all other users. Assume that application process A holds a lock on a table space that process B also wants to access. DB2 requests, on behalf of B, a lock of some particular mode. If the mode of A's lock permits B's request, the two locks (or modes) are said to be *compatible*.

**Effects of incompatibility:** If the two locks are not compatible, B cannot proceed. It must wait until A releases its lock. (And, in fact, it must wait until all existing incompatible locks are released.)

**Compatible lock modes:** Compatibility for page and row locks is easy to define. Table 135 shows whether page locks of any two modes, or row locks of any two modes, are compatible (Yes) or not (No). No question of compatibility of a page lock with a row lock can arise, because a table space cannot use both page and row locks.

Table 135. Compatibility of page lock and row lock modes

Lock Mode	S	U	X
S	Yes	Yes	No
U	Yes	No	No
X	No	No	No

Compatibility for table space locks is slightly more complex. Table 136 shows whether or not table space locks of any two modes are compatible.

Table 136. Compatibility of table and table space (or partition) lock modes

Lock Mode	IS	IX	S	U	SIX	X
IS	Yes	Yes	Yes	Yes	Yes	No
IX	Yes	Yes	No	No	No	No
S	Yes	No	Yes	Yes	No	No
U	Yes	No	Yes	No	No	No
SIX	Yes	No	No	No	No	No
X	No	No	No	No	No	No

## The object of a lock

### Definition and examples

The *object* of a lock is the resource being locked.

You might have to consider locks on any of the following objects:

- **User data in target tables.** A *target table* is a table that is accessed specifically in an SQL statement, either by name or through a view. Locks on those tables are the most common concern, and the ones over which you have most control.

- **User data in related tables.** Operations subject to referential constraints can require locks on related tables. For example, if you delete from a parent table, DB2 might delete rows from the dependent table as well. In that case, DB2 locks data in the dependent table as well as in the parent table.

Similarly, operations on rows that contain LOB values might require locks on the LOB table space and possibly on LOB values within that table space. See “LOB locks” on page 864 for more information.

If your application uses triggers, any triggered SQL statements can cause additional locks to be acquired.

- **DB2 internal objects.** Most of these you are never aware of, but you might notice the following locks on internal objects:
  - Portions of the **DB2 catalog**. For more information, see “Locks on the DB2 catalog.”
  - The **skeleton cursor table** (SKCT) representing an application plan.
  - The **skeleton package table** (SKPT) representing a package. For more information on skeleton tables, see “Locks on the skeleton tables (SKCT and SKPT)” on page 829.
  - The **database descriptor** (DBD) representing a DB2 database. For more information, see “Locks on the database descriptors (DBDs)” on page 829.

## Indexes and data-only locking

No index page locks are acquired during processing. Instead, DB2 uses a technique called *data-only locking* to serialize changes. Index page latches are acquired to serialize changes within a page and guarantee that the page is physically consistent. Acquiring page latches ensures that transactions accessing the same index page concurrently do not see the page in a partially changed state.

The underlying data page or row locks are acquired to serialize the reading and updating of index entries to ensure the data is logically consistent, meaning that the data is committed and not subject to rollback or abort. The data locks can be held for a long duration such as until commit. However, the page latches are only held for a short duration while the transaction is accessing the page. Because the index pages are not locked, hot spot insert scenarios (which involve several transactions trying to insert different entries into the same index page at the same time) do not cause contention problems in the index.

A query that uses index-only access might lock the data page or row, and that lock can contend with other processes that lock the data. However, using lock avoidance techniques can reduce the contention. See “Lock avoidance” on page 859 for more information about lock avoidance.

## Locks on the DB2 catalog

SQL data definition statements, GRANT statements, and REVOKE statements require locks on the DB2 catalog. If different application processes are issuing these types of statements, catalog contention can occur. You can take action to avoid contention.

**Contention within table space SYSDBASE:** SQL statements that update the catalog table space SYSDBASE contend with each other when those statements are on the same table space. Those statements are:

- CREATE TABLESPACE, TABLE, and INDEX
- ALTER TABLESPACE, TABLE, INDEX
- DROP TABLESPACE, TABLE, and INDEX

- CREATE VIEW, SYNONYM, and ALIAS
- DROP VIEW and SYNONYM, and ALIAS
- COMMENT ON and LABEL ON
- GRANT and REVOKE of table privileges
- RENAME TABLE
- ALTER VIEW

**Recommendation:** Reduce the concurrent use of statements that update SYSDBASE for the same table space. When you alter a table or table space, quiesce other work on that object.

**Contention independent of databases:** The following limitations on concurrency are independent of the referenced database:

- CREATE and DROP statements for a table space or index that uses a storage group contend significantly with other such statements.
- CREATE, ALTER, and DROP DATABASE, and GRANT and REVOKE database privileges all contend with each other and with any other function that requires a database privilege.
- CREATE, ALTER, and DROP STOGROUP contend with any SQL statements that refer to a storage group and with extensions to table spaces and indexes that use a storage group.
- GRANT and REVOKE for plan, package, system, or use privileges contend with other GRANT and REVOKE statements for the same type of privilege and with data definition statements that require the same type of privilege.

### Locks on the skeleton tables (SKCT and SKPT)

The SKCT of a plan, or the SKPT of a package, is locked while the plan or package is running. The following operations require incompatible locks on the SKCT or SKPT, whichever is applicable, and cannot run concurrently:

- Binding, rebinding, or freeing the plan or package
- Dropping a resource or revoking a privilege that the plan or package depends on
- In some cases, altering a resource that the plan or package depends on

### Locks on the database descriptors (DBDs)

Whether a process locks a target DBD depends largely on whether the DBD is already in the EDM DBD cache.

**If the DBD is not in the EDM DBD cache,** most processes acquire locks on the database descriptor table space (DBD01). That has the effect of locking the DBD and can cause conflict with other processes.

**If the DBD is in the EDM DBD cache,** the lock on the DBD depends on the type of process, as shown in Table 137.

Table 137. Contention for locks on a DBD in the EDM DBD cache

Process Type	Process	Lock acquired	Conflicts with process type
1	Static DML statements (SELECT, DELETE, INSERT, UPDATE) <sup>1</sup>	None	None
2	Dynamic DML statements <sup>2</sup>	S	3
3	Data definition statements (ALTER, CREATE, DROP)	X	2,3,4

Table 137. Contention for locks on a DBD in the EDM DBD cache (continued)

Process Type	Process	Lock acquired	Conflicts with process type
4	Utilities	S	3

**Notes:**

1. Static DML statements can conflict with other processes because of locks on data.
2. If caching of dynamic SQL is turned on, no lock is taken on the DBD when a statement is prepared for insertion in the cache or for a statement in the cache.

## DB2 choices of lock types

**Overview:** For the locks acquired on target tables by different types of SQL data manipulation statements, see:

- “Modes of locks acquired for SQL statements”

The lock acquired because of an SQL statement is not always a constant throughout the time of execution. For two situations in which DB2 can change acquired locks during execution, see:

- “Lock promotion” on page 833
- “Lock escalation” on page 834

For a summary of the locks acquired by other operations, see:

- “Modes of transaction locks for various processes” on page 835

### Modes of locks acquired for SQL statements

Table 138 on page 831 shows the modes of locks that a process acquires. The mode depends on:

- The type of processing being done
- The value of LOCKSIZE for the target table
- The isolation level of the plan, package, or statement
- The method of access to data

For details about:

- LOCKSIZE, see “LOCKSIZE clause of CREATE and ALTER TABLESPACE” on page 842
- ISOLATION, see “The ISOLATION option” on page 851
- Access methods, see Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931

**Reading the table:** The following SQL statements and sample steps provide a way to understand the table that shows the modes of locks.

```
EXEC SQL DELETE FROM DSN8810.EMP WHERE CURRENT OF C1;
```

Use the following sample steps to understand the table:

1. Find the portion of the table that describes DELETE operations using a cursor.
2. Find the row for the appropriate values of LOCKSIZE and ISOLATION. Table space DSN8810 is defined with LOCKSIZE ANY. If the value of ISOLATION was not specifically chosen, it is RR by default.
3. Find the subrow for the expected access method. The operation probably uses the index on employee number. Because the operation deletes a row, it must update the index. Hence, you can read the locks acquired in the subrow for “Index, updated”:

- An IX lock on the table space
  - An IX lock on the table (but see the step that follows)
  - An X lock on the page containing the row that is deleted
4. Check the notes to the entries you use, at the end of the table. For this sample operation, see:
- Note 2, on the column heading for “Table”. If the table is not segmented, there is no separate lock on the table.
  - Note 3, on the column heading for “Data Page or Row”. Because LOCKSIZE for the table space is ANY, DB2 can choose whether to use page locks, table locks, or table space locks. Typically it chooses page locks.

Table 138. Modes of locks acquired for SQL statements

LOCKSIZE	ISOLATION	Access method <sup>1</sup>	Lock mode		
			Table space <sup>9</sup>	Table <sup>2</sup>	Data page or row <sup>3</sup>
<b>Processing statement: SELECT with read-only or ambiguous cursor, or with no cursor. UR isolation is allowed and requires none of these locks.</b>					
TABLESPACE	CS RS RR	Any	S	n/a	n/a
TABLE <sup>2</sup>	CS RS RR	Any	IS	S	n/a
PAGE, ROW, or ANY	CS	Index, any use	IS <sup>4,10</sup>	IS <sup>4</sup>	S <sup>5</sup>
		Table space scan	IS <sup>4,10</sup>	IS <sup>4</sup>	S <sup>5</sup>
PAGE, ROW, or ANY	RS	Index, any use	IS <sup>4,10</sup>	IS <sup>4</sup>	S <sup>5</sup> , U <sup>11</sup> , or X <sup>11</sup>
		Table space scan	IS <sup>4,10</sup>	IS <sup>4</sup>	S <sup>5</sup> , U <sup>11</sup> , or X <sup>11</sup>
PAGE, ROW, or ANY	RR	Index/data probe	IS <sup>4</sup>	IS <sup>4</sup>	S <sup>5</sup> , U <sup>11</sup> , or X <sup>11</sup>
		Index scan <sup>6</sup>	IS <sup>4</sup> or S	S, IS <sup>4</sup> , or n/a	S <sup>5</sup> , U <sup>11</sup> , X <sup>11</sup> , or n/a
		Table space scan <sup>6</sup>	IS <sup>2</sup> or S	S or n/a	n/a
<b>Processing statement: INSERT ... VALUES(...) or INSERT ... fullselect<sup>7</sup></b>					
TABLESPACE	CS RS RR	Any	X	n/a	n/a
TABLE <sup>2</sup>	CS RS RR	Any	IX	X	n/a
## PAGE, ROW, or ANY <sup>12</sup>	CS RS RR	Any	IX	IX	X
<b>Processing statement: UPDATE or DELETE, without cursor. Data page and row locks apply only to selected data.</b>					
TABLESPACE	CS RS RR	Any	X	n/a	n/a
TABLE <sup>2</sup>	CS RS RR	Any	IX	X	n/a
PAGE, ROW, or ANY	CS	Index selection	IX	IX	• For delete: X • For update: U→X
		Index/data selection	IX	IX	U→X
		Table space scan	IX	IX	U→X
PAGE, ROW, or ANY	RS	Index selection	IX	IX	• For update: S or U <sup>8</sup> →X • For delete: [S→X] or X
		Index/data selection	IX	IX	S or U <sup>8</sup> →X
		Table space scan	IX	IX	S or U <sup>8</sup> →X

2. Used for segmented table spaces only.
3. These locks are taken on pages if LOCKSIZE is PAGE or on rows if LOCKSIZE is ROW. When the maximum number of locks per table space (LOCKMAX) is reached, locks escalate to a table lock for tables in a segmented table space, or to a table space lock for tables in a non-segmented table space. Using LOCKMAX 0 in CREATE or ALTER TABLESPACE disables lock escalation.
4. If the table or table space is started for read-only access, DB2 attempts to acquire an S lock. If an incompatible lock already exists, DB2 acquires the IS lock.
5. SELECT statements that do not use a cursor, or that use read-only or ambiguous cursors and are bound with CURRENTDATA(NO), might not require any lock if DB2 can determine that the data to be read is committed. This is known as *lock avoidance*.
6. Even if LOCKMAX is 0, the bind process can promote the lock size to TABLE or TABLESPACE. If that occurs, SQLCODE +806 is issued.
7. The locks listed are acquired on the object into which the insert is made. A subselect acquires additional locks on the objects it reads, as if for SELECT with read-only cursor or ambiguous cursor, or with no cursor.
8. An installation option determines whether the lock is S, U, or X. For a full description, see “The option U LOCK FOR RR/RS” on page 845. If you use the WITH clause to specify the isolation as RR or RS, you can use the USE AND KEEP UPDATE LOCKS option to obtain and hold a U lock instead of an S lock, or you can use the USE AND KEEP EXCLUSIVE LOCKS option to obtain and hold an X lock instead of an S lock.
9. Includes partition locks. Does not include LOB table space locks. See “LOB locks” on page 864 for information about locking LOB table spaces.
10. If the table space is partitioned, locks can be avoided on the partitions.
11. If you use the WITH clause to specify the isolation as RR or RS, you can use the USE AND KEEP UPDATE LOCKS option to obtain and hold a U lock instead of an S lock, or you can use the USE AND KEEP EXCLUSIVE LOCKS option to obtain and hold an X lock instead of an S lock.
12. When a unique index exists on the table that receives the INSERT and the value of a pseudo deleted key is the same as the value of the key to be inserted, an S lock is requested on the data that is referenced by the pseudo deleted key entry to determine whether the deletion is committed.
13. The type of lock that is acquired for isolation levels RS and RR depends on the setting of the RRULOCK subsystem parameter. If RRULOCK=YES, an S lock is acquired for isolation levels RR and RS. Otherwise, a U lock is acquired.

## Lock promotion

**Definition:** *Lock promotion* is the action of exchanging one lock on a resource for a more restrictive lock on the same resource, held by the same application process.

**Example:** An application reads data, which requires an IS lock on a table space. Based on further calculation, the application updates the same data, which requires an IX lock on the table space. The application is said to *promote* the table space lock from mode IS to mode IX.

**Effects:** When promoting the lock, DB2 first waits until any incompatible locks held by other processes are released. When locks are promoted, they are promoted in

the direction of increasing control over resources: from IS to IX, S, or X; from IX to SIX or X; from S to X; from U to X; and from SIX to X.

## Lock escalation

**Definition:** *Lock escalation* is the act of releasing a large number of page, row or LOB locks, held by an application process on a single table or table space, to acquire a table or table space lock, or a set of partition locks, of mode S or X instead. When it occurs, DB2 issues message DSNI031I, which identifies the table space for which lock escalation occurred, and some information to help you identify what plan or package was running when the escalation occurred.

Lock counts are always kept on a table or table space level. For an application process that is accessing LOBs, the LOB lock count on the LOB table space is maintained separately from the base table space, and lock escalation occurs separately from the base table space.

When escalation occurs for a partitioned table space, only partitions that are currently locked are escalated. Unlocked partitions remain unlocked. After lock escalation occurs, any unlocked partitions that are subsequently accessed are locked with a gross lock.

For an application process that is using Sysplex query parallelism, the lock count is maintained on a member basis, not globally across the group for the process. Thus, escalation on a table space or table by one member does not cause escalation on other members.

**Example:** Assume that a segmented table space is defined with LOCKSIZE ANY and LOCKMAX 2000. DB2 can use page locks for a process that accesses a table in the table space and can escalate those locks. If the process attempts to lock more than 2000 pages in the table at one time, DB2 promotes its intent locks on the table to mode S or X and then releases its page locks.

If the process is using Sysplex query parallelism and a table space that it accesses has a LOCKMAX value of 2000, lock escalation occurs for a member only if more than 2000 locks are acquired for that member.

**When it occurs:** Lock escalation balances concurrency with performance by using page or row locks while a process accesses relatively few pages or rows, and then changing to table space, table, or partition locks when the process accesses many. When it occurs, lock escalation varies by table space, depending on the values of LOCKSIZE and LOCKMAX, as described in

- “LOCKSIZE clause of CREATE and ALTER TABLESPACE” on page 842
- “LOCKMAX clause of CREATE and ALTER TABLESPACE” on page 844

Lock escalation is suspended during the execution of SQL statements for ALTER, CREATE, DROP, GRANT, and REVOKE.

See “Controlling LOB lock escalation” on page 868 for information about lock escalation for LOBs.

**Recommendations:** The DB2 statistics and performance traces can tell you how often lock escalation has occurred and whether it has caused timeouts or deadlocks. As a rough estimate, if one quarter of your lock escalations cause timeouts or deadlocks, then escalation is not effective for you. You might alter the table to increase LOCKMAX and thus decrease the number of escalations.

Alternatively, if lock escalation is a problem, use LOCKMAX 0 to disable lock escalation.

**Example:** Assume that a table space is used by transactions that require high concurrency and that a batch job updates almost every page in the table space. For high concurrency, you should probably create the table space with LOCKSIZE PAGE and make the batch job commit every few seconds.

LOCKSIZE ANY is a possible choice, if you take other steps to avoid lock escalation. If you use LOCKSIZE ANY, specify a LOCKMAX value large enough so that locks held by transactions are not normally escalated. Also, LOCKS PER USER must be large enough so that transactions do not reach that limit.

If the batch job is:

- *Concurrent* with transactions, then it must use page or row locks and commit frequently: for example, every 100 updates. Review LOCKS PER USER to avoid exceeding the limit. The page or row locking uses significant processing time. Binding with ISOLATION(CS) may discourage lock escalation to an X table space lock for those applications that read a lot and update occasionally. However, this may not prevent lock escalation for those applications that are update intensive.
- *Non-concurrent* with transactions, then it need not use page or row locks. The application could explicitly lock the table in exclusive mode, described under “The LOCK TABLE statement” on page 863.

### Modes of transaction locks for various processes

The rows in Table 139 show a sample of several types of DB2 processes. The columns show the most restrictive mode of locks used for different objects and the possible conflicts between application processes.

Table 139. Modes of DB2 transaction locks

Process	Catalog table spaces	Skeleton tables (SKCT and SKPT)	Database descriptor (DBD) (1)	Target table space (2)
Transaction with static SQL	IS (3)	S	n/a (4)	Any (5)
Query with dynamic SQL	IS (6)	S	S	Any (5)
BIND process	IX	X	S	n/a
SQL CREATE TABLE statement	IX	n/a	X	n/a
SQL ALTER TABLE statement	IX	X (7)	X	n/a
SQL ALTER TABLESPACE statement	IX	X (9)	X	n/a
SQL DROP TABLESPACE statement	IX	X (8)	X	n/a
SQL GRANT statement	IX	n/a	n/a	n/a
SQL REVOKE statement	IX	X (8)	n/a	n/a

#### Notes for Table 139:

1. In a lock trace, these locks usually appear as locks on the DBD.
2. The target table space is one of the following table spaces:
  - Accessed and locked by an application process
  - Processed by a utility
  - Designated in the data definition statement
3. The lock is held briefly to check EXECUTE authority.

4. If the required DBD is not already in the EDM DBD cache, locks are acquired on table space DBD01, which effectively locks the DBD.
5. For details, see Table 138 on page 831.
6. Except while checking EXECUTE authority, IS locks on catalog tables are held until a commit point.
7. The plan or package using the SKCT or SKPT is marked invalid if a referential constraint (such as a new primary key or foreign key) is added or changed, or the AUDIT attribute is added or changed for a table.
8. The plan or package using the SKCT or SKPT is marked invalid as a result of this operation.
9. These locks are not held when ALTER TABLESPACE is changing the following options: PRIQTY, SECQTY, PCTFREE, FREEPAGE, CLOSE, and ERASE.

---

## Options for tuning locks

The following sections describes the options that affect transaction locks:

- “IRLM startup procedure options”
- “Installation options for wait times” on page 837
- “Other options that affect locking” on page 841
- “Bind options” on page 847
- “Isolation overriding with SQL statements” on page 862
- “The LOCK TABLE statement” on page 863

### IRLM startup procedure options

When you issue the z/OS command `START irImproc`, the values of the options are passed to the startup procedure for the DB2 internal resource lock manager (IRLM). (If an option is not explicitly specified on the command, the value of its corresponding installation parameter is used.)

The options relevant to DB2 locking are:

<b>SCOPE</b>	Whether IRLM is used for data sharing (GLOBAL) or not (LOCAL). Use LOCAL unless you are using data sharing. If you use data sharing, specify GLOBAL.
<b>DEADLOK</b>	The two values of this option specify: <ol style="list-style-type: none"> <li>1. The number of seconds between two successive scans for a local deadlock</li> <li>2. The number of local scans that occur before a scan for global deadlock starts</li> </ol>
<b>PC</b>	Ignored by IRLM. However, PC is positional and must be maintained in the IRLM for compatibility.
<b>MAXCSA</b>	Ignored by IRLM. However, MAXCSA is positional and must be maintained in the IRLM for compatibility.

The maximum amount of storage available for IRLM locks is limited to 90% of the total space given to the IRLM private address space during the startup procedure. The other 10% is reserved for IRLM system services, z/OS system services, and “must complete” processes to prevent the IRLM address space from abending, which would bring down your DB2 system. When the storage limit is reached, lock requests are rejected with an out-of-storage reason code.

You can use the `F irlmproc,STATUS,STOR` command to monitor the amount of storage that is available for locks and the `MODIFY irlmproc,SET` command to dynamically change the maximum amount of IRLM private storage to use for locks.

### Estimating the storage needed for locks

For a conservative figure, assume:

- 540 bytes of storage for each lock.
- All concurrent threads hold the maximum number of row or page locks (LOCKS PER USER on installation panel DSNTIPJ). The number of table and table space locks is negligible.
- The maximum number of concurrent threads are active.

Then calculate:  $\text{Storage} = 540 \times (\text{LOCKS PER USER}) \times (\text{MAX USERS})$ .

That value is calculated when DB2 is installed.

## Installation options for wait times

These options determine how long it takes DB2 to identify that a process must be timed out or is deadlocked. They affect locking in your entire DB2 subsystem.

The following fields of the installation panels are relevant to transaction locks:

- “DEADLOCK TIME on installation panel DSNTIPJ”
- “RESOURCE TIMEOUT on installation panel DSNTIPI”
- “IDLE THREAD TIMEOUT on installation panel DSNTIPR” on page 840

The following field is relevant to drain locks:

- “UTILITY TIMEOUT on installation panel DSNTIPI” on page 840

### DEADLOCK TIME on installation panel DSNTIPJ

*Effect:* DB2 scans for deadlocked processes at regular intervals. This field sets the length of the interval, in seconds.

*Default:* 1 second.

**Recommendation:** Determining the best value for deadlock detection is dependent on your workload. Deadlock detection can cause latch suspensions; therefore, for systems in which deadlocking is not a problem, have deadlock detection run less frequently for the best performance and concurrency (but don't choose a number greater than 5). However, if your system is prone to deadlocks, you want those detected as quickly as possible. In that case, choose 1.

### RESOURCE TIMEOUT on installation panel DSNTIPI

*Effect:* Specifies a minimum number of seconds before a timeout can occur. A small value can cause a large number of timeouts. With a larger value, suspended processes more often resume normally, but they remain inactive for longer periods.

*Default:* 60 seconds.

**Recommendation:** If you can allow a suspended process to remain inactive for 60 seconds, use the defaults for both RESOURCE TIMEOUT and DEADLOCK TIME. To specify a different inactive period, you must consider how DB2 times out a process that is waiting for a transaction lock, as described in “Wait time for transaction locks” on page 838.

## Wait time for transaction locks

In a scanning schedule to determine whether a process waiting for a transaction lock has timed out, DB2 uses the following two factors:

- A timeout period
- An operation multiplier

**The timeout period:** From the value of RESOURCE TIMEOUT and DEADLOCK TIME, DB2 calculates a timeout period. Assume that DEADLOCK TIME is 5 and RESOURCE TIMEOUT is 18.

1. Divide RESOURCE TIMEOUT by DEADLOCK TIME ( $18/5 = 3.6$ ). IRLM limits the result of this division to 255.
2. Round the result to the next largest integer (Round up 3.6 to 4).
3. Multiply the DEADLOCK TIME by that integer ( $4 * 5 = 20$ ).

The result, the timeout period (20 seconds), is always at least as large as the value of RESOURCE TIMEOUT (18 seconds), except when the RESOURCE TIMEOUT divided by DEADLOCK TIME exceeds 255.

**The timeout multiplier:** Requests from different types of processes wait for different multiples of the timeout period. In a data sharing environment, you can add another multiplier to those processes to wait for retained locks.

In some cases, you can modify the multiplier value. Table 140 indicates the multiplier by type of process, and whether you can change it.

Table 140. Timeout multiplier by type

Type	Multiplier	Modifiable?
IMS MPP, IMS Fast Path Message Processing, CICS, QMF, CAF, TSO batch and online, RRSAP, global transactions	1	No
IMS BMPs	4	Yes
IMS DL/I batch	6	Yes
IMS Fast Path Non-message processing	6	No
BIND subcommand processing	3	No
STOP DATABASE command processing	10	No
Utilities	6	Yes
Retained locks for all types	0	Yes

See “UTILITY TIMEOUT on installation panel DSNTIPI” on page 840 for information about modifying the utility timeout multiplier.

**Changing the multiplier for IMS BMP and DL/I batch:** You can modify the multipliers for IMS BMP and DL/I batch by modifying the following subsystem parameters on installation panel DSNTIPI:

**IMS BMP TIMEOUT** The timeout multiplier for IMS BMP connections. A value from 1 to 254 is acceptable. The default is 4.

**DL/I BATCH TIMEOUT** The timeout multiplier for IMS DL/I batch connections. A value from 1 to 254 is acceptable. The default is 6.

**Additional multiplier for retained locks:** For data sharing, you can specify an additional timeout multiplier to be applied to the connection's normal timeout multiplier. This multiplier is used when the connection is waiting for a retained lock, which is a lock held by a failed member of a data sharing group. A zero means don't wait for retained locks. See *DB2 Data Sharing: Planning and Administration* for more information about retained locks.

**The scanning schedule:** Figure 86 illustrates the following example of scanning to detect a timeout:

#

- DEADLOCK TIME is set to 5 seconds.
- RESOURCE TIMEOUT was chosen to be 18 seconds. Therefore, the timeout period is 20 seconds.
- A bind operation starts 4 seconds before the next scan. The operation multiplier for a bind operation is 3.

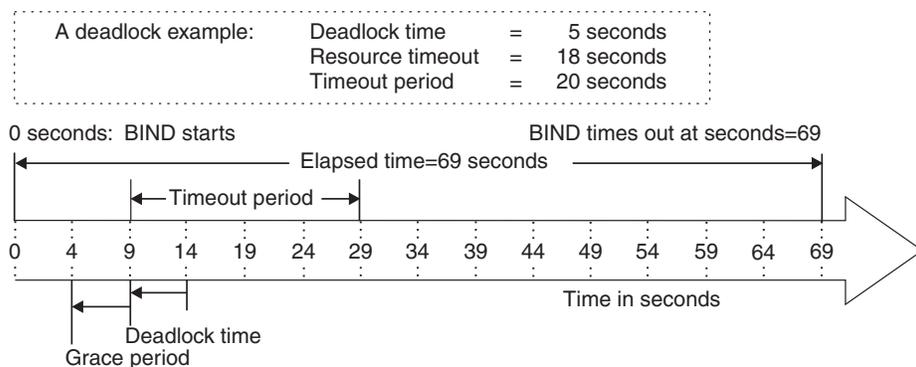

Figure 86. An example of scanning for timeout

The scans proceed through the following steps:

1. A scan starts 4 seconds after the bind operation requests a lock. As determined by the DEADLOCK TIME, scans occur every 5 seconds. The first scan in the example detects that the operation is inactive.
2. IRLM allows at least one full interval of DEADLOCK TIME as a “grace period” for an inactive process. After that, its lock request is judged to be waiting. At 9 seconds, the second scan detects that the bind operation is waiting.
3. The bind operation continues to wait for a multiple of the timeout period. In the example, the multiplier is 3 and the timeout period is 20 seconds. The bind operation continues to wait for 60 seconds longer.
4. The scan that starts 69 seconds after the bind operation detects that the process has timed out.

**Effects:** An operation can remain inactive for longer than the value of RESOURCE TIMEOUT.

If you are in a data sharing environment, the deadlock and timeout detection process is longer than that for non-data-sharing systems. See *DB2 Data Sharing: Planning and Administration* for more information about global detection processing and elongation of the timeout period.

**Recommendation:** Consider the length of inaction time when choosing your own values of DEADLOCK TIME and RESOURCE TIMEOUT.

## **IDLE THREAD TIMEOUT on installation panel DSNTIPR**

# *Effect:* Specifies a period for which an active distributed thread can hold locks  
# without doing any processing. After that period, a regular scan (at 2-minute  
# intervals) detects that the thread has been idle for the specified period, and DB2  
# cancels the thread.

The cancellation applies only to active threads. If your installation permits distributed threads to be inactive and hold no resources, those threads are allowed to remain idle indefinitely.

*Default:* 0. That value disables the scan to time out idle threads. The threads can then remain idle indefinitely.

# **Recommendation:** If you have experienced distributed users leaving an application  
# idle while it holds locks, pick an appropriate value other than 0 for this period.  
# Because the scan occurs only at 2-minute intervals, your idle threads will generally  
# remain idle for somewhat longer than the value you specify.

## **UTILITY TIMEOUT on installation panel DSNTIPI**

*Effect:* Specifies an operation multiplier for utilities waiting for a drain lock, for a transaction lock, or for claims to be released.

*Default:* 6.

**Recommendation:** With the default value, a utility generally waits longer for a resource than does an SQL application. To specify a different inactive period, you must consider how DB2 times out a process that is waiting for a drain, as described in “Wait time for drains.”

### **Wait time for drains**

A process that requests a drain might wait for two events:

1. Acquiring the drain lock. If another user holds the needed drain lock in an incompatible lock mode, then the drainer waits.
2. Releasing all claims on the object. Even after the drain lock is acquired, the drainer waits until all claims are released before beginning to process.

If the process drains more than one claim class, it must wait for those events to occur for *each claim class* it drains.

Hence, to calculate the maximum amount of wait time:

1. Start with the wait time for a drain lock.
2. Add the wait time for claim release.
3. Multiply the result by the number of claim classes drained.

*Wait times for drain lock and claim release:* Both wait times are based on the timeout period that is calculated in “RESOURCE TIMEOUT on installation panel DSNTIPI” on page 837. For the REORG utility with the SHRLEVEL REFERENCE or SHRLEVEL CHANGE option, you can use utility parameters to specify the wait time for a drain lock and to indicate if additional attempts should be made to acquire the drain lock. For more information, see *DB2 Utility Guide and Reference*.

**Drainer**  
Utility  
Other process

**Each wait time is:**  
(timeout period) \* (value of UTILITY TIMEOUT)  
timeout period

**Maximum wait time:** Because the maximum wait time for a drain lock is the same as the maximum wait time for releasing claims, you can calculate the total maximum wait time as follows:

For **utilities:**

$2 * (\text{timeout period}) * (\text{UTILITY TIMEOUT}) * (\text{number of claim classes})$

For **other processes:**

$2 * (\text{timeout period}) * (\text{operation multiplier}) * (\text{number of claim classes})$

**Example:** Suppose that LOAD must drain 3 claim classes, that the timeout period is 20 seconds, and that the value of UTILITY TIMEOUT is 6. Use the following calculation to determine how long the LOAD might utility be suspended before being timed out:

Maximum wait time =  $2 * 20 * 6 * 3 = 720$  seconds

**Wait times less than maximum:** The maximum drain wait time is the longest possible time a drainer can wait for a drain, **not** the length of time it always waits.

**Example:** Table 141 lists the steps LOAD takes to drain the table space and the maximum amount of wait time for each step. A timeout can occur at any step. At step 1, the utility can wait 120 seconds for the repeatable read drain lock. If that lock is not available by then, the utility times out after 120 seconds. It does not wait 720 seconds.

Table 141. Maximum drain wait times: LOAD utility

Step	Maximum Wait Time (seconds)
1. Get repeatable read drain lock	120
2. Wait for all RR claims to be released	120
3. Get cursor stability read drain lock	120
4. Wait for all CS claims to be released	120
5. Get write drain lock	120
6. Wait for all write claims to be released	120
<b>Total</b>	<b>720</b>

## Other options that affect locking

You can use various options to control such things as how many locks are used and which mode is used for certain locks. This section describes the following installation options and SQL statement clauses:

- “LOCKS PER USER field of installation panel DSNTIPJ” on page 842
- “LOCKSIZE clause of CREATE and ALTER TABLESPACE” on page 842
- “LOCKMAX clause of CREATE and ALTER TABLESPACE” on page 844
- “LOCKS PER TABLE(SPACE) field of installation panel DSNTIPJ” on page 844
- “The option U LOCK FOR RR/RS” on page 845
- “Option to release locks for cursors defined WITH HOLD” on page 845
- “Option XLOCK for searched updates/deletes” on page 845
- “Option to avoid locks during predicate evaluation” on page 846
- “Option to disregard uncommitted inserts” on page 846

See “Effects of table spaces of different types” on page 822 for information about the LOCKPART clause of CREATE and ALTER TABLESPACE.

## **LOCKS PER USER field of installation panel DSNTIPJ**

*Effect:* Specifies the maximum number of page, row, or LOB locks that can be held by a single process at any one time. It includes locks for both the DB2 catalog and directory and for user data.

When a request for a page, row, or LOB lock exceeds the specified limit, it receives SQLCODE -904: "resource unavailable" (SQLSTATE '57011'). The requested lock cannot be acquired until some of the existing locks are released.

*Default:* 10 000

**Recommendation:** The default should be adequate for 90 percent of the work load when using page locks. If you use row locks on very large tables, you might want a higher value. If you use LOBs, you might need a higher value.

Review application processes that require higher values to see if they can use table space locks rather than page, row, or LOB locks. The accounting trace shows the maximum number of page, row, or LOB locks a process held while running.

Remember that the value specified is for a single application. Each concurrent application can potentially hold up to the maximum number of locks specified. Do not specify zero or a very large number unless it is required to run your applications.

## **LOCKSIZE clause of CREATE and ALTER TABLESPACE**

The information under this heading, up to "LOCKMAX clause of CREATE and ALTER TABLESPACE" on page 844, is General-use Programming Interface and Associated Guidance Information, as defined in "Notices" on page 1437.

*Effect:* Specifies the size for locks held on a table or table space by any application process that accesses it. In addition to using the ALTER TABLESPACE statement to change the lock size for user data, you can also change the lock size of any DB2 catalog table space that is neither a LOB table space nor a table space that contains links. The options are:

### **LOCKSIZE TABLESPACE**

A process acquires no table, page, row, or LOB locks within the table space.

That improves performance by reducing the number of locks maintained, but greatly inhibits concurrency.

### **LOCKSIZE TABLE**

A process acquires table locks on tables in a segmented table space. If the table space contains more than one table, this option can provide acceptable concurrency with little extra cost in processor resources.

### **LOCKSIZE PAGE**

A process acquires page locks, plus table, partition, or table space locks of modes that permit page locks (IS, IX, or SIX). The effect is not absolute: a process can still acquire a table, partition, or table space lock of mode S or X, without page locks, if that is needed. In that case, the bind process issues a message warning that the lock size has been promoted as described under "Lock promotion" on page 833.

### **LOCKSIZE ROW**

A process acquires row locks, plus table, partition, or table space locks of modes that permit row locks (IS, IX, or SIX). The effect is not absolute: a process can still acquire a table or table space lock of mode S or X, without

row locks, if that is needed. In that case, the bind process issues a message warning that the lock size has been promoted as described under “Lock promotion” on page 833.

#### **LOCKSIZE ANY**

DB2 chooses the size of the lock, usually LOCKSIZE PAGE.

#### **LOCKSIZE LOB**

If a LOB must be accessed, a process acquires LOB locks and the necessary LOB table space locks (IS or IX). This option is valid only for LOB table spaces. See “LOB locks” on page 864 for more information about LOB locking.

DB2 attempts to acquire an S lock on table spaces that are started with read-only access. If the LOCKSIZE is PAGE or ROW, and DB2 cannot get the S lock, it requests an IS lock. If a partition is started with read-only access, DB2 attempts to get an S lock on the partition that is started RO. For a complete description of how the LOCKSIZE clause affects lock attributes, see “DB2 choices of lock types” on page 830.

*Default:* LOCKSIZE ANY

*Catalog record:* Column LOCKRULE of table SYSIBM.SYSTABLESPACE.

**Recommendation:** If you do not use the default, base your choice upon the results of monitoring applications that use the table space. When considering changing the lock size for a DB2 catalog table space, be aware that, in addition to user queries, DB2 internal processes such as bind and authorization checking and utility processing can access the DB2 catalog.

*Row locks or page locks?* The question of whether to use row or page locks depends on your data and your applications. If you are experiencing contention on data pages of a table space now defined with LOCKSIZE PAGE, consider LOCKSIZE ROW. But consider also the trade-offs.

The resource required to acquire, maintain, and release a row lock is about the same as that required for a page lock. If your data has 10 rows per page, a table space scan or an index scan can require nearly 10 times as much resource for row locks as for page locks. But locking only a row at a time, rather than a page, might reduce the chance of contention with some other process by 90%, especially if access is random. (Row locking is not recommended for sequential processing.)

Lock avoidance is very important when row locking is used. Therefore, use ISOLATION(CS) CURRENTDATA(NO) or ISOLATION(UR) whenever possible. In many cases, DB2 can avoid acquiring a lock when reading data that is known to be committed. Thus, if only 2 of 10 rows on a page contain uncommitted data, DB2 must lock the entire page when using page locks, but might ask for locks on only the 2 rows when using row locks. Then, the resource required for row locks would be only twice as much, not 10 times as much, as that required for page locks.

On the other hand, if two applications update the same rows of a page, and not in the same sequence, then row locking might even increase contention. With page locks, the second application to access the page must wait for the first to finish and might time out. With row locks, the two applications can access the same page simultaneously, and might deadlock while trying to access the same set of rows.

In short, no single answer fits all cases.

## LOCKMAX clause of CREATE and ALTER TABLESPACE

The information under this heading, up to “LOCKS PER TABLE(SPACE) field of installation panel DSNTIPJ,” is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

*Effect:* You can specify these values not only for tables of user data but also, by using ALTER TABLESPACE, for tables in the DB2 catalog.

### LOCKMAX *n*

Specifies the maximum number of page or row locks that a single application process can hold on the table space before those locks are escalated as described in “Lock escalation” on page 834. For LOB table spaces, this value specifies the number of LOB locks that the application process can hold before escalating. For an application that uses Sysplex query parallelism, a lock count is maintained on each member.

### LOCKMAX SYSTEM

Specifies that *n* is effectively equal to the system default set by the field LOCKS PER TABLE(SPACE) of installation panel DSNTIPJ.

### LOCKMAX 0

Disables lock escalation entirely.

*Default:* The default depends on the value of LOCKSIZE, as shown in Table 142.

Table 142. How the default for LOCKMAX is determined

LOCKSIZE	Default for LOCKMAX
ANY	SYSTEM
other	0

*Catalog record:* Column LOCKMAX of table SYSIBM.SYSTABLESPACE.

**Recommendations:** If you do not use the default, base your choice upon the results of monitoring applications that use the table space.

Aim to set the value of LOCKMAX high enough that, when lock escalation occurs, one application already holds so many locks that it significantly interferes with others. For example, if an application holds half a million locks on a table with a million rows, it probably already locks out most other applications. Yet lock escalation can prevent it from potentially acquiring another half million locks.

If you alter a table space from LOCKSIZE PAGE or LOCKSIZE ANY to LOCKSIZE ROW, consider increasing LOCKMAX to allow for the increased number of locks that applications might require.

## LOCKS PER TABLE(SPACE) field of installation panel DSNTIPJ

*Effect:* The value becomes the default value (SYSTEM) for the LOCKMAX clause of the SQL statements CREATE TABLESPACE and ALTER TABLESPACE.

*Default:* 1000

**Recommendation:** Use the default or, if you are migrating from a previous release of DB2, continue to use the existing value. The value should be less than the value for LOCKS PER USER, unless the value or LOCKS PER USER is 0. When you

create or alter a table space, especially when you alter one to use row locks, use the LOCKMAX clause explicitly for that table space.

### The option U LOCK FOR RR/RS

This option, on installation panel DSNTIPI, determines the mode of the lock first acquired on a row or page, table, partition, or table space for certain statements bound with RR or RS isolation. Those statements include:

- SELECT with FOR UPDATE OF

Table 143 shows which mode of lock is held on rows or pages when you specify the SELECT using the WITH RS or WITH RR isolation clause.

*Table 143. Which mode of lock is held on rows or pages when you specify the SELECT using the WITH RS or WITH RR isolation clause*

Option Value	Lock Mode
USE AND KEEP EXCLUSIVE LOCKS	X
USE AND KEEP UPDATE LOCKS	U
USE AND KEEP SHARE LOCKS	S

- UPDATE and DELETE, without a cursor

Table 144 shows which mode of lock is held on rows or pages when you specify an update or a delete without a cursor.

*Table 144. Which mode of lock is held on rows or pages when you specify an update or a delete without a cursor*

Option Value	Lock Mode
NO (default)	S
YES	U or X

The YES option can avoid deadlocks but reduces concurrency.

### Option to release locks for cursors defined WITH HOLD

*Effect:* The RELEASE LOCKS field of installation panel DSNTIP8 lets you indicate that you want DB2 to release a data page or row lock after a COMMIT is issued for cursors defined WITH HOLD. This lock is not necessary for maintaining cursor position.

*Default:* YES

**Recommendation:** The default, YES, causes DB2, at commit time, to release the data page or row lock for the row on which the cursor is positioned. This lock is unnecessary for maintaining cursor position. To improve concurrency, specify YES. Specify NO only for those cases in which existing applications rely on that particular data lock.

### Option XLOCK for searched updates/deletes

*Effect:* A subsystem parameter XLKUPDLT lets you disable update lock (ULOCK) on searched UPDATES and DELETES so that you do not have to issue a second lock request to upgrade the lock from U to X (exclusive lock) for each updated row.

*Default:* NO

**Recommendation:** This feature is primarily beneficial in a data sharing environment. It should be used when most or all searched UPDATES/DELETES

use an index or can be evaluated by stage 1 processing. When NO is specified, DB2 uses an S lock or a U lock when scanning for qualifying rows. The lock on any qualifying row or page is then upgraded to an X lock before performing the update or delete. For non-qualifying rows or pages, the lock is released if ISOLATION(CS) is used. For ISOLATION(RS) or ISOLATION(RR), an S lock is retained on the row or page until the next commit point. This option is best for achieving the highest rates of concurrency.

When YES is specified, DB2 uses an X lock on rows or pages that qualify during stage 1 processing. With ISOLATION(CS), the lock is released if the row or page is not updated or deleted because it is rejected by stage 2 processing. With ISOLATION(RR) or ISOLATION(RS), DB2 acquires an X lock on all rows that fall within the range of the selection expression. Thus, a lock upgrade request is not needed for qualifying rows though the lock duration is changed from manual to commit. The lock duration change is not as costly as a lock upgrade.

### Option to avoid locks during predicate evaluation

#  
#  
#  
#  
#  
#  
*Effect:*The EVALUATE UNCOMMITTED field of installation panel DSNTIP8 indicates if predicate evaluation can occur on uncommitted data of other transactions. The option applies only to stage 1 predicate processing that uses table access (table space scan, index-to-data access, and RID list processing) for queries with isolation level RS or CS.

Although this option influences whether predicate evaluation can occur on uncommitted data, it does not influence whether uncommitted data is returned to an application. Queries with isolation level RS or CS will return only committed data. They will never return the uncommitted data of other transactions, even if predicate evaluation occurs on such. If data satisfies the predicate during evaluation, the data is locked as needed, and the predicate is re-evaluated as needed before the data is returned to the application.

A value of NO specifies that predicate evaluation occurs only on committed data (or on the application's own uncommitted changes). NO ensures that all qualifying data is always included in the answer set.

A value of YES specifies that predicate evaluation can occur on uncommitted data of other transactions. With YES, data might be excluded from the answer set. Data that does not satisfy the predicate during evaluation but then, because of undo processing (ROLLBACK or statement failure), reverts to a state that does satisfy the predicate is missing from the answer set. A value of YES enables DB2 to take fewer locks during query processing. The number of locks avoided depends on:

- The query's access path
- The number of evaluated rows that do not satisfy the predicate
- The number of those rows that are on overflow pages

*Default:* NO

**Recommendation:** Specify YES to improve concurrency if your applications can tolerate returned data to falsely exclude any data that would be included as the result of undo processing (ROLLBACK or statement failure).

### Option to disregard uncommitted inserts

|  
|  
|  
|  
|  
*Effect:* The SKIP UNCOMM INSERTS field on installation panel DSNTIP8 controls whether uncommitted inserts are ignored. DB2 can handle uncommitted inserts in the following ways:

- DB2 can wait until the INSERT transaction completes (commits or rolls back) and return data accordingly. This is the default option, NO.
- DB2 can ignore uncommitted inserts, which in many cases can improve concurrency. This behavior must be specified as YES.

*Default:* NO

**Recommendation:** In general, YES produces greater concurrency and is preferred for most applications. However, the following examples indicate some instances when the default option, NO, is preferred.

**Example:** Suppose that an initial transaction produces a second transaction. The initial transaction passes information to the second transaction by inserting data into a table that the second transaction reads. In this case, NO should be used.

**Example:** Suppose that you frequently modify data by deleting the data and inserting the new image of the data. In such cases that avoid UPDATE statements, the default should be used.

## Bind options

The information under this heading, up to “Isolation overriding with SQL statements” on page 862, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

These options determine when an application process acquires and releases its locks and to what extent it isolates its actions from possible effects of other processes acting concurrently.

These options of bind operations are relevant to transaction locks:

- “The ACQUIRE and RELEASE options”
- “The ISOLATION option” on page 851
- “The CURRENTDATA option” on page 858

### The ACQUIRE and RELEASE options

*Effects:* The ACQUIRE and RELEASE options of bind determine when DB2 locks an object (table, partition, or table space) your application uses and when it releases the lock. (The ACQUIRE and RELEASE options do not affect page, row, or LOB locks.) The options apply to static SQL statements, which are bound before your program executes. If your program executes dynamic SQL statements, the objects they lock are locked when first accessed and released at the next commit point though some locks acquired for dynamic SQL may be held past commit points. See 848.

#### ACQUIRE(ALLOCATE)

Acquires the lock when the object is allocated. This option is not allowed for BIND or REBIND PACKAGE.

#### ACQUIRE(USE)

Acquires the lock when the object is first accessed.

#### RELEASE(DEALLOCATE)

Releases the lock when the object is deallocated (the application ends). The value has no effect on dynamic SQL statements, which always use RELEASE(COMMIT), unless you are using dynamic statement caching. For information about the RELEASE option with dynamic statement caching, see 848. The value also has no effect on packages that are executed on a DB2 server through a DRDA connection with the client system.

## RELEASE(COMMIT)

Releases the lock at the next commit point, unless there are held cursors or held locators. If the application accesses the object again, it must acquire the lock again.

**Example:** An application selects employee names and telephone numbers from a table, according to different criteria. Employees can update their own telephone numbers. They can perform several searches in succession. The application is bound with the options ACQUIRE(USE) and RELEASE(DEALLOCATE), for these reasons:

- The alternative to ACQUIRE(USE), ACQUIRE(ALLOCATE), gets a lock of mode IX on the table space as soon as the application starts, because that is needed if an update occurs. But most uses of the application do not update the table and so need only the less restrictive IS lock. ACQUIRE(USE) gets the IS lock when the table is first accessed, and DB2 promotes the lock to mode IX if that is needed later.
- Most uses of this application do not update and do not commit. For those uses, there is little difference between RELEASE(COMMIT) and RELEASE(DEALLOCATE). But administrators might update several phone numbers in one session with the application, and the application commits after each update. In that case, RELEASE(COMMIT) releases a lock that DB2 must acquire again immediately. RELEASE(DEALLOCATE) holds the lock until the application ends, avoiding the processing needed to release and acquire the lock several times.

**Partition locks:** Partition locks follow the same rules as table space locks, and **all** partitions are held for the same duration. Thus, if one package is using RELEASE(COMMIT) and another is using RELEASE(DEALLOCATE), all partitions use RELEASE(DEALLOCATE).

# **The RELEASE option and dynamic statement caching:** Generally, the RELEASE  
# option has no effect on dynamic SQL statements with one exception. When you  
# use the bind options RELEASE(DEALLOCATE) and KEEP DYNAMIC(YES), and  
# your subsystem is installed with YES for field CACHE DYNAMIC SQL on  
# installation panel DSNTIP8, DB2 retains prepared SELECT, INSERT, UPDATE, and  
# DELETE statements in memory past commit points. For this reason, DB2 can honor  
# the RELEASE(DEALLOCATE) option for these dynamic statements. The locks are  
# held until deallocation, or until the commit after the prepared statement is freed  
# from memory, in the following situations:  
#

- The application issues a PREPARE statement with the same statement identifier.
- The statement is removed from memory because it has not been used.
- An object that the statement is dependent on is dropped or altered, or a privilege needed by the statement is revoked.
- RUNSTATS is run against an object that the statement is dependent on.

If a lock is to be held past commit and it is an S, SIX, or X lock on a table space or a table in a segmented table space, DB2 sometimes demotes that lock to an intent lock (IX or IS) at commit. DB2 demotes a gross lock if it was acquired for one of the following reasons:

- DB2 acquired the gross lock because of lock escalation.
- The application issued a LOCK TABLE.
- The application issued a mass delete (DELETE FROM ... without a WHERE clause).

For partitioned table spaces, lock demotion occurs for each partition for which there is a lock.

**Defaults:** The defaults differ for different types of bind operations, as shown in Table 145.

*Table 145. Default ACQUIRE and RELEASE values for different bind options*

Operation	Default values
BIND PLAN	ACQUIRE(USE) and RELEASE(COMMIT).
BIND PACKAGE	There is no option for ACQUIRE; ACQUIRE(USE) is always used. At the local server the default for RELEASE is the value used by the plan that includes the package in its package list. At a remote server the default is COMMIT.
REBIND PLAN or PACKAGE	The existing values for the plan or package that is being rebound.

**Recommendation:** Choose a combination of values for ACQUIRE and RELEASE based on the characteristics of the particular application.

*The RELEASE option and DDL operations for remote requesters:* When you perform DDL operations on behalf of remote requesters and RELEASE(DEALLOCATE) is in effect, be aware of the following condition. When a package that is bound with RELEASE(DEALLOCATE) accesses data at a server, it might prevent other remote requesters from performing CREATE, ALTER, DROP, GRANT, or REVOKE operations at the server.

To allow those operations to complete, you can use the command STOP DDF MODE(SUSPEND). The command suspends server threads and terminates their locks so that DDL operations from remote requesters can complete. When these operations complete, you can use the command START DDF to resume the suspended server threads. However, even after the command STOP DDF MODE(SUSPEND) completes successfully, database resources might be held if DB2 is performing any activity other than inbound DB2 processing. You might have to use the command CANCEL THREAD to terminate other processing and thereby free the database resources.

### Advantages and disadvantages of the combinations

Different combinations of bind options have advantages and disadvantages for certain situations.

**ACQUIRE(ALLOCATE) / RELEASE(DEALLOCATE):** In some cases, this combination can avoid deadlocks by locking all needed resources as soon as the program starts to run. This combination is most useful for a long-running application that runs for hours and accesses various tables, because it prevents an untimely deadlock from wasting that processing.

- All tables or table spaces used in DBRMs bound directly to the plan are locked when the plan is allocated.
- All tables or table spaces are unlocked only when the plan terminates.
- The locks used are the most restrictive needed to execute all SQL statements in the plan regardless of whether the statements are actually executed.
- Restrictive states are not checked until the page set is accessed. Locking when the plan is allocated insures that the job is compatible with other SQL jobs.

Waiting until the first access to check restrictive states provides greater availability; however, it is possible that an SQL transaction could:

- Hold a lock on a table space or partition that is stopped
- Acquire a lock on a table space or partition that is started for DB2 utility access only (ACCESS(UT))
- Acquire an exclusive lock (IX, X) on a table space or partition that is started for read access only (ACCESS(RO)), thus prohibiting access by readers

**Disadvantages:** This combination reduces concurrency. It can lock resources in high demand for longer than needed. Also, the option ACQUIRE(ALLOCATE) turns off selective partition locking; if you are accessing a partitioned table space, all partitions are locked.

**Restriction:** This combination is not allowed for BIND PACKAGE. Use this combination if processing efficiency is more important than concurrency. It is a good choice for batch jobs that would release table and table space locks only to reacquire them almost immediately. It might even improve concurrency, by allowing batch jobs to finish sooner. Generally, do not use this combination if your application contains many SQL statements that are often not executed.

**ACQUIRE(USE) / RELEASE(DEALLOCATE):** This combination results in the most efficient use of processing time in most cases.

- A table, partition, or table space used by the plan or package is locked only if it is needed while running.
- All tables or table spaces are unlocked only when the plan terminates.
- The least restrictive lock needed to execute each SQL statement is used, with the exception that if a more restrictive lock remains from a previous statement, that lock is used without change.

**Disadvantages:** This combination can increase the frequency of deadlocks. Because all locks are acquired in a sequence that is predictable only in an actual run, more concurrent access delays might occur.

**ACQUIRE(USE) / RELEASE(COMMIT):** This combination is the default combination and provides the greatest concurrency, but it requires more processing time if the application commits frequently.

- A table or table space is locked only when needed. That locking is important if the process contains many SQL statements that are rarely used or statements that are intended to access data only in certain circumstances.
- Table, partition, or table space locks are released at the next commit point unless the cursor is defined WITH HOLD. See “The effect of WITH HOLD for a cursor” on page 861 for more information.
- The least restrictive lock needed to execute each SQL statement is used except when a more restrictive lock remains from a previous statement. In that case, that lock is used without change.

**Disadvantages:** This combination can increase the frequency of deadlocks. Because all locks are acquired in a sequence that is predictable only in an actual run, more concurrent access delays might occur.

**ACQUIRE(ALLOCATE) / RELEASE(COMMIT):** This combination is not allowed; it results in an error message from BIND.

## The ISOLATION option

*Effects:* The ISOLATION option Specifies the degree to which operations are isolated from the possible effects of other operations acting concurrently. Based on this information, DB2 releases S and U locks on rows or pages as soon as possible. You can use the following ISOLATION options:

### ISOLATION(CS)

*Cursor stability:* A row or page lock is held only long enough to allow the cursor to move to another row or page. For data that satisfies the search condition of the application, the lock is held until the application locks the next row or page. For data that does not satisfy the search condition, the lock is immediately released.

The data returned to an application that uses ISOLATION(CS) is committed, but if the application process returns to the same page, another application might have since updated or deleted the data, or might have inserted additional qualifying rows. This is especially true if DB2 returns data from a result table in a work file.

For example, if DB2 has to put an answer set in a result table (such as for a sort), DB2 releases the lock immediately after it puts the row or page in the result table in the work file. Using cursor stability, the base table can change while your application is processing the result of the sort output.

In some cases, DB2 can avoid taking the lock altogether, depending on the value of the CURRENTDATA bind option or the value of the EVALUATE UNCOMMITTED field on installation panel DSNTIP8.

- *Lock avoidance on committed data:* If DB2 can determine that the data it is reading has already been committed, it can avoid taking the lock altogether. For rows that do not satisfy the search condition, this lock avoidance is possible with CURRENTDATA(YES) or CURRENTDATA(NO). For a row that satisfies the search condition on a singleton SELECT, lock avoidance is possible with CURRENTDATA(YES) or CURRENTDATA(NO). For other rows that satisfy the search condition, lock avoidance is possible only when you use the option CURRENTDATA(NO). For more details, see “The CURRENTDATA option” on page 858.
- *Lock avoidance on uncommitted data:* For rows that do not satisfy the search condition, lock avoidance is possible when the value of EVALUATE UNCOMMITTED is YES. For details, see “Option to avoid locks during predicate evaluation” on page 846.

### ISOLATION(UR)

*Uncommitted read:* The application acquires no page or row locks and can run concurrently with most other operations.<sup>6</sup> But the application is in danger of reading data that was changed by another operation but not yet committed. A UR application can acquire LOB locks, as described in “LOB locks” on page 864.

For restrictions on isolation UR, see “Restrictions” on page 855 for more information.

### ISOLATION(RS)

*Read stability:* A row or page lock is held for rows or pages that are returned to an application at least until the next commit point. If a row or

---

6. The exceptions are mass delete operations and utility jobs that drain all claim classes.

page is rejected during stage 2 processing, its lock is still held, even though it is not returned to the application. For multiple-row fetch, the lock is released if the stage 2 predicate fails.

If the application process returns to the same page and reads the same row again, another application cannot have changed the rows, although additional qualifying rows might have been inserted by another application process. A similar situation can also occur if a row or page that is not returned to the application is updated by another application process. If the row now satisfies the search condition, it appears.

When determining whether a row satisfies the search condition, DB2 can avoid taking the lock altogether if the row contains uncommitted data. If the row does not satisfy the predicate, lock avoidance is possible when the value of the EVALUATE UNCOMMITTED field of installation panel DSNTIP8 is YES. For details, see "Option to avoid locks during predicate evaluation" on page 846.

### ISOLATION(RR)

*Repeatable read:* A row or page lock is held for all accessed rows, qualifying or not, at least until the next commit point. If the application process returns to the same page and reads the same row again, another application cannot have changed the rows nor have inserted any new qualifying rows.

The repeatability of the read is guaranteed only until the application commits. Even if a cursor is held on a specific row or page, the result set can change after a commit.

*Default:* The default differs for different types of bind operations, as shown in.

Table 146. The default ISOLATION values for different bind operations

Operation	Default value
BIND PLAN	ISOLATION(RR)
BIND PACKAGE	The value used by the plan that includes the package in its package list
REBIND PLAN or PACKAGE	The existing value for the plan or package being rebound

For more detailed examples, see *DB2 Application Programming and SQL Guide*.

**Recommendation:** Choose an ISOLATION value based on the characteristics of the particular application.

### Advantages and disadvantages of the isolation values

The various isolation levels offer less or more concurrency at the cost of more or less protection from other application processes. The values you choose should be based primarily on the needs of the application. This section presents the isolation levels in order of recommendation, from the most recommended (CS) to the least recommended (RR). For ISOLATION (CS), CURRENTDATA(NO) is preferred over CURRENTDATA(YES). For more information on the CURRENTDATA option, see "The CURRENTDATA option" on page 858.

Regardless of the isolation level, uncommitted claims on DB2 objects can inhibit the execution of DB2 utilities or commands. For more information about how claims can affect concurrency see “Claims and drains for concurrency control” on page 869.

### ISOLATION (CS)

Allows maximum concurrency with data integrity. However, after the process leaves a row or page, another process can change the data. With CURRENTDATA(NO), the process doesn't have to leave a row or page to allow another process to change the data. If the first process returns to read the same row or page, the data is not necessarily the same. Consider these consequences of that possibility:

- For table spaces created with LOCKSIZE ROW, PAGE, or ANY, a change can occur even while executing a single SQL statement, if the statement reads the same row more than once. In the following example:

```
SELECT * FROM T1
WHERE COL1 = (SELECT MAX(COL1) FROM T1);
```

data read by the inner SELECT can be changed by another transaction before it is read by the outer SELECT. Therefore, the information returned by this query might be from a row that is no longer the one with the maximum value for COL1.

- In another case, if your process reads a row and returns later to update it, that row might no longer exist or might not exist in the state that it did when your application process originally read it. That is, another application might have deleted or updated the row. **If your application is doing non-cursor operations on a row under the cursor, make sure the application can tolerate “not found” conditions.**

Similarly, assume another application updates a row after you read it. If your process returns later to update it based on the value you originally read, you are, in effect, erasing the update made by the other process. **If you use isolation (CS) with update, your process might need to lock out concurrent updates.** One method is to declare a cursor with the FOR UPDATE clause.

### Product-sensitive Programming Interface

For packages and plans that contain updatable static scrollable cursors, ISOLATION(CS) lets DB2 use *optimistic concurrency control*. DB2 can use optimistic concurrency control to shorten the amount of time that locks are held in the following situations:

- Between consecutive fetch operations
- Between fetch operations and subsequent positioned update or delete operations

DB2 cannot use optimistic concurrency control for dynamic scrollable cursors. With dynamic scrollable cursors, the most recently fetched row or page from the base table remains locked to maintain position for a positioned update or delete.

Figure 87 on page 854 and Figure 88 on page 854 show processing of positioned update and delete operations without optimistic concurrency control and with optimistic concurrency control.

**Example:** An application tracks the movement of work from station to station along an assembly line. As items move from one station to another, the application subtracts from the count of items at the first station and adds to the count of items at the second. Assume you want to query the count of items at all the stations, while the application is running concurrently.

What can happen if your query reads data that the application has changed but has not committed?

If the application subtracts an amount from one record before adding it to another, *the query could miss the amount entirely.*

If the application adds first and then subtracts, *the query could add the amount twice.*

#  
#  
#  
#

When an application uses ISO(UR) and runs concurrently with applications that update variable-length records such that the update creates a double-overflow record, the ISO(UR) application might miss rows that are being updated.

If those situations can occur and are unacceptable, do not use UR isolation.

**Restrictions:** You cannot use UR isolation for the following types of statements:

- INSERT, UPDATE, and DELETE
- Any cursor defined with a FOR UPDATE clause

If you bind with ISOLATION(UR) and the statement does not specify WITH RR or WITH RS, DB2 uses CS isolation for these types of statements.

**When can you use uncommitted read (UR)?** You can probably use UR isolation in cases like the following ones:

- **When errors cannot occur.**

**Example:** A reference table, like a table of descriptions of parts by part number. It is rarely updated, and reading an uncommitted update is probably no more damaging than reading the table 5 seconds earlier. Go ahead and read it with ISOLATION(UR).

**Example:** The employee table of Spiffy Computer, our hypothetical user. For security reasons, updates can be made to the table only by members of a single department. And that department is also the only one that can query the entire table. It is easy to restrict queries to times when no updates are being made and then run with UR isolation.

- **When an error is acceptable.**

**Example:** Spiffy wants to do some statistical analysis on employee data. A typical question is, "What is the average salary by sex within education level?" Because reading an occasional uncommitted record cannot affect the averages much, UR isolation can be used.

- **When the data already contains inconsistent information.**

**Example:** Spiffy gets sales leads from various sources. The data is often inconsistent or wrong, and end users of the data are accustomed to dealing with that. Inconsistent access to a table of data on sales leads does not add to the problem.

**Do not use uncommitted read (UR) in the following cases:**

**When the computations must balance**

**When the answer must be accurate**

**When you are not sure it can do no damage**

## ISOLATION (RS)

Allows the application to read the same pages or rows more than once without allowing qualifying rows to be updated or deleted by another process. It offers possibly greater concurrency than repeatable read, because although other applications cannot change rows that are returned to the original application, they can insert new rows or update rows that did not satisfy the original application's search condition. Only those rows or pages that satisfy the stage 1 predicate (and all rows or pages evaluated during stage 2 processing) are locked until the application commits. Figure 89 illustrates this. In the example, the rows held by locks L2 and L4 satisfy the predicate.

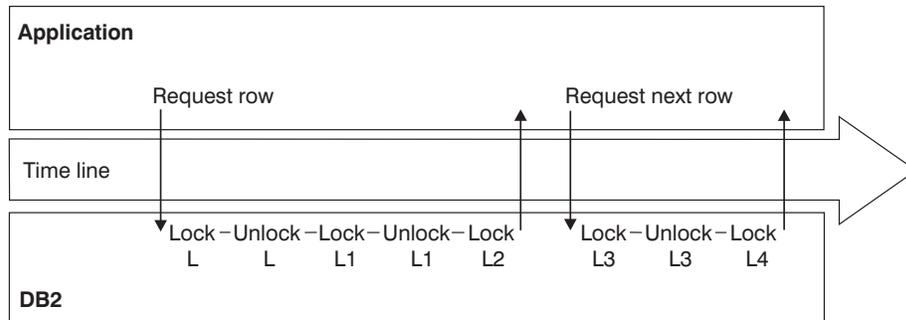

Figure 89. How an application using RS isolation acquires locks when no lock avoidance techniques are used. Locks L2 and L4 are held until the application commits. The other locks aren't held.

Applications using read stability can leave rows or pages locked for long periods, especially in a distributed environment.

If you do use read stability, plan for frequent commit points.

An installation option determines the mode of lock chosen for a cursor defined with the FOR UPDATE OF clause and bound with read stability. For details, see "The option U LOCK FOR RR/RS" on page 845.

## ISOLATION (RR)

Allows the application to read the same pages or rows more than once without allowing any UPDATE, INSERT, or DELETE by another process. All accessed rows or pages are locked, even if they do not satisfy the predicate.

Figure 90 on page 857 shows that all locks are held until the application commits. In the following example, the rows held by locks L2 and L4 satisfy the predicate.

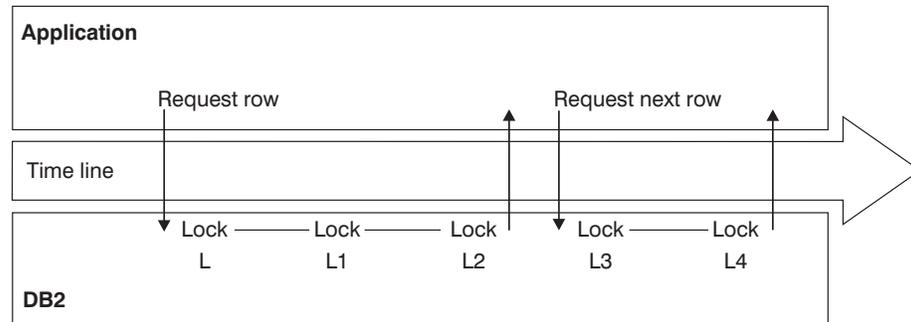

Figure 90. How an application using RR isolation acquires locks. All locks are held until the application commits.

Applications that use repeatable read can leave rows or pages locked for longer periods, especially in a distributed environment, and they can claim more logical partitions than similar applications using cursor stability.

Applications that use repeatable read and access a nonpartitioned index cannot run concurrently with utility operations that drain all claim classes of the nonpartitioned index, even if they are accessing different logical partitions. For example, an application bound with ISOLATION(RR) cannot update partition 1 while the LOAD utility loads data into partition 2. Concurrency is restricted because the utility needs to drain all the repeatable-read applications from the nonpartitioned index to protect the repeatability of the reads by the application.

Because so many locks can be taken, lock escalation might take place. Frequent commits release the locks and can help avoid lock escalation.

With repeatable read, lock promotion occurs for table space scan to prevent the insertion of rows that might qualify for the predicate. (If access is via index, DB2 locks the key range. If access is via table space scans, DB2 locks the table, partition, or table space.)

An installation option determines the mode of lock chosen for a cursor defined with the FOR UPDATE OF clause and bound with repeatable read. For details, see “The option U LOCK FOR RR/RS” on page 845.

**Plans and packages that use UR isolation:** Auditors and others might need to determine what plans or packages are bound with UR isolation. For queries that select that information from the catalog, see “Ensuring that concurrent users access consistent data” on page 295.

**Restrictions on concurrent access:** An application using UR isolation cannot run concurrently with a utility that drains all claim classes. Also, the application must acquire the following locks:

- A special *mass delete lock* acquired in S mode on the target table or table space. A “mass delete” is a DELETE statement without a WHERE clause; that operation must acquire the lock in X mode and thus cannot run concurrently.
- An IX lock on any table space used in the work file database. That lock prevents dropping the table space while the application is running.
- If LOB values are read, LOB locks and a lock on the LOB table space. If the LOB lock is not available because it is held by another application in an incompatible lock state, the UR reader skips the LOB and moves on to the next LOB that satisfies the query.

## The CURRENTDATA option

The CURRENTDATA option has different effects, depending on if access is local or remote:

- For **local** access, the option tells whether the data upon which your cursor is positioned must remain identical to (or “current with”) the data in the local base table. For cursors positioned on data in a work file, the CURRENTDATA option has no effect. This effect only applies to read-only or *ambiguous* cursors in plans or packages bound with CS isolation.

A cursor is “ambiguous” if DB2 cannot tell whether it is used for update or read-only purposes. If the cursor appears to be used only for read-only, but dynamic SQL could modify data through the cursor, then the cursor is ambiguous. If you use CURRENTDATA to indicate an ambiguous cursor is read-only when it is actually targeted by dynamic SQL for modification, you’ll get an error. See “Problems with ambiguous cursors” on page 860 for more information about ambiguous cursors.

- For a request to a **remote** system, CURRENTDATA has an effect for ambiguous cursors using isolation levels RR, RS, or CS. For ambiguous cursors, it turns block fetching on or off. (Read-only cursors and UR isolation always use block fetch.) Turning on block fetch offers best performance, but it means the cursor is not current with the base table at the remote site.

**Local access:** Locally, CURRENTDATA(YES) means that the data upon which the cursor is positioned cannot change while the cursor is positioned on it. If the cursor is positioned on data in a local base table or index, then the data returned with the cursor is current with the contents of that table or index. If the cursor is positioned on data in a work file, the data returned with the cursor is current only with the contents of the work file; it is not necessarily current with the contents of the underlying table or index.

Figure 91 shows locking with CURRENTDATA(YES).

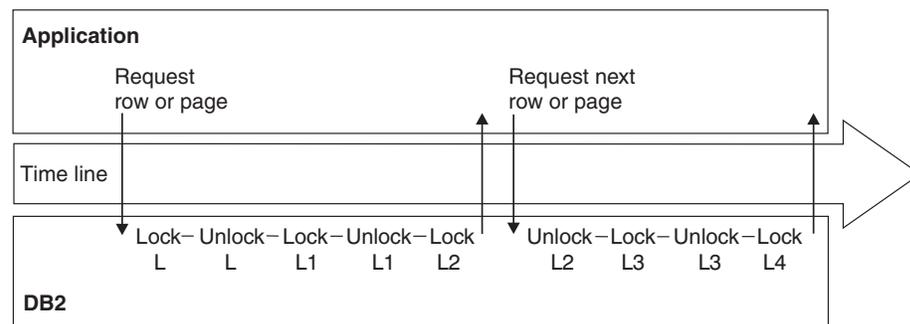

Figure 91. How an application using CS isolation with CURRENTDATA(YES) acquires locks. This figure shows access to the base table. The L2 and L4 locks are released after DB2 moves to the next row or page. When the application commits, the last lock is released.

As with work files, if a cursor uses query parallelism, data is not necessarily current with the contents of the table or index, regardless of whether a work file is used. Therefore, for work file access or for parallelism on read-only queries, the CURRENTDATA option has no effect.

If you are using parallelism but want to maintain currency with the data, you have the following options:

- Disable parallelism (Use SET DEGREE = '1' or bind with DEGREE(1)).
- Use isolation RR or RS (parallelism can still be used).

- Use the LOCK TABLE statement (parallelism can still be used).

For local access, **CURRENTDATA(NO)** is similar to **CURRENTDATA(YES)** except for the case where a cursor is accessing a base table rather than a result table in a work file. In those cases, although **CURRENTDATA(YES)** can guarantee that the cursor and the base table are current, **CURRENTDATA(NO)** makes no such guarantee.

**Remote access:** For access to a remote table or index, **CURRENTDATA(YES)** turns off block fetching for ambiguous cursors. The data returned with the cursor is current with the contents of the remote table or index for ambiguous cursors. See “Ensuring block fetch” on page 1011 for information about the effect of **CURRENTDATA** on block fetch.

**Lock avoidance:** With **CURRENTDATA(NO)**, you have much greater opportunity for avoiding locks. DB2 can test to see if a row or page has committed data on it. If it has, DB2 does not have to obtain a lock on the data at all. Unlocked data is returned to the application, and the data can be changed while the cursor is positioned on the row. (For **SELECT** statements in which no cursor is used, such as those that return a single row, a lock is not held on the row unless you specify **WITH RS** or **WITH RR** on the statement.)

To take the best advantage of this method of avoiding locks, make sure all applications that are accessing data concurrently issue **COMMITs** frequently.

Figure 92 shows how DB2 can avoid taking locks and Table 152 summarizes the factors that influence lock avoidance.

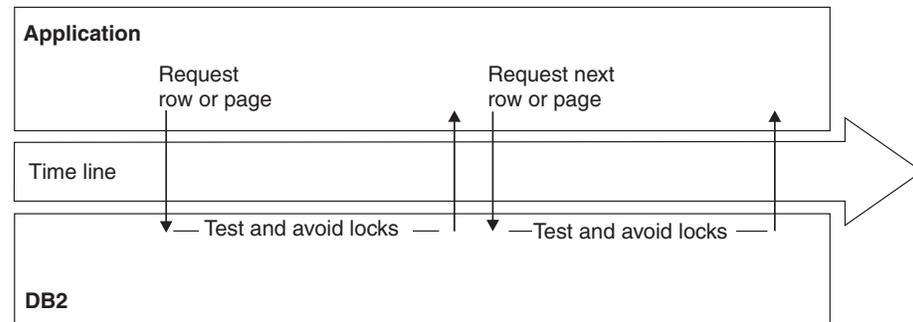

Figure 92. Best case of avoiding locks using **CS** isolation with **CURRENTDATA(NO)**. This figure shows access to the base table. If DB2 must take a lock, then locks are released when DB2 moves to the next row or page, or when the application commits (the same as **CURRENTDATA(YES)**).

Table 152. Lock avoidance factors. “Returned data” means data that satisfies the predicate. “Rejected data” is that which does not satisfy the predicate.

Isolation	CURRENTDATA	Cursor type	Avoid locks on returned data?	Avoid locks on rejected data?
UR	N/A	Read-only	N/A	N/A

Table 152. Lock avoidance factors (continued). “Returned data” means data that satisfies the predicate. “Rejected data” is that which does not satisfy the predicate.

Isolation	CURRENTDATA	Cursor type	Avoid locks on returned data?	Avoid locks on rejected data?
CS	YES	Read-only	No	Yes <sup>1</sup>
		Updatable		
		Ambiguous		
	NO	Read-only	Yes	
		Updatable	No	
		Ambiguous	Yes	
RS	N/A	Read-only	No	Yes <sup>1, 2</sup>
		Updatable		
		Ambiguous		
RR	N/A	Read-only	No	No
		Updatable		
		Ambiguous		

**Note:**

- Locks are avoided when the row is disqualified after stage 1 processing
- When using ISO(RS) and multi-row fetch, DB2 releases locks that were acquired on Stage 1 qualified rows, but which subsequently failed to qualify for stage 2 predicates at the next fetch of the cursor.

**Problems with ambiguous cursors:** As shown in Table 152 on page 859, ambiguous cursors can sometimes prevent DB2 from using lock avoidance techniques. However, misuse of an ambiguous cursor can cause your program to receive a -510 SQLCODE:

- The plan or package is bound with CURRENTDATA(NO)
- An OPEN CURSOR statement is performed *before* a dynamic DELETE WHERE CURRENT OF statement against that cursor is prepared
- One of the following conditions is true for the open cursor:
  - Lock avoidance is successfully used on that statement.
  - Query parallelism is used.
  - The cursor is distributed, and block fetching is used.

In all cases, it is a good programming technique to eliminate the ambiguity by declaring the cursor with either the FOR FETCH ONLY or the FOR UPDATE clause.

**When plan and package options differ**

A plan bound with one set of options can include packages in its package list that were bound with different sets of options. In general, statements in a DBRM bound as a package use the options that the package was bound with, and statements in DBRMs bound to a plan use the options that the plan was bound with.

For example, the plan value for CURRENTDATA has no effect on the packages executing under that plan. If you do not specify a CURRENTDATA option explicitly when you bind a package, the default is CURRENTDATA(YES).

The rules are slightly different for the bind options RELEASE and ISOLATION. The values of those two options are set when the lock on the resource is acquired and usually stay in effect until the lock is released. But a conflict can occur if a statement that is bound with one pair of values requests a lock on a resource that is already locked by a statement that is bound with a different pair of values. DB2 resolves the conflict by resetting each option with the available value that causes the lock to be held for the greatest duration.

If the conflict is between RELEASE(COMMIT) and RELEASE(DEALLOCATE), then the value used is RELEASE(DEALLOCATE).

Table 153 shows how conflicts between isolation levels are resolved. The first column is the existing isolation level, and the remaining columns show what happens when another isolation level is requested by a new application process.

Table 153. Resolving isolation conflicts

	UR	CS	RS	RR
UR	n/a	CS	RS	RR
CS	CS	n/a	RS	RR
RS	RS	RS	n/a	RR
RR	RR	RR	RR	n/a

### The effect of WITH HOLD for a cursor

For a cursor defined as WITH HOLD, the cursor position is maintained past a commit point. Hence, locks and claims needed to maintain that position are not released immediately, even if they were acquired with ISOLATION(CS) or RELEASE(COMMIT).

For locks and claims that are needed for cursor position, the following exceptions exist for special cases:

#  
#  
#  
#  
#  
#

**Page and row locks:** If you specify NO on the RELEASE LOCKS field on installation panel DSNTIP8, described in “Option to release locks for cursors defined WITH HOLD” on page 845, a page or row lock, if the lock is not successfully avoided through lock avoidance, is held past the commit point. This page or row lock is not necessary for cursor position, but the NO option is provided for compatibility with applications that might rely on this lock. However, an X or U lock is demoted to an S lock at that time. (Because changes have been committed, exclusive control is no longer needed.) After the commit point, the lock is released at the next commit point, provided that no cursor is still positioned on that page or row.

#  
#

If your installation specifies YES on the RELEASE LOCKS field on installation panel DSNTIP8, data page or row locks are not held past commit.

**Table, table space, and DBD locks:** All necessary locks are held past the commit point. After that, they are released according to the RELEASE option under which they were acquired: for COMMIT, at the next commit point after the cursor is closed; for DEALLOCATE, when the application is deallocated.

**Claims:** All claims, for any claim class, are held past the commit point. They are released at the next commit point after all held cursors have moved off the object or have been closed.

## Isolation overriding with SQL statements

The information under this heading, up to “The LOCK TABLE statement” on page 863 is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

*Function of the WITH clause:* You can override the isolation level with which a plan or package is bound by the WITH clause on certain SQL statements.

**Example:** This statement:

```
SELECT MAX(BONUS), MIN(BONUS), AVG(BONUS)
       INTO :MAX, :MIN, :AVG
       FROM DSN8810.EMP
       WITH UR;
```

finds the maximum, minimum, and average bonus in the sample employee table. The statement is executed with uncommitted read isolation, regardless of the value of ISOLATION with which the plan or package containing the statement is bound.

*Rules for the WITH clause:* The WITH clause:

- Can be used on these statements:
  - Select-statement
  - SELECT INTO
  - Searched delete
  - INSERT from fullselect
  - Searched update
- Cannot be used on subqueries.
- Can specify the isolation levels that specifically apply to its statement. (For example, because WITH UR applies only to read-only operations, you cannot use it on an INSERT statement.)
- Overrides the isolation level for the plan or package only for the statement in which it appears.

*USE AND KEEP ... LOCKS options of the WITH clause:* If you use the WITH RR or WITH RS clause, you can use the USE AND KEEP EXCLUSIVE LOCKS, USE AND KEEP UPDATE LOCKS, USE AND KEEP SHARE LOCKS options in SELECT and SELECT INTO statements.

**Example:** To use these options, specify them as shown in the following example:

```
SELECT ...
       WITH RS USE KEEP UPDATE LOCKS;
```

By using one of these options, you tell DB2 to acquire and hold a specific mode of lock on all the qualified pages or rows. Table 154 shows which mode of lock is held on rows or pages when you specify the SELECT using the WITH RS or WITH RR isolation clause.

*Table 154. Which mode of lock is held on rows or pages when you specify the SELECT using the WITH RS or WITH RR isolation clause*

Option Value	Lock Mode
USE AND KEEP EXCLUSIVE LOCKS	X
USE AND KEEP UPDATE LOCKS	U
USE AND KEEP SHARE LOCKS	S

| With read stability (RS) isolation, a row or page that is rejected during stage 2  
| processing might still have a lock held on it, even though it is not returned to the  
| application.

| With repeatable read (RR) isolation, DB2 acquires locks on all pages or rows that  
| fall within the range of the selection expression.

| All locks are held until the application commits. Although this option can reduce  
| concurrency, it can prevent some types of deadlocks and can better serialize access  
| to data.

## The LOCK TABLE statement

The information under this heading, up to “Claims and drains for concurrency control” on page 869 is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

For information about using LOCK TABLE on an auxiliary table, see “The LOCK TABLE statement for LOBs” on page 868.

### The purpose of LOCK TABLE

Use the LOCK TABLE statement to override DB2’s rules for choosing initial lock attributes. Two examples are:

```
LOCK TABLE table-name IN SHARE MODE;  
LOCK TABLE table-name PART n IN EXCLUSIVE MODE;
```

Executing the statement requests a lock immediately, unless a suitable lock exists already. The bind option RELEASE determines when locks acquired by LOCK TABLE or LOCK TABLE with the PART option are released.

You can use LOCK TABLE on any table, including auxiliary tables of LOB table spaces. See “The LOCK TABLE statement for LOBs” on page 868 for information about locking auxiliary tables.

LOCK TABLE has no effect on locks acquired at a remote server.

### When to use LOCK TABLE

The statement is often appropriate for a particularly high-priority application. The statement can improve performance if LOCKMAX disables lock escalation or sets a high threshold for it.

For example, suppose that you intend to execute an SQL statement to change job code 21A to code 23 in a table of employee data. The table is defined with:

- The name PERSADM1.EMPLOYEE\_DATA
- LOCKSIZE ROW
- LOCKMAX 0, which disables lock escalation

Because the change affects about 15% of the employees, the statement can require many row locks of mode X. To avoid the overhead for locks, first execute:

```
LOCK TABLE PERSADM1.EMPLOYEE_DATA IN EXCLUSIVE MODE;
```

If EMPLOYEE\_DATA is a partitioned table space, you could choose to lock individual partitions as you update them. An example is:

```
LOCK TABLE PERSADM1.EMPLOYEE_DATA PART 1 IN EXCLUSIVE MODE;
```

When the statement is executed, DB2 locks partition 1 with an X lock. The lock has no effect on locks that already exist on other partitions in the table space.

## The effect of LOCK TABLE

Table 155 shows the modes of locks acquired in segmented and nonsegmented table spaces for the SHARE and EXCLUSIVE modes of LOCK TABLE. Auxiliary tables of LOB table spaces are considered nonsegmented table spaces and have the same locking behavior.

*Table 155. Modes of locks acquired by LOCK TABLE.* LOCK TABLE on partitions behave the same as nonsegmented table spaces.

LOCK TABLE IN	Nonsegmented Table Space	Segmented Table Space	
		Table	Table Space
EXCLUSIVE MODE	X	X	IX
SHARE MODE	S or SIX	S or SIX	IS

**Note:** The SIX lock is acquired if the process already holds an IX lock. SHARE MODE has no effect if the process already has a lock of mode SIX, U, or X.

## LOB locks

The locking activity for LOBs is described separately from transaction locks because the purpose of LOB locks is different than that of regular transaction locks.

A lock that is taken on a LOB value in a LOB table space is called a *LOB lock*.

In this section, the following topics are described:

- “Relationship between transaction locks and LOB locks”
- “Hierarchy of LOB locks” on page 865
- “LOB and LOB table space lock modes” on page 866
- “LOB lock and LOB table space lock duration” on page 866
- “Instances when LOB table space locks are not taken” on page 867
- “Control of the number of LOB locks” on page 867
- “The LOCK TABLE statement for LOBs” on page 868
- “LOCKSIZE clause for LOB table spaces” on page 868

## Relationship between transaction locks and LOB locks

As described in *DB2 Application Programming and SQL Guide*, LOB column values are stored in a different table space, a LOB table space, from the values in the base table. An application that reads or updates a row in a table that contains LOB columns obtains its normal transaction locks on the base table. The locks on the base table also control concurrency for the LOB table space. When locks are not acquired on the base table, such as for ISO(UR), DB2 maintains data consistency by using locks on the LOB table space. Even when locks are acquired on the base table, DB2 still obtains locks on the LOB table space. When a conditional LOB lock cannot be acquired for some SQL statements with UR isolation, DB2 might return no rows and issue an SQL return code +100.

#  
#  
#

DB2 also obtains locks on the LOB table space and the LOB values stored in that LOB table space, but those locks have the following primary purposes:

- To determine whether space from a deleted LOB can be reused by an inserted or updated LOB

Storage for a deleted LOB is not reused until no more readers (including held locators) are on the LOB and the delete operation has been committed.

- To prevent deallocating space for a LOB that is currently being read

A LOB can be deleted from one application's point-of-view while a reader from another application is reading the LOB. The reader continues reading the LOB because all readers, including those readers that are using uncommitted read isolation, acquire S-locks on LOBs to prevent the storage for the LOB they are reading from being deallocated. That lock is held until commit. A held LOB locator or a held cursor cause the LOB lock and LOB table space lock to be held past commit.

In summary, the main purpose of LOB locks is for managing the space used by LOBs and to ensure that LOB readers do not read partially updated LOBs. Applications need to free held locators so that the space can be reused.

Table 156 shows the relationship between the action that is occurring on the LOB value and the associated LOB table space and LOB locks that are acquired.

*Table 156. Locks that are acquired for operations on LOBs.* This table does not account for gross locks that can be taken because of LOCKSIZE TABLESPACE, the LOCK TABLE statement, or lock escalation.

Action on LOB value	LOB table space lock	LOB lock	Comment
Read (including UR)	IS	S	Prevents storage from being reused while the LOB is being read or while locators are referencing the LOB
Insert	IX	X	Prevents other processes from seeing a partial LOB
Delete	IS	S	To hold space in case the delete is rolled back. (The X is on the base table row or page.) Storage is not reusable until the delete is committed and no other readers of the LOB exist.
Update	IS->IX	Two LOB locks: an S-lock for the delete and an X-lock for the insert.	Operation is a delete followed by an insert.
Update the LOB to null or zero-length	IS	S	No insert, just a delete.
Update a null or zero-length LOB to a value	IX	X	No delete, just an insert.

**ISOLATION(UR) or ISOLATION(CS):** When an application is reading rows using uncommitted read or lock avoidance, no page or row locks are taken on the base table. Therefore, these readers must take an S LOB lock to ensure that they are not reading a partial LOB or a LOB value that is inconsistent with the base row.

## Hierarchy of LOB locks

Just as page locks (or row locks) and table space locks have a hierarchical relationship, LOB locks and locks on LOB table spaces have a hierarchical

relationship. (See Figure 84 on page 822 for a picture of the hierarchical relationship.) If the LOB table space is locked with a gross lock, then LOB locks are not acquired. In a data sharing environment, the lock on the LOB table space is used to determine whether the lock on the LOB must be propagated beyond the local IRLM.

## LOB and LOB table space lock modes

This section describes the modes of LOB locks and LOB table space locks.

### Modes of LOB locks

The following LOB lock modes are possible:

#### S (SHARE)

The lock owner and any concurrent processes can read, update, or delete the locked LOB. Concurrent processes can acquire an S lock on the LOB. The purpose of the S lock is to reserve the space used by the LOB.

#### X (EXCLUSIVE)

The lock owner can read or change the locked LOB. Concurrent processes cannot access the LOB.

### Modes of LOB table space locks

The following locks modes are possible on the LOB table space:

#### IS (INTENT SHARE)

The lock owner can update LOBs to null or zero-length, or read or delete LOBs in the LOB table space. Concurrent processes can both read and change LOBs in the same table space. The lock owner acquires a LOB lock on any data that it reads or deletes.

#### IX (INTENT EXCLUSIVE)

The lock owner and concurrent processes can read and change data in the LOB table space. The lock owner acquires a LOB lock on any data it accesses.

#### S (SHARE)

The lock owner and any concurrent processes can read and delete LOBs in the LOB table space. The lock owner does not need LOB locks.

#### SIX (SHARE with INTENT EXCLUSIVE)

The lock owner can read and change data in the LOB table space. If the lock owner is inserting (INSERT or UPDATE), the lock owner obtains a LOB lock. Concurrent processes can read or delete data in the LOB table space (or update to a null or zero-length LOB).

#### X (EXCLUSIVE)

The lock owner can read or change LOBs in the LOB table space. The lock owner does not need LOB locks. Concurrent processes cannot access the data.

## LOB lock and LOB table space lock duration

This section describes the duration of LOB locks and LOB table space locks.

### The duration of LOB locks

Locks on LOBs are taken when they are needed and are usually released at commit. However, if that LOB value is assigned to a LOB locator, the S lock remains until the application commits.

If the application uses HOLD LOCATOR, the LOB lock is not freed until the first commit operation after a FREE LOCATOR statement is issued, or until the thread is deallocated.

If a cursor is defined WITH HOLD, LOB locks are held through commit operations.

Because LOB locks are held until commit and because locks are put on each LOB column in both a source table and a target table, it is possible that a statement such as an INSERT with a fullselect that involves LOB columns can accumulate many more locks than a similar statement that does not involve LOB columns. To prevent system problems caused by too many locks, you can:

- Ensure that you have lock escalation enabled for the LOB table spaces that are involved in the INSERT. In other words, make sure that LOCKMAX is non-zero for those LOB table spaces.
- Alter the LOB table space to change the LOCKSIZE to TABLESPACE before executing the INSERT with fullselect.
- Increase the LOCKMAX value on the table spaces involved and ensure that the user lock limit is sufficient.
- Use LOCK TABLE statements to lock the LOB table spaces. (Locking the auxiliary table that is contained in the LOB table space locks the LOB table space.)

### The duration of LOB table space locks

# Locks on LOB table spaces are acquired when they are needed; that is, the  
# ACQUIRE option of BIND has no effect on when the table space lock on the LOB  
# table space is taken. When the table space lock is released is determined by a  
# combination of factors:

- # • The RELEASE option of bind
- # • Whether the SQL statement is static or dynamic
- # • Whether there are held cursors or held locators

# When the release option is COMMIT, the lock is released at the next commit point,  
# unless there are held cursors or held locators. If the release option is  
# DEALLOCATE, the lock is released when the object is deallocated (the application  
# ends). The BIND option has no effect on dynamic SQL statements, which always  
# use RELEASE(COMMIT), unless you use dynamic statement caching.

### Instances when LOB table space locks are not taken

A lock might not be acquired on a LOB table space at all. For example, if a row is deleted from a table and the value of the LOB column is null, the LOB table space associated with that LOB column is not locked. DB2 does not access the LOB table space if the application:

- Selects a LOB that is null or zero length
- Deletes a row where the LOB is null or zero length
- Inserts a null or zero length LOB
- Updates a null or zero-length LOB to null or zero-length

### Control of the number of LOB locks

This section describes how you can control the number of LOB locks that are taken.

## Controlling the number of LOB locks that are acquired for a user

LOB locks are counted toward the total number of locks allowed per user. Control this number by the value you specify on the LOCKS PER USER field of installation panel DSNTIPJ. The number of LOB locks that are acquired during a unit of work is reported in IFCID 0020.

## Controlling LOB lock escalation

As with any table space, use the LOCKMAX clause of the CREATE or ALTER TABLESPACE statement to control the number of LOB locks that are acquired within a particular LOB table space before the lock is escalated. See “LOCKMAX clause of CREATE and ALTER TABLESPACE” on page 844 for more information. When the number of LOB locks reaches the maximum you specify in the LOCKMAX clause, the LOB locks escalate to a gross lock on the LOB table space, and the LOB locks are released.

Information about LOB locks and lock escalation is reported in IFCID 0020.

## The LOCK TABLE statement for LOBs

“The LOCK TABLE statement” on page 863 describes how and why you might use a LOCK TABLE statement on a table. The reasons for using LOCK TABLE on an auxiliary table are somewhat different than that for regular tables.

- You can use LOCK TABLE to control the number of locks acquired on the auxiliary table.
- You can use LOCK TABLE IN SHARE MODE to prevent other applications from inserting LOBs.

With auxiliary tables, LOCK TABLE IN SHARE MODE does not prevent any changes to the auxiliary table. The statement does prevent LOBs from being inserted into the auxiliary table, but it does not prevent deletes. Updates are generally restricted also, except where the LOB is updated to a null value or a zero-length string.

- You can use LOCK TABLE IN EXCLUSIVE MODE to prevent other applications from accessing LOBs.

With auxiliary tables, LOCK TABLE IN EXCLUSIVE MODE also prevents access from uncommitted readers.

- Either statement eliminates the need for lower-level LOB locks.

## LOCKSIZE clause for LOB table spaces

The LOCKSIZE TABLE, PAGE, and ROW options are not valid for LOB table spaces. The other options act as follows:

### LOCKSIZE TABLESPACE

A process acquires no LOB locks.

### LOCKSIZE ANY

DB2 chooses the size of the lock. For a LOB table space, this is usually LOCKSIZE LOB.

### LOCKSIZE LOB

If LOBs are accessed, a process acquires LOB locks and the necessary LOB table space locks (IS or IX).

---

## Claims and drains for concurrency control

DB2 utilities, commands, and some ALTER, CREATE, and DROP statements can take over access to some objects independently of any transaction locks that are held on the object.

### Objects that are subject to takeover

DB2 utilities, commands, and some ALTER, CREATE, and DROP statements can take over access to the following table and index spaces:

- Simple and segmented table spaces
- Partitions of table spaces
- LOB table spaces
- Nonpartitioned index spaces
- Partitions of index spaces
- Logical partitions of nonpartitioned indexes

The effects of those takeovers are described in the following sections:

- “Claims”
- “Drains” on page 870
- “Usage of drain locks” on page 870
- “Utility locks on the catalog and directory” on page 871
- “Compatibility of utilities” on page 871
- “Concurrency during REORG” on page 872
- “Utility operations with nonpartitioned indexes” on page 873

### Claims

*Definition:* A *claim* is a notification to DB2 that an object is being accessed.

**Example:** When an application first accesses an object, within a unit of work, it makes a claim on the object. It releases the claim at the next commit point.

*Effects of a claim:* Claims have the following effects:

- Unlike a transaction lock, a claim normally does not persist past the commit point. To access the object in the next unit of work, the application must make a new claim. However, there is an exception. If a cursor defined with the clause WITH HOLD is positioned on the claimed object, the claim is not released at a commit point. For more about cursors defined as WITH HOLD, see “The effect of WITH HOLD for a cursor” on page 861.
- A claim indicates to DB2 that there is activity on or interest in a particular page set or partition. Claims prevent drains from occurring until the claim is released.
- Agents get a claim on data before they get a claim on an index.
- For partitioned table spaces, agents get a claim at the table space level before they claim partitions or indexes.

*Three classes of claims:* Table 157 shows the three classes of claims and the actions that they allow.

Table 157. Three classes of claims and the actions that they allow

Claim class	Actions allowed
Write	Reading, updating, inserting, and deleting
Repeatable read	Reading only, with repeatable read (RR) isolation
Cursor stability read	Reading only, with read stability (RS), cursor stability (CS), or uncommitted read (UR) isolation

#  
#  
#

| *Detecting long-running read claims:* DB2 issues a warning message and generates a  
| trace record for each time period that a task holds an uncommitted read claim. You  
| can set the length of the period in minutes by using the LRDRTHLD subsystem  
| parameter.

## Drains

*Definition:* A *drain* is the action of taking over access to an object by preventing new claims and waiting for existing claims to be released.

**Example:** A utility can drain a partition when applications are accessing it.

*Effects of a drain:* The drain quiesces the applications by allowing each one to reach a commit point, but preventing any of them, or any other applications, from making a new claim. When no more claims exist, the process that drains (the drainer) controls access to the drained object. The applications that were drained can still hold transaction locks on the drained object, but they cannot make new claims until the drainer has finished.

*Claim classes drained:* A drainer does not always need complete control. It could drain the following combinations of claim classes:

- Only the write claim class
- Only the repeatable read claim class
- All claim classes

**Example:** The CHECK INDEX utility needs to drain only writers from an index space and its associated table space. RECOVER, however, must drain all claim classes from its table space. The REORG utility can drain either writers (with DRAIN WRITERS) or all claim classes (with DRAIN ALL).

## Usage of drain locks

| *Definition:* A *drain lock* prevents conflicting processes from trying to drain the same  
| object at the same time. Processes that drain only writers can run concurrently; but  
| a process that drains all claim classes cannot drain an object concurrently with any  
| other process. To drain an object, a drainer first acquires one or more drain locks  
| on the object, one for each claim class that it needs to drain. When the locks are in  
| place, the drainer can begin after all processes with claims on the object have  
| released their claims.

A drain lock also prevents new claimers from accessing an object while a drainer has control of it.

*Types of drain locks:* Three types of drain locks on an object correspond to the three claim classes:

- Write
- Repeatable read
- Cursor stability read

In general, after an initial claim has been made on an object by a user, no other user in the system needs a drain lock. When the drain lock is granted, no drains on the object are in process for the claim class needed, and the claimer can proceed.

**Exception:** The claimer of an object requests a drain lock in two exceptional cases:

- A drain on the object is in process for the claim class needed. In this case, the claimer waits for the drain lock.
- The claim is the first claim on an object before its data set has been physically opened. Here, acquiring the drain lock ensures that no exception states prohibit allocating the data set.

When the claimer gets the drain lock, it makes its claim and releases the lock before beginning its processing.

## Utility locks on the catalog and directory

When the target of a utility is an object in the catalog or directory, such as a catalog table, the utility either drains or claims the object.

When the target is a user-defined object, the utility claims or drains it but also uses the directory and, perhaps, the catalog; for example, to check authorization. In those cases, the utility uses transaction locks on catalog and directory tables. It acquires those locks in the same way as an SQL transaction does. For information about the SQL statements that require locks on the catalog, see “Locks on the DB2 catalog” on page 828.

*The UTSERIAL lock:* Access to the SYSUTILX table space in the directory is controlled by a unique lock called UTSERIAL. A utility must acquire the UTSERIAL lock to read or write in SYSUTILX, whether SYSUTILX is the target of the utility or is used only incidentally.

## Compatibility of utilities

*Definition:* Two utilities are considered *compatible* if they do not need access to the same object at the same time in incompatible modes.

*Compatibility rules:* The concurrent operation of two utilities is not typically controlled by either drain locks or transaction locks, but merely by a set of compatibility rules.

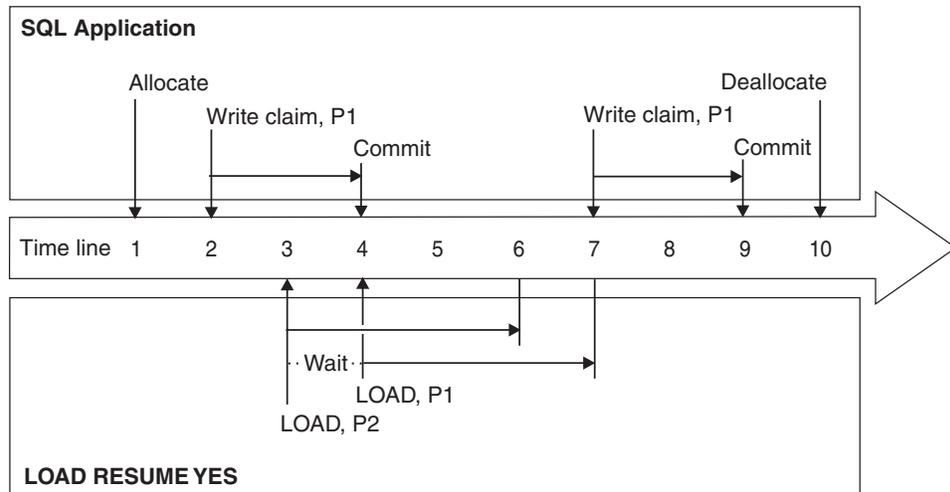

Before a utility starts, it is checked against all other utilities running on the same target object. The utility starts only if all the others are compatible.

The check for compatibility obeys the following rules:

- The check is made for each target object, but only for target objects. Typical utilities access one or more table spaces or indexes, but if two utility jobs use none of the same target objects, the jobs are always compatible.  
An exception is a case in which one utility must update a catalog or directory table space that is not the direct target of the utility. For example, the LOAD utility on a user table space updates DSNDB06.SYSCOPY. Therefore, other utilities that have DSNDB06.SYSCOPY as a target might not be compatible.
- Individual data and index partitions are treated as distinct target objects. Utilities operating on different partitions in the same table or index space are compatible.
- When two utilities access the same target object, their most restrictive access modes determine whether they are compatible. For example, if utility job 1 reads a table space during one phase and writes during the next, it is considered a writer. It cannot start concurrently with utility 2, which allows only readers on the table space. (Without this restriction, utility 1 might start and run concurrently with utility 2 for one phase; but then it would fail in the second phase, because it could not become a writer concurrently with utility 2.)

For details on which utilities are compatible, refer to each utility's description in *DB2 Utility Guide and Reference*.

Figure 93 illustrates how SQL applications and DB2 utilities can operate concurrently on separate partitions of the same table space.

- | Time  | Event                                                                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $t1$  | An SQL application obtains a transaction lock on every partition in the table space. The duration of the locks extends until the table space is deallocated.                                                          |
| $t2$  | The SQL application makes a write claim on data partition 1 and index partition 1.                                                                                                                                    |
| $t3$  | The LOAD jobs begin draining all claim classes on data partitions 1 and 2 and index partitions 1 and 2. LOAD on partition 2 operates concurrently with the SQL application on partition 1. LOAD on partition 1 waits. |
| $t4$  | The SQL application commits, releasing its write claims on partition 1. LOAD on partition 1 can begin.                                                                                                                |
| $t6$  | LOAD on partition 2 completes.                                                                                                                                                                                        |
| $t7$  | LOAD on partition 1 completes, releasing its drain locks. The SQL application (if it has not timed out) makes another write claim on data partition 1.                                                                |
| $t10$ | The SQL application deallocates the table space and releases its transaction locks.                                                                                                                                   |

Figure 93. SQL and utility concurrency. Two LOAD jobs execute concurrently on two partitions of a table space

## Concurrency during REORG

If you are getting deadlocks when you use REORG with the SHRLEVEL CHANGE option, run the REORG utility with the DRAIN ALL option. The default is DRAIN WRITERS, which is done in the log phase. The specification of DRAIN ALL indicates that both writers and readers will be drained when the MAXRO threshold is reached. The DRAIN ALL option should be considered in environments where a lot of update activity occurs during the log phase. With this specification, there is no need for a subsequent drain in the switch phase.

When multiple REORG utility jobs with the SHRLEVEL CHANGE or REFERENCE and the FASTSWITCH options run against separate partitions of the same partitioned table space, some of the utilities might fail with reason code 00E40012. This code, which indicates the unavailability of the database descriptor block

(DBD) is caused by multiple utilities arriving at the SWITCH phase simultaneously. The switch phase times out if it cannot acquire the DBD within the timeout period specified by the UTILITY TIMEOUT field on installation panel DSNTIPI. Increase the value of the installation parameter to alleviate the problem.

## Utility operations with nonpartitioned indexes

In the example of Figure 93 on page 872, two LOAD jobs execute concurrently on different partitions of the same table space. When the jobs proceed to build a partitioned index, either a partitioning index or a secondary index, they operate on different partitions of the index and can operate concurrently. Concurrent operations on different partitions are possible because the index entries in an index partition refer only to data in the corresponding data partition for the table.

However, in a nonpartitioned index, either a partitioning index or a secondary index, an entry can refer to any partition in the underlying table space. DB2 can process a set of entries of a nonpartitioned index that all refer to a single partition and achieve the same results as for a partition of a partitioned index. (Such a set of entries is called a *logical partition* of the nonpartitioned index.)

Utility processing can be more efficient with partitioned indexes because, with the correspondence of index partitions to data partitions, they promote partition-level independence. For example, the REORG utility with the PART option can run faster and with more concurrency when the indexes are partitioned. REORG rebuilds the parts for each partitioned index during the BUILD phase, which can increase parallel processing and reduce the lock contention of nonpartitioned indexes. In addition, for REORG PART with the SHRLEVEL CHANGE or REFERENCE option, the BUILD2 phase can be eliminated. Nonpartitioned indexes are corrected during BUILD2. Thus, if all the indexes on the table are partitioned, the utility skips the BUILD2 phase.

Similarly, for the LOAD PART and REBUILD INDEX PART utilities, the parts for each partitioned index can be built in parallel during the BUILD phase, which reduces lock contention and improves concurrency. The LOAD PART utility also processes partitioned indexes with append logic, instead of the insert logic that it uses to process nonpartitioned indexes, which also improves performance.

---

## Monitoring of DB2 locking

If you have problems with suspensions, timeouts, or deadlocks, you will want to monitor DB2's use of locks.

**Recommendation:** As described in “Continuous performance monitoring” on page 638, always have statistics classes 1, 3, and 4 and accounting classes 1 and 3 running. The statistics reports provide counters for timeouts, deadlocks and suspensions. Statistics class 3 includes IFCID 0172 (deadlocks) and IFCID 0196 (deadlocks). If deadlocks or timeouts are a concern, print these detail records to investigate the situation during exceptional situations.

The accounting reports show the locking activity under the heading of LOCKING (as shown in Figure 95 on page 876). The other key indication of locking problems are the class 3 suspensions LOCK/LATCH(DB2+IRLM) (C in Figure 96 on page 878). If locking and latching are increasing the elapsed time of your transactions or batch work, you want to investigate further.

Use EXPLAIN to monitor the locks required by a particular SQL statement, or all the SQL in a particular plan or package, and see “Using EXPLAIN to tell which locks DB2 chooses.”

Use the statistics trace to monitor the system-wide use of locks, the accounting trace to monitor locks used by a particular application process, and see “Using the statistics and accounting traces to monitor locking” on page 875.

For an example of resolving a particular locking problem, see “Scenario for analyzing concurrency” on page 876.

## Using EXPLAIN to tell which locks DB2 chooses

The information under this heading, up to “Using the statistics and accounting traces to monitor locking” on page 875, is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

### *Procedure:*

1. Use the EXPLAIN statement, or the EXPLAIN option of the BIND and REBIND subcommands, to determine which modes of table and table space locks DB2 initially assigns for an SQL statement. Follow the instructions under “Obtaining PLAN\_TABLE information from EXPLAIN” on page 932. (EXPLAIN does not return information about the locks acquired on LOB table spaces.)
2. EXPLAIN stores its results in a table called PLAN\_TABLE. To review the results, query PLAN\_TABLE. After running EXPLAIN, each row of PLAN\_TABLE describes the processing for a single table, either one named explicitly in the SQL statement that is being explained or an intermediate table that DB2 has to create. The column TSLOCKMODE of PLAN\_TABLE shows an initial lock mode for that table. The lock mode applies to the table or the table space, depending on the value of LOCKSIZE and whether the table space is segmented or nonsegmented.
3. In Table 158, find what table or table space lock is used and whether page or row locks are used also, for the particular combination of lock mode and LOCKSIZE you are interested in.

*For statements executed remotely:* EXPLAIN gathers information only about data access in the DBMS where the statement is run or the bind operation is carried out. To analyze the locks obtained at a remote DB2 location, you must run EXPLAIN at that location. For more information on running EXPLAIN, and a fuller description of PLAN\_TABLE, see Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931.

*Table 158. Which locks DB2 chooses.* N/A = Not applicable; Yes = Page or row locks are acquired; No = No page or row locks are acquired.

Table space structure	Lock mode from EXPLAIN				
	IS	S	IX	U	X
For nonsegmented table spaces:					
Table space lock acquired is:	IS	S	IX	U	X
Page or row locks acquired?	Yes	No	Yes	No	No

**Note:** For partitioned table spaces, the lock mode applies only to those partitions that are locked. Lock modes for LOB table spaces are not reported with EXPLAIN.

Table 158. Which locks DB2 chooses (continued). N/A = Not applicable; Yes = Page or row locks are acquired; No = No page or row locks are acquired.

Table space structure	Lock mode from EXPLAIN				
	IS	S	IX	U	X
For segmented table spaces with: LOCKSIZE ANY, ROW, or PAGE					
Table space lock acquired is:	IS	IS	IX	n/a	IX
Table lock acquired is:	IS	S	IX	n/a	X
Page or row locks acquired?	Yes	No	Yes	n/a	No
LOCKSIZE TABLE					
Table space lock acquired is:	n/a	IS	n/a	IX	IX
Table lock acquired is:	n/a	S	n/a	U	X
Page or row locks acquired?	n/a	No	n/a	No	No
LOCKSIZE TABLESPACE					
Table space lock acquired is:	n/a	S	n/a	U	X
Table lock acquired is:	n/a	n/a	n/a	n/a	n/a
Page or row locks acquired?	n/a	No	n/a	No	No

## Using the statistics and accounting traces to monitor locking

The statistics and accounting trace records contain information on locking. OMEGAMON provides one way to view the trace results. The OMEGAMON reports for the Accounting Trace and Statistics Trace each corresponds to a single DB2 trace record. (Details of those reports are subject to change without notification from DB2 and are available in the appropriate OMEGAMON documentation).

Figure 94 shows a portion of the Statistics Trace, which tells how many suspensions (**A**), timeouts (**B**), deadlocks (**C**), and lock escalations (**D**) occur in the trace record. You can also use the statistics trace to monitor each occurrence of lock escalation.

LOCKING ACTIVITY	QUANTITY	/SECOND	/THREAD	/COMMIT
SUSPENSIONS (ALL) <b>A</b>	2	0.02	1.00	0.40
SUSPENSIONS (LOCK ONLY)	2	0.02	1.00	0.40
SUSPENSIONS (IRLM LATCH)	0	0.00	0.00	0.00
SUSPENSIONS (OTHER)	0	0.00	0.00	0.00
TIMEOUTS <b>B</b>	0	0.00	0.00	0.00
DEADLOCKS <b>C</b>	1	0.01	0.50	0.20
LOCK REQUESTS	17	0.18	8.50	3.40
UNLOCK REQUESTS	12	0.13	6.00	2.40
QUERY REQUESTS	0	0.00	0.00	0.00
CHANGE REQUESTS	5	0.05	2.50	1.00
OTHER REQUESTS	0	0.00	0.00	0.00
LOCK ESCALATION (SHARED) <b>D</b>	0	0.00	0.00	0.00
LOCK ESCALATION (EXCLUSIVE)	0	0.00	0.00	0.00
DRAIN REQUESTS	0	0.00	0.00	0.00
DRAIN REQUESTS FAILED	0	0.00	0.00	0.00
CLAIM REQUESTS	7	0.08	3.50	1.40
CLAIM REQUESTS FAILED	0	0.00	0.00	0.00

Figure 94. Locking activity blocks from statistics trace

Figure 95 shows a portion of the Accounting Trace, which gives the same information for a particular application (suspensions **A**, timeouts **B**, deadlocks **C**, lock escalations **D**). It also shows the maximum number of concurrent page locks held and acquired during the trace (E and F). Review applications with a large number to see if this value can be lowered. This number is the basis for the proper setting of LOCKS PER USER and, indirectly, LOCKS PER TABLE(SPACE).

LOCKING	TOTAL
-----	-----
TIMEOUTS <b>B</b>	0
DEADLOCKS <b>C</b>	0
ESCAL. (SHAR) <b>D</b>	0
ESCAL. (EXCL)	0
MAX PG/ROW LCK HELD <b>E</b>	2
LOCK REQUEST <b>F</b>	8
UNLOCK REQST	2
QUERY REQST	0
CHANGE REQST	5
OTHER REQST	0
LOCK SUSPENS.	1
IRLM LATCH SUSPENS.	0
OTHER SUSPENS.	0
TOTAL SUSPENS. <b>A</b>	1
DRAIN/CLAIM	TOTAL
-----	-----
DRAIN REQST	0
DRAIN FAILED	0
CLAIM REQST	4
CLAIM FAILED	0

Figure 95. Locking activity blocks from accounting trace

To determine the effect of lock suspensions on your applications, examine the class 3 LOCK/LATCH time in the Accounting Report (**C** in Figure 96 on page 878).

## Scenario for analyzing concurrency

The concurrency problem analyzed in this section illustrates the approach described in "A general approach to problem analysis in DB2" on page 652. It follows the CONCURRENCY PROBLEM branch of Figure 70 on page 655 and makes use of OMEGAMON reports. In OMEGAMON, a report titled "Trace" corresponds to a single DB2 trace record; a report titled "Report" summarizes information from several trace records. This scenario makes use of:

- Accounting report - long
- Locking suspension report
- Lockout report
- Lockout trace

"Scenario description" includes a description of the scenario, an explanation of how each report helps to analyze the situation, and some general information about corrective approaches.

### Scenario description

An application, which has recently been moved into production, is experiencing timeouts. Other applications have not been significantly affected in this example.

To investigate the problem, determine a period when the transaction is likely to time out. When that period begins:

1. Start the GTF.
2. Start the DB2 accounting classes 1, 2, and 3 to GTF to allow for the production of OMEGAMON accounting reports.
3. Stop GTF and the traces after about 15 minutes.
4. Produce and analyze the OMEGAMON accounting report - long.
5. Use the DB2 performance trace selectively for detailed problem analysis.

In some cases, the initial and detailed stages of tracing and analysis presented in this chapter can be consolidated into one. In other cases, the detailed analysis might not be required at all.

To analyze the problem, generally start with the accounting report - long. (If you have enough information from program and system messages, you can skip this first step.)

### **Accounting report**

Figure 96 on page 878 shows a portion of the accounting report - long.

Figure 96. Excerpt from accounting report - long

The accounting report - long shows the average elapsed times and the average number of suspensions per plan execution. In Figure 96:

- The class 1 average elapsed time **A** (AET) is 0.072929 seconds. The class 2 times show that 0.029443 seconds **B** of that are spent in DB2; the rest is spent in the application.
- The class 2 AET is spent mostly in lock or latch suspensions (LOCK/LATCH **C** is 0.000011 seconds).
- The HIGHLIGHTS section **D** of the report (upper right) shows #OCCURRENCES as 193; that is the number of accounting (IFCID 3) records.

### Lock suspension report

To prepare for using the lock suspension report, start DB2 performance class 6 to GTF. Because that class traces only suspensions, it does not significantly reduce

performance. Figure 97 shows the OMEGAMON lock suspension report.

```

:
PRIMAUTH  --- L O C K   R E S O U R C E  --- TOTAL  LOCAL  --SUSPEND REASONS--  ----- R E S U M E   R E A S O N S -----

-----
FPB
PARALLEL  PARTITION DB =PARADABA          2      2      0      0      0      N/C      2 303.277805  0      N/C
              OB =TAB1TS
              PART= 1
LOCKING REPORT COMPLETE

```

Figure 97. Portion of the OMEGAMON Lock suspension report

The lock suspension report shows:

- Which plans are suspended, by plan name within primary authorization ID. For statements bound to a package, see the information about the plan that executes the package.
- What IRLM requests and which lock types are causing suspensions.
- Whether suspensions are normally resumed or end in timeouts or deadlocks.
- What the average elapsed time (AET) per suspension is.

The report also shows the reason for the suspensions, as described in Table 159.

Table 159. Reasons for suspensions

Reason	Includes
LOCAL	Contention for a local resource
LATCH	Contention for latches within IRLM (with brief suspension)
GLOB.	Contention for a global resource
IRLMQ	An IRLM queued request
S.NFY	Intersystem message sending
OTHER	Page latch or drain suspensions, suspensions because of incompatible retained locks in data sharing, or a value for service use

The preceding list shows only the first reason for a suspension. When the original reason is resolved, the request could remain suspended for a second reason.

Each suspension results in either a normal resume, a timeout, or a deadlock.

The report shows that the suspension causing the delay involves access to partition 1 of table space PARADABA.TAB1TS by plan PARALLEL. Two LOCAL suspensions time out after an average of 5 minutes, 3.278 seconds (303.278 seconds).

### Lockout report

Figure 98 on page 880 shows the OMEGAMON lockout report. This report shows that plan PARALLEL contends with the plan DSNESPRR. It also shows that contention is occurring on partition 1 of table space PARADABA.TAB1TS.

PRMAUTH PLANNAME	--- L O C K R E S O U R C E ---				----- A G E N T S -----

LOCKING TRACE COMPLETE

```

Figure 99. Portion of the OMEGAMON lockout trace

At this point in the investigation, the following information is known:

- The applications that contend for resources
- The page sets for which there is contention
- The impact, frequency, and type of the contentions

The application or data design must be reviewed to reduce the contention.

## Corrective decisions

The preceding discussion is a general approach when lock suspensions are unacceptably long or timeouts occur. In such cases, the DB2 performance trace for locking and the OMEGAMON reports can be used to isolate the resource causing the suspensions. The lockout report identifies the resources involved. The lockout trace tells what contending process (agent) caused the timeout.

In Figure 97 on page 879, the number of suspensions is low (only 2) and both have ended in a timeout. Rather than use the DB2 performance trace for locking, use the

preferred option, DB2 statistics class 3 and DB2 performance trace class 1. Then produce the OMEGAMON locking timeout report to obtain the information necessary to reduce overheads.

For specific information about OMEGAMON reports and their usage, see *OMEGAMON Report Reference* and *Using IBM Tivoli OMEGAMON XE on z/OS*.

### **OMEGAMON online locking conflict display**

You can monitor locking conflicts by using the OMEGAMON online locking conflict display. The display shows what is waiting for resources and what is holding resources when a thread is suspended.

---

## **Deadlock detection scenarios**

The following section includes an examination of two different deadlock scenarios and an explanation of the use of the OMEGAMON deadlock detail report to determine the cause of the deadlock.

The OMEGAMON Locking Trace - Deadlock report formats the information contained in trace record IFCID 0172 (statistics class 3). The report outlines all the resources and agents involved in a deadlock and the significant locking parameters, such as lock state and duration, related to their requests.

These examples assume that statistics class 3 and performance class 1 are activated. Performance class 1 is activated to get IFCID 105 records, which contain the translated names for the database ID and the page set OBID.

The scenarios that follow use three of the DB2 sample tables, DEPT, PROJ, and ACT. They are all defined with LOCKSIZE ANY. Type 2 indexes are used to access all three tables. As a result, contention for locks is only on data pages.

### **Scenario 1: Two-way deadlock with two resources**

In this classic deadlock example, two agents contend for resources; the result is a deadlock in which one of the agents is rolled back. Two transactions and two resources are involved.

First, transaction LOC2A acquires a lock on one resource while transaction LOC2B acquires a lock on another. Next, the two transactions each request locks on the resource held by the other.

The transactions execute as follows:

#### **LOC2A**

1. Declare and open a cursor for update on DEPT and fetch from page 2.
2. Declare and open a cursor for update on PROJ and fetch from page 8.
3. Update page 2.
4. Update page 8.
5. Close both cursors and commit.

#### **LOC2B**

1. Declare and open a cursor for update on PROJ and fetch from page 8.
2. Declare and open a cursor for update on DEPT and fetch from page 2.
3. Update page 8.
4. Update page 2.
5. Close both cursors and commit.

Events take place in the following sequence:

1. LOC2A obtains a U lock on page 2 in table DEPT, to open its cursor for update.
2. LOC2B obtains a U lock on a page 8 in table PROJ, to open its cursor for update.
3. LOC2A attempts to access page 8, to open its cursor but cannot proceed because of the lock held by LOC2B.
4. LOC2B attempts to access page 2, to open its cursor but cannot proceed because of the lock held by LOC2A.

DB2 selects one of the transactions and rolls it back, releasing its locks. That allows the other transaction to proceed to completion and release its locks also.

Figure 100 shows the OMEGAMON Locking Trace - Deadlock report that is produced for this situation.

The report shows that the only transactions involved came from plans LOC2A and LOC2B. Both transactions came in from BATCH.

Figure 100. Deadlock scenario 1: Two transactions and two resources

The lock held by transaction 1 (LOC2A) is a data page lock on the DEPT table and is held in U state. (The value of MANUAL for duration means that, if the plan was bound with isolation level CS and the page was not updated, then DB2 is free to release the lock before the next commit point.)

Transaction 2 (LOC2B) was requesting a lock on the same resource, also of mode U and hence incompatible.

The specifications of the lock held by transaction 2 (LOC2B) are the same. Transaction 1 was requesting an incompatible lock on the same resource. Hence, the deadlock.

Finally, note that the entry in the trace, identified at **A**, is LOC2A. That is the selected thread (the “victim”) whose work is rolled back to let the other proceed.

## Scenario 2: Three-way deadlock with three resources

In this scenario, three agents contend for resources and the result is a deadlock in which one of the agents is rolled back. Three transactions and three resources are involved.

First, the three transactions each acquire a lock on a different resource. LOC3A then requests a lock on the resource held by LOC3B, LOC3B requests a lock on the resource held by LOC3C, and LOC3C requests a lock on the resource held by LOC3A.

The transactions execute as follows:

### LOC3A

1. Declare and open a cursor for update on DEPT and fetch from page 2.
2. Declare and open a cursor for update on PROJ and fetch from page 8.
3. Update page 2.
4. Update page 8.
5. Close both cursors and commit.

### LOC3B

1. Declare and open a cursor for update on PROJ and fetch from page 8.
2. Declare and open a cursor for update on ACT and fetch from page 8.
3. Update page 6.
4. Update page 8.
5. Close both cursors and commit.

### LOC3C

1. Declare and open a cursor for update on ACT and fetch from page 6.
2. Declare and open a cursor for update on DEPT and fetch from page 2.
3. Update page 6.
4. Update page 2.
5. Close both cursors and commit.

Events take place in the following sequence:

1. LOC3A obtains a U lock on page 2 in DEPT, to open its cursor for update.
2. LOC3B obtains a U lock on page 8 in PROJ, to open its cursor for update.
3. LOC3C obtains a U lock on page 6 in ACT, to open its cursor for update.
4. LOC3A attempts to access page 8 in PROJ but cannot proceed because of the lock held by LOC3B.
5. LOC3B attempts to access page 6 in ACT cannot proceed because of the lock held by LOC3C.
6. LOC3C attempts to access page 2 in DEPT but cannot proceed, because of the lock held by LOC3A.

DB2 rolls back LOC3C and releases its locks. That allows LOC3B to complete and release the lock on PROJ so that LOC3A can complete. LOC3C can then retry.

Figure 101 on page 884 shows the OMEGAMON Locking Trace - Deadlock report produced for this situation.

## Chapter 32. Using materialized query tables

The information in this chapter is Product-sensitive Programming Interface Information, as defined under “Notices” on page 1437.

*Materialized query tables* are tables that contain information that is derived and summarized from other tables. Materialized query tables pre-calculate and store the results of queries with expensive join and aggregation operations. By providing this summary information, materialized query tables can simplify query processing and greatly improve the performance of dynamic SQL queries. Materialized query tables are particularly effective in data warehousing applications.

*Automatic query rewrite* is the process DB2 uses to access data in a materialized query table. If you enable automatic query rewrite, DB2 determines if it can resolve a dynamic query or part of the query by using a materialized query table. If so, DB2 can rewrite the query to use the materialized query table instead of the underlying base tables. Keep in mind that a materialized query table can yield query results that are not current if the base tables change after the materialized query table is updated.

This chapter presents the following topics:

- “Introduction to materialized query tables and automatic query rewrite”
- “Defining a materialized query table” on page 887
- “Populating and maintaining materialized query tables” on page 890
- “Using multilevel security with materialized query tables” on page 892
- “Exploiting automatic query rewrite” on page 893
- “Materialized query table examples shipped with DB2” on page 902

---

### Introduction to materialized query tables and automatic query rewrite

Because databases have grown substantially over the years, queries must operate over huge amounts of data. For example, in a data warehouse environment, decision-support queries might need to operate over 1 to 10 terabytes of data, performing multiple joins and complex aggregation. As the amount of data has increased, so has the demand for more interactive queries.

Despite the increasing amount of data, these queries still require a response time in the order of minutes or seconds. In some cases, the only solution is to pre-compute the whole or parts of each query. You can store these pre-computed results in a materialized query table. You can then use the materialized query table to answer these complicated queries when the system receives them. Using a process called automatic query rewrite, DB2 recognizes when it can transparently rewrite a submitted query to use the stored results in a materialized query table. By querying the materialized query table instead of computing the results from the underlying base tables, DB2 can process some complicated queries much more efficiently. If the estimated cost of the rewritten query is less than the estimated cost of the original query, DB2 uses the rewritten query.

## Example of automatic query rewrite using a materialized query table

The following example shows how DB2 can use a materialized query table to improve the performance of a simple query. Although most uses of materialized query tables are much more complex than this example, this example does illustrate some basic concepts.

Suppose that you have a very large table named TRANS that contains one row for each transaction that a certain company processes. You want to tally the total amount of transactions by some time period. Although the table contains many columns, you are most interested in these four columns:

- YEAR, MONTH, DAY, which contain the date of a transaction
- AMOUNT, which contains the amount of the transaction

To total the amount of all transactions between 1995 and 2000, by year, you would use the following query:

```
SELECT YEAR, SUM(AMOUNT)
FROM TRANS
WHERE YEAR >= '1995' AND YEAR <= '2000'
GROUP BY YEAR
ORDER BY YEAR;
```

This query might be very expensive to run, particularly if the TRANS table is a very large table with millions of rows and many columns.

Now suppose that you define a materialized query table named STRANS by using the following CREATE TABLE statement:

```
CREATE TABLE STRANS AS
  (SELECT YEAR AS SYEAR,
        MONTH AS SMONTH,
        DAY AS SDAY,
        SUM(AMOUNT) AS SSUM
   FROM TRANS
   GROUP BY YEAR, MONTH, DAY)
DATA INITIALLY DEFERRED REFRESH DEFERRED;
```

After you populate STRANS with a REFRESH TABLE statement, the table contains one row for each day of each month and year in the TRANS table.

Using the automatic query rewrite process, DB2 can rewrite the original query into a new query. The new query uses the materialized query table STRANS instead of the original base table TRANS:

```
SELECT SYEAR, SUM(SSUM)
FROM STRANS
WHERE SYEAR >= '1995' AND SYEAR <= '2000'
GROUP BY SYEAR
ORDER BY SYEAR
```

If you maintain data currency in the materialized query table STRANS, the rewritten query provides the same results as the original query. The rewritten query offers better response time and requires less CPU time.

## Steps for using automatic query rewrite

To take advantage of using automatic query rewrite with materialized query tables, you should follow these steps:

1. Define materialized query tables.

2. Populate materialized query tables. Refresh materialized query tables periodically to maintain data currency with base tables. However, realize that refreshing materialized query tables can be an expensive process.
3. Enable automatic query rewrite, and exploit its functions by submitting read-only dynamic queries.
4. Evaluate the effectiveness of the materialized query tables. Drop under-utilized tables, and create new tables as necessary.

---

## Defining a materialized query table

A materialized query table contains pre-computed data that is a result of a query. The query not only defines the table, but also helps to populate the table. When you define a materialized query table, specify these attributes:

- **Type.** You can define a materialized query table as user-maintained or system-maintained.
- **Refreshability.** You can update user-maintained and system-maintained materialized query table with the REFRESH TABLE statement. You can update user-maintained materialized query tables with the LOAD utility and the UPDATE, INSERT, and DELETE SQL statements.
- **Query optimization enablement.** You can enable or disable the use of a materialized query table in automatic query rewrite.

This section includes the following topics:

- “Creating a new materialized query table”
- “Registering an existing table as a materialized query table” on page 888
- “Altering a materialized query table” on page 890

## Creating a new materialized query table

To create a new table as a materialized query table, use the CREATE TABLE statement, specifying a fullselect.

**Example:** The following CREATE TABLE statement defines a materialized query table named TRANSCNT. TRANSCNT summarizes the number of transactions in table TRANS by account, location, and year:

```
CREATE TABLE TRANSCNT (ACCTID, LOCID, YEAR, CNT) AS
  (SELECT ACCOUNTID, LOCATIONID, YEAR, COUNT(*)
   FROM TRANS
   GROUP BY ACCOUNTID, LOCATIONID, YEAR )
DATA INITIALLY DEFERRED
REFRESH DEFERRED
MAINTAINED BY SYSTEM
ENABLE QUERY OPTIMIZATION;
```

The fullselect, together with the DATA INITIALLY DEFERRED clause and the REFRESH DEFERRED clause, defines the table as a materialized query table.

You can explicitly specify the column names of the materialized query table or allow DB2 to derive the column names from the fullselect. The column definitions of a materialized query table are the same as those for a declared global temporary table that is defined with the same fullselect.

You must include the DATA INITIALLY DEFERRED and REFRESH DEFERRED clauses when you define a materialized query table.

- DATA INITIALLY DEFERRED means that DB2 does not populate the materialized query table when you create the table. You must explicitly populate the materialized query table.
  - For system-maintained materialized query tables, populate the tables for the first time by using the REFRESH TABLE statement.
  - For user-maintained materialized query tables, populate the table by using the LOAD utility, INSERT statement, or REFRESH TABLE statement.
- REFRESH DEFERRED means that DB2 does not immediately update the data in the materialized query table when its base tables are updated. You can use the REFRESH TABLE statement at any time to update materialized query tables and maintain data currency with underlying base tables.

The MAINTAINED BY SYSTEM clause, which is the default, specifies that the materialized query table is a system-maintained materialized query table. You cannot update a system-maintained materialized query table by using the LOAD utility or the INSERT, UPDATE, or DELETE statements. You can update a system-maintained materialized query table only by using the REFRESH TABLE statement.

Use the MAINTAINED BY USER clause to specify that the table is a user-maintained materialized query table. You can update a user-maintained materialized query table by using the LOAD utility, the INSERT, UPDATE, and DELETE statements, as well as the REFRESH TABLE statement.

The ENABLE QUERY OPTIMIZATION clause, which is the default, specifies that DB2 can consider the materialized query table in automatic query rewrite. Alternatively, you can specify DISABLE QUERY OPTIMIZATION to indicate that DB2 cannot consider the materialized query table in automatic query rewrite. When you enable query optimization, DB2 is more restrictive of what you can select in the fullselect for a materialized query table.

**Recommendation:** When creating a user-maintained materialized query table, initially disable query optimization. Otherwise, DB2 might automatically rewrite queries to use the empty materialized query table. After you populate the user-maintained materialized query table, you can alter the table to enable query optimization.

The isolation level of the materialized table is the isolation level at which the CREATE TABLE statement is executed.

After you create a materialized query table, it looks and behaves like other tables in the database system, with a few exceptions. DB2 allows materialized query tables in database operations wherever it allows other tables, with a few restrictions. The restrictions are listed in the description of the CREATE TABLE statement in *DB2 SQL Reference*. As with any other table, you can create indexes on the materialized query table; however, the indexes that you create must not be unique. Instead, DB2 uses the materialized query table's definition to determine if it can treat the index as a unique index for query optimization.

For information about using the CREATE TABLE statement to create a materialized query table, see *DB2 SQL Reference*.

## Registering an existing table as a materialized query table

You might already have manually created base tables that act like materialized query tables and have queries that directly access the base tables. These base tables

are often referred to as summary tables. To take advantage of automatic query rewrite for existing summary tables, you must use the ALTER TABLE statement to register them as materialized query tables.

**Example:** Assume that you have an existing summary table named TRANSCOUNT. TRANSCOUNT has four columns to track the number of transactions by account, location, and year. Assume that TRANSCOUNT was created with this CREATE TABLE statement:

```
CREATE TABLE TRANSCOUNT
  (ACCTID  INTEGER NOT NULL
   LOCID   INTEGER NOT NULL
   YEAR    INTEGER NOT NULL
   CNT     INTEGER NOT NULL);
```

The following SELECT statement then populated TRANSCOUNT with data that was derived from aggregating values in the TRANS table:

```
SELECT ACCTID, LOCID, YEAR, COUNT(*)
FROM TRANS
GROUP BY ACCTID, LOCID, YEAR ;
```

You could use the following ALTER TABLE statement to register TRANSCOUNT as a materialized query table. The statement specifies the ADD MATERIALIZED QUERY clause:

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY
  (SELECT ACCTID, LOCID, YEAR, COUNT(*) as cnt
   FROM TRANS
   GROUP BY ACCTID, LOCID, YEAR )
  DATA INITIALLY DEFERRED
  REFRESH DEFERRED
  MAINTAINED BY USER;
```

The fullselect must specify the same number of columns as the table you register as a materialized query table. The columns must have the same definitions and have the same column names in the same ordinal positions.

The DATA INITIALLY DEFERRED clause indicates that the table data is to remain the same when the ALTER statement completes. The MAINTAINED BY USER clause indicates that the table is user-maintained. You can continue to update the data in the table by using the LOAD utility or the INSERT, UPDATE, or DELETE statements. You can also use the REFRESH TABLE statement to update the data in the table. The table becomes immediately eligible for use in automatic query rewrite.

To ensure the accuracy of data that is used in automatic query rewrite, ensure that the summary table is current before registering it as a materialized query table. Alternatively, you can follow these steps:

- Register the summary table as a materialized query table with automatic query rewrite disabled.
- Update the newly registered materialized query table to refresh the data.
- Use the ALTER TABLE statement on the materialized query table to enable automatic query rewrite.

The isolation level of the materialized query table is the isolation level at which the ALTER TABLE statement is executed.

For more information about using the ALTER TABLE statement to register a base table as a materialized query table, see *DB2 SQL Reference*.

## Altering a materialized query table

You can use the ALTER TABLE statement to perform the following actions on a materialized query table:

- Change the attributes of a materialized query table.

You can enable or disable automatic query rewrite for a materialized query table with the ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION clause. You can change the type of materialized query table between system-maintained and user-maintained by using the MAINTAINED BY SYSTEM or MAINTAINED BY USER clause.

Altering a materialized query table to enable it for query optimization makes the table immediately eligible for use in automatic query rewrite. You must ensure that the data in the materialized query table is current. Otherwise, automatic query rewrite might return results that are not current.

- Change a materialized query table into a base table.

**Example:** Assume that you no longer want TRANSCOUNT to be a materialized query table. The following ALTER TABLE statement, which specifies the DROP MATERIALIZED QUERY clause, changes the materialized query table into a base table.

```
ALTER TABLE TRANSCOUNT DROP MATERIALIZED QUERY;
```

The column definitions and the data in the table do not change. However, DB2 can no longer use the table in automatic query rewrite. You can no longer update the table with the REFRESH TABLE statement. One reason you might want to change a materialized query table into a base table is to perform table operations that are restricted for a materialized query table.

**Example:** You might want to rotate the partitions on your partitioned materialized query table. In order to rotate the partitions, you must change your materialized query table into a base table. While the table is a base table, you can rotate the partitions. After you rotate the partitions, you can change the table back to a materialized query table.

In addition to using the ALTER TABLE statement, you can change a materialized query table by dropping the table and recreating the materialized query table with a different definition.

---

## Populating and maintaining materialized query tables

After you define a materialized query table, you need to maintain the accuracy of the data in the table. This maintenance includes populating the table for the first time and periodically refreshing the data in the table. You need to refresh the data because any changes that are made to the base tables are not automatically reflected in the materialized query table.

The only way to change the data in a system-maintained materialized query table is through the REFRESH TABLE statement. The INSERT, UPDATE, and DELETE statements, and the LOAD utility cannot refer to a system-maintained materialized query table as a target table. Therefore, a system-maintained materialized query table is read-only. Any view or cursor that is defined on a system-maintained materialized query table is read-only. However, for a user-maintained materialized query table, you can alter the data with the INSERT, UPDATE, and DELETE statements, and the LOAD utility. This section includes the following topics:

- “Using the REFRESH TABLE statement” on page 891
- “Using INSERT, UPDATE, DELETE, and LOAD for materialized query tables” on page 891

- “Collecting statistics on materialized query tables” on page 892

## Using the REFRESH TABLE statement

When you create a materialized query table with the CREATE TABLE statement, the table is not immediately populated. You can populate the table for the first time by using the REFRESH TABLE statement.

**Example:** The following REFRESH TABLE statement populates a materialized query table named SALESCNT:

```
REFRESH TABLE SALESCNT;
```

You can also use the REFRESH TABLE statement to refresh the data in any materialized query table at any time. The REFRESH TABLE statement performs the following actions:

- Deletes all the rows in the materialized query table
- Executes the fullselect in the materialized query table definition to recalculate the data from the tables that are specified in the fullselect with the isolation level for the materialized query table
- Inserts the calculated result into the materialized query table
- Updates the DB2 catalog with a refresh timestamp and the cardinality of the materialized query table

Although the REFRESH TABLE statement involves both deleting and inserting data, DB2 completes these operations in a single commit scope. Therefore, if a failure occurs during execution of the REFRESH TABLE statement, DB2 rolls back all changes that the statement made.

The REFRESH TABLE statement is an explainable statement. The explain output contains rows for INSERT with the fullselect in the materialized query table definition.

**Recommendation:** Create materialized query tables in segmented table spaces. Because the REFRESH TABLE statement triggers **mass** delete, the statement performs better if you put the materialized query table in a segmented table space. (See “Using INSERT, UPDATE, DELETE, and LOAD for materialized query tables” for information about how to refresh user-maintained materialized query tables in partitioned tables spaces more efficiently.)

## Using INSERT, UPDATE, DELETE, and LOAD for materialized query tables

For a user-maintained materialized query table, you can alter the data by using the INSERT, UPDATE, and DELETE statements, and the LOAD utility. You cannot use the INSERT, UPDATE, or DELETE statements, or the LOAD utility to change system-maintained materialized query tables.

**Recommendation:** Avoid the REFRESH TABLE statement. Because the REFRESH TABLE statement uses a fullselect to refresh a materialized query table, the statement can result in a long-running query. Therefore, using insert, update, delete, or load operations might be more efficient than using the REFRESH TABLE statement. For example, you might find it faster to generate the data for your materialized query table and execute the LOAD utility to populate the data.

Depending on the size and frequency of changes in base tables, you might use different strategies to refresh your materialized query tables. For example, for infrequent, minor changes to dimension tables, you could immediately propagate the changes to the materialized query tables by using triggers. For larger or more frequent changes, you might consider refreshing your user-maintained materialized query tables incrementally to improve performance.

**Example:** Assume that you need to add a large amount of data to a fact table. Then, you need to refresh your materialized query table to reflect the new data in the fact table. To do this, perform these steps:

- Collect and stage the new data in a separate table.
- Evaluate the new data and apply it to the materialized table as necessary.
- Merge the new data into the fact table

For an example of such code, see member DSNTEJ3M in DSN810.SDSNSAMP, which is shipped with DB2.

## Collecting statistics on materialized query tables

When you run the REFRESH TABLE statement, the only statistic that DB2 updates for the materialized query table is the cardinality statistic. For optimal performance of materialized query tables, you need to provide DB2 with accurate catalog statistics for access path selection. To keep catalog statistics current, you should run the RUNSTATS utility after executing a REFRESH TABLE statement or after changing the materialized query table significantly. Otherwise, DB2 uses default or out-of-date statistics. The estimated performance of queries that are generated by automatic rewrite might inaccurately compare less favorably to the original query.

---

## Using multilevel security with materialized query tables

Tables with multilevel security enabled contain a security label column, which is defined with the AS SECURITY LABEL clause. The values in the security label column indicate which users can access the data in each row. If source tables have multilevel security with row-level granularity enabled, some additional rules apply to working with the materialized query table and the source tables.

This section describes the rules that are specific to tables with multilevel security enabled. For more information about multilevel security, see “Multilevel security” on page 192.

## Creating a materialized query table

If one or more source tables in the materialized query table definition contain a security label column, the following rules apply to creating a materialized query table:

- If only one source table contains a security label column, the following conditions apply:
  - You must define the security label column in the materialized query table definition with the AS SECURITY LABEL clause.
  - The materialized query table inherits the security label column from the source table.
  - The MAINAINED BY USER option is allowed.
- If only one source table contains a security label column and the materialized query table is defined with the DEFINITION ONLY clause, the materialized

| query table inherits the values in the security label column from the source  
| table. However, the inherited column is not a security label column.

- If more than one source table contains a security label column, DB2 returns an error code and the materialized query table is not created.

## | **Altering a source table**

| An ALTER TABLE statement to add a security label column to a table fails if the  
| table is a source table for a materialized query table.

## | **Refreshing a materialized query table**

| The REFRESH TABLE statement deletes the data in a materialized query table and  
| then repopulates the materialized query table according to its table definition.  
| During this refresh process, DB2 does not check for multilevel security with  
| row-level granularity.

---

## | **Exploiting automatic query rewrite**

| Automatic query rewrite compares user queries with the fullselect query that  
| defined a materialized query table. It then determines whether the contents of a  
| materialized query table overlap with the contents of a query. When an overlap  
| exists, the query and the materialized query table are said to **match**. After  
| discovering a match, DB2 rewrites the query to access the matched materialized  
| query table instead of the one or more base tables that the original query specified.  
| If a materialized query table overlaps with only part of a query, automatic query  
| rewrite can use the partial match. Automatic query rewrite compensates for the  
| non-overlapping parts of the query by accessing the tables that are specified in the  
| original query.

| Automatic query rewrite tries to search for materialized query tables that result in  
| an access path with the lowest cost after the rewrite. DB2 compares the estimated  
| costs of the rewritten query and of the original query and chooses the query with  
| the lower estimated cost.

| Many factors determine how well DB2 can exploit automatic query rewrite. This  
| section describes the following factors:

- “Making materialized query tables eligible”
- “Query requirements and the rewrite process” on page 895
- “Recommendations for materialized query table and base table design” on page 901

## | **Making materialized query tables eligible**

| The following criteria determine whether DB2 can consider using a materialized  
| query table in automatic query rewrite:

- The definition of the materialized query table
- The isolation level of the materialized query table
- The value of two special registers for the materialized query table

| To be eligible for use in automatic query rewrite, a materialized query table must  
| be defined with the ENABLE QUERY OPTIMIZATION clause. Additionally, the  
| isolation level of the table must be equal to or higher than the isolation level of the  
| dynamic query being considered for automatic query rewrite. Finally, special  
| registers CURRENT REFRESH AGE and CURRENT MAINTAINED TABLE TYPES  
| FOR OPTIMIZATION also affect whether a materialized query table is eligible for  
| use.

The value in special register CURRENT REFRESH AGE represents a *refresh age*. The refresh age of a materialized query table is the time since the REFRESH TABLE statement last refreshed the table. (When you run the REFRESH TABLE statement, you update the timestamp in the REFRESH\_TIME column in catalog table SYSVIEWS.) The special register CURRENT REFRESH AGE specifies the maximum refresh age that a materialized query table can have. Specifying the maximum age ensures that automatic query rewrite does not use materialized query tables with old data. In Version 8, the CURRENT REFRESH AGE has only two values: 0 or ANY. A value of 0 means that DB2 will consider no materialized query tables in automatic query rewrite. A value of ANY means that DB2 will consider all materialized query tables in automatic query rewrite.

The refresh age of a user-maintained materialized query table might not truly represent the freshness of the data in the table. In addition to the REFRESH TABLE statement, user-maintained query tables can be updated with the INSERT, UPDATE, and DELETE statements and the LOAD utility. Therefore, you can use the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register to determine which type of materialized query tables, system-maintained or user-maintained, are considered in automatic query rewrite. The special register has four possible values that indicate which materialized query tables DB2 considers for automatic query rewrite:

- SYSTEM** DB2 considers only system-maintained materialized query tables.
- USER** DB2 considers only user-maintained materialized query tables.
- ALL** DB2 considers both types of materialized query tables.
- NONE** DB2 considers no materialized query tables.

The CURRENT REFRESH AGE and CURRENT MAINT TYPES fields on installation panel DSNTIP4 determine the initial values of the registers. The default value for the CURRENT REFRESH AGE field is 0, and the default value for CURRENT MAINT TYPES is SYSTEM. If your DB2 subsystem is used exclusively for data warehousing, your applications might tolerate data that is not current. If so, set the parameters on the installation panel to enable automatic query rewrite for both system-maintained and user-maintained materialized query tables by default.

Table 160 summarizes how to use the CURRENT REFRESH AGE and CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special registers together. The table shows which materialized query tables DB2 considers in automatic query rewrite.

Table 160. The relationship between CURRENT REFRESH AGE and CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special registers

Value of CURRENT REFRESH AGE	Value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION			
	SYSTEM	USER	ALL	None
ANY	All system-maintained materialized query tables	All user-maintained materialized query tables	All materialized query tables (both system-maintained and user-maintained)	None
0	None	None	None	None

You must populate a system-maintained materialized query table before DB2 considers it in automatic query rewrite.

## Query requirements and the rewrite process

DB2 supports automatic query rewrite only for read-only, dynamic queries that do not contain parameter markers. DB2 cannot automatically rewrite statically bound queries. You can always refer to a materialized query table explicitly in a statically bound query or in a dynamically prepared query. However, you should consider updating materialized query table data more frequently if you frequently query the table directly. Also, allowing end users to refer directly to materialized query tables reduces an installation's flexibility of dropping and creating materialized query tables without affecting applications.

### Query rewrite analysis

In general, DB2 considers automatic query rewrite at the query block level. A read-only, dynamic query can contain multiple query blocks. For example, it might contain a subselect of UNION or UNION ALL, temporarily materialized views, materialized table expressions, and subquery predicates. DB2 processes the query without automatic query rewrite if the query block is or contains any of the following items:

- A fullselect in the UPDATE SET statement.
- A fullselect in the INSERT statement.
- A fullselect in the materialized query table definition in the REFRESH TABLE statement.
- An outer join.
- A query block contains user-defined scalar or table functions with the EXTERNAL ACTION attribute or the NON-DETERMINISTIC attribute, or with the built-in function RAND.
- Parameter markers.

If none of these items exist in the query block, DB2 considers automatic query rewrite. DB2 analyzes the query block in the user query and the fullselect in the materialized query table definition to determine if it can rewrite the query. The materialized query table must contain the data from the source tables (both columns and rows) that DB2 needs to satisfy the query. For DB2 to choose a rewritten query, the rewritten query must provide the same results as the user query. (DB2 assumes data currency in the materialized query table.) Furthermore, the rewritten query must offer better performance than the original user query.

DB2 performs a sophisticated analysis to determine whether it can obtain the results for the query from a materialized query table:

- DB2 compares the set of base tables that were used to populate the materialized query table to the set of base tables that are referenced by the user query. If these sets of tables share base tables in common, the query is a candidate for query rewrite.
- DB2 compares the predicates in the materialized query table fullselect to the predicates in the user query. The following factors influence the comparison:
  - The materialized query table fullselect might contain predicates that are not in the user query. If so, DB2 assumes that these predicates might have resulted in discarded rows when the materialized query table was refreshed. Thus, any rewritten query that makes use of the materialized query table might not give the correct results. The query is not a candidate for query rewrite.

**Exception:** DB2 behavior differs if a predicate joins a common base table to an extra table that is unique to the materialized query table fullselect. The predicate does not result in discarded data if you define a referential constraint between the two base tables to make the predicate *lossless*.

However, the materialized query table fullselect must not have any local predicates that reference this extra table.

For an example of a lossless predicate, see Example 2 under “Examples of automatic query rewrite.”

- Referential constraints on the source tables are very important in determining whether automatic query rewrite uses a materialized query table.
  - Predicates are much more likely to match if you code the predicate in the user query so that it is the same or very similar to the predicate in the materialized query table fullselect. Otherwise, the matching process might fail on some complex predicates. For example, the matching process between the simple equal predicates such as  $COL1 = COL2$  and  $COL2 = COL1$  succeeds. Furthermore, the matching process between simple equal predicates such as  $COL1 * (COL2 + COL3) = COL5$  and  $COL5 = (COL3 + COL2) * COL1$  succeeds. However, the matching process between equal predicates such as  $(COL1 + 3) * 10 = COL2$  and  $COL1 * 10 + 30 = COL2$  fails.
  - The items in an IN-list predicate do not need to be in exactly the same order for predicate matching to succeed.
- DB2 compares GROUP BY clauses in the user query to GROUP BY clauses in the materialized query table fullselect. If the user query requests data at the same or higher grouping level as the data in the materialized query table fullselect, the materialized query table remains a candidate for query rewrite. DB2 uses functional dependency information and column equivalence in this analysis.
  - DB2 compares the columns that are requested by the user query with the columns in the materialized query table. If DB2 can derive the result columns from one or more columns in the materialized query table, the materialized query table remains a candidate for query rewrite. DB2 uses functional dependency information and column equivalence in this analysis.
  - DB2 examines predicates in the user query that are not identical to predicates in the materialized query table fullselect. Then, DB2 determines if it can derive references to columns in the base table from columns in the materialized query table instead. If DB2 can derive the result columns from the materialized query table, the materialized query table remains a candidate for query rewrite.

If all of the preceding analyses succeed, DB2 rewrites the user query. DB2 replaces all or some of the references to base tables with references to the materialized query table. If DB2 finds several materialized query tables that it can use to rewrite the query, it might use multiple tables simultaneously. If DB2 cannot use the tables simultaneously, it uses heuristic rules to choose which one to use. After DB2 writes the new query, DB2 determines the cost and the access path of that query. DB2 uses the rewritten query if the estimated cost of the rewritten query is less than the estimated cost of the original query. The rewritten query might give only approximate results if the data in the materialized query table is not up to date.

### **Examples of automatic query rewrite**

The following examples help you understand how DB2 applies automatic query rewrite to improve query performance. Assume a scenario in which a data warehouse has a star schema. The star schema represents the data of a simplified credit card application, as shown in Figure 102 on page 897.

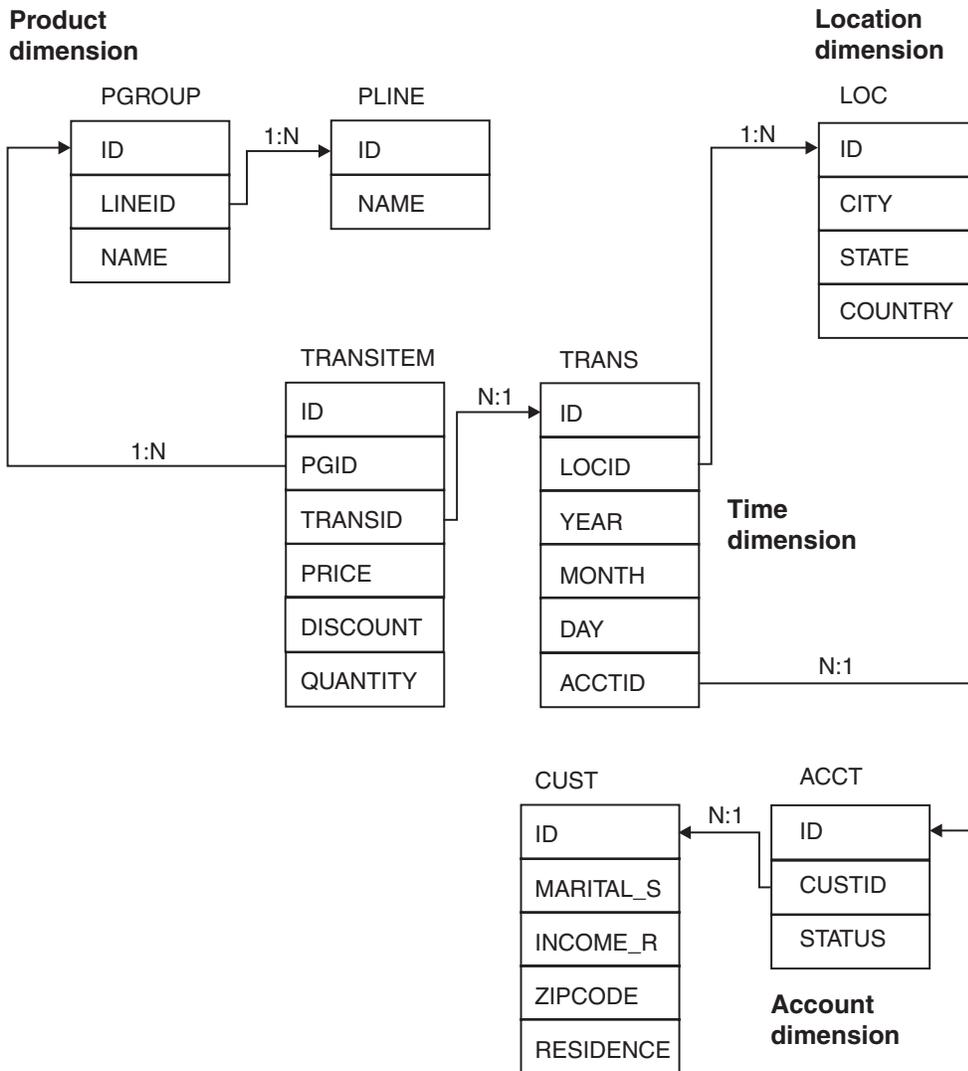

Figure 102. Multi-fact star schema. In this simplified credit card application, the fact tables TRANSITEM and TRANS form the hub of the star schema. The schema also contains four dimensions: product, location, account, and time.

The data warehouse records transactions that are made with credit cards. Each transaction consists of a set of items that are purchased together. At the center of the data warehouse are two large fact tables. TRANS records the set of credit card purchase transactions. TRANSITEM records the information about the items that are purchased. Together, these two fact tables are the hub of the star schema. The star schema is a multi-fact star schema because it contains these two fact tables. The fact tables are continuously updated for each new credit card transaction.

In addition to the two fact tables, the schema contains four dimensions that describe transactions: product, location, account, and time.

- The product dimension consists of two normalized tables, PGROUP and PLINE, that represent the product group and product line.
- The location dimension consists of a single, denormalized table, LOC, that contains city, state, and country.
- The account dimension consists of two normalized tables, ACCT and CUST, that represent the account and the customer.
- The time dimension consists of the TRANS table that contains day, month, and year.

Analysts of such a credit card application are often interested in the aggregation of the sales data. Their queries typically perform joins of one or more dimension tables with fact tables. The fact tables contain significantly more rows than the dimension tables, and complicated queries that involve large fact tables can be very costly. In many cases, you can use materialized query table to summarize and store information from the fact tables. Using materialized query tables can help you avoid costly aggregations and joins against large fact tables.

**Example 1:** An analyst submits the following query to count the number of transactions that are made in the United States for each credit card. The analyst requests the results grouped by credit card account, state, and year:

```
UserQ1
-----
SELECT T.ACCTID, L.STATE, T.YEAR, COUNT(*) AS CNT
      FROM TRANS T, LOC L
      WHERE T.LOCID = L.ID AND
            L.COUNTRY = 'USA'
      GROUP BY T.ACCTID, L.STATE, T.YEAR;
```

Assume that the following CREATE TABLE statement created a materialized query table named TRANSCNT:

```
CREATE TABLE TRANSCNT AS
  (SELECT ACCTID, LOCID, YEAR, COUNT(*) AS CNT
   FROM TRANS
   GROUP BY ACCTID, LOCID, YEAR )
 DATA INITIALLY DEFERRED
 REFRESH DEFERRED;
```

If you enable automatic query rewrite, DB2 can rewrite UserQ1 as NewQ1. NewQ1 accesses the TRANSCNT materialized query table instead of the TRANS fact table.

```
NewQ1
-----
SELECT A.ACCTID, L.STATE, A.YEAR, SUM(A.CNT) AS CNT
      FROM TRANSCNT A, LOC L
      WHERE A.LOCID = L.ID AND
            L.COUNTRY = 'USA'
      GROUP BY A.ACCTID, L.STATE, A.YEAR;
```

DB2 can use query rewrite in this case because of the following reasons:

- The TRANS table is common to both UserQ1 and TRANSCNT.
- DB2 can derive the columns of the query result from TRANSCNT.
- The GROUP BY in the query requests data that are grouped at a higher level than the level in the definition of TRANSCNT.

Because customers typically make several hundred transactions per year with most of them in the same city, TRANSCNT is about hundred times smaller than TRANS. Therefore, rewriting UserQ1 into a query that uses TRANSCNT instead of TRANS improves response time significantly.

**Example 2:** Assume that an analyst wants to find the number of televisions, with a price over 100 and a discount greater than 0.1, that were purchased by each credit card account. The analyst submits the following query:

```
UserQ2
-----
SELECT T.ID, TI.QUANTITY * TI.PRICE * (1 - TI.DISCOUNT) AS AMT
      FROM TRANSITEM TI, TRANS T, PGROUP PG
      WHERE TI.TRANSID = T.ID AND
```

```

TI.PGID = PG.ID    AND
TI.PRICE > 100    AND
TI.DISCOUNT > 0.1 AND
PG.NAME = 'TV';

```

If you define the following materialized query table TRANSIAB, DB2 can rewrite UserQ2 as NewQ2:

```

TRANSIAB
-----
CREATE TABLE TRANSIAB AS
(SELECT TI.TRANSID, TI.PRICE, TI.DISCOUNT, TI.PGID,
      L.COUNTRY, TI.PRICE * TI.QUANTITY as VALUE
 FROM TRANSITEM TI, TRANS T, LOC L
 WHERE TI.TRANSID = T.ID AND
       T.LOCID = L.ID    AND
       TI.PRICE > 1     AND
       TI.DISCOUNT > 0.1)
DATA INITIALLY DEFERRED
REFRESH DEFERRED;

```

```

NewQ2
-----
SELECT A.TRANSID, A.VALUE * (1 - A.DISCOUNT) as AM
 FROM TRANSIAB A, PGROUP PG
 WHERE A.PGID = PG.ID    AND
       A.PRICE > 100    AND
       PG.NAME = 'TV';

```

DB2 can rewrite UserQ2 as a new query that uses materialized query table TRANSIAB because of the following reasons:

- Although the predicate T.LOCID = L.ID appears only in the materialized query table, it does not result in rows that DB2 might discard. The referential constraint between the TRANS.LOCID and LOC.ID columns makes the join between TRANS and LOC in the materialized query table definition lossless. The join is lossless only if the foreign key in the constraint is NOT NULL.
- The predicates TI.TRANSID = T.ID and TI.DISCOUNT > 0.1 appear in both the user query and the TRANSIAB fullselect.
- The fullselect predicate TI.PRICE > 1 in TRANSIAB subsumes the user query predicate TI.PRICE > 100 in UserQ2. Because the fullselect predicate is more inclusive than the user query predicate, DB2 can compute the user query predicate from TRANSIAB.
- The user query predicate PG.NAME = 'TV' refers to a table that is not in the TRANSIAB fullselect. However, DB2 can compute the predicate from the PGROUP table. A predicate like PG.NAME='TV' does not disqualify other predicates in a query from qualifying for automatic query rewrite. In this case PGROUP is a relatively small dimension table, so a predicate that refers to the table is not overly costly.
- DB2 can derive the query result from the materialized query table definition, even when the derivation is not readily apparent:
  - DB2 derives T.ID in the query from T.TRANSID in the TRANSIAB fullselect. Although these two columns originate from different tables, they are equivalent because of the predicate T.TRANSID = T.ID. DB2 recognizes such column equivalency through join predicates. Thus, DB2 derives T.ID from T.TRANSID, and the query qualifies for automatic query rewrite.
  - DB2 derives AMT in the query UserQ2 from DISCOUNT and VALUE in the TRANSIAB fullselect.

*Example 3:* This example shows how DB2 matches GROUP BY items and aggregate functions between the user query and the materialized query table fullselect. Assume that an analyst submits the following query to find the average value of the transaction items for each year:

```
UserQ3
-----
SELECT YEAR, AVG(QUANTITY * PRICE) AS AVGVAL
  FROM TRANSITEM TI, TRANS T
  WHERE TI.TRANSID = T.ID
  GROUP BY YEAR;
```

If you define the following materialized query table TRANSAVG, DB2 can rewrite UserQ3 as NewQ3:

```
TRANSAVG
-----
CREATE TABLE TRANSAVG AS
  (SELECT T.YEAR, T.MONTH, SUM(QUANTITY * PRICE) AS TOTVAL, COUNT(*) AS CNT
   FROM TRANSITEM TI, TRANS T
   WHERE TI.TRANSID = T.ID
   GROUP BY T.YEAR, T.MONTH )
  DATA INITIALLY DEFERRED
  REFRESH DEFERRED;
```

```
NewQ3
-----
SELECT YEAR, CASE WHEN SUM(CNT) = 0 THEN NULL
                  ELSE SUM(TOTVAL)/SUM(CNT)
                  END AS AVGVAL
  FROM TRANSAVG
  GROUP BY YEAR;
```

DB2 can rewrite UserQ3 as a new query that uses materialized query table TRANSAVG because of the following reasons:

- DB2 considers YEAR in the user query and YEAR in the materialized query table fullselect to match exactly.
- DB2 can derive the AVG function in the user query from the SUM function and the COUNT function in the materialized query table fullselect.
- The GROUP BY in the query NewQ3 requests data at a higher level than the level in the definition of TRANSAVG.
- DB2 can compute the yearly average in the user query by using the monthly sums and counts of transaction items in TRANSAVG. DB2 derives the yearly averages from the CNT and TOTVAL columns of the materialized query table by using a case expression.

### Determining if query rewrite occurred

You can use EXPLAIN to determine if DB2 has rewritten a user query to use a materialized query table. When DB2 rewrites the query, the PLAN TABLE shows the name of the materialized query that DB2 uses. The value of the TABLE\_TYPE column is M to indicate that the table is a materialized query table.

*Example:* Consider the following user query (from Example 3):

```
SELECT YEAR, AVG(QUANTITY * PRICE) AS AVGVAL
  FROM TRANSITEM TI, TRANS T
  WHERE TI.TRANSID = T.ID
  GROUP BY YEAR;
```

If DB2 rewrites the query to use a materialized query table, a portion of the plan table output might look like Table 161 on page 901.

Table 161. Plan table output for an example with a materialized query table

PLANNO	METHOD	TNAME	JOIN_TYPE	TABLE_TYPE
1	0	TRANSAVG	-	M
2	3	2	-	?

The value M in TABLE\_TYPE indicates that DB2 used a materialized query table. TNAME shows that DB2 used the materialized query table named TRANSAVG. You can also obtain this information from a performance trace (IFCID 0022).

## Recommendations for materialized query table and base table design

Implementing the following recommendations might improve the performance of your materialized query tables and the queries that use them. These recommendations, however, do not represent a complete design theory.

### Materialized query table design

The following recommendations refer directly to designing your materialized query tables:

- Include aggregate functions strategically in the fullselect of a materialized query table definition:
  - Include COUNT(\*) and SUM(expression).
  - Include SUM(expression\*expression) only if you plan to query VAR(expression), STDDEV(expression), VAR\_SAMP(expression), or STDDEV\_SAMP(expression).
  - Include COUNT(expression) in addition to COUNT(\*) if expression is nullable.
  - Include MIN(expression) and MAX(expression) if you will query them.
  - Do not include AVG(expression), VAR(expression), or STDDEV(expression) directly if you include either of the following parameter combinations:
    - SUM(expression), SUM(expression\*expression), and COUNT(\*)
    - SUM(expression), SUM(expression\*expression), and COUNT(expression)
 DB2 can derive AVG(expression), VAR(expression), and STDDEV(expression) from SUM(expression), SUM(expression\*expression), and the appropriate COUNT aggregate function.
- Include the foreign key of a dimension table in the GROUP BY clause of a materialized query table definition. For example, if you include PGROUP.ID, also include PGROUP.LINEID. Then DB2 can use the materialized query table to derive a summary at the LINEID level, without rejoining PGROUP.
- Include all the higher-level columns in the materialized query table if DB2 does not know the functional dependency in a denormalized dimension table. For example, if you include CITY in a GROUP BY clause, also include STATE and COUNTRY in the clause. Similarly, if you include MONTH in the GROUP BY clause, also include YEAR in the clause.
- Do not use the HAVING clause in your materialized query tables. A materialized query table with a HAVING clause in its definition has limited usability during query rewrite.
- Create indexes on materialized query tables as you would for base tables.

## Base table design

The following recommendations refer to base table design strategies that might increase the performance and eligibility of your materialized query tables:

- Define referential integrity as either ENFORCED or NOT ENFORCED whenever possible. Also, define an index as unique if it is truly unique.
- Define all base table columns as NOT NULL if possible, so that COUNT(X) is the same as COUNT(\*). Then you do not need to include COUNT(X) for each nullable column X in a materialized query table definition. If necessary, use a special value to replace NULL.
- Prefer normalized dimension design to denormalized dimension design in your base tables. When you use normalized dimension design, you do not need to include non-primary key columns in a materialized query table, thereby saving you storage space. DB2 compensates for the lack of non-primary key columns by deriving these columns through a re-join of the dimension table. If performance is a concern due to normalization, you can define materialized query tables to denormalize the snowflake dimensions, if necessary.

---

## Materialized query table examples shipped with DB2

In addition to the examples shown in this chapter, DB2 provides a number of samples to help you design materialized query tables for automatic query rewrite. The samples are based on a data warehouse with a star schema database. The star schema contains one fact table, SALESFACT, and these four hierarchical dimensions:

- A time dimension that consists of one dimension table
- A product dimension that is a snowflake that consists of four fully normalized tables
- A location dimension that is a snowflake that consists of five partially normalized tables
- A customer dimension that is a snowflake that consists of four fully normalized tables

See member DSNTEJ3M in data set DSN810.SDSNSAMP for all of the code, including the following items:

- SQL statements to create and populate the star schema
- SQL statements to create and populate the materialized query tables
- Queries that DB2 rewrites to use the materialized query table

---

## Chapter 33. Maintaining statistics in the catalog

Statistics that are stored in the DB2 catalog help DB2 to determine the access paths for your SQL statements and help to optimize performance. This chapter contains the following sections related to catalog statistics:

- “Statistics used for access path selection”
- “Setting default statistics for created temporary tables” on page 912
- “History statistics” on page 913
- “Gathering monitor statistics and update statistics” on page 916
- “Updating the catalog” on page 917
- “Querying the catalog for statistics” on page 920
- “Improving index and table space access” on page 920
- “Modeling your production system” on page 927

*Other considerations for access path selection:* In addition to considering catalog statistics, database design, and the SQL statement, the optimizer also considers the central processor model, number of central processors, buffer pool size, and RID pool size. The number of processors is used only when determining degrees of parallelism.

Access path selection uses buffer pool statistics for several calculations. Access path selection also considers the central processor model. These two factors can change your queries’ access paths from one system to another, even if all the catalog statistics are identical. You should keep this in mind when migrating from a test system to a production system, or when modeling a new application.

Mixed central processor models in a data sharing group can also affect access path selection. For more information on data sharing, see *DB2 Data Sharing: Planning and Administration*.

---

### Statistics used for access path selection

Table 162 lists the statistics in the DB2 catalog that are used for access path selection, the values that trigger the use of a default value, and the corresponding defaults.

Information in the catalog tables SYSTABLES and SYSTABLESPACE tells how much data is in your table and how many pages hold data. Information in SYSINDEXES lets you compare the available indexes on a table to determine which one is the most efficient for a query. SYSCOLUMNS and SYSCOLDIST provide information to estimate filter factors for predicates.

*Table 162. Catalog data used for access path selection or collected by RUNSTATS*

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
<b>In every table updated by RUNSTATS:</b>				

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
STATTIME	Yes	Yes	No	If updated most recently by RUNSTATS, the date and time of that update, not updatable in SYSINDEXPART and SYSTABLEPART. Used for access path selection for SYSCOLDIST if duplicate column values exist for the same column (by user insertion).
<b>SYSIBM.SYSCOLDIST</b>				
CARDF	Yes	Yes	Yes	The number of distinct values for the column group, -1 if TYPE is F
COLGROUPCOLNO	Yes	Yes	Yes	The set of columns associated with the statistics. Contains an empty string if NUMCOLUMNS = 1.
COLVALUE	Yes	Yes	Yes	Frequently occurring value in the distribution
FREQUENCYF	Yes	Yes	Yes	A number which, multiplied by 100, gives the percentage of rows that contain the value of COLVALUE. For example, 1 means 100% of the rows contain the value and .15 indicates that 15% of the rows contain the value.
NUMCOLUMNS	Yes	Yes	Yes	The number of columns associated with the statistics. The <b>default value</b> is 1.
TYPE	Yes	Yes	Yes	The type of statistics gathered, either cardinality (C) or frequent value (F)
<b>SYSIBM.SYSCOLDISTSTATS: contains statistics by partition</b>				
CARDF	Yes	Yes	No	The number of distinct values for the column group, -1 if TYPE is F
COLGROUPCOLNO	Yes	Yes	No	The set of columns associated with the statistics
COLVALUE	Yes	Yes	No	Frequently occurring value in the distribution
FREQUENCYF	Yes	Yes	No	A number which, multiplied by 100, gives the percentage of rows that contain the value of COLVALUE. For example, 1 means 100% of the rows contain the value and .15 indicates that 15% of the rows contain the value.
KEYCARDATA	Yes	Yes	No	The internal representation of the estimate of the number of distinct values in the partition.
NUMCOLUMNS	Yes	Yes	No	The number of columns associated with the statistics. The <b>default value</b> is 1.
TYPE	Yes	Yes	No	The type of statistics gathered, either cardinality (C) or frequent value (F)
<b>SYSIBM.SYSCOLSTATS: contains statistics by partition</b>				

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
COLCARD	Yes	Yes	No	The number of distinct values in the partition. Do not update this column manually without first updating COLCARDATA to a value of length 0.
COLCARDATA	Yes	Yes	No	The internal representation of the estimate of the number of distinct values in the partition. A value appears here only if RUNSTATS TABLESPACE is run on the partition. Otherwise, this column contains a string of length 0, indicating that the actual value is in COLCARD.
HIGHKEY	Yes	Yes	No	First 2000 bytes of the highest value of the column within the partition. Blank if LOB column.
HIGH2KEY	Yes	Yes	No	First 2000 bytes of the second highest value of the column within the partition. Blank if LOB column.
LOWKEY	Yes	Yes	No	First 2000 bytes of the lowest value of the column within the partition. Blank if LOB column.
LOW2KEY	Yes	Yes	No	First 2000 bytes of the second lowest value of the column within the partition. Blank if LOB column.
<b>SYSIBM.SYSCOLUMNS</b>				
COLCARDF	Yes	Yes	Yes	Estimated number of distinct values in the column, -1 to trigger DB2's use of the <b>default value</b> (25) and -2 for the first column of an index of an auxiliary table
HIGH2KEY	Yes	Yes	Yes	First 2000 bytes of the second highest value in this column. Blank for auxiliary index.
LOW2KEY	Yes	Yes	Yes	First 2000 bytes of the second lowest value in this column. Blank for auxiliary index.
<b>SYSIBM.SYSINDEXES</b>				
AVGKEYLEN	Yes	Yes	No	Average key length
CLUSTERED	Yes	Yes	No	Whether the table is actually clustered by the index. Blank for auxiliary index.
CLUSTERING	No	No	Yes	Whether the index was created using CLUSTER

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
CLUSTERRATIOF	Yes	Yes	Yes	A number which, when multiplied by 100, gives the percentage of rows in clustering order. For example, 1 indicates that all rows are in clustering order and .87825 indicates that 87.825% of the rows are in clustering order. For a partitioned index, it is the weighted average of all index partitions in terms of the number of rows in the partition. For an auxiliary index it is -2. If this column contains the default, 0, DB2 uses the value in CLUSTERRATIO, a percentage, for access path selection.
FIRSTKEYCARDF	Yes	Yes	Yes	Number of distinct values of the first key column, or an estimate if updated while collecting statistics on a single partition, -1 to trigger DB2's use of the <b>default value</b> (25)
FULLKEYCARDF	Yes	Yes	Yes	Number of distinct values of the full key, -1 to trigger DB2's use of the <b>default value</b> (25)
NLEAF	Yes	Yes	Yes	Number of active leaf pages in the index, -1 to trigger DB2's use of the <b>default value</b> (SYSTABLES.CARD/300)
NLEVELS	Yes	Yes	Yes	Number of levels in the index tree, -1 to trigger DB2's use of the <b>default value</b> (2)
SPACEF	Yes	Yes	No	Disk storage in KB
<b>SYSIBM.SYSINDEXPART:</b> contains statistics for space utilization				
I AVGKEYLEN	Yes	Yes	No	Average key length.
CARDF	Yes	No	No	Number of rows or LOBs referenced by the index or partition
DSNUM	Yes	Yes	No	Number of data sets
EXTENTS	Yes	Yes	No	Number of data set extents (when there are multiple pieces, the value is for the extents in the last data set)
FAROFFPOSF	Yes	No	No	Number of referenced rows far from the optimal position because of an insert into a full page
LEAFDIST	Yes	No	No	100 times the number of pages between successive leaf pages.
LEAFFAR	Yes	Yes	No	Number of leaf pages located physically far away from previous leaf pages for successive active leaf pages accessed in an index scan. See "LEAFNEAR and LEAFFAR columns" on page 925 for more information.

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
LEAFNEAR	Yes	Yes	No	Number of leaf pages located physically near previous leaf pages for successive active leaf pages. See "LEAFNEAR and LEAFFAR columns" on page 925 for more information.
LIMITKEY	No	No	Yes	The limit key of the partition in an internal format, 0 if the index is not partitioned
NEAROFFPOSF	Yes	No	No	Number of referenced rows near but not at the optimal position because of an insert into a full page
PQTY	Yes	No	No	The primary space allocation in 4K blocks for the data set
PSEUDO_DEL_ENTRIES	Yes	Yes	No	Number of pseudo deleted keys
SECQTYI	Yes	No	No	Secondary space allocation in units of 4 KB, stored in integer format instead of small integer format supported by SQTY. If a storage group is not used, the value is 0.
SPACE	Yes	No	No	The number of KB of space currently allocated for all extents (contains the accumulated space used by all pieces if a page set contains multiple pieces)
SQTY	Yes	No	No	The secondary space allocation in 4 KB blocks for the data set
SPACEF	Yes	Yes	No	Disk storage in KB
<b>SYSIBM.SYSINDEXSTATS:</b> contains statistics by partition				
CLUSTERRATIOF	Yes	Yes	No	A number which, when multiplied by 100, gives the percentage of rows in clustering order. For example, 1 indicates that all rows are in clustering order and .87825 indicates that 87.825% of the rows are in clustering order.
FIRSTKEYCARDF	Yes	Yes	No	Number of distinct values of the first key column, or an estimate if updated while collecting statistics on a single partition
FULLKEYCARDDATA	Yes	Yes	No	The internal representation of the number of distinct values of the full key
FULLKEYCARDF	Yes	Yes	No	Number of distinct values of the full key
KEYCOUNTF	Yes	Yes	No	Number of rows in the partition, -1 to trigger DB2's use of the value in KEYCOUNT
NLEAF	Yes	Yes	No	Number of leaf pages in the index
NLEVELS	Yes	Yes	No	Number of levels in the index tree
<b>SYSIBM.SYSLOBSTATS:</b> contains LOB table space statistics				
AVGSIZE	Yes	Yes	No	Average size of a LOB in bytes
FREESPACE	Yes	Yes	No	The number of KB of available space in the LOB table space

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
# ORGRATIO	Yes	Yes	No	The percentage of organization in the LOB table space. A value of 100 indicates perfect organization of the LOB table space. A value of 1 indicates that the LOB table space is disorganized.
#				
#				
#				
#				
#				A value of 0.00 indicates that the LOB table space is totally disorganized. An empty table space has an ORGRATIO value of 100.00.
#				
#				
#				
<b>SYSIBM.SYSROUTINES:</b> Contains statistics for table functions. See "Updating catalog statistics" on page 804 for more information about using these statistics.				
CARDINALITY	No	Yes	Yes	The predicted cardinality of a table function, -1 to trigger DB2's use of the <b>default value</b> (10 000)
INITIAL_INSTS	No	Yes	Yes	Estimated number of instructions executed the first and last time the function is invoked, -1 to trigger DB2's use of the <b>default value</b> (40 000)
INITIAL_IOS	No	Yes	Yes	Estimated number of IOs performed the first and last time the function is invoked, -1 to trigger DB2's use of the <b>default value</b> (0)
INSTS_PER_INVOC	No	Yes	Yes	Estimated number of instructions per invocation, -1 to trigger DB2's use of the <b>default value</b> (4 000)
IOS_PER_INVOC	No	Yes	Yes	Estimated number of IOs per invocation, -1 to trigger DB2's use of the <b>default value</b> (0)
<b>SYSIBM.SYSTABLEPART:</b> contains statistics for space utilization				
I AVGROWLEN	Yes	No	No	Average row length
CARDF	Yes	No	No	Total number of rows in the table space or partition. For LOB table spaces, the number of LOBs in the table space.
DSNUM	Yes	Yes	No	Number of data sets
EXTENTS	Yes	Yes	No	Number of data set extents (when there are multiple pieces, the value is for the extents in the last data set)
FARINDREF	Yes	No	No	Number of rows relocated far from their original page
NEARINDREF	Yes	No	No	Number of rows relocated near their original page
PAGESAVE	Yes	No	No	Percentage of pages, times 100, saved in the table space or partition as a result of using data compression
PERCACTIVE	Yes	No	No	Percentage of space occupied by active rows, containing actual data from active tables, -2 for LOB table spaces

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
PERCDROP	Yes	No	No	For nonsegmented table spaces, the percentage of space occupied by rows of data from dropped tables; for segmented table spaces, 0
PQTY	Yes	No	No	The primary space allocation in 4K blocks for the data set
SECQTYI	Yes	No	No	Secondary space allocation in units of 4 KB, stored in integer format instead of small integer format supported by SQTY. If a storage group is not used, the value is 0.
SPACE	Yes	No	No	The number of KB of space currently allocated for all extents (contains the accumulated space used by all pieces if a page set contains multiple pieces)
SPACEF	Yes	Yes	No	Disk storage in KB
SQTY	Yes	No	No	The secondary space allocation in 4K blocks for the data set
<b>SYSIBM.SYSTABLES:</b>				
AVGROWLEN	Yes	Yes	No	Average row length of the table specified in the table space
CARDF	Yes	Yes	Yes	Total number of rows in the table or total number of LOBs in an auxiliary table, -1 to trigger DB2's use of the <b>default value</b> (10 000)
EDPROC	No	No	Yes	Nonblank value if an edit exit routine is used
NPAGES	Yes	Yes	Yes	Total number of pages on which rows of this table appear, -1 to trigger DB2's use of the <b>default value</b> (CEILING(1 + CARD/20))
NPAGESF	Yes	Yes	Yes	Number of pages used by the table
PCTPAGES	Yes	Yes	No	For nonsegmented table spaces, percentage of total pages of the table space that contain rows of the table; for segmented table spaces, the percentage of total pages in the set of segments assigned to the table that contain rows of the table
PCTROWCOMP	Yes	Yes	Yes	Percentage of rows compressed within the total number of active rows in the table
SPACEF	Yes	Yes	No	Disk storage in KB
<b>SYSIBM.SYSTABLESPACE:</b>				
# AVGROWLEN	Yes	No	No	Average row length

Table 162. Catalog data used for access path selection or collected by RUNSTATS (continued)

Column name	Set by RUNSTATS?	User can update?	Used for access paths? <sup>1</sup>	Description
NACTIVEF	Yes	Yes	Yes	Number of active pages in the table space, the number of pages touched if a cursor is used to scan the entire file, 0 to trigger DB2's use of the value in the NACTIVE column instead. If NACTIVE contains 0, DB2 uses the <b>default value</b> (CEILING(1 + CARD/20)).
SPACE	Yes	No	No	Disk storage in KB
SPACEF	Yes	Yes	No	Disk storage in KB
<b>SYSIBM.SYSTABSTATS:</b> contains statistics by partition				
CARDF	Yes	Yes	Yes	Total number of rows in the partition, -1 to trigger DB2's use of the value in the CARD column. If CARD is -1, DB2 uses a <b>default value</b> (10 000)
NACTIVE	Yes	Yes	No	Number of active pages in the partition
NPAGES	Yes	Yes	Yes	Total number of pages on which rows of the partition appear, -1 to trigger DB2's use of the <b>default value</b> (CEILING(1 + CARD/20))
PCTPAGES	Yes	Yes	No	Percentage of total active pages in the partition that contain rows of the table
PCTROWCOMP	Yes	Yes	No	Percentage of rows compressed within the total number of active rows in the partition, -1 to trigger DB2's use of the <b>default value</b> (0)

**Note:** <sup>1</sup> Statistics on LOB-related values are not used for access path selection. SYSCOLDISTSTATS and SYSINDEXSTATS are not used for parallelism access paths. SYSCOLSTATS information (CARD, HIGHKEY, LOWKEY, HIGH2KEY, and LOW2KEY) is used to determine the degree of parallelism.

## Filter factors and catalog statistics

DB2 needs an accurate estimate of the number of rows that will qualify after applying each predicate to determine optimal access paths. When multiple tables are accessed, filtering also affects the cost of join order and join method. The catalog tables SYSIBM.SYSCOLUMNS and SYSIBM.SYSCOLDIST are the main source of statistics for calculating predicate filter factors. The following columns are particularly important:

- SYSCOLUMNS.COLCARDF indicates whether statistics exist for a column or not. A positive value is an estimate of the number of distinct values in the column (cardinality). A value of '-1' results in the use of default statistics.

The value of COLCARDF generated by RUNSTATS TABLESPACE is an estimate determined by a sampling method. If you know a more accurate number for COLCARDF, you can supply it by updating the catalog. If the column is the first column of an index, the value generated by RUNSTATS INDEX is exact.

- Columns in SYSCOLDIST contain statistics about the frequency (or distribution) of values for a single column. It can also contain statistics about the cardinality of a group of columns and the frequency of values for that group.

When frequency statistics do not exist, DB2 assumes that the data is uniformly distributed and all values in the column occur with the same frequency. This assumption can lead to an inaccurate estimate of the number of qualifying rows if the data is skewed, which can result in performance problems.

**Example:** Assume that a column (AGE\_CATEGORY) contains five distinct values (COLCARDF), each of which occur with the following frequencies:

AGE_CATEGORY	FREQUENCY
INFANT	5%
CHILD	15%
ADOLESCENT	25%
ADULT	40%
SENIOR	15%

Without this frequency information, DB2 would use a default filter factor of 1/5 (1/COLCARDF), or 20%, to estimate the number of rows that qualify for predicate AGE\_CATEGORY=ADULT. However, the actual frequency of that age category is 40%. Thus, the number of qualifying rows is underestimated by 50%.

When collecting statistics about indexes, you can specify the KEYCARD option of RUNSTATS to collect cardinality statistics on the specified indexes. You can also specify the FREQVAL option with KEYCARD to specify whether distribution statistics are collected for what number of concatenated index columns. By default, distribution statistics are collected on the first column of each index for the 10 most frequently occurring values. FIRSTKEYCARDF and FULLKEYCARDF are also collected by default.

The value of FULLKEYCARDF generated by RUNSTATS on a DPSI type index is an estimate determined by a sampling method. If you know a more accurate number for FULLKEYCARDF, you can supply it by updating the catalog.

When collecting statistics at the table level, you can specify the COLUMN option of RUNSTATS to collect cardinality statistics on just the specified columns. You can also use the COLGROUP option to specify a group of columns for which to collect cardinality statistics. If you use the FREQVAL option with COLGROUP, you can also collect distribution statistics for the column group.

To limit the resources required to collect statistics, you only need to collect column cardinality and frequency statistics that have changed. For example, a column on GENDER is likely to have a COLCARDF of 2, with M and F as the possible values. It is unlikely that the cardinality for this column will ever change. The distribution of the values in the column may or may not change often, depending on the volatility of the data.

**Recommendation:** If query performance is not satisfactory, consider the following actions:

- Collect cardinality statistics on all columns that are used as predicates in a WHERE clause.
- Collect frequencies for all columns with a low cardinality that are used as COL op literal predicates.
- Collect frequencies for a column when the column can contain default data, the default data is skewed, and the column is used as a COL op literal predicate.
- Collect KEYCARD on all candidate indexes.
- Collect column group statistics on all join columns.
- LOW2KEY and HIGH2KEY columns are limited to storing the first 2000 bytes of a key value. If the column is nullable, values are limited to 1999 bytes.
- The closer SYSINDEXES.CLUSTERRATIOF is to 100% (a value of 1), the more closely the ordering of the index entries matches the physical ordering of the

table rows. Refer to Figure 103 on page 922 to see how an index with a high cluster ratio differs from an index with a low cluster ratio.

For information about using the RUNSTATS utility, see Part 2 of *DB2 Utility Guide and Reference*.

## Statistics for partitioned table spaces

For a partitioned table space, DB2 keeps statistics separately by partition and also collectively for the entire table space. Table 163 shows the catalog tables that contain statistics by partition and, for each one, the table that contains the corresponding aggregate statistics.

*Table 163. The catalog tables that contain statistics by partition and the table that contains the corresponding aggregate statistics*

Statistics by partition are in	Aggregate statistics are in
SYSTABSTATS	SYSTABLES
SYSINDEXSTATS	SYSINDEXES
SYSCOLSTATS	SYSCOLUMNS
SYSCOLDISTSTATS	SYSCOLDIST

If you run RUNSTATS for separate partitions of a table space, DB2 uses the results to update the aggregate statistics for the entire table space. For recommendations about running RUNSTATS on separate partitions, see “Gathering monitor statistics and update statistics” on page 916. (You should either run RUNSTATS once on the entire object before collecting statistics on separate partitions or use the appropriate option to ensure that the statistics are aggregated appropriately, especially if some partitions are not loaded with data.)

---

## Setting default statistics for created temporary tables

When preparing an SQL statement that refers to a created temporary table, if the table has been instantiated, DB2 uses the cardinality and number of pages maintained for that table in storage. If the table has not been instantiated, DB2 looks at the CARDF and NPAGES columns of the SYSTABLES row for the created temporary table. These values are normally -1 because RUNSTATS cannot run against a created temporary table.

You can establish default statistical values for the cardinality and number of pages if you can estimate the normal cardinality and number of pages that used the values for a particular created temporary table. You can manually update the values in the CARDF and NPAGES columns of the SYSTABLES row for the created temporary table. These values become the default values used if more accurate values are not available or more accurate values cannot be used. The more accurate values are available only for dynamic SQL statements that are prepared after the instantiation of the created temporary table, but within the same unit of work. These more accurate values are not used if the result of the dynamic bind is destined for the Dynamic Statement Cache.

## History statistics

Several catalog tables provide historical statistics for other catalog tables. These catalog history tables include:

- SYSIBM.SYSCOLDIST\_HIST
- SYSIBM.SYSCOLUMNS\_HIST
- SYSIBM.SYSINDEXES\_HIST
- SYSIBM.SYSINDEXPART\_HIST
- SYSIBM.SYSINDEXSTATS\_HIST
- SYSIBM.SYSLOBSTATS\_HIST
- SYSIBM.SYSTABLEPART\_HIST
- SYSIBM.SYSTABLES\_HIST
- SYSIBM.SYSTABSTATS\_HIST

For example, SYSIBM.SYSTABLESPACE\_HIST provides statistics for activity in SYSIBM.SYSTABLESPACE, SYSIBM.SYSTABLEPART\_HIST provides statistics for activity in SYSIBM.SYSTABLEPART, and so on.

When DB2 adds or changes rows in a catalog table, DB2 might also write information about the rows to the corresponding catalog history table. Although the catalog history tables are not identical to their counterpart tables, they do contain the same columns for access path information and space utilization information. The history statistics provide a way to study trends, to determine when utilities, such as REORG, should be run for maintenance, and to aid in space management.

Table 164 lists the catalog data that are collected for historical statistics. For information on how to gather these statistics, see “Gathering monitor statistics and update statistics” on page 916.

Table 164. Catalog data collected for historical statistics

Column name	Provides access path statistics <sup>1</sup>	Provides space statistics	Description
<b>SYSIBM.SYSCOLDIST_HIST</b>			
CARDF	Yes	No	Number of distinct values gathered
COLGROUPCOLNO	Yes	No	Identifies the columns involved in multi-column statistics
COLVALUE	Yes	No	Frequently occurring value in the key distribution
FREQUENCYF	Yes	No	A number, which multiplied by 100, gives the percentage of rows that contain the value of COLVALUE
NUMCOLUMNS	Yes	No	Number of columns involved in multi-column statistics
TYPE	Yes	No	Type of statistics gathered, either cardinality (c) or frequent value (F)
<b>SYSIBM.SYSCOLUMNS_HIST</b>			
COLCARDF	Yes	No	Estimated number of distinct values in the column
HIGH2KEY	Yes	No	Second highest value of the column, or blank
LOW2KEY	Yes	No	Second lowest value of the column, or blank
<b>SYSIBM.SYSINDEXES_HIST</b>			

Table 164. Catalog data collected for historical statistics (continued)

Column name	Provides access path statistics <sup>1</sup>	Provides space statistics	Description
CLUSTERING	Yes	No	Whether the index was created with CLUSTER
CLUSTERRATIOF	Yes	No	A number, when multiplied by 100, gives the percentage of rows in the clustering order
FIRSTKEYCARDF	Yes	No	Number of distinct values in the first key column
FULLKEYCARDF	Yes	No	Number of distinct values in the full key
NLEAF	Yes	No	Number of active leaf pages
NLEVELS	Yes	No	Number of levels in the index tree
<b>SYSIBM.SYSINDEXPART_HIST</b>			
CARDF	No	Yes	Number of rows or LOBs referenced
DSNUM	No	Yes	Number of data sets
EXTENTS	No	Yes	Number of data set extents (when there are multiple pieces, the value is for the extents in the last data set)
FAROFFPOSF	No	Yes	Number of rows referenced far from the optimal position
LEAFDIST	No	Yes	100 times the number of pages between successive leaf pages
LEAFFAR	No	Yes	Number of leaf pages located physically far away from previous leaf pages for successive active leaf pages accessed in an index scan
LEAFNEAR	No	Yes	Number of leaf pages located physically near previous leaf pages for successive active leaf pages
NEAROFFPOSF	No	Yes	Number of rows referenced near but not at the optimal position
PQTY	No	Yes	Primary space allocation in 4K blocks for the data set
PSEUDO_DEL_ENTRIES	No	Yes	Number of pseudo deleted keys
SECQTYI	No	Yes	Secondary space allocation in 4K blocks for the data set.
SPACEF	No	Yes	Disk storage in KB
<b>SYSIBM.SYSINDEXSTATS_HIST</b>			
CLUSTERRATIO	Yes	No	A number, which when multiplied by 100, gives the percentage of rows in the clustering order
FIRSTKEYCARDF	Yes	No	Number of distinct values of the first key column
FULLKEYCARDF	Yes	No	Number of distinct values of the full key
KEYCOUNTF	Yes	No	Total number of rows in the partition
NLEAF	Yes	No	Number of leaf pages
NLEVELS	Yes	No	Number of levels in the index tree
<b>SYSIBM.SYSLOBSTATS_HIST</b>			
FREESPACE	No	Yes	The amount of free space in the LOB table space

Table 164. Catalog data collected for historical statistics (continued)

Column name	Provides access path statistics <sup>1</sup>	Provides space statistics	Description
# ORGRATIO	No	Yes	The percentage of organization in the LOB table space. A value of 100 indicates perfect organization of the LOB table space. A value of 1 indicates that the LOB table space is disorganized.
#			
#			
#			
#			A value of 0.00 indicates that the LOB table space is totally disorganized. An empty table space has an ORGRATIO value of 100.00.
#			
#			
#			
<b>SYSIBM.SYSTABLEPART_HIST</b>			
CARDF	No	Yes	Number of rows in the table space or partition
DSNUM	No	Yes	Number of data sets
EXTENTS	No	Yes	Number of data set extents (when there are multiple pieces, the value is for the extents in the last data set)
FARINDREF	No	Yes	Number of rows relocated far from their original position
NEARINDREF	No	Yes	Number of rows relocated near their original position
PAGESAVE	No	Yes	Percentage of pages saved by data compression
PERCACTIVE	No	Yes	Percentage of space occupied by active pages
PERCDROP	No	Yes	Percentage of space occupied by pages from dropped tables
PQTY	No	Yes	Primary space allocation in 4K blocks for the data set
SECQTYI	No	Yes	Secondary space allocation in 4K blocks for the data set.
SPACEF	No	Yes	The number of KB of space currently used
<b>SYSIBM.SYSTABLES_HIST</b>			
AVGROWLEN	No	Yes	Average row length of the table specified in the table space
CARDF	Yes	No	Number of rows in the table or number of LOBs in an auxiliary table
NPAGESF	Yes	No	Number of pages used by the table
PCTPAGES	No	Yes	Percentage of pages that contain rows
PCTROWCOMP	Yes	No	Percentage of active rows compressed
<b>SYSIBM.SYSTABSTATS_HIST</b>			
CARDF	Yes	No	Number of rows in the partition
NPAGES	Yes	No	Total number of pages with rows
<b>Note:</b> <sup>1</sup> The access path statistics in the history tables are collected for historical purposes and are not used for access path selection.			

---

## Gathering monitor statistics and update statistics

The DB2 utility RUNSTATS can update the DB2 catalog tables with statistical information about data and indexes. For a list of the catalog columns for which RUNSTATS collects statistics, see Table 162 on page 903. For instructions on using RUNSTATS, see Part 2 of *DB2 Utility Guide and Reference*.

You can choose which DB2 catalog tables you want RUNSTATS to update: those used to optimize the performance of SQL statements or those used by database administrators to assess the status of a particular table space or index. You can monitor these catalog statistics in conjunction with EXPLAIN to make sure that your queries access data efficiently.

After you use the LOAD, REBUILD INDEX, or REORG utilities, you can gather statistics inline with those utilities by using the STATISTICS option.

**Why gather statistics:** Maintaining your statistics is a critical part of performance monitoring and tuning. DB2 must have correct statistical information to make the best choices for the access path.

**When to gather statistics:** To ensure that information in the catalog is current, gather statistics in situations in which the data or index changes significantly, such as in the following situations:

- After loading a table and before binding application plans and packages that access the table.
- After creating an index with the CREATE INDEX statement, to update catalog statistics related to the new index. (Before an application can use a new index, you must rebind the application plan or package.)
- After reorganizing a table space or an index. Then rebind plans or packages for which performance remains a concern. See “Whether to rebind after gathering statistics” on page 927 for more information. (It is not necessary to rebind after reorganizing a LOB table space, because those statistics are not used for access path selection.)
- After heavy insert, update, and delete activity. Again, rebind plans or packages for which performance is critical.
- Periodically. By comparing the output of one execution with previous executions, you can detect a performance problem early.
- Against the DB2 catalog to provide DB2 with more accurate information for access path selection of users’ catalog queries.

To obtain information from the catalog tables, use a SELECT statement, or specify REPORT YES when you invoke RUNSTATS. When used routinely, RUNSTATS provides data about table spaces and indexes over a period of time. For example, when you create or drop tables or indexes or insert many rows, run RUNSTATS to update the catalog. Then rebind your applications so that DB2 can choose the most efficient access paths.

**Collecting statistics by partition:** You can collect statistics for a single data partition or index partition. This information allows you to avoid the cost of running utilities against unchanged partitions. When you run utilities by partition, DB2 uses the results to update the aggregate statistics for the entire table space or index. If statistics do not exist for each separate partition, DB2 can calculate the aggregate statistics only if the utilities are executed with the FORCEROLLUP YES keyword (or FORCEROLLUP keyword is omitted and the value of the STATISTICS

ROLLUP field on installation panel DSNTIPO is YES). If you do not use the keyword or installation panel field setting to force the roll up of the aggregate statistics, you must run utilities once on the entire object before running utilities on separate partitions.

*Collecting history statistics:* When you collect statistics with RUNSTATS or gather them inline with the LOAD, REBUILD, or REORG utilities, you can use the HISTORY option to collect history statistics. With the HISTORY option, the utility stores the statistics that were updated in the catalog tables in history records in the corresponding catalog history tables. (For information on the catalog data that is collected for history statistics, see Table 164 on page 913.)

To remove old statistics that are no longer needed in the catalog history tables, use the MODIFY STATISTICS utility or the SQL DELETE statement. Deleting outdated information from the catalog history tables can help improve the performance of processes that access the data in these tables.

*Recommendations for performance:*

- To reduce the processor consumption WHEN collecting column statistics, use the SAMPLE option. The SAMPLE option allows you to specify a percentage of the rows to examine for column statistics. Consider the effect on access path selection before choosing sampling. There is likely to be little or no effect on access path selection if the access path has a matching index scan and very few predicates. However, if the access path joins of many tables with matching index scans and many predicates, the amount of sampling can affect the access path. In these cases, start with 25 percent sampling and see if there is a negative effect on access path selection. If not, you could consider reducing the sampling percent until you find the percent that gives you the best reduction in processing time without negatively affecting the access path.
- To reduce the elapsed time of gathering statistics immediately after a LOAD, REBUILD INDEX, or REORG, gather statistics inline with those utilities by using the STATISTICS option.

---

## Updating the catalog

If you have sufficient privileges, you can change all of the values listed in Table 162 on page 903 by executing SQL UPDATE statements.

*Running RUNSTATS after UPDATE:* If you change values in the catalog and later run RUNSTATS to update those values, your changes are lost.

**Recommendation:** Keep track of the changes you make and of the plans or packages that have an access path change due to changed statistics.

## Correlations in the catalog

The following relationships exist among certain columns of the catalog tables:

- Columns within table SYSCOLUMNS
- Columns in the tables SYSCOLUMNS and SYSINDEXES
- Columns in the tables SYSCOLUMNS and SYSCOLDIST
- Columns in the tables SYSCOLUMNS, SYSCOLDIST, and SYSINDEXES
- Columns with table space statistics and columns for partition-level statistics, as described in “Statistics for partitioned table spaces” on page 912.

If you plan to update some values, keep in mind the following correlations:

- COLCARDF and FIRSTKEYCARDF. For a column that is the first column of an index, those two values are equal. If the index has only that one column, the two values are also equal to the value of FULLKEYCARDF.
- COLCARDF, LOW2KEY, and HIGH2KEY. If the COLCARDF value is not '-1', DB2 assumes that statistics exist for the column. In particular, it uses the values of LOW2KEY and HIGH2KEY in calculating filter factors. If COLCARDF = 1 or if COLCARDF = 2, DB2 uses HIGH2KEY and LOW2KEY as domain statistics, and generates frequencies on HIGH2KEY and LOW2KEY.
- CARDF in SYSCOLDIST. CARDF is related to COLCARDF in SYSIBM.SYSCOLUMNS and to FIRSTKEYCARDF and FULLKEYCARDF in SYSIBM.SYSINDEXES. CARDF must be the minimum of the following:
  - A value between FIRSTKEYCARDF and FULLKEYCARDF if the index contains the same set of columns
  - A value between MAX(COLCARDF of each column in the column group) and the product of multiplying together the COLCARDF of each column in the column group

**Example:** Assume the following set of statistics:

```
CARDF = 1000
NUMCOLUMNS = 3
COLGROUPCOLNO = 2,3,5
```

```
INDEX1 on columns 2,3,5,7,8
FIRSTKEYCARDF = 100          CARDF must be between 100
FULLKEYCARDF = 10000        and 10000
```

```
column 2 COLCARDF = 100
column 3 COLCARDF = 50
column 5 COLCARDF = 10
```

The range between FIRSTKEYCARDF and FULLKEYCARDF is 100 and 10 000. The maximum of the COLCARDF values is 50 000. Thus, the allowable range is between 100 and 10 000.

- CARDF in SYSTABLES. CARDF must be equal to or larger than any of the other cardinalities, SUCH AS COLCARDF, FIRSTKEYCARDF, FULLKEYCARDF, and CARDF in SYSIBM.SYSCOLDIST.
- FREQUENCYF and COLCARDF or CARDF. The number of frequencies collected must be less than or equal to COLCARDF for the column or CARDF for the column group.
- FREQUENCYF. The sum of frequencies collected for a column or column group must be less than or equal to 1.

## Recommendation for COLCARDF and FIRSTKEYCARDF

On partitioned indexes, RUNSTATS INDEX calculates the number of distinct column values and saves it in SYSCOLSTATS.COLCARD by partition. When the statistics by partition are used to form the aggregate, the aggregate might not be exact because some column values might occur in more than one partition. Without scanning all parts of the index, DB2 cannot detect that overlap. The overlap never skews COLCARD by more than the number of partitions, which is usually not a problem for large values. For small values, update the aggregate COLCARDF value in SYSCOLUMNS because DB2 uses the COLCARDF value when determining access paths.

The exception and the remedy for COLCARD and COLCARDF are also true for the FIRSTKEYCARDF column in SYSIBM.SYSINDEXES and the FIRSTKEYCARDF column in SYSIBM.SYSINDEXSTATS.

## Recommendation for HIGH2KEY and LOW2KEY

If you update the COLCARDF value for a column, also update HIGH2KEY and LOW2KEY for the column. HIGH2KEY and LOW2KEY are defined as VARCHAR(2000); thus, an UPDATE statement must provide a character or hexadecimal value. Entering a character value is quite straightforward: SET LOW2KEY = 'ALAS', for instance. But to enter a numeric, date, or time value you must use the hexadecimal value of the DB2 internal format. See “Dates, times, and timestamps for edit and validation routines” on page 1112 and “DB2 codes for numeric data in edit and validation routines” on page 1114. Be sure to allow for a null indicator in keys that allow nulls. See also “Null values for edit procedures, field procedures, and validation routines” on page 1111.

If you update the COLCARDF value for a column, also update HIGH2KEY and LOW2KEY for the column. HIGH2KEY and LOW2KEY are defined as VARCHAR(2000). To update HIGH2KEY and LOW2KEY:

- Specify a character or hexadecimal value on the UPDATE statement.  
Entering a character value is quite straightforward: SET LOW2KEY = 'ALAS', for example. But to enter a numeric, date, or time value you must use the hexadecimal value of the DB2 internal format. See “Dates, times, and timestamps for edit and validation routines” on page 1112 and “DB2 codes for numeric data in edit and validation routines” on page 1114. Be sure to allow for a null indicator in keys that allow nulls. See also “Null values for edit procedures, field procedures, and validation routines” on page 1111.
- Ensure that the padding characteristics for the columns are the same as the padding characteristics for COLCARDF.  
For example, if the statistics values that are collected for COLCARDF are padded, then the statistics collected for HIGH2KEY or LOW2KEY must also be padded. You can check the STATS\_FORMAT column in SYSCOLUMNS and SYSCOLSTATS to determine whether the statistics gathered for these columns are padded or not.

## Statistics for distributions

Statistics for distributions are stored in the catalog tables SYSCOLDIST and SYSCOLDISTSTATS. Although you can use RUNSTATS to collect distribution statistics on any column or group of columns, by default, DB2 inserts the 10 most frequent values for the first key column of an index as well as the first and last key values. See Part 2 of *DB2 Utility Guide and Reference* for information about collecting more statistics related to columns that are correlated.

You can insert, update, or delete distribution information for any column in these catalog tables. However, to enter a numeric, date, or time value you must use the hexadecimal value of the DB2 internal format. See “Dates, times, and timestamps for edit and validation routines” on page 1112 and “DB2 codes for numeric data in edit and validation routines” on page 1114. Be sure to allow for a null indicator in keys that allow nulls. See also “Null values for edit procedures, field procedures, and validation routines” on page 1111.

## Recommendation for using the TIMESTAMP column

Statistics gathered by RUNSTATS include timestamps. Every row updated or inserted during a particular invocation of RUNSTATS contains the same timestamp value. Update column STATSTIME whenever you update statistics in the catalog, so that you can always determine when they were last updated.

---

## Querying the catalog for statistics

The following SELECT statements show how to retrieve some of the important statistics for access path selection. The catalog queries shown here are included in DSNTESP in SDSNSAMP and can be used as input to SPUFI. See Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 for more information about how these statistics are used in access path selection. See Appendix F of *DB2 SQL Reference* for the table definitions and descriptions of all DB2 catalog tables.

---

### Product-sensitive Programming Interface

---

To access information about your data and how it is organized, use the following queries:

```
SELECT CREATOR, NAME, CARDF, NPAGES, PCTPAGES
  FROM SYSIBM.SYSTABLES
  WHERE DBNAME = 'xxx'
  AND TYPE = 'T';

SELECT NAME, UNIQUERULE, CLUSTERRATIOF, FIRSTKEYCARD, FULLKEYCARD,
  NLEAF, NLEVELS, PGSIZE
  FROM SYSIBM.SYSINDEXES
  WHERE DBNAME = 'xxx';

SELECT NAME, DBNAME, NACTIVE, CLOSERULE, LOCKRULE
  FROM SYSIBM.SYSTABLESPACE
  WHERE DBNAME = 'xxx';

SELECT NAME, TBNAME, COLCARD, HIGH2KEY, LOW2KEY, HEX(HIGH2KEY),
  HEX(LOW2KEY)
  FROM SYSIBM.SYSCOLUMNS
  WHERE TBCREATOR = 'xxx' AND COLCARD <> -1;

SELECT NAME, FREQUENCYF, COLVALUE, HEX(COLVALUE), CARDF,
  COLGROUPCOLNO, HEX(COLGROUPCOLNO), NUMCOLUMNS, TYPE
  FROM SYSIBM.SYSCOLDIST
  WHERE TBNAME = 'ttt'
  ORDER BY NUMCOLUMNS, NAME, COLGROUPCOLNO, TYPE, FREQUENCYF DESC;

SELECT NAME, TSNAME, CARD, NPAGES
  FROM SYSIBM.SYSTABSTATS
  WHERE DBNAME='xxx';
```

---

### End of Product-sensitive Programming Interface

---

If the statistics in the DB2 catalog no longer correspond to the true organization of your data, you should reorganize the necessary tables, run RUNSTATS, and rebind the plans or packages that contain any affected queries. See “When to reorganize indexes and table spaces” on page 924 and the description of REORG in Part 2 of *DB2 Utility Guide and Reference* for information on how to determine which table spaces and indexes qualify for reorganization. This includes the DB2 catalog table spaces as well as user table spaces. Then DB2 has accurate information to choose appropriate access paths for your queries. Use the EXPLAIN statement to verify the chosen access paths for your queries.

---

## Improving index and table space access

Statistics from the DB2 catalog help determine the most economical access path. The statistics described in this section are used to determine index access cost and are found in the corresponding columns of the SYSIBM.SYSINDEXES catalog table.

The statistics show distribution of data within the allocated space, from which you can judge clustering and the need to reorganize.

Space utilization statistics can also help you make sure that access paths that use the index or table space are as efficient as possible. By reducing gaps between leaf pages in an index, or to ensure that data pages are close together, you can reduce sequential I/Os.

**Recommendation:** To provide the most accurate data, gather statistics routinely to provide data about table spaces and indexes over a period of time.

**Recommendation:** Run RUNSTATS some time **after** reorganizing the data or indexes. By gathering the statistics after you reorganize, you ensure that access paths reflect a more “average” state of the data.

This section describes the following topics:

- “How clustering affects access path selection”
- “What other statistics provide index costs” on page 923
- “When to reorganize indexes and table spaces” on page 924
- “Whether to rebind after gathering statistics” on page 927

## How clustering affects access path selection

In general, CLUSTERRATIOF gives an indication of how closely the order of the index entries on the index leaf pages matches the actual ordering of the rows on the data pages. The closer CLUSTERRATIOF is to 100%, the more closely the ordering of the index entries matches the actual ordering of the rows on the data pages. The actual formula is quite complex and accounts for indexes with many duplicates; in general, for a given index, the more duplicates, the higher the CLUSTERRATIOF value.

Here are some things to remember about the effect of CLUSTERRATIOF on access paths:

- CLUSTERRATIOF is an important input to the cost estimates that are used to determine whether an index is used for an access path, and, if so, which index to use.
- If the access is INDEXONLY, then this value does not apply.
- The higher the CLUSTERRATIOF value, the lower the cost of referencing data pages during an index scan is.
- For an index that has a CLUSTERRATIOF less than 80%, sequential prefetch is not used to access the data pages.
- A slight reduction in CLUSTERRATIOF for a table with a large number of rows can represent a much more significant number of unclustered rows than for a table with a small number of rows.

**Example:** A CLUSTERRATIOF of 99% for a table with 100 000 000 rows represents 100 000 unclustered rows. Whereas, the CLUSTERRATIOF of 95% for a table with 100 000 rows represents 5000 unclustered rows.

Figure 103 on page 922 shows an index scan on an index with a high cluster ratio. Compare that with Figure 104 on page 923, which shows an index scan on an index with a low cluster ratio.

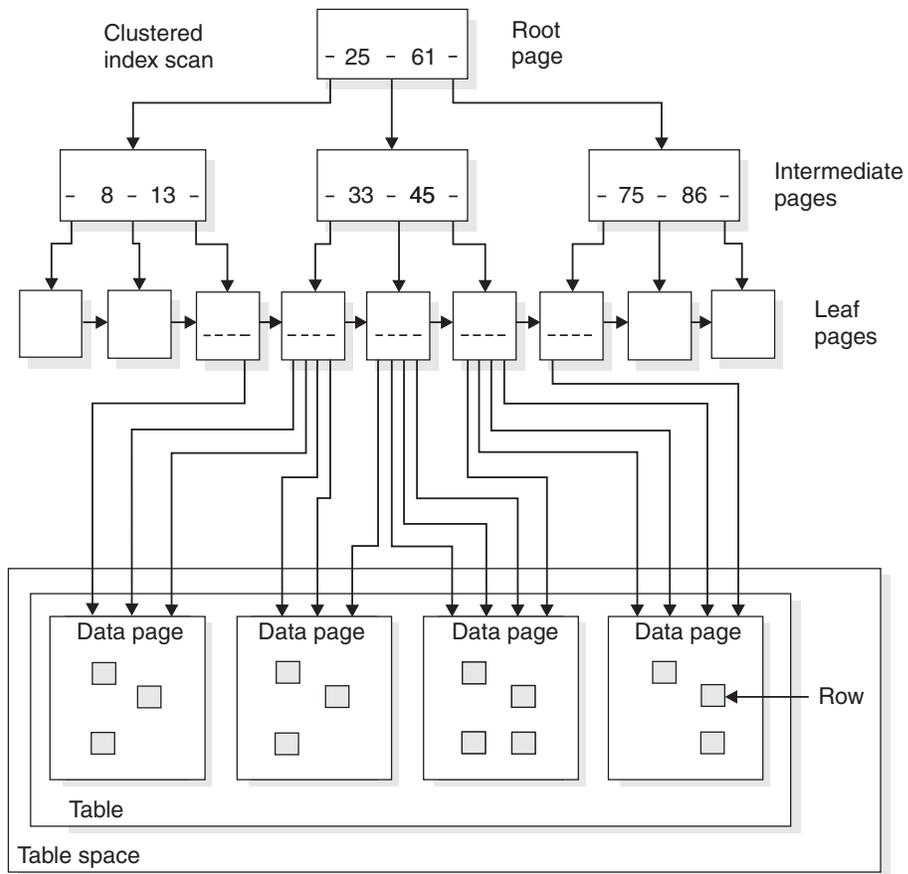

Figure 103. A clustered index scan. This figure assumes that the index is 100% clustered.

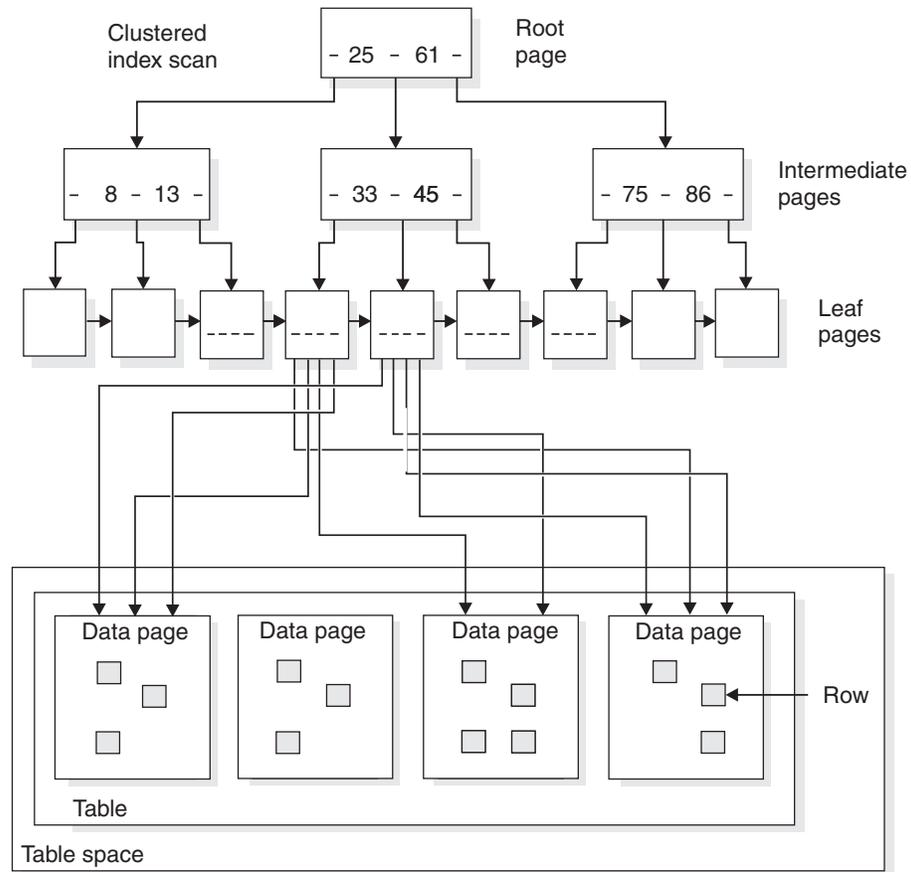

Figure 104. A nonclustered index scan. In some cases, DB2 can access the data pages in order even when a nonclustered index is used.

## What other statistics provide index costs

The following statistics in SYSINDEXES also give information about costs to process the index.

**FIRSTKEYCARDF:** The number of distinct values of the first index key column. When an indexable equal predicate is specified on the first index key column,  $1/\text{FIRSTKEYCARDF}$  is the filter factor for the predicate and the index. The higher the number is, the less the cost is.

**FULLKEYCARDF:** The number of distinct values for the entire index key. When indexable equal predicates are specified on all the index key columns,  $1/\text{FULLKEYCARDF}$  is the filter factor for the predicates and the index. The higher the number is, the less the cost is.

When the number of matching columns is greater than 1 and less than the number of index key columns, the filtering of the index is located between  $1/\text{FIRSTKEYCARDF}$  and  $1/\text{FULLKEYCARDF}$ .

**NLEAF:** The number of active leaf pages in the index. NLEAF is a portion of the cost to scan the index. The smaller the number is, the less the cost is. It is also less when the filtering of the index is high, which comes from FIRSTKEYCARDF, FULLKEYCARDF, and other indexable predicates.

**NLEVELS:** The number of levels in the index tree. NLEVELS is another portion of the cost to traverse the index. The same conditions as NLEAF apply. The smaller the number is, the less the cost is.

## When to reorganize indexes and table spaces

Data that is organized well physically can improve the performance of access paths that rely on index or data scans. Well-organized data can also help reduce the amount of disk storage used by the index or table space. If your main reason for reorganizing is performance, the best way to determine when to reorganize is to watch your statistics for increased I/O, getpages, and processor consumption. When performance degrades to an unacceptable level, analyze the statistics described in the guidelines in this section to help you develop your own rules for when to reorganize in your particular environment. Consider the following general guidelines for when to run the REORG utility:

- **Using useful catalog queries:** Catalog queries you can use to help you determine when to reorganize are included in DSNTESP in SDSNSAMP and can be used as input to SPUFI.
- **Using the REORG utility to determine whether to reorganize:** The REORG utility imbeds the function of catalog queries. If a query returns a certain result (you can use the default or supply your own), REORG will either reorganize or not. Optionally, you can have REORG run a report instead of actually doing the reorganization.

The REORG options that imbed these catalog queries are:

- OFFPOSLIMIT and INDREFLIMIT options of REORG TABLESPACE
- LEAFDISTLIMIT of REORG INDEX

The REORG utility does not imbed any function to help you determine when to reorganize LOB table spaces.

- **Reorganizing after table definition changes:** Another time to consider reorganizing data to improve performance is when ALTER TABLE statements have been used to add a column to the table or to change the data types or the lengths of existing columns. Such changes cause the table space to be placed in advisory REORG-pending (AREO\*) status.

In the case of changing the definition of existing column, the table space is placed in AREO\* status because the existing data is not immediately converted to its new definition. Reorganizing the table space causes the rows to be reloaded with the data converted to the new definition. Until the table space is reorganized, the changes must be tracked and applied as the data is accessed, possibly degrading performance. For example, depending on the number of changes, you may see decreased performance for dynamic SQL queries, updates and deletes, other ALTER statements (especially those that are run concurrently). In addition, running multiple REORG and LOAD utilities concurrently may perform slower or create timeouts. It may also take longer to unload a table that has had many changes prior to it being reorganized.

See Part 2 of *DB2 Utility Guide and Reference* for more information about the REORG utility.

## Reorganizing Indexes

To understand index organization, you must understand the LEAFNEAR and LEAFFAR columns of SYSIBM.SYSINDEXPART. This section describes how to interpret those values and then describes some rules of thumb for determining when to reorganize the index.

**LEAFNEAR and LEAFFAR columns:** The LEAFNEAR and LEAFFAR columns of SYSIBM.SYSINDEXPART measure the disorganization of physical leaf pages by indicating the number of pages that are not in an optimal position. Leaf pages can have page gaps whenever index pages are deleted or when there are index leaf page splits caused by an insert that cannot fit onto a full page. If the key cannot fit on the page, DB2 moves half the index entries onto a new page, which might be far away from the “home” page.

Figure 105 shows the logical and physical view of an index.

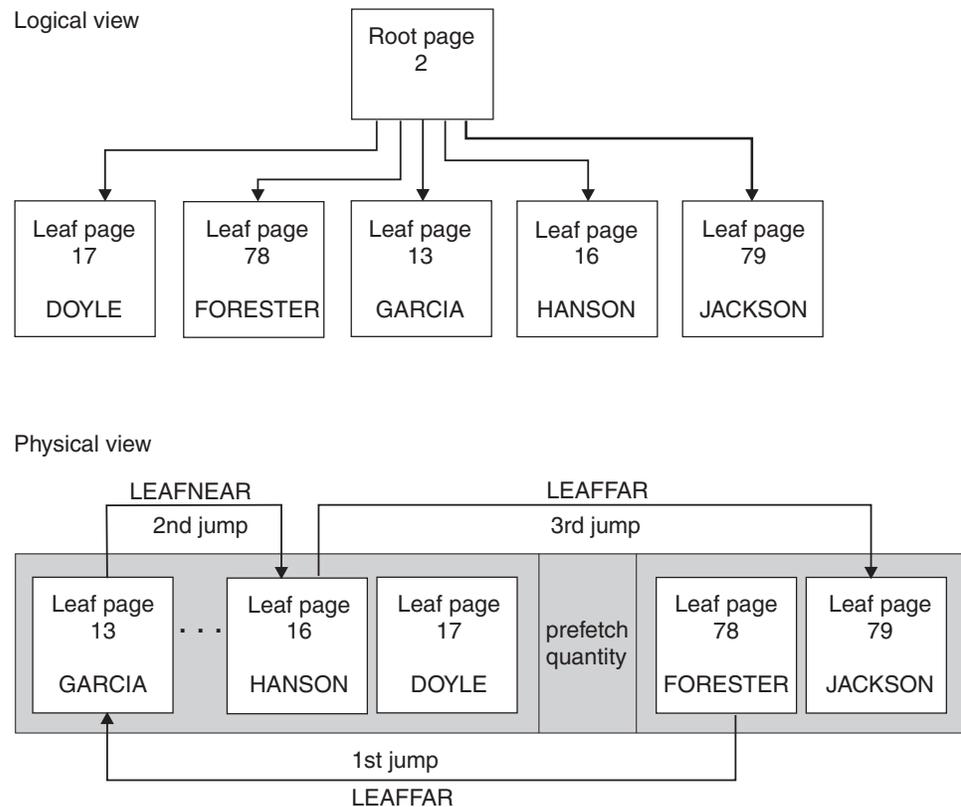

Figure 105. Logical and physical views of an index in which LEAFNEAR=1 and LEAFFAR=2

The logical view at the top of the figure shows that for an index scan four leaf pages need to be scanned to access the data for FORESTER through JACKSON. The physical view at the bottom of the figure shows how the pages are physically accessed. The first page is at physical leaf page 78, and the other leaf pages are at physical locations 79, 13, and 16. A jump forward or backward of more than one page represents non-optimal physical ordering. LEAFNEAR represents the number of jumps within the prefetch quantity, and LEAFFAR represents the number of jumps outside the prefetch quantity. In this example, assuming that the prefetch quantity is 32, there are two jumps outside the prefetch quantity. A jump from page 78 to page 13, and one from page 16 to page 79. Thus, LEAFFAR is 2. Because of the jump within the prefetch quantity from page 13 to page 16, LEAFNEAR is 1.

LEAFNEAR has a smaller impact than LEAFFAR because the LEAFNEAR pages, which are located within the prefetch quantity, are typically read by prefetch without incurring extra I/Os.

The optimal value of the LEAFNEAR and LEAFFAR catalog columns is zero. However, immediately after you run the REORG and gather statistics, LEAFNEAR for a large index might be greater than zero. A non-zero value could be caused by free pages that result from the FREEPAGE option on CREATE INDEX, non-leaf pages, or various system pages; the jumps over these pages are included in LEAFNEAR.

**Recommendations:** Fields in the SYSIBM.INDEXSPACESTATS table can help you determine when to reorganize an index.

Consider running REORG INDEX when any of the following conditions are true. These conditions are based on values in the SYSIBM.INDEXSPACESTATS table.

- REORGPSEUDODELETES/TOTALENTRIES > 10% in a non-data sharing environment, or REORGPSEUDODELETES/TOTALENTRIES > 5% in a data sharing environment.
- REORGLEAFFAR/NACTIVE > 10%
- REORGININSERTS/TOTALENTRIES > 25%
- REORGDELETES/TOTALENTRIES > 25%
- REORGAPPENDINSERT/TOTALENTRIES > 20%
- EXTENTS > 254

You should also consider running REORG if one of the following conditions are true:

- The index is in the advisory REORG-pending state (AREO\*) as a result of an ALTER statement.
- An index is in the advisory REBUILD-pending state (ARBDP) as a result an ALTER statement.

## Reorganizing table spaces

Fields in the SYSIBM.TABLESPACESTATS table can help you determine when to reorganize a table space.

Consider running REORG TABLESPACE when any of the following conditions are true. These conditions are based on values in the SYSIBM.TABLESPACESTATS table.

- REORGUNCLUSTINS/TOTALROWS > 10%  
Do not use REORGUNCLUSTINS to determine if you should run REORG if access to the table space is predominantly random access.
- (REORGNEARINDREF+REORGFARINDREF)/TOTALROWS > 5% in a data sharing environment, or (REORGNEARINDREF+REORGFARINDREF)/TOTALROWS >10% in non-data sharing environment
- REORGININSERTS/TOTALROWS > 25%
- REORGDELETES/TOTALROWS > 25%
- EXTENTS > 254
- REORGDISORGL0B/TOTALROWS > 50%
- SPACE > 2 \* (DATASIZE / 1024)
- REORGMASDELETE > 0

You should also consider running REORG if one of the following conditions are true:

- The table space is in the advisory REORG-pending state (AREO\*) as a result of an ALTER TABLE statement.

- An index on a table in the table space is in the advisory REBUILD-pending state (ARBDP) as result an ALTER TABLE statement.

### Reorganizing LOB table spaces

SYSIBM.SYSLOBSTATS contains information about how the data in the table space is physically stored. Consider running REORG on the LOB table space when the percentage in the ORGRATIO column is less than 80.

Additionally, you can use real-time statistics to identify DB2 objects that should be reorganized, have their statistics updated, or be image copied.

## Whether to rebind after gathering statistics

It is not always necessary to rebind all applications after you gather statistics. A rebind is necessary only if the access path statistics change significantly from the last time you bound the applications and if performance suffers as a result.

When performance degrades to an unacceptable level, analyze the statistics described in the recommendations in this section to help you develop your own guidelines for when to rebind.

Consider the following guidelines regarding when to rebind:

- CLUSTERRATIOF changes to less or more than 80% (a value of 0.80).
- NLEAF changes more than 20% from the previous value.
- NLEVELS changes (only if it was more than a two-level index to begin with).
- NPAGES changes more than 20% from the previous value.
- NACTIVEF changes more than 20% from the previous value.
- The range of HIGH2KEY to LOW2KEY range changes more than 20% from the range previously recorded.
- Cardinality changes more than 20% from previous range.
- Distribution statistics change the majority of the frequent column values.

---

## Modeling your production system

To see what access paths your production queries will use, consider updating the catalog statistics on your test system to be the same as your production system.

To do that, run RUNSTATS on your production tables to get current statistics for access path selection. Then retrieve them and use them to build SQL statements to update the catalog of the test system.

**Example:** You can use queries similar to the following queries to build those statements. To successfully model your production system, the table definitions must be the same on both the test and production systems. For example, they must have the same creator, name, indexes, number of partitions, and so on.

Use the following statements to update SYSTABLESPACE, SYSTABLES, SYSINDEXES, and SYSCOLUMNS:

```
SELECT DISTINCT 'UPDATE SYSIBM.SYSTABLESPACE SET NACTIVEF='
CONCAT STRIP(CHAR(NACTIVEF))
CONCAT ',NACTIVE='CONCAT STRIP(CHAR(NACTIVE))
CONCAT ' WHERE NAME=''' CONCAT TS.NAME
CONCAT ''' AND DBNAME ='''CONCAT TS.DBNAME CONCAT''*'
FROM SYSIBM.SYSTABLESPACE TS, SYSIBM.SYSTABLES TBL
WHERE TS.NAME = TSNAME
```

```

AND TBL.CREATOR IN (table_creator_list)
AND TBL.NAME IN (table_list)
AND (NACTIVEF >=0 OR NACTIVE >=0);

SELECT 'UPDATE SYSIBM.SYSTABLES SET CARDF='
CONCAT STRIP(CHAR(CARDF))
CONCAT',NPAGES='CONCAT STRIP(CHAR(NPAGES))
CONCAT',PCTROWCOMP='CONCAT STRIP(CHAR(PCTROWCOMP))
CONCAT ' WHERE NAME='''CONCAT NAME
CONCAT ''' AND CREATOR ='''CONCAT CREATOR CONCAT''*'
FROM SYSIBM.SYSTABLES WHERE
CREATOR IN (creator_list)
AND NAME IN (table_list)
AND CARDF >= 0;

SELECT 'UPDATE SYSIBM.SYSINDEXES SET FIRSTKEYCARDF='
CONCAT STRIP(CHAR(FIRSTKEYCARDF))
CONCAT ',FULLKEYCARDF='CONCAT STRIP(CHAR(FULLKEYCARDF))
CONCAT',NLEAF='CONCAT STRIP(CHAR(NLEAF))
CONCAT',NLEVELS='CONCAT STRIP(CHAR(NLEVELS))
CONCAT',CLUSTERRATIO='CONCAT STRIP(CHAR(CLUSTERRATIO))
CONCAT',CLUSTERRATIOF='CONCAT STRIP(CHAR(CLUSTERRATIOF))
CONCAT' WHERE NAME='''CONCAT NAME
CONCAT ''' AND CREATOR ='''CONCAT CREATOR CONCAT''*'
FROM SYSIBM.SYSINDEXES
WHERE TBcreator IN (creator_list)
AND TBNAME IN (table_list)
AND FULLKEYCARDF >= 0;

SELECT 'UPDATE SYSIBM.SYSCOLUMNS SET COLCARDF='
CONCAT STRIP(CHAR(COLCARDF))
CONCAT',HIGH2KEY= X''' CONCAT HEX(HIGH2KEY)
CONCAT''',LOW2KEY= X''' CONCAT HEX(LOW2KEY)
CONCAT''' WHERE TBNAME=''' CONCAT TBNAME CONCAT ''' AND COLNO='
CONCAT STRIP(CHAR(COLNO))
CONCAT ' AND TBcreator =''' CONCAT TBcreator CONCAT''*'
FROM SYSIBM.SYSCOLUMNS
WHERE TBcreator IN (creator_list)
AND TBNAME IN (table_list)
AND COLCARDF >= 0;

```

SYSTABSTATS and SYSCOLDIST require deletes and inserts.

Delete statistics from SYSTABSTATS on the test subsystem for the specified tables by using the following statement:

```

DELETE FROM (TEST_SUBSYSTEM).SYSTABSTATS
WHERE OWNER IN (creator_list)
AND NAME IN (table_list)

```

Use INSERT statements to repopulate SYSTABSTATS with production statistics that are generated from the following statement:

```

SELECT 'INSERT INTO SYSIBM.SYSTABSTATS'
CONCAT '(CARD,NPAGES,PCTPAGES,NACTIVE,PCTROWCOMP'
CONCAT ',STATTIME,IBMREQD,DBNAME,TSNAME,PARTITION'
CONCAT ',OWNER,NAME,CARDF) VALUES('
CONCAT STRIP(CHAR(CARD))          CONCAT ', '
CONCAT STRIP(CHAR(NPAGES))        CONCAT ', '
CONCAT STRIP(CHAR(PCTPAGES))      CONCAT ', '
CONCAT STRIP(CHAR(NACTIVE))       CONCAT ', '
CONCAT STRIP(CHAR(PCTROWCOMP))    CONCAT ', '
CONCAT '''' CONCAT CHAR(STATTIME)  CONCAT ''', '
CONCAT '''' CONCAT IBMREQD          CONCAT ''', '
CONCAT '''' CONCAT STRIP(DBNAME)    CONCAT ''', '
CONCAT '''' CONCAT STRIP(TSNAME)    CONCAT ''', '
CONCAT STRIP(CHAR(PARTITION))     CONCAT ', '

```

```

CONCAT ' ' || CONCAT STRIP(OWNER) || CONCAT ' ', '
CONCAT ' ' || CONCAT STRIP(NAME) || CONCAT ' ', '
CONCAT STRIP(CHAR(CARDF)) || CONCAT ')*'
FROM SYSIBM.SYSTABSTATS
WHERE OWNER IN (creator_list)
AND NAME IN (table_list);

```

Delete statistics from SYSCOLDIST on the test subsystem for the specified tables by using the following statement:

```

DELETE FROM (TEST_SUBSYSTEM).SYSCOLDIST
WHERE TOWNER IN (creator_list)
AND TBNAME IN (table_list);

```

Use INSERT statements to repopulate SYSCOLDIST with production statistics that are generated from the following statement:

```

SELECT 'INSERT INTO SYSIBM.SYSCOLDIST '
CONCAT '(FREQUENCY,STATSTIME,IBMREQD,TOWNER'
CONCAT ',TBNAME,NAME,COLVALUE,TYPE,CARDF,COLGROUPCOLNO'
CONCAT ',NUMCOLUMNS,FREQUENCYF) VALUES( '
CONCAT STRIP(CHAR(FREQUENCY)) || CONCAT ' ', '
CONCAT ' ' || CONCAT CHAR(STATSTIME) || CONCAT ' ', '
CONCAT ' ' || CONCAT IBMREQD || CONCAT ' ', '
CONCAT ' ' || CONCAT STRIP(TOWNER) || CONCAT ' ', '
CONCAT ' ' || CONCAT STRIP(TBNAME) || CONCAT ' ', '
CONCAT ' ' || CONCAT STRIP(NAME) || CONCAT ' ', '
CONCAT 'X' || CONCAT STRIP(HEX(COLVALUE)) || CONCAT ' ', '
CONCAT ' ' || CONCAT TYPE || CONCAT ' ', '
CONCAT STRIP(CHAR(CARDF)) || CONCAT ' ', '
CONCAT 'X' || CONCAT STRIP(HEX(COLGROUPCOLNO)) || CONCAT ' ', '
CONCAT CHAR(NUMCOLUMNS) || CONCAT ' ', '
CONCAT STRIP(CHAR(FREQUENCYF)) || CONCAT ')*'
FROM SYSIBM.SYSCOLDIST
WHERE TOWNER IN (creator_list)
AND TBNAME IN (table_list);

```

**Note about SPUFI:**

- If you use SPUFI to execute the preceding SQL statements, you might need to increase the default maximum character column width to avoid truncation.
- Asterisks (\*) appear in the examples to avoid having the semicolon interpreted as the end of the SQL statement. Edit the result to change the asterisk to a semicolon.

**Access path differences from test to production:** When you bind applications on the test system with production statistics, access paths should be similar but still may be different to what you see when the same query is bound on your production system. The access paths from test to production could be different for the following possible reasons:

- The processor models are different.
- The number of processors are different. (Differences in the number of processors can affect the degree of parallelism that is obtained.)
- The buffer pool sizes are different.
- The RID pool sizes are different.
- Data in SYSIBM.SYSCOLDIST is mismatched. (This mismatch occurs only if some of the previously mentioned steps mentioned are not followed exactly).
- The service levels are different.
- The values of optimization subsystem parameters, such as STARJOIN, NPGTHRSH, and PARAMDEG (MAX DEGREE on installation panel DSNTIP8) are different.

```

#
#
#

```

- The use of techniques such as optimization hints and volatile tables are different.

*Tools to help:* If your production system is accessible from your test system, you can use DB2 PM EXPLAIN on your test system to request EXPLAIN information from your production system. This request can reduce the need to simulate a production system by updating the catalog.

You can also use the DB2 Visual Explain feature to display the current PLAN\_TABLE output or the graphed access paths for statements within any particular subsystem from your workstation environment. For example, if you have your test system on one subsystem and your production system on another subsystem, you can visually compare the PLAN\_TABLE outputs or access paths simultaneously with some window or view manipulation. You can then access the catalog statistics for certain referenced objects of an access path from either of the displayed PLAN\_TABLEs or access path graphs. For information on using Visual Explain, see DB2 Visual Explain online help.

---

## Chapter 34. Using EXPLAIN to improve SQL performance

The information under this heading, up to the end of this chapter, is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

**Definitions and purpose:** EXPLAIN is a monitoring tool that produces information about the following:

- A plan, package, or SQL statement when it is bound. The output appears in a table that you create called PLAN\_TABLE, which is also called a *plan table*. For experienced users, you can use PLAN\_TABLE to give optimization hints to DB2. See “Giving optimization hints to DB2” on page 806 for more information.
- An estimated cost of executing an SQL SELECT, INSERT, UPDATE, or DELETE statement. The output appears in a table that you create called DSN\_STATEMENT\_TABLE, which is also called a *statement table*. For more information about statement tables, see “Estimating a statement’s cost” on page 985.
- User-defined functions referred to in the statement, including the specific name and schema. The output appears in a table that you create called DSN\_FUNCTION\_TABLE, which is also called a *function table*. For more information about function tables, see Part 3 of *DB2 Application Programming and SQL Guide*.

**Other tools:** The following tools can help you tune SQL queries:

- **DB2 Visual Explain**

Visual Explain is a graphical workstation feature of DB2 that provides:

- An easy-to-understand display of a selected access path
- Suggestions for changing an SQL statement
- An ability to invoke EXPLAIN for dynamic SQL statements
- An ability to provide DB2 catalog statistics for referenced objects of an access path
- A subsystem parameter browser with keyword 'Find' capabilities

For information about using DB2 Visual Explain, which is a separately packaged CD-ROM provided with your DB2 UDB for z/OS Version 8 license, see *DB2 Visual Explain online help*.

- **OMEGAMON Performance Expert**

OMEGAMON is a performance monitoring tool that formats performance data. OMEGAMON combines information from EXPLAIN and from the DB2 catalog. It displays access paths, indexes, tables, table spaces, plans, packages, DBRMs, host variable definitions, ordering, table access and join sequences, and lock types. Output is presented in a dialog rather than as a table, making the information easy to read and understand. DB2 Performance Monitor (DB2 PM) performs some of the functions of OMEGAMON Performance Expert. For more information about OMEGAMON and DB2 PM, see “OMEGAMON” on page 1202.

- **DB2 Estimator**

DB2 Estimator for Windows is an easy-to-use, stand-alone tool for estimating the performance of DB2 UDB for z/OS applications. You can use it to predict the performance and cost of running the applications, transactions, SQL statements,

triggers, and utilities. For instance, you can use DB2 Estimator for estimating the impact of adding or dropping an index from a table, estimating the change in response time from adding processor resources, and estimating the amount of time a utility job will take to run. DB2 Estimator for Windows can be downloaded from the Web.

- # • DB2-supplied EXPLAIN stored procedure. Users with authority to run EXPLAIN
- # directly can obtain access path information by calling the DB2-supplied
- # EXPLAIN stored procedure. For more information about the DB2-supplied
- # EXPLAIN stored procedure, see Appendix J, “DB2-supplied stored procedures,”
- # on page 1261.

**Chapter overview:** This chapter includes the following topics:

- “Obtaining PLAN\_TABLE information from EXPLAIN”
- “Asking questions about data access” on page 943
- “Interpreting access to a single table” on page 951
- “Interpreting access to two or more tables (join)” on page 959
- “Interpreting data prefetch” on page 973
- “Determining sort activity” on page 977
- “Processing for views and nested table expressions” on page 979
- “Estimating a statement’s cost” on page 985

See also Chapter 35, “Parallel operations and query performance,” on page 991.

---

## Obtaining PLAN\_TABLE information from EXPLAIN

The information in PLAN\_TABLE can help you to:

- Design databases, indexes, and application programs
- Determine when to rebind an application
- Determine the access path chosen for a query

For each access to a single table, EXPLAIN tells you if an index access or table space scan is used. If indexes are used, EXPLAIN tells you how many indexes and index columns are used and what I/O methods are used to read the pages. For joins of tables, EXPLAIN tells you which join method and type are used, the order in which DB2 joins the tables, and when and why it sorts any rows.

The primary use of EXPLAIN is to observe the access paths for the SELECT parts of your statements. For UPDATE and DELETE WHERE CURRENT OF, and for INSERT, you receive somewhat less information in your plan table. And some accesses EXPLAIN does not describe: for example, the access to LOB values, which are stored separately from the base table, and access to parent or dependent tables needed to enforce referential constraints.

The access paths shown for the example queries in this chapter are intended only to illustrate those examples. If you execute the queries in this chapter on your system, the access paths chosen can be different.

**Steps to obtain PLAN\_TABLE information:** Use the following overall steps to obtain information from EXPLAIN:

1. Have appropriate access to a plan table. To create the table, see “Creating PLAN\_TABLE” on page 933.
2. Populate the table with the information you want. For instructions, see “Populating and maintaining a plan table” on page 940.
3. Select the information you want from the table. For instructions, see “Reordering rows from a plan table” on page 943.

## Creating PLAN\_TABLE

| Before you can use EXPLAIN, a PLAN\_TABLE must be created to hold the results  
| of EXPLAIN. A copy of the statements that are needed to create the table are in the  
DB2 sample library, under the member name DSNTESC. (Unless you need the  
information that they provide, you do not need to create a function table or  
statement table to use EXPLAIN.)

# **Important::** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN  
# tables must be created with CCSID UNICODE. This includes, but is  
# not limited to, mixed data strings that are used for tokens, SQL  
# statements, application names, program names, correlation names, and  
# collection IDs.

| Figure 106 on page 934 shows most current format of a plan table, which consists  
| of 58 columns. Table 165 on page 936 shows the content of each column.

```

CREATE TABLE userid.PLAN_TABLE
  (QUERYNO          INTEGER          NOT NULL,
   QBLOCKNO        SMALLINT         NOT NULL,
   APPLNAME        CHAR(8)          NOT NULL,
   | PROGNAM        VARCHAR(128)     NOT NULL,
   | PLANNO         SMALLINT         NOT NULL,
   | METHOD          SMALLINT         NOT NULL,

   | STMTOKEN      VARCHAR(240)    )
  IN database-name.table-space-name
  CCSID EBCDIC;

```

Figure 106. 58-column format of PLAN\_TABLE

Your plan table can use many other formats with fewer columns, as shown in Figure 107. However, use the 58-column format because it gives you the most information. If you alter an existing plan table with fewer than 58 columns to the 58-column format:

- If they exist, change the data type of columns: PROGNAME, CREATOR, TNAME, ACESSTYPE, ACCESSNAME, REMARKS, COLLID, CORRELATION\_NAME, IBM\_SERVICE\_DATA, OPTHINT, and HINT\_USED. Use the values shown in Figure 106 on page 934.
- Add the missing columns to the table. Use the column definitions shown in Figure 106 on page 934. For most columns added, specify NOT NULL WITH DEFAULT so that default values are included for the rows in the table. However, as the figure shows, certain columns do allow nulls. Do not specify those columns as NOT NULL WITH DEFAULT.

QUERYNO	INTEGER	NOT NULL	ACCESS_DEGREE	SMALLINT	
QBLOCKNO	SMALLINT	NOT NULL	ACCESS_PGROUP_ID	SMALLINT

Figure 107. Formats of PLAN\_TABLE prior to the 58-column format

Table 165 on page 936 shows the descriptions of the columns in PLAN\_TABLE.

Table 165. Descriptions of columns in PLAN\_TABLE

Column Name	Description
QUERYNO	<p>A number intended to identify the statement being explained. For a row produced by an EXPLAIN statement, specify the number in the QUERYNO clause. For a row produced by non-EXPLAIN statements, specify the number using the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE and DELETE statement syntax. Otherwise, DB2 assigns a number based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values greater than 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of TIMESTAMP is unique.</p>
QBLOCKNO	A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.
APPLNAME	The name of the application plan for the row. Applies only to embedded EXPLAIN statements executed from a plan or to statements explained when binding a plan. Blank if not applicable.
PROGNAME	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. Blank if not applicable.
PLANNO	The number of the step in which the query indicated in QBLOCKNO was processed. This column indicates the order in which the steps were executed.
METHOD	<p>A number (0, 1, 2, 3, or 4) that indicates the join method used for the step:</p> <p><b>0</b> First table accessed, continuation of previous table accessed, or not used.</p> <p><b>1</b> <i>Nested loop</i> join. For each row of the present composite table, matching rows of a new table are found and joined.</p> <p><b>2</b> <i>Merge scan</i> join. The present composite table and the new table are scanned in the order of the join columns, and matching rows are joined.</p> <p><b>3</b> Sorts needed by ORDER BY, GROUP BY, SELECT DISTINCT, UNION, a quantified predicate, or an IN predicate. This step does not access a new table.</p> <p><b>4</b> <i>Hybrid</i> join. The current composite table is scanned in the order of the join-column rows of the new table. The new table is accessed using list prefetch.</p>
CREATOR	The creator of the new table accessed in this step, blank if METHOD is 3.
TNAME	The name of a table, materialized query table, created or declared temporary table, materialized view, or materialized table expression. The value is blank if METHOD is 3. The column can also contain the name of a table in the form DSNWFQB( <i>qblockno</i> ). DSNWFQB( <i>qblockno</i> ) is used to represent the intermediate result of a UNION ALL or an outer join that is materialized. If a view is merged, the name of the view does not appear.
TABNO	Values are for IBM use only.

Table 165. Descriptions of columns in PLAN\_TABLE (continued)

Column Name	Description
ACCESSTYPE	The method of accessing the new table: <b>I</b> By an index (identified in ACCESSCREATOR and ACCESSNAME) <b>I1</b> By a one-fetch index scan <b>M</b> By a multiple index scan (followed by MX, MI, or MU) <b>MI</b> By an intersection of multiple indexes <b>MU</b> By a union of multiple indexes <b>MX</b> By an index scan on the index named in ACCESSNAME <b>N</b> By an index scan when the matching predicate contains the IN keyword <b>R</b> By a table space scan <b>RW</b> By a work file scan of the result of a materialized user-defined table function <b>T</b> By a sparse index (star join work files) <b>V</b> By buffers for an INSERT statement within a SELECT <b>blank</b> Not applicable to the current row
MATCHCOLS	For ACCESSTYPE I, I1, N, or MX, the number of index keys used in an index scan; otherwise, 0.
ACCESSCREATOR	For ACCESSTYPE I, I1, N, or MX, the creator of the index; otherwise, blank.
ACCESSNAME	For ACCESSTYPE I, I1, N, or MX, the name of the index; otherwise, blank.
INDEXONLY	Whether access to an index alone is enough to carry out the step, or whether data too must be accessed. Y=Yes; N=No. For exceptions, see "Is the query satisfied using only the index? (INDEXONLY=Y)" on page 946.
SORTN_UNIQ	Whether the new table is sorted to remove duplicate rows. Y=Yes; N=No.
SORTN_JOIN	Whether the new table is sorted for join method 2 or 4. Y=Yes; N=No.
SORTN_ORDERBY	Whether the new table is sorted for ORDER BY. Y=Yes; N=No.
SORTN_GROUPBY	Whether the new table is sorted for GROUP BY. Y=Yes; N=No.
SORTC_UNIQ	Whether the composite table is sorted to remove duplicate rows. Y=Yes; N=No.
SORTC_JOIN	Whether the composite table is sorted for join method 1, 2 or 4. Y=Yes; N=No.
SORTC_ORDERBY	Whether the composite table is sorted for an ORDER BY clause or a quantified predicate. Y=Yes; N=No.
SORTC_GROUPBY	Whether the composite table is sorted for a GROUP BY clause. Y=Yes; N=No.
TSLOCKMODE	An indication of the mode of lock to be acquired on either the new table, or its table space or table space partitions. If the isolation can be determined at bind time, the values are: <b>IS</b> Intent share lock <b>IX</b> Intent exclusive lock <b>S</b> Share lock <b>U</b> Update lock <b>X</b> Exclusive lock <b>SIX</b> Share with intent exclusive lock <b>N</b> UR isolation; no lock If the isolation cannot be determined at bind time, then the lock mode determined by the isolation at run time is shown by the following values. <b>NS</b> For UR isolation, no lock; for CS, RS, or RR, an S lock. <b>NIS</b> For UR isolation, no lock; for CS, RS, or RR, an IS lock. <b>NSS</b> For UR isolation, no lock; for CS or RS, an IS lock; for RR, an S lock. <b>SS</b> For UR, CS, or RS isolation, an IS lock; for RR, an S lock.  The data in this column is right justified. For example, IX appears as a blank followed by I followed by X. If the column contains a blank, then no lock is acquired.
TIMESTAMP	Usually, the time at which the row is processed, to the last .01 second. If necessary, DB2 adds .01 second to the value to ensure that rows for two successive queries have different values.

Table 165. Descriptions of columns in PLAN\_TABLE (continued)

Column Name	Description
REMARKS	A field into which you can insert any character string of 762 or fewer characters.
PREFETCH	Whether data pages are to be read in advance by prefetch:
#	<b>S</b> Pure sequential prefetch
#	<b>L</b> Prefetch through a page list
#	<b>D</b> Possible candidate for dynamic prefetch
#	<b>blank</b> Unknown or no prefetch
COLUMN_FN_EVAL	When an SQL aggregate function is evaluated. R = while the data is being read from the table or index; S = while performing a sort to satisfy a GROUP BY clause; blank = after data retrieval and after any sorts.
MIXOPSEQ	The sequence number of a step in a multiple index operation.
	<b>1, 2, ... n</b> For the steps of the multiple index procedure (ACCESSTYPE is MX, MI, or MU.)
	<b>0</b> For any other rows (ACCESSTYPE is I, I1, M, N, R, or blank.)
VERSION	The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. Blank if not applicable.
COLLID	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. Blank if not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
<p><b>Note:</b> The following nine columns, from ACCESS_DEGREE through CORRELATION_NAME, contain the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, each of them can contain null if the method it refers to does not apply.</p>	
ACCESS_DEGREE	The number of parallel tasks or operations activated by a query. This value is determined at bind time; the actual number of parallel operations used at execution time could be different. This column contains 0 if there is a host variable.
ACCESS_PGROUP_ID	The identifier of the parallel group for accessing the new table. A parallel group is a set of consecutive operations, executed in parallel, that have the same number of parallel tasks. This value is determined at bind time; it could change at execution time.
JOIN_DEGREE	The number of parallel operations or tasks used in joining the composite table with the new table. This value is determined at bind time and can be 0 if there is a host variable. The actual number of parallel operations or tasks used at execution time could be different.
JOIN_PGROUP_ID	The identifier of the parallel group for joining the composite table with the new table. This value is determined at bind time; it could change at execution time.
SORTC_PGROUP_ID	The parallel group identifier for the parallel sort of the composite table.
SORTN_PGROUP_ID	The parallel group identifier for the parallel sort of the new table.
PARALLELISM_MODE	The kind of parallelism, if any, that is used at bind time: <b>I</b> Query I/O parallelism <b>C</b> Query CP parallelism <b>X</b> Sysplex query parallelism
MERGE_JOIN_COLS	The number of columns that are joined during a merge scan join (Method=2).
CORRELATION_NAME	The correlation name of a table or view that is specified in the statement. If there is no correlation name, then the column is null.
PAGE_RANGE	Whether the table qualifies for page range screening, so that plans scan only the partitions that are needed. Y = Yes; blank = No.

Table 165. Descriptions of columns in PLAN\_TABLE (continued)

Column Name	Description
JOIN_TYPE	The type of join: <b>F</b> FULL OUTER JOIN <b>L</b> LEFT OUTER JOIN <b>S</b> STAR JOIN <b>blank</b> INNER JOIN or no join RIGHT OUTER JOIN converts to a LEFT OUTER JOIN when you use it, so that JOIN_TYPE contains L.
GROUP_MEMBER	The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.
IBM_SERVICE_DATA	Values are for IBM use only.
WHEN_OPTIMIZE	When the access path was determined: <b>blank</b> At bind time, using a default filter factor for any host variables, parameter markers, or special registers. <b>B</b> At bind time, using a default filter factor for any host variables, parameter markers, or special registers; however, the statement is reoptimized at run time using input variable values for input host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS) or REOPT(ONCE) must be specified for reoptimization to occur. <b>R</b> At run time, using input variables for any host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS) or REOPT(ONCE) must be specified for this to occur.
QBLOCK_TYPE	For each query block, an indication of the type of SQL operation performed. For the outermost query, this column identifies the statement type. Possible values: <b>SELECT</b> SELECT <b>INSERT</b> INSERT <b>UPDATE</b> UPDATE <b>DELETE</b> DELETE <b>SELUPD</b> SELECT with FOR UPDATE OF <b>DELCUR</b> DELETE WHERE CURRENT OF CURSOR <b>UPDCUR</b> UPDATE WHERE CURRENT OF CURSOR <b>CORSUB</b> Correlated subselect or fullselect <b>NCOSUB</b> Noncorrelated subselect or fullselect <b>TABLEX</b> Table expression <b>TRIGGR</b> WHEN clause on CREATE TRIGGER <b>UNION</b> UNION <b>UNIONA</b> UNION ALL
# BIND_TIME	For static SQL statements, the time at which the plan or package for this statement or query block was bound. For cached dynamic SQL statements, the time at which the statement entered the cache. For static and cached dynamic SQL statements, this is a full-precision timestamp value. For non-cached dynamic SQL statements, this is the value contained in the TIMESTAMP column of PLAN_TABLE appended by 4 zeroes.
OPTHINT	A string that you use to identify this row as an optimization hint for DB2. DB2 uses this row as input when choosing an access path.
HINT_USED	If DB2 used one of your optimization hints, it puts the identifier for that hint (the value in OPTHINT) in this column.

Table 165. Descriptions of columns in PLAN\_TABLE (continued)

Column Name	Description
PRIMARY_ACCESSTYPE	Indicates whether direct row access will be attempted first:  <b>D</b> DB2 will try to use direct row access. If DB2 cannot use direct row access at run time, it uses the access path described in the ACCESSTYPE column of PLAN_TABLE. See "Is direct row access possible? (PRIMARY_ACCESSTYPE = D)" on page 946 for more information.  <b>blank</b> DB2 will not try to use direct row access.
PARENT_QBLOCKNO	A number that indicates the QBLOCKNO of the parent query block.
TABLE_TYPE	The type of new table: <b>B</b> Buffers for an INSERT statement within a SELECT <b>C</b> Common table expression <b>F</b> Table function <b>M</b> Materialized query table <b>Q</b> Temporary intermediate result table (not materialized). For the name of a view or nested table expression, a value of Q indicates that the materialization was virtual and not actual. Materialization can be virtual when the view or nested table expression definition contains a UNION ALL that is not distributed. <b>R</b> Recursive common table expression <b>T</b> Table <b>W</b> Work file The value of the column is null if the query uses GROUP BY, ORDER BY, or DISTINCT, which requires an implicit sort.
TABLE_ENCODE	The encoding scheme of the table. If the table has a single CCSID set, possible values are: <b>A</b> ASCII <b>E</b> EBCDIC <b>U</b> Unicode  M is the value of the column when the table contains multiple CCSID set, the value of the column is M.
TABLE_SCCSID	The SBCS CCSID value of the table. If column TABLE_ENCODE is M, the value is 0.
# TABLE_MCCSID #	The mixed CCSID value of the table. If column TABLE_ENCODE is M, the value is 0. If MIXED=NO in the DSHDECP module, the value is -2.
# TABLE_DCCSID #	The DBCS CCSID value of the table. If column TABLE_ENCODE is M, the value is 0. If MIXED=NO in the DSHDECP module, the value is -2.
ROUTINE_ID	Values are for IBM use only.
CTEREF	If the referenced table is a common table expression, the value is the top-level query block number.
STMTTOKEN	User-specified statement token.

## Populating and maintaining a plan table

For the two distinct ways to populate a plan table, see:

- "Executing the SQL statement EXPLAIN" on page 941
- "Binding with the option EXPLAIN(YES)" on page 941

When you populate the plan table through EXPLAIN, any INSERT triggers on the table are not activated. If you insert rows yourself, then those triggers are activated.

For a variation on executing the EXPLAIN statement, see "Executing EXPLAIN under DB2 QMF" on page 941.

For tips on maintaining a growing plan table, see “Maintaining a plan table” on page 943.

### Executing the SQL statement EXPLAIN

You can populate a PLAN\_TABLE by executing the SQL statement EXPLAIN. In the statement, specify a single explainable SQL statement in the FOR clause.

If an alias is defined on a PLAN\_TABLE that was created with a different authorization ID, and you have the appropriate SELECT and INSERT privileges, you can populate that PLAN\_TABLE even if you do not own it.

You can execute EXPLAIN either statically from an application program, or dynamically, using QMF or SPUFI. For instructions and for details of the authorization that you need on PLAN\_TABLE, see *DB2 SQL Reference*.

### Binding with the option EXPLAIN(YES)

You can populate a plan table when you bind or rebind a plan or package. Specify the option EXPLAIN(YES). EXPLAIN obtains information about the access paths for all explainable SQL statements in a package or the DBRMs of a plan. The information appears in table *package\_owner.PLAN\_TABLE* or *plan\_owner.PLAN\_TABLE*. For dynamically prepared SQL, the qualifier of PLAN\_TABLE is the current SQLID.

If the plan owner or the package owner has an alias on a PLAN\_TABLE that was created by another owner, *other\_owner.PLAN\_TABLE* is populated instead of *package\_owner.PLAN\_TABLE* or *plan\_owner.PLAN\_TABLE*.

**Performance considerations:** EXPLAIN as a bind option should not be a performance concern. The same processing for access path selection is performed, regardless of whether you use EXPLAIN(YES) or EXPLAIN (NO). With EXPLAIN(YES), there is only a small amount of overhead processing to put the results in a plan table.

If a plan or package that was previously bound with EXPLAIN(YES) is automatically rebound, the value of field EXPLAIN PROCESSING on installation panel DSNTIPO determines whether EXPLAIN is run again during the automatic rebound. Again, there is a small amount of overhead for inserting the results into a plan table.

**EXPLAIN for remote binds:** A remote requester that accesses DB2 can specify EXPLAIN(YES) when binding a package at the DB2 server. The information appears in a plan table at the server, not at the requester. If the requester does not support the propagation of the option EXPLAIN(YES), rebound the package at the requester with that option to obtain access path information. You cannot get information about access paths for SQL statements that use private protocol.

### Executing EXPLAIN under DB2 QMF

You can use DB2 QMF to display the results of EXPLAIN to the terminal. You can create your own form to display the output or use the default form for DB2 QMF.

**Use parameter markers for host variables:** If you have host variables in a predicate for an original query in a static application and if you are using DB2 QMF or SPUFI to execute EXPLAIN for the query, in most cases, use parameter markers where you use host variables in the original query. If you use a literal value instead, you might see different access paths for your static and dynamic queries. For instance, compare the following queries:

Original Static SQL	QMF Query Using Parameter Marker	QMF Query Using Literal
DECLARE C1 CURSOR FOR SELECT * FROM T1 WHERE C1 > HOST VAR.	EXPLAIN PLAN SET QUERYNO=1 FOR SELECT * FROM T1 WHERE C1 > ?	EXPLAIN PLAN SET QUERYNO=1 FOR SELECT * FROM T1 WHERE C1 > 10

Using the literal '10' would likely produce a different filter factor and maybe a different access path from the original static SQL. (A filter factor is the proportion of rows that remain after a predicate has "filtered out" the rows that do not satisfy it. For more information about filter factors, see "Predicate filter factors" on page 766.) The parameter marker behaves just like a host variable, in that the predicate is assigned a default filter factor.

**When to use a literal:** If you know that the static plan or package was bound with REOPT(ALWAYS) and you have some idea of what is returned in the host variable, it can be more accurate to include the literal in the DB2 QMF EXPLAIN. REOPT(ALWAYS) means that DB2 will replace the value of the host variable with the true value at run time and then determine the access path. For more information about REOPT(ALWAYS) see "Changing the access path at run time" on page 779.

**Expect these differences:** Even when using parameter markers, you could see different access paths for static and dynamic queries. DB2 assumes that the value that replaces a parameter marker has the same length and precision as the column it is compared to. That assumption determines whether the predicate is stage 1 indexable or stage 2, which is always nonindexable.

If the column definition and the host variable definition are both strings, the predicate becomes stage 1 but not indexable when any of the following conditions are true:

- The column definition is CHAR or VARCHAR, and the host variable definition is GRAPHIC or VARGRAPHIC.
- The column definition is GRAPHIC or VARGRAPHIC, the host variable definition is CHAR or VARCHAR, and the length of the column definition is less than the length of the host variable definition.
- Both the column definition and the host variable definition are CHAR or VARCHAR, the length of the column definition is less than the length of the host variable definition, and the comparison operator is any operator other than "=".
- Both the column definition and the host variable definition are GRAPHIC or VARGRAPHIC, the length of the column definition is less than the length of the host variable definition, and the comparison operator is any operator other than "=".

The predicate becomes stage 2 when any of the following conditions are true:

- The column definition is DECIMAL(p,s), where p>15, and the host variable definition is REAL or FLOAT.
- The column definition is CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC, and the host variable definition is DATE, TIME, or TIMESTAMP.

## Maintaining a plan table

DB2 adds rows to PLAN\_TABLE as you choose; it does not automatically delete rows. To clear the table of obsolete rows, use DELETE, just as you would for deleting rows from any table. You can also use DROP TABLE to drop a plan table completely.

## Reordering rows from a plan table

Several processes can insert rows into the same plan table. To understand access paths, you must retrieve the rows for a particular query in an appropriate order.

### Retrieving rows for a plan

The rows for a particular plan are identified by the value of APPLNAME. The following query to a plan table returns the rows for all the explainable statements in a plan in their logical order:

```
SELECT * FROM JOE.PLAN_TABLE
  WHERE APPLNAME = 'APPL1'
  ORDER BY TIMESTAMP, QUERYNO, QBLOCKNO, PLANNO, MIXOPSEQ;
```

The result of the ORDER BY clause shows whether there are:

- Multiple QBLOCKNOs within a QUERYNO
- Multiple PLANNOs within a QBLOCKNO
- Multiple MIXOPSEQs within a PLANNO

All rows with the same non-zero value for QBLOCKNO and the same value for QUERYNO relate to a step within the query. QBLOCKNOs are not necessarily executed in the order shown in PLAN\_TABLE. But within a QBLOCKNO, the PLANNO column gives the substeps in the order they execute.

For each substep, the TNAME column identifies the table accessed. Sorts can be shown as part of a table access or as a separate step.

*What if QUERYNO=0?* For entries that contain QUERYNO=0, use the timestamp, which is guaranteed to be unique, to distinguish individual statements.

### Retrieving rows for a package

The rows for a particular package are identified by the values of PROGNAME, COLLID, and VERSION. Those columns correspond to the following four-part naming convention for packages:

```
LOCATION.COLLECTION.PACKAGE_ID.VERSION
```

COLLID gives the COLLECTION name, and PROGNAME gives the PACKAGE\_ID. The following query to a plan table return the rows for all the explainable statements in a package in their logical order:

```
SELECT * FROM JOE.PLAN_TABLE
  WHERE PROGNAME = 'PACK1' AND COLLID = 'COLL1' AND VERSION = 'PROD1'
  ORDER BY QUERYNO, QBLOCKNO, PLANNO, MIXOPSEQ;
```

---

## Asking questions about data access

When you examine your EXPLAIN results, try to answer the following questions:

- “Is access through an index? (ACCESSTYPE is I, I1, N or MX)” on page 944
- “Is access through more than one index? (ACCESSTYPE=M)” on page 944
- “How many columns of the index are used in matching? (MATCHCOLS=n)” on page 945
- “Is the query satisfied using only the index? (INDEXONLY=Y)” on page 946

- “Is direct row access possible? (PRIMARY\_ACCESSTYPE = D)” on page 946
- “Is a view or nested table expression materialized?” on page 948
- “Was a scan limited to certain partitions? (PAGE\_RANGE=Y)” on page 948
- “What kind of prefetching is expected? (PREFETCH = L, S, D, or blank)” on page 949
- “Is data accessed or processed in parallel? (PARALLELISM\_MODE is I, C, or X)” on page 949
- “Are sorts performed?” on page 949
- “Is a subquery transformed into a join?” on page 950
- “When are aggregate functions evaluated? (COLUMN\_FN\_EVAL)” on page 950
- “How many index screening columns are used?” on page 950
- “Is a complex trigger WHEN clause used? (QBLOCKTYPE=TRIGGR)” on page 950

As explained in this section, they can be answered in terms of values in columns of a plan table.

### Is access through an index? (ACCESSTYPE is I, I1, N or MX)

If the column ACCESSTYPE in the plan table has one of those values, DB2 uses an index to access the table that is named in column TNAME. The columns ACCESSCREATOR and ACCESSNAME identify the index. For a description of methods of using indexes, see “Index access paths” on page 954.

### Is access through more than one index? (ACCESSTYPE=M)

The value M indicates that DB2 uses a set of indexes to access a single table. A set of rows in the plan table contain information about the multiple index access. The rows are numbered in column MIXOPSEQ in the order of execution of steps in the multiple index access. (If you retrieve the rows in order by MIXOPSEQ, the result is similar to postfix arithmetic notation.)

Both of the following examples have these indexes: IX1 on T(C1) and IX2 on T(C2).

**Example:** Suppose that you issue the following SELECT statement:

```
SELECT * FROM T
WHERE C1 = 1 AND C2 = 1;
```

DB2 processes the query by performing the following steps:

1. DB2 retrieves all the qualifying record identifiers (RIDs) where C1=1, by using index IX1.
2. DB2 retrieves all the qualifying RIDs where C2=1, by using index IX2. The intersection of these lists is the final set of RIDs.
3. DB2 accesses the data pages that are needed to retrieve the qualified rows by using the final RID list.

The plan table for this example is shown in Table 166.

Table 166. PLAN\_TABLE output for example with intersection (AND) operator

TNAME	ACCESS- TYPE	MATCH- COLS	ACCESS- NAME	INDEX- ONLY	PREFETCH	MIXOP- SEQ
T	M	0		N	L	0
T	MX	1	IX1	Y		1

Table 166. *PLAN\_TABLE* output for example with intersection (AND) operator (continued)

TNAME	ACCESS-TYPE	MATCH-COLS	ACCESS-NAME	INDEX-ONLY	PREFETCH	MIXOP-SEQ
T	MX	1	IX2	Y		2
T	MI	0		N		3

**Example:** Suppose that you issue the following SELECT statement:

```
SELECT * FROM T
  WHERE C1 BETWEEN 100 AND 199 OR
        C1 BETWEEN 500 AND 599;
```

In this case, the same index can be used more than once in a multiple index access because more than one predicate could be matching. DB2 processes the query by performing the following steps:

1. DB2 retrieves all RIDs where C1 is between 100 and 199, using index IX1.
2. DB2 retrieves all RIDs where C1 is between 500 and 599, again using IX1. The union of those lists is the final set of RIDs.
3. DB2 retrieves the qualified rows by using the final RID list.

The plan table for this example is shown in Table 167.

Table 167. *PLAN\_TABLE* output for example with union (OR) operator

TNAME	ACCESS-TYPE	MATCH-COLS	ACCESS-NAME	INDEX-ONLY	PREFETCH	MIXOP-SEQ
T	M	0		N	L	0
T	MX	1	IX1	Y		1
T	MX	1	IX1	Y		2
T	MU	0		N		3

## How many columns of the index are used in matching? (MATCHCOLS=n)

If MATCHCOLS is 0, the access method is called a *nonmatching index scan*. All the index keys and their RIDs are read.

If MATCHCOLS is greater than 0, the access method is called a *matching index scan*: the query uses predicates that match the index columns.

In general, the matching predicates on the leading index columns are equal or IN predicates. The predicate that matches the final index column can be an equal, IN, NOT NULL, or range predicate (<, <=, >, >=, LIKE, or BETWEEN).

The following example illustrates matching predicates:

```
SELECT * FROM EMP
  WHERE JOBCODE = '5' AND SALARY > 60000 AND LOCATION = 'CA';
```

```
INDEX XEMP5 on (JOBCODE, LOCATION, SALARY, AGE);
```

The index XEMP5 is the chosen access path for this query, with MATCHCOLS = 3. Two equal predicates are on the first two columns and a range predicate is on the third column. Though the index has four columns in the index, only three of them can be considered matching columns.

## Is the query satisfied using only the index? (INDEXONLY=Y)

In this case, the method is called *index-only access*. For a SELECT operation, all the columns needed for the query can be found in the index and DB2 does not access the table. For an UPDATE or DELETE operation, only the index is required to read the selected row.

Index-only access to data is not possible for any step that uses list prefetch, which is described under “What kind of prefetching is expected? (PREFETCH = L, S, D, or blank)” on page 949. Index-only access is not possible for padded indexes when varying-length data is returned or a VARCHAR column has a LIKE predicate, unless the VARCHAR FROM INDEX field of installation panel DSNTIP8 is set to YES and plan or packages have been rebound to pick up the change. See Part 2 of *DB2 Installation Guide* for more information. Index-only access is always possible for nonpadded indexes.

If access is by more than one index, INDEXONLY is Y for a step with access type MX, because the data pages are not actually accessed until all the steps for intersection (MI) or union (MU) take place.

When an SQL application uses index-only access for a ROWID column, the application claims the table space or table space partition. As a result, contention may occur between the SQL application and a utility that drains the table space or partition. Index-only access to a table for a ROWID column is not possible if the associated table space or partition is in an incompatible restrictive state. For example, an SQL application can make a read claim on the table space only if the restrictive state allows readers.

## Is direct row access possible? (PRIMARY\_ACCESTYPE = D)

If an application selects a row from a table that contains a ROWID column, the row ID value implicitly contains the location of the row. If you use that row ID value in the search condition of subsequent SELECTs, DELETEs, or UPDATEs, DB2 might be able to navigate directly to the row. This access method is called *direct row access*.

Direct row access is very fast, because DB2 does not need to use the index or a table space scan to find the row. Direct row access can be used on any table that has a ROWID column.

To use direct row access, you first select the values of a row into host variables. The value that is selected from the ROWID column contains the location of that row. Later, when you perform queries that access that row, you include the row ID value in the search condition. If DB2 determines that it can use direct row access, it uses the row ID value to navigate directly to the row.

### Which predicates qualify for direct row access?

For a query to qualify for direct row access, the search condition must be a Boolean term *stage 1* predicate that fits one of these descriptions:

1. A simple Boolean term predicate of the form COL=*noncolumn expression*, where COL has the ROWID data type and *noncolumn expression* contains a row ID
2. A simple Boolean term predicate of the form COL IN *list*, where COL has the ROWID data type and the values in *list* are row IDs, and an index is defined on COL
3. A compound Boolean term that combines several simple predicates using the AND operator, and one of the simple predicates fits description 1 or 2

However, just because a query qualifies for direct row access does not mean that access path is always chosen. If DB2 determines that another access path is better, direct row access is not chosen.

**Examples:** In the following predicate example, ID is a ROWID column in table T1. A unique index exists on that ID column. The host variables are of the ROWID type.

```
WHERE ID IN (:hv_rowid1,:hv_rowid2,:hv_rowid3)
```

The following predicate also qualifies for direct row access:

```
WHERE ID = ROWID(X'F0DFD230E3C0D80D81C201AA0A280100000000000203')
```

*Searching for propagated rows:* If rows are propagated from one table to another, do not expect to use the same row ID value from the source table to search for the same row in the target table, or vice versa. This does not work when direct row access is the access path chosen.

**Example:** Assume that the host variable in the following statement contains a row ID from SOURCE:

```
SELECT * FROM TARGET
  WHERE ID = :hv_rowid
```

Because the row ID location is not the same as in the source table, DB2 will probably not find that row. Search on another column to retrieve the row you want.

## Reverting to ACESSTYPE

Although DB2 might plan to use direct row access, circumstances can cause DB2 to not use direct row access at run time. DB2 remembers the location of the row as of the time it is accessed. However, that row can change locations (such as after a REORG) between the first and second time it is accessed, which means that DB2 cannot use direct row access to find the row on the second access attempt. Instead of using direct row access, DB2 uses the access path that is shown in the ACESSTYPE column of PLAN\_TABLE.

If the predicate you are using to do direct row access is not indexable and if DB2 is unable to use direct row access, then DB2 uses a table space scan to find the row. This can have a profound impact on the performance of applications that rely on direct row access. Write your applications to handle the possibility that direct row access might not be used. Some options are to:

- Ensure that your application does not try to remember ROWID columns across reorganizations of the table space.

When your application commits, it releases its claim on the table space; it is possible that a REORG can run and move the row, which disables direct row access. Plan your commit processing accordingly; use the returned row ID value before committing, or re-select the row ID value after a commit is issued.

If you are storing ROWID columns from another table, update those values after the table with the ROWID column is reorganized.

- Create an index on the ROWID column, so that DB2 can use the index if direct row access is disabled.
- Supplement the ROWID column predicate with another predicate that enables DB2 to use an existing index on the table. For example, after reading a row, an application might perform the following update:

```
EXEC SQL UPDATE EMP
SET SALARY = :hv_salary + 1200
WHERE EMP_ROWID = :hv_emp_rowid
AND EMPNO = :hv_empno;
```

If an index exists on EMPNO, DB2 can use index access if direct access fails. The additional predicate ensures DB2 does not revert to a table space scan.

### Using direct row access and other access methods

**Parallelism:** Direct row access and parallelism are mutually exclusive. If a query qualifies for both direct row access and parallelism, direct row access is used. If direct row access fails, DB2 does not revert to parallelism; instead it reverts to the backup access type (as designated by column ACCESSTYPE in the PLAN\_TABLE). This might result in a table space scan. To avoid a table space scan in case direct row access fails, add an indexed column to the predicate.

**RID list processing:** Direct row access and RID list processing are mutually exclusive. If a query qualifies for both direct row access and RID list processing, direct row access is used. If direct row access fails, DB2 does not revert to RID list processing; instead it reverts to the backup access type.

### Is a view or nested table expression materialized?

When the column TNAME names a view or nested table expression and column TABLE\_TYPE contains a W, it indicates that the view or nested table expression is materialized. *Materialization* means that the data rows that are selected by the view or nested table expression are put into a work file that is to be processed like a table. (For a more detailed description of materialization, see “Processing for views and nested table expressions” on page 979.)

### Was a scan limited to certain partitions? (PAGE\_RANGE=Y)

DB2 can limit a scan of data in a partitioned table space to one or more partitions. The method is called a *limited partition scan*. The query must provide a predicate on the first key column of the partitioning index. DB2 can use all leading columns of the partitioning key. The rules for using a partitioning column to limit partitions are the same as the rules for determining a matching column on an index. If a partitioning column is a candidate to be a matching column, that column can limit partitions.

A limited partition scan can be combined with other access methods. For example, consider the following query:

```
SELECT .. FROM T
WHERE (C1 BETWEEN '2002' AND '3280'
OR C1 BETWEEN '6000' AND '8000')
AND C2 = '6';
```

Assume that table T has a partitioned index on column C1 and that values of C1 between 2002 and 3280 all appear in partitions 3 and 4 and the values between 6000 and 8000 appear in partitions 8 and 9. Assume also that T has another index on column C2. DB2 could choose any of these access methods:

- A matching index scan on column C1. The scan reads index values and data only from partitions 3, 4, 8, and 9. (PAGE\_RANGE=N)
- A matching index scan on column C2. (DB2 might choose that if few rows have C2=6.) The matching index scan reads all RIDs for C2=6 from the index on C2 and corresponding data pages from partitions 3, 4, 8, and 9. (PAGE\_RANGE=Y)

- A table space scan on T. DB2 avoids reading data pages from any partitions except 3, 4, 8 and 9. (PAGE\_RANGE=Y)

## What kind of prefetching is expected? (PREFETCH = L, S, D, or blank)

*Prefetching* is a method of determining in advance that a set of data pages is about to be used and then reading the entire set into a buffer with a single asynchronous I/O operation. If the value of PREFETCH is:

- S, the method is called *sequential prefetch*. The data pages that are read in advance are sequential. A table space scan always uses sequential prefetch. An index scan might not use it. For a more complete description, see “Sequential prefetch (PREFETCH=S)” on page 973.
- L, the method is called *list prefetch*. One or more indexes are used to select the RIDs for a list of data pages to be read in advance; the pages need not be sequential. Usually, the RIDs are sorted. The exception is the case of a hybrid join (described under “Hybrid join (METHOD=4)” on page 965) when the value of column SORTN\_JOIN is N. For a more complete description, see “List prefetch (PREFETCH=L)” on page 974.
- D, the method is called *dynamic prefetch*. DB2 expects that the pages to be accessed will be sufficiently nonsequential to invoke dynamic prefetch.
- Blank, prefetching is not expected. However, depending on the pattern of the page access, data can be prefetched at execution time through a process called *sequential detection*. For a description of that process, see “Sequential detection at execution time” on page 976.

## Is data accessed or processed in parallel? (PARALLELISM\_MODE is I, C, or X)

Parallel processing applies only to read-only queries.

If mode is:	DB2 plans to use:
I	Parallel I/O operations
C	Parallel CP operations
X	Sysplex query parallelism

Non-null values in columns ACCESS\_DEGREE and JOIN\_DEGREE indicate to what degree DB2 plans to use parallel operations. At execution time, however, DB2 might not actually use parallelism, or it might use fewer operations in parallel than were originally planned. For a more complete description, see Chapter 35, “Parallel operations and query performance,” on page 991. For more information about Sysplex query parallelism, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*.

## Are sorts performed?

**SORTN\_JOIN and SORTC\_JOIN:** SORTN\_JOIN indicates that the new table of a join is sorted before the join. (For hybrid join, this is a sort of the RID list.) When SORTN\_JOIN and SORTC\_JOIN are both ‘Y’, two sorts are performed for the join. The sorts for joins are indicated on the same row as the new table access.

**METHOD 3 sorts:** These are used for ORDER BY, GROUP BY, SELECT DISTINCT, UNION, or a quantified predicate. A quantified predicate is ‘col = ANY (fullselect)’ or ‘col = SOME (fullselect)’. They are indicated on a separate row. A single row of the plan table can indicate two sorts of a composite table, but only one sort is actually done.

*SORTC\_UNIQ and SORTC\_ORDERBY*: SORTC\_UNIQ indicates a sort to remove duplicates, as might be needed by a SELECT statement with DISTINCT or UNION. SORTC\_ORDERBY usually indicates a sort for an ORDER BY clause. But SORTC\_UNIQ and SORTC\_ORDERBY also indicate when the results of a noncorrelated subquery are sorted, both to remove duplicates and to order the results. One sort does both the removal and the ordering.

## Is a subquery transformed into a join?

For better access paths, DB2 sometimes transforms subqueries into joins, as described in “Conditions for DB2 to transform a subquery into a join” on page 788. A plan table shows that a subquery is transformed into a join by the value in column QBLOCKNO.

- If the subquery is not transformed into a join, that means it is executed in a separate operation, and its value of QBLOCKNO is greater than the value for the outer query.
- If the subquery is transformed into a join, it and the outer query have the same value of QBLOCKNO. A join is also indicated by a value of 1, 2, or 4 in column METHOD.

## When are aggregate functions evaluated? (COLUMN\_FN\_EVAL)

When the aggregate functions are evaluated is based on the access path chosen for the SQL statement.

- If the ACESSTYPE column is I1, then a MAX or MIN function can be evaluated by one access of the index named in ACCESSNAME.
- For other values of ACESSTYPE, the COLUMN\_FN\_EVAL column tells when DB2 is evaluating the aggregate functions.

Value	Functions are evaluated ...
S	While performing a sort to satisfy a GROUP BY clause
R	While the data is being read from the table or index
blank	After data retrieval and after any sorts

Generally, values of R and S are considered better for performance than a blank.

*Use variance and standard deviation with care*: The VARIANCE and STDDEV functions are always evaluated late (that is, COLUMN\_FN\_EVAL is blank). This causes other functions in the same query block to be evaluated late as well. For example, in the following query, the sum function is evaluated later than it would be if the variance function was not present:

```
SELECT SUM(C1), VARIANCE(C1) FROM T1;
```

## How many index screening columns are used?

The plan table does not provide the answer to this question. However, you can use Visual Explain to determine how many index screening columns are used. For information about Visual Explain, see DB2 Visual Explain online help.

## Is a complex trigger WHEN clause used? (QBLOCKTYPE=TRIGGR)

The plan table does not report simple trigger WHEN clauses, such as WHEN (N.C1 < 5). However, the plan table does report complex trigger WHEN clauses,

which are clauses that involve other base tables and transition tables. The QBLOCK\_TYPE column of the top level query block shows TRIGGR to indicate a complex trigger WHEN clause.

**Example:** Consider the following trigger:

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW TABLE AS NT OLD AS O
  FOR EACH STATEMENT MODE DB2SQL
  WHEN (O.ON_HAND < (SELECT MAX(ON_HAND) FROM NT))
  BEGIN ATOMIC
    INSERT INTO ORDER_LOG VALUES (O.PARTNO, O.ON_HAND);
  END
```

Table 168 shows the corresponding plan table for the WHEN clause.

Table 168. Plan table for the WHEN clause

QBLOCKNO	PLANNO	TABLE	ACCESSTYPE	QBLOCK_TYPE	PARENT_QBLOCKNO
1	1			TRIGGR	0
2	1	NT	R	NCOSUB	1

## Interpreting access to a single table

The following sections describe different access paths that values in a plan table can indicate, along with suggestions for supplying better access paths for DB2 to choose from:

- Table space scans (ACCESSTYPE=R PREFETCH=S)
- “Overview of index access” on page 952
- “Index access paths” on page 954
- “UPDATE using an index” on page 958

### Table space scans (ACCESSTYPE=R PREFETCH=S)

Table space scan is most often used for one of the following reasons:

- Access is through a created temporary table. (Index access is not possible for created temporary tables.)
- A matching index scan is not possible because an index is not available, or no predicates match the index columns.
- A high percentage of the rows in the table is returned. In this case, an index is not really useful because most rows need to be read anyway.
- The indexes that have matching predicates have low cluster ratios and are therefore efficient only for small amounts of data.

Assume that table T has no index on C1. The following is an example that uses a table space scan:

```
SELECT * FROM T WHERE C1 = VALUE;
```

In this case, at least every row in T must be examined to determine whether the value of C1 matches the given value.

### Table space scans of nonsegmented table spaces

DB2 reads and examines every page in the table space, regardless of which table the page belongs to. It might also read pages that have been left as free space and space not yet reclaimed after deleting data.

## Table space scans of segmented table spaces

If the table space is segmented, DB2 first determines which segments need to be read. It then reads only the segments in the table space that contain rows of T. If the prefetch quantity, which is determined by the size of your buffer pool, is greater than the SEGSIZE and if the segments for T are not contiguous, DB2 might read unnecessary pages. Use a SEGSIZE value that is as large as possible, consistent with the size of the data. A large SEGSIZE value is best to maintain clustering of data rows. For very small tables, specify a SEGSIZE value that is equal to the number of pages required for the table.

*Recommendation for SEGSIZE value:* Table 169 summarizes the recommendations for SEGSIZE, depending on how large the table is.

Table 169. Recommendations for SEGSIZE

Number of pages	SEGSIZE recommendation
≤ 28	4 to 28
> 28 < 128 pages	32
≥ 128 pages	64

## Table space scans of partitioned table spaces

Partitioned table spaces are nonsegmented. A table space scan on a partitioned table space is more efficient than on a nonpartitioned table space. DB2 takes advantage of the partitions by a limited partition scan, as described under “Was a scan limited to certain partitions? (PAGE\_RANGE=Y)” on page 948.

## Table space scans and sequential prefetch

Regardless of the type of table space, DB2 plans to use sequential prefetch for a table space scan. For a segmented table space, DB2 might not actually use sequential prefetch at execution time if it can determine that fewer than four data pages need to be accessed. For guidance on monitoring sequential prefetch, see “Sequential prefetch (PREFETCH=S)” on page 973.

If you do not want to use sequential prefetch for a particular query, consider adding to it the clause OPTIMIZE FOR 1 ROW.

## Overview of index access

Indexes can provide efficient access to data. In fact, that is the only purpose of nonunique indexes. Unique indexes have the additional purpose of ensuring that key values are unique.

### Using indexes to avoid sorts

As well as providing selective access to data, indexes can also order data, sometimes eliminating the need for sorting. Some sorts can be avoided if index keys are in the order needed by ORDER BY, GROUP BY, a join operation, or DISTINCT in an aggregate function. In other cases, as when list prefetch is used, the index does not provide useful ordering, and the selected data might have to be sorted.

When it is absolutely necessary to prevent a sort, consider creating an index on the column or columns necessary to provide that ordering. Consider also using the clause OPTIMIZE FOR 1 ROW to discourage DB2 from choosing a sort for the access path.

Consider the following query:

```

SELECT C1,C2,C3 FROM T
  WHERE C1 > 1
     ORDER BY C1 OPTIMIZE FOR 1 ROW;

```

An ascending index on C1 or an index on (C1,C2,C3) could eliminate a sort. For more information about OPTIMIZE FOR n ROWS, see “Minimizing overhead for retrieving few rows: OPTIMIZE FOR n ROWS” on page 795.

**Backward index scan:** In some cases, DB2 can use a backward index scan on a descending index to avoid a sort on ascending data. Similarly, an ascending index can be used to avoid a sort on descending data. For DB2 to use a backward index scan, the following conditions must be true:

- The index includes the columns in the ORDER BY clause in the same order that they appear in the ORDER BY clause.
- Each column in the sequence must have the opposite sequence (ASC or DESC) of the ORDER BY clause.

**Example:** Suppose that an index exists on the ACCT\_STAT table. The index is defined by the following columns: ACCT\_NUM, STATUS\_DATE, STATUS\_TIME. All of the columns in the index are in ascending order. Now, consider the following SELECT statements:

```

SELECT STATUS_DATE, STATUS
  FROM ACCT_STAT
 WHERE ACCT_NUM = :HV
 ORDER BY STATUS_DATE DESC, STATUS_TIME DESC;

SELECT STATUS_DATE, STATUS
  FROM ACCT_STAT
 WHERE ACCT_NUM = :HV
 ORDER BY STATUS_DATE ASC, STATUS_TIME ASC;

```

By using a backward index scan, DB2 can use the same index for both statements.

Not all sorts are inefficient. For example, if the index that provides ordering is not an efficient one and many rows qualify, it is possible that using another access path to retrieve and then sort the data could be more efficient than the inefficient, ordering index.

Indexes that are created to avoid sorts can sometimes be non-selective. If these indexes require data access and if the cluster ratio is poor, these indexes are unlikely to be chosen. Accessing many rows by using a poorly clustered index is often less efficient than accessing rows by using a table space scan and sort. Both table space scan and sort benefit from sequential access.

## Costs of indexes

Before you begin creating indexes, consider carefully their costs:

- Indexes require storage space. Padded indexes require more space than nonpadded indexes for long index keys. For short index keys, nonpadded indexes can take more space.
- Each index requires an index space and a data set, or as many data sets as the number of data partitions if the index is partitioned, and operating system restrictions exist on the number of open data sets.
- Indexes must be changed to reflect every insert or delete operation on the base table. If an update operation updates a column that is in the index, then the index must also be changed. The time required by these operations increases accordingly.

- Indexes can be built automatically when loading data, but this takes time. They must be recovered or rebuilt if the underlying table space is recovered, which might also be time-consuming.

**Recommendation:** In reviewing the access paths described in “Index access paths,” consider indexes as part of your database design. See Part 2, “Designing a database: advanced topics,” on page 23 for details about database design in general. For a query with a performance problem, ask yourself:

- Would adding a column to an index allow the query to use index-only access?
- Do you need a new index?
- Is your choice of clustering index correct?

## Index access paths

DB2 uses the following index access paths:

- “Matching index scan (MATCHCOLS>0)”
- “Index screening” on page 955
- “Nonmatching index scan (ACCESSTYPE=I and MATCHCOLS=0)” on page 955
- “IN-list index scan (ACCESSTYPE=N)” on page 955
- “Multiple index access (ACCESSTYPE is M, MX, MI, or MU)” on page 956
- “One-fetch access (ACCESSTYPE=I1)” on page 957
- “Index-only access (INDEXONLY=Y)” on page 958
- “Equal unique index (MATCHCOLS=number of index columns)” on page 958

# For dynamic SQL queries, DB2 avoids choosing indexes in which all of the  
# partitions of the index are in a restricted state. If only some partitions are in a  
# restricted state, and index might be chosen, because subsequent access might  
# require only unrestricted partitions to be touched. This behavior allows an efficient  
# index to be available as long as there is a possibility that it could be used  
# successfully. For static queries, DB2 does not consider the state of the index  
# partitions when choosing an index.

### Matching index scan (MATCHCOLS>0)

In a *matching index scan*, predicates are specified on either the leading or all of the index key columns. These predicates provide *filtering*; only specific index pages and data pages need to be accessed. If the degree of filtering is high, the matching index scan is efficient.

In the general case, the rules for determining the number of matching columns are simple, although there are a few exceptions.

- Look at the index columns from leading to trailing. For each index column, search for an indexable boolean term predicate on that column. (See “Properties of predicates” on page 755 for a definition of boolean term.) If such a predicate is found, then it can be used as a matching predicate.

Column MATCHCOLS in a plan table shows how many of the index columns are matched by predicates.

- If no matching predicate is found for a column, the search for matching predicates stops.
- If a matching predicate is a range predicate, then there can be no more matching columns. For example, in the matching index scan example that follows, the range predicate C2>1 prevents the search for additional matching columns.
- For star joins, a missing key predicate does not cause termination of matching columns that are to be used on the fact table index.

The exceptional cases are:

- At most one IN-list predicate can be a matching predicate on an index.
- For MX accesses and index access with list prefetch, IN-list predicates cannot be used as matching predicates.
- Join predicates cannot qualify as matching predicates when doing a merge join (METHOD=2). For example, T1.C1=T2.C1 cannot be a matching predicate when doing a merge join, although any local predicates, such as C1=5' can be used. Join predicates can be used as matching predicates on the inner table of a nested loop join or hybrid join.

**Matching index scan example:** Assume there is an index on T(C1,C2,C3,C4):

```
SELECT * FROM T
  WHERE C1=1 AND C2>1
         AND C3=1;
```

Two matching columns occur in this example. The first one comes from the predicate C1=1, and the second one comes from C2>1. The range predicate on C2 prevents C3 from becoming a matching column.

### Index screening

In *index screening*, predicates are specified on index key columns but are not part of the matching columns. Those predicates improve the index access by reducing the number of rows that qualify while searching the index. For example, with an index on T(C1,C2,C3,C4) in the following SQL statement, C3>0 and C4=2 are index screening predicates.

```
SELECT * FROM T
  WHERE C1 = 1
         AND C3 > 0 AND C4 = 2
         AND C5 = 8;
```

The predicates can be applied on the index, but they are not matching predicates. C5=8 is not an index screening predicate, and it must be evaluated when data is retrieved. The value of MATCHCOLS in the plan table is 1.

EXPLAIN does not directly tell when an index is screened; however, if MATCHCOLS is less than the number of index key columns, it indicates that index screening is possible.

### Nonmatching index scan (ACCESSTYPE=I and MATCHCOLS=0)

In a *nonmatching index scan* no matching columns are in the index. Hence, all the index keys must be examined.

Because a nonmatching index usually provides no filtering, only a few cases provide an efficient access path. The following situations are examples:

- When index screening predicates exist  
In that case, not all of the data pages are accessed.
- When the clause OPTIMIZE FOR n ROWS is used  
That clause can sometimes favor a nonmatching index, especially if the index gives the ordering of the ORDER BY clause or GROUP BY clause.
- When more than one table exists in a nonsegmented table space  
In that case, a table space scan reads irrelevant rows. By accessing the rows through the nonmatching index, fewer rows are read.

### IN-list index scan (ACCESSTYPE=N)

An *IN-list index scan* is a special case of the matching index scan, in which a single indexable IN predicate is used as a matching equal predicate.

You can regard the IN-list index scan as a series of matching index scans with the values in the IN predicate being used for each matching index scan. The following example has an index on (C1,C2,C3,C4) and might use an IN-list index scan:

```
SELECT * FROM T
  WHERE C1=1 AND C2 IN (1,2,3)
     AND C3>0 AND C4<100;
```

The plan table shows MATCHCOLS = 3 and ACCESTYPE = N. The IN-list scan is performed as the following three matching index scans:

```
(C1=1,C2=1,C3>0), (C1=1,C2=2,C3>0), (C1=1,C2=3,C3>0)
```

Parallelism is supported for queries that involve IN-list index access. These queries used to run sequentially in previous releases of DB2, although parallelism could have been used when the IN-list access was for the inner table of a parallel group. Now, in environments in which parallelism is enabled, you can see a reduction in elapsed time for queries that involve IN-list index access for the outer table of a parallel group.

### Multiple index access (ACCESTYPE is M, MX, MI, or MU)

*Multiple index access* uses more than one index to access a table. It is a good access path when:

- No single index provides efficient access.
- A combination of index accesses provides efficient access.

RID lists are constructed for each of the indexes involved. The unions or intersections of the RID lists produce a final list of qualified RIDs that is used to retrieve the result rows, using list prefetch. You can consider multiple index access as an extension to list prefetch with more complex RID retrieval operations in its first phase. The complex operators are union and intersection.

DB2 chooses multiple index access for the following query:

```
SELECT * FROM EMP
  WHERE (AGE = 34) OR
     (AGE = 40 AND JOB = 'MANAGER');
```

For this query:

- EMP is a table with columns EMPNO, EMPNAME, DEPT, JOB, AGE, and SAL.
- EMPX1 is an index on EMP with key column AGE.
- EMPX2 is an index on EMP with key column JOB.

The plan table contains a sequence of rows describing the access. For this query, ACCESTYPE uses the following values:

#### Value Meaning

<b>M</b>	Start of multiple index access processing
<b>MX</b>	Indexes are to be scanned for later union or intersection
<b>MI</b>	An intersection (AND) is performed
<b>MU</b>	A union (OR) is performed

The following steps relate to the previous query and the values shown for the plan table in Table 170 on page 957:

- ```
# 1. Index EMPX1, with matching predicate AGE = 40, provides a set of candidates
#   for the result of the query. The value of MIXOPSEQ is 1.
# 2. Index EMPX2, with matching predicate JOB = 'MANAGER', also provides a set
#   of candidates for the result of the query. The value of MIXOPSEQ is 2.
```

3. The first intersection (AND) is done, and the value of MIXOPSEQ is 3. This MI removes the two previous candidate lists (produced by MIXOPSEQs 2 and 3) by intersecting them to form an intermediate candidate list, IR1, which is not shown in PLAN\_TABLE.
4. Index EMPX1, with matching predicate AGE = 34, also provides a set of candidates for the result of the query. The value of MIXOPSEQ is 4.
5. The last step, where the value MIXOPSEQ is 5, is a union (OR) of the two remaining candidate lists, which are IR1 and the candidate list produced by MIXOPSEQ 1. This final union gives the result for the query.

Table 170. Plan table output for a query that uses multiple indexes. Depending on the filter factors of the predicates, the access steps can appear in a different order.

| PLAN-NO | TNAME | ACCESS-TYPE | MATCH-COLS | ACCESS-NAME | PREFETCH | MIXOP-SEQ |
|---------|-------|-------------|------------|-------------|----------|-----------|
| 1       | EMP   | M           | 0          |             | L        | 0         |
| 1       | EMP   | MX          | 1          | EMPX1       |          | 1         |
| 1       | EMP   | MX          | 1          | EMPX2       |          | 2         |
| 1       | EMP   | MI          | 0          |             |          | 3         |
| 1       | EMP   | MX          | 1          | EMPX1       |          | 4         |
| 1       | EMP   | MU          | 0          |             |          | 5         |

The multiple index steps are arranged in an order that uses RID pool storage most efficiently and for the least amount of time.

### One-fetch access (ACCESSTYPE=I1)

*One-fetch index access* requires retrieving only one row. It is the best possible access path and is chosen whenever it is available. It applies to a statement with a MIN or MAX aggregate function: the order of the index allows a single row to give the result of the function.

One-fetch index access is a possible access path when:

- The query includes only one table.
- The query includes only one aggregate function (either MIN or MAX).
- Either no predicate or all predicates are matching predicates for the index.
- The query includes no GROUP BY clause.
- Aggregate functions are on:
  - The first index column if no predicates exist
  - The last matching column of the index if the last matching predicate is a range type
  - The next index column (after the last matching column) if all matching predicates are equal type

**Queries using one-fetch index access:** Assuming that an index exists on T(C1,C2,C3), the following queries use one-fetch index scan:

```

SELECT MIN(C1) FROM T;
SELECT MIN(C1) FROM T WHERE C1>5;
SELECT MIN(C1) FROM T WHERE C1>5 AND C1<10;
SELECT MIN(C2) FROM T WHERE C1=5;
SELECT MAX(C1) FROM T;
SELECT MAX(C2) FROM T WHERE C1=5 AND C2<10;
SELECT MAX(C2) FROM T WHERE C1=5 AND C2>5 AND C2<10;
SELECT MAX(C2) FROM T WHERE C1=5 AND C2 BETWEEN 5 AND 10;

```

## Index-only access (INDEXONLY=Y)

With *index-only access*, the access path does not require any data pages because the access information is available in the index. Conversely, when an SQL statement requests a column that is not in the index, updates any column in the table, or deletes a row, DB2 has to access the associated data pages. Because the index is almost always smaller than the table itself, an index-only access path usually processes the data efficiently.

With an index on T(C1,C2), the following queries can use index-only access:

```
SELECT C1, C2 FROM T WHERE C1 > 0;  
SELECT C1, C2 FROM T;  
SELECT COUNT(*) FROM T WHERE C1 = 1;
```

## Equal unique index (MATCHCOLS=number of index columns)

An index that is fully matched and unique, and in which all matching predicates are equal-predicates, is called an *equal unique index* case. This case guarantees that only one row is retrieved. If there is no one-fetch index access available, this is considered the most efficient access over all other indexes that are not equal unique. (The uniqueness of an index is determined by whether or not it was defined as unique.)

Sometimes DB2 can determine that an index that is not fully matching is actually an equal unique index case. Assume the following case:

```
Unique Index1: (C1, C2)  
Unique Index2: (C2, C1, C3)
```

```
SELECT C3 FROM T  
WHERE C1 = 1 AND C2 = 5;
```

Index1 is a fully matching equal unique index. However, Index2 is also an equal unique index even though it is not fully matching. Index2 is the better choice because, in addition to being equal and unique, it also provides index-only access.

## UPDATE using an index

If no index key columns are updated, you can use an index while performing an UPDATE operation.

To use a matching index scan to update an index in which its key columns are being updated, the following conditions must be met:

- Each updated key column must have a corresponding predicate of the form "index\_key\_column = constant" or "index\_key\_column IS NULL".
- If a view is involved, WITH CHECK OPTION must not be specified.

For updates that do not involve dynamic scrollable cursors, DB2 can use list prefetch, multiple index access, or IN-list access. With list prefetch or multiple index access, any index or indexes can be used in an UPDATE operation. Of course, to be chosen, those access paths must provide efficient access to the data.

A positioned update that uses a dynamic scrollable cursor cannot use an access path with list prefetch, or multiple index access. This means that indexes that do not meet the preceding criteria cannot be used to locate the rows to be updated.

## Interpreting access to two or more tables (join)

A *join* operation retrieves rows from more than one table and combines them. The operation specifies at least two tables, but they need not be distinct.

This section begins with “Definitions and examples of join operations” and continues with descriptions of the methods of joining that can be indicated in a plan table:

- “Nested loop join (METHOD=1)” on page 961
- “Merge scan join (METHOD=2)” on page 963
- “Hybrid join (METHOD=4)” on page 965
- “Star join (JOIN\_TYPE='S’)” on page 967

### Definitions and examples of join operations

This section contains definitions and examples that are related to join operations.

**Definitions:** A *composite table* represents the result of accessing one or more tables in a query. If a query contains a single table, only one composite table exists. If one or more joins are involved, an *outer composite table* consists of the intermediate result rows from the previous join step. This intermediate result may, or may not, be materialized into a work file.

The *new table* (or *inner table*) in a join operation is the table that is newly accessed in the step.

A join operation can involve more than two tables. In these cases, the operation is carried out in a series of steps. For non-star joins, each step joins only two tables.

**Example:** Figure 108 shows a two-step join operation.

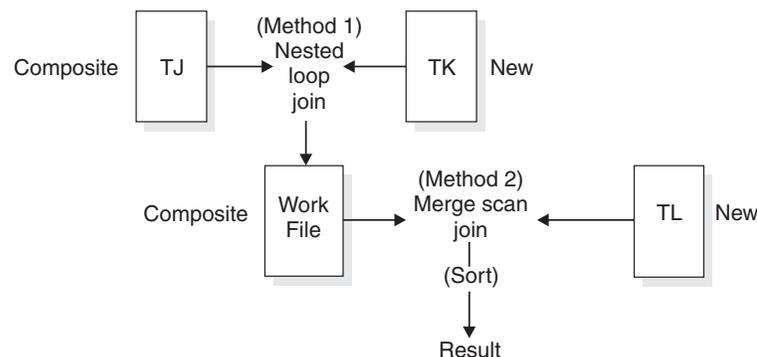

Figure 108. Two-step join operation

DB2 performs the following steps to complete the join operation:

1. Accesses the first table (METHOD=0), named TJ (TNAME), which becomes the composite table in step 2.
2. Joins the new table TK to TJ, forming a new composite table.
3. Sorts the new table TL (SORTN\_JOIN=Y) and the composite table (SORTC\_JOIN=Y), and then joins the two sorted tables.
4. Sorts the final composite table (TNAME is blank) into the desired order (SORTC\_ORDERBY=Y).

Figure 108

Table 171 and Table 172 show a subset of columns in a plan table for this join operation.

Table 171. Subset of columns for a two-step join operation

| METHOD | TNAME | ACCESS-TYPE | MATCH-COLS | ACCESS-NAME | INDEX-ONLY | TSLOCK-MODE |
|--------|-------|-------------|------------|-------------|------------|-------------|
| 0      | TJ    | I           | 1          | TJX1        | N          | IS          |
| 1      | TK    | I           | 1          | TKX1        | N          | IS          |
| 2      | TL    | I           | 0          | TLX1        | Y          | S           |
| 3      |       |             | 0          |             | N          |             |

Table 172. Subset of columns for a two-step join operation

| SORTN UNIQ | SORTN JOIN | SORTN ORDERBY | SORTN GROUPBY | SORTC UNIQ | SORTC JOIN | SORTC ORDERBY | SORTC GROUPBY |
|------------|------------|---------------|---------------|------------|------------|---------------|---------------|
| N          | N          | N             | N             | N          | N          | N             | N             |
| N          | N          | N             | N             | N          | N          | N             | N             |
| N          | Y          | N             | N             | N          | Y          | N             | N             |
| N          | N          | N             | N             | N          | N          | Y             | N             |

**Definitions:** A join operation typically matches a row of one table with a row of another on the basis of a *join condition*. For example, the condition might specify that the value in column A of one table equals the value of column X in the other table (WHERE T1.A = T2.X).

Two kinds of joins differ in what they do with rows in one table that do not match on the join condition with any row in the other table:

- An *inner join* discards rows of either table that do not match any row of the other table.
- An *outer join* keeps unmatched rows of one or the other table, or of both. A row in the composite table that results from an unmatched row is filled out with null values. As Table 173 shows, outer joins are distinguished by which unmatched rows they keep.

Table 173. Join types and kept unmatched rows

| Outer join type  | Included unmatched rows     |
|------------------|-----------------------------|
| Left outer join  | The composite (outer) table |
| Right outer join | The new (inner) table       |
| Full outer join  | Both tables                 |

**Example:** Suppose that you issue the following statement to explain an outer join:

```
EXPLAIN PLAN SET QUERYNO = 10 FOR
SELECT PROJECT, COALESCE(PROJECTS.PROD#, PRODNUM) AS PRODNUM,
      PRODUCT, PART, UNITS
FROM PROJECTS LEFT JOIN
      (SELECT PART,
      COALESCE(PARTS.PROD#, PRODUCTS.PROD#) AS PRODNUM,
      PRODUCTS.PRODUCT
FROM PARTS FULL OUTER JOIN PRODUCTS
      ON PARTS.PROD# = PRODUCTS.PROD#) AS TEMP
ON PROJECTS.PROD# = PRODNUM
```

Table 174 shows a subset of the plan table for the outer join.

Table 174. Plan table output for an example with outer joins

| QUERYNO | QBLOCKNO | PLANNO | TNAME    | JOIN_TYPE |
|---------|----------|--------|----------|-----------|
| 10      | 1        | 1      | PROJECTS |           |
| 10      | 1        | 2      | TEMP     | L         |
| 10      | 2        | 1      | PRODUCTS |           |
| 10      | 2        | 2      | PARTS    | F         |

Column JOIN\_TYPE identifies the type of outer join with one of these values:

- F for FULL OUTER JOIN
- L for LEFT OUTER JOIN
- Blank for INNER JOIN or no join

At execution, DB2 converts every right outer join to a left outer join; thus JOIN\_TYPE never identifies a right outer join specifically.

**Materialization with outer join:** Sometimes DB2 has to materialize a result table when an outer join is used in conjunction with other joins, views, or nested table expressions. You can tell when this happens by looking at the TABLE\_TYPE and TNAME columns of the plan table. When materialization occurs, TABLE\_TYPE contains a W, and TNAME shows the name of the materialized table as DSNWFQB(xx), where xx is the number of the query block (QBLOCKNO) that produced the work file.

## Nested loop join (METHOD=1)

This section describes nested loop join, which is common join method. Figure 109 illustrates a nested loop join.

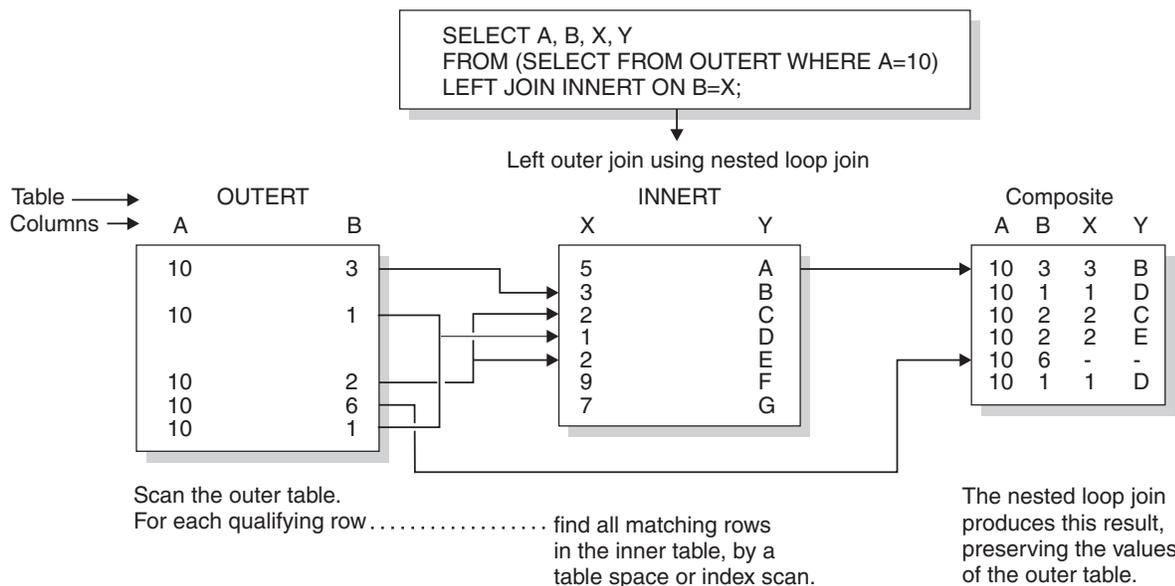

Figure 109. Nested loop join for a left outer join

### Method of joining

DB2 scans the composite (outer) table. For each row in that table that qualifies (by satisfying the predicates on that table), DB2 searches for matching rows of the new

(inner) table. It concatenates any it finds with the current row of the composite table. If no rows match the current row, then:

- For an inner join, DB2 discards the current row.
- For an outer join, DB2 concatenates a row of null values.

Stage 1 and stage 2 predicates eliminate unqualified rows during the join. (For an explanation of those types of predicate, see “Stage 1 and stage 2 predicates” on page 757.) DB2 can scan either table using any of the available access methods, including table space scan.

### Performance considerations

The nested loop join repetitively scans the inner table. That is, DB2 scans the outer table once, and scans the inner table as many times as the number of qualifying rows in the outer table. Therefore, the nested loop join is usually the most efficient join method when the values of the join column passed to the inner table are in sequence and the index on the join column of the inner table is clustered, or the number of rows retrieved in the inner table through the index is small.

### When nested loop join is used

Nested loop join is often used if:

- The outer table is small.
- Predicates with small filter factors reduce the number of qualifying rows in the outer table.
- An efficient, highly clustered index exists on the join columns of the inner table.
- The number of data pages accessed in the inner table is small.
- No join columns exist. Hybrid and sort merge joins require join columns; nested loop joins do not.

**Example: left outer join:** Figure 109 on page 961 illustrates a nested loop for a left outer join. The outer join preserves the unmatched row in OUTERT with values A=10 and B=6. The same join method for an inner join differs only in discarding that row.

**Example: one-row table priority:** For a case like the following example, with a unique index on T1.C2, DB2 detects that T1 has only one row that satisfies the search condition. DB2 makes T1 the first table in a nested loop join.

```
SELECT * FROM T1, T2
  WHERE T1.C1 = T2.C1 AND
        T1.C2 = 5;
```

**Example: Cartesian join with small tables first:** A *Cartesian join* is a form of nested loop join in which there are no join predicates between the two tables. DB2 usually avoids a Cartesian join, but sometimes it is the most efficient method, as in the following example. The query uses three tables: T1 has 2 rows, T2 has 3 rows, and T3 has 10 million rows.

```
SELECT * FROM T1, T2, T3
  WHERE T1.C1 = T3.C1 AND
        T2.C2 = T3.C2 AND
        T3.C3 = 5;
```

Join predicates are between T1 and T3 and between T2 and T3. There is no join predicate between T1 and T2.

Assume that 5 million rows of T3 have the value C3=5. Processing time is large if T3 is the outer table of the join and tables T1 and T2 are accessed for each of 5 million rows.

However if all rows from T1 and T2 are joined, without a join predicate, the 5 million rows are accessed only six times, once for each row in the Cartesian join of T1 and T2. It is difficult to say which access path is the most efficient. DB2 evaluates the different options and could decide to access the tables in the sequence T1, T2, T3.

**Sorting the composite table:** Your plan table could show a nested loop join that includes a sort on the composite table. DB2 might sort the composite table (the outer table in Figure 109) if the following conditions exist:

- The join columns in the composite table and the new table are not in the same sequence.
- The join column of the composite table has no index.
- The index is poorly clustered.

Nested loop join with a sorted composite table has the following performance advantages:

- Uses sequential detection efficiently to prefetch data pages of the new table, reducing the number of synchronous I/O operations and the elapsed time.
- Avoids repetitive full probes of the inner table index by using the index look-aside.

## Merge scan join (METHOD=2)

*Merge scan join* is also known as *merge join* or *sort merge join*. For this method, there must be one or more predicates of the form TABLE1.COL1=TABLE2.COL2, where the two columns have the same data type and length attribute.

### Method of joining

Figure 110 illustrates a merge scan join.

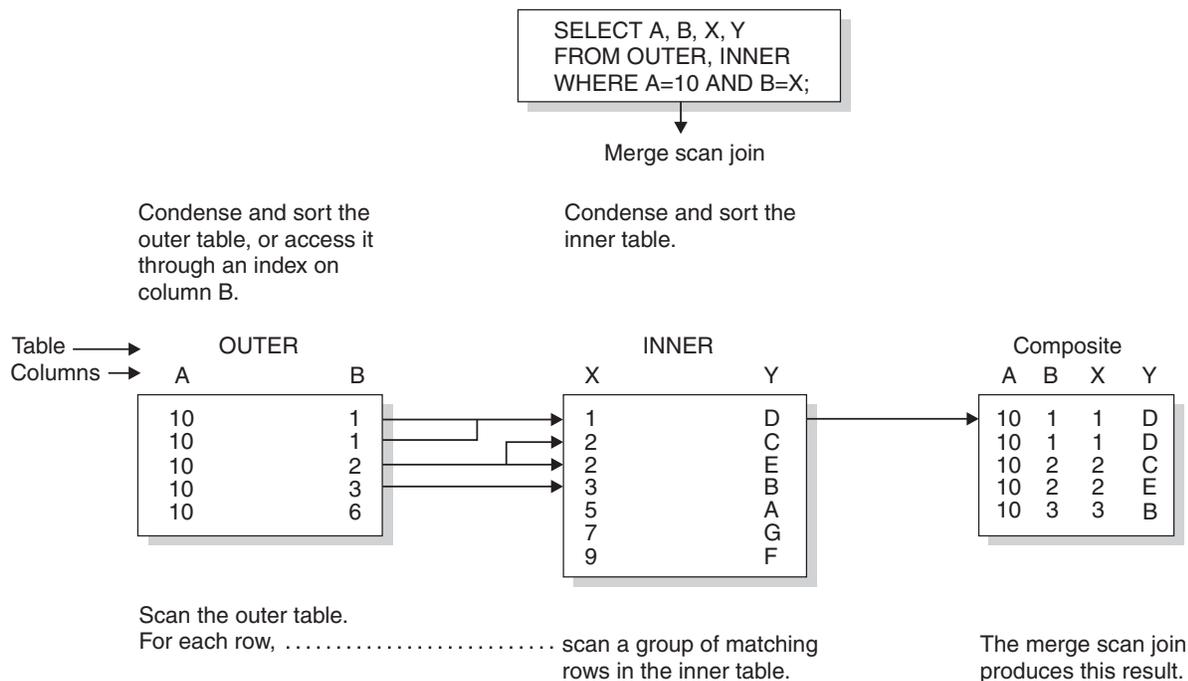

Figure 110. Merge scan join

DB2 scans both tables in the order of the join columns. If no efficient indexes on the join columns provide the order, DB2 might sort the outer table, the inner table, or both. The inner table is put into a work file; the outer table is put into a work file only if it must be sorted. When a row of the outer table matches a row of the inner table, DB2 returns the combined rows.

DB2 then reads another row of the inner table that might match the same row of the outer table and continues reading rows of the inner table as long as there is a match. When there is no longer a match, DB2 reads another row of the outer table.

- If that row has the same value in the join column, DB2 reads again the matching group of records from the inner table. Thus, a group of duplicate records in the inner table is scanned as many times as there are matching records in the outer table.
- If the outer row has a new value in the join column, DB2 searches ahead in the inner table. It can find any of the following rows:
  - Unmatched rows in the inner table, with lower values in the join column.
  - A new matching inner row. DB2 then starts the process again.
  - An inner row with a higher value of the join column. Now the row of the outer table is unmatched. DB2 searches ahead in the outer table, and can find any of the following rows:
    - Unmatched rows in the outer table.
    - A new matching outer row. DB2 then starts the process again.
    - An outer row with a higher value of the join column. Now the row of the inner table is unmatched, and DB2 resumes searching the inner table.

If DB2 finds an unmatched row:

For an inner join, DB2 discards the row.

For a left outer join, DB2 discards the row if it comes from the inner table and keeps it if it comes from the outer table.

For a full outer join, DB2 keeps the row.

When DB2 keeps an unmatched row from a table, it concatenates a set of null values as if that matched from the other table. A merge scan join must be used for a full outer join.

### **Performance considerations**

A full outer join by this method uses all predicates in the ON clause to match the two tables and reads every row at the time of the join. Inner and left outer joins use only stage 1 predicates in the ON clause to match the tables. If your tables match on more than one column, it is generally more efficient to put all the predicates for the matches in the ON clause, rather than to leave some of them in the WHERE clause.

For an inner join, DB2 can derive extra predicates for the inner table at bind time and apply them to the sorted outer table to be used at run time. The predicates can reduce the size of the work file needed for the inner table.

If DB2 has used an efficient index on the join columns, to retrieve the rows of the inner table, those rows are already in sequence. DB2 puts the data directly into the work file without sorting the inner table, which reduces the elapsed time.

### **When merge scan join is used**

A merge scan join is often used if:

- The qualifying rows of the inner and outer table are large, and the join predicate does not provide much filtering; that is, in a many-to-many join.
- The tables are large and have no indexes with matching columns.
- Few columns are selected on inner tables. This is the case when a DB2 sort is used. The fewer the columns to be sorted, the more efficient the sort is.

## Hybrid join (METHOD=4)

The method applies only to an inner join and requires an index on the join column of the inner table. Figure 111 illustrates a hybrid join.

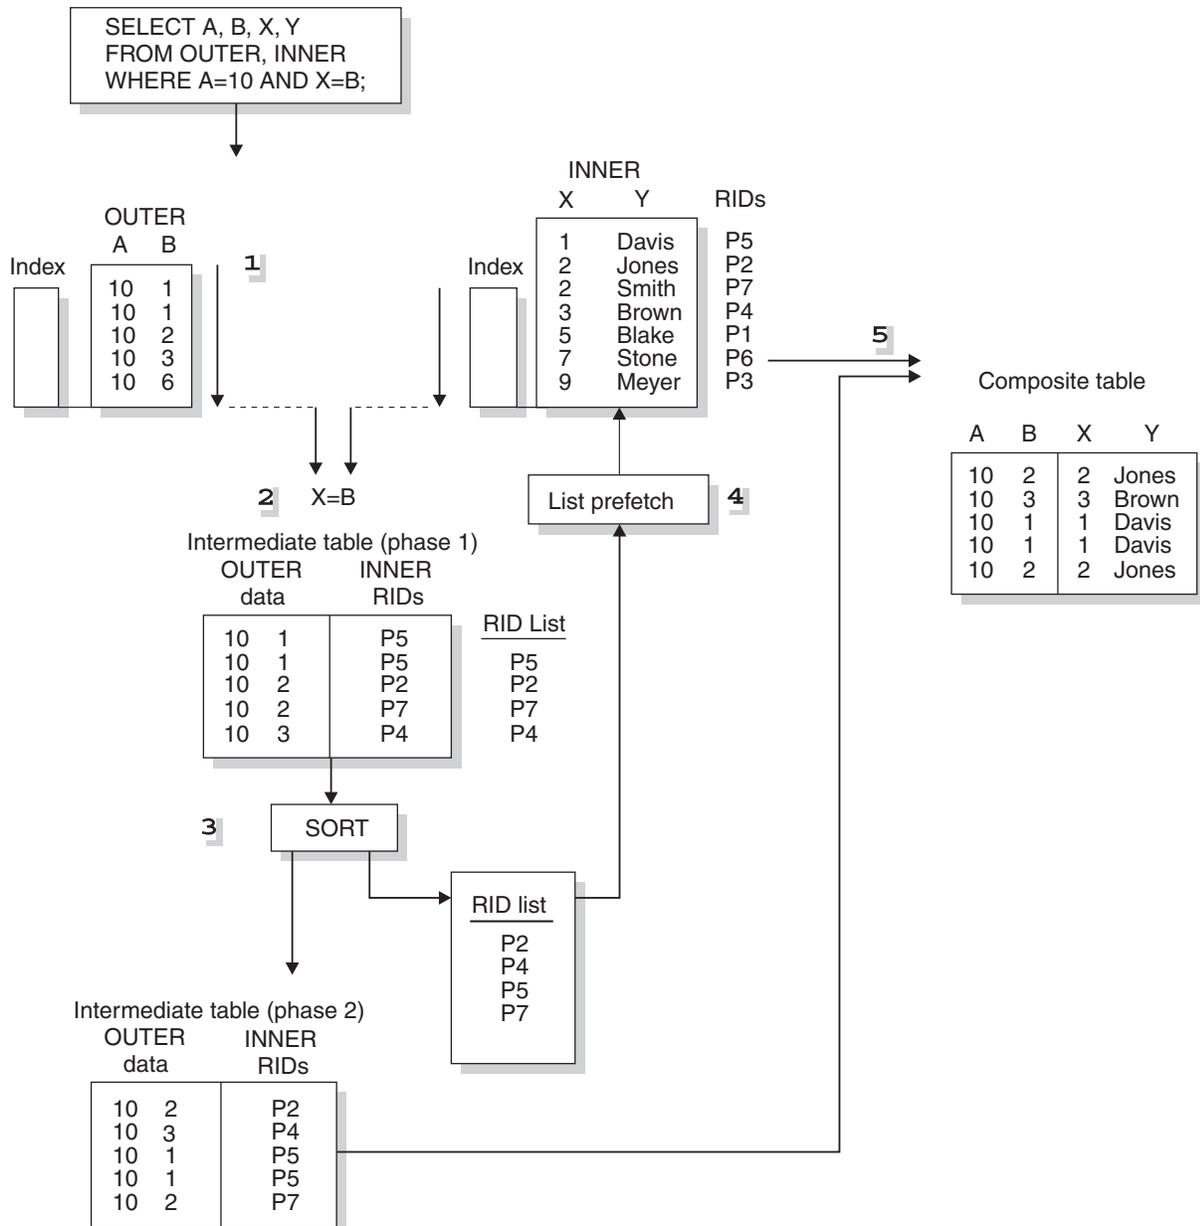

Figure 111. Hybrid join (SORTN\_JOIN='Y')

## Method of joining

The method requires obtaining RIDs in the order needed to use list prefetch. The steps are shown in Figure 111 on page 965. In that example, both the outer table (OUTER) and the inner table (INNER) have indexes on the join columns.

DB2 performs the following steps:

- 1** Scans the outer table (OUTER).
- 2** Joins the outer table with RIDs from the index on the inner table. The result is the phase 1 intermediate table. The index of the inner table is scanned for every row of the outer table.
- 3** Sorts the data in the outer table and the RIDs, creating a sorted RID list and the phase 2 intermediate table. The sort is indicated by a value of Y in column SORTN\_JOIN of the plan table. If the index on the inner table is a well-clustered index, DB2 can skip this sort; the value in SORTN\_JOIN is then N.
- 4** Retrieves the data from the inner table, using list prefetch.
- 5** Concatenates the data from the inner table and the phase 2 intermediate table to create the final composite table.

## Possible results from EXPLAIN for hybrid join

Table 181 shows possible EXPLAIN results from a hybrid join and an explanation of each column value.

Table 181. Explanation of EXPLAIN results for a hybrid join

| Column value   | Explanation                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| METHOD='4'     | A hybrid join was used.                                                                                                                |
| SORTC_JOIN='Y' | The composite table was sorted.                                                                                                        |
| SORTN_JOIN='Y' | The intermediate table was sorted in the order of inner table RIDs. A non-clustered index accessed the inner table RIDs.               |
| SORTN_JOIN='N' | The intermediate table RIDs were not sorted. A clustered index retrieved the inner table RIDs, and the RIDs were already well ordered. |
| PREFETCH='L'   | Pages were read using list prefetch.                                                                                                   |

## Performance considerations

Hybrid join uses list prefetch more efficiently than nested loop join, especially if there are indexes on the join predicate with low cluster ratios. It also processes duplicates more efficiently because the inner table is scanned only once for each set of duplicate values in the join column of the outer table.

If the index on the inner table is highly clustered, there is no need to sort the intermediate table (SORTN\_JOIN=N). The intermediate table is placed in a table in memory rather than in a work file.

## When hybrid join is used

Hybrid join is often used if:

- A nonclustered index or indexes are used on the join columns of the inner table.
- The outer table has duplicate qualifying rows.

## Star join (JOIN\_TYPE='S')

Star join is a special join technique that DB2 uses to efficiently join tables that form a star schema. A star schema is a logical database design that is included in decision support applications. A star schema is composed of a fact table and a number of dimension tables that are connected to it. A dimension table contains several values that are given an ID, which is used in the fact table instead of all the values.

You can think of the fact table, which is much larger than the dimension tables, as being in the center surrounded by dimension tables; the result resembles a star formation. Figure 112 illustrates the star formation.

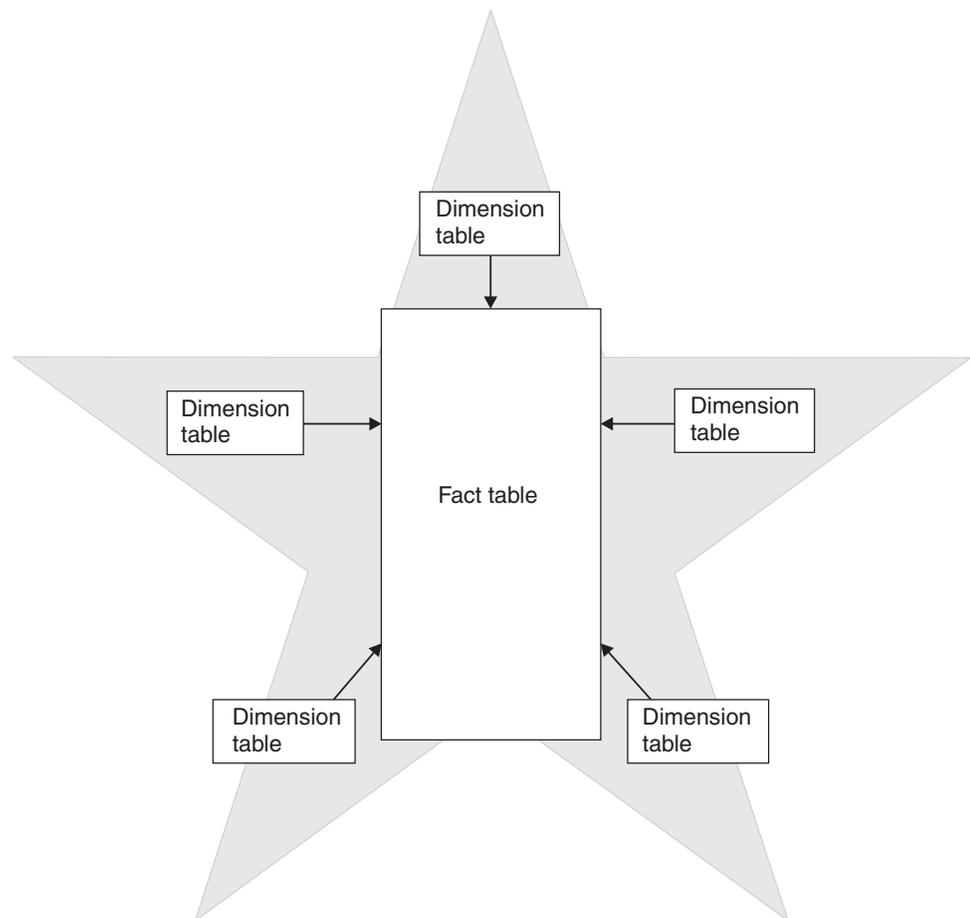

Figure 112. Star schema with a fact table and dimension tables

Unlike the steps in the other join methods (nested loop join, merge scan join, and hybrid join) in which only two tables are joined in each step, a step in the star join method can involve three or more tables. Dimension tables are joined to the fact table via a multi-column index that is defined on the fact table. Therefore, having a well-defined, multi-column index on the fact table is critical for efficient star join processing.

### Example of a star schema

For an example of a star schema consider the following scenario. A star schema is composed of a fact table for sales, with dimension tables connected to it for time, products, and geographic locations. The time table has an ID for each month, its

quarter, and the year. The product table has an ID for each product item and its class and its inventory. The geographic location table has an ID for each city and its country.

In this scenario, the sales table contains three columns with IDs from the dimension tables for time, product, and location instead of three columns for time, three columns for products, and two columns for location. Thus, the size of the fact table is greatly reduced. In addition, if you needed to change an item, you would do it once in a dimension table instead of several times for each instance of the item in the fact table.

You can create even more complex star schemas by normalizing a dimension table into several tables. The normalized dimension table is called a *snowflake*. Only one of the tables in the snowflake joins directly with the fact table.

### When star join is used

To access the data in a star schema, you often write SELECT statements that include join operations between the fact table and the dimension tables, but no join operations between dimension tables. DB2 uses star join processing as the join type for the query if the following conditions are true:

- The query references at least two dimensions.
- All join predicates are between the fact table and the dimension tables, or within tables of the same snowflake. If a snowflake is connected to the fact table, only one table in the snowflake (the central dimension table) can be joined to the fact table.
- All join predicates between the fact table and dimension tables are equi-join predicates.
- All join predicates between the fact table and dimension tables are Boolean term predicates. For more information, see “Boolean term (BT) predicates” on page 758.
- There are no instances of predicates that consist of a local predicate on a dimension table and a local predicate on a different table that are connected with an OR logical operator.
- No correlated subqueries cross dimensions.
- No single fact table column is joined to columns of different dimension tables in join predicates. For example, fact table column F1 cannot be joined to column D1 of dimension table T1 and also joined to column D2 of dimension table T2.
- After DB2 simplifies join operations, no outer join operations exist. For more information, see “When DB2 simplifies join operations” on page 775.
- The data type and length of both sides of a join predicate are the same.
- The value of subsystem parameter STARJOIN is 1, or the cardinality of the fact table to the largest dimension table meets the requirements specified by the value of the subsystem parameter. The values of STARJOIN and cardinality requirements are:
  - 1 Star join is disabled. This is the default.
  - 1 Star join is enabled. The one table with the largest cardinality is the fact table. However, if there is more than one table with this cardinality, star join is not enabled.
  - 0 Star join is enabled if the cardinality of the fact table is at least 25 times the cardinality of the largest dimension that is a base table that is joined to the fact table.

$n$  Star join is enabled if the cardinality of the fact table is at least  $n$  times the cardinality of the largest dimension that is a base table that is joined to the fact table, where  $2 \leq n \leq 32768$ .

You can set the subsystem parameter STARJOIN by using the STAR JOIN QUERIES field on the DSNTIP8 installation panel.

- The number of tables in the star schema query block, including the fact table, dimensions tables, and snowflake tables, meet the requirements that are specified by the value of subsystem parameter SJTABLES. The value of SJTABLES is considered only if the subsystem parameter STARJOIN qualifies the query for star join. The values of SJTABLES are:

**1, 2, or 3**

Star join is always considered.

**4 to 255**

Star join is considered if the query block has at least the specified number of tables. If star join is enabled, 10 is the default value.

**256 and greater**

Star join will never be considered.

Star join, which can reduce bind time significantly, does not provide optimal performance in all cases. Performance of star join depends on a number of factors such as the available indexes on the fact table, the cluster ratio of the indexes, and the selectivity of rows through local and join predicates. Follow these general guidelines for setting the value of SJTABLES:

- If you have queries that reference less than 10 tables in a star schema database and you want to make the star join method applicable to all qualified queries, set the value of SJTABLES to the minimum number of tables used in queries that you want to be considered for star join.

**Example:** Suppose that you query a star schema database that has one fact table and three dimension tables. You should set SJTABLES to 4.

- If you want to use star join for relatively large queries that reference a star schema database but are not necessarily suitable for star join, use the default. The star join method will be considered for all qualified queries that have 10 or more tables.
- If you have queries that reference a star schema database but, in general, do not want to use star join, consider setting SJTABLES to a higher number, such as 15, if you want to drastically cut the bind time for large queries and avoid a potential bind time SQL return code -101 for large qualified queries.

For recommendations on indexes for star schemas, see “Creating indexes for efficient star-join processing” on page 801.

**Examples: query with three dimension tables:** Suppose that you have a store in San Jose and want information about sales of audio equipment from that store in 2000. For this example, you want to join the following tables:

- A fact table for SALES (S)
- A dimension table for TIME (T) with columns for an ID, month, quarter, and year
- A dimension table for geographic LOCATION (L) with columns for an ID, city, region, and country
- A dimension table for PRODUCT (P) with columns for an ID, product item, class, and inventory

You could write the following query to join the tables:

```
#
# SELECT *
# FROM SALES S, TIME T, PRODUCT P, LOCATION L
# WHERE S.TIME = T.ID AND
# S.PRODUCT = P.ID AND
# S.LOCATION = L.ID AND
# T.YEAR = 2000 AND
# P.CLASS = 'AUDIO' AND
# L.LOCATION = 'SAN JOSE';
```

You would use the following index:

```
CREATE INDEX XSALES_TPL ON SALES (TIME, PRODUCT, LOCATION);
```

You EXPLAIN output looks like Table 182.

| Table 182. Plan table output for a star join example with TIME, PRODUCT, and LOCATION

| QUERYNO | QBLOCKNO | METHOD | TNAME    | JOIN TYPE | SORTN JOIN | ACCESS TYPE |
|---------|----------|--------|----------|-----------|------------|-------------|
| 1       | 1        | 0      | TIME     | S         | Y          | R           |
| 1       | 1        | 1      | PRODUCT  | S         | Y          | R           |
| 1       | 1        | 1      | LOCATION | S         | Y          | R           |
| 1       | 1        | 1      | SALES    | S         |            | I           |

All snowflakes are processed before the central part of the star join, as individual query blocks, and are materialized into work files. There is a work file for each snowflake. The EXPLAIN output identifies these work files by naming them DSN\_DIM\_TBLX(*nm*), where *nm* indicates the corresponding QBLOCKNO for the snowflake.

This next example shows the plan for a star join that contains two snowflakes. Suppose that two new tables MANUFACTURER (M) and COUNTRY (C) are added to the tables in the previous example to break dimension tables PRODUCT (P) and LOCATION (L) into snowflakes:

- The PRODUCT table has a new column MID that represents the manufacturer.
- Table MANUFACTURER (M) has columns for MID and name to contain manufacturer information.
- The LOCATION table has a new column CID that represents the country.
- Table COUNTRY (C) has columns for CID and name to contain country information.

You could write the following query to join all the tables:

```
SELECT *
FROM SALES S, TIME T, PRODUCT P, MANUFACTURER M,
LOCATION L, COUNTRY C
WHERE S.TIME = T.ID AND
S.PRODUCT = P.ID AND
P.MID = M.MID AND
S.LOCATION = L.ID AND
L.CID = C.CID AND
T.YEAR = 2000 AND
M.NAME = 'some_company';
```

The joined table pairs (PRODUCT, MANUFACTURER) and (LOCATION, COUNTRY) are snowflakes. The EXPLAIN output of this query looks like Table 183 on page 971.

Table 183. Plan table output for a star join example with snowflakes

| QUERYNO | QBLOCKNO | METHOD | TNAME            | JOIN TYPE | SORTN JOIN | ACCESS TYPE |
|---------|----------|--------|------------------|-----------|------------|-------------|
| 1       | 1        | 0      | TIME             | S         | Y          | R           |
| 1       | 1        | 1      | DSN_DIM_TBLX(02) | S         | Y          | R           |
| 1       | 1        | 1      | SALES            | S         |            | I           |
| 1       | 1        | 1      | DSN_DIM_TBLX(03) |           | Y          | T           |
| 1       | 2        | 0      | PRODUCT          |           |            | R           |
| 1       | 2        | 1      | MANUFACTURER     |           |            | I           |
| 1       | 3        | 0      | LOCATION         |           |            | R           |
| 1       | 3        | 4      | COUNTRY          |           |            | I           |

**Note:** This query consists of three query blocks:

- QBLOCKNO=1: The main star join block
- QBLOCKNO=2: A snowflake (PRODUCT, MANUFACTURER) that is materialized into work file DSN\_DIM\_TBLX(02)
- QBLOCKNO=3: A snowflake (LOCATION, COUNTRY) that is materialized into work file DSN\_DIM\_TBLX(03)

The joins in the snowflakes are processed first, and each snowflake is materialized into a work file. Therefore, when the main star join block (QBLOCKNO=1) is processed, it contains four tables: SALES (the fact table), TIME (a base dimension table), and the two snowflake work files.

In this example, in the main star join block, the star join method is used for the first three tables (as indicated by S in the JOIN TYPE column of the plan table) and the remaining work file is joined by the nested loop join with sparse index access on the work file (as indicated by T in the ACCESSTYPE column for DSN\_DIM\_TBLX(3)).

### Dedicated virtual memory pool for star join operations

You can create a dedicated virtual memory pool for star join operations. When the virtual memory pool is enabled for star joins, DB2 caches data from work files that are used by star join queries. A virtual memory pool dedicated to star join operations has the following advantages:

- Immediate data availability. During a star join operation, work files might be scanned many times. If the work-file data is cached in the dedicated virtual memory pool, that data is immediately available for join operations.
- Reduced buffer pool contention. Because the dedicated virtual memory pool caches data separately from the work-file buffer pool, contention with the buffer pool is reduced. Reduced contention improves performance particularly when sort operations are performed concurrently.

To determine the size of the virtual memory pool, perform the following steps:

1. Determine the value of A. Estimate the number of star join queries that run concurrently.
2. Determine the value of B. Estimate the average number of work files that a star join query uses. In typical cases, with highly normalized star schemas, the average number is about three to six work files.
3. Determine the value of C. Estimate the number of work-file rows, the maximum length of the key, and the total of the maximum length of the

relevant columns. Multiply these three values together to find the size of the data caching space for the work file, or the value of C.

4. Multiply (A) \* (B) \* (C) to determine the size of the pool in MB.

The default virtual memory pool size is 20 MB. To set the pool size, use the SJMXPOOL parameter on the DSNTIP8 installation panel.

**Example:** The following example shows how to determine the size of the virtual memory pool. Suppose that you issue the following star join query, where SALES is the fact table:

```
SELECT C.COUNTRY, P.PRDNAME, SUM(F.SPRICE)
FROM SALES F, TIME T, PROD P, LOC L, SCOUN C
WHERE F.TID = T.TID AND
      F.PID = P.PID AND
      F.LID = L.LID AND
      L.CID = C.CID AND
      P.PCODE IN (4, 7, 21, 22, 53)
GROUP BY .COUNTRY, P.PRDNAME;
```

The EXPLAIN output of this query looks like Table 184.

Table 184. EXPLAIN output for a star join query

| QBLOCKNO | PLANNO | TNAME            | METHOD | JOIN_ TYPE | ACCESS TYPE | ACCESS NAME |
|----------|--------|------------------|--------|------------|-------------|-------------|
| 1        | 1      | TIME             | 0      | S          | R           |             |
| 1        | 2      | PROD             | 1      | S          | T           |             |
| 1        | 3      | SALES            | 1      | S          | I           | XSALES      |
| 1        | 4      | DSN_DIM_TBLX(02) | 1      |            | T           |             |
| 1        | 5      |                  | 3      |            |             |             |
| 2        | 1      | LOC              | 0      |            | R           |             |
| 2        | 2      | SCOUN            | 4      |            | I           | XSCOUN      |

For this query, two work files can be cached in memory. These work files, PROD and DSN\_DIM\_TBLX(02), are indicated by ACCESTYPE=T.

To determine the size of the dedicated virtual memory pool, perform the following steps:

1. Determine the value of A. Estimate the number of star join queries that run concurrently.

In this example, based on the type of operation, up to 12 star join queries are expected run concurrently. Therefore, A = 12.

2. Determine the value of B. Estimate the average number of work files that a star join query uses.

In this example, the star join query uses two work files, PROD and DSN\_DIM\_TBLX(02). Therefore B = 2.

3. Determine the value of C. Estimate the number of work-file rows, the maximum length of the key, and the total of the maximum length of the relevant columns. Multiply these three values together to find the size of the data caching space for the work file, or the value of C.

Both PROD and DSN\_DIM\_TBLX(02) are used to determine the value of C.

**Recommendation:** Average the values for a representative sample of work files, and round the value up to determine an estimate for a value of C.

- The number of work-file rows depends on the number of rows that match the predicate. For PROD, 87 rows are stored in the work file because 87 rows match the IN-list predicate. No selective predicate is used for DSN\_DIM\_TBLX(02), so the entire result of the join is stored in the work file. The work file for DSN\_DIM\_TBLX(02) holds 2800 rows.
- The maximum length of the key depends on the data type definition of the table's key column. For PID, the key column for PROD, the maximum length is 4. DSN\_DIM\_TBLX(02) is a work file that results from the join of LOC and SCOUN. The key column that is used in the join is LID from the LOC table. The maximum length of LID is 4.
- The maximum data length depends on the maximum length of the key column and the maximum length of the column that is selected as part of the star join. Add to the maximum data length 1 byte for nullable columns, 2 bytes for varying length columns, and 3 bytes for nullable and varying length columns.

For the PROD work file, the maximum data length is the maximum length of PID, which is 4, plus the maximum length of PRDNAME, which is 24. Therefore, the maximum data length for the PROD work file is 28. For the DSN\_DIM\_TBLX(02) workfile, the maximum data length is the maximum length of LID, which is 4, plus the maximum length of COUNTRY, which is 36. Therefore, the maximum data length for the DSN\_DIM\_TBLX(02) work file is 40.

For PROD,  $C = (87) * (4 + 28) = 2784$  bytes. For DSN\_DIM\_TBLX(02),  $C = (2800) * (4 + 40) = 123200$  bytes.

The average of these two estimated values for C is approximately 62 KB. Because the number of rows in each work file can vary depending on the selection criteria in the predicate, the value of C should be rounded up to the nearest multiple of 100 KB. Therefore  $C = 100$  KB.

4. Multiply  $(A) * (B) * (C)$  to determine the size of the pool in MB.

The size of the pool is determined by multiplying  $(12) * (2) * (100KB) = 2.4$  MB.

---

## Interpreting data prefetch

*Prefetch* is a mechanism for reading a set of pages, usually 32, into the buffer pool with only one asynchronous I/O operation. Prefetch can allow substantial savings in both processor cycles and I/O costs. To achieve those savings, monitor the use of prefetch.

A plan table can indicate the use of three kinds of prefetch:

- "Sequential prefetch (PREFETCH=S)"
- "Dynamic prefetch (PREFETCH=D)" on page 974
- "List prefetch (PREFETCH=L)" on page 974

Additionally, you can choose not to use prefetch.

If DB2 does not choose prefetch at bind time, it can sometimes use it at execution time nevertheless. The method is described in "Sequential detection at execution time" on page 976.

## Sequential prefetch (PREFETCH=S)

*Sequential prefetch* reads a sequential set of pages. The maximum number of pages read by a request issued from your application program is determined by the size of the buffer pool used. For each buffer pool size (4 KB, 8 KB, 16 KB, and 32 KB),

Table 185 shows the number pages read by prefetch for each asynchronous I/O.

*Table 185. The number of pages read by prefetch, by buffer pool size*

| Buffer pool size | Number of buffers | Pages read by prefetch (for each asynchronous I/O) |
|------------------|-------------------|----------------------------------------------------|
| 4 KB             | <=223 buffers     | 8 pages                                            |
|                  | 224-999 buffers   | 16 pages                                           |
|                  | 1000+ buffers     | 32 pages                                           |
| 8 KB             | <=112 buffers     | 4 pages                                            |
|                  | 113-499 buffers   | 8 pages                                            |
|                  | 500+ buffers      | 16 pages                                           |
| 16 KB            | <=56 buffers      | 2 pages                                            |
|                  | 57-249 buffers    | 4 pages                                            |
|                  | 250+ buffers      | 8 pages                                            |
| 32 KB            | <=16 buffers      | 0 pages (prefetch disabled)                        |
|                  | 17-99 buffers     | 2 pages                                            |
|                  | 100+ buffers      | 4 pages                                            |

For certain utilities (LOAD, REORG, RECOVER), the prefetch quantity can be twice as much.

*When sequential prefetch is used:* Sequential prefetch is generally used for a table space scan.

For an index scan that accesses eight or more consecutive data pages, DB2 requests sequential prefetch at bind time. The index must have a cluster ratio of 80% or higher. Both data pages and index pages are prefetched.

## Dynamic prefetch (PREFETCH=D)

Dynamic prefetch can reduce paging and improve performance over sequential prefetch for some data access that involves data that is not on consecutive pages. When DB2 expects that *dynamic prefetch* will be used, DB2 sets PREFETCH=D. At runtime, dynamic prefetch might or might not actually be used. However, DB2 expects dynamic prefetch and optimizes for that behavior.

*When dynamic prefetch is used:* Dynamic prefetch is used in prefetch situations when the pages that DB2 will access are distributed in a nonconsecutive manner. If the pages are distributed in a sufficiently consecutive manner, sequential prefetch is used instead.

## List prefetch (PREFETCH=L)

*List prefetch* reads a set of data pages determined by a list of RIDs taken from an index. The data pages need not be contiguous. The maximum number of pages that can be retrieved in a single list prefetch is 32 (64 for utilities).

List prefetch can be used in conjunction with either single or multiple index access.

### The access method

List prefetch uses the following three steps:

1. RID retrieval: A list of RIDs for needed data pages is found by matching index scans of one or more indexes.
2. RID sort: The list of RIDs is sorted in ascending order by page number.
3. Data retrieval: The needed data pages are prefetched in order using the sorted RID list.

List prefetch does not preserve the data ordering given by the index. Because the RIDs are sorted in page number order before accessing the data, the data is not retrieved in order by any column. If the data must be ordered for an ORDER BY clause or any other reason, it requires an additional sort.

In a hybrid join, if the index is highly clustered, the page numbers might not be sorted before accessing the data.

List prefetch can be used with most matching predicates for an index scan. IN-list predicates are the exception; they cannot be the matching predicates when list prefetch is used.

### **When list prefetch is used**

List prefetch is used:

- Usually with a single index that has a cluster ratio lower than 80%
- Sometimes on indexes with a high cluster ratio, if the estimated amount of data to be accessed is too small to make sequential prefetch efficient, but large enough to require more than one regular read
- Always to access data by multiple index access
- Always to access data from the inner table during a hybrid join
- Usually for updatable cursors when the index contains columns that might be updated.

### **Bind time and execution time thresholds**

DB2 does not consider list prefetch if the estimated number of RIDs to be processed would take more than 50% of the RID pool when the query is executed. You can change the size of the RID pool in the field RID POOL SIZE on installation panel DSNTIPC. The maximum size of a RID pool is 10 000 MB. The maximum size of a single RID list is approximately 26 million RIDs. For information about calculating RID pool size, see “Increasing RID pool size” on page 689.

During execution, DB2 ends list prefetching if more than 25% of the rows in the table (with a minimum of 6524) must be accessed. Record IFCID 0125 in the performance trace, mapped by macro DSNDQW01, indicates whether list prefetch ended.

When list prefetch ends, the query continues processing by a method that depends on the current access path.

- For access through a single index or through the union of RID lists from two indexes, processing continues by a table space scan.
- For index access before forming an intersection of RID lists, processing continues with the next step of multiple index access. If no step remains and no RID list has been accumulated, processing continues by a table space scan.

When DB2 forms an intersection of RID lists, if any list has 32 or fewer RIDs, intersection stops and the list of 32 or fewer RIDs is used to access the data.

## Sequential detection at execution time

If DB2 does not choose prefetch at bind time, it can sometimes use prefetch at execution time nevertheless. The method is called *sequential detection*.

### When sequential detection is used

DB2 can use sequential detection for both index leaf pages and data pages. It is most commonly used on the inner table of a nested loop join, if the data is accessed sequentially.

If a table is accessed repeatedly using the same statement (for example, DELETE in a do-while loop), the data or index leaf pages of the table can be accessed sequentially. This is common in a batch processing environment. Sequential detection can then be used if access is through:

- SELECT or FETCH statements
- UPDATE and DELETE statements
- INSERT statements when existing data pages are accessed sequentially

DB2 can use sequential detection if it did not choose sequential prefetch at bind time because of an inaccurate estimate of the number of pages to be accessed.

Sequential detection is not used for an SQL statement that is subject to referential constraints.

### How to tell whether sequential detection was used

A plan table does not indicate sequential detection, which is not determined until run time. You can determine whether sequential detection was used from record IFCID 0003 in the accounting trace or record IFCID 0006 in the performance trace.

### How to tell if sequential detection might be used

The pattern of accessing a page is tracked when the application scans DB2 data through an index. Tracking is done to detect situations where the access pattern that develops is sequential or nearly sequential.

The most recent eight pages are tracked. A page is considered page-sequential if it is within  $P/2$  advancing pages of the current page, where  $P$  is the prefetch quantity.  $P$  is usually 32.

If a page is page-sequential, DB2 determines further if data access is sequential or nearly sequential. Data access is declared sequential if more than 4 out of the last eight pages are page-sequential; this is also true for index-only access. The tracking is continuous, allowing access to slip into and out of data access sequential.

When data access is first declared sequential, which is called *initial data access* sequential, three page ranges are calculated as follows:

- Let  $A$  be the page being requested. RUN1 is defined as the page range of length  $P/2$  pages starting at  $A$ .
- Let  $B$  be page  $A + P/2$ . RUN2 is defined as the page range of length  $P/2$  pages starting at  $B$ .
- Let  $C$  be page  $B + P/2$ . RUN3 is defined as the page range of length  $P$  pages starting at  $C$ .

For example, assume that page  $A$  is 10. Figure 113 on page 977 illustrates the page ranges that DB2 calculates.

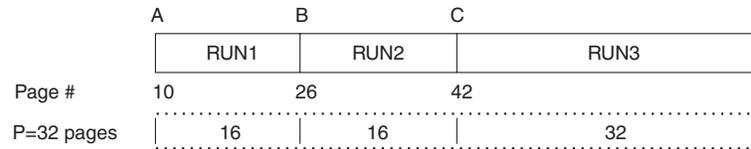

Figure 113. Initial page ranges to determine when to use prefetch

For initial data access sequential, prefetch is requested starting at page A for P pages (RUN1 and RUN2). The prefetch quantity is always P pages.

For subsequent page requests where the page is 1) page sequential and 2) data access sequential is still in effect, prefetch is requested as follows:

- If the desired page is in RUN1, no prefetch is triggered because it was already triggered when data access sequential was first declared.
- If the desired page is in RUN2, prefetch for RUN3 is triggered and RUN2 becomes RUN1, RUN3 becomes RUN2, and RUN3 becomes the page range starting at C+P for a length of P pages.

If a data access pattern develops such that data access sequential is no longer in effect and, thereafter, a new pattern develops that is sequential, then initial data access sequential is declared again and handled accordingly.

Because, at bind time, the number of pages to be accessed can only be estimated, sequential detection acts as a safety net and is employed when the data is being accessed sequentially.

In extreme situations, when certain buffer pool thresholds are reached, sequential prefetch can be disabled. See “Buffer pool thresholds” on page 673 for a description of these thresholds.

---

## Determining sort activity

DB2 can use two general types of sorts that DB2 can use when accessing data. One is a sort of data rows; the other is a sort of row identifiers (RIDs) in a RID list.

### Sorts of data

After you run EXPLAIN, DB2 sorts are indicated in PLAN\_TABLE. The sorts can be either sorts of the composite table or the new table. If a single row of PLAN\_TABLE has a ‘Y’ in more than one of the sort composite columns, then one sort accomplishes two things. (DB2 will not perform two sorts when two ‘Y’s are in the same row.) For instance, if both SORTC\_ORDERBY and SORTC\_UNIQ are ‘Y’ in one row of PLAN\_TABLE, then a single sort puts the rows in order and removes any duplicate rows as well.

The only reason DB2 sorts the new table is for join processing, which is indicated by SORTN\_JOIN.

### Sorts for group by and order by

These sorts are indicated by SORTC\_ORDERBY, and SORTC\_GROUPBY in PLAN\_TABLE. If there is both a GROUP BY clause and an ORDER BY clause, and if every item in the ORDER-BY list is in the GROUP-BY list, then only one sort is performed, which is marked as SORTC\_ORDERBY.

The performance of the sort by the GROUP BY clause is improved when the query accesses a single table and when the GROUP BY column has no index.

### **Sorts to remove duplicates**

This type of sort is used to process a query with SELECT DISTINCT, with a set function such as COUNT(DISTINCT COL1), or to remove duplicates in UNION processing. It is indicated by SORTC\_UNIQ in PLAN\_TABLE.

### **Sorts used in join processing**

Before joining two tables, it is often necessary to first sort either one or both of them. For hybrid join (METHOD 4) and nested loop join (METHOD 1), the composite table can be sorted to make the join more efficient. For merge join (METHOD 2), both the composite table and new table need to be sorted unless an index is used for accessing these tables that gives the correct order already. The sorts needed for join processing are indicated by SORTN\_JOIN and SORTC\_JOIN in the PLAN\_TABLE.

### **Sorts needed for subquery processing**

When a noncorrelated IN or NOT IN subquery is present in the query, the results of the subquery are sorted and put into a work file for later reference by the parent query. The results of the subquery are sorted because this allows the parent query to be more efficient when processing the IN or NOT IN predicate. Duplicates are not needed in the work file, and are removed. Noncorrelated subqueries used with =ANY or =ALL, or NOT=ANY or NOT=ALL also need the same type of sort as IN or NOT IN subqueries. When a sort for a noncorrelated subquery is performed, you see both SORTC\_ORDERBY and SORTC\_UNIQUE in PLAN\_TABLE. This is because DB2 removes the duplicates and performs the sort.

SORTN\_GROUPBY, SORTN\_ORDERBY, and SORTN\_UNIQ are not currently used by DB2.

## **Sorts of RIDs**

To perform list prefetch, DB2 sorts RIDs into ascending page number order. This sort is very fast and is done totally in memory. A RID sort is usually not indicated in the PLAN\_TABLE, but a RID sort normally is performed whenever list prefetch is used. The only exception to this rule is when a hybrid join is performed and a single, highly clustered index is used on the inner table. In this case SORTN\_JOIN is 'N', indicating that the RID list for the inner table was not sorted.

## **The effect of sorts on OPEN CURSOR**

The type of sort processing required by the cursor affects the amount of time it can take for DB2 to process the OPEN CURSOR statement. This section outlines the effect of sorts and parallelism on OPEN CURSOR.

### *Without parallelism:*

- If no sorts are required, then OPEN CURSOR does not access any data. It is at the first fetch that data is returned.
- If a sort is required, then the OPEN CURSOR causes the materialized result table to be produced. Control returns to the application after the result table is materialized. If a cursor that requires a sort is closed and reopened, the sort is performed again.
- If there is a RID sort, but no data sort, then it is not until the first row is fetched that the RID list is built from the index and the first data record is returned. Subsequent fetches access the RID pool to access the next data record.

*With parallelism:*

- At OPEN CURSOR, parallelism is asynchronously started, regardless of whether a sort is required. Control returns to the application immediately after the parallelism work is started.
- If there is a RID sort, but no data sort, then parallelism is not started until the first fetch. This works the same way as with no parallelism.

---

## Processing for views and nested table expressions

This section describes how DB2 processes views and nested table expressions. A nested table expression (which is called *table expression* in this description) is the specification of a subquery in the FROM clause of an SQL SELECT statement. The processing of table expressions is similar to a view. Two methods are used to satisfy your queries that reference views or table expressions:

- “Merge”
- “Materialization” on page 980

You can determine the methods that are used by executing EXPLAIN for the statement that contains the view or nested table expression. In addition, you can use EXPLAIN to determine when UNION operators are used and how DB2 might eliminate unnecessary subselects to improve the performance of a query.

### Merge

The merge process is more efficient than materialization, as described in “Performance of merge versus materialization” on page 985. In the merge process, the statement that references the view or table expression is combined with the fullselect that defined the view or table expression. This combination creates a logically equivalent statement. This equivalent statement is executed against the database.

**Example:** Consider the following statements, one of which defines a view, the other of which references the view:

View-defining statement:

```
CREATE VIEW VIEW1 (VC1,VC21,VC32) AS
  SELECT C1,C2,C3 FROM T1
  WHERE C1 > C3;
```

View referencing statement:

```
SELECT VC1,VC21
  FROM VIEW1
  WHERE VC1 IN (A,B,C);
```

The fullselect of the view-defining statement can be merged with the view-referencing statement to yield the following logically equivalent statement:

Merged statement:

```
SELECT C1,C2 FROM T1
  WHERE C1 > C3 AND C1 IN (A,B,C);
```

**Example:** The following statements show another example of when a view and table expression can be merged:

```
SELECT * FROM V1 X
  LEFT JOIN
    (SELECT * FROM T2) Y ON X.C1=Y.C1
  LEFT JOIN T3 Z ON X.C1=Z.C1;
```

Merged statement:

```
SELECT * FROM V1 X
  LEFT JOIN
    T2 ON X.C1 = T2.C1
  LEFT JOIN T3 Z ON X.C1 = Z.C1;
```

## Materialization

Views and table expressions cannot always be merged.

**Example:** Look at the following statements:

View defining statement:

```
CREATE VIEW VIEW1 (VC1,VC2) AS
  SELECT SUM(C1),C2 FROM T1
  GROUP BY C2;
```

View referencing statement:

```
SELECT MAX(VC1)
  FROM VIEW1;
```

Column VC1 occurs as the argument of a aggregate function in the view referencing statement. The values of VC1, as defined by the view-defining fullselect, are the result of applying the aggregate function SUM(C1) to groups after grouping the base table T1 by column C2. No equivalent single SQL SELECT statement can be executed against the base table T1 to achieve the intended result. There is no way to specify that aggregate functions should be applied successively.

### Two steps of materialization

In the previous example, DB2 performs materialization of the view or table expression, which is a two step process.

1. The fullselect that defines the view or table expression is executed against the database, and the results are placed in a temporary copy of a result table.
2. The statement that references the view or table expression is then executed against the temporary copy of the result table to obtain the intended result.

Whether materialization is needed depends upon the attributes of the referencing statement, or logically equivalent referencing statement from a prior merge, and the attributes of the fullselect that defines the view or table expression.

### When views or table expressions are materialized

In general, DB2 uses materialization to satisfy a reference to a view or table expression when there is aggregate processing (grouping, aggregate functions, distinct), indicated by the defining fullselect, in conjunction with either aggregate processing indicated by the statement referencing the view or table expression, or by the view or table expression participating in a join. For views and table expressions that are defined with UNION or UNION ALL, DB2 can often distribute aggregate processing, joins, and qualified predicates to avoid materialization. For more information, see "Using EXPLAIN to determine UNION activity and query rewrite" on page 983.

Table 186 indicates some cases in which materialization occurs. DB2 can also use materialization in statements that contain multiple outer joins, outer joins that combine with inner joins, or merges that cause a join of greater than 15 tables.

Table 186. Cases when DB2 performs view or table expression materialization. The "X" indicates a case of materialization. Notes follow the table.

| SELECT FROM view or table expression uses... <sup>1</sup> | View definition or table expression uses... <sup>2</sup> |          |                    |                             |       |              |
|-----------------------------------------------------------|----------------------------------------------------------|----------|--------------------|-----------------------------|-------|--------------|
|                                                           | GROUP BY                                                 | DISTINCT | Aggregate function | Aggregate function DISTINCT | UNION | UNION ALL(4) |
| Joins (3)                                                 | X                                                        | X        | X                  | X                           | X     |              |
| GROUP BY                                                  | X                                                        | X        | X                  | X                           | X     |              |
| DISTINCT                                                  |                                                          | X        |                    | X                           | X     |              |

Table 186. Cases when DB2 performs view or table expression materialization (continued). The "X" indicates a case of materialization. Notes follow the table.

| SELECT FROM view or table expression uses... <sup>1</sup> | View definition or table expression uses... <sup>2</sup> |          |                    |                             |       |              |
|-----------------------------------------------------------|----------------------------------------------------------|----------|--------------------|-----------------------------|-------|--------------|
|                                                           | GROUP BY                                                 | DISTINCT | Aggregate function | Aggregate function DISTINCT | UNION | UNION ALL(4) |
| Aggregate function                                        | X                                                        | X        | X                  | X                           | X     | X            |
| Aggregate function DISTINCT                               | X                                                        | X        | X                  | X                           | X     |              |
| SELECT subset of view or table expression columns         |                                                          | X        |                    |                             | X     |              |

**Notes to Table 186 on page 980:**

1. If the view is referenced as the target of an INSERT, UPDATE, or DELETE, then view merge is used to satisfy the view reference. Only updatable views can be the target in these statements. See Chapter 5 of *DB2 SQL Reference* for information about which views are read-only (not updatable).

An SQL statement can reference a particular view multiple times where some of the references can be merged and some must be materialized.

2. If a SELECT list contains a host variable in a table expression, then materialization occurs. For example:

```
SELECT C1 FROM
  (SELECT :HV1 AS C1 FROM T1) X;
```

If a view or nested table expression is defined to contain a user-defined function, and if that user-defined function is defined as NOT DETERMINISTIC or EXTERNAL ACTION, then the view or nested table expression is always materialized.

3. Additional details about materialization with outer joins:

- If a WHERE clause exists in a view or table expression, and it does not contain a column, materialization occurs.

**Example:**

```
SELECT X.C1 FROM
  (SELECT C1 FROM T1
   WHERE 1=1) X LEFT JOIN T2 Y
   ON X.C1=Y.C1;
```

- If the outer join is a full outer join and the SELECT list of the view or nested table expression does not contain a standalone column for the column that is used in the outer join ON clause, then materialization occurs.

**Example:**

```
SELECT X.C1 FROM
  (SELECT C1+10 AS C2 FROM T1) X FULL JOIN T2 Y
   ON X.C2=Y.C2;
```

- If there is no column in a SELECT list of a view or nested table expression, materialization occurs.

**Example:**

```
SELECT X.C1 FROM
  (SELECT 1+2+:HV1 AS C1 FROM T1) X LEFT JOIN T2 Y
   ON X.C1=Y.C1;
```

- If the SELECT list of a view or nested table expression contains a CASE expression, and the result of the CASE expression is referenced in the outer query block, then materialization occurs.

**Example:**

```
SELECT X.C1 FROM
      T1 X LEFT JOIN
      (SELECT CASE C2 WHEN 5 THEN 10 ELSE 20 END AS YC1 FROM T2) Y
      ON X.C1 = Y.YC1;
```

4. DB2 cannot avoid materialization for UNION ALL in all cases. Some of the situations in which materialization occurs includes:
  - When the view is the operand in an outer join for which nulls are used for non-matching values, materialization occurs. This situation happens when the view is either operand in a full outer join, the right operand in a left outer join, or the left operand in a right outer join.
  - If the number of tables would exceed 225 after distribution, then distribution will not occur, and the result will be materialized.

## Using EXPLAIN to determine when materialization occurs

For each reference to a view or table expression that is materialized, rows describing the access path for both steps of the materialization process appear in the PLAN\_TABLE. These rows describe the access path used to formulate the temporary result indicated by the view's defining fullselect, and they describe the access to the temporary result as indicated by the referencing statement. The defining fullselect can also refer to views or table expressions that need to be materialized.

When DB2 chooses materialization, TNAME contains the name of the view or table expression, and TABLE\_TYPE contains a W. A value of Q in TABLE\_TYPE for the name of a view or nested table expression indicates that the materialization was virtual and not actual. (Materialization can be virtual when the view or nested table expression definition contains a UNION ALL that is not distributed.) When DB2 chooses merge, EXPLAIN data for the merged statement appears in PLAN\_TABLE; only the names of the base tables on which the view or table expression is defined appear.

**Example:** Consider the following statements, which define a view and reference the view:

View defining statement:

```
CREATE VIEW V1DIS (SALARY, WORKDEPT) as
  (SELECT DISTINCT SALARY, WORKDEPT FROM DSN8810.EMP)
```

View referencing statement:

```
SELECT * FROM DSN8810.DEPT
  WHERE DEPTNO IN (SELECT WORKDEPT FROM V1DIS)
```

Table 187 shows a subset of columns in a plan table for the query.

*Table 187. Plan table output for an example with view materialization*

| QBLOCKNO | PLANNO | QBLOCK_ TYPE | TNAME | TABLE_ TYPE | METHOD |
|----------|--------|--------------|-------|-------------|--------|
| 1        | 1      | SELECT       | DEPT  | T           | 0      |
| 2        | 1      | NOCOSUB      | V1DIS | W           | 0      |
| 2        | 2      | NOCOSUB      |       | ?           | 3      |

Table 187. Plan table output for an example with view materialization (continued)

| QBLOCKNO | PLANNO | QBLOCK_ TYPE | TNAME | TABLE_ TYPE | METHOD |
|----------|--------|--------------|-------|-------------|--------|
| 3        | 1      | NOCOSUB      | EMP   | T           | 0      |
| 3        | 2      | NOCOSUB      |       | ?           | 3      |

Notice how TNAME contains the name of the view and TABLE\_TYPE contains W to indicate that DB2 chooses materialization for the reference to the view because of the use of SELECT DISTINCT in the view definition.

**Example:** Consider the following statements, which define a view and reference the view:

View defining statement:

```
CREATE VIEW V1NODIS (SALARY, WORKDEPT) as
(SELECT SALARY, WORKDEPT FROM DSN8810.EMP)
```

View referencing statement:

```
SELECT * FROM DSN8810.DEPT
WHERE DEPTNO IN (SELECT WORKDEPT FROM V1NODIS)
```

If the VIEW was defined without DISTINCT, DB2 would choose merge instead of materialization. In the sample output, the name of the view does not appear in the plan table, but the table name on which the view is based does appear.

Table 188 shows a sample plan table for the query.

Table 188. Plan table output for an example with view merge

| QBLOCKNO | PLANNO | QBLOCK_ TYPE | TNAME | TABLE_ TYPE | METHOD |
|----------|--------|--------------|-------|-------------|--------|
| 1        | 1      | SELECT       | DEPT  | T           | 0      |
| 2        | 1      | NOCOSUB      | EMP   | T           | 0      |
| 2        | 2      | NOCOSUB      |       | ?           | 3      |

For an example of when a view definition contains a UNION ALL and DB2 can distribute joins and aggregations and avoid materialization, see “Using EXPLAIN to determine UNION activity and query rewrite.” When DB2 avoids materialization in such cases, TABLE\_TYPE contains a Q to indicate that DB2 uses an intermediate result that is not materialized, and TNAME shows the name of this intermediate result as DSNWFQB(xx), where xx is the number of the query block that produced the result.

## Using EXPLAIN to determine UNION activity and query rewrite

For each reference to a view or table expression that is defined with UNION or UNION ALL operators, DB2 tries to rewrite the query into a logically equivalent statement with improved performance by:

- Distributing qualified predicates, joins, and aggregations across the subselects of UNION ALL. Such distribution helps to avoid materialization. No distribution is performed for UNION.
- Eliminating unnecessary subselects of the view or table expression. For DB2 to eliminate subselects, the referencing query and the view or table definition must have predicates that are based on common columns.

The QBLOCK\_TYPE column in the plan table indicates union activity. For a UNION ALL, the column contains 'UNIONA'. For UNION, the column contains 'UNION'. When QBLOCK\_TYPE='UNION', the METHOD column on the same row is set to 3 and the SORTC\_UNIQ column is set to 'Y' to indicate that a sort is necessary to remove duplicates. As with other views and table expressions, the plan table also shows when DB2 uses materialization instead of merge.

**Example:** Consider the following statements, which define a view, reference the view, and show how DB2 rewrites the referencing statement:

View defining statement: View is created on three tables that contain weekly data

```
CREATE VIEW V1 (CUSTNO, CHARGES, DATE) as
  SELECT CUSTNO, CHARGES, DATE
  FROM WEEK1
  WHERE DATE BETWEEN '01/01/2000' And '01/07/2000'
UNION ALL
  SELECT CUSTNO, CHARGES, DATE
  FROM WEEK2
  WHERE DATE BETWEEN '01/08/2000' And '01/14/2000'
UNION ALL
  SELECT CUSTNO, CHARGES, DATE
  FROM WEEK3
  WHERE DATE BETWEEN '01/15/2000' And '01/21/2000';
```

View referencing statement: For each customer in California, find the average charges during the first and third Friday of January 2000

```
SELECT V1.CUSTNO, AVG(V1.CHARGES)
  FROM CUST, V1
  WHERE CUST.CUSTNO=V1.CUSTNO
  AND CUST.STATE='CA'
  AND DATE IN ('01/07/2000','01/21/2000')
  GROUP BY V1.CUSTNO;
```

Rewritten statement (assuming that CHARGES is defined as NOT NULL):

```
SELECT CUSTNO_U, SUM(SUM_U)/SUM(CNT_U)
  FROM
  ( SELECT WEEK1.CUSTNO, SUM(CHARGES), COUNT(CHARGES)
    FROM CUST, WEEK1
    Where CUST.CUSTNO=WEEK1.CUSTNO AND CUST.STATE='CA'
    AND DATE BETWEEN '01/01/2000' And '01/07/2000'
    AND DATE IN ('01/07/2000','01/21/2000')
    GROUP BY WEEK1.CUSTNO
  UNION ALL
  SELECT WEEK3.CUSNTO, SUM(CHARGES), COUNT(CHARGES)
    FROM CUST,WEEK3
    WHERE CUST.CUSTNO=WEEK3 AND CUST.STATE='CA'
    AND DATE BETWEEN '01/15/2000' And '01/21/2000'
    AND DATE IN ('01/07/2000','01/21/2000')
    GROUP BY WEEK3.CUSTNO
  ) AS X(CUSTNO_U,SUM_U,CNT_U)
  GROUP BY CUSNTO_U;
```

Table 189 shows a subset of columns in a plan table for the query.

Table 189. Plan table output for an example with a view with UNION ALLs

| QBLOCKNO | PLANNO | TNAME       | TABLE_TYPE | METHOD | QBLOCK_TYPE | PARENT_QBLOCKNO |
|----------|--------|-------------|------------|--------|-------------|-----------------|
| 1        | 1      | DSNWFQB(02) | Q          | 0      |             | 0               |
| 1        | 2      |             | ?          | 3      |             | 0               |
| 2        | 1      |             | ?          | 0      | UNIONA      | 1               |
| 3        | 1      | CUST        | T          | 0      |             | 2               |

Table 189. Plan table output for an example with a view with UNION ALLs (continued)

| QBLOCKNO | PLANNO | TNAME | TABLE_TYPE | METHOD | QBLOCK_TYPE | PARENT_QBLOCKNO |
|----------|--------|-------|------------|--------|-------------|-----------------|
| 3        | 2      | WEEK1 | T          | 1      |             | 2               |
| 4        | 1      | CUST  | T          | 0      |             | 2               |
| 4        | 2      | WEEK3 | T          | 2      |             | 2               |

Notice how DB2 eliminates the second subselect of the view definition from the rewritten query and how the plan table indicates this removal by showing a UNION ALL for only the first and third subselect in the view definition. The Q in the TABLE\_TYPE column indicates that DB2 does not materialize the view.

## Performance of merge versus materialization

Merge performs better than materialization. For materialization, DB2 uses a table space scan to access the materialized temporary result. DB2 materializes a view or table expression only if it cannot merge.

Materialization is a two-step process with the first step resulting in the formation of a temporary result. The smaller the temporary result, the more efficient is the second step. To reduce the size of the temporary result, DB2 attempts to evaluate certain predicates from the WHERE clause of the referencing statement at the first step of the process rather than at the second step. Only certain types of predicates qualify. First, the predicate must be a simple Boolean term predicate. Second, it must have one of the forms shown in Table 190.

Table 190. Predicate candidates for first-step evaluation

| Predicate                                 | Example                      |
|-------------------------------------------|------------------------------|
| COL op literal                            | V1.C1 > hv1                  |
| COL IS (NOT) NULL                         | V1.C1 IS NOT NULL            |
| COL (NOT) BETWEEN literal AND literal     | V1.C1 BETWEEN 1 AND 10       |
| COL (NOT) LIKE constant (ESCAPE constant) | V1.C2 LIKE 'p\%%' ESCAPE '\' |
| COL IN (list)                             | V1.C2 IN (a,b,c)             |

**Note:** Where "op" is =, <>, >, <, <=, or >=, and literal is either a host variable, constant, or special register. The literals in the BETWEEN predicate need not be identical.

Implied predicates generated through predicate transitive closure are also considered for first step evaluation.

## Estimating a statement's cost

You can use EXPLAIN to populate a statement table, *owner.DSN\_STATEMNT\_TABLE*, at the same time as your *PLAN\_TABLE* is being populated. DB2 provides cost estimates, in service units and in milliseconds, for SELECT, INSERT, UPDATE, and DELETE statements, both static and dynamic. The estimates do not take into account several factors, including cost adjustments that are caused by parallel processing, or the use of triggers or user-defined functions.

Use the information provided in the statement table to:

- Help you determine if a statement is not going to perform within range of your service-level agreements and to tune accordingly.

DB2 puts its cost estimate into one of two *cost categories*: category A or category B. Estimates that go into cost category A are the ones for which DB2 has

a data type of CHAR(18). However, use the most current format because it gives you the most information. You can alter a statement table in the older format to a statement table in the current format.

Table 191 shows the content of each column.

Table 191. Descriptions of columns in DSN\_STATEMNT\_TABLE

| Column Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO       | A number that identifies the statement being explained. See the description of the QUERYNO column in Table 165 on page 936 for more information. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.                                                                                                                                                                                              |
| APPLNAME      | The name of the application plan for the row, or blank. See the description of the APPLNAME column in Table 165 on page 936 for more information.                                                                                                                                                                                                                                                            |
| PROGNAME      | The name of the program or package containing the statement being explained, or blank. See the description of the PROGNAME column in Table 165 on page 936 for more information.                                                                                                                                                                                                                             |
| COLLID        | The collection ID for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. Blank if not applicable. The value DSN_DYNAMICSQLCACHE indicates that the row is for a cached statement.                                                                                                                                |
| GROUP_MEMBER  | The member name of the DB2 that executed EXPLAIN, or blank. See the description of the GROUP_MEMBER column in Table 165 on page 936 for more information.                                                                                                                                                                                                                                                    |
| EXPLAIN_TIME  | The time at which the statement is processed. This time is the same as the BIND_TIME column in PLAN_TABLE.                                                                                                                                                                                                                                                                                                   |
| STMT_TYPE     | The type of statement being explained. Possible values are:<br><b>SELECT</b> SELECT<br><b>INSERT</b> INSERT<br><b>UPDATE</b> UPDATE<br><b>DELETE</b> DELETE<br><b>SELUPD</b> SELECT with FOR UPDATE OF<br><b>DELCUR</b> DELETE WHERE CURRENT OF CURSOR<br><b>UPDCUR</b> UPDATE WHERE CURRENT OF CURSOR                                                                                                       |
| COST_CATEGORY | Indicates if DB2 was forced to use default values when making its estimates. Possible values:<br><b>A</b> Indicates that DB2 had enough information to make a cost estimate without using default values.<br><b>B</b> Indicates that some condition exists for which DB2 was forced to use default values. See the values in REASON to determine why DB2 was unable to put this estimate in cost category A. |
| PROCMS        | The estimated processor cost, in milliseconds, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 milliseconds, which is equivalent to approximately 24.8 days. If the estimated value exceeds this maximum, the maximum value is reported.                                                                                          |
| PROCSU        | The estimated processor cost, in service units, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 service units. If the estimated value exceeds this maximum, the maximum value is reported.                                                                                                                                        |

Table 191. Descriptions of columns in DSN\_STATEMNT\_TABLE (continued)

| Column Name             | Description                                                                                                                                                                                                                                                                                                                                             |   |       |   |        |   |         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|-------|---|--------|---|---------|
| REASON                  | A string that indicates the reasons for putting an estimate into cost category B.                                                                                                                                                                                                                                                                       |   |       |   |        |   |         |
| HAVING CLAUSE           | A subselect in the SQL statement contains a HAVING clause.                                                                                                                                                                                                                                                                                              |   |       |   |        |   |         |
| HOST VARIABLES          | The statement uses host variables, parameter markers, or special registers.                                                                                                                                                                                                                                                                             |   |       |   |        |   |         |
| REFERENTIAL CONSTRAINTS | Referential constraints of the type CASCADE or SET NULL exist on the target table of a DELETE statement.                                                                                                                                                                                                                                                |   |       |   |        |   |         |
| TABLE CARDINALITY       | The cardinality statistics are missing for one or more of the tables that are used in the statement. Or, the statement required the materialization of views or nested table expressions.                                                                                                                                                               |   |       |   |        |   |         |
| TRIGGERS                | Triggers are defined on the target table of an INSERT, UPDATE, or DELETE statement.                                                                                                                                                                                                                                                                     |   |       |   |        |   |         |
| UDF                     | The statement uses user-defined functions.                                                                                                                                                                                                                                                                                                              |   |       |   |        |   |         |
| STMT_ENCODE             | Encoding scheme of the statement. If the statement represents a single CCSID set, the possible values are:<br><table border="0" style="margin-left: 20px;"> <tr> <td>A</td> <td>ASCII</td> </tr> <tr> <td>E</td> <td>EBCDIC</td> </tr> <tr> <td>U</td> <td>Unicode</td> </tr> </table> <p>If the statement has multiple CCSID sets, the value is M.</p> | A | ASCII | E | EBCDIC | U | Unicode |
| A                       | ASCII                                                                                                                                                                                                                                                                                                                                                   |   |       |   |        |   |         |
| E                       | EBCDIC                                                                                                                                                                                                                                                                                                                                                  |   |       |   |        |   |         |
| U                       | Unicode                                                                                                                                                                                                                                                                                                                                                 |   |       |   |        |   |         |

## Populating and maintaining a statement table

You populate a statement table at the same time as you populate the corresponding plan table. For more information, see “Populating and maintaining a plan table” on page 940.

Just as with the plan table, DB2 just adds rows to the statement table; it does not automatically delete rows. INSERT triggers are not activated unless you insert rows yourself using and SQL INSERT statement.

To clear the table of obsolete rows, use DELETE, just as you would for deleting rows from any table. You can also use DROP TABLE to drop a statement table completely.

## Retrieving rows from a statement table

To retrieve all rows in a statement table, you can use a query like the following statement, which retrieves all rows about the statement that is represented by query number 13:

```
SELECT * FROM JOE.DSN_STATEMNT_TABLE
WHERE QUERYNO = 13;
```

The QUERYNO, APPLNAME, PROGNAME, COLLID, and EXPLAIN\_TIME columns contain the same values as corresponding columns of PLAN\_TABLE for a given plan. You can use these columns to join the plan table and statement table:

```
SELECT A.*, PROCMS, COST_CATEGORY
FROM JOE.PLAN_TABLE A, JOE.DSN_STATEMNT_TABLE B
WHERE A.APPLNAME = 'APPL1' AND
A.APPLNAME = B.APPLNAME AND
```

```
#
      A.QUERYNO = B.QUERYNO AND  A.PROGNAME = B.PROGNAME AND
      A.COLLID  = B.COLLID AND
      A.BIND_TIME = B.EXPLAIN_TIME
ORDER BY A.QUERYNO, A.QBLOCKNO, A.PLANNO, A.MIXOPSEQ;
```

## The implications of cost categories

Cost categories are DB2's way of differentiating estimates for which adequate information is available from those for which it is not. You probably wouldn't want to spend a lot of time tuning a query based on estimates that are returned in cost category B, because the actual cost could be radically different based on such things as what value is in a host variable, or how many levels of nested triggers and user-defined functions exist.

Similarly, if system administrators use these estimates as input into the resource limit specification table for governing (either predictive or reactive), they probably would want to give much greater latitude for statements in cost category B than for those in cost category A.

Because of the uncertainty involved, category B statements are also good candidates for reactive governing.

*What goes into cost category B?* DB2 puts a statement's estimate into cost category B when any of the following conditions exist:

- The statement has UDFs.
- Triggers are defined for the target table:
  - The statement is INSERT, and insert triggers are defined on the target table.
  - The statement is UPDATE, and update triggers are defined on the target table.
  - The statement is DELETE, and delete triggers are defined on the target table.
- The target table of a delete statement has referential constraints defined on it as the parent table, and the delete rules are either CASCADE or SET NULL.
- The WHERE clause predicate has one of the following forms:
  - COL op literal, and the literal is a host variable, parameter marker, or special register. The operator can be >, >=, <, <=, LIKE, or NOT LIKE.
  - COL BETWEEN literal AND literal where either literal is a host variable, parameter marker, or special register.
  - LIKE with an escape clause that contains a host variable.
- The cardinality statistics are missing for one or more tables that are used in the statement.
- A subselect in the SQL statement contains a HAVING clause.

*What goes into cost category A?* DB2 puts everything that doesn't fall into category B into category A.

---

## Chapter 35. Parallel operations and query performance

When DB2 plans to access data from a table or index in a partitioned table space, it can initiate multiple parallel operations. The response time for data or processor-intensive queries can be significantly reduced.

Query I/O parallelism manages concurrent I/O requests for a single query, fetching pages into the buffer pool in parallel. This processing can significantly improve the performance of I/O-bound queries. I/O parallelism is used only when one of the other parallelism modes cannot be used.

Query CP parallelism enables true multitasking within a query. A large query can be broken into multiple smaller queries. These smaller queries run simultaneously on multiple processors accessing data in parallel. This reduces the elapsed time for a query.

To expand even farther the processing capacity available for processor-intensive queries, DB2 can split a large query across different DB2 members in a data sharing group. This is known as Sysplex query parallelism. For more information about Sysplex query parallelism, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*.

DB2 can use parallel operations for processing:

- Static and dynamic queries
- Local and remote data access
- Queries using single table scans and multi-table joins
- Access through an index, by table space scan or by list prefetch
- Sort operations

Parallel operations usually involve at least one table in a partitioned table space. Scans of large partitioned table spaces have the greatest performance improvements where both I/O and central processor (CP) operations can be carried out in parallel.

***Parallelism for partitioned and nonpartitioned table spaces:*** Both partitioned and nonpartitioned table spaces can take advantage of query parallelism. Parallelism is now enabled to include non-clustering indexes. Thus, table access can be run in parallel when the application is bound with DEGREE (ANY) and the table is accessed through a non-clustering index.

This chapter contains the following topics:

- “Comparing the methods of parallelism” on page 992
- “Partitioning for optimal parallel performance” on page 994
- “Enabling parallel processing” on page 997
- “Restrictions for parallelism” on page 998
- “Interpreting EXPLAIN output” on page 999
- “Monitoring parallel operations” on page 1001
- “Tuning parallel processing” on page 1004
- “Disabling query parallelism” on page 1005

## Comparing the methods of parallelism

The figures in this section show how the parallel methods compare with sequential prefetch and with each other. All three techniques assume access to a table space with three partitions, P1, P2, and P3. The notations P1, P2, and P3 are partitions of a table space. R1, R2, R3, and so on, are requests for sequential prefetch. The combination P2R1, for example, means the first request from partition 2.

Figure 115 shows **sequential processing**. With sequential processing, DB2 takes the 3 partitions in order, completing partition 1 before starting to process partition 2, and completing 2 before starting 3. Sequential prefetch allows overlap of CP processing with I/O operations, but I/O operations do not overlap with each other. In the example in Figure 115, a prefetch request takes longer than the time to process it. The processor is frequently waiting for I/O.

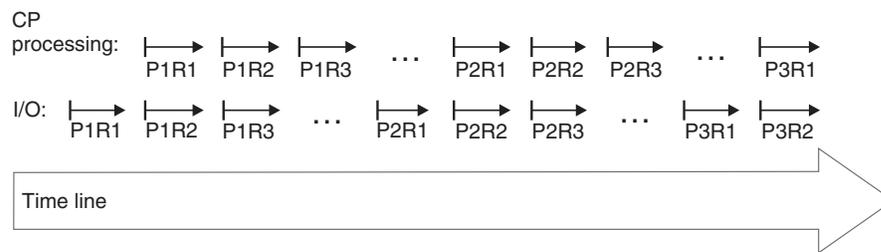

Figure 115. CP and I/O processing techniques. Sequential processing.

Figure 116 shows **parallel I/O operations**. With parallel I/O, DB2 prefetches data from the 3 partitions at one time. The processor processes the first request from each partition, then the second request from each partition, and so on. The processor is not waiting for I/O, but there is still only one processing task.

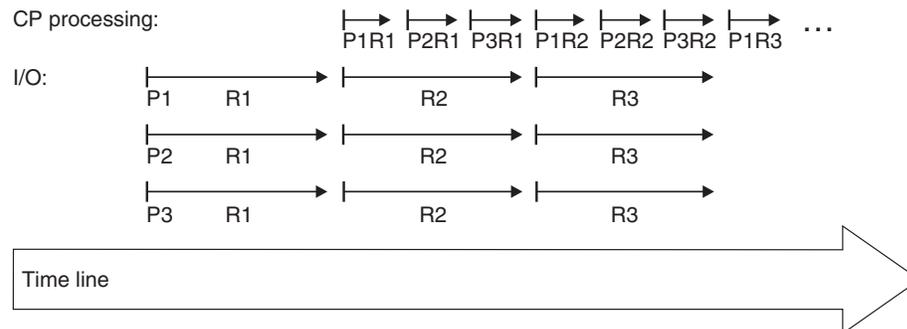

Figure 116. CP and I/O processing techniques. Parallel I/O processing.

Figure 117 on page 993 shows **parallel CP processing**. With CP parallelism, DB2 can use multiple parallel tasks to process the query. Three tasks working concurrently can greatly reduce the overall elapsed time for data-intensive and processor-intensive queries. The same principle applies for **Sysplex query parallelism**, except that the work can cross the boundaries of a single CPC.

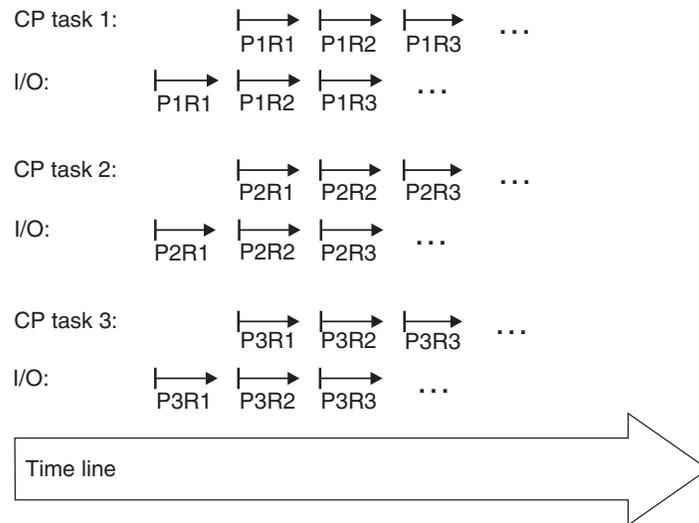

Figure 117. CP and I/O processing techniques. Query processing using CP parallelism. The tasks can be contained within a single CPC or can be spread out among the members of a data sharing group.

**Queries that are most likely to take advantage of parallel operations:** Queries that can take advantage of parallel processing are:

- Those in which DB2 spends most of the time fetching pages—an I/O-intensive query

A typical I/O-intensive query is something like the following query, assuming that a table space scan is used on many pages:

```
SELECT COUNT(*) FROM ACCOUNTS
WHERE BALANCE > 0 AND
      DAYS_OVERDUE > 30;
```

- Those in which DB2 spends a lot of processor time and also, perhaps, I/O time, to process rows. Those include:
  - *Queries with intensive data scans and high selectivity.* Those queries involve large volumes of data to be scanned but relatively few rows that meet the search criteria.
  - *Queries containing aggregate functions.* Column functions (such as MIN, MAX, SUM, AVG, and COUNT) usually involve large amounts of data to be scanned but return only a single aggregate result.
  - *Queries accessing long data rows.* Those queries access tables with long data rows, and the ratio of rows per page is very low (one row per page, for example).
  - *Queries requiring large amounts of central processor time.* Those queries might be read-only queries that are complex, data-intensive, or that involve a sort.

A typical processor-intensive query is something like:

```
SELECT MAX(QTY_ON_HAND) AS MAX_ON_HAND,
      AVG(PRICE) AS AVG_PRICE,
      AVG(DISCOUNTED_PRICE) AS DISC_PRICE,
      SUM(TAX) AS SUM_TAX,
      SUM(QTY_SOLD) AS SUM_QTY_SOLD,
      SUM(QTY_ON_HAND - QTY_BROKEN) AS QTY_GOOD,
      AVG(DISCOUNT) AS AVG_DISCOUNT,
      ORDERSTATUS,
      COUNT(*) AS COUNT_ORDERS
FROM   ORDER_TABLE
```

```

WHERE SHIPPER = 'OVERNIGHT' AND
      SHIP_DATE < DATE('1996-01-01')
GROUP BY ORDERSTATUS
ORDER BY ORDERSTATUS;

```

**Terminology:** When the term **task** is used with information about parallel processing, the context should be considered. For parallel query CP processing or Sysplex query parallelism, a task is an actual z/OS execution unit used to process a query. For parallel I/O processing, a task simply refers to the processing of one of the concurrent I/O streams.

A **parallel group** is the term used to name a particular set of parallel operations (parallel tasks or parallel I/O operations). A query can have more than one parallel group, but each parallel group within the query is identified by its own unique ID number.

|  
|  
|  
#  
#  
#  
#  
#  
#

The **degree of parallelism** is the number of parallel tasks or I/O operations that DB2 determines can be used for the operations on the parallel group. The maximum of parallel operations that DB2 can generate is 254. However, for most queries and DB2 environments, DB2 chooses a lower number. You might need to limit the maximum number further because more parallel operations consume processor, real storage, and I/O resources. If resource consumption is high in your parallelism environment, use the MAX DEGREE field on installation panel DSNTIP8 to explicitly limit the maximum number of parallel operations that DB2 generates, as explain in “Enabling parallel processing” on page 997.

In a parallel group, an **originating task** is the TCB (SRB for distributed requests) that coordinates the work of all the **parallel tasks**. Parallel tasks are executable units composed of special SRBs, which are called **preemptable SRBs**.

With preemptable SRBs, the z/OS dispatcher can interrupt a task at any time to run other work at the same or higher dispatching priority. For non-distributed parallel work, parallel tasks run under a type of preemptable SRB called a **client SRB**, which lets the parallel task inherit the importance of the originating address space. For distributed requests, the parallel tasks run under a preemptable SRB called an **enclave SRB**. Enclave SRBs are described more fully in “Using z/OS workload management to set performance objectives” on page 745.

---

## Partitioning for optimal parallel performance

This section includes some general considerations for how to partition data for the best performance when using parallel processing. Bear in mind that DB2 does not always choose parallelism, even if you partition the data.

This exercise assumes the following:

- You have narrowed the focus to a few, critical queries that are running sequentially. It is best to include a mix of I/O-intensive and processor-intensive queries into this initial set. You know how long those queries take now and what your performance objectives for those queries are. Although tuning for one set of queries might not work for all queries, overall performance and throughput can be improved.
- You are optimizing for query-at-a-time operations, and you want a query to make use of all the processor and I/O resources available to it.

When running many queries at the same time, you will probably have to increase the number of partitions and the amount of processing power to achieve similar elapsed times.

This section guides you through the following analyses:

1. Determining the nature of the query (what balance of processing and I/O resources it needs)
2. Determining how many partitions the table space should have to meet your performance objective, number based on the nature of the query and on the processor and I/O configuration at your site

## Determining if a query is I/O- or processor-intensive

To determine if your sequential queries are I/O or processor-intensive, examine the DB2 accounting reports:

- If the “other read I/O time” is close to the total query elapsed time, then the query is I/O-intensive. “Other read I/O time” is the time that DB2 is waiting for pages to be read in to the buffer pools.
- If “CPU time” is close to the total query elapsed time, then the query is processor-intensive.
- If the processor time is somewhere between 30 and 70 percent of the elapsed time, then the query is pretty well-balanced.

## Determining the number of partitions

This section is intended to give you some general guidance on determining the number of partitions. Again, you must take into account the I/O subsystem, the nature of the queries you run, and, if necessary, plan for the data to grow. If your physical and logical design are not closely tied together, thus allowing you to specify any number of partitions, it does no harm to specify more partitions than you need immediately. However, start with a reasonable number of partitions because you can always add more partitions later with the ALTER TABLESPACE statement.

Consider also the operational complexity of managing many partitions. This complexity may not be as much of an issue at sites that use tools, such as the DB2 Automated Utilities Generator and job schedulers.

In general, the number of partitions falls in a range between the number of CPs and the maximum number of I/O paths to the data. When determining the number of partitions that use a mixed set of processor- and I/O-intensive queries, always choose the largest number of partitions in the range you determine.

- **For processor-intensive queries**, specify, at a minimum, a number that is equal to the number of CPs in the system that you want to use for parallelism, whether you have a single CPC or multiple CPCs in a data sharing group. If the query is processor-intensive, it can use all CPs available in the system. If you plan to use Sysplex query parallelism, then choose a number that is close to the total number of CPs (including partial allocation of CPs) that you plan to allocate for decision support processing across the data sharing group. Do not include processing resources that are dedicated to other, higher priority, work. For more information about Sysplex query parallelism, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*.
- **For I/O-intensive queries**, calculate the ratio of elapsed time to processor time. Multiply this ratio by the number of processors allocated for decision support processing. Round up this number to determine how many partitions you can use to the best advantage, assuming that these partitions can be on separate devices and have adequate paths to the data. This calculation also assumes that you have adequate processing power to handle the increase in partitions. (This might not be much of an issue with an extremely I/O-intensive query.)

By partitioning the amount indicated previously, the query is brought into balance by reducing the I/O wait time. If the number of partitions is less than the number of CPs available on your system, increase this number close to the number of CPs available. By doing so, other queries that read this same table, but that are more processor-intensive, can take advantage of the additional processing power.

**Example:** Suppose that you have a 10-way CPC and the calculated number of partitions is five. Instead of limiting the table space to five partitions, use 10, to equal the number of CPs in the CPC.

*Example configurations for an I/O-intensive query:* If the I/O cost of your queries is about twice as much as the processing cost, the optimal number of partitions when run on a 10-way processor is 20 (2 \* number of processors). Figure 118 shows an I/O configuration that minimizes the elapsed time and allows the CPC to run at 100% busy. It assumes the suggested guideline of four devices per control unit and four channels per control unit.<sup>7</sup>

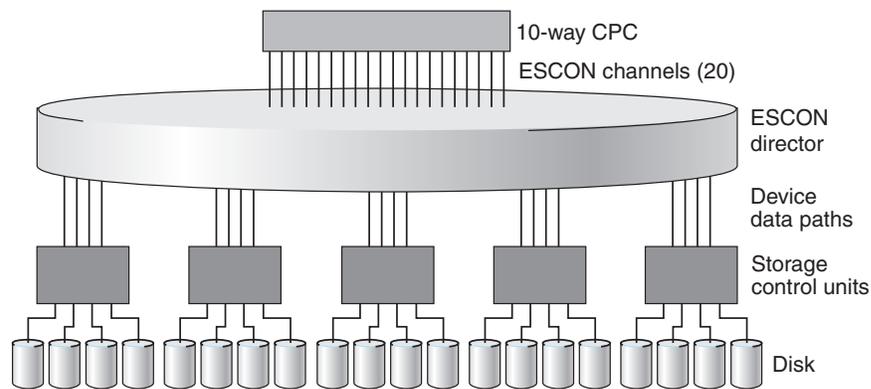

Figure 118. I/O configuration that maximizes performance for an I/O-intensive query

## Working with a table space that is already partitioned

Assume that a table space already has 10 partitions and a particular query uses CP parallelism on a 10-way CPC. When you add “other read I/O wait time” (from accounting class 3) and processing time (from accounting class 2) you determine that I/O cost is three times more than the processing cost. In this case, the optimal number of partitions is 30 (three times more I/O paths). However, if you can run on a data sharing group and you add another DB2 to the group that is running on a 10-way CPC, the I/O configuration that minimizes the elapsed time and allows both CPCs to run at 100% would be 60 partitions.

## Making the partitions the same size

The degree of parallelism is influenced by the size of the largest physical partition. In most cases, DB2 divides the table space into logical pieces, called *work ranges* to differentiate these from physical pieces, based on the size of the largest physical partition of a given table. Suppose that a table consists of 10 000 pages and 10 physical partitions, the largest of which is 5000 pages. DB2 is most likely to create only two work ranges, and the degree of parallelism would be 2. If the same table has evenly sized partitions of 1000 pages each and the query is I/O-intensive, then

7. A lower-cost configuration could use as few as two to three channels per control unit shared among all controllers using an ESCON director. However, using four paths minimizes contention and provides the best performance. Paths might also need to be taken offline for service.

ten logical work ranges might be created. This example would result in a degree of parallelism of 10 and reduced elapsed time.

DB2 tries to create equal work ranges by dividing the total cost of running the work by the logical partition cost. This division often has some left over work. In this case, DB2 creates an additional task to handle the extra work, rather than making all the work ranges larger, which would reduce the degree of parallelism.

To rebalance partitions that have become skewed, reorganize the table space, specifying the REBALANCE keyword on the REORG utility statement.

## Working with partitioned indexes

Similar to partitioned table spaces, the degree of parallelism for accessing partitioned indexes depends on the nature of the query and on the processor and I/O configuration at your site. For an I/O-intensive query, the degree of a parallelism for access to a partitioned index depends on the number of index partitions that are referenced, whereas the degree of parallelism for access to a nonpartitioned index depends on the number of CPs in the system. For a processor-intensive query, the degree of parallelism for both partitioned and nonpartitioned indexes is influenced by the number of CPs in the system.

---

## Enabling parallel processing

Queries can only take advantage of parallelism if you enable parallel processing. Use the following actions to enable parallel processing:

- For **static SQL**, specify DEGREE(ANY) on BIND or REBIND. This bind option affects static SQL only and does not enable parallelism for dynamic statements.
- For **dynamic SQL**, set the CURRENT DEGREE special register to 'ANY'. Setting the special register affects dynamic statements only. It will have no effect on your static SQL statements. You should also make sure that parallelism is not disabled for your plan, package, or authorization ID in the RLST. You can set the special register with the following SQL statement:

```
SET CURRENT DEGREE='ANY';
```

```
# You can also change the special register default from 1 to ANY for the entire
# DB2 subsystem by modifying the CURRENT DEGREE field on installation panel
# DSNTIP8.
```

- If you bind with isolation CS, choose also the option CURRENTDATA(NO), if possible. This option can improve performance in general, but it also ensures that DB2 will consider parallelism for ambiguous cursors. If you bind with CURRENTDATA(YES) and DB2 cannot tell if the cursor is read-only, DB2 does not consider parallelism. When a cursor is read-only, it is recommended that you specify the FOR FETCH ONLY or FOR READ ONLY clause on the DECLARE CURSOR statement to explicitly indicate that the cursor is read-only.
- The virtual buffer pool parallel sequential threshold (VPPSEQT) value must be large enough to provide adequate buffer pool space for parallel processing. For more information about VPPSEQT, see “Buffer pool thresholds” on page 673.

If you enable parallel processing when DB2 estimates a given query’s I/O and central processor cost is high, multiple parallel tasks can be activated if DB2 estimates that elapsed time can be reduced by doing so.

**Recommendation:** For parallel sorts, allocate sufficient work files to maintain performance.

**Special requirements for CP parallelism:** DB2 must be running on a central processor complex that contains two or more tightly coupled processors (sometimes called central processors, or CPs). If only one CP is online when the query is bound, DB2 considers only parallel I/O operations.

DB2 also considers only parallel I/O operations if you declare a cursor WITH HOLD and bind with isolation RR or RS. For more restrictions on parallelism, see Table 192.

For complex queries, run the query in parallel within a member of a data sharing group. With Sysplex query parallelism, use the power of the data sharing group to process individual complex queries on many members of the data sharing group. For more information about how you can use the power of the data sharing group to run complex queries, see Chapter 6 of *DB2 Data Sharing: Planning and Administration*.

# **Limiting the degree of parallelism:** If you want to limit the maximum number of parallel tasks that DB2 generates, you can use the MAX DEGREE field on installation panel DSNTIP8. Changing MAX DEGREE, however, is not the way to turn parallelism off. You use the DEGREE bind parameter or CURRENT DEGREE special register to turn parallelism off.

## Restrictions for parallelism

**When parallelism is not used:** Parallelism is not used for all queries; for some access paths, it doesn't make sense to incur parallelism overhead. For example, if you are selecting from a temporary table, parallelism is not used. Check Table 192 to determine whether your query uses any of the access paths that do not allow parallelism.

Table 192. Checklist of parallel modes and query restrictions

| If query uses this...                                                         | Is parallelism allowed? |       |         | Comments                                                                                                                                                                                   |
|-------------------------------------------------------------------------------|-------------------------|-------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                               | I/O                     | CP    | Sysplex |                                                                                                                                                                                            |
| Access via RID list (list prefetch and multiple index access)                 | Yes                     | Yes   | No      | Indicated by an "L" in the PREFETCH column of PLAN_TABLE, or an M, MX, ML, or MQ in the ACESSTYPE column of PLAN_TABLE.                                                                    |
| Queries that return LOB values                                                | Yes                     | Yes   | No      |                                                                                                                                                                                            |

*Access paths that are restricted by parallelism:* Certain access paths that would reduce the effectiveness of parallelism are removed from consideration when parallelism is enabled. To ensure that you can take advantage of parallelism, DB2 does not select certain access paths when parallelism is enabled. When the plan or package is bound with DEGREE(ANY) or the CURRENT DEGREE special register is set to 'ANY,' DB2:

- Does not choose Hybrid joins with SORTN\_JOIN=Y.
- Does not transform certain subqueries to joins.

---

## Interpreting EXPLAIN output

To understand how DB2 plans to use parallelism, examine your PLAN\_TABLE output. (Details on all columns in PLAN\_TABLE are described in Table 165 on page 936.) This section describes a method for examining PLAN\_TABLE columns for parallelism and gives several examples.

### A method for examining PLAN\_TABLE columns for parallelism

The steps for interpreting the output for parallelism are as follows:

1. **Determine if DB2 plans to use parallelism:**

For each query block (QBLOCKNO) in a query (QUERYNO), a non-null value in ACCESS\_DEGREE or JOIN\_DEGREE indicates that some degree of parallelism is planned.

2. **Identify the parallel groups in the query:**

All steps (PLANNO) with the same value for ACCESS\_PGROUP\_ID, JOIN\_PGROUP\_ID, SORTN\_PGROUP\_ID, or SORTC\_PGROUP\_ID indicate that a set of operations are in the same parallel group. Usually, the set of operations involves various types of join methods and sort operations. Parallel group IDs can appear in the same row of PLAN\_TABLE output, or in different rows, depending on the operation being performed. The examples in "PLAN\_TABLE examples showing parallelism" help clarify this concept.

3. **Identify the parallelism mode:**

The column PARALLELISM\_MODE tells you the kind of parallelism that is planned: I for query I/O, C for query CP, and X for Sysplex query. Within a query block, you cannot have a mixture of "I" and "C" parallel modes. However, a statement that uses more than one query block, such as a UNION, can have "I" for one query block and "C" for another. You can have a mixture of "C" and "X" modes in a query block, but not in the same parallel group.

If the statement was bound while this DB2 is a member of a data sharing group, the PARALLELISM\_MODE column can contain "X" even if only this one DB2 member is active. This lets DB2 take advantage of extra processing power that might be available at execution time. If other members are not available at execution time, then DB2 runs the query within the single DB2 member.

### PLAN\_TABLE examples showing parallelism

For these examples, the other values would not change whether the PARALLELISM\_MODE is I, C, or X.

- **Example 1: single table access**

Assume that DB2 decides at bind time to initiate three concurrent requests to retrieve data from table T1. Part of PLAN\_TABLE appears as shown in Table 193. If DB2 decides not to use parallel operations for a step, ACCESS\_DEGREE and ACCESS\_PGROUP\_ID contain null values.

Table 193. Part of PLAN\_TABLE for single table access

| TNAME | METHOD | ACCESS_DEGREE | ACCESS_PGROUP_ID | JOIN_DEGREE | JOIN_PGROUP_ID | SORTC_PGROUP_ID | SORTN_PGROUP_ID |
|-------|--------|---------------|------------------|-------------|----------------|-----------------|-----------------|
| T1    | 0      | 3             | 1                | (null)      | (null)         | (null)          | (null)          |

- **Example 2: nested loop join**

Consider a query that results in a series of nested loop joins for three tables, T1, T2 and T3. T1 is the outermost table, and T3 is the innermost table. DB2 decides at bind time to initiate three concurrent requests to retrieve data from each of the three tables. Each request accesses part of T1 and all of T2 and T3. For the nested loop join method with sort, all the retrievals are in the same parallel group except for star join with ACCESTYPE=T (sparse index). Part of PLAN\_TABLE appears as shown in Table 194:

Table 194. Part of PLAN\_TABLE for a nested loop join

| TNAME | METHOD | ACCESS_DEGREE | ACCESS_PGROUP_ID | JOIN_DEGREE | JOIN_PGROUP_ID | SORTC_PGROUP_ID | SORTN_PGROUP_ID |
|-------|--------|---------------|------------------|-------------|----------------|-----------------|-----------------|
| T1    | 0      | 3             | 1                | (null)      | (null)         | (null)          | (null)          |
| T2    | 1      | 3             | 1                | 3           | 1              | (null)          | (null)          |
| T3    | 1      | 3             | 1                | 3           | 1              | (null)          | (null)          |

- **Example 3: merge scan join**

Consider a query that causes a merge scan join between two tables, T1 and T2. DB2 decides at bind time to initiate three concurrent requests for T1 and six concurrent requests for T2. The scan and sort of T1 occurs in one parallel group. The scan and sort of T2 occurs in another parallel group. Furthermore, the merging phase can potentially be done in parallel. Here, a third parallel group is used to initiate three concurrent requests on each intermediate sorted table. Part of PLAN\_TABLE appears as shown in Table 195:

Table 195. Part of PLAN\_TABLE for a merge scan join

| TNAME | METHOD | ACCESS_DEGREE | ACCESS_PGROUP_ID | JOIN_DEGREE | JOIN_PGROUP_ID | SORTC_PGROUP_ID | SORTN_PGROUP_ID |
|-------|--------|---------------|------------------|-------------|----------------|-----------------|-----------------|
| T1    | 0      | 3             | d                | (null)      | (null)         | d               | (null)          |
| T2    | 2      | 6             | 2                | 3           | 3              | d               | d               |

In a multi-table join, DB2 might also execute the sort for a composite that involves more than one table in a parallel task. DB2 uses a cost basis model to determine whether to use parallel sort in all cases. When DB2 decides to use parallel sort, SORTC\_PGROUP\_ID and SORTN\_PGROUP\_ID indicate the parallel group identifier. Consider a query that joins three tables, T1, T2, and T3, and uses a merge scan join between T1 and T2, and then between the composite and T3. If DB2 decides, based on the cost model, that all sorts in this query are to be performed in parallel, part of PLAN\_TABLE appears as shown in Table 196 on page 1001:

Table 196. Part of PLAN\_TABLE for a multi-table, merge scan join

| TNAME | METHOD | ACCESS_DEGREE | ACCESS_PGROUP_ID | JOIN_DEGREE | JOIN_PGROUP_ID | SORTC_PGROUP_ID | SORTN_PGROUP_ID |
|-------|--------|---------------|------------------|-------------|----------------|-----------------|-----------------|
| T1    | 0      | 3             | 1                | (null)      | (null)         | (null)          | (null)          |
| T2    | 2      | 6             | 2                | 6           | 3              | 1               | 2               |
| T3    | 2      | 6             | 4                | 6           | 5              | 3               | 4               |

- **Example 4: hybrid join**

Consider a query that results in a hybrid join between two tables, T1 and T2. Furthermore, T1 needs to be sorted; as a result, in PLAN\_TABLE the T2 row has SORTC\_JOIN=Y. DB2 decides at bind time to initiate three concurrent requests for T1 and six concurrent requests for T2. Parallel operations are used for a join through a clustered index of T2.

Because T2's RIDs can be retrieved by initiating concurrent requests on the clustered index, the joining phase is a parallel step. The retrieval of T2's RIDs and T2's rows are in the same parallel group. Part of PLAN\_TABLE appears as shown in Table 197:

Table 197. Part of PLAN\_TABLE for a hybrid join

| TNAME | METHOD | ACCESS_DEGREE | ACCESS_PGROUP_ID | JOIN_DEGREE | JOIN_PGROUP_ID | SORTC_PGROUP_ID | SORTN_PGROUP_ID |
|-------|--------|---------------|------------------|-------------|----------------|-----------------|-----------------|
| T1    | 0      | 3             | 1                | (null)      | (null)         | (null)          | (null)          |
| T2    | 4      | 6             | 2                | 6           | 2              | 1               | (null)          |

## Monitoring parallel operations

The number of parallel operations or tasks used to access data is initially determined at bind time, and later adjusted when the query is executed.

**Bind time:** At bind time, DB2 collects partition statistics from the catalog, estimates the processor cycles for the costs of processing the partitions, and determines the optimal number of parallel tasks to achieve minimum elapsed time.

When a planned degree exceeds the number of online CPs, the query might not be completely processor-bound. Instead it might be approaching the number of partitions because it is I/O-bound. In general, the more I/O-bound a query is, the closer the degree of parallelism is to the number of partitions.

In general, the more processor-bound a query is, the closer the degree of parallelism is to the number of online CPs, and it can even exceed the number of CPs by one.

**Example:** Suppose that you have a processor-intensive query on a 10-partition table, and that this query is running on a 6-way CPC. The degree of parallelism can be up to 7 in this case.

To help DB2 determine the optimal degree of parallelism, use the utility RUNSTATS to keep your statistics current.

PLAN\_TABLE shows the planned degree of parallelism in the columns ACCESS\_DEGREE and JOIN\_DEGREE.

**Execution time:** For each parallel group, parallelism (either CP or I/O) can execute at a reduced degree or degrade to sequential operations for the following reasons:

- Amount of virtual buffer pool space available
- Host variable values
- Availability of the hardware sort assist facility
- Ambiguous cursors
- A change in the number or configuration of online processors
- The join technique that DB2 uses (I/O parallelism not supported when DB2 uses the star join technique)

At execution time, a plan using Sysplex query parallelism can use CP parallelism. All parallelism modes can degenerate to a sequential plan. No other changes are possible.

## Using DISPLAY BUFFERPOOL

You can use the output from DISPLAY BUFFERPOOL DETAIL report to see how well the buffer pool is able to satisfy parallel operations.

```
DSNB440I = PARALLEL ACTIVITY -  
          PARALLEL REQUEST =      282  DEGRADED PARALLEL=      5
```

The PARALLEL REQUEST field in this example shows that DB2 was negotiating buffer pool resource for 282 parallel groups. Of those 282 groups, only 5 were degraded because of a lack of buffer pool resource. A large number in the DEGRADED PARALLEL field could indicate that there are not enough buffers that can be used for parallel processing.

## Using DISPLAY THREAD

DISPLAY THREAD displays parallel tasks. Whereas previously you would only see information about the originating task, now you can see information about the parallel tasks associated with that originating task. The status field contains PT for parallel tasks. All parallel tasks are displayed immediately after their corresponding originating thread.

See Chapter 2 of *DB2 Command Reference* for information about the syntax of the command DISPLAY THREAD.

## Using DB2 trace

The statistics trace indicates when parallel groups do not run to the planned degree or run sequentially. These are possible indicators that there are queries that are not achieving the best possible response times. Use the accounting trace to ensure that your parallel queries are meeting their response time goals. If there appears to be a problem with a parallel query, then use the performance trace to do further analysis.

### Accounting trace

By default, DB2 rolls task accounting into an accounting record for the originating task. OMEGAMON also summarizes all accounting records generated for a parallel query and presents them as one logical accounting record. OMEGAMON presents the times for the originating tasks separately from the accumulated times for all the parallel tasks.

As shown in Figure 119 on page 1003 CPU TIME-AGENT is the time for the originating tasks, while CPU TIME-PAR.TASKS ( **A** ) is the accumulated processing time for the parallel tasks.

| TIMES/EVENTS | APPL (CLASS 1)       | DB2 (CLASS 2) | CLASS 3 SUSP.  | ELAPSED TIME |

Figure 119. Partial accounting trace, query parallelism

As the report shows, the values for CPU TIME and I/O WAIT TIME are larger than the elapsed time. The processor and suspension time can be greater than the elapsed time because these two times are accumulated from multiple parallel tasks. The elapsed time would be less than the processor and suspension time if these two times are accumulated sequentially.

If you have baseline accounting data for the same thread run without parallelism, the elapsed times and processor times should not be significantly larger when that query is run in parallel. If it is significantly larger, or if response time is poor, you need to examine the accounting data for the individual tasks. Use the OMEGAMON Record Trace for the IFCID 0003 records of the thread you want to examine. Use the performance trace if you need more information to determine the cause of the response time problem.

### Performance trace

The performance trace can give you information about tasks within a group. To determine the actual number of parallel tasks used, refer to field QW0221AD in IFCID 0221, as mapped by macro DSNDQW03. The 0221 record also gives you information about the key ranges used to partition the data.

IFCID 0222 contains the elapsed time information for each parallel task and each parallel group in each SQL query. OMEGAMON presents this information in its SQL Activity trace.

If your queries are running sequentially or at a reduced degree because of a lack of buffer pool resources, the QW0221C field of IFCID 0221 indicates which buffer pool is constrained.

---

## Tuning parallel processing

Much of the information in this section applies also to Sysplex query parallelism. See Chapter 6 of *DB2 Data Sharing: Planning and Administration* for more information.

If there are many parallel groups that do not run at the planned degree (see **B** in Figure 119 on page 1003), check the following factors:

- Buffer pool availability

Depending on buffer pool availability, DB2 could reduce the degree of parallelism (see **C** in Figure 119 on page 1003) or revert to a sequential plan before executing the parallel group (**F** in the figure).

To determine which buffer pool is short on storage, see section QW0221C in IFCID 0221. You can use the ALTER BUFFERPOOL command to increase the buffer pool space available for parallel operations by modifying the following parameters:

- VPSIZE, the size of the virtual buffer pool
- VPSEQT, the sequential steal threshold
- VPPSEQT, the parallel sequential threshold
- VPXPSEQT, the assisting parallel sequential threshold, used only for Sysplex query parallelism.

If the buffer pool is busy with parallel operations, the sequential prefetch quantity might also be reduced.

The parallel sequential threshold also has an impact on **work file processing** for parallel queries. DB2 assumes that you have all your work files of the same size (4KB or 32KB) in the same buffer pool and makes run time decisions based on a single buffer pool. A lack of buffer pool resources for the work files can lead to a reduced degree of parallelism or cause the query to run sequentially.

If increasing the parallel thresholds does not help solve the problem of reduced degree, you can increase the total buffer pool size (VPSIZE). Use information from the statistics trace to determine the amount of buffer space you need. Use the following formula:

$$(QBSTJIS \div QBSTPQF) \times 32 = \text{buffer increase value}$$

QBSTJIS is the total number of requested prefetch I/O streams that were denied because of a storage shortage in the buffer pool. (There is one I/O stream per parallel task.) QBSTPQF is the total number of times that DB2 could not allocate enough buffer pages to allow a parallel group to run to the planned degree.

As an example, assume QBSTJIS is 100 000 and QBSTPQF is 2500:

$$(100000 \div 2500) \times 32 = 1280$$

Use ALTER BUFFERPOOL to increase the current VPSIZE by 2560 buffers to alleviate the degree degradation problem. Use the DISPLAY BUFFERPOOL command to see the current VPSIZE.

- Physical contention

As much as possible, put data partitions on separate physical devices to minimize contention. Try not to use more partitions than there are internal paths in the controller.

- Run time host variables

A host variable can determine the qualifying partitions of a table for a given query. In such cases, DB2 defers the determination of the planned degree of parallelism until run time, when the host variable value is known.

- Updatable cursor

At run time, DB2 might determine that an ambiguous cursor is updatable. This appears in **D** in the accounting report.

- Proper hardware and software support

If you do not have the hardware sort facility at run time, and a sort merge join is needed, you see a value in **E**.

- A change in the configuration of online processors

If there are fewer online processors at run time than at bind time, DB2 reformulates the parallel degree to take best advantage of the current processing power. This reformulation is indicated by a value in **H** in the accounting report.

**Locking considerations for repeatable read applications:** For CP parallelism, locks are obtained independently by each task. Be aware that this situation can possibly increase the total number of locks taken for applications that:

- Use an isolation level of repeatable read
- Use CP parallelism
- Repeatedly access the table space using a lock mode of IS without issuing COMMITs

**Recommendation:** As is recommended for all repeatable-read applications, issue frequent COMMITs to release the lock resources that are held. Repeatable read or read stability isolation cannot be used with Sysplex query parallelism.

---

## Disabling query parallelism

To disable parallel operations, do any of the following actions:

- For static SQL, rebind to change the option DEGREE(ANY) to DEGREE(1). You can do this by using the DB2I panels, the DSN subcommands, or the DSNH CLIST. The default is DEGREE(1).

- For dynamic SQL, execute the following SQL statement:

```
SET CURRENT DEGREE = '1';
```

The default value for CURRENT DEGREE is 1 unless your installation has changed the default for the CURRENT DEGREE special register.

- Set the parallel sequential threshold (VPPSEQT) to 0.
- Add a row to your resource limit facility's specification table (RLST) for your plan, package, or authorization ID with the RLFFUNC value set to "3" to disable I/O parallelism, "4" to disable CP parallelism, or "5" to disable Sysplex query parallelism. To disable all types of parallelism, you need a row for all three types (assuming that Sysplex query parallelism is enabled on your system.) In a system with a very high processor utilization rate (that is, greater than 98 percent), I/O parallelism might be a better choice because of the increase in processor overhead with CP parallelism. In this case, you could disable CP parallelism for your dynamic queries by putting a "4" in the resource limit specification table for the plan or package.

If you have a Sysplex, you might want to use a "5" to disable Sysplex query parallelism, depending on how high processor utilization is in the members of the data sharing group.

To determine if parallelism has been disabled by a value in your resource limit specification table (RLST), look for a non-zero value in field QXRLFDPA in IFCID 0002 or 0003 (shown in **6** in Figure 119 on page 1003). The QW0022RP field in IFCID 0022 indicates whether this particular statement was disabled. For more information about how the resource limit facility governs modes of parallelism, see “Descriptions of the RLST columns” on page 725.

---

## Chapter 36. Tuning and monitoring in a distributed environment

This chapter describes some ways you can tune your systems and applications that use DRDA or DB2 private protocol for distributed data access.

This chapter contains the following sections:

- “Remote access types: DRDA and private protocol”
- “Tuning distributed applications” on page 1008
- “Monitoring DB2 in a distributed environment” on page 1017
- “Monitoring distributed processing with RMF” on page 1021

---

### Remote access types: DRDA and private protocol

DB2 supports two different types of remote access between the requesting relational database management system (DBMS) and the serving relational database management system. The two types of access are *DRDA access* and *DB2 private protocol access*. When three-part named objects are referenced (or aliases for three-part name objects are referenced), DB2 chooses between the two connection types based on the bind option that you choose (or the default protocol set at your site).

**Recommendation:** Use DRDA for new applications, and migrate existing private protocol applications to DRDA. No enhancements are planned for private protocol.

#### Characteristics of DRDA

With DRDA, the application can remotely bind packages and can execute packages of static or dynamic SQL that have previously been bound at that location. DRDA has the following characteristics and benefits:

- With DRDA access, an application can access data at any server that supports DRDA, not just a DB2 server on a z/OS operating system.
- DRDA supports all SQL features, including user-defined functions, LOBs, and stored procedures.
- DRDA can avoid multiple binds and minimize the number of binds that are required.
- DRDA supports multiple-row FETCH.

DRDA is the preferred method for remote access with DB2.

#### Characteristics of DB2 private protocol

Private protocol is an older method for remote access. It can be used only between DB2 subsystems and only over a SNA network. Private protocol has not been enhanced to support many new SQL features. Because of these limitations, it is highly recommended that you migrate to DRDA protocol for communicating between DB2 subsystems.

---

## Tuning distributed applications

A query sent to a remote system can sometimes take longer to execute than the same query, accessing tables of the same size, on the local DB2 subsystem. The principal reasons for this potential increase in execution time are:

- The time required to send messages across the network
- Overhead processing, including startup and communication subsystem session management

Some aspects of overhead processing, for instance, network processing, are not under DB2 control. (Suggestions for tuning your network are in Part 3 of *DB2 Installation Guide*.)

Monitoring and tuning performance in a distributed environment is a complex task that requires knowledge of several products. Some guidelines follow for improving the performance of distributed applications. The guidelines are divided into the following areas:

- “Application and requesting systems”
- “Serving system” on page 1016

### Application and requesting systems

Minimizing the number of messages sent between the requester and the server is a primary way to improve performance. This section describes the following topics:

- “BIND options”
- “SQL statement options”
- “Block fetching result sets” on page 1009
- “Optimizing for very large results sets for DRDA” on page 1014
- “Optimizing for small results sets for DRDA” on page 1015

#### BIND options

If appropriate for your applications, consider the following bind options to improve performance:

- Use the DEFER(PREPARE) bind option, which can reduce the number of messages that must be sent back and forth across the network. For more information on using the DEFER(PREPARE) option, see Part 4 of *DB2 Application Programming and SQL Guide*.
- Bind application plans and packages with ISOLATION(CS) to reduce contention and message overhead.

#### SQL statement options

If appropriate for your applications, consider using the following strategies to improve the performance of SQL statements:

##### Commit frequently

Commit frequently to avoid holding resources at the server.

##### Minimize SQL statements

Avoid using several SQL statements when one well-tuned SQL statement can retrieve the desired results. Alternatively, put your SQL statements in a stored procedure, issue your SQL statements at the server through the stored procedure, and return the result. Using a stored procedure creates only one send and receive operation (for the CALL statement) instead of a potential send and receive operation for each SQL statement.

Depending on how many SQL statements are in your application, using stored procedures can significantly decrease your elapsed time and may

decrease your processor costs. For more information on how to use stored procedures, see Part 6 of *DB2 Application Programming and SQL Guide*.

**Use the RELEASE statement and the DISCONNECT(EXPLICIT) bind option**

The RELEASE statement minimizes the network traffic that is needed to release a remote connection at commit time. For example, if the application has connections to several different servers, specify the RELEASE statement when the application has completed processing for each server. The RELEASE statement does not close cursors, release any resources, or prevent further use of the connection until the COMMIT is issued. It just makes the processing at COMMIT time more efficient.

The bind option DISCONNECT(EXPLICIT) destroys all remote connections for which RELEASE was specified.

**Use the COMMIT ON RETURN YES clause**

Consider using the COMMIT ON RETURN YES clause of the CREATE PROCEDURE statement to indicate that DB2 should issue an implicit COMMIT on behalf of the stored procedure upon return from the CALL statement. Using the clause can reduce the length of time locks are held and can reduce network traffic. With COMMIT ON RETURN YES, any updates made by the client before calling the stored procedure are committed with the stored procedure changes. See Part 6 of *DB2 Application Programming and SQL Guide* for more information.

**Set the CURRENT RULES special register to DB2**

When requesting LOB data, set the CURRENT RULES special register to DB2 instead of to STD before performing a CONNECT. A value of DB2, which is the default, can offer performance advantages. When a DB2 UDB for z/OS server receives an OPEN request for a cursor, the server uses the value in the CURRENT RULES special register to determine whether the application intends to switch between LOB values and LOB locator values when fetching different rows in the cursor. If you specify a value of DB2 for CURRENT RULES, the application indicates that the first FETCH request will specify the format for each LOB column in the answer set and that the format will not change in a subsequent FETCH request. However, if you set the value of CURRENT RULES to STD, the application intends to fetch a LOB column into either a LOB locator host variable or a LOB host variable.

Although a value of STD for CURRENT RULES gives you more programming flexibility when you retrieve LOB data, you can get better performance if you use a value of DB2. With the STD option, the server will not block the cursor, while with the DB2 option it may block the cursor where it is possible to do so. For more information, see “LOB data and its effect on block fetch for DRDA” on page 1011.

**Block fetching result sets**

*Block fetch* can significantly decrease the number of messages sent across the network. Block fetch is used only with cursors that will not update or delete data. With block fetch, DB2 groups the rows that are retrieved by an SQL query into as large a “block” of rows as will fit in a message buffer. DB2 then transmits the block over the network, without requiring a separate message for each row.

DB2 can use two different types of block fetch:

- Limited block fetch
- Continuous block fetch

Both types of block fetch are used for DRDA and private protocol, but the implementation of continuous block fetch for DRDA is slightly different than that for private protocol.

**Continuous block fetch:** In terms of response times, continuous block fetch is most efficient for larger result sets because fewer messages are transmitted and because overlapped processing is performed at the requester and the server. However, continuous block fetch uses more networking resources than limited block fetch. When networking resources are critical, use limited block fetch to run applications.

The requester can use both forms of blocking at the same time and with different servers.

If an application is doing read-only processing and can use continuous block fetch, the sequence goes like this:

1. The requester sends a message to open a cursor and begins fetching the block of rows at the server.
2. The server sends back a block of rows and the requester begins processing the first row.
3. The server continues to send blocks of rows to the requester, without further prompting. The requester processes the second and later rows as usual, but fetches them from a buffer on the requester's system.

For private protocol, continuous block fetch uses one conversation for each open cursor. Having a dedicated conversation for each cursor allows the server to continue sending until all the rows are returned.

For DRDA, only one conversation is used, and it must be made available to the other SQL statements that are in the application. Thus, the server usually sends back a subset of all the rows. The number of rows that the server sends depends on the following factors:

- The size of each row
- The number of extra blocks that are requested by the requesting system compared to the number of extra blocks that the server will return

For a DB2 UDB for z/OS requester, the EXTRA BLOCKS REQ field on installation panel DSNTIP5 determines the maximum number of extra blocks requested. For a DB2 UDB for z/OS server, the EXTRA BLOCKS SRV field on installation panel DSNTIP5 determines the maximum number of extra blocks allowed.

**Example:** Suppose that the requester asks for 100 extra query blocks and that the server allows only 50. The server returns no more than 50 extra query blocks. The server might choose to return fewer than 50 extra query blocks for any number of reasons that DRDA allows.

- Whether continuous block fetch is enabled, and the number of extra rows that the server can return if it regulates that number.

To enable continuous block fetch for DRDA and to regulate the number of extra rows sent by a DB2 UDB for z/OS server, you must use the OPTIMIZE FOR n ROWS clause on your SELECT statement. See "Optimizing for very large results sets for DRDA" on page 1014 for more information.

If you want to use continuous block fetch for DRDA, have the application fetch all the rows of the cursor before doing any other SQL. Fetching all the rows first

prevents the requester from having to buffer the data, which can consume a lot of storage. Choose carefully which applications should use continuous block fetch for DRDA.

**Limited block fetch:** Limited block fetch guarantees the transfer of a minimum amount of data in response to each request from the requesting system. With limited block fetch, a single conversation is used to transfer messages and data between the requester and server for multiple cursors. Processing at the requester and server is synchronous. The requester sends a request to the server, which causes the server to send a response back to the requester. The server must then wait for another request to tell it what should be done next.

**Block fetch with scrollable cursors for DRDA:** When a DB2 UDB for z/OS requester uses a scrollable cursor to retrieve data from a DB2 UDB for z/OS server, the following conditions are true:

- The requester never requests more than 64 rows in a query block, even if more rows fit in the query block. In addition, the requester never requests extra query blocks. This is true even if the setting of field EXTRA BLOCKS REQ in the DISTRIBUTED DATA FACILITY PANEL 2 installation panel on the requester allows extra query blocks to be requested.
- The requester discards rows of the result table if the application does not use those rows.

**Example:** If the application fetches row  $n$  and then fetches row  $n+2$ , the requester discards row  $n+1$ .

The application gets better performance for a blocked scrollable cursor if it mostly scrolls forward, fetches most of the rows in a query block, and avoids frequent switching between FETCH ABSOLUTE statements with negative and positive values.

- If the scrollable cursor does not use block fetch, the server returns one row for each FETCH statement.

**LOB data and its effect on block fetch for DRDA:** For a non-scrollable blocked cursor, the server sends all the non-LOB data columns for a block of rows in one message, including LOB locator values. As each row is fetched by the application, the requester obtains the non-LOB data columns directly from the query block. If the row contains non-null and non-zero length LOB values, those values are retrieved from the server at that time. This behavior limits the impact to the network by pacing the amount of data that is returned at any one time. If all LOB data columns are retrieved into LOB locator host variables or if the row does not contain any non-null or non-zero length LOB columns, then the whole row can be retrieved directly from the query block.

For a scrollable blocked cursor, the LOB data columns are returned at the same time as the non-LOB data columns. When the application fetches a row that is in the block, a separate message is not required to get the LOB columns.

#### Ensuring block fetch:

#### General-use Programming Interface

To use either limited or continuous block fetch, DB2 must determine that the cursor is not used for updating or deleting. The easiest way to indicate that the cursor does not modify data is to add the FOR FETCH ONLY or FOR READ ONLY clause to the query in the DECLARE CURSOR statement as in the following example:

```

EXEC SQL
  DECLARE THISEMP CURSOR FOR
    SELECT EMPNO, LASTNAME, WORKDEPT, JOB
    FROM DSN8810.EMP
    WHERE WORKDEPT = 'D11'
    FOR FETCH ONLY
END-EXEC.

```

If you do not use FOR FETCH ONLY or FOR READ ONLY, DB2 still uses block fetch for the query if the following conditions are true:

- The cursor is a non-scrollable cursor, and the result table of the cursor is read-only. This applies to static and dynamic cursors except for read-only views. (See Chapter 5 of *DB2 SQL Reference* for information about declaring a cursor as read-only.)
- The cursor is a scrollable cursor that is declared as INSENSITIVE, and the result table of the cursor is read-only.
- The cursor is a scrollable cursor that is declared as SENSITIVE, the result table of the cursor is read-only, and the value of bind option CURRENTDATA is NO.
- The result table of the cursor is not read-only, but the cursor is ambiguous, and the value of bind option CURRENTDATA is NO. A cursor is ambiguous when:
  - It is not defined with the clauses FOR FETCH ONLY, FOR READ ONLY, or FOR UPDATE OF.
  - It is not defined on a read-only result table.
  - It is not the target of a WHERE CURRENT clause on an SQL UPDATE or DELETE statement.
  - It is in a plan or package that contains the SQL statements PREPARE or EXECUTE IMMEDIATE.

DB2 triggers block fetch for static SQL only when it can detect that no updates or deletes are in the application. For dynamic statements, because DB2 cannot detect what follows in the program, the decision to use block fetch is based on the declaration of the cursor.

DB2 does not use continuous block fetch if the following conditions are true:

- The cursor is referred to in the statement DELETE WHERE CURRENT OF elsewhere in the program.
- The cursor statement appears that it can be updated at the requesting system. (DB2 does not check whether the cursor references a view at the server that cannot be updated.)

The following three tables summarize the conditions under which a DB2 server uses block fetch.

Table 198 shows the conditions for a non-scrollable cursor.

*Table 198. Effect of CURRENTDATA and cursor type on block fetch for a non-scrollable cursor*

| Isolation level | CURRENTDATA | Cursor type | Block fetch |
|-----------------|-------------|-------------|-------------|
| CS, RR, or RS   | Yes         | Read-only   | Yes         |
|                 |             | Updatable   | No          |
|                 |             | Ambiguous   | No          |
|                 | No          | Read-only   | Yes         |
|                 |             | Updatable   | No          |
|                 |             | Ambiguous   | Yes         |
| UR              | Yes         | Read-only   | Yes         |
|                 | No          | Read-only   | Yes         |

Table 199 shows the conditions for a scrollable cursor that is not used to retrieve a stored procedure result set.

*Table 199. Effect of CURRENTDATA and isolation level on block fetch for a scrollable cursor that is not used for a stored procedure result set*

| Isolation level | Cursor sensitivity | CURRENTDATA | Cursor type | Block fetch |
|-----------------|--------------------|-------------|-------------|-------------|
| CS, RR, or RS   | INSENSITIVE        | Yes         | Read-only   | Yes         |
|                 |                    | No          | Read-only   | Yes         |
|                 | SENSITIVE          | Yes         | Read-only   | No          |
|                 |                    |             | Updatable   | No          |
|                 |                    | No          | Read-only   | Yes         |
|                 |                    |             | Updatable   | No          |
| UR              | INSENSITIVE        | Yes         | Read-only   | Yes         |
|                 |                    | No          | Read-only   | Yes         |
|                 | SENSITIVE          | Yes         | Read-only   | Yes         |
|                 |                    | No          | Read-only   | Yes         |

Table 200 shows the conditions for a scrollable cursor that is used to retrieve a stored procedure result set.

*Table 200. Effect of CURRENTDATA and isolation level on block fetch for a scrollable cursor that is used for a stored procedure result set*

| Isolation level | Cursor sensitivity | CURRENTDATA | Cursor type | Block fetch |
|-----------------|--------------------|-------------|-------------|-------------|
| CS, RR, or RS   | INSENSITIVE        | Yes         | Read-only   | Yes         |
|                 |                    | No          | Read-only   | Yes         |
|                 | SENSITIVE          | Yes         | Read-only   | No          |
|                 |                    | No          | Read-only   | Yes         |

Table 200. Effect of CURRENTDATA and isolation level on block fetch for a scrollable cursor that is used for a stored procedure result set (continued)

| Isolation level | Cursor sensitivity | CURRENTDATA | Cursor type | Block fetch |
|-----------------|--------------------|-------------|-------------|-------------|
| UR              | INSENSITIVE        | Yes         | Read-only   | Yes         |
|                 |                    | No          | Read-only   | Yes         |
|                 | SENSITIVE          | Yes         | Read-only   | Yes         |

End of General-use Programming Interface

## Optimizing for very large results sets for DRDA

Enabling a DB2 client to request multiple query blocks on each transmission can reduce network activity and improve performance significantly for applications that use DRDA access to download large amounts of data. You can specify a large value of *n* in the OPTIMIZE FOR *n* ROWS clause of a SELECT statement to increase the number of DRDA query blocks that a DB2 server returns in each network transmission for a non-scrollable cursor. If *n* is greater than the number of rows that fit in a DRDA query block, OPTIMIZE FOR *n* ROWS lets the DRDA client request multiple blocks of query data on each network transmission instead of requesting a new block when the first block is full. This use of OPTIMIZE FOR *n* ROWS is intended only for applications in which the application opens a cursor and downloads great amounts of data. The OPTIMIZE FOR *n* ROWS clause has no effect on scrollable cursors.

**Recommendation:** Because the application SQL uses only one conversation, do not try to do other SQL work until the entire answer set is processed. If the application issues another SQL statement before the previous statement's answer set has been received, DDF must buffer them in its address space. You can buffer up to 10 MB in this way.

Because specifying a large number of network blocks can saturate the network, limit the number of blocks according to what your network can handle. You can limit the number of blocks used for these large download operations. When the client supports extra query blocks, DB2 chooses the **smallest** of the following values when determining the number of query blocks to send:

- The number of blocks into which the number of rows (*n*) on the OPTIMIZE clause will fit. For example, assume you specify 10000 rows for *n*, and the size of each row that is returned is approximately 100 bytes. If the block size used is 32 KB (32768 bytes), the calculation is as follows:  

$$(10000 * 100) / 32768 = 31 \text{ blocks}$$
- The DB2 server value for the EXTRA BLOCKS SRV field on installation panel DSNTIP5. The maximum value that you can specify is 100.
- The client's extra query block limit, which is obtained from the DRDA MAXBLKEXT parameter received from the client. When DB2 UDB for z/OS acts as a DRDA client, you set this parameter at installation time with the EXTRA BLOCKS REQ field on installation panel DSNTIP5. The maximum value that you can specify is 100. DB2 Connect sets the MAXBLKEXT parameter to -1 (unlimited).

If the client does not support extra query blocks, the DB2 server on z/OS automatically reduces the value of *n* to match the number of rows that fit within a DRDA query block.

**Recommendation for cursors that are defined WITH HOLD:** Do not set a large number of query blocks for cursors that are defined WITH HOLD. If the application commits while there are still a lot of blocks in the network, DB2 buffers the blocks in the requester's memory (the *ssnmDIST* address space if the requester is a DB2 UDB for z/OS) before the commit can be sent to the server.

For examples of performance problems that can occur from not using OPTIMIZE FOR *n* ROWS when downloading large amounts of data, see Part 4 of *DB2 Application Programming and SQL Guide*.

### Optimizing for small results sets for DRDA

When a client does not need all the rows from a potentially large result set, preventing the DB2 server from returning all the rows for a query can reduce network activity and improve performance significantly for DRDA applications. You can use either the OPTIMIZE FOR *n* ROWS clause or the FETCH FIRST *n* ROWS ONLY clause of a SELECT statement to limit the number of rows returned to a client program.

**Using OPTIMIZE FOR *n* ROWS:** When you specify OPTIMIZE FOR *n* ROWS and *n* is less than the number of rows that fit in the DRDA query block (default size on z/OS is 32 KB), the DB2 server prefetches and returns only as many rows as fit into the query block. For example, if the client application is interested in seeing only one screen of data, specify OPTIMIZE FOR *n* ROWS, choosing a small number for *n*, such as 3 or 4. The OPTIMIZE FOR *n* ROWS clause has no effect on scrollable cursors.

| **Using FETCH FIRST *n* ROWS ONLY:** The FETCH FIRST *n* ROWS ONLY clause  
| does not affect network blocking. If FETCH FIRST *n* ROWS ONLY is specified and  
| OPTIMIZE FOR *n* ROWS is not specified, DB2 uses the FETCH FIRST value to  
| optimize the access path. However, DRDA does not consider this value when it  
| determines network blocking.

| When both the FETCH FIRST *n* ROWS ONLY clause and the OPTIMIZE FOR *n*  
| ROWS clause are specified, the value for the OPTIMIZE FOR *n* ROWS clause is  
| used for access path selection.

| **Example:** Suppose that you submit the following SELECT statement:

```
| SELECT * FROM EMP  
| FETCH FIRST 5 ROWS ONLY  
| OPTIMIZE FOR 20 ROWS;
```

| The OPTIMIZE FOR value of 20 rows is used for network blocking and access path  
| selection.

When you use FETCH FIRST *n* ROWS ONLY, DB2 might use a *fast implicit close*. Fast implicit close means that during a distributed query, the DB2 server automatically closes the cursor when it prefetches the *n*th row if FETCH FIRST *n* ROWS ONLY is specified or when there are no more rows to return. Fast implicit close can improve performance because it can save an additional network transmission between the client and the server.

DB2 uses fast implicit close when the following conditions are true:

- The query uses limited block fetch.
- The query retrieves no LOBs.
- The cursor is not a scrollable cursor.
- Either of the following conditions is true:

- The cursor is declared WITH HOLD, and the package or plan that contains the cursor is bound with the KEEP DYNAMIC(YES) option.
- The cursor is declared WITH HOLD and the DRDA client passes the QRYCLSIMP parameter set to SERVER MUST CLOSE, SERVER DECIDES, or SERVER MUST NOT CLOSE.
- The cursor is not defined WITH HOLD.

When you use FETCH FIRST *n* ROWS ONLY and DB2 does a fast implicit close, the DB2 server closes the cursor after it prefetches *n* rows, or when there are no more rows.

### Data encryption security options

Data encryption security options provide added security for the security-sensitive data that an application requests from the system. However, the encryption options can also have a negative impact on performance. The following encryption options have a larger performance cost than other options:

- Encrypted user ID and encrypted security-sensitive data
- Encrypted user ID, encrypted password, and encrypted security-sensitive data

**Recommendation:** To maximize performance of requester systems, use the minimum level of security that is required by the sensitivity of the data.

## Serving system

For access using DB2 private protocol, the serving system is the DB2 system on which the SQL is dynamically executed. For access using DRDA, the serving system is the system on which your remotely bound package executes.

If you are executing a package on a remote DBMS, then improving performance on the server depends on the nature of the server. If the remote DBMS on which the package executes is another DB2, then the information in Chapter 34, "Using EXPLAIN to improve SQL performance," on page 931 is appropriate for access path considerations.

Other considerations that could affect performance on a DB2 server are:

- The maximum number of database access threads that the server allows to be allocated concurrently. (This is the MAX REMOTE ACTIVE field on installation panel DSNTIPE.) A request can be queued while waiting for an available thread. Making sure that requesters commit frequently can let threads be used by other requesters. See "Setting thread limits for database access threads" on page 741 for more information.
- The priority of database access threads on the remote system. A low priority could impede your application's distributed performance. See "Using z/OS workload management to set performance objectives" on page 745 for more information.
- For instructions on avoiding RACF calls at the server, see "Controlling requests from remote applications" on page 238, and more particularly "Do you manage inbound IDs through DB2 or RACF?" on page 243.

When DB2 is the server, it is a good idea to activate accounting trace class 7. This provides accounting information at the package level, which can be very useful in determining performance problems.

---

## Monitoring DB2 in a distributed environment

DB2 provides several ways to monitor DB2 data and events in a distributed environment. You can use the DISPLAY command and the trace facility to obtain information. DB2 can also return server-elapsed time to certain types of client applications.

### The DISPLAY command

The DB2 DISPLAY command gives you information about the status of threads, databases, tracing, allied subsystems, and applications. Several forms of the DISPLAY command are particularly helpful for monitoring DB2: DISPLAY THREAD, DISPLAY LOCATION, DISPLAY DDF DETAIL, DISPLAY DATABASE, and DISPLAY TRACE. For the detailed syntax of each command, refer to Chapter 2 of *DB2 Command Reference*. See also:

- “Monitoring threads” on page 383
- “The command DISPLAY LOCATION” on page 407
- “The command DISPLAY DDF” on page 406

### Tracing distributed events

A number of IFCIDs, including IFCID 0001 (statistics) and IFCID 0003 (accounting), record distributed data and events.

If your applications update data at other sites, turn on the statistics class 4 trace and always keep it active. This statistics trace covers error situations surrounding in doubt threads; it provides a history of events that might impact data availability and data consistency.

DB2 accounting records are created separately at the requester and each server. Events are recorded in the accounting record at the location where they occur. When a thread becomes active, the accounting fields are reset. Later, when the thread becomes inactive or is terminated, the accounting record is created.

Figure 120 on page 1018 shows the relationship of the accounting class 1 and 2 times and the requester and server accounting records. Figure 121 on page 1019 and Figure 122 on page 1020 show the server and requester distributed data facility blocks from the OMEGAMON accounting long trace.

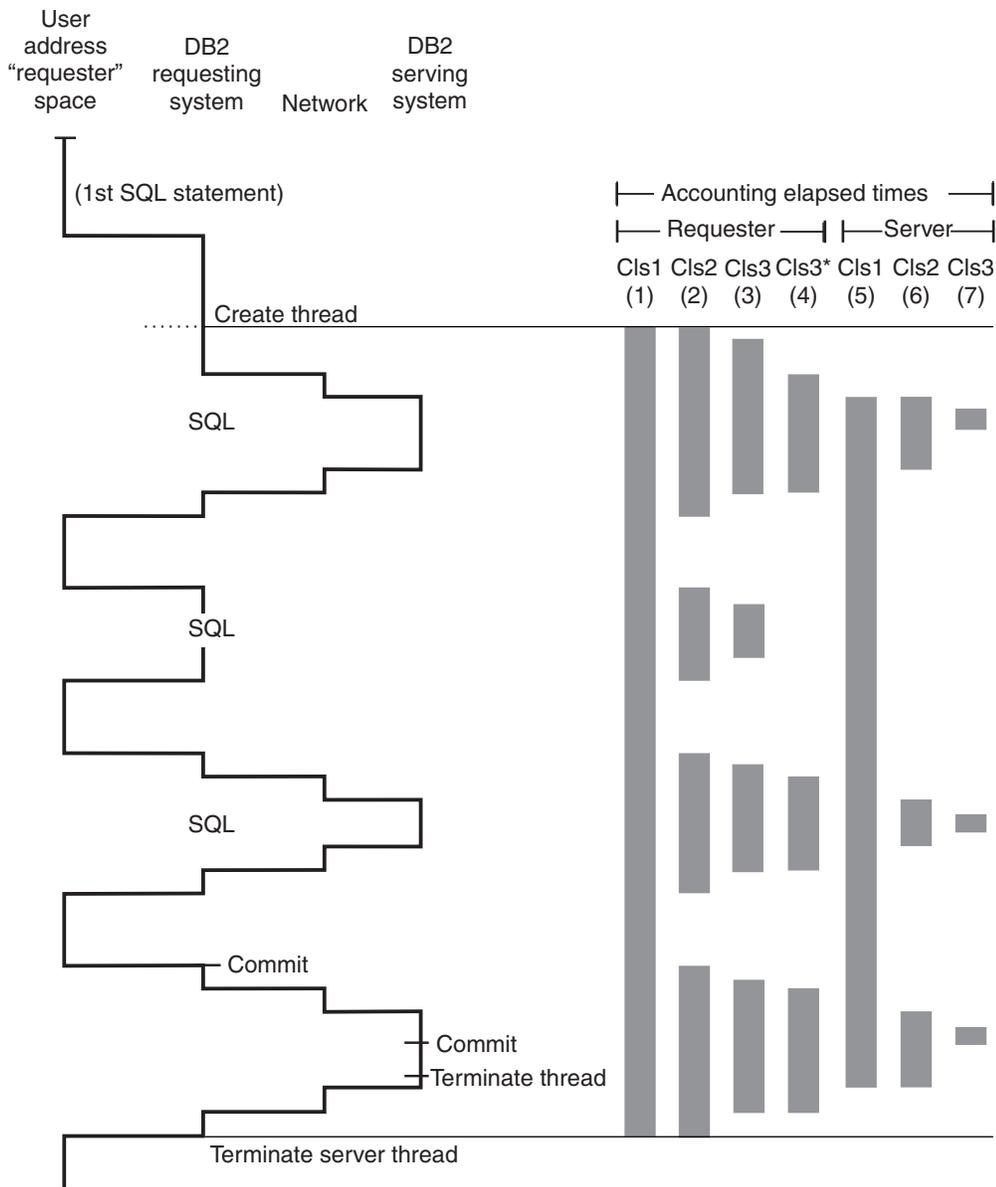

Figure 120. Elapsed times in a DDF environment as reported by OMEGAMON. These times are valid for access that uses either DRDA or private protocol (except as noted).

This figure is a simplified picture of the processes that go on in the serving system. It does not show block fetch statements and is only applicable to a single row retrieval.

The various elapsed times referred to in the header are:

- (1) - Requester Cls1  
This time is reported in the ELAPSED TIME field under the APPL (CLASS 1) column near the top of the OMEGAMON accounting long trace for the requesting DB2 subsystem. It represents the elapsed time from the creation of the allied distributed thread until the termination of the allied distributed thread.
- (2) - Requester Cls2  
This time is reported in the ELAPSED TIME field under the DB2 (CLASS 2) column near the top of the OMEGAMON accounting long trace for the

requesting DB2 subsystem. It represents the elapsed time from when the application passed the SQL statements to the local DB2 system until return. This is considered "In DB2" time.

- (3) - Requester Cls3

This time is reported in the TOTAL CLASS 3 field under the CLASS 3 SUSP column near the top of the OMEGAMON accounting long trace for the requesting DB2 system. It represents the amount of time the requesting DB2 system spent suspended waiting for locks or I/O.

- (4) - Requester Cls3\* (Requester wait time for activities not in DB2)

This time is reported in the SERVICE TASK SWITCH, OTHER SERVICE field of the OMEGAMON accounting report for the requesting DB2 subsystem. It is typically time spent waiting for the network and server to process the request.

- (5) - Server Cls1

This time is reported in the ELAPSED TIME field under the APPL (CLASS 1) column near the top of the OMEGAMON accounting long trace for the serving DB2 subsystem. It represents the elapsed time from the creation of the database access thread until the termination of the database access thread.

- (6) - Server Cls2

This time is reported in the ELAPSED TIME field under the DB2 (CLASS 2) column near the top of the OMEGAMON accounting long trace of the serving DB2 subsystem. It represents the elapsed time to process the SQL statements and the commit at the server.

- (7) - Server Cls3

This time is reported in the TOTAL CLASS 3 field under the CLASS 3 SUSP column near the top of the OMEGAMON accounting long trace for the serving DB2 subsystem. It represents the amount of time the serving DB2 system spent suspended waiting for locks or I/O.

The Class 2 processing time (the TCB time) at the requester does not include processing time at the server. To determine the total Class 2 processing time, add the Class 2 time at the requester to the Class 2 time at the server.

Likewise, add the getpage counts, prefetch counts, locking counts, and I/O counts of the requester to the equivalent counts at the server. For private protocol, SQL activity is counted at both the requester and server. For DRDA, SQL activity is counted only at the server.

Figure 122. DDF block of a server thread from a OMEGAMON accounting long trace

The accounting distributed fields for each serving or requesting location are collected from the viewpoint of this thread communicating with the other location identified. For example, SQL *sent* from the requester is SQL *received* at the server. Do not add together the distributed fields from the requester and the server.

Several fields in the distributed section merit specific attention. The number of conversations is reported in several fields:

- The number of conversation allocations is reported as CONVERSATIONS INITIATED ( **A** ).
- The number of conversation requests queued during allocation is reported as CONVERSATIONS QUEUED ( **B** ).
- The number of successful conversation allocations is reported as SUCCESSFULLY ALLOC.CONV ( **C** ).
- The number of times a switch was made from continuous block fetch to limited block fetch is reported as CONT->LIM.BL.FTCH ( **D** ). This is only applicable to access that uses DB2 private protocol.

You can use the difference between initiated allocations and successful allocations to identify a session resource constraint problem. If the number of conversations queued is high, or if the number of times a switch was made from continuous to limited block fetch is high, you might want to tune VTAM to increase the number of conversations. VTAM and network parameter definitions are important factors in the performance of DB2 distributed processing. For more information, see *VTAM for MVS/ESA Network Implementation Guide*.

Bytes sent, bytes received, messages sent, and messages received are recorded at both the requester and the server. They provide information on the volume of data transmitted. However, because of the way distributed SQL is processed for private protocol, more bytes may be reported as sent than are reported as received.

To determine the percentage of the rows transmitted by block fetch, compare the total number of rows sent to the number of rows sent in a block fetch buffer, which is reported as MSG.IN BUFFER ( **E** ). The number of rows sent is reported at the server, and the number of rows received is reported at the requester. Block fetch can significantly affect the number of rows sent across the network.

The number of SQL statements bound for remote access is the number of statements dynamically bound at the server for private protocol. This field is maintained at the requester and is reported as STMT BOUND AT SER ( **F** ).

Because of the manner in which distributed SQL is processed, the number of rows that are reported might differ slightly from the number of rows that are received. However, a significantly lower number of rows received may indicate that the application did not fetch the entire answer set. This is especially true for access that uses DB2 private protocol.

## Reporting server-elapsed time

Client applications that access DB2 data using DRDA access can request that DB2 return the server-elapsed time. server-elapsed time allows remote clients to determine the actual amount of time it takes for DB2 to parse a remote request, process any SQL statements required to satisfy the request, and generate the reply. Because server-elapsed time does not include any of the network time used to receive the request or send the reply, client applications can use the information to quickly isolate poor response times to the network or to the DB2 server without you having to perform traces on the server. Only application clients using DB2 Connect Version 7 or later can request the server-elapsed time. When the System Monitor statement switch has been turned on, DB2 returns server-elapsed time information as a new element through the regular Snapshot Monitoring APIs.

---

## Monitoring distributed processing with RMF

If you use RMF to monitor DDF work, understand how DDF is using the enclave SRBs described in “Using z/OS workload management to set performance objectives” on page 745. The information that is reported using RMF or an equivalent product in the SMF 72 records are the portions of the client’s request that are covered by individual enclaves. The way DDF uses enclaves relates directly to whether the DDF thread can become inactive.

## Duration of an enclave

“Using threads in INACTIVE MODE for DRDA-only connections” on page 742 describes the difference between threads that are always active and those that can be pooled. If the thread is always active, the duration of the thread is the duration of the enclave. If the thread can be pooled, the following conditions determine the duration of an enclave:

- If the associated package is bound with `KEEPDYNAMIC(NO)`, or there are no open held cursors, or there are active declared temporary tables, the duration of the enclave is the period during which the thread is active.
- If the associated package is bound with `KEEPDYNAMIC(YES)`, and no held cursors or active declared temporary tables exist, and only `KEEPDYNAMIC(YES)` keeps the thread from being pooled, the duration of the enclave is the period from the beginning to the end of the transaction.

While a thread is pooled, such as during think time, it is not using an enclave. Therefore, SMF 72 record does not report inactive periods.

ACTIVE MODE threads are treated as a single enclave from the time it is created until the time it is terminated. This means that the entire life of the database access thread is reported in the SMF 72 record, regardless of whether SQL work is actually being processed. Figure 123 on page 1022 contrasts the two types of threads.

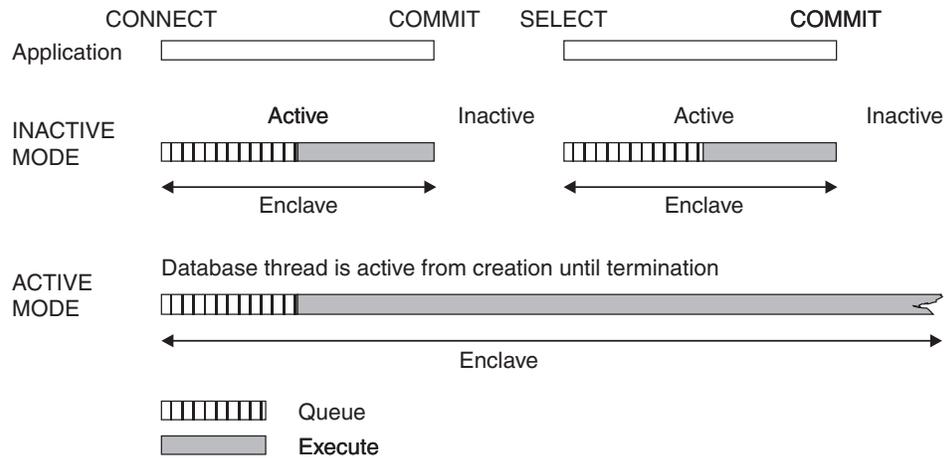

Figure 123. Contrasting ACTIVE MODE threads and POOLED MODE threads

**Queue time:** Note that the information that is reported back to RMF includes queue time. This particular queue time includes waiting for a new or existing thread to become available.

## RMF records for enclaves

The two most frequently used SMF records are types 30 and 72. The type 30 record contains resource consumption at the address space level. You can pull out total enclave usage from the record, but you must use DB2 accounting traces to see resource consumption for a particular enclave.

| Each enclave contributes its data to one type 72 record for the service class and to  
 | zero or one (0 or 1) type 72 records for the report class. You can use WLM  
 | classification rules to separate different enclaves into different service or report  
 | classes. Separating the enclaves in this way enables you to understand the DDF  
 | work better.

---

## Chapter 37. Monitoring and tuning stored procedures and user-defined functions

Stored procedures that are created in Version 8 of DB2 and all user-defined functions must run in WLM-established address spaces. This chapter primarily presents performance tuning information for user-defined functions and stored procedures in WLM-established address spaces, which is the same for both.

This chapter contains these topics:

- “Controlling address space storage”
- “Assigning procedures and functions to WLM application environments” on page 1024
- “Providing DB2 cost information for accessing user-defined table functions” on page 1025
- “Monitoring stored procedures with the accounting trace” on page 1026
- “Accounting for nested activities” on page 1028

Stored procedures that were created in a release of DB2 prior to Version 8 can run in a DB2-established stored procedures address space. For information about a DB2-established address space and how it compares to WLM-established address spaces, see “Comparing the types of stored procedure address spaces” on page 1029.

---

### Controlling address space storage

To maximize the number of procedures or functions that can run concurrently in a WLM-established stored procedures address space, use the following guidelines:

- Set REGION size for the address spaces to REGION=0 to obtain the largest possible amount of storage below the 16-MB line.
- Limit storage required by application programs below the 16-MB line by:
  - Linking editing programs above the line with AMODE(31) and RMODE(ANY) attributes
  - Using the RES and DATA(31) compiler options for COBOL programs
- Limit storage required by Language Environment by using these run-time options:
  - HEAP(,,ANY) to allocate program heap storage above the 16-MB line
  - STACK(,,ANY) to allocate program stack storage above the 16-MB line
  - STORAGE(,,4K) to reduce reserve storage area below the line to 4 KB
  - BELOWHEAP(4K,,) to reduce the heap storage below the line to 4 KB
  - LIBSTACK(4K,,) to reduce the library stack below the line to 4 KB
  - ALL31(ON) to indicate all programs contained in the stored procedure run with AMODE(31) and RMODE(ANY)

Each task control block that runs in a WLM-established stored procedures address space uses approximately 200 KB below the 16-MB line. DB2 needs this storage for stored procedures and user-defined functions because you can create both main programs and subprograms, and DB2 must create an environment for each.

A stored procedure can invoke only one utility in one address space at any given time because of the resource requirements of utilities. On the WLM Application-Environment panel, set NUMTCB to 1. See Figure 124 on page 1025. With NUMTCB=1 or NUMTCB being forced to 1, multiple WLM address spaces are created to run each concurrent utility request that comes from a stored procedure call.

**Dynamically extending load libraries:** Use partitioned data set extended (PDSEs) for load libraries containing stored procedures. Using PDSEs may eliminate your need to stop and start the stored procedures address space due to growth of the load libraries. If a load library grows from additions or replacements, the library may have to be extended.

If you use PDSEs for the load libraries, the new extent information is dynamically updated and you do not need to stop and start the address space. If PDSs are used, load failures may occur because the new extent information is not available.

---

## Assigning procedures and functions to WLM application environments

Workload manager routes work to address spaces based on the application environment name and service class associated with the stored procedure or function. You must use WLM panels to associate an application environment name with the JCL procedure used to start an address space. See *z/OS MVS Planning: Workload Management* for details about workload management panels.

Other tasks must be completed before a stored procedure or user-defined function can run in a WLM-established stored procedures address space. Here is a summary of those tasks:

1. Make sure you have a numeric value specified in the TIMEOUT VALUE field of installation panel DSNTIPX. If you have problems with setting up the environment, this timeout value ensures that your request to execute a stored procedure will not wait for an unlimited amount of time.
2. When you want to move stored procedures from a DB2-established environment to a WLM-established environment, you must link edit them or code them so that they use the Resource Recovery Services attachment facility (RRSAF) instead of the call attachment facility. Use the JCL startup procedure for WLM-established stored procedures address space that was created when you installed or migrated as a model. (The default name is *ssnmWLM*.)

Unless a particular application environment or caller's service class is not used for a long time, WLM creates on demand at least one address space for each combination of application environment name and caller's service class that is encountered in the workload. For example, if there are five application environment names that each have calling threads with six possible service classes, and all those combinations are in demand, it is possible to have 30 address spaces containing stored procedures or user-defined functions.

To prevent creating too many address spaces, create a relatively small number of WLM application environments and z/OS service classes.

3. Use the WLM application environment panels to associate the environment name with the JCL procedure. Figure 124 on page 1025 is an example of this panel.

```

Application-Environment  Notes  Options  Help
-----
                          Create an Application Environment
Command ==>> _____

Application Environment Name . . : WLMENV2
Description . . . . . Large Stored Proc Env.
Subsystem Type . . . . . DB2
Procedure Name . . . . . DSN1WLM
Start Parameters . . . . . DB2SSN=DB2A,NUMTCB=2,APPLENV=WLMENV2
                          _____

Select one of the following options.
1  1. Multiple server address spaces are allowed.
   2. Only 1 server address space per MVS system is allowed.

```

Figure 124. WLM panel to create an application environment. You can also use the variable &IWMSSNM for the DB2SSN parameter (DB2SSN=&IWMSSNM). This variable represents the name of the subsystem for which you are starting this address space. This variable is useful for using the same JCL procedure for multiple DB2 subsystems.

4. Specify the WLM application environment name for the WLM\_ENVIRONMENT option on CREATE or ALTER PROCEDURE (or FUNCTION) to associate a stored procedure or user-defined function with an application environment.
5. Using the install utility in the WLM application, install the WLM service definition that contains information about this application environment into the couple data set.
6. Activate a WLM policy from the installed service definition.
7. Begin running stored procedures.

## Providing DB2 cost information for accessing user-defined table functions

User-defined table functions add additional access cost to the execution of an SQL statement. For DB2 to factor in the effect of user-defined table functions in the selection of the best access path for an SQL statement, the total cost of the user-defined table function must be determined.

The total cost of a table function consists of the following three components:

- The initialization cost that results from the first call processing
- The cost that is associated with acquiring a single row
- The final call cost that performs the clean up processing

These costs, though, are not known to DB2 when I/O costs are added to the CPU cost.

To assist DB2 in determining the cost of user-defined table functions, you can use four fields in SYSIBM.SYSROUTINES. Use the following fields to provide cost information:

- IOS\_PER\_INVOC for the estimated number of I/Os per row
- INSTS\_PER\_INVOC for the estimated number of instructions
- INITIAL\_IOS for the estimated number of I/Os performed the first and last time the function is invoked
- INITIAL\_INSTS for the estimated number of instructions for the first and last time the function is invoked

These values, along with the CARDINALITY value of the table being accessed, are used by DB2 to determine the cost. The results of the calculations can influence such things as the join sequence for a multi-table join and the cost estimates generated for and used in predictive governing.

Determine values for the four fields by examining the source code for the table function. Estimate the I/Os by examining the code executed during the FIRST call and FINAL call. Look for the code executed during the OPEN, FETCH, and CLOSE calls. The costs for the OPEN and CLOSE calls can be amortized over the expected number of rows returned. Estimate the I/O cost by providing the number of I/Os that will be issued. Include the I/Os for any file access.

Calculate the instruction cost by counting the number of high level instructions executed in the user-defined table function and multiplying it by a factor of 20. For assembler programs, the instruction cost is the number of assembler instructions.

If SQL statements are issued within the user-defined table function, use DB2 Estimator to determine the number of instructions and I/Os for the statements. Examining the JES job statistics for a batch program doing equivalent functions can also be helpful. For all fields, a precise number of instructions is not required. Because DB2 already accounts for the costs of invoking table functions, these costs should not be included in the estimates.

**Example:** The following statement shows how these fields can be updated. The authority to update is the same authority as that required to update any catalog statistics column.

```
UPDATE SYSIBM.SYSROUTINES SET
  IOS_PER_INVOC = 0.0,
  INSTS_PER_INVOC = 4.5E3,
  INITIAL_IOS = 2.0
  INITIAL_INSTS = 1.0E4,
  CARDINALITY = 5E3
WHERE
  SCHEMA = 'SYSADM' AND
  SPECIFICNAME = 'FUNCTION1' AND
  ROUTINETYPE = 'F';
```

---

## Monitoring stored procedures with the accounting trace

Through a stored procedure, one SQL statement generates other SQL statements under the same thread. The processing that is performed by the stored procedure is included in class 1 and class 2 times for accounting.

The accounting report on the server has several fields that specifically relate to stored procedures processing, as shown in Figure 125 on page 1027.

| AVERAGE                  | APPL (CL.1) | DB2 (CL.2) | IFI (CL.5) | CLASS 3 SUSPENSIONS  | AVERAGE TIME | AV.EVENT | HIGHLIGHTS                |
|--------------------------|-------------|------------|------------|----------------------|--------------|----------|---------------------------|
| ELAPSED TIME             | 0.072929    | 0.029443   | N/P        | LOCK/LATCH(DB2+IRLM) | 0.000011     | 0.04     | #OCCURRENCES : 193        |
| NONNESTED                | 0.072929    | 0.029443   | N/A        | SYNCHRON. I/O        | 0.010170     | 9.16     | #ALLIEDS : 0              |

Figure 125. Partial long accounting report for stored procedures

#### Descriptions of fields:

- The part of the total CPU time that was spent satisfying stored procedures requests is indicated in **A**.
- The amount of time spent waiting for a stored procedure to be scheduled and the time that is needed to return control to DB2 after the stored procedure has completed is indicated in **B**.
- The number of calls to stored procedures is indicated in **C**.
- The number of times a stored procedure timed out waiting to be scheduled is shown in **D**.

**What to do for excessive timeouts or wait time:** If you have excessive wait time (**B**) or timeouts (**D**) for user-defined functions or stored procedures, the possible causes include:

- The goal of the service class that is assigned to the WLM stored procedure's address space, as it was initially started, is not high enough. The address space uses this goal to honor requests to start processing stored procedures.
- The priority of the service class that is running the stored procedure is not high enough.
- Make sure that the application environment is available by using the z/OS command `DISPLAY WLM,APPLENV=applenv`. If the application environment is quiesced, WLM does not start any address spaces for that environment; CALL statements are queued or rejected.

## Accounting for nested activities

The accounting class 1 and class 2 CPU and elapsed times for triggers, stored procedures, and user-defined functions are accumulated in separate fields and exclude any time accumulated in other nested activity. These CPU and elapsed times are accumulated for each category during the execution of each agent until agent deallocation. Package accounting can be used to break out accounting data for execution of individual stored procedures, user-defined functions, or triggers. Figure 126 shows an agent that executes multiple types of DB2 nested activities.

| Time | Application | DB2                         | Stored procedure                 | User-defined function            |
|------|-------------|-----------------------------|----------------------------------|----------------------------------|
| T0   | Code        |                             |                                  |                                  |
| T1   | SQL         | ----->                      |                                  |                                  |
| T2   |             | <-----                      |                                  |                                  |
| T3   | SQL         | ----->                      |                                  |                                  |
| T4   |             | Trigger                     |                                  |                                  |
| T5   |             | SQL                         |                                  |                                  |

| T19  |             | Trigger ends                |                                  |                                  |
| T20  | Code        | <-----Return to Application |                                  |                                  |
| T21  | End         |                             |                                  |                                  |

Figure 126. Time spent executing nested activities

Table 202 shows the formula used to determine time for nested activities.

Table 202. Sample for time used for execution of nested activities

|  | Count for                                  | Formula                   | Class |
|--|--------------------------------------------|---------------------------|-------|
|  | Application elapsed                        | T21-T0                    | 1     |
|  | Application task control block (TU)        | T21-T0                    | 1     |
|  | Application in DB2 elapsed                 | T2-T1 + T4-T3 + T20-T19   | 2     |
|  | Application in DB2 task control block (TU) | T2-T1 + T4-T3 + T20-T19   | 2     |
|  | Trigger in DB2 elapsed                     | T6-T4 + T19-T18           | 2     |
|  | Trigger in DB2 task control block (TU)     | T6-T4 + T19-T18           | 2     |
|  | Wait for STP time                          | T7-T6 + T18-T17           | 3     |
|  | Stored procedure elapsed                   | T11-T6 + T18-T16          | 1     |
|  | Stored procedure task control block (TU)   | T11-T6 + T18-T16          | 1     |
|  | Stored procedure SQL elapsed               | T9-T8 + T11-T10 + T17-T16 | 2     |
|  | Stored procedure SQL elapsed               | T9-T8 + T11-T10 + T17-T16 | 2     |

Table 202. Sample for time used for execution of nested activities (continued)

| Count for                                         | Formula | Class |
|---------------------------------------------------|---------|-------|
| Wait for user-defined function time               | T12-T11 | 3     |
| User-defined function elapsed                     | T16-T11 | 1     |
| User-defined function task control block (TU)     | T16-T11 | 1     |
| User-defined function SQL elapsed                 | T14-T13 | 2     |
| User-defined function SQL task control block (TU) | T14-T13 | 2     |

**Note:** TU = time used.

The total class 2 time is the total of the "in DB2" times for the application, trigger, stored procedure, and user-defined function. The class 1 "wait" times for the stored procedures and user-defined functions need to be added to the total class 3 times.

## Comparing the types of stored procedure address spaces

Table 203 summarizes the differences between stored procedures that run in WLM-established stored procedures address spaces and those that run in a DB2-established stored procedures address space. You cannot run any user-defined functions in a DB2-established stored procedures address space. Only those stored procedures that were created in a release of DB2 prior to Version 8 can be run in a DB2-established address space.

Table 203. Comparing WLM-established and DB2-established stored procedures

| DB2-established                                                                                                                                                                                                                                                                                                                                                                              | WLM-established                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | More information                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <p>Use a single address space for stored procedures:</p> <ul style="list-style-type: none"> <li>• A failure in one stored procedure can affect other stored procedures that are running in that address space.</li> <li>• Can be difficult to support more than 50 stored procedures running at the same time because of storage that language products need below the 16MB line.</li> </ul> | <p>Use many address spaces for stored procedures and user-defined functions:</p> <ul style="list-style-type: none"> <li>• Possible to isolate procedures and functions from one another so that failures do not affect others that are running in other address spaces.</li> <li>• Reduces demand for storage below the 16MB line and thereby removes the limitation on the number of procedures and functions that can run concurrently.</li> <li>• Only one utility can be invoked by a stored procedure in one address space at any given time. The start parameter NUMTCB on the WLM Application-Environment panel has to be set to 1.</li> </ul> | <p>"Controlling address space storage" on page 1023 and Figure 124 on page 1025</p> |
| <p>Incoming requests for stored procedures are handled in a first-in, first-out order.</p>                                                                                                                                                                                                                                                                                                   | <p>Requests are handled in priority order.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>"Using z/OS workload management to set performance objectives" on page 745</p>   |
| <p>Stored procedures run at the priority of the stored procedures address space.</p>                                                                                                                                                                                                                                                                                                         | <p>Stored procedures inherit the z/OS dispatching priority of the DB2 thread that issues the CALL statement. User-defined functions inherit the priority of the DB2 thread that invoked the procedure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            | <p>"Using z/OS workload management to set performance objectives" on page 745</p>   |

Table 203. Comparing WLM-established and DB2-established stored procedures (continued)

| DB2-established                                                                                                            | WLM-established                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | More information                                                                  |
|----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| No ability to customize the environment.                                                                                   | Each address space is associated with a WLM <i>application environment</i> that you specify. An application environment is an attribute that you associate on the CREATE statement for the function or procedure. The environment determines which JCL procedure is used to run a particular stored procedure.                                                                                                                                                                                                                  | “Assigning procedures and functions to WLM application environments” on page 1024 |
| # Must run as a MAIN program.<br>#<br>#<br>#<br>#                                                                          | Can run as a MAIN or SUB program. SUB programs can run significantly faster, but the subprogram must do more initialization and cleanup processing itself rather than relying on Language Environment to handle that.                                                                                                                                                                                                                                                                                                           | <i>DB2 Application Programming and SQL Guide</i>                                  |
| You can access non-relational data, but that data is not included in your SQL unit of work. It is a separate unit of work. | You can access non-relational data. If the non-relational data is managed by RRS, the updates to that data are part of your SQL unit of work.                                                                                                                                                                                                                                                                                                                                                                                   | <i>DB2 Application Programming and SQL Guide</i>                                  |
| Stored procedures access protected z/OS resources with the authority of the stored procedures address space.               | Procedures or functions can access protected z/OS resources with one of three authorities, as specified on the SECURITY option of the CREATE FUNCTION or CREATE PROCEDURE statement: <ul style="list-style-type: none"> <li>• The authority of the WLM-established address space (SECURITY=DB2)</li> <li>• The authority of the invoker of the stored procedure or user-defined function (SECURITY=USER)</li> <li>• The authority of the definer of the stored procedure or user-defined function (SECURITY=DEFINER)</li> </ul> | <i>DB2 Administration Guide</i>                                                   |

The tuning information for stored procedures in a DB2-established address space is very similar to the information for user-defined functions and stored procedures in a WLM-established address space:

- You can control address space storage as described in “Controlling address space storage” on page 1023. Each task control block that runs in the DB2-established stored procedures address space requires approximately 100 KB below the 16MB line.
- As described in “Monitoring stored procedures with the accounting trace” on page 1026 “Accounting for nested activities” on page 1028, the processing done by a stored procedure running in a DB2-established address spaces is included in DB2’s class 1 and class 2 accounting times.

Possible causes of excessive wait time include:

- Someone issued the DB2 command STOP PROCEDURE ACTION(Queue) that caused requests to queue up for a long time and time out.
- The stored procedures are hanging onto the *ssnmSPAS* task control blocks for too long. In this case, you need to find out why this is happening.

If you get many DB2 lock suspensions, you might have too many *ssnmSPAS* task control blocks, causing them to encounter too many lock conflicts with one another. You might need to make code changes to your application or change your database design to reduce the number of lock suspensions.

- If the stored procedures are starting and stopping quickly, you might not have enough *ssmm*SPAS task control blocks to handle the work load. In this case, increase the number on field NUMBER OF TCBS on installation panel DSNTIPX.

---

## Part 6. Appendixes

---

## Appendix A. DB2 sample tables

The information in this appendix is General-use Programming Interface and Associated Guidance Information as defined in “Notices” on page 1437.

Most of the examples in this book refer to the tables described in this appendix. As a group, the tables include information that describes employees, departments, projects, and activities, and make up a sample application that exemplifies most of the features of DB2. The sample storage group, databases, tablespaces, tables, and views are created when you run the installation sample jobs DSNTEJ1 and DSNTEJ7. DB2 sample objects that include LOBs are created in job DSNTEJ7. All other sample objects are created in job DSNTEJ1. The CREATE INDEX statements for the sample tables are not shown here; they, too, are created by the DSNTEJ1 and DSNTEJ7 sample jobs.

Authorization on all sample objects is given to PUBLIC in order to make the sample programs easier to run. The contents of any table can easily be reviewed by executing an SQL statement, for example SELECT \* FROM DSN8810.PROJ. For convenience in interpreting the examples, the department and employee tables are listed here in full.

The following topics provide additional information:

- “Activity table (DSN8810.ACT)”
- “Department table (DSN8810.DEPT)” on page 1036
- “Employee table (DSN8810.EMP)” on page 1038
- “Employee photo and resume table (DSN8810.EMP\_PHOTO\_RESUME)” on page 1041
- “Project table (DSN8810.PROJ)” on page 1042
- “Project activity table (DSN8810.PROJACT)” on page 1043
- “Employee to project activity table (DSN8810.EMPPROJACT)” on page 1044
- “Unicode sample table (DSN8810.DEMO\_UNICODE)” on page 1045
- “Relationships among the sample tables” on page 1046
- “Views on the sample tables” on page 1046
- “Storage of sample application tables” on page 1051

---

### Activity table (DSN8810.ACT)

The activity table describes the activities that can be performed during a project. The table resides in database DSN8D81A and is created with the following statement:

```
CREATE TABLE DSN8810.ACT
  (ACTNO    SMALLINT      NOT NULL,
   ACTKWD   CHAR(6)       NOT NULL,
   ACTDESC  VARCHAR(20)   NOT NULL,
   PRIMARY KEY (ACTNO)
)
IN DSN8D81A.DSN8S81P
CCSID EBCDIC;
```

**Content of the activity table:**

Table 204 shows the content of the columns.

*Table 204. Columns of the activity table*

| Column | Column Name | Description                             |
|--------|-------------|-----------------------------------------|
| 1      | ACTNO       | Activity ID (the primary key)           |
| 2      | ACTKWD      | Activity keyword (up to six characters) |
| 3      | ACTDESC     | Activity description                    |

The activity table has these indexes:

*Table 205. Indexes of the activity table*

| Name          | On Column | Type of Index      |
|---------------|-----------|--------------------|
| DSN8810.XACT1 | ACTNO     | Primary, ascending |
| DSN8810.XACT2 | ACTKWD    | Unique, ascending  |

#### **Relationship to other tables:**

The activity table is a parent table of the project activity table, through a foreign key on column ACTNO.

---

## **Department table (DSN8810.DEPT)**

The department table describes each department in the enterprise and identifies its manager and the department to which it reports.

The table, shown in Table 208 on page 1037, resides in table space DSN8D81A.DSN8S81D and is created with the following statement:

```
CREATE TABLE DSN8810.DEPT
  (DEPTNO   CHAR(3)           NOT NULL,
   DEPTNAME VARCHAR(36)       NOT NULL,
   MGRNO    CHAR(6)           ,
   ADMRDEPT CHAR(3)           NOT NULL,
   LOCATION CHAR(16)          ,
   PRIMARY KEY (DEPTNO)      )
IN DSN8D81A.DSN8S81D
CCSID EBCDIC;
```

Because the table is self-referencing, and also is part of a cycle of dependencies, its foreign keys must be added later with these statements:

```
ALTER TABLE DSN8810.DEPT
  FOREIGN KEY RDD (ADMRDEPT) REFERENCES DSN8810.DEPT
  ON DELETE CASCADE;
```

```
ALTER TABLE DSN8810.DEPT
  FOREIGN KEY RDE (MGRNO) REFERENCES DSN8810.EMP
  ON DELETE SET NULL;
```

#### **Content of the department table:**

Table 206 shows the content of the columns.

*Table 206. Columns of the department table*

| Column | Column Name | Description                    |
|--------|-------------|--------------------------------|
| 1      | DEPTNO      | Department ID, the primary key |

Table 206. Columns of the department table (continued)

| Column | Column Name | Description                                                                                                  |
|--------|-------------|--------------------------------------------------------------------------------------------------------------|
| 2      | DEPTNAME    | A name describing the general activities of the department                                                   |
| 3      | MGRNO       | Employee number (EMPNO) of the department manager                                                            |
| 4      | ADMRDEPT    | ID of the department to which this department reports; the department at the highest level reports to itself |
| 5      | LOCATION    | The remote location name                                                                                     |

Table 207 shows the indexes of the department table:

Table 207. Indexes of the department table

| Name           | On Column | Type of Index      |
|----------------|-----------|--------------------|
| DSN8810.XDEPT1 | DEPTNO    | Primary, ascending |
| DSN8810.XDEPT2 | MGRNO     | Ascending          |
| DSN8810.XDEPT3 | ADMRDEPT  | Ascending          |

Table 208 shows the content of the department table:

Table 208. DSN8810.DEPT: department table

| DEPTNO | DEPTNAME                        | MGRNO  | ADMRDEPT | LOCATION |

The LOCATION column contains nulls until sample job DSNTJ6 updates this column with the location name.

#### Relationship to other tables:

The table is self-referencing: the value of the administering department must be a department ID.

The table is a parent table of:

- The employee table, through a foreign key on column WORKDEPT
- The project table, through a foreign key on column DEPTNO.

It is a dependent of the employee table, through its foreign key on column MGRNO.

---

## Employee table (DSN8810.EMP)

The employee table identifies all employees by an employee number and lists basic personnel information.

The table shown in Table 211 on page 1039 and Table 212 on page 1040 resides in the partitioned table space DSN8D81A.DSN8S81E. Because it has a foreign key referencing DEPT, that table and the index on its primary key must be created first. Then EMP is created with the following statement:

```
CREATE TABLE DSN8810.EMP
  (EMPNO      CHAR(6)                NOT NULL,
   FIRSTNME   VARCHAR(12)           NOT NULL,
   MIDINIT    CHAR(1)               NOT NULL,
   LASTNAME   VARCHAR(15)           NOT NULL,
   WORKDEPT   CHAR(3)               ,
   PHONENO    CHAR(4)               CONSTRAINT NUMBER CHECK
     (PHONENO >= '0000' AND
      PHONENO <= '9999')           ,
   HIREDATE   DATE                  ,
   JOB        CHAR(8)               ,
   EDLEVEL    SMALLINT              ,
   SEX        CHAR(1)               ,
   BIRTHDATE  DATE                  ,
   SALARY     DECIMAL(9,2)          ,
   BONUS      DECIMAL(9,2)          ,
   COMM       DECIMAL(9,2)          ,
   PRIMARY KEY (EMPNO)              ,
   FOREIGN KEY REF (WORKDEPT) REFERENCES DSN8810.DEPT
     ON DELETE SET NULL            )
EDITPROC DSN8EAE1
IN DSN8D81A.DSN8S81E
CCSID EBCDIC;
```

### Content of the employee table:

Table 209 shows the content of the columns. The table has a check constraint, NUMBER, which checks that the phone number is in the numeric range 0000 to 9999.

*Table 209. Columns of the employee table*

| Column | Column Name | Description                                  |
|--------|-------------|----------------------------------------------|
| 1      | EMPNO       | Employee number (the primary key)            |
| 2      | FIRSTNME    | First name of employee                       |
| 3      | MIDINIT     | Middle initial of employee                   |
| 4      | LASTNAME    | Last name of employee                        |
| 5      | WORKDEPT    | ID of department in which the employee works |
| 6      | PHONENO     | Employee telephone number                    |
| 7      | HIREDATE    | Date of hire                                 |
| 8      | JOB         | Job held by the employee                     |
| 9      | EDLEVEL     | Number of years of formal education          |

Table 209. Columns of the employee table (continued)

| Column | Column Name | Description                  |
|--------|-------------|------------------------------|
| 10     | SEX         | Sex of the employee (M or F) |
| 11     | BIRTHDATE   | Date of birth                |
| 12     | SALARY      | Yearly salary in dollars     |
| 13     | BONUS       | Yearly bonus in dollars      |
| 14     | COMM        | Yearly commission in dollars |

Table 210 shows the indexes of the employee table:

Table 210. Indexes of the employee table

| Name          | On Column | Type of Index                   |
|---------------|-----------|---------------------------------|
| DSN8810.XEMP1 | EMPNO     | Primary, partitioned, ascending |
| DSN8810.XEMP2 | WORKDEPT  | Ascending                       |

Table 211 and Table 212 on page 1040 show the content of the employee table:

Table 211. Left half of DSN8810.EMP: employee table. Note that a blank in the MIDINIT column is an actual value of " " rather than null.

**Relationship to other tables:**

The table is a parent table of:

- The department table, through a foreign key on column MGRNO
- The project table, through a foreign key on column RESPEMP.

It is a dependent of the department table, through its foreign key on column WORKDEPT.

---

## Employee photo and resume table (DSN8810.EMP\_PHOTO\_RESUME)

The employee photo and resume table complements the employee table. Each row of the photo and resume table contains a photo of the employee, in two formats, and the employee's resume. The photo and resume table resides in table space DSN8D81A.DSN8S81E. The following statement creates the table:

```
CREATE TABLE DSN8810.EMP_PHOTO_RESUME
  (EMPNO      CHAR(06) NOT NULL,
   EMP_ROWID  ROWID NOT NULL GENERATED ALWAYS,
   PSEG_PHOTO BLOB(500K),
   BMP_PHOTO  BLOB(100K),
   RESUME     CLOB(5K))
  PRIMARY KEY (EMPNO)
  IN DSN8D81L.DSN8S81B
  CCSID EBCDIC;
```

DB2 requires an auxiliary table for each LOB column in a table. These statements define the auxiliary tables for the three LOB columns in DSN8810.EMP\_PHOTO\_RESUME:

```
CREATE AUX TABLE DSN8810.AUX_BMP_PHOTO
  IN DSN8D81L.DSN8S81M
  STORES DSN8810.EMP_PHOTO_RESUME
  COLUMN BMP_PHOTO;
```

```
CREATE AUX TABLE DSN8810.AUX_PSEG_PHOTO
  IN DSN8D81L.DSN8S81L
  STORES DSN8810.EMP_PHOTO_RESUME
  COLUMN PSEG_PHOTO;
```

```
CREATE AUX TABLE DSN8810.AUX_EMP_RESUME
  IN DSN8D81L.DSN8S81N
  STORES DSN8810.EMP_PHOTO_RESUME
  COLUMN RESUME;
```

**Content of the employee photo and resume table:**

Table 213 shows the content of the columns.

Table 213. Columns of the employee photo and resume table

| Column | Column Name | Description                   |
|--------|-------------|-------------------------------|
| 1      | EMPNO       | Employee ID (the primary key) |

Table 213. Columns of the employee photo and resume table (continued)

| Column | Column Name | Description                                                                                |
|--------|-------------|--------------------------------------------------------------------------------------------|
| 2      | EMP_ROWID   | Row ID to uniquely identify each row of the table. DB2 supplies the values of this column. |
| 3      | PSEG_PHOTO  | Employee photo, in PSEG format                                                             |
| 4      | BMP_PHOTO   | Employee photo, in BMP format                                                              |
| 5      | RESUME      | Employee resume                                                                            |

Table 214 shows the indexes for the employee photo and resume table:

Table 214. Indexes of the employee photo and resume table

| Name                      | On Column | Type of Index      |
|---------------------------|-----------|--------------------|
| DSN8810.XEMP_PHOTO_RESUME | EMPNO     | Primary, ascending |

Table 215 shows the indexes for the auxiliary tables for the employee photo and resume table:

Table 215. Indexes of the auxiliary tables for the employee photo and resume table

| Name                    | On Table               | Type of Index |
|-------------------------|------------------------|---------------|
| DSN8810.XAUX_BMP_PHOTO  | DSN8810.AUX_BMP_PHOTO  | Unique        |
| DSN8810.XAUX_PSEG_PHOTO | DSN8810.AUX_PSEG_PHOTO | Unique        |
| DSN8810.XAUX_EMP_RESUME | DSN8810.AUX_EMP_RESUME | Unique        |

#### Relationship to other tables:

The table is a parent table of the project table, through a foreign key on column RESPEMP.

## Project table (DSN8810.PROJ)

The project table describes each project that the business is currently undertaking. Data contained in each row include the project number, name, person responsible, and schedule dates.

The table resides in database DSN8D81A. Because it has foreign keys referencing DEPT and EMP, those tables and the indexes on their primary keys must be created first. Then PROJ is created with the following statement:

```
CREATE TABLE DSN8810.PROJ
    (PROJNO CHAR(6) PRIMARY KEY NOT NULL,
    PROJNAME VARCHAR(24) NOT NULL WITH DEFAULT
    'PROJECT NAME UNDEFINED',
    DEPTNO CHAR(3) NOT NULL REFERENCES
    DSN8810.DEPT ON DELETE RESTRICT,
    RESPEMP CHAR(6) NOT NULL REFERENCES
    DSN8810.EMP ON DELETE RESTRICT,
    PRSTAFF DECIMAL(5, 2) ,
    PRSTDATE DATE ,
    PRENDATE DATE ,
    MAJPROJ CHAR(6))
IN DSN8D81A.DSN8S81P
CCSID EBCDIC;
```

Because the table is self-referencing, the foreign key for that restraint must be added later with:

```
ALTER TABLE DSN8810.PROJ
    FOREIGN KEY RPP (MAJPROJ) REFERENCES DSN8810.PROJ
    ON DELETE CASCADE;
```

### Content of the project table:

Table 216 shows the content of the columns.

*Table 216. Columns of the project table*

| Column | Column Name | Description                                                                                                                   |
|--------|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| 1      | PROJNO      | Project ID (the primary key)                                                                                                  |
| 2      | PROJNAME    | Project name                                                                                                                  |
| 3      | DEPTNO      | ID of department responsible for the project                                                                                  |
| 4      | RESPEMP     | ID of employee responsible for the project                                                                                    |
| 5      | PRSTAFF     | Estimated mean number of persons needed between PRSTDATE and PRENDATE to achieve the whole project, including any subprojects |
| 6      | PRSTDATE    | Estimated project start date                                                                                                  |
| 7      | PRENDATE    | Estimated project end date                                                                                                    |
| 8      | MAJPROJ     | ID of any project of which this project is a part                                                                             |

Table 217 shows the indexes for the project table:

*Table 217. Indexes of the project table*

| Name           | On Column | Type of Index      |
|----------------|-----------|--------------------|
| DSN8810.XPROJ1 | PROJNO    | Primary, ascending |
| DSN8810.XPROJ2 | RESPEMP   | Ascending          |

### Relationship to other tables:

The table is self-referencing: a nonnull value of MAJPROJ must be a project number. The table is a parent table of the project activity table, through a foreign key on column PROJNO. It is a dependent of:

- The department table, through its foreign key on DEPTNO
- The employee table, through its foreign key on RESPEMP.

---

## Project activity table (DSN8810.PROJACT)

The project activity table lists the activities performed for each project. The table resides in database DSN8D81A. Because it has foreign keys referencing PROJ and ACT, those tables and the indexes on their primary keys must be created first. Then PROJACT is created with the following statement:

```
CREATE TABLE DSN8810.PROJACT
    (PROJNO CHAR(6) NOT NULL,
    ACTNO SMALLINT NOT NULL,
    ACSTAFF DECIMAL(5,2) ,
    ACSTDATE DATE NOT NULL,
    ACENDATE DATE ,
    PRIMARY KEY (PROJNO, ACTNO, ACSTDATE),
    FOREIGN KEY RPAP (PROJNO) REFERENCES DSN8810.PROJ
```

```

                                ON DELETE RESTRICT,
FOREIGN KEY RPAA (ACTNO) REFERENCES DSN8810.ACT
                                ON DELETE RESTRICT)
IN DSN8D81A.DSN8S81P
CCSID EBCDIC;

```

### Content of the project activity table:

Table 218 shows the content of the columns.

*Table 218. Columns of the project activity table*

| Column | Column Name | Description                                                     |
|--------|-------------|-----------------------------------------------------------------|
| 1      | PROJNO      | Project ID                                                      |
| 2      | ACTNO       | Activity ID                                                     |
| 3      | ACSTAFF     | Estimated mean number of employees needed to staff the activity |
| 4      | ACSTDATE    | Estimated activity start date                                   |
| 5      | ACENDATE    | Estimated activity completion date                              |

Table 219 shows the index of the project activity table:

*Table 219. Index of the project activity table*

| Name             | On Columns                 | Type of Index      |
|------------------|----------------------------|--------------------|
| DSN8810.XPROJAC1 | PROJNO, ACTNO,<br>ACSTDATE | primary, ascending |

### Relationship to other tables:

The table is a parent table of the employee to project activity table, through a foreign key on columns PROJNO, ACTNO, and EMSTDATE. It is a dependent of:

- The activity table, through its foreign key on column ACTNO
- The project table, through its foreign key on column PROJNO

## Employee to project activity table (DSN8810.EMPPROJACT)

The employee to project activity table identifies the employee who performs an activity for a project, tells the proportion of the employee's time required, and gives a schedule for the activity.

The table resides in database DSN8D81A. Because it has foreign keys referencing EMP and PROJACT, those tables and the indexes on their primary keys must be created first. Then EMPPROJACT is created with the following statement:

```

CREATE TABLE DSN8810.EMPPROJACT
  (EMPNO    CHAR(6)                NOT NULL,
   PROJNO   CHAR(6)                NOT NULL,
   ACTNO    SMALLINT              NOT NULL,
   EMPTIME  DECIMAL(5,2)          ,
   EMSTDATE DATE                  ,
   EMENDATE DATE                  ,
   FOREIGN KEY REPAPA (PROJNO, ACTNO, EMSTDATE)
     REFERENCES DSN8810.PROJACT
     ON DELETE RESTRICT,

```

```

FOREIGN KEY REPAE (EMPNO) REFERENCES DSN8810.EMP
ON DELETE RESTRICT)
IN DSN8D81A.DSN8S81P
CCSID EBCDIC;

```

### Content of the employee to project activity table:

Table 220 shows the content of the columns.

Table 220. Columns of the employee to project activity table

| Column | Column Name | Description                                                                                  |
|--------|-------------|----------------------------------------------------------------------------------------------|
| 1      | EMPNO       | Employee ID number                                                                           |
| 2      | PROJNO      | Project ID of the project                                                                    |
| 3      | ACTNO       | ID of the activity within the project                                                        |
| 4      | EMPTIME     | A proportion of the employee's full time (between 0.00 and 1.00) to be spent on the activity |
| 5      | EMSTDATE    | Date the activity starts                                                                     |
| 6      | EMENDATE    | Date the activity ends                                                                       |

Table 221 shows the indexes for the employee to project activity table:

Table 221. Indexes of the employee to project activity table

| Name                 | On Columns                     | Type of Index     |
|----------------------|--------------------------------|-------------------|
| DSN8810.XEMPPROJECT1 | PROJNO, ACTNO, EMSTDATE, EMPNO | Unique, ascending |
| DSN8810.XEMPPROJECT2 | EMPNO                          | Ascending         |

### Relationship to other tables:

The table is a dependent of:

- The employee table, through its foreign key on column EMPNO
- The project activity table, through its foreign key on columns PROJNO, ACTNO, and EMSTDATE.

## Unicode sample table (DSN8810.DEMO\_UNICODE)

The Unicode sample table is used to verify that data conversions to and from EBCDIC and Unicode are working as expected. The table resides in database DSN8D81A, and is defined with the following statement:

```

CREATE TABLE DSN8810.DEMO_UNICODE
  (LOWER_A_TO_Z CHAR(26) ,
  UPPER_A_TO_Z CHAR(26) ,
  ZERO_TO_NINE CHAR(10) ,
  X00_TO_XFF VARCHAR(256) FOR BIT DATA)
IN DSN8D81E.DSN8S81U
CCSID UNICODE;

```

### Content of the Unicode sample table:

Table 222 shows the content of the columns:

Table 222. Columns of the Unicode sample table

| Column | Column Name  | Description                         |
|--------|--------------|-------------------------------------|
| 1      | LOWER_A_TO_Z | Array of characters, 'a' to 'z'     |
| 2      | UPPER_A_TO_Z | Array of characters, 'A' to 'Z'     |
| 3      | ZERO_TO_NINE | Array of characters, '0' to '9'     |
| 4      | X00_TO_XFF   | Array of characters, x'00' to x'FF' |

This table has no indexes

**Relationship to other tables:**

This table has no relationship to other tables.

## Relationships among the sample tables

Figure 127 shows relationships among the tables. These are established by foreign keys in dependent tables that reference primary keys in parent tables. You can find descriptions of the columns with descriptions of the tables.

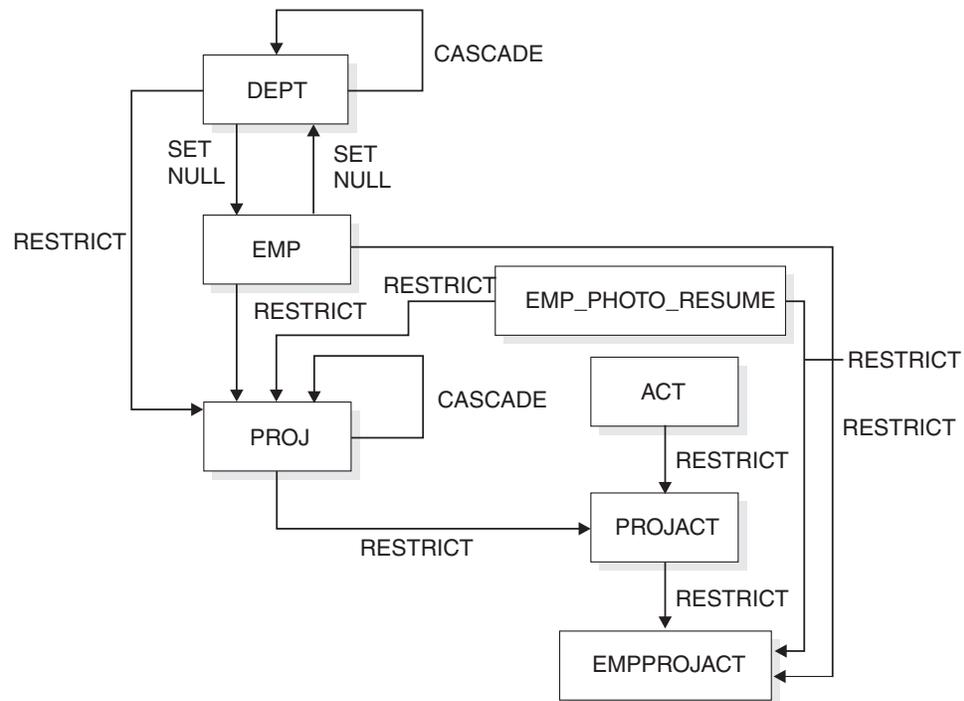

Figure 127. Relationships among tables in the sample application

## Views on the sample tables

DB2 creates a number of views on the sample tables for use in the sample applications. Table 223 on page 1047 indicates the tables on which each view is defined and the sample applications that use the view. All view names have the qualifier DSN8810.

Table 223. Views on sample tables

| View name   | On tables or views       | Used in application                                 |
|-------------|--------------------------|-----------------------------------------------------|
| VDEPT       | DEPT                     | Organization<br>Project                             |
| VHDEPT      | DEPT                     | Distributed organization                            |
| VEMP        | EMP                      | Distributed organization<br>Organization<br>Project |
| VPROJ       | PROJ                     | Project                                             |
| VACT        | ACT                      | Project                                             |
| VPROJACT    | PROJACT                  | Project                                             |
| VEMPPROJACT | EMPPROJACT               | Project                                             |
| VDEPMG1     | DEPT<br>EMP              | Organization                                        |
| VEMPDPT1    | DEPT<br>EMP              | Organization                                        |
| VASTRDE1    | DEPT                     |                                                     |
| VASTRDE2    | VDEPMG1<br>EMP           | Organization                                        |
| VPROJRE1    | PROJ<br>EMP              | Project                                             |
| VPSTRDE1    | VPROJRE1<br>VPROJRE2     | Project                                             |
| VPSTRDE2    | VPROJRE1                 | Project                                             |
| VFORPLA     | VPROJRE1<br>EMPPROJACT   | Project                                             |
| VSTAFAC1    | PROJACT<br>ACT           | Project                                             |
| VSTAFAC2    | EMPPROJACT<br>ACT<br>EMP | Project                                             |
| VPHONE      | EMP<br>DEPT              | Phone                                               |
| VEMPLP      | EMP                      | Phone                                               |

The following SQL statements are used to create the sample views:

```
CREATE VIEW DSN8810.VDEPT
AS SELECT ALL DEPTNO ,
DEPTNAME,
MGRNO ,
ADMRDEPT
FROM DSN8810.DEPT;
```

Figure 128. VDEPT

```

CREATE VIEW DSN8810.VHDEPT
  AS SELECT ALL      DEPTNO  ,
                    DEPTNAME,
                    MGRNO   ,
                    ADMRDEPT,

## Storage of sample application tables

Figure 147 shows how the sample tables are related to databases and storage groups. Two databases are used to illustrate the possibility. Normally, related data is stored in the same database.

vr is a 2-digit version identifier.

Figure 147. Relationship among sample databases and table spaces

In addition to the storage group and databases shown in Figure 147, the storage group DSN8G81U and database DSN8D81U are created when you run DSNTEJ2A.

## Storage group

The default storage group, *SYSDEFLT*, created when DB2 is installed, is not used to store sample application data. The storage group used to store sample application data is defined by this statement:

```
CREATE STOGROUP DSN8G810
  VOLUMES (DSNV01)
  VCAT DSN810;
```

## Databases

The default database, created when DB2 is installed, is not used to store the sample application data. *DSN8D81P* is the database that is used for tables that are related to programs. The remainder of the databases are used for tables that are related to applications. They are defined by the following statements:

```
CREATE DATABASE DSN8D81A
  STOGROUP DSN8G810
  BUFFERPOOL BP0
  CCSID EBCDIC;
```

```
CREATE DATABASE DSN8D81P
  STOGROUP DSN8G810
  BUFFERPOOL BP0
  CCSID EBCDIC;
```

```
CREATE DATABASE DSN8D81L
  STOGROUP DSN8G810
  BUFFERPOOL BP0
  CCSID EBCDIC;
```

```
CREATE DATABASE DSN8D81E
  STOGROUP DSN8G810
  BUFFERPOOL BP0
  CCSID UNICODE;
```

```
CREATE DATABASE DSN8D81U
  STOGROUP DSN8G81U
  CCSID EBCDIC;
```

## Table spaces

The following table spaces are explicitly defined by the following statements. The table spaces not explicitly defined are created implicitly in the *DSN8D81A* database, using the default space attributes.

```
CREATE TABLESPACE DSN8S81D
  IN DSN8D81A
  USING STOGROUP DSN8G810
  PRIQTY 20
  SECQTY 20
  ERASE NO
  LOCKSIZE PAGE LOCKMAX SYSTEM
  BUFFERPOOL BP0
  CLOSE NO
  CCSID EBCDIC;
```

```
CREATE TABLESPACE DSN8S81E

## Appendix B. Writing exit routines

The information in this appendix is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

DB2 provides installation-wide exit points to routines that you provide. These exit points are described in the following sections:

- “Connection routines and sign-on routines”
- “Access control authorization exit routine” on page 1065
- “Edit routines” on page 1081
- “Validation routines” on page 1084
- “Date and time routines” on page 1087
- “Conversion procedures” on page 1090
- “Field procedures” on page 1093
- “Log capture routines” on page 1105
- “Routines for dynamic plan selection in CICS” on page 1107
- “Routine for CICS transaction invocation stored procedure” on page 1108
- “General considerations for writing exit routines” on page 1108
- “Row formats for edit and validation routines” on page 1110
- “RACF access control module” on page 1114

---

### Connection routines and sign-on routines

Your DB2 subsystem has two exit points for authorization routines, one in connection processing and one in sign-on processing. Both exit points perform crucial steps in the assignment of values to primary IDs, secondary IDs, and SQL IDs. You must have a routine for each exit. Default routines are provided for both. DSN3@ATH is the default exit routine for connections, and DSN3@SGN is the default exit routine for sign-ons.

If your installation has a connection exit routine and you plan to use CONNECT with the USER/USING clause, you should examine your exit routine and take the following into consideration. DB2 does not update the following to reflect the user ID and password that are specified in the USER/USING clause of the CONNECT statement:

- The security-related control blocks that are normally associated with the thread
- The address space that your exit can access

For a general overview of the roles of exit routines in assigning authorization IDs, see Chapter 11, “Controlling access to a DB2 subsystem,” on page 231. That chapter explains how to implement the security features that you want by assigning identifiers through RACF, or some similar program, and by using the sample connection routines and sign-on routines that are provided by IBM.

This section describes the interfaces for those routines and the functions that they provide. If you want to use secondary authorization IDs, you must replace the default routines with the sample routines, or with routines of your own.

“General considerations for writing exit routines” on page 1108 applies to these routines. One exception to the description of execution environments is that the routines execute in non-cross-memory mode.

## Specifying connection and sign-on routines

Your connection routine must have a CSECT name and entry point of DSN3@ATH. The connection routine's load module name can be the same, or it can be a different name. Your sign-on routine must have a CSECT name and entry point of DSN3@SGN. The sign-on routine's load module name can be the same, or it can be a different name.

You can use an ALIAS statement of the linkage editor to provide the entry-point name.

Default routines exist in library *prefix*.SDSNLOAD. To use your routines instead, place your routines in library *prefix*.SDSNEXIT. You can use the install job DSNTIJEX to assemble and link-edit the routines and place them in the new library. If you use any other library, you might need to change the STEPLIB or JOBLIB concatenations in the DB2 start-up procedures.

You can combine both routines into one CSECT and load module if you wish, but the module must include both entry points, DSN3@ATH and DSN3@SGN. Use standard assembler and linkage editor control statements to define the entry points. DB2 loads the module twice at startup, by issuing the z/OS LOAD macro first for entry point DSN3@ATH and then for entry point DSN3@SGN. However, because the routines are reentrant, only one copy of each remains in virtual storage.

## Sample connection and sign-on routines

The sample exit routines provide examples of the functions and interfaces that are described in this section. These exit routines are provided in source code as members of *prefix*.SDSNSAMP. To examine the sample connection routine, list or assemble member DSN3SATH. To examine the sample sign-on routine, list or assemble member DSN3SSGN. Because both routines use features that are not available in Assembler XF, you must use Assembler H to assemble them.

**Change required for some CICS users:** You must change the sample sign-on exit routine (DSN3SSGN) before assembling and using it, if the following conditions are true:

- You attach to DB2 with an AUTH parameter in the RCT other than AUTH=GROUP.
- You have the RACF list-of-groups option active.
- You have transactions whose initial primary authorization ID is not defined to RACF

To change the sample sign-on exit routine (DSN3SSGN), perform the following steps:

1. Locate the following statement in DSN3SSGN as a reference point:  
SSGN035 DS OH BLANK BACKSCAN LOOP REENTRY
2. Locate the following statement, which comes after the reference point:  
B SSGN037 ENTIRE NAME IS BLANK, LEAVE
3. Replace the statement with the following statement:  
B SSGN090 NO GROUP NAME... BYPASS RACF CHECK

By changing the statement, you avoid an abend with SQLCODE -922. The routine with the new statement provides no secondary IDs unless you use AUTH=GROUP.

## When connection and sign-on routines are taken

Different local processes enter the access control procedure at different points, depending on the environment from which they originate. Different criteria apply to remote requests, which are described in “Controlling requests from remote applications” on page 238.

The following processes go through connection processing only:

- Requests that originate in TSO foreground and background (including online utilities and requests through the call attachment facility)
- JES-initiated batch jobs
- Requests through started task control address spaces (from the MVS START command)

The following processes go through connection processing, and can later go through the sign-on exit:

- The IMS control region
- The CICS recovery coordination task
- DL/I batch
- Requests through the Resource Recovery Services attachment facility (RRSAF)

The following processes go through sign-on processing:

- Requests from IMS-dependent regions (including MPP, BMP, and Fast Path)
- CICS transaction subtasks

For instructions on controlling the IDs that are associated with connection requests, see “Processing connections” on page 232. For instructions on controlling the IDs associated with sign-on requests, see “Processing sign-ons” on page 236.

## EXPL for connection and sign-on routines

Figure 148 shows how the parameter list points to other information.

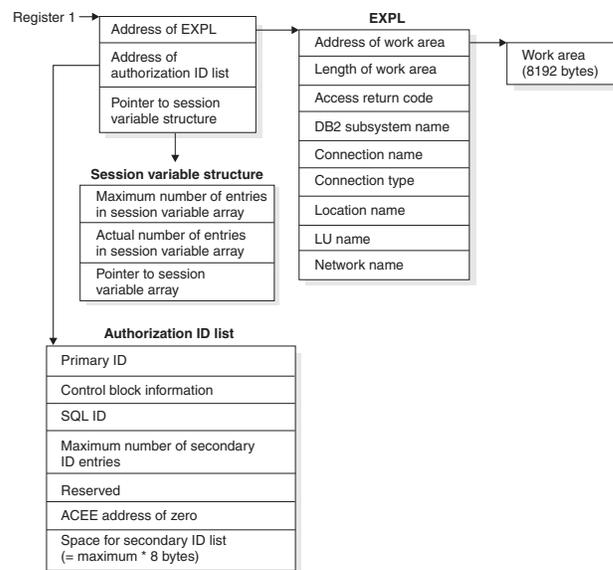

Figure 148. How a connection or sign-on parameter list points to other information

## Exit parameter list for connection and sign-on routines

Connection routines and sign-on routines use 28 more bytes of the exit parameter list EXPL than other routines. Table 224 shows the entire list of connection routines and sign-on routines. The exit parameter list is described by macro DSNDEXPL.

Table 224. Exit parameter list for connection routines and sign-on routines

| Name     | Hex offset | Data type             | Description                                                                                                                                                        |
|----------|------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXPLWA   | 0          | Address               | Address of a 8192-byte work area to be used by the routine.                                                                                                        |
| EXPLWL   | 4          | Signed 4-byte integer | Length of the work area, in bytes; value is 8192.                                                                                                                  |
| EXPLRSV1 | 8          | Signed 2-byte integer | Reserved.                                                                                                                                                          |
| EXPLRC1  | A          | Signed 2-byte integer | Not used.                                                                                                                                                          |
| EXPLRC2  | C          | Signed 4-byte integer | Not used.                                                                                                                                                          |
| EXPLARC  | 10         | Signed 4-byte integer | Access return code. Values can be:<br><b>0</b> Access allowed; DB2 continues processing.<br><b>12</b> Access denied; DB2 terminates processing with an error.      |
| EXPLSSNM | 14         | Character, 8 bytes    | DB2 subsystem name, left justified; for example, 'DSN '.                                                                                                           |
| EXPLCONN | 1C         | Character, 8 bytes    | Connection name for requesting location.                                                                                                                           |
| EXPLTYPE | 24         | Character, 8 bytes    | Connection type for requesting location. For DDF threads, the connection type is 'DIST '.                                                                          |
| EXPLSITE | 2C         | Character, 16 bytes   | For SNA protocols, this is the location name of the requesting location or <luname>. For TCP/IP protocols, this is the dotted decimal IP address of the requester. |
| EXPLLUNM | 3C         | Character, 8 bytes    | For SNA protocols, this is the locally known LU name of the requesting location. For TCP/IP protocols, this is the character string 'TCPIP '.                      |
| EXPLNTID | 44         | Character, 17 bytes   | For SNA protocols, the fully qualified network name of the requesting location. For TCP/IP protocols, this field is reserved.                                      |

## Authorization ID parameter list for connection and sign-on routines

The second parameter list, which is specific to connection routines and sign-on routines, is called an authorization ID list. Its contents are shown in Table 225 on page 1059. The description is given by macro DSNDAIDL.

Table 225. Authorization ID list for a connection or sign-on exit routine

| Name     | Hex offset | Data type                    | Description                                                                                                                                                                                                       |
|----------|------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AIDLPRIM | 0          | Character, 8 bytes           | Primary authorization ID for input and output; see descriptions in the text.                                                                                                                                      |
| AIDLCODE | 8          | Character, 2 bytes           | Control block identifier.                                                                                                                                                                                         |
| AIDLTLEN | A          | Signed 2-byte integer        | Total length of control block.                                                                                                                                                                                    |
| AIDLEYE  | C          | Character, 4 bytes           | Eyecatcher for block, "AIDL".                                                                                                                                                                                     |
| AIDLSQL  | 10         | Character, 8 bytes           | On output, the current SQL ID.                                                                                                                                                                                    |
| AIDLSCNT | 18         | Signed 4-byte integer        | Number of entries allocated to secondary authorization ID list. Always equal to 1012.                                                                                                                             |
| AIDLSAPM | 1C         | Address                      | For a sign-on routine only, the address of an 8-character additional authorization ID. If RACF is active, the ID is the user ID's connected group name. If the address was not provided, the field contains zero. |
| AIDLCKEY | 20         | Character, 1 byte            | Storage key of the ID pointed to by AIDLSAPM. To move that ID, use the "move with key" (MVCK) instruction, specifying this key.                                                                                   |
| AIDLRV1  | 21         | Character, 3 bytes           | Reserved                                                                                                                                                                                                          |
| AIDLRV2  | 24         | Signed 4-byte integer        | Reserved                                                                                                                                                                                                          |
| AIDLACEE | 28         | Signed 4-byte integer        | The address of the ACEE structure, if known; otherwise, zero                                                                                                                                                      |
| AIDLRACL | 2C         | Signed 4-byte integer        | Length of data area returned by RACF, plus 4 bytes                                                                                                                                                                |
| AIDLRACR | 30         | 26 bytes                     | Reserved                                                                                                                                                                                                          |
| AIDLSEC  | 4A         | Character, maximum x 8 bytes | List of the secondary authorization IDs, 8 bytes each                                                                                                                                                             |

## Input values for connection routines

The input values for a connection routine are as follows:

- The initial primary authorization ID for a local request can be obtained from the z/OS address space extension block (ASXB).

The ASXB contains at most only a seven-character value. That is always sufficient for a TSO user ID or a user ID from an z/OS JOB statement, and the ASXB is always used for those cases.

For CICS, IMS, or other started tasks, z/OS can also pass an eight-character ID. If an eight-character ID is available, and if its first seven characters agree with the ASXB value, then DB2 uses the eight-character ID. Otherwise it uses the ASXB value.

You can alter the sample exit routine to use the ASXB value always. For instructions, see "Processing in the sample connection and sign-on routines" on page 1061.

If RACF is active, the field used contains a verified RACF user ID; otherwise, it contains blanks.

- The primary ID for a remote request is the ID passed in the conversation attach request header (SNA FMH5) or in the DRDA SECCHK command.
- The SQL ID contains blanks.
- The list of secondary IDs contains blanks.

## Input values for sign-on routines

The input values for a sign-on routine are as follows:

- The initial primary ID depends on the sign-on method. See “Processing sign-ons” on page 236 for information about how the primary ID is determined.
- The SQL ID and all secondary IDs contain blanks.
- Field AIDLSAPM in the authorization ID list can contain the address of an 8-character additional authorization ID, obtained by the CICS attachment facility using the RACROUTE REQUEST=EXTRACT service with the requester's user ID. If RACF is active, this ID is the RACF-connected group name from the ACEE corresponding to the requester's user ID. Otherwise, this field contains blanks. IMS does not pass this parameter.
- Field AIDLCKEY contains the storage key of the identifier pointed to by AIDLSAPM. To move that ID, use the “move with key” (MVCK) instruction, specifying this key.
- Field AIDLACEE contains the ACEE address only for a sign-on through the CICS attachment facility and only when the CICS RCT uses AUTH=GROUP.

## Expected output for connection and sign-on routines

DB2 uses the output values of the primary ID, the SQL ID, and the secondary IDs. Your routines can set these IDs to any value that is an SQL short identifier.

**Important:** If your identifier does not meet the 8-character criteria, the request abends. Therefore, you should add blanks to the end of short identifiers to ensure that they meet the criteria.

If the values that are returned **are not blank**, DB2 interprets them in the following ways:

- The primary ID becomes the primary authorization ID.
- The list of secondary IDs, down to the first blank entry or to a maximum of 1012 entries, becomes the list of secondary authorization IDs. The space allocated for the secondary ID list is only large enough to contain the maximum number of authorization IDs. This number is in field AIDLSCNT.

**Attention:** If you allow more than 1012 secondary authorization IDs, abends and storage overlays can occur.

- The SQL ID is checked to see if it is the same as the primary or one of the secondary IDs. If it is not, the connection or sign-on process abends. Otherwise, the validated ID becomes the current SQL ID.

If the returned value of the primary ID is **blank**, DB2 takes the following steps:

- In connection processing, the default ID that is defined when DB2 is installed (UNKNOWN AUTHID on panel DSNTIPP) is substituted as the primary authorization ID and the current SQL ID. The list of secondary IDs is set to blanks.
- Sign-on processing abends. No default value exists for the primary ID.

If the returned value of the SQL ID is blank, DB2 makes it equal to the value of the primary ID. If the list of secondary IDs is blank, it remains blank. No default secondary IDs exist.

Your routine must also set a return code in word 5 of the exit parameter list to allow or deny access (field EXPLARC). By those means you can deny the connection altogether. The code must have one of the values that are shown in Table 226.

Table 226. Required return code in EXPLARC

| Value | Meaning                              |
|-------|--------------------------------------|
| 0     | Access allowed; continue processing. |
| 12    | Access denied; terminate.            |

Any other value will cause an abend.

## Processing in the sample connection and sign-on routines

The sample routines provided by IBM can serve as models for the processing that is required in connection routines and sign-on routines.

**Recommendation:** Consider using the sample routines as a starting point when you write your own routines.

Both the sample connection routine (DSN3SATH) and the sample sign-on routine have similar sections for setup, constants, and storage areas. Both routines set values of the primary ID, the SQL ID, and the secondary IDs in three numbered sections.

*In the sample connection routine (DSN3SATH):* The three sections of the sample connection routine perform the following functions:

### Section 1

Section 1 provides the same function as in the default connection routine. It determines whether the first character of the input primary ID has a value that is greater than blank (hex 40), and performs the following operations:

- If the first character is greater than hex 40, the value is not changed.
- If the first character is not greater than hex 40, the value is set according to the following rules:
  - If the request is from a TSO foreground address space, the primary ID is set to the logon ID.
  - If the request is not from a TSO foreground address space, the primary ID is set to the job user ID from the JES job control table.
  - If no primary ID is located, Section 2 is bypassed.

### Section 2

At the beginning of Section 2, you can restore one commented-out instruction, which then truncates the primary authorization ID to 7 characters. (The instruction is identified by comments in the code.)

Section 2 next tests RACF options and makes the following changes in the list of secondary IDs, which is initially blank:

- If RACF is not active, the list remains blank.
- If the list of groups option is not active, but an ACEE exists, the connected group name is copied as the only secondary ID.
- If the list of groups option is active, the list of group names from the ICHPCGRP block is copied into AIDLSEC in the authorization ID list.

### Section 3

Section 3 performs the following steps:

1. The SQL ID is set equal to the primary ID.
2. If the TSO data set name prefix is a valid primary or secondary ID, the SQL ID is replaced with the TSO data set name prefix. Otherwise, the SQL ID remains set to the primary ID.

*In the sample sign-on routine (DSN3SSGN):* The three sections of the sample sign-on routine perform the following functions:

#### Section 1

Section 1 does not change the primary ID.

#### Section 2

Section 2 sets the SQL ID to the value of the primary ID.

#### Section 3

Section 3 tests RACF options and makes the following changes in the list of secondary IDs, which is initially blank:

- If RACF is not active, the list remains blank.
- If the list of groups option is active, section 3 attempts to find an existing ACEE from which to copy the authorization ID list.
  - If AIDLACEE contains a valid ACEE, it is used.  
Otherwise, look for a valid ACEE chained from the TCB or from the ASXB or, if no usable ACEE exists, issue RACROUTE to have RACF build an ACEE structure for the primary ID.  
Copy the list of group names from the ACEE structure into the secondary authorization list.
  - If the exit issued RACROUTE to build an ACEE, another RACROUTE macro is issued and the structure is deleted.
- If a list of secondary authorization IDs has not been built, and AIDLSAPM is not zero, the data that is pointed to by AIDLSAPM is copied into AIDLSEC.

## Performance considerations for connection and sign-on routines

Your sign-on exit routine is part of the critical path for transaction processing in IMS and CICS, so you want it to execute as quickly as possible. Avoid writing SVC calls like GETMAIN, FREEMAIN, and ATTACH. Also avoid I/O operations to any data set or database. To improve performance, you might be able to delete the list of groups that process in Section 3 of the sample sign-on exit.

The sample sign-on exit routine can issue the RACF RACROUTE macro with the default option SMC=YES. If another product issues RACROUTE with SMC=NO, a deadlock might occur.

Your routine can also enhance the performance of later authorization checking. Authorization for dynamic SQL statements is checked first for the CURRENT SQLID, then for the primary authorization ID, and then for the secondary authorization IDs. If you know that a user's privilege most often comes from a secondary authorization ID, then set the CURRENT SQLID to this secondary ID within your exit routine.

## Debugging connection and sign-on routines

The diagnostic aids that are described in this section can assist you in debugging connection exit routines and sign-on exit routines.

*Subsystem support identify recovery:* The identify ESTAE recovery routine, DSN3IDES, generates the VRADATA entries that are shown in Table 227. The last entry, key VRAIMO, is generated only if the abend occurred within the connection exit routine.

Table 227. VRADATA entries that are generated by DSN3IDES

| VRA keyname | Key hex value | Data length | Content                                                                                                                                                                                                                                                             |
|-------------|---------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VRAFPI      | 22            | 8           | Constant 'IDESTRAK'                                                                                                                                                                                                                                                 |
| VRAFP       | 23            | 24          | <ul style="list-style-type: none"><li>• 32-bit recovery tracking flags</li><li>• 32-bit integer AGNT block unique identifier</li><li>• AGNT block address</li><li>• AIDL block address</li><li>• Initial primary authorization ID as copied from ASXBUSER</li></ul> |
| VRAIMO      | 7C            | 10          | <ul style="list-style-type: none"><li>• Connection exit load module load point address</li><li>• Connection exit entry point address</li><li>• Offset of failing address in the PSW from the connection exit entry point address</li></ul>                          |

*Subsystem support sign-on recovery:* The sign-on ESTAE recovery routine DSN3SIES generates the VRADATA entries that are shown in Table 228. The last entry, key VRAIMO, is generated only if the abend occurred within the sign-on exit routine.

Table 228. VRADATA entries that are generated by DSN3SIES

| VRA keyname | Key hex value | Data length | Content                                                                                                                                                                                                                           |
|-------------|---------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VRAFPI      | 22            | 8           | Constant 'SIESTRAK'                                                                                                                                                                                                               |
| VRAFP       | 23            | 20          | <ul style="list-style-type: none"><li>• Primary authorization ID (CCBUSER)</li><li>• AGNT block address</li><li>• Identify-level CCB block address</li><li>• Sign-on-level CCB block address</li></ul>                            |
| VRAIMO      | 7C            | 10          | <ul style="list-style-type: none"><li>• Sign-on exit load module load point address</li><li>• Sign-on exit entry point address</li><li>• Offset of failing address in the PSW from the sign-on exit entry point address</li></ul> |

*Diagnostics for connection exit routines and sign-on exit routines:* The connection (identify) recovery routine and the sign-on recovery routine provide diagnostics for the corresponding exit routines. The diagnostics are produced only when the abend occurs in the exit routine. The following diagnostics are available:

### Dump title

The component failing module name is "DSN3@ATH" for a connection exit or "DSN3@SGN" for a sign-on exit.

### z/OS and RETAIN<sup>®</sup> symptom data

SDWA symptom data fields SDWACSCT (CSECT/) and SDWAMODN (MOD/) are set to "DSN3@ATH" or "DSN3@SGN", as appropriate.

### Summary dump additions

The AIDL, if addressable, and the SADL, if present, are included in the summary dump for the failing allied agent. If the failure occurred in connection or sign-on processing, the exit parameter list (EXPL) is also included. If the failure occurred in the system services address space, the entire SADL storage pool is included in the summary dump.

## Session variables in connection and sign-on routines

DB2 supplies default session variables, as described in *DB2 SQL Reference*. In addition to the default session variables, the connection exit routine and the sign-on exit routine support up to 10 more session variables. You can define these additional session variables and use them to provide information to applications by using the GETVARIABLE function.

**The session variable structure:** The connection exit routine and the sign-on exit routine point to the session variable structure (DSNDSVS). DSNDSVS specifies the maximum number of entries in the session array, the actual number of entries in the session array, and a pointer to the session variable array. The default value for the actual number of session variables is zero.

**Defining session variables:** To define session variables, use the session variable array (DSNDSVA) to list up to 10 session variables as name and value pairs. The session variables that you establish in the connection exit routine and the sign-on exit routine are defined in the SESSION schema. The values that the exit routine supplies in the session variable array replace the previous values.

**Example:** The session variable array that is shown in Table 229 lists six session variables.

Table 229. Sample session variable array

| Name             | Value      |
|------------------|------------|
| default_database | DATAXM     |
| default_driver   | PZN4Y7     |
| location         | Kyoto      |
| member_of        | GROUP_42   |
| filename         | report.txt |
| account_number   | A1-X142783 |

The unqualified names are defined as VARCHAR(128), and the values are defined as VARCHAR(255). The exit routines must provide these values in Unicode CCSID 1208.

---

## Access control authorization exit routine

### Is this exit routine right for you?

Using the RACF (Security Server for OS/390 or z/OS) to perform access control is not the best choice for every customer. Consider the following points before choosing RACF to perform access control:

- If you want the database administrators to manage security, integration with DB2 is very important. Using RACF access control provides less integration with DB2. In most of these cases, DB2 authorization provides advantages.
- If you want security administrators to manage security, integration with the security server is more important. In most of these cases, using RACF for access control provides advantages. Furthermore, if you want a security group to define authorization and a centralized security control point, RACF access control is an excellent match.

If you change from DB2 authorization to RACF access control, you must change to RACF methods for some authorization techniques, and you must understand how DB2 and RACF work together. Expect to make the following changes when you implement RACF access control:

- Plan to use RACF facilities (such as groups and patterns) more.
- Plan to use patterns instead of individual item access profiles and permissions.
- Plan to use RACF groups instead of secondary authorization IDs, which are not implemented in RACF. OWNER(secondaryID) generally must be a valid group.
- Find an alternative to BINDAGENT. BINDAGENT is based on secondary authorization IDs, which are not implemented in RACF. BINDAGENT provides a relatively weak security separation. Customers have found alternatives.
- Understand how SET CURRENT SQLID works with RACF. SET CURRENT SQLID can set a qualifier, but does not change authorization.
- Know that authorizations are not dropped when objects are dropped or renamed.
- Be aware of the relationship between objects and revoked privileges. Plans and packages are not invalidated when authorizations are revoked. Views are not dropped when authorizations are revoked.

DB2 provides an exit point that lets you provide your own access control authorization exit routine, or lets RACF or an equivalent security system perform DB2 authorization checking. Your routine specifies whether the authorization checking should all be done by RACF only, or by both RACF and DB2. (Also, the routine can be called and still let all checking be performed by DB2.) For more information about how to use the routine that is provided, see *DB2 RACF Access Control Module Guide*.

When DB2 invokes the routine, it passes three possible functions to the routine:

- Initialization (DB2 startup)
- Authorization check
- Termination (DB2 shutdown)

The bulk of the work in the routine is for authorization checking. When DB2 must determine the authorization for a privilege, it invokes your routine. The routine determines the authorization for the privilege and then indicates to DB2 whether the privilege is authorized or not authorized, or whether DB2 should do its own authorization check, instead.

*When the exit routine is bypassed:* In the following situations, the exit routine is not called to check authorization:

- # • The authorization ID that DB2 uses to determine access has installation
- # SYSADM or installation SYSOPR authority (where installation SYSOPR authority
- # is sufficient to authorize the request). This authorization check is made strictly
- # within DB2. For example, if the execute privilege is being checked on a package,
- # DB2 performs the check on the plan owner that this package is in. If the plan
- # owner has installation SYSADM, the routine is not called.
- DB2 security has been disabled. (You can disable DB2 security by specifying NO
- on the USE PROTECTION field of installation panel DSNTIPP).
- Authorization has been cached from a prior check.
- In a prior invocation of the exit routine, the routine indicated that it should not
- be called again.
- GRANT statements.

The routine executes in the *ssnmDBM1* address space of DB2.

“General considerations for writing exit routines” on page 1108 applies to this routine, but with the following exceptions to the description of execution environments:

- The routine executes in non-cross-memory mode during initialization and termination (XAPLFUNC of 1 or 3, described in Table 230 on page 1071).
- During authorization checking the routine can execute under a TCB or SRB in cross-memory or non-cross-memory mode.

## Specifying the access control authorization routine

Your access control authorization routine must have a CSECT name and an entry point of DSNX@XAC. The load module name or alias name must also be DSNX@XAC. A default routine with this name and entry point exists in library *prefix.SDSNLOAD*. To use your routine instead, place it in the *prefix.SDSNEXIT* library. Use installation job DSNTIJEX to assemble and link-edit the routine and to place it in the *prefix.SDSNEXIT* library. If you use any other library, you might need to change the STEPLIB or JOBLIB concatenations in the DB2 start-up procedures.

The source code for the default routine is in *prefix.SDSNSAMP* as DSNXSXAC. You can use it to write your own exit routine. To assemble it, you must use Assembler H.

- # RACF provides a sample exit routine DSNRXAC, which is shipped with DB2. It
- # can be found in *prefix.SDSNSAMP*. For more information, see *DB2 RACF Access*
- # *Control Module Guide*.

## The default access control authorization routine

The default exit routine returns a code to the DB2 authorization module. The code indicates that a user-defined access control authorization exit routine is not available. DB2 then performs normal authorization checking and does not attempt to invoke this exit routine again.

## When the access control authorization routine is taken

This exit routine is taken in the following three instances:

### At DB2 startup

This exit routine is taken when DB2 starts to allow the external authorization checking application to perform any required setup prior to authorization checking. For example, loading authorization profiles into storage is a required setup task. DB2 uses the reason code that the exit routine sets during startup to determine how to handle exception situations. See "Exception processing" on page 1079 for details.

### When an authorization check is to be performed on a privilege

This exit routine is taken when DB2 accesses security tables in the catalog to check authorization on a privilege. The exit routine is taken only if none of the prior invocations have indicated that the exit routine must not be called again.

### At DB2 shutdown

This exit routine is taken when DB2 is stopping, to let the external authorization checking application perform its cleanup before DB2 stops.

## Considerations for the access control authorization routine

This section discusses special considerations for using the access control authorization exit routine.

### When DB2 cannot provide an ACEE

Sometimes DB2 cannot provide an ACEE.

| **Example:** If you are not using external security in CICS (that is, SEC=NO is  
| specified in the DFHSIT), CICS does not pass an ACEE to the CICS attachment  
| facility. The ACEE address is passed for CICS transactions, if available.

When DB2 does not have an ACEE, it passes zeros in the XAPLACEE field. If this happens, your routine can return a 4 in the EXPLRC1 field, and let DB2 handle the authorization check.

# DB2 does not pass the ACEE address for IMS transactions. The ACEE address is  
# passed for CICS transactions, if available.

# DB2 does pass the ACEE address when it is available for DB2 commands that are  
# issued from a logged on z/OS console. DB2 does not pass the ACEE address for  
# DB2 commands that are issued from a console that is not logged on, or for the  
# START DB2 command, or commands issued automatically during DB2 startup.

### Authorization IDs and ACEEs

XAPL has two authorization ID fields, XAPLUPRM (the primary authorization ID) and XAPLUCHK (the authorization ID that DB2 uses to perform the authorization). These two fields might have different values.

The ACEE passed in XAPLACEE is that of the primary authorization ID, XAPLUPRM.

# The implications of the XAPLUPRM and XAPLUCHK relationship need to be  
# clearly understood. XAPLUCHK, the authorization ID that DB2 uses to perform  
# authorization may be the primary authorization ID (XAPLUPRM), a secondary  
# authorization ID, or another authorization ID such as a package owner.

If the RACF access control module is used, the following rules apply:

- RACF uses the ACEE of the primary authorization ID (XAPLUPRM) to perform authorization.
- Secondary authorization IDs are not implemented in RACF. RACF groups should be used instead.

**Examples:** The following examples show how the rules apply:

- A plan or package may be bound successfully by using the privileges of the binder (XAPLUPRM). Then only the EXECUTE privilege on the plan or package is needed to execute it. If at some point this plan or package is marked invalid (for instance, if a table it depends upon is dropped and recreated), the next execution of it will cause an AUTOBIND, which will usually fail. It fails because the AUTOBIND checks the privilege on the runner. The plan or package must be rebound by using an authorization ID that has the necessary privileges.
- If the OWNER on the BIND command is based on secondary authorization IDs, which are not supported by RACF. RACF groups should be used instead.
- SET CURRENT SQLID can set a qualifier, but it cannot change authorization.
- The DYNAMICRULES settings have a limited effect on which authorization ID is checked. Only the primary authorization ID and secondary IDs that are valid RACF groups for this user are considered. For dynamic statements with the DYNAMICRULES(BIND) option to work, for example, the package owner must be the primary authorization ID or one of the RACF groups of the user who executes the statements.
- User-defined function and stored procedure authorizations involve several authorization IDs, such as implementer, definer, invoker, and so forth. Only the primary authorization ID and secondary IDs that are RACF groups are considered.

## Stored procedure authorization

At run time, DB2 checks the EXECUTE privilege on stored procedure packages.

The only authorization ID that is available to check at run time is the primary authorization ID that runs the stored procedure package. If your security plan requires that you do not grant the EXECUTE privilege to all authorization IDs, the ID that runs the stored procedure package might not have it.

However, you can ensure that the ID can run the package without granting the EXECUTE privilege on the stored procedure package to it. To do this, grant the privilege to the ID that binds the plan that calls the stored procedure package, and satisfy the following conditions:

- The stored procedure definition must not specify COLLID.
- The program that calls the stored procedure must be bound directly to the plan that calls it by using the MEMBER bind option and by specifying the name of the calling program. The stored procedure package must be referenced in the PKLIST as *collection-id.\** or *collection-id.stored-procedure-package-id* with the VALIDATE(BIND) option.

- The SET CURRENT PACKAGESET statement must not be used before the stored procedure is called in the program.

### **Invalid and inoperative plans and packages**

In DB2, when a privilege that is required by a plan or package is revoked, the plan or package is invalidated. If you use an authorization access control routine, it cannot tell DB2 that a privilege is revoked. Therefore, DB2 cannot know to invalidate the plan or package.

If the revoked privilege is the EXECUTE privilege on a user-defined function, DB2 marks the plan or package inoperative instead of invalid.

If a privilege that the plan or package depends on is revoked, and if you want to invalidate the plan or package or make it inoperative, you must use the SQL GRANT statement to grant the revoked privilege and then use the SQL REVOKE statement to revoke it.

### **View authorization**

DB2 passes specific base table information to an access control authorization exit (ACAE) routine. This information helps the routine to effectively control data access through views.

For the DELETE and INSERT privileges, DB2 passes the schema and name of the base table in the XAPLBSCM and XAPLBSNAM fields, along with the information about the view itself. For the UPDATE privilege, DB2 additionally passes the name of the base table column in the XAPLBCOL field that is being updated.

For any view in a nested stack, DB2 passes the base table information in addition to that of the view itself. All the intermediate views between the base table and the view that is being processed are ignored.

In the cases when the view is not updatable, the view information will be repeated in the XAPLBSCM, XAPLBSNAM, and XAPLBCOL fields. For example, if the view is specified with the Instead of Trigger, the base table of the view is not being updated using the view because all processing is based on the content of the trigger package. The view information is repeated in the base table fields to facilitate any view authorization check.

When a view is created, DB2 checks whether the owner of the view has the INSERT, UPDATE and DELETE privileges on the underlying base table. DB2 performs this check to determine what privileges should be granted to the view owner. This processing occurs whether or not an ACAE routine, like the RACF access control module, is in effect. If an ACAE routine is in effect, the result of the DB2 authorization check does not impact the creation of the view or the privileges that the view owner gets on the view. In the case when the view is created based on another view, the base view information will be repeated in the XAPLBSCM, XAPLBSNAM, and XAPLBCOL fields.

### **Dropping views**

When a privilege that is required to create a view is revoked, the view is dropped. Similar to the revocation of plan privileges, such an event is not communicated to DB2 by the authorization checking routine.

If you want DB2 to drop the view when a privilege is revoked, you must use the SQL statements GRANT and REVOKE.

## **Caching of EXECUTE on plans, packages, and routines**

The results of authorization checks on the EXECUTE privilege for plans are not cached when those checks are performed by the exit routine.

The results of authorization checks on the EXECUTE privilege for packages and routines are cached (assuming that package and routine authorization caching is enabled on your system). If this privilege is revoked in the exit routine, the cached information is not updated to reflect the revoke. You must use the GRANT statement and the REVOKE statement to update the cached information.

## **Caching of dynamic SQL statements**

Dynamic statements can be cached when they have passed the authorization checks (assuming that dynamic statement caching is enabled on your system). If the privileges that this statement requires are revoked from the authorization ID that is cached with the statement, this cached statement must be invalidated. If the privilege is revoked in the exit routine this does not happen, and you must use the SQL statements GRANT and REVOKE to refresh the cache.

## **Resolution of user-defined functions**

The create timestamp for the user-defined function must be older than the bind timestamp for the package or plan in which the user-defined function is invoked. If DB2 authorization checking is in effect, and DB2 performs an automatic rebind on a plan or package that invokes a user-defined function, any user-defined functions that were created after the original BIND or REBIND of the invoking plan or package are not candidates for execution.

If you use an access control authorization exit routine, some user-defined functions that were not candidates for execution before the original BIND or REBIND of the invoking plan or package might become candidates for execution during the automatic rebind of the invoking plan or package. If a user-defined function is invoked during an automatic rebind, and that user-defined function is invoked from a trigger body and receives a transition table, the form of the invoked function that DB2 uses for function selection includes only the columns of the transition table that existed at the time of the original BIND or REBIND of the package or plan for the invoking program.

## **Creating materialized query tables**

When a materialized query table is created, a CRTVUAUTT authorization check is performed. The CRTVUAUTT check is used to determine whether the creator of a materialized query table can provide the required SELECT privileges on base tables to the owner of the materialized query table. If the owner of the materialized query table has the required privileges, the CRTVUAUTT authorization check proves redundant. However, the check is performed before the owner of the materialized query table's privileges are determined. Therefore, if the materialized query table owner holds the necessary privileges and the creator of the materialized query table does not, the CRTVUAUTT check can produce unwanted error messages.

For an ACA exit routine to suppress unwanted error messages during the creation of materialized query tables, XAPLFSUP is turned on.

## **Parameter list for the access control authorization routine**

Figure 149 on page 1071 shows how the parameter list points to other information.

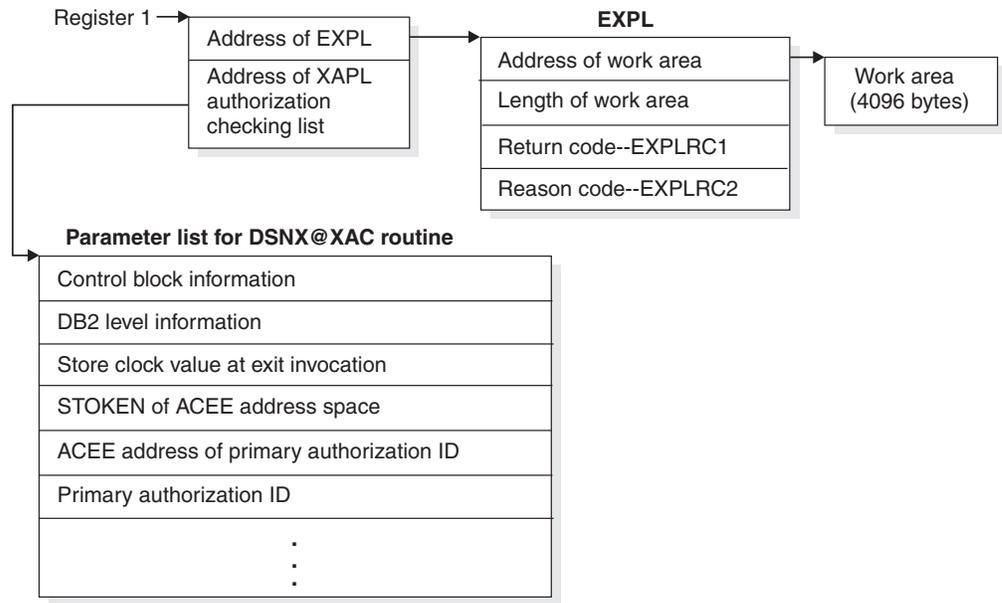

Figure 149. How an authorization routine's parameter list points to other information

The work area (4096 bytes) is obtained once during the startup of DB2 and only released when DB2 is shut down. The work area is shared by all invocations to the exit routine.

At invocation, registers are set as described in "Registers at invocation for exit routines" on page 1109, and the authorization checking routine uses the standard exit parameter list (EXPL) described there. Table 230 shows the exit-specific parameter list, described by macro DSNDXAPL.

# Table 230. Parameter list for the access control authorization routine. Field names indicated by an asterisk (\*) apply to initialization, termination, and authorization checking. Other fields apply to authorization checking only.

| # Name      | Hex offset | Data type              | Input or output | Description                                                                                                               |
|-------------|------------|------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------|
| # XAPLCBID* | 0          | Character, 2-bytes     | Input           | Control block identifier; value X'216A'.                                                                                  |
| # XAPLLEN*  | 2          | Signed, 2-byte integer | Input           | Length of XAPL; value X'100' (decimal 256).                                                                               |
| # XAPLEYE*  | 4          | Character, 4 bytes     | Input           | Control block eye catcher; value "XAPL".                                                                                  |
| # XAPLLVL*  | 8          | Character, 8 bytes     | Input           | DB2 version and level; for example, "VxRxMx".                                                                             |
| # XAPLSTCK* | 10         | Character, 8 bytes     | Input           | The store clock value when the exit is invoked. Use this to correlate information to this specific invocation.            |
| # XAPLSTKN* | 18         | Character, 8 bytes     | Input           | STOKEN of the address space in which XAPLACEE resides. Binary zeroes indicate that XAPLACEE is in the home address space. |

# Table 230. Parameter list for the access control authorization routine (continued). Field names indicated by an asterisk (\*) apply to initialization, termination, and authorization checking. Other fields apply to authorization checking only.

| # | # Name     | Hex offset | Data type              | Input or output | Description                                                                                                                                                                                                                                                                                                                                                                                              |

| XAPLDBDA | C          | Character, 1 byte  | Output          | <p>Required by DB2 from the exit routine for CREATE VIEW.</p> <p>A value of Y and EXPLRC1=0 indicate that the user ID in field XAPLUCCHK has database administrator authority on the database in field XAPLDBNM.</p> <p>When the exit checks if XAPLUCCHK can create a view for another authorization ID, it first checks for SYSADM or SYSCTRL authority. If the check is successful, no more checking is necessary because SYSCTRL authority (for non-user tables) or SYSADM authority satisfies the requirement that the view owner has the SELECT privilege for all tables and views that the view might be based on. This is indicated by a blank value and EXPLRC1=0.</p> <p>If the authorization ID does not have SYSADM or SYSCTRL authority, the exit checks if the view creator has DBADM on each database of the tables that the view is based on because the DBADM authority on the database of the base table satisfies the requirement that the view owner has the SELECT privilege for all base tables in that database.</p> |

## Expected output for the access control authorization routine

Your authorization exit routine is expected to return certain fields when it is called. These output fields are indicated in Table 230 on page 1071. If an unexpected value is returned in any of these fields an abend occurs. Register 3 points to the field in error, and abend code 00E70009 is issued.

| Field    | Required or optional                                     |
|----------|----------------------------------------------------------|
| EXPLRC1  | Required                                                 |
| EXPLRC2  | Optional                                                 |
| XAPLONWT | Required only for UPDATE and REFERENCES table privileges |
| XAPLDIAG | Optional                                                 |

## Handling return codes

Place return codes from the exit routine in the EXPL field named EXPLRC1.

*Return codes during initialization:* EXPLRC1 must have one of the values that are shown in Table 234 during initialization.

*Table 234. Required values in EXPLRC1 during initialization*

| Value | Meaning                                           |
|-------|---------------------------------------------------|
| 0     | Initialization successful.                        |
| 12    | Unable to service request; don't call exit again. |

See "Exception processing" on page 1079 for an explanation of how the EXPLRC1 value affects DB2 processing.

*Return codes during termination:* DB2 does not check EXPLRC1 on return from the exit routine.

*Return codes during authorization check:* Make sure that EXPLRC1 has one of the values that are shown in Table 235 during the authorization check.

Table 235. Required values in EXPLRC1 during authorization check

| Value | Meaning                                                  |
|-------|----------------------------------------------------------|
| 0     | Access permitted.                                        |
| 4     | Unable to determine; perform DB2 authorization checking. |
| 8     | Access denied.                                           |
| 12    | Unable to service request; don't call exit again.        |

See "Exception processing" for an explanation of how the EXPLRC1 value affects DB2 processing. On authorization failures, the return code is included in the IFCID 0140 trace record.

## Handling reason codes

*Reason codes during initialization:* The reason code (EXPLRC2) that the exit routine returns after initialization determines how DB2 processes the return code (EXPLRC1) that the exit returns during initialization and authorization checking. The reason codes are shown in Table 236. See "Exception processing" for details.

Table 236. Reason codes during initialization

| Value | Meaning                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -1    | Identifies the default exit routine shipped with DB2. If you replace or modify the default exit, you should not use this value.                                                                                                                                                                                                                                                                |
| 16    | Indicates to DB2 that it should terminate if the exit routine returns EXPLRC1=12, an invalid EXPLRC1 or abnormally terminates during initialization or authorization checking. <b>When the exit routine sets the reason code to 16, DB2 does an immediate shutdown, without waiting for tasks to end.</b> For long-running tasks, an immediate shutdown can mean that recovery times are long. |
| Other | Ignored by DB2.                                                                                                                                                                                                                                                                                                                                                                                |

*Reason codes during authorization check:* Field EXPLRC2 lets you put in any code that would be of use in determining why the authorization check in the exit routine failed. On authorization failures, the reason code is included in the IFCID 0140 trace record.

## Exception processing

During initialization or authorization checking, DB2 issues diagnostic message DSNX210I to the operator's console, if one of the following conditions occur:

- The authorization exit returns a return code of 12 or an invalid return code.
- The authorization exit abnormally terminates.

Additional actions that DB2 performs depend on the reason code that the exit returns during initialization. Table 237 on page 1080 summarizes these actions.

Table 237. How an error condition affects DB2 actions during initialization and authorization checking

| Exit result                                                                                                                                | Reason code of 16 returned by exit routine during initialization                                                                                                                                                                                                                                               | Reason code other than 16 or -1 returned by exit routine during initialization <sup>1</sup>                                                                                                                                                                                                                                            |

On the eleventh abnormal termination, the exit stops and DB2 terminates.</p> | <p>You can use the subsystem parameter AEXITLIM to control how DB2 and the exit behave.</p> <p><b>Example:</b> If you set AEXITLIM to 10, the exit routine continues to run after the first 10 abnormal terminations. On the eleventh abnormal termination, the exit routine stops and DB2 switches to DB2 authorization checking.</p> |
| <b>Notes:</b>                                                                                                                              |                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                        |
| 1. During initialization, DB2 sets a value of -1 to identify the default exit. The user exit routine should not set the reason code to -1. |                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                        |
| 2. During initialization, the task is DB2 startup. During authorization checking, the task is the application.                             |                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                        |
| 3. AEXITLI (authorization exit limit) can be updated online. Refer to SET SYSPARM in <i>DB2 Command Reference</i> .                        |                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                        |

## Debugging the access control authorization routine

You can use IFCID 0314 to provide a trace record of the parameter list on return from the exit routine. You can activate this trace by turning on performance trace class 22.

## Determining whether the access control authorization routine is active

To determine whether the exit routine or DB2 is performing authorization checks, perform the following steps:

1. Start audit trace class 1.
2. Choose a DB2 table on which to issue a SELECT statement and an authorization ID to perform the SELECT. The authorization ID must not have the DB2 SELECT privilege or the external security system SELECT privilege on the table.

3. Use the authorization ID to issue a SELECT statement on the table. The SELECT statement should fail.
4. Format the trace data and examine the return code (QW0140RC) in the IFCID 0140 trace record.
  - QW0140RC = -1 indicates that DB2 performed the authorization check and denied access.
  - QW0140RC = 8 indicates that the external security system performed the authorization check and denied access.

---

## Edit routines

Edit routines are assigned to a table by the EDITPROC clause of CREATE TABLE. An edit routine receives the entire row of the base table in internal DB2 format; it can transform that row when it is stored by an INSERT or UPDATE SQL statement, or by the LOAD utility. It also receives the transformed row during retrieval operations and must change it back to its original form. Typical uses are to compress the storage representation of rows to save space on DASD and to encrypt the data.

You cannot use an edit routine on a table that contains a LOB or a ROWID column.

#  
#

You cannot use EDITPROC on a table with a column name that is longer than 18 EBCDIC bytes. If you do, you will receive an error message.

The transformation your edit routine performs on a row (possibly encryption or compression) is called *edit-encoding*. The same routine is used to undo the transformation when rows are retrieved; that operation is called *edit-decoding*.

**Important:** The edit-decoding function must be the exact inverse of the edit-encoding function. For example, if a routine encodes 'ALABAMA' to '01', it must decode '01' to 'ALABAMA'. A violation of this rule can lead to an abend of the DB2 connecting thread, or other undesirable effects.

Your edit routine can encode the entire row of the table, including any index keys. However, index keys are extracted from the row before the encoding is done, therefore, index keys are stored in the index in *edit-decoded* form. Hence, for a table with an edit routine, index keys in the table **are** edit-coded; index keys in the index **are not** edit-coded.

The sample application contains a sample edit routine, DSN8EAE1. To print it, use ISPF facilities, IEBTPCH, or a program of your own. Or, assemble it and use the assembly listing.

There is also a sample routine that does Huffman data compression, DSN8HUFF in library *prefix*.SDSNSAMP. That routine not only exemplifies the use of the exit parameters, it also has potentially some use for data compression. If you intend to use the routine in any production application, please pay particular attention to the warnings and restrictions given as comments in the code. You might prefer to let DB2 compress your data. For instructions, see "Compressing your data" on page 708.

"General considerations for writing exit routines" on page 1108 applies to edit routines.

## Specifying the edit routine routine

To name an edit routine for a table, use the EDITPROC clause of the CREATE TABLE statement, followed by the name of the routine. If you plan to use an edit routine, specify it when you create the table. In operation, the routine is loaded on demand.

You cannot add an edit routine to a table that already exists: you must drop the table and re-create it. Also, you cannot alter a table with an edit routine to add a column. Again, you must drop the table and re-create it, and presumably also alter the edit routine in some way to account for the new column.

## When the edit routine is taken

An edit routine is invoked to edit-code a row whenever DB2 inserts or updates one, including inserts made by the LOAD utility. It is invoked *after* any date routine, time routine, or field procedure. If there is also a validation routine, the edit routine is invoked **after** the validation routine. Any changes made to the row by the edit routine do not change entries made in an index.

The same edit routine is invoked to edit-decode a row whenever DB2 retrieves one. On retrieval, it is invoked *before* any date routine, time routine, or field procedure. If retrieved rows are sorted, the edit routine is invoked *before* the sort. An edit routine is not invoked for a DELETE operation without a WHERE clause that deletes an entire table in a segmented table space.

## Parameter lists for the edit routine

At invocation, registers are set as described in “Registers at invocation for exit routines” on page 1109, and the edit routine uses the standard exit parameter list (EXPL) described there. Table 238 shows the exit-specific parameter list, described by macro DSNDEDIT. Figure 150 on page 1083 shows how the parameter list points to other row information.

Table 238. Parameter list for an edit routine

| Name     | Hex offset | Data type             | Description                                                                                                                                         |
|----------|------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| EDITCODE | 0          | Signed 4-byte integer | Edit code telling the type of function to be performed, as follows:                                                                                 |
|          |            |                       | 0 Edit-encode row for insert or update                                                                                                              |
|          |            |                       | 4 Edit-decode row for retrieval                                                                                                                     |
| EDITROW  | 4          | Address               | Address of a row description. Its format is shown in Table 280 on page 1113.                                                                        |
|          | 8          | Signed 4-byte integer | Reserved                                                                                                                                            |
| EDITLTH  | C          | Signed 4-byte integer | Length of the input row                                                                                                                             |
| EDITPTR  | 10         | Address               | Address of the input row                                                                                                                            |
| EDITOLTH | 14         | Signed 4-byte integer | Length of output row. On entry, this is the size of the area in which to place the output row. The exit must not modify storage beyond this length. |
| EDITOPTR | 18         | Address               | Address of the output row                                                                                                                           |

## Processing requirements for edit routines

Your routine must be based on the DB2 data formats; see “Row formats for edit and validation routines” on page 1110.

## Incomplete rows and edit routines

Sometimes DB2 passes, to an edit routine, an input row that has fewer fields than there are columns in the table. In that case, the routine must stop processing the row after the last input field. Columns for which no input field is provided are always at the end of the row and are never defined as NOT NULL; either they allow nulls, they are defined as NOT NULL WITH DEFAULT, or the column is a ROWID column.

Use macro DSNDEDIT to get the starting address and row length for edit exits. Add the row length to the starting address to get the first invalid address beyond the end of the input buffer; your routine must *not* process any address as large as that.

Figure 150 shows how the parameter list points to other row information.

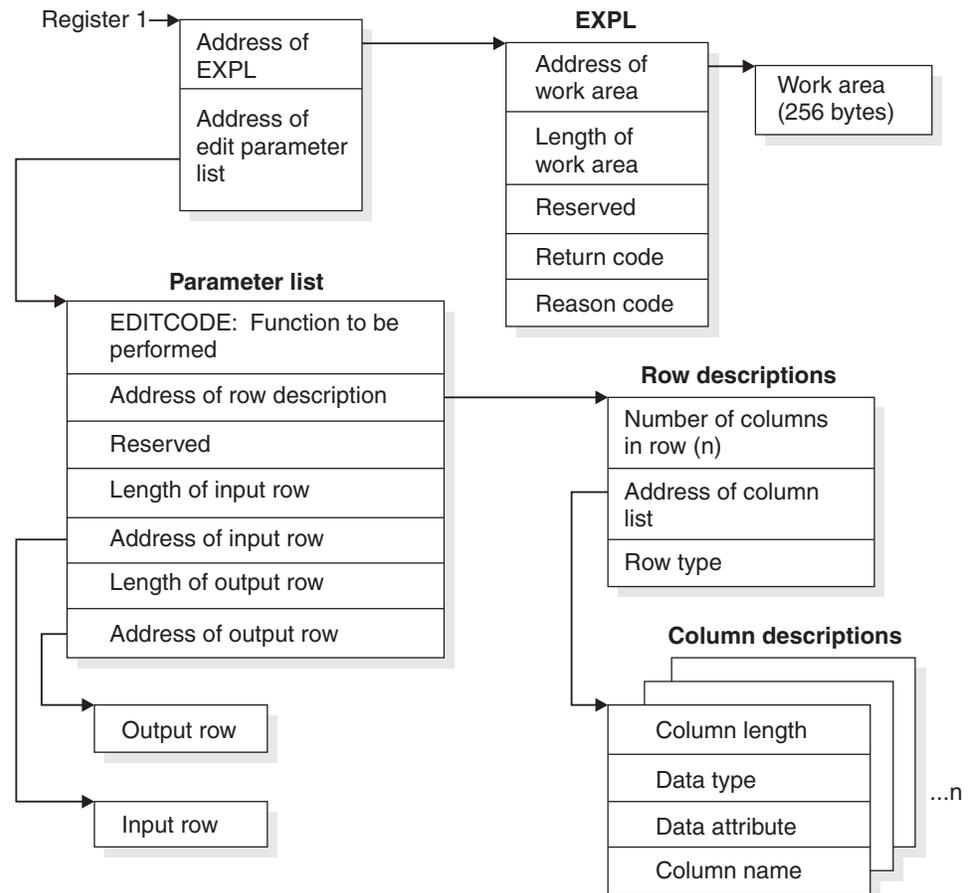

Figure 150. How the edit exit parameter list points to row information. The address of the  $n$ th column description is given by:  $RFMTAFLD + (n-1) \times (FFMTE - FFMTE)$ ; see “Parameter list for row format descriptions” on page 1112.

## Expected output for edit routines

If **EDITCODE** contains **0**, the input row is in decoded form. Your routine must encode it.

In that case, the maximum length of the output area, in **EDITOLTH**, is 10 bytes more than the maximum length of the record. In counting the maximum length, “record” includes fields for the lengths of **VARCHAR** and **VARGRAPHIC** columns, and for null indicators, but does not include the 6-byte record header.

If **EDITCODE** contains **4**, the input row is in coded form. Your routine must decode it.

In that case, **EDITOLTH** contains the maximum length of the record. As before, “record” includes fields for the lengths of **VARCHAR** and **VARGRAPHIC** columns, and for null indicators, but not the 6-byte record header.

**In either case**, put the result in the output area, pointed to by **EDITOPTR**, and put the length of your result in **EDITOLTH**. The length of your result must not be greater than the length of the output area, as given in **EDITOLTH** on invocation, and your routine must not modify storage beyond the end of the output area.

**Required return code:** Your routine must also leave a return code in **EXPLRC1**, with the meanings that are listed in Table 239:

Table 239. Required return code in **EXPLRC1**

| Value   | Meaning                          |
|---------|----------------------------------|
| 0       | Function performed successfully. |
| Nonzero | Function failed.                 |

If the function fails, the routine might also leave a reason code in **EXPLRC2**. DB2 returns **SQLCODE -652 (SQLSTATE '23506')** to the application program and puts the reason code in field **SQLERRD(6)** of the SQL communication area (**SQLCA**).

---

## Validation routines

Validation routines are assigned to a table by the **VALIDPROC** clause of **CREATE TABLE** and **ALTER TABLE**. A validation routine receives an entire row of a base table as input, and can return an indication of whether or not to allow a following **INSERT**, **UPDATE**, or **DELETE** operation. Typically, a validation routine is used to impose limits on the information that can be entered in a table; for example, allowable salary ranges, perhaps dependent on job category, for the employee sample table.

Although **VALIDPROC**s can be specified for a table that contains a **LOB** column, the **LOB** values are not passed to the validation routine. The indicator column takes the place of the **LOB** column.

# You cannot use **VALIDPROC** on a table with a column name that is longer than 18  
# EBCDIC bytes. If you do, you will receive an error message.

The return code from a validation routine is checked for a 0 value before any insert, update, or delete is allowed.

“General considerations for writing exit routines” on page 1108 applies to validation routines.

## Specifying the validation routine

To name a validation routine for a table, use the VALIDPROC clause of the CREATE TABLE or ALTER TABLE statement, followed by the name of the routine. In operation, the routine is loaded on demand.

You can add a validation routine to a table that is already in existence, but it is not invoked to validate data already in the table. You can also cancel any validation routine for a table, by using VALIDPROC NULL in an ALTER TABLE statement.

## When the validation routine is taken

A validation routine for a table is invoked when DB2 inserts or updates a row, including inserts made by the LOAD utility. The routine is invoked for most delete operations, including a mass delete of all the rows of a table made by a DELETE statement without a WHERE clause. If there are other exit routines, the validation routine is invoked *before* any edit routine, and *after* any date routine, time routine, or field procedure.

#  
#  
#

## Parameter lists for the validation routine

At invocation, registers are set as described in “Registers at invocation for exit routines” on page 1109, and the validation routine uses the standard exit parameter list (EXPL) described there. Table 240 shows the exit-specific parameter list, described by macro DSNDRVAL.

Table 240. Parameter list for a validation routine

| Name     | Hex offset | Data type               | Description                                                                                                     |
|----------|------------|-------------------------|-----------------------------------------------------------------------------------------------------------------|
|          | 0          | Signed 4-byte integer   | Reserved                                                                                                        |
| RVALROW  | 4          | Address                 | Address of a row description. The format of the row description is shown in Table 280 on page 1113.             |
|          | 8          | Signed 4-byte integer   | Reserved                                                                                                        |
| RVALROWL | C          | Signed 4-byte integer   | Length of the input row to be validated                                                                         |
| RVALROWP | 10         | Address                 | Address of the input row to be validated                                                                        |
|          | 14         | Signed 4-byte integer   | Reserved                                                                                                        |
|          | 18         | Signed 4-byte integer   | Reserved                                                                                                        |
| RVALPLAN | 1C         | Character, 8 bytes      | Name of the plan issuing the request                                                                            |
| RVALOPER | 24         | Unsigned 1-byte integer | Code identifying the operation being performed, as follows:<br>1 Insert, update, or load<br>2 Delete            |
| RVALFL1  | 25         | Character, 1 byte       | The high-order bit is on if the requester has installation SYSADM authority. The remaining 7 bits are reserved. |
| RVALCSTC | 26         | Character, 2 bytes      | Connection system type code. Values are defined in macro DSNDCSTC.                                              |

## Processing requirements for validation routines

Your routine must be based on the DB2 data formats; see “Row formats for edit and validation routines” on page 1110.

## Incomplete rows and validation routines

Sometimes DB2 passes, to a validation routine, an input row that has fewer fields than there are columns in the table. In that case, the routine must stop processing the row after the last input field. Columns for which no input field is provided are always at the end of the row and are never defined as NOT NULL; either they allow nulls, they are defined as NOT NULL WITH DEFAULT, or the column is a ROWID column.

Use macro DSNDRVAL to get the starting address and row length for validation exits. Add the row length to the starting address to get the first invalid address beyond the end of the input buffer; your routine must **not** process any address as large as that.

## Expected output for validation routines

Your routine must leave a return code in EXPLRC1, with the meanings that are listed in Table 241.

*Table 241. Required return code in EXPLRC1*

| Value   | Meaning                                |
|---------|----------------------------------------|
| 0       | Allow insert, update, or delete        |
| Nonzero | Do not allow insert, update, or delete |

If the operation is not allowed, the routine might also leave a reason code in EXPLRC2. DB2 returns SQLCODE -652 (SQLSTATE '23506') to the application program and puts the reason code in field SQLERRD(6) of the SQL communication area (SQLCA).

Figure 151 on page 1087 shows how the parameter list points to other information.

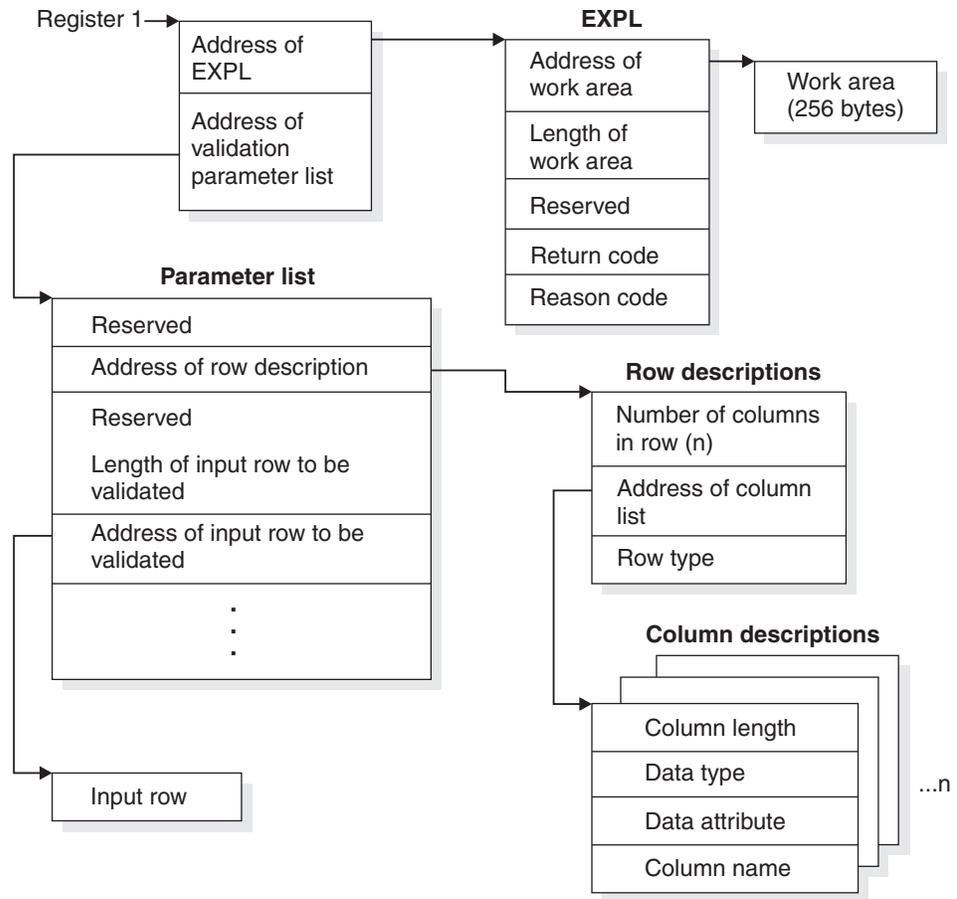

Figure 151. How a validation parameter list points to information. The address of the  $n$ th column description is given by:  $RFMTAFLD + (n-1) \times (FFMTE - FFMTE)$ ; see "Parameter list for row format descriptions" on page 1112.

## Date and time routines

A date routine is a user-written exit routine to change date values from a locally defined format into a format recognized by DB2, when loading or inserting them into a column with data type DATE; and from the ISO format into the locally-defined format, when retrieving the values and assigning them to a host variable. Similarly, a time routine changes time values from a locally-defined format into one recognized by DB2, and from ISO into the locally-defined format. Table 242 shows the formats recognized by DB2.

Table 242. Date and time formats

| Format name                                | Abbreviation | Typical date | Typical time |
|--------------------------------------------|--------------|--------------|--------------|
| IBM European standard                      | EUR          | 25.12.2004   | 13.30.05     |
| International Standards Organization       | ISO          | 2004-12-25   | 13.30.05     |
| Japanese Industrial Standard Christian Era | JIS          | 2004-12-25   | 13:30:05     |
| IBM USA standard                           | USA          | 12/25/2004   | 1:30 PM      |

**Example:** Suppose that you want to insert and retrieve dates in a format like “September 21, 1992”. You can use a date routine that transforms the date to a format that is recognized by DB2 on insertion, such as ISO: “2004-09-21”. On retrieval, the routine can transform “2004-09-21” to “September 21, 2004”.

You can have either a date routine, a time routine, or both. These routines do not apply to timestamps. Special rules apply if you execute queries at a remote DBMS, through the distributed data facility. For that case, see *DB2 SQL Reference*.

## Specifying the date and time routine

**To establish a date or time routine,** set LOCAL DATE LENGTH or LOCAL TIME LENGTH, when installing DB2, to the length of the longest field required to hold a date or time in your local format. Allowable values range from 10 to 254. For example, if you intend to insert and retrieve dates in the form “September 21, 2004”, then you need an 18-byte field. Set LOCAL DATE LENGTH to 18.

# Also, replace all of the IBM-supplied exit routines, using CSECTs DSNXVDTX,  
# DSNXVDTA, and DSNXVDTU for a date routine, and DSNXVTMX, DSNXVTMA,  
# and DSNXVTMU for a time routine. The routines are loaded when DB2 starts.

**To make the local date or time format the default for retrieval,** set DATE FORMAT or TIME FORMAT to LOCAL when installing DB2. That has the effect that DB2 *always* takes the exit routine when you retrieve from a DATE or TIME column. In our example, suppose that you want to retrieve dates in your local format only occasionally; most of the time you use the USA format. Set DATE FORMAT to USA.

The install parameters for LOCAL DATE LENGTH, LOCAL TIME LENGTH, DATE FORMAT, and TIME FORMAT can also be updated after DB2 is installed. For instructions, see Part 2 of *DB2 Installation Guide*. If you change a length parameter, you may have to rebind applications.

## When date and time routines are taken

**On insertion:** A date or time routine is invoked to change a value from the locally-defined format to a format recognized by DB2 in the following circumstances:

- When a date or time value is entered by an INSERT or UPDATE statement, or by the LOAD utility
- When a constant or host variable is compared to a column with a data type of DATE, TIME, or TIMESTAMP
- When the DATE or TIME scalar function is used with a string representation of a date or time in LOCAL format
- When a date or time value is supplied for a limit of a partitioned index in a CREATE INDEX statement

The exit is taken before any edit or validation routine.

- **If the default is LOCAL,** DB2 takes the exit immediately. If the exit routine does not recognize the data (EXPLRC1=8), DB2 then tries to interpret it as a date or time in one of the recognized formats (EUR, ISO JIS, or USA). DB2 rejects the data only if that interpretation also fails.
- **If the default is not LOCAL,** DB2 first tries to interpret the data as a date or time in one of the recognized formats. If that interpretation fails, DB2 then takes the exit routine, if it exists.

DB2 checks that the value supplied by the exit routine represents a valid date or time in some recognized format, and then converts it into an internal format for storage or comparison. If the value is entered into a column that is a key column in an index, the index entry is also made in the internal format.

**On retrieval:** A date or time routine can be invoked to change a value from ISO to the locally-defined format when a date or time value is retrieved by a SELECT or FETCH statement. If LOCAL is the default, the routine is always invoked unless overridden by a precompiler option or by the CHAR function, as by specifying CHAR(HIREDATE, ISO); that specification always retrieves a date in ISO format. If LOCAL is not the default, the routine is invoked only when specifically called for by CHAR, as in CHAR(HIREDATE, LOCAL); that always retrieves a date in the format supplied by your date exit routine.

On retrieval, the exit is invoked after any edit routine or DB2 sort. A date or time routine is not invoked for a DELETE operation without a WHERE clause that deletes an entire table in a segmented table space.

## Parameter lists for date and time routines

At invocation, registers are set as described in “Registers at invocation for exit routines” on page 1109, and the date or time routine uses the standard exit parameter list (EXPL) described there. Table 243 shows its exit-specific parameter list, described by macro DSNDDTXXP.

Table 243. Parameter list for a date or time routine

| Name    | Hex offset | Data type | Description                                                                                                                                                             |
|---------|------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DTXPFN  | 0          | Address   | Address of a 2-byte integer containing a function code. The codes and their meanings are:<br>4 Convert from local format to ISO.<br>8 Convert from ISO to local format. |
| DTXPLN  | 4          | Address   | Address of a 2-byte integer containing the length in bytes of the local format. This is the length given as LOCAL DATE LENGTH or LOCAL TIME LENGTH when installing DB2. |
| DTXPLOC | 8          | Address   | Address of the date or time value in local format                                                                                                                       |
| DTXPISO | C          | Address   | Address of the date or time value in ISO format (DTXPISO). The area pointed to is 10 bytes long for a date, 8 bytes for a time.                                         |

## Expected output for date and time routines

**If the function code is 4,** the input value is in local format, in the area pointed to by DTXPLOC. Your routine must change it to ISO, and put the result in the area pointed to by DTXPISO.

**If the function code is 8,** the input value is in ISO, in the area pointed to by DTXPISO. Your routine must change it to your local format, and put the result in the area pointed to by DTXPLOC.

Your routine must also leave a return code in EXPLRC1, a 4-byte integer and the third word of the EXPL area. The return code can have the meanings that are shown in Table 244 on page 1090.

Table 244. Required return code in EXPLRC1

| Value | Meaning                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | No errors; conversion was completed.                                                                                                                                                                      |
| 4     | Invalid date or time value.                                                                                                                                                                               |
| 8     | Input value not in valid format; if the function is insertion, and LOCAL is the default, DB2 next tries to interpret the data as a date or time in one of the recognized formats (EUR, ISO, JIS, or USA). |
| 12    | Error in exit routine.                                                                                                                                                                                    |

Figure 152 shows how the parameter list points to other information.

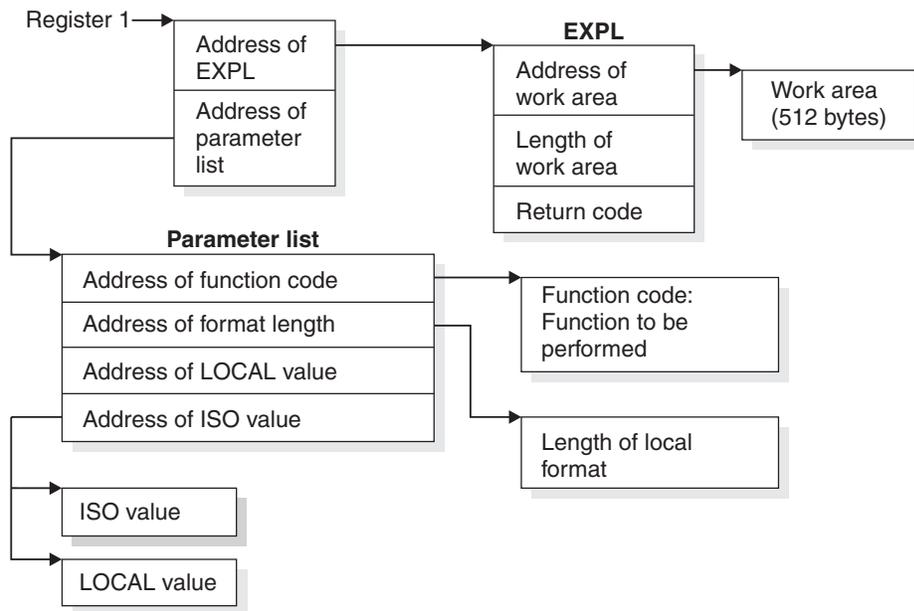

Figure 152. How a date or time parameter list points to other information

## Conversion procedures

A conversion procedure is a user-written exit routine that converts characters from one coded character set to another coded character set. (For a general discussion of character sets, and definitions of those terms, see Appendix A of *DB2 Installation Guide*.) In most cases, any conversion that is needed can be done by routines provided by IBM. The exit for a user-written routine is available to handle exceptions.

“General considerations for writing exit routines” on page 1108 applies to conversion routines.

## Specifying a conversion procedure

To establish a conversion procedure, insert a row into the catalog table SYSIBM.SYSSTRINGS. The row must contain values for the following columns:

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <b>INCCSID</b>  | The coded character set identifier (CCSID) of the source string. |
| <b>OUTCCSID</b> | The CCSID of the converted string.                               |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TRANSTYPE</b> | The nature of the conversion. Values can be:<br>GG ASCII GRAPHIC to EBCDIC GRAPHIC<br>MM EBCDIC MIXED to EBCDIC MIXED<br>MP EBCDIC MIXED to ASCII MIXED<br>MS EBCDIC MIXED to EBCDIC SBCS<br>PM ASCII MIXED to EBCDIC MIXED<br>PP ASCII MIXED to ASCII MIXED<br>PS ASCII MIXED to EBCDIC SBCS<br>SM EBCDIC SBCS to EBCDIC MIXED<br>SP SBCS (ASCII or EBCDIC) to ASCII MIXED<br>SS EBCDIC SBCS to EBCDIC SBCS |
| <b>TRANSPROC</b> | The name of your conversion procedure.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>IBMREQD</b>   | Must be N.                                                                                                                                                                                                                                                                                                                                                                                                   |

DB2 does not use the following columns, but checks them for the allowable values listed. Values you insert can be used by your routine in any way. If you insert no value in one of these columns, DB2 inserts the default value listed.

|                  |                                                                                         |
|------------------|-----------------------------------------------------------------------------------------|
| <b>ERRORBYTE</b> | Any character, or null. The default is null.                                            |
| <b>SUBBYTE</b>   | Any character not equal to the value of ERRORBYTE, or null. The default is null.        |
| <b>TRANSTAB</b>  | Any character string of length 256 or the empty string. The default is an empty string. |

## When conversion procedures are taken

The exit is taken, and your procedure invoked, whenever a conversion is required from the coded character set identified by INCCSID to the coded character set identified by OUTCCSID.

## Parameter lists for conversion procedures

At invocation, registers are set as described in “Registers at invocation for exit routines” on page 1109, and the conversion procedure uses the standard exit parameter list (EXPL) described there. A conversion procedure does *not* use an exit-specific parameter list, as described in “Parameter lists for exit routines” on page 1110. Instead, the area pointed to by register 1 at invocation includes three words, which contain the addresses of the following items:

1. The EXPL parameter list
2. A string value descriptor that contains the character string to be converted
3. A copy of a row from SYSIBM.SYSSTRINGS that names the conversion procedure identified in TRANSPROC.

The length of the work area pointed to by the exit parameter list is generally 512 bytes. However, if the string to be converted is ASCII MIXED data (the value of TRANSTYPE in the row from SYSSTRINGS is PM or PS), then the length of the work area is 256 bytes, plus the length attribute of the string.

*The string value descriptor:* The descriptor has the format shown in Table 245 on page 1092.

Table 245. Format of string value descriptor for a conversion procedure

| Name     | Hex offset | Data type             | Description                                                                                                                                                                                                             |      |       |    |         |    |            |
|----------|------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|----|---------|----|------------|
| FPVDTYPE | 0          | Signed 2-byte integer | Data type of the value:<br><br><table border="1"> <thead> <tr> <th>Code</th> <th>Means</th> </tr> </thead> <tbody> <tr> <td>20</td> <td>VARCHAR</td> </tr> <tr> <td>28</td> <td>VARGRAPHIC</td> </tr> </tbody> </table> | Code | Means | 20 | VARCHAR | 28 | VARGRAPHIC |
| Code     | Means      |                       |                                                                                                                                                                                                                         |      |       |    |         |    |            |
| 20       | VARCHAR    |                       |                                                                                                                                                                                                                         |      |       |    |         |    |            |
| 28       | VARGRAPHIC |                       |                                                                                                                                                                                                                         |      |       |    |         |    |            |
| FPVDVLEN | 2          | Signed 2-byte integer | The maximum length of the string                                                                                                                                                                                        |      |       |    |         |    |            |
| FPVDVALE | 4          | None                  | The string. The first halfword is the string's actual length in characters. If the string is ASCII MIXED data, it is padded out to the maximum length by undefined bytes.                                               |      |       |    |         |    |            |

*The row from SYSSTRINGS:* The row copied from the catalog table SYSIBM.SYSSTRINGS is in the standard DB2 row format described in "Row formats for edit and validation routines" on page 1110. The fields ERRORBYTE and SUBBYTE each include a null indicator. The field TRANSTAB is of varying length and begins with a 2-byte length field.

## Expected output for conversion procedures

Except in the case of certain errors, your conversion procedure should replace the string in FPVDVALE with the converted string. When converting MIXED data, your procedure must ensure that the result is well-formed. In any conversion, if you change the length of the string, you must set the length control field in FPVDVALE to the proper value. Over-writing storage beyond the maximum length of the FPVDVALE causes an abend.

Your procedure must also set a return code in field EXPLRC1 of the exit parameter list.

With the two codes that are shown in Table 246, provide the converted string in FPVDVALE.

Table 246. Codes for the converted string in FPVDVALE

| Code | Meaning                      |
|------|------------------------------|
| 0    | Successful conversion        |
| 4    | Conversion with substitution |

For the remaining codes that are shown in Table 247, DB2 does not use the converted string.

Table 247. Remaining codes for the FPVDVALE

| Code | Meaning            |
|------|--------------------|
| 8    | Length exception   |
| 12   | Invalid code point |
| 16   | Form exception     |
| 20   | Any other error    |
| 24   | Invalid CCSID      |

**Exception conditions:** Return a length exception (code 8) when the converted string is longer than the maximum length allowed.

For an invalid code point (code 12), place the 1- or 2-byte code point in field EXPLRC2 of the exit parameter list.

Return a form exception (code 16) for EBCDIC MIXED data when the source string does not conform to the rules for MIXED data.

Any other uses of codes 8 and 16, or of EXPLRC2, are optional.

**Error conditions:** On return, DB2 considers any of the following conditions as a “conversion error”:

- EXPLRC1 is greater than 16.
- EXPLRC1 is 8, 12, or 16 and the operation that required the conversion is *not* an assignment of a value to a host variable with an indicator variable.
- FPVDTYPE or FPVDVLEN has been changed.
- The length control field of FPVDVALE is greater than the original value of FPVDVLEN or is negative.

In the case of a conversion error, DB2 sets the SQLERRMC field of the SQLCA to HEX(EXPLRC1) CONCAT X'FF' CONCAT HEX(EXPLRC2).

Figure 153 shows how the parameter list points to other information.

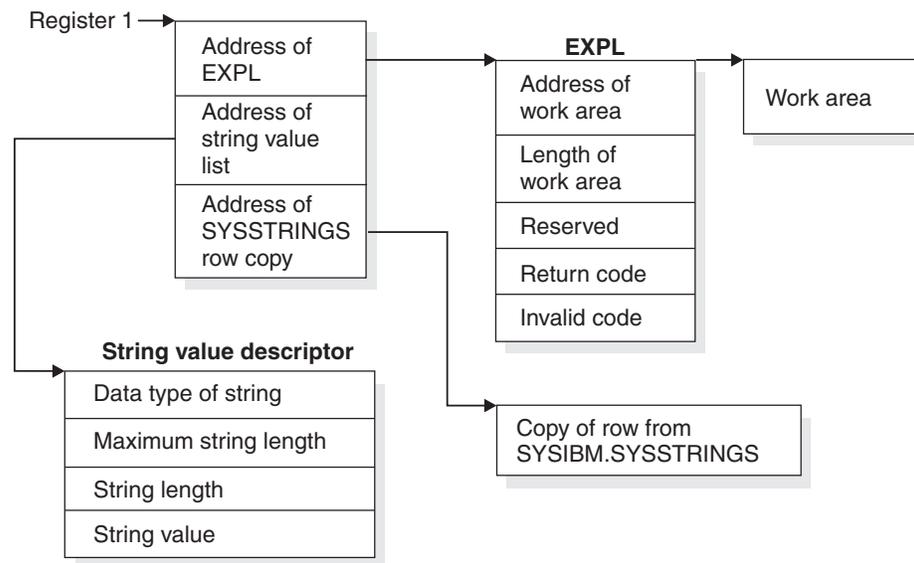

Figure 153. Pointers at entry to a conversion procedure

## Field procedures

Field procedures are assigned to a table by the FIELDPROC clause of CREATE TABLE and ALTER TABLE. A field procedure is a user-written exit routine to transform values in a single short-string column. When values in the column are changed, or new values inserted, the field procedure is invoked for each value, and can transform that value (encode it) in any way. The encoded value is then stored. When values are retrieved from the column, the field procedure is invoked for each value, which is encoded, and must decode it back to the original string value.

Any indexes, including partitioned indexes, defined on a column that uses a field procedure are built with encoded values. For a partitioned index, the encoded value of the limit key is put into the LIMITKEY column of the SYSINDEXPART table. Hence, a field procedure might be used to alter the sorting sequence of values entered in a column. For example, telephone directories sometimes require that names like “McCabe” and “MacCabe” appear next to each other, an effect that the standard EBCDIC sorting sequence does not provide. And languages that do not use the Roman alphabet have similar requirements. However, if a column is provided with a suitable field procedure, it can be correctly ordered by ORDER BY.

The transformation your field procedure performs on a value is called *field-encoding*. The same routine is used to undo the transformation when values are retrieved; that operation is called *field-decoding*. Values in columns with a field procedure are described to DB2 in two ways:

1. The description of the column as defined in CREATE TABLE or ALTER TABLE appears in the catalog table SYSIBM.SYSCOLUMNS. That is the description of the field-decoded value, and is called the *column description*.
2. The description of the encoded value, as it is stored in the data base, appears in the catalog table SYSIBM.SYSFIELDS. That is the description of the field-encoded value, and is called the *field description*.

**Important:** The field-decoding function must be the exact inverse of the field-encoding function. For example, if a routine encodes 'ALABAMA' to '01', it must decode '01' to 'ALABAMA'. A violation of this rule can lead to an abend of the DB2 connecting thread, or other undesirable effects.

“General considerations for writing exit routines” on page 1108 applies to field procedures.

## Field definition for field procedures

The field procedure is also invoked when the table is created or altered, to define the data type and attributes of an encoded value to DB2; that operation is called *field-definition*. The data type of the encoded value can be any valid SQL data type except DATE, TIME, TIMESTAMP, LONG VARCHAR, or LONG VARGRAPHIC; the allowable types are listed in the description of field FPVDTYPE in Table 250 on page 1099. The length, precision, or scale of the encoded value must be compatible with its data type.

A user-defined data type can be a valid field if the source type of the data type is a short string column that has a null default value. DB2 casts the value of the column to the source type before it passes it to the field procedure.

## Specifying the field procedure

To name a field procedure for a column, use the FIELDPROC clause of the CREATE TABLE or ALTER TABLE statement, followed by the name of the procedure and, optionally, a list of parameters. You can use a field procedure only with a short string column. You cannot use a field procedure on a column defined using NOT NULL WITH DEFAULT.

If you plan to use a field procedure, specify it when you create the table. In operation, the procedure is loaded on demand. You cannot add a field procedure to an existing column of a table; you can, however, use ALTER TABLE to add to an existing table a new column that uses a field procedure.

You cannot use a field procedure on a LOB or a ROWID column. Field procedures can be specified for other columns of a table that contains a LOB or ROWID column.

#  
#

You cannot use a field procedure on a column if the column name is longer than 18 EBCDIC bytes. If you do, you will receive an error message.

The optional parameter list that follows the procedure name is a list of constants, enclosed in parentheses, called the *literal list*. The literal list is converted by DB2 into a data structure called the *field procedure parameter value list* (FPPVL). That structure is passed to the field procedure during the field-definition operation. At that time, the procedure can modify it or return it unchanged. The output form of the FPPVL is called the *modified FPPVL*; it is stored in the DB2 catalog as part of the field description. The modified FPPVL is passed again to the field procedure whenever that procedure is invoked for field-encoding or field-decoding.

## When field procedures are taken

A field procedure specified for a column is invoked in three general situations:

1. **For field-definition**, when the CREATE TABLE or ALTER TABLE statement that names the procedure is executed. During this invocation, the procedure is expected to:
  - Determine whether the data type and attributes of the column are valid.
  - Verify the literal list, and change it if wanted.
  - Provide the field description of the column.
  - Define the amount of working storage needed by the field-encoding and field-decoding processes.
2. **For field-encoding**, when a column value is to be field-encoded. That occurs for any value that:
  - Is inserted in the column by an SQL INSERT statement, or loaded by the DB2 LOAD utility.
  - Is changed by an SQL UPDATE statement.
  - Is compared to a column with a field procedure, unless the comparison operator is LIKE. The value being encoded is a host variable or constant. (When the comparison operator is LIKE, the column value is decoded.)
  - Defines the limit of a partition of an index. The value being encoded follows ENDING AT in the PARTITION clause of CREATE INDEX.

|  
|

If there are any other exit routines, the field procedure is invoked *before* any of them.

3. **For field-decoding**, when a stored value is to be field-decoded back into its original string value. This occurs for any value that is:
  - Retrieved by an SQL SELECT or FETCH statement, or by the unload phase of the REORG utility.
  - Compared to another value with the LIKE comparison operator. The value being decoded is from the column that uses the field procedure.

In this case, the field procedure is invoked *after* any edit routine or DB2 sort.

A field procedure is never invoked to process a null value, nor for a DELETE operation without a WHERE clause on a table in a segmented table space.

**A warning about blanks:** When DB2 compares the values of two strings with different lengths, it temporarily pads the shorter string with blanks (in EBCDIC or

double-byte characters, as needed) up to the length of the longer string. If the shorter string is the value of a column with a field procedure, the padding is done to the encoded value, but the pad character is **not** encoded. Therefore, if the procedure changes blanks to some other character, encoded blanks at the end of the longer string are not equal to padded blanks at the end of the shorter string. That situation can lead to errors; for example, some strings that ought to be equal might not be recognized as such. Therefore, encoding blanks in a field procedure is not recommended.

## **Control blocks for execution of field procedures**

This section describes certain control blocks that are used to communicate to a field procedure:

- “The field procedure parameter list (FPPL)”
- “The work area for field procedures” on page 1097
- “The field procedure information block (FPIB)” on page 1097
- “The field procedure parameter value list (FPPVL)” on page 1098
- “Value descriptors for field procedures” on page 1098

Next, this section describes specific requirements for the three operations of field-definition:

- “Field-definition (function code 8)” on page 1099
- “Field-encoding (function code 0)” on page 1102
- “Field-decoding (function code 4)” on page 1103

The contents of registers at invocation and at exit are different for each of those operations, and are described with the requirements for the operations.

### **The field procedure parameter list (FPPL)**

The field procedure parameter list is pointed to by register 1 on entry to a field procedure. It, in turn, contains the addresses of five other areas, as shown in Figure 154 on page 1097. Those areas are described in the following pages. The FPPL and the areas it points to are all described by the mapping macro DSNDFPFB.

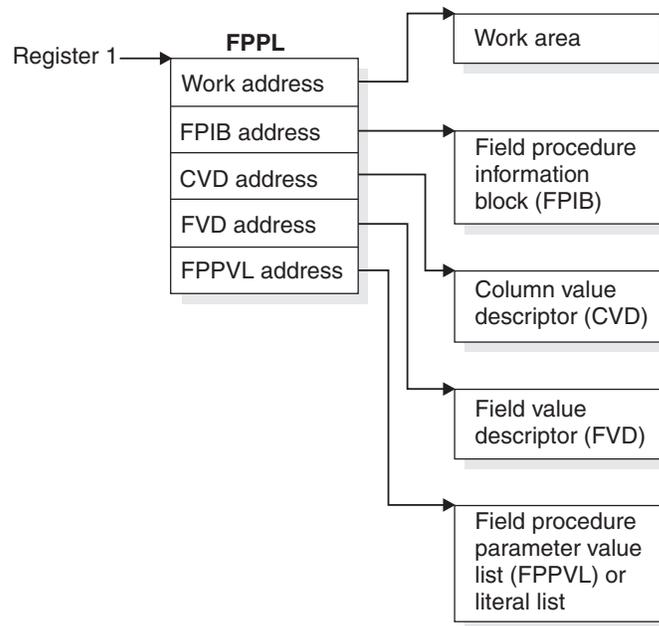

Figure 154. Field procedure parameter list

### The work area for field procedures

The work area is a contiguous, uninitialized area of locally addressable, pageable, swappable, and fetch-protected storage that is obtained in storage key 7 and subpool 229.

The work area can be used by a field procedure as working storage. A new area is provided each time the procedure is invoked. The size of the area that you need depends on the way you program your field-encoding and field-decoding operations.

At field-definition time, DB2 allocates a 512-byte work area and passes the value of 512 bytes as the work area size to your routine for the field-definition operation. If subsequent field-encoding and field-decoding operations need a work area of 512 bytes or less, your field definition doesn't need to change the value as provided by DB2. If those operations need a work area larger than 512 bytes (i.e. 1024 bytes), your field definition must change the work area size to the larger size and pass it back to DB2 for allocation.

Whenever your field procedure is invoked for encoding or decoding operations, DB2 allocates a work area based on the size (i.e. 1024 bytes) that was passed back to it. Your field definition must not use a work area larger than what is allocated by DB2, even though subsequent operations need the larger work area.

### The field procedure information block (FPIB)

The field procedure information block communicates general information to a field procedure. For example, it tells what operation is to be done, allows the field procedure to signal errors, and gives the size of the work area.

It has the format shown in Table 248.

Table 248. Format of FPIB, defined in copy macro DSNDFPPB

| Name     | Hex offset | Data type             | Description                                                                                                              |
|----------|------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------|
| FPBFCD   | 0          | Signed 2-byte integer | Function code                                                                                                            |
|          |            |                       | <b>Code</b> <b>Means</b>                                                                                                 |
|          |            |                       | 0        Field-encoding                                                                                                  |
|          |            |                       | 4        Field-decoding                                                                                                  |
|          |            |                       | 8        Field-definition                                                                                                |
| FPBWKLN  | 2          | Signed 2-byte integer | Length of work area; the maximum is 32767 bytes.                                                                         |
| FPBSORC  | 4          | Signed 2-byte integer | Reserved                                                                                                                 |
| FPBRTNC  | 6          | Character, 2 bytes    | Return code set by field procedure                                                                                       |
| FPBRNSCD | 8          | Character, 4 bytes    | Reason code set by field procedure                                                                                       |
| FPBTOKPT | C          | Address               | Address of a 40-byte area, within the work area or within the field procedure's static area, containing an error message |

### The field procedure parameter value list (FPPVL)

The field procedure parameter value list communicates the literal list, supplied in the CREATE TABLE or ALTER TABLE statement, to the field procedure during field-definition. At that time the field procedure can reformat the FPPVL; it is the reformatted FPPVL that is stored in SYSIBM.SYSFIELDS and communicated to the field procedure during field-encoding and field-decoding as the *modified FPPVL*.

The FPPVL has the format shown in Table 249.

Table 249. Format of FPPVL, defined in copy macro DSNDFPPB

| Name    | Hex offset | Data type             | Description                                                                                                                                                                                                                                                                            |
|---------|------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FPPVLEN | 0          | Signed 2-byte integer | Length in bytes of the area containing FPPVCNT and FPPVDS. At least 254 for field-definition.                                                                                                                                                                                          |
| FPPVCNT | 2          | Signed 2-byte integer | Number of value descriptors that follow, equal to the number of parameters in the FIELDPROC clause. Zero if no parameters were listed.                                                                                                                                                 |
| FPPVDS  | 4          | Structure             | For each parameter in the FIELDPROC clause, there is: <ol style="list-style-type: none"> <li>1. A signed 4-byte integer giving the length of the following value descriptor, which includes the lengths of FPVDTYPE, FPVDVLEN, and FPVDVALE.</li> <li>2. A value descriptor</li> </ol> |

### Value descriptors for field procedures

A value descriptor describes the data type and other attributes of a value. Value descriptors are used with field procedures in these ways:

- During field-definition, they describe each constant in the field procedure parameter value list (FPPVL). The set of these value descriptors is part of the FPPVL control block.
- During field-encoding and field-decoding, the decoded (column) value and the encoded (field) value are described by the column value descriptor (CVD) and the field value descriptor (FVD).

The *column value descriptor (CVD)* contains a description of a column value and, if appropriate, the value itself. During field-encoding, the CVD describes the value to be encoded. During field-decoding, it describes the decoded value to be supplied by the field procedure. During field-definition, it describes the column as defined in the CREATE TABLE or ALTER TABLE statement.

The *field value descriptor (FVD)* contains a description of a field value and, if appropriate, the value itself. During field-encoding, the FVD describes the encoded value to be supplied by the field procedure. During field-decoding, it describes the value to be decoded. Field-definition must put into the FVD a description of the encoded value.

Value descriptors have the format shown in Table 250.

Table 250. Format of value descriptors

| Name     | Hex offset | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |      |       |   |         |   |          |   |       |    |         |    |      |    |         |    |         |    |            |
|----------|------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|---|---------|---|----------|---|-------|----|---------|----|------|----|---------|----|---------|----|------------|
| FPVDTYPE | 0          | Signed 2-byte integer | Data type of the value:<br><table border="1"> <thead> <tr> <th>Code</th> <th>Means</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>INTEGER</td> </tr> <tr> <td>4</td> <td>SMALLINT</td> </tr> <tr> <td>8</td> <td>FLOAT</td> </tr> <tr> <td>12</td> <td>DECIMAL</td> </tr> <tr> <td>16</td> <td>CHAR</td> </tr> <tr> <td>20</td> <td>VARCHAR</td> </tr> <tr> <td>24</td> <td>GRAPHIC</td> </tr> <tr> <td>28</td> <td>VARGRAPHIC</td> </tr> </tbody> </table> | Code | Means | 0 | INTEGER | 4 | SMALLINT | 8 | FLOAT | 12 | DECIMAL | 16 | CHAR | 20 | VARCHAR | 24 | GRAPHIC | 28 | VARGRAPHIC |

| FPVDVLEN | 2          | Signed 2-byte integer | <ul style="list-style-type: none"> <li>• For a varying-length string value, its maximum length</li> <li>• For a decimal number value, its precision (byte 1) and scale (byte 2)</li> <li>• For any other value, its length</li> </ul>                                                                                                                                                                                                                        |      |       |   |         |   |          |   |       |    |         |    |      |    |         |    |         |    |            |
| FPVDVALE | 4          | None                  | The value. The value is in external format, not DB2 internal format. If the value is a varying-length string, the first halfword is the value's actual length in bytes. This field is not present in a CVD, or in an FVD used as input to the field-definition operation. An empty varying-length string has a length of zero with no data following.                                                                                                        |      |       |   |         |   |          |   |       |    |         |    |      |    |         |    |         |    |            |

## Field-definition (function code 8)

The input provided to the field-definition operation, and the output required, are as follows:

## On entry

The **registers** have the information that is listed in Table 251:

Table 251. Contents of the registers on entry

| Register     | Contains                                                                                                   |
|--------------|------------------------------------------------------------------------------------------------------------|
| 1            | Address of the field procedure parameter list (FPPL); see Figure 154 on page 1097 for a schematic diagram. |
| 2 through 12 | Unknown values that must be restored on exit.                                                              |
| 13           | Address of the register save area.                                                                         |
| 14           | Return address.                                                                                            |
| 15           | Address of entry point of exit routine.                                                                    |

The contents of all other registers, and of fields not listed in the following tables, are unpredictable.

The **work area** consists of 512 contiguous uninitialized bytes.

The **FPIB** has the information that is listed in Table 252:

Table 252. Contents of the FPIB on entry

| Field    | Contains                         |
|----------|----------------------------------|
| FPBFCODE | 8, the function code             |
| FPBWKLN  | 512, the length of the work area |

The **CVD** has the information that is listed in Table 253:

Table 253. Contents of the CVD on entry

| Field    | Contains                                                                                                                                                                                                                                                                                                  |      |       |    |      |    |         |    |         |    |            |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|----|------|----|---------|----|---------|----|------------|
| FPVDTYPE | One of these codes for the data type of the column value:<br><table border="1"><thead><tr><th>Code</th><th>Means</th></tr></thead><tbody><tr><td>16</td><td>CHAR</td></tr><tr><td>20</td><td>VARCHAR</td></tr><tr><td>24</td><td>GRAPHIC</td></tr><tr><td>28</td><td>VARGRAPHIC</td></tr></tbody></table> | Code | Means | 16 | CHAR | 20 | VARCHAR | 24 | GRAPHIC | 28 | VARGRAPHIC |
| Code     | Means                                                                                                                                                                                                                                                                                                     |      |       |    |      |    |         |    |         |    |            |
| 16       | CHAR                                                                                                                                                                                                                                                                                                      |      |       |    |      |    |         |    |         |    |            |
| 20       | VARCHAR                                                                                                                                                                                                                                                                                                   |      |       |    |      |    |         |    |         |    |            |
| 24       | GRAPHIC                                                                                                                                                                                                                                                                                                   |      |       |    |      |    |         |    |         |    |            |
| 28       | VARGRAPHIC                                                                                                                                                                                                                                                                                                |      |       |    |      |    |         |    |         |    |            |
| FPVDVLEN | The length attribute of the column                                                                                                                                                                                                                                                                        |      |       |    |      |    |         |    |         |    |            |

The FPVDVALE field is omitted.

The **FVD** provided is 4 bytes long.

The **FPPVL** has the information that is listed in Table 254:

Table 254. Contents of the FPPVL on entry

| Field   | Contains                                                                                                                          |
|---------|-----------------------------------------------------------------------------------------------------------------------------------|
| FPPVLEN | The length, in bytes, of the area containing the parameter value list. The minimum value is 254, even if there are no parameters. |
| FPPVCNT | The number of value descriptors that follow; zero if there are no parameters.                                                     |

Table 254. Contents of the FPPVL on entry (continued)

| Field   | Contains                                                                                                                           |
|---------|------------------------------------------------------------------------------------------------------------------------------------|
| FPPVVDS | A contiguous set of value descriptors, one for each parameter in the parameter value list, each preceded by a 4-byte length field. |

## On exit

The registers must have the information that is listed in Table 255:

Table 255. Contents of the registers on exit

| Register     | Contains                                                                                                                           |
|--------------|------------------------------------------------------------------------------------------------------------------------------------|
| 2 through 12 | The values that they contained on entry.                                                                                           |
| 15           | The integer zero if the column described in the CVD is valid for the field procedure; otherwise the value must <i>not</i> be zero. |

The following fields must be set as shown; all other fields must remain as on entry.

The FPIB must have the information that is listed in Table 256:

Table 256. Contents of the FPIB on exit

| Field   | Contains                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| FPBWKLN | The length, in bytes, of the work area to be provided to the field-encoding and field-decoding operations; 0 if no work area is required.           |
| FPBRTNC | An optional 2-byte character return code, defined by the field procedure; blanks if no return code is given.                                        |
| FPBRSNC | An optional 4-byte character reason code, defined by the field procedure; blanks if no reason code is given.                                        |
| FPBTOKP | Optionally, the address of a 40-byte error message residing in the work area or in the field procedure's static area; zeros if no message is given. |

Errors signalled by a field procedure result in SQLCODE -681 (SQLSTATE '23507'), which is set in the SQL communication area (SQLCA). The contents of FPBRTNC and FPBRSNC, and the error message pointed to by FPBTOKP, are also placed into the tokens, in SQLCA, as field SQLERRMT. The meaning of the error message is determined by the field procedure.

The FVD must have the information that is listed in Table 257:

Table 257. Contents of the FVD on exit

| Field    | Contains                                                                                                                |
|----------|-------------------------------------------------------------------------------------------------------------------------|
| FPVDTYPE | The numeric code for the data type of the field value. Any of the data types listed in Table 250 on page 1099 is valid. |
| FPVDVLEN | The length of the field value.                                                                                          |

Field FPVDVALE must not be set; the length of the FVD is 4 bytes only.

The FPPVL can be redefined to suit the field procedure, and returned as the *modified FPPVL*, subject to the following restrictions:

- The field procedure must not increase the length of the FPPVL.

- FPPVLEN must contain the actual length of the modified FPPVL, or 0 if no parameter list is returned.

The modified FPPVL is recorded in the catalog table SYSIBM.SYSFIELDS, and is passed again to the field procedure during field-encoding and field-decoding. The modified FPPVL need not have the format of a field procedure parameter list, and it need not describe constants by value descriptors.

## Field-encoding (function code 0)

The input provided to the field-encoding operation, and the output required, are as follows:

### On entry

The **registers** have the information that is listed in Table 258:

*Table 258. Contents of the registers on entry*

| Register     | Contains                                                                                                   |
|--------------|------------------------------------------------------------------------------------------------------------|
| 1            | Address of the field procedure parameter list (FPPL); see Figure 154 on page 1097 for a schematic diagram. |
| 2 through 12 | Unknown values that must be restored on exit.                                                              |
| 13           | Address of the register save area.                                                                         |
| 14           | Return address.                                                                                            |
| 15           | Address of entry point of exit routine.                                                                    |

The contents of all other registers, and of fields not listed, are unpredictable.

The **work area** is contiguous, uninitialized, and of the length specified by the field procedure during field-definition.

The **FPIB** has the information that is listed in Table 259:

*Table 259. Contents of the FPIB on entry*

| Field    | Contains                    |
|----------|-----------------------------|
| FPBFCODE | 0, the function code        |
| FPBWKLN  | The length of the work area |

The **CVD** has the information that is listed in Table 260:

*Table 260. Contents of the CVD on entry*

| Field    | Contains                                                                                           |
|----------|----------------------------------------------------------------------------------------------------|
| FPVDTYPE | The numeric code for the data type of the column value, as shown in Table 250 on page 1099.        |
| FPVDVLEN | The length of the column value.                                                                    |
| FPVDVALE | The column value; if the value is a varying-length string, the first halfword contains its length. |

The **FVD** has the information that is listed in Table 261:

Table 261. Contents of the **FVD** on entry

| Field    | Contains                                                             |
|----------|----------------------------------------------------------------------|
| FPVDTYPE | The numeric code for the data type of the field value.               |
| FPVDVLEN | The length of the field value.                                       |
| FPVDVALE | An area of unpredictable content that is as long as the field value. |

The *modified* **FPPVL**, produced by the field procedure during field-definition, is provided.

### On exit

The **registers** have the information that is listed in Table 262:

Table 262. Contents of the registers on exit

| Register     | Contains                                                                                                                           |
|--------------|------------------------------------------------------------------------------------------------------------------------------------|
| 2 through 12 | The values that they contained on entry.                                                                                           |
| 15           | The integer zero if the column described in the <b>CVD</b> is valid for the field procedure; otherwise the value must not be zero. |

The **FVD** must contain the encoded (field) value in field **FPVDVALE**. If the value is a varying-length string, the first halfword must contain its length.

The **FPIB** can have the information that is listed in Table 263:

Table 263. Contents of the **FPIB** on exit

| Field   | Contains                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| FPBRTNC | An optional 2-byte character return code, defined by the field procedure; blanks if no return code is given.                                        |
| FPBRSNC | An optional 4-byte character reason code, defined by the field procedure; blanks if no reason code is given.                                        |
| FPBTOKP | Optionally, the address of a 40-byte error message residing in the work area or in the field procedure's static area; zeros if no message is given. |

Errors signalled by a field procedure result in **SQLCODE** -681 (**SQLSTATE** '23507'), which is set in the **SQL** communication area (**SQLCA**). The contents of **FPBRTNC** and **FPBRSNC**, and the error message pointed to by **FPBTOKP**, are also placed into the tokens, in **SQLCA**, as field **SQLERRMT**. The meaning of the error message is determined by the field procedure.

All other fields must remain as on entry.

## Field-decoding (function code 4)

The input provided to the field-decoding operation, and the output required, are as follows:

## On entry

The **registers** have the information that is listed in Table 264:

Table 264. Contents of the registers on entry

| Register     | Contains                                                                                                   |
|--------------|------------------------------------------------------------------------------------------------------------|
| 1            | Address of the field procedure parameter list (FPPL); see Figure 154 on page 1097 for a schematic diagram. |
| 2 through 12 | Unknown values that must be restored on exit.                                                              |
| 13           | Address of the register save area.                                                                         |
| 14           | Return address.                                                                                            |
| 15           | Address of entry point of exit routine.                                                                    |

The contents of all other registers, and of fields not listed, are unpredictable.

The **work area** is contiguous, uninitialized, and of the length specified by the field procedure during field-definition.

The **FPIB** has the information that is listed in Table 265:

Table 265. Contents of the FPIB on entry

| Field  | Contains                    |
|--------|-----------------------------|
| FPBFCD | 4, the function code        |
| FPBWKL | The length of the work area |

The **CVD** has the information that is listed in Table 266:

Table 266. Contents of the CVD on entry

| Field    | Contains                                                                                           |
|----------|----------------------------------------------------------------------------------------------------|
| FPVDTYPE | The numeric code for the data type of the column value, as shown in Table 250 on page 1099.        |
| FPVDVLEN | The length of the column value.                                                                    |
| FPVDVALE | The column value. If the value is a varying-length string, the first halfword contains its length. |

The **FVD** has the information that is listed in Table 267:

Table 267. Contents of the FVD on entry

| Field    | Contains                                                                                          |
|----------|---------------------------------------------------------------------------------------------------|
| FPVDTYPE | The numeric code for the data type of the field value.                                            |
| FPVDVLEN | The length of the field value.                                                                    |
| FPVDVALE | The field value. If the value is a varying-length string, the first halfword contains its length. |

The *modified* FPPVL, produced by the field procedure during field-definition, is provided.

## On exit

The **registers** have the information that is listed in Table 268:

Table 268. Contents of the registers on exit

| Register     | Contains                                                                                                                    |
|--------------|-----------------------------------------------------------------------------------------------------------------------------|
| 2 through 12 | The values they contained on entry.                                                                                         |
| 15           | The integer zero if the column described in the FVD is valid for the field procedure; otherwise the value must not be zero. |

The **CVD** must contain the decoded (column) value in field FPVDVALE. If the value is a varying-length string, the first halfword must contain its length.

The **FPIB** can have the information that is listed in Table 269:

Table 269. Contents of the FPIB on exit

| Field   | Contains                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| FPBRTNC | An optional 2-byte character return code, defined by the field procedure; blanks if no return code is given.                                        |
| FPBRSNC | An optional 4-byte character reason code, defined by the field procedure; blanks if no reason code is given.                                        |
| FPBTOKP | Optionally, the address of a 40-byte error message residing in the work area or in the field procedure's static area; zeros if no message is given. |

Errors signalled by a field procedure result in **SQLCODE** -681 (**SQLSTATE** '23507'), which is set in the **SQL** communication area (**SQLCA**). The contents of **FPBRTNC** and **FPBRSNC**, and the error message pointed to by **FPBTOKP**, are also placed into the tokens, in **SQLCA**, as field **SQLERRMT**. The meaning of the error message is determined by the field procedure.

All other fields must remain as on entry.

---

## Log capture routines

A log capture exit routine makes **DB2** log data available for recovery purposes in real time. The routine receives data when **DB2** writes data to the active log. Your local specifications determine what the routine does with that data. The routine does not enter or return data to **DB2**.

**Performance factor:** Your log capture routine receives control often. Design it with care: a poorly designed routine can seriously degrade system performance. Whenever possible, use the instrumentation facility interface (IFI), rather than a log capture exit routine, to read data from the log. For instructions, see "Reading log records with IFI" on page 1126.

"General considerations for writing exit routines" on page 1108 applies, but with the following exceptions to the description of execution environments:

A log capture routine can execute in either **TCB** mode or **SRB** mode, depending on the function it is performing. When in **SRB** mode, it must not perform any I/O operations nor invoke any **SVC** services or **ESTAE** routines.

## Specifying the log capture routine

The module name for the routine is **DSNJL004**. Its entry point is **DSNJW117**.

The module is loaded during DB2 initialization and deleted during DB2 termination. You must link the module into either the *prefix.SDSNEXIT* or the DB2 *prefix.SDSNLOAD* library. Specify the REPLACE parameter of the link-edit job to replace a module that is part of the standard DB2 library for this release. The module should have attributes AMODE(31) and RMODE(ANY).

## When log capture routines are taken

The log capture exit is taken in three possible situations, identified by a character in the exit parameter list. In two of those situations, processing operates in TCB mode; in one situation, processing operates in SRB mode. The two modes have different processing capabilities, which your routine must be aware of. The character identifications, situations, and modes are:

- I=Initialization, Mode=TCB

The TCB mode allows all z/OS DFSMSdfp functions to be utilized, including ENQ, ALLOCATION, and OPEN. No buffer addresses are passed in this situation. The routine runs in supervisor state, key 7, and enabled.

This is the **only** situation in which DB2 checks a return code from the user's log capture exit routine. The DB2 subsystem is sensitive to a return code of X'20' here. **Never return X'20'** in register 15 in this situation.

- W=Write, Mode=SRB (service request block)

The SRB mode restricts the exit routine's processing capabilities. No supervisor call (SVC) instructions can be used, including ALLOCATION, OPEN, WTO, any I/O instruction, and so on. At the exit point, DB2 is running in supervisor state, key 7, and is enabled.

Upon entry, the exit routine has access to buffers that have log control intervals with "blocked log records". The first and last buffer address and control interval size fields can be used to determine how many buffers are being passed.

See *z/OS MVS Programming: Authorized Assembler Services Guide* for additional material on SRB-mode processing.

**Performance warning:** All processing time required by the exit routine lengthens the time required to write the DB2 log. The DB2 address space usually has a high priority, and all work done in it in SRB mode precedes all TCB access, so any errors or long processing times can impact all DB2 processing and cause system-wide performance problems. The performance of your routine is *extremely* critical in this phase.

- T=Termination, Mode=TCB

Processing capabilities are the same as for initialization.

A log control interval can be passed more than once. Use the timestamp to determine the last occurrence of the control interval. This last occurrence should replace all others. The timestamp is found in the control interval.

## Parameter lists for log capture routines

At invocation, registers are set as described in "Registers at invocation for exit routines" on page 1109, and the log capture routine uses the standard exit parameter list (EXPL) described there. (The reason and return codes in that list can be ignored.) Table 270 on page 1107 shows the exit-specific parameter list; it is mapped by macro DSNDLOGX.

Table 270. Log capture routine specific parameter list

| Name     | Hex offset | Data type             | Description                                                                                                                               |
|----------|------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| LOGXEYE  | 00         | Character, 4 bytes    | Eye catcher: LOGX                                                                                                                         |
| LOGXLNG  | 04         | Signed 2-byte integer | Length of parameter list                                                                                                                  |
|          | 06         |                       | Reserved                                                                                                                                  |
|          | 08         |                       | Reserved                                                                                                                                  |
| LOGXTYPE | 10         | Character, 1 byte     | Situation identifier:<br><b>I</b> Initialization<br><b>W</b> Write<br><b>T</b> Termination<br><b>P</b> Partial control interval (CI) call |
| LOGXFLAG | 11         | Hex                   | Mode identifier.<br><b>X'00'</b> SRB mode<br><b>X'01'</b> TCB mode                                                                        |
| LOGXSRBA | 12         | Character, 6 bytes    | First log RBA, set when DB2 is started. The value remains constant while DB2 is active.                                                   |
| LOGXARBA | 18         | Character, 6 bytes    | Highest log archive RBA used. The value is updated after completion of each log archive operation.                                        |
|          | 1E         |                       | Reserved                                                                                                                                  |
| LOGXRBUF | 20         | Character, 8 bytes    | Range of consecutive log buffers:<br>Address of first log buffer<br>Address of last log buffer                                            |
| LOGXBUFL | 28         | Signed 4-byte integer | Length of single log buffer (constant 4096)                                                                                               |
| LOGXSSID | 2C         | Character, 4 bytes    | DB2 subsystem ID, 4 characters left justified                                                                                             |
| LOGXSTIM | 30         | Character, 8 bytes    | DB2 subsystem startup time (TIME format with DEC option:<br>0CYDDDDFHHMMSSTH)                                                             |
| LOGXREL  | 38         | Character, 3 bytes    | DB2 subsystem release level                                                                                                               |
| LOGXMAXB | 3B         | Character, 1 byte     | Maximum number of buffers that can be passed on one call. The value remains constant while DB2 is active.                                 |
|          | 3C         | 8 bytes               | Reserved                                                                                                                                  |
| LOGXUSR1 | 44         | Character, 4 bytes    | First word of a doubleword work area for the user routine. (The content is not changed by DB2.)                                           |
| LOGXUSR2 | 48         | Character, 4 bytes    | Second word of user work area.                                                                                                            |

## Routines for dynamic plan selection in CICS

#  
#  
#  
#

You can create application packages and plans that allow application programs to access DB2 data at execution time. In a CICS environment, you can design CICS transactions around the application packages and plans or use dynamic plan allocation.

```

# You can enable dynamic plan allocation by using one of the following techniques:
#
# • Use DB2 packages and versioning to manage the relationship between CICS
#   transactions and DB2 plans. This technique can help minimize plan outage time,
#   processor time, and catalog contention.
#
# • Use a dynamic plan exit routine to determine the plan to use for each CICS
#   transaction.
#
# Recommendation: Use DB2 packages and versioning, instead of a CICS dynamic
#   plan exit routine, for dynamic plan allocation. For more information on using
#   packages, see CICS Transaction Server for z/OS: DB2 Guide.
#
# For guidance on using packages, see DB2 Application Programming and SQL Guide.

```

---

## Routine for CICS transaction invocation stored procedure

The DB2-supplied CICS transaction routine stored procedure invokes a user exit that you use to change values that the stored procedure caller provides. For information about this stored procedure, see Appendix I of *DB2 Application Programming and SQL Guide*.

---

## General considerations for writing exit routines

The rules, requirements, and suggestions in this section apply to most of the foregoing exit routines.

**Important:** Using an exit routine requires coordination with your system programmers. An exit routine runs as an extension of DB2 and has all the privileges of DB2. It can impact the security and integrity of the database. Conceivably, an exit routine could also expose the integrity of the operating system. Instructions for avoiding that exposure can be found in the appropriate z/OS publication.

## Coding rules for exit routines

An exit routine must conform to these rules:

- It must be written in assembler.
- It must reside in an authorized program library, either the library containing DB2 modules (*prefix.SDSNLOAD*) or in a library concatenated ahead of *prefix.SDSNLOAD* in the procedure for the database services started task (the procedure named *ssnmDBM1*, where *ssnm* is the DB2 subsystem name). Authorization routines must be accessible to the *ssnmMSTR* procedure. For all routines, we recommend using the library *prefix.SDSNEXIT*, which is concatenated ahead of *prefix.SDSNLOAD* in both started-task procedures.
- Routines that are listed in Table 271 *must* have the names shown. The name of other routines should not start with “DSN”, to avoid conflict with the DB2 modules.

Table 271. Required load module name

| Type of routine | Required load module name |
|-----------------|---------------------------|
| Date            | DSNXVDTX                  |
| Time            | DSNXVTMX                  |
| Connection      | DSN3@ATH                  |
| Sign-on         | DSN3@SGN                  |

- It must be written to be reentrant and must restore registers before return.
- It must be link-edited with the REENTRANT parameter.
- In the MVS/ESA™ environment, it must be written and link-edited to execute AMODE(31),RMODE(ANY).
- It must not invoke any DB2 services—for example, through SQL statements.
- It must not invoke any SVC services or ESTAE routines.

Even though DB2 has functional recovery routines of its own, you can establish your own functional recovery routine (FRR), specifying MODE=FULLXM and EUT=YES.

## Modifying exit routines

Because exit routines operate as extensions of DB2, they should not be changed or modified while DB2 is running.

## Execution environment for exit routines

Exit routines are invoked by standard CALL statements. With some exceptions, which are noted under “General Considerations” in the description of particular types of routine, the execution environment is:

- Supervisor state
- Enabled for interrupts
- PSW key 7
- No MVS locks held
- For local requests, under the TCB of the application program that requested the DB2 connection
- For remote requests, under a TCB within the DB2 distributed data facility address space
- 31-bit addressing mode
- Cross-memory mode

In cross-memory mode, the current primary address space is not equal to the home address space. Therefore, some z/OS macro services you cannot use at all, and some you can use only with restrictions. For more information about cross-memory restrictions for macro instructions, which macros can be used fully, and the complete description of each macro, refer to the appropriate z/OS publication.

## Registers at invocation for exit routines

When DB2 passes control to an exit routine, the registers are set as listed in Table 272:

Table 272. Contents of registers when DB2 passes control to an exit routine

| Register | Contains                                                                                                                                                                                                 |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | Address of pointer to the exit parameter list (shown in Table 273 on page 1110). For a <i>field procedure</i> , the address is that of the field procedure parameter list (see Figure 154 on page 1097). |
| 13       | Address of the register save area.                                                                                                                                                                       |
| 14       | Return address.                                                                                                                                                                                          |
| 15       | Address of entry point of exit routine.                                                                                                                                                                  |

## Parameter lists for exit routines

Register 1 points to the address of parameter list EXPL, described by macro DSNDEXPL and shown in Figure 155. The word following points to a second parameter list, which differs for each type of exit routine.

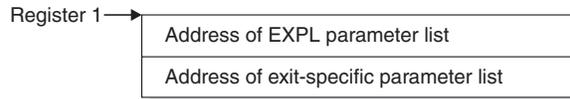

Figure 155. Use of register 1 on invoking an exit routine. (Field procedures and translate procedures do not use the standard exit-specific parameter list.)

Table 273 shows the EXPL parameter list. Its description is given by macro DSNDEXPL.

Table 273. Contents of EXPL parameter list

| Name     | Hex offset | Data type             | Description                                                                                                                                                                                                                |
|----------|------------|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXPLWA   | 0          | Address               | Address of a work area to be used by the routine                                                                                                                                                                           |
| EXPLWL   | 4          | Signed 4-byte integer | Length of the work area. The value is:<br>2048 for connection routines and sign-on routines<br>512 for date and time routines and translate procedures (see Note 1).<br>256 for edit, validation, and log capture routines |
| EXPLRSV1 | 8          | Signed 2-byte integer | Reserved                                                                                                                                                                                                                   |
| EXPLRC1  | A          | Signed 2-byte integer | Return code                                                                                                                                                                                                                |
| EXPLRC2  | C          | Signed 4-byte integer | Reason code                                                                                                                                                                                                                |
| EXPLARC  | 10         | Signed 4-byte integer | Used only by connection routines and sign-on routines                                                                                                                                                                      |
| EXPLSSNM | 14         | Character, 8 bytes    | Used only by connection routines and sign-on routines                                                                                                                                                                      |

| EXPLTYPE | 24         | Character, 8 bytes    | Used only by connection routines and sign-on routines                                                                                                                                                                      |

**Notes:**

1. When translating a string of type PC MIXED, a translation procedure has a work area of 256 bytes plus the length attribute of the string.

## Row formats for edit and validation routines

In writing an edit or validation routine, you must be aware of the format in which DB2 stores the rows of tables. This section describes the special features of that format.

## Column boundaries for edit and validation routines

DB2 stores columns contiguously, regardless of word boundaries in physical storage.

LOB columns are an exception. LOB values are not stored contiguously. An indicator column is stored in a base table in place of the LOB value.

Edit procedures cannot be specified for any table that contains a LOB column or a ROWID column. In addition, LOB values are not available to validation routines; indicator columns and ROWID columns represent LOB columns as input to a validation procedure.

## Null values for edit procedures, field procedures, and validation routines

If null values are allowed for a column, an extra byte is stored before the actual column value. This byte is X'00' if the column value is **not** null; it is X'FF' if the value is null.

The extra byte is included in the column length attribute (parameter FFMTFLEN in Table 281 on page 1113).

## Fixed-length rows for edit and validation routines

If all columns in a table are fixed-length, its rows are stored in fixed-length format. The rows are byte strings.

**Example:** The sample project activity table has five fixed-length columns. The first two columns do not allow nulls; the last three do. Table 274 shows a row in the table.

Table 274. A row in fixed-length format

| Column 1 | Column 2 | Column 3 |     | Column 4 |        | Column 5 |        |
|----------|----------|----------|-----|----------|--------|----------|--------|
| MA2100   | 10       | 00       | 0.5 | 00       | 820101 | 00       | 821101 |

## Varying-length rows for edit and validation routines

If a table has any varying-length columns, its rows contain varying-length values, and are varying-length rows. Each varying-length value has a 2-byte length field in front of it. Those 2 bytes are **not** included in the column length attribute (FFMTFLEN).

Table 275 shows a row of the sample department table.

Table 275. A varying-length row in the sample department table.. The first value in Column 2 indicates the column length as a hexadecimal value.

| Column 1 | Column 2 |                    | Column 3 | Column 4 |
|----------|----------|--------------------|----------|----------|
| C01      | 0012     | Information center | 000030   | A00      |

There are no gaps after varying-length columns. Hence, columns that appear after varying-length columns are at variable offsets in the row. To get to such a column, you must scan the columns sequentially after the first varying-length column. An empty string has a length of zero with no data following.

ROWID and indicator columns are treated like varying length columns. Row IDs are VARCHAR(17). An indicator columns is VARCHAR(4); it is stored in a base table in place of a LOB column, and indicates whether the LOB value for the column is null or zero length.

## Varying-length rows with nulls for edit and validation routines

A varying-length column can also allow null values. The value in the length field includes the null indicator byte but does not include the length field itself.

Table 276 shows how the row in Table 275 on page 1111 would look in storage if nulls were allowed in Column 2.

*Table 276. A varying-length row in the sample department table..* The first value in Column 2 indicates the column length as a hexadecimal value.

| Column 1 | Column 2 | Column 3           | Column 4 |
|----------|----------|--------------------|----------|
| C01      | 0013     | Information center | 000030   |
|          |          |                    | A00      |

An empty string has a length of one, a X'00' null indicator, and no data following.

## Dates, times, and timestamps for edit and validation routines

The values in columns with data types of DATE, TIME, and TIMESTAMP are stored in the formats that are shown in the following tables. For each format, each byte consists of two packed decimal digits.

Table 277 shows the DATE format, which consists of 4 total bytes

*Table 277. DATE format*

| Year    | Month  | Day    |
|---------|--------|--------|
| 2 bytes | 1 byte | 1 byte |

Table 278 shows the TIME format, which consists of 3 total bytes.

*Table 278. TIME format*

| Hours  | Minutes | Seconds |
|--------|---------|---------|
| 1 byte | 1 byte  | 1 byte  |

Table 279 shows the TIMESTAMP format, which consists of 10 total bytes.

*Table 279. TIMESTAMP format*

| Year    | Month  | Day    | Hours  | Minutes | Seconds | Microseconds |
|---------|--------|--------|--------|---------|---------|--------------|
| 2 bytes | 1 byte | 1 byte | 1 byte | 1 byte  | 1 byte  | 3 bytes      |

## Parameter list for row format descriptions

DB2 passes a description of the row format to an edit or validation routine through a parameter list, generated by macro DSNDROW. The description includes both the general row characteristics and the characteristics of each column. Table 280 on page 1113 shows the general row description.

Table 280. Description of a row format

| Name     | Hex offset | Data type               | Description                                                                                   |
|----------|------------|-------------------------|-----------------------------------------------------------------------------------------------|
| RFMTNFLD | 0          | Signed fullword integer | Number of columns in a row                                                                    |
| RFMTAFLD | 4          | Address                 | Address of a list of column descriptions. The format of each column is shown in Table 281.    |
| RFMTTYPE | 8          | Character, 1 byte       | Row type:<br>X'00' = row with fixed-length columns<br>X'04' = row with varying-length columns |
|          | 9          | Character, 3 bytes      | Reserved                                                                                      |

Table 281 shows the description of each column.

Table 281. Description of a column format

| Name     | Hex offset | Data type               | Description                                                                                 |
|----------|------------|-------------------------|---------------------------------------------------------------------------------------------|
| FFMTFLEN | 0          | Signed fullword integer | Column length attribute (see Table 282)                                                     |
| FFMTFTYP | 4          | Character, 1 byte       | Data type code (see Table 282)                                                              |
| FFMTNULL | 5          | Character, 1 byte       | Data attribute:<br>X'00' = Null values are allowed.<br>X'04' = Null values are not allowed. |
| FFMTFNAM | 6          | Character, 18 bytes     | Column name                                                                                 |

Table 282 shows a description of data type codes and length attributes.

Table 282. Description of data type codes and length attributes

| Data type                | Code (FFMTFTYP) | Length attribute (FFMTFLEN)                  |
|--------------------------|-----------------|----------------------------------------------|
| INTEGER                  | X'00'           | 4                                            |
| SMALLINT                 | X'04'           | 2                                            |
| FLOAT (single precision) | X'08'           | 4                                            |
| FLOAT (double precision) | X'08'           | 8                                            |
| DECIMAL                  | X'0C'           | INTEGER( $p/2$ ), where $p$ is the precision |
| CHAR                     | X'10'           | The length of the string                     |
| VARCHAR                  | X'14'           | The length of the string                     |
| DATE                     | X'20'           | 4                                            |
| TIME                     | X'24'           | 3                                            |
| TIMESTAMP                | X'28'           | 10                                           |
| ROWID                    | X'2C'           | 17                                           |
| INDICATOR COLUMN         | X'30'           | 4                                            |

## DB2 codes for numeric data in edit and validation routines

DB2 stores numeric data in a specially encoded format. That format is called *DB2-coded*. To retrieve numeric data in its original form, you must DB2-decode it, according to its data type, as is listed in Table 283:

Table 283. DB2 decoding procedure according to data type

| Data type | DB2 decoding procedure                                                                                                                                                                                                                               |                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| SMALLINT  | Invert the sign bit (high order bit).                                                                                                                                                                                                                |                                    |
|           | <b>Value</b>                                                                                                                                                                                                                                         | <b>Meaning</b>                     |
|           | 8001                                                                                                                                                                                                                                                 | 0001 (+1 decimal)                  |
|           | 7FF3                                                                                                                                                                                                                                                 | FFF3 (-13 decimal)                 |
| INTEGER   | Invert the sign bit (high order bit).                                                                                                                                                                                                                |                                    |
|           | <b>Value</b>                                                                                                                                                                                                                                         | <b>Meaning</b>                     |
|           | 800001F2                                                                                                                                                                                                                                             | 000001F2 (+498 decimal)            |
|           | 7FFFFFF85                                                                                                                                                                                                                                            | FFFFFF85 (-123 decimal)            |
| FLOAT     | If the sign bit (high order bit) is 1, invert only that bit. Otherwise, invert all bits.                                                                                                                                                             |                                    |
|           | <b>Value</b>                                                                                                                                                                                                                                         | <b>Meaning</b>                     |
|           | C110000000000000                                                                                                                                                                                                                                     | 4110000000000000<br>(+1.0 decimal) |
|           | 3EEFFFFFFFFFFFFFFF                                                                                                                                                                                                                                   | C110000000000000<br>(-1.0 decimal) |
| DECIMAL   | Save the high-order hexadecimal digit (sign digit). Shift the number to the left one hexadecimal digit. If the sign digit is 'F', put 'C' in the low-order position. Otherwise, invert all bits in the number and put 'D' in the low-order position. |                                    |
|           | <b>Value</b>                                                                                                                                                                                                                                         | <b>Meaning</b>                     |
|           | F001                                                                                                                                                                                                                                                 | 001C (+1)                          |
|           | 0FFE                                                                                                                                                                                                                                                 | 001D (-1)                          |

## RACF access control module

The RACF access control module allows you to use RACF as an alternative to DB2 authorization checking for DB2 objects, authorities, and utilities. You can activate the RACF access control module at the DB2 access control authorization exit point (DSNX@XAC), where you can replace the default routine. The RACF access control module is provided as an assembler source module in the DSNXRXAC member of DB2.SDSNSAMP.

For more information about the RACF access control module, see *DB2 RACF Access Control Module Guide*.

---

## Appendix C. Reading log records

The information in this appendix is Product-sensitive Programming Interface and Associated Guidance Information as defined in “Notices” on page 1437.

This appendix discusses the following information about the log:

“Contents of the log”

“The physical structure of the log” on page 1120

For diagnostic or recovery purposes, it can be useful to read DB2 log records. This appendix also discusses three approaches to writing programs that read log records:

- “Reading log records with IFI” on page 1126

This is an online method using the instrumentation facility interface (IFI) when DB2 is running. You use the READA (read asynchronously) command of IFI to read log records into a buffer and the READS (read synchronously) command to pick up specific log control intervals from a buffer.

- “Reading log records with OPEN, GET, and CLOSE” on page 1130

This is a stand-alone method that can be used when DB2 is down. You use the assembler language macro DSNJSLR to submit OPEN, GET, and CLOSE functions. This method can be used to capture log records that you cannot pick up with IFI after DB2 goes down.

- “Reading log records with the log capture exit routine” on page 1138

This is an online method using the log capture exit when DB2 is running. You write an exit routine to use this exit to capture and transfer log records in real time.

---

### Contents of the log

The log contains the information needed to recover the results of program execution, the contents of the database, and the DB2 subsystem. It does not contain information for accounting, statistics, traces, or performance evaluation.

There are three main types of log records which are described under these headings:

“Unit of recovery log records” on page 1116

“Checkpoint log records” on page 1119

“Database page set control records” on page 1120

Exception information that is not included in any of these types is described under “Other exception information” on page 1120.

Each log record has a header that indicates its type, the DB2 subcomponent that made the record, and, for unit-of-recovery records, the unit-of-recovery identifier. The log records can be extracted and printed by the DSN1LOGP program. For instructions, refer to Part 3 of *DB2 Utility Guide and Reference*.

**The log relative byte address and log record sequence number:** The DB2 log can contain up to  $2^{48}$  bytes, where  $2^{48}$  is 2 to the 48th power. Each byte is addressable by its offset from the beginning of the log. That offset is known as its *relative byte address* (RBA).

A log record is identifiable by the RBA of the first byte of its header; that RBA is called the *relative byte address of the record*. The record RBA is like a timestamp because it uniquely identifies a record that starts at a particular point in the continuing log.

In the data sharing environment, each member has its own log. The *log record sequence number (LRSN)* uniquely identifies the log records of a data sharing member. The LRSN is a 6-byte hexadecimal value derived from a store clock timestamp. DB2 uses the LRSN for recovery in the data sharing environment.

**Effects of ESA data compression:** Log records can contain compressed data if a table contains compressed data. For example, if the data in a DB2 row are compressed, all data logged because of changes to that row (resulting from inserts, updates and deletes) are compressed. If logged, the record prefix is not compressed, but all of the data in the record are in compressed format. Reading compressed data requires access to the dictionary that was in use when the data was compressed.

## Unit of recovery log records

Most of the log records describe changes to the DB2 database. All such changes are made within units of recovery. This section describes changes to the DB2 database, the effects of these changes, and the log records that correspond to the changes.

### Undo and redo records

When a change is made to the database, DB2 logs an *undo/redo* record that describes the change. The *redo* information is required if the work is committed and later must be recovered. The *undo* information is used to back out work that is not committed.

If the work is rolled back, the *undo/redo* record is used to remove the change. At the same time that the change is removed, a new *redo/undo* record is created that contains information, called *compensation information*, that is used if necessary to reverse the change. For example, if a value of 3 is changed to 5, redo compensation information changes it back to 3.

If the work must be recovered, DB2 scans the log forward and applies the redo portions of log records and the redo portions of compensation records, without keeping track of whether the unit of recovery was committed or rolled back. If the unit of recovery had been rolled back, DB2 would have written compensation redo log records to record the original undo action as a redo action. Using this technique, the data can be completely restored by applying only redo log records on a single forward pass of the log.

DB2 also logs the creation and deletion of data sets. If the work is rolled back, the operations are reversed. For example, if a table space is created using DB2-managed data sets, DB2 creates a data set; if rollback is necessary, the data set is deleted. If a table space using DB2-managed data sets is dropped, DB2 deletes the data set when the work is committed, not immediately. If the work is rolled back, DB2 does nothing.

### Database exception table records

Database exception table (DBET) log records register several types of information: exception states and image copies of special table spaces. DBET log records also register exception information that is not related to units of recovery (see “Other exception information” on page 1120 for more information).

**Exception states:** DBET log records register whether any database, table space, index space, or partition is in an exception state. To list all objects in a database that are in an exception state, use the command `DISPLAY DATABASE (database name) RESTRICT`. For a further explanation of the list produced and of the exception states, see the description of message `DSNT392I` in Part 2 of *DB2 Messages*.

**Image copies of special table spaces:** Image copies of `DSNDB01.SYSUTILX`, `DSNDB01.DBD01`, and `DSNDB06.SYSCOPY` are registered in the DBET log record rather than in `SYSCOPY`. During recovery, they are recovered from the log, and then image copies of other table spaces are located from the recovered `SYSCOPY`.

## Typical unit of recovery log records

Table 284 shows a sequence of log records that might be written for an insert of one row via TSO. The following record types are included:

### Begin\_UR

The first request to change a database begins a unit of recovery. The log record of that event is identified by its log RBA. That same RBA serves as an ID for the entire unit of recovery (the URID). All records related to that unit have that RBA in their log record headers (LRH). For rapid backout, the records are also linked by a backward chain in the LRH.

### Undo/Redo

Log records are written for each insertion, deletion, or update of a row. They register the changes to the stored data, but not the SQL statement that caused the change. Each record identifies one data or index page and its changes.

### End Phase 2 records

The end of a UR is marked by log records that tell whether the UR was committed or rolled back, and whether DB2 has completed the work associated with it. If DB2 terminates before a UR has completed, it completes the work at the next restart.

Table 284. Example of a log record sequence for an `INSERT` of one row using TSO

| Type of record          | Information recorded                                                                                                                                                                                                                                                 |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Begin_UR             | Beginning of the unit of recovery. Includes the connection name, correlation name, authorization ID, plan name, and LUWID.                                                                                                                                           |
| 2. Undo/Redo for data   | Insertion of data. Includes the database ID (DBID), page set ID, page number, internal record identifier (RID), and the data inserted.                                                                                                                               |
| 3. Undo/Redo for Index  | Insertion of index entry. Includes the DBID, index space object ID, page number, and index entry to be added.                                                                                                                                                        |
| 4. Begin Commit 1       | The beginning of the commit process. The application has requested a commit either explicitly ( <code>EXEC SQL COMMIT</code> ) or implicitly (for example, by ending the program).                                                                                   |
| 5. Phase 1-2 Transition | The agreement to commit in TSO. In CICS and IMS, an End Phase 1 record notes that DB2 agrees to commit. If both parties agree, a Begin Phase 2 record is written; otherwise, a Begin Abort record is written, noting that the unit of recovery is to be rolled back. |
| 6. End Phase 2          | Completion of all work required for commit.                                                                                                                                                                                                                          |

Table 285 shows the log records for processing and rolling back an insertion.

*Table 285. Log records written for rolling back an insertion*

| Type of record            | Information recorded                                                                                                                            |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 1. Begin_UR               | Beginning of the unit of recovery.                                                                                                              |
| 2. Undo/Redo for data     | Insertion of data. Includes the database ID (DBID), page set ID, page number, internal record identifier, and the data inserted.                |
| 3. Begin_Abort            | Beginning of the rollback process.                                                                                                              |
| 4. Compensation Redo/Undo | Backing-out of data. Includes the database ID (DBID), page set ID, page number, internal record ID (RID), and data to undo the previous change. |
| 5. End_Abort              | End of the unit of recovery, with rollback complete.                                                                                            |

### Classes of changes to data

Table 286 summarizes the information logged for data and index changes.

*Table 286. Information logged for database changes*

| Operation                                                                                                                                          | Information logged                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Insert data                                                                                                                                        | The new row <ul style="list-style-type: none"> <li>• On redo, the row is inserted with its original RID.</li> <li>• On undo, the row is deleted and the RID is made available for another row.</li> </ul> |
| Delete data                                                                                                                                        | The deleted row <ul style="list-style-type: none"> <li>• On redo, the RID is made available for another row.</li> <li>• On undo, the row is inserted again with its former RID.</li> </ul>                |
| Update data                                                                                                                                        | The old and new values of the changed data. <ul style="list-style-type: none"> <li>• On redo, the new data is replaced.</li> <li>• On undo, the old data is replaced.</li> </ul>                          |
| <b>Note:</b> If an update occurs to a table defined with DATA CAPTURE(CHANGES), the entire before-image and after-image of the data row is logged. |                                                                                                                                                                                                           |
| Insert index entry                                                                                                                                 | The new key value and the data RID.                                                                                                                                                                       |
| Delete index entry                                                                                                                                 | The deleted key value and the data RID.                                                                                                                                                                   |

There are three basic classes of changes to a data page:

- Changes to control information. Those changes include pages that map available space and indicators that show that a page has been modified. The COPY utility uses that information when making incremental image copies.
- Changes to database pointers. Pointers are used in two situations:
  - The DB2 catalog and directory, but not user databases, contain pointers that connect related rows. Insertion or deletion of a row changes pointers in related data rows.
  - When a row in a user database becomes too long to fit in the available space, it is moved to a new page. An address, called an *overflow pointer*, that points to the new location is left in the original page. With this technique, index entries and other pointers do not have to be changed. Accessing the row in its original position gives a pointer to the new location.

- Changes to data. In DB2, a row is confined to a single page. Each row is uniquely identified by a RID containing:
  - The number of the page
  - A 1-byte ID that identifies the row within the page. A single page can contain up to 255 rows; <sup>8</sup> IDs are reused when rows are deleted.

The log record identifies the RID, the operation (insert, delete, or update), and the data. Depending on the data size and other variables, DB2 can write a single log record with both undo and redo information, or it can write separate log records for undo and redo.

## Checkpoint log records

To reduce restart time, DB2 takes periodic checkpoints during normal operation, in the following circumstances:

- When a predefined number of log records have been written or a predetermined amount of time in minutes has elapsed.

This number is defined by field CHECKPOINT\_FREQ on installation panel DSNTIPL described in Part 2 of *DB2 Installation Guide*.

- When switching from one active log data set to another
- At the end of a successful restart
- At normal termination

At a checkpoint, DB2 logs its current status and registers the log RBA of the checkpoint in the bootstrap data set (BSDS). At restart, DB2 uses the information in the checkpoint records to reconstruct its state when it terminated.

Many log records can be written for a single checkpoint. DB2 can write one to begin the checkpoint; others can then be written, followed by a record to end the checkpoint. Table 287 summarizes the information logged.

*Table 287. Contents of checkpoint log records*

| Type of log record         | Information logged                                                                                                                                                                                                                                                                                                           |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Begin_Checkpoint           | Marks the start of the summary information. All later records in the checkpoint have type X'0100' (in the LRH).                                                                                                                                                                                                              |
| Unit of Recovery Summary   | Identifies an incomplete unit of recovery (by the log RBA of the Begin_UR log record). Includes the date and time of its creation, its connection ID, correlation ID, authorization ID, the plan name it used, and its current state (inflight, indoubt, in-commit, or in-abort).                                            |
| Page Set Summary           | Contains information for allocating and opening objects at restart, and identifies (by the log RBA) the earliest checkpoint interval containing log records about data changes that have not been applied to the DASD version of the data or index. There is one record for each open page set (table space or index space). |
| Page Set Exception Summary | Identifies the type of exception state. For descriptions of the states, see "Database page set control records" on page 1120. There is one record for each database and page set with an exception state.                                                                                                                    |
| Page Set UR Summary Record | Identifies page sets modified by any active UR (inflight, in-abort, or in-commit) at the time of the checkpoint.                                                                                                                                                                                                             |

8. A page in a catalog table space that has links can contain up to 127 rows.

Table 287. Contents of checkpoint log records (continued)

| Type of log record | Information logged                                           |
|--------------------|--------------------------------------------------------------|
| End_Checkpoint     | Marks the end of the summary information about a checkpoint. |

## Database page set control records

Page set control records primarily register the allocation, opening, and closing of every page set (table space or index space). That same information is in the DB2 directory (SYSIBM.SYSLGRNX). It is also registered in the log so that it is available at restart.

## Other exception information

Entries for data pages that are logically in error (logical page list or LPL entries) or physically in error (write error page range or WEPR entries) are registered in the DBET log record.

---

## The physical structure of the log

Each active log data set must be a VSAM linear data set (LDS). The physical output unit written to the active log data set is a control interval (CI) of 4096 bytes (4 KB). Each CI contains one VSAM record.

## Physical and logical log records

The VSAM CI provides 4089 bytes to hold DB2 information. That space is called a *physical* record. The information to be logged at a particular time forms a *logical* record, whose length varies independently of the space available in the CI. Hence, one physical record can contain several logical records, one or more logical records and part of another, or only part of one logical record. The physical record must also contain 21 bytes of DB2 control information, called the *log control interval definition* (LCID), which is further described in “The log control interval definition (LCID)” on page 1122.

Figure 156 on page 1121 shows a VSAM CI containing four log records or segments, namely:

- The last segment of a log record of 768 bytes (X'0300'). The length of the segment is 100 bytes (X'0064').
- A complete log record of 40 bytes (X'0028').
- A complete log record of 1024 bytes (X'0400').
- The first segment of a log record of 4108 bytes (X'100C'). The length of the segment is 2911 bytes (X'0B5F').

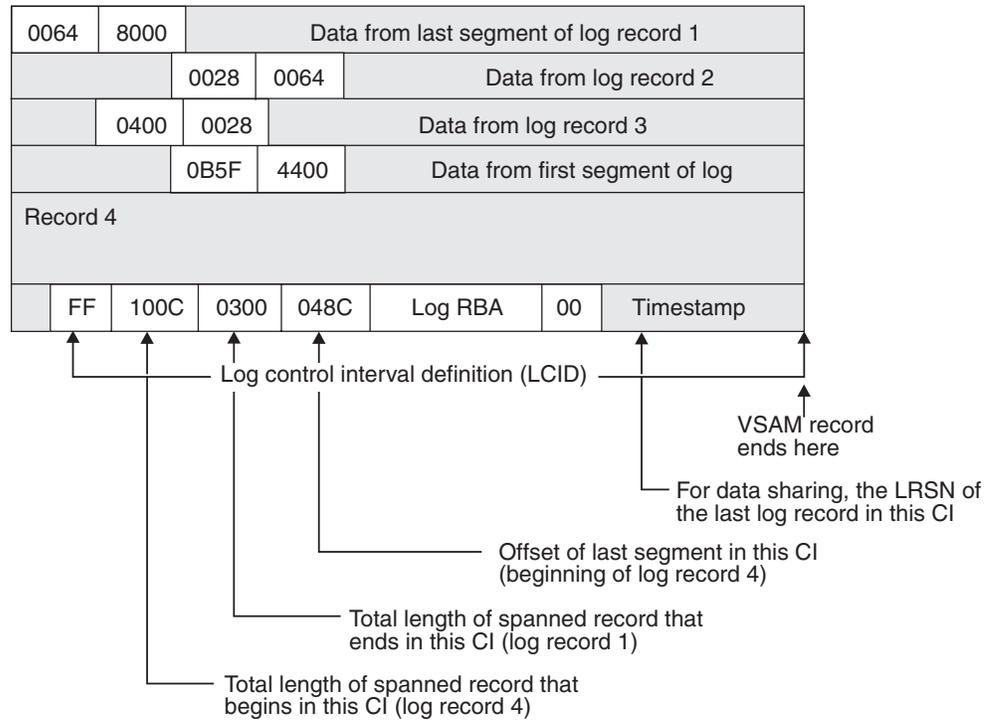

Figure 156. A VSAM CI and its contents

The term *log record* refers to a logical record, unless the term *physical log record* is used. A part of a logical record that falls within one physical record is called a *segment*.

## The log record header

Each logical record includes a prefix, called a *log record header* (LRH), which contains control information. For the contents of the log record header see Table 288.

The first segment of a log record must contain the header and some bytes of data. If the current physical record has too little room for the minimum segment of a new record, the remainder of the physical record is unused, and a new log record is written in a new physical record.

The log record can span many VSAM CIs. For example, a minimum of nine CIs are required to hold the maximum size log record of 32815 bytes. Only the first segment of the record contains the entire LRH; later segments include only the first two fields. When a specific log record is needed for recovery, all segments are retrieved and presented together as if the record were stored continuously.

Table 288. Contents of the log record header

| Hex offset | Length | Information                      |
|------------|--------|----------------------------------|
| 00         | 2      | Length of this record or segment |

Table 288. Contents of the log record header (continued)

| Hex offset | Length | Information                                                                                                                                                                                                                                               |
|------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 02         | 2      | Length of any previous record or segment in this CI; 0 if this is the first entry in the CI. The two high-order bits tell the segment type:<br>B'00' A complete log record<br>B'01' The first segment<br>B'11' A middle segment<br>B'10' The last segment |
| 04         | 2      | Type of log record <sup>1</sup>                                                                                                                                                                                                                           |
| 06         | 2      | Subtype of the log record <sup>1</sup>                                                                                                                                                                                                                    |
| 08         | 1      | Resource manager ID (RMID) of the DB2 component that created the log record                                                                                                                                                                               |
| 09         | 1      | Flags                                                                                                                                                                                                                                                     |
| 0A         | 6      | Unit of recovery ID, if this record relates to a unit of recovery <sup>2</sup> ; otherwise, 0                                                                                                                                                             |
| 10         | 6      | Log RBA of the previous log record, if this record relates to a unit of recovery <sup>2</sup> ; otherwise, 0                                                                                                                                              |
| 16         | 1      | Release identifier                                                                                                                                                                                                                                        |
| 17         | 1      | Length of header                                                                                                                                                                                                                                          |
| 18         | 6      | Undo next LSN                                                                                                                                                                                                                                             |
| 1E         | 8      | LRHTIME                                                                                                                                                                                                                                                   |

**Notes:**

1. For record types and subtypes, see “Log record type codes” on page 1124 and “Log record subtype codes” on page 1124.
2. For a description of units of recovery, see “Unit of recovery log records” on page 1116

## The log control interval definition (LCID)

Each physical log record includes a suffix called the *log control interval definition* (LCID), which tells how record segments are placed in the physical control interval. For the contents of the LCID, see Table 289.

Table 289. Contents of the log control interval definition

| Hex offset | Length | Information                                                                                                                                                                  |
|------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00         | 1      | An indication of whether the CI contains free space: X'00' = Yes, X'FF' = No                                                                                                 |
| 01         | 2      | Total length of a segmented record that begins in this CI; 0 if no segmented record begins in this CI                                                                        |
| 03         | 2      | Total length of a segmented record that ends in this CI; 0 if no segmented record ends in this CI                                                                            |
| 05         | 2      | Offset of the last record or segment in the CI                                                                                                                               |
| 07         | 6      | Log RBA of the start of the CI                                                                                                                                               |
| 0D         | 6      | Timestamp, reflecting the date and time that the log buffer was written to the active log data set. The timestamp is the high-order 7 bytes of the store clock value (STCK). |
| 13         | 2      | Reserved                                                                                                                                                                     |

Each recovery log record consists of two parts: a *header*, which describes the record, and data. Figure 157 shows the format schematically; the following list describes each field.

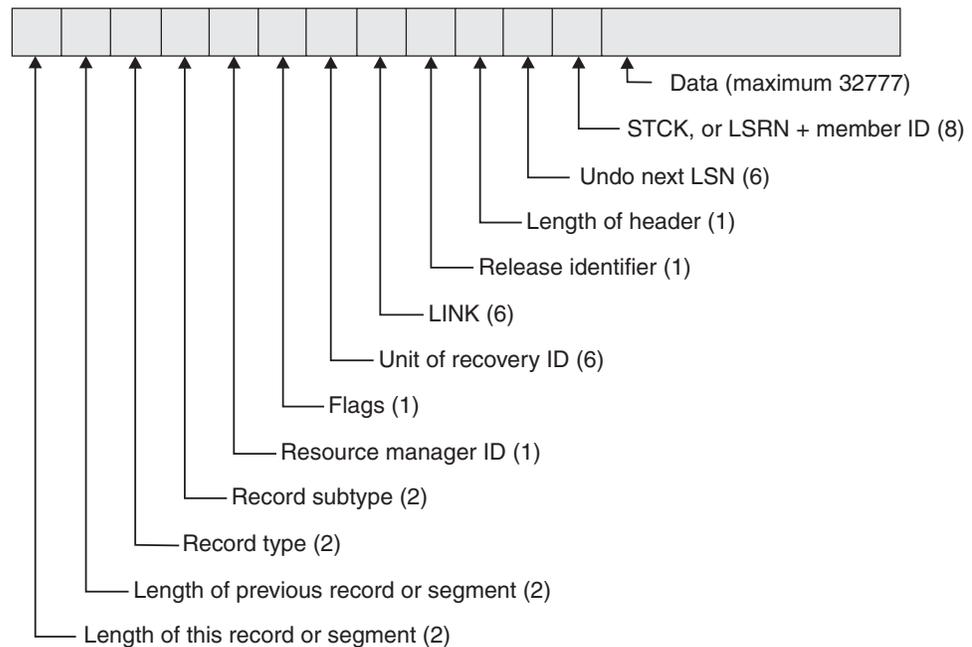

Figure 157. Format of a DB2 recovery log record

The fields are:

**Length of this record**

The total length of the record in bytes.

**Length of previous record**

The total length of the previous record in bytes.

**Type** The code for the type of recovery log record. See “Log record type codes” on page 1124.

**Subtype**

Some types of recovery log records are further divided into subtypes. See “Log record subtype codes” on page 1124.

**Resource manager ID**

Identifier of the resource manager that wrote the record into the log. When the log is read, the record can be given for processing to the resource manager that created it.

**Unit of recovery ID**

A unit of recovery to which the record is related. Other log records can be related to the same unit of recovery; all of them must be examined to recover the data. The URID is the RBA (relative byte address) of the Begin-UR log record, and indicates the start of that unit of recovery in the log.

**LINK** Chains all records written using their RBAs. For example, the link in an end checkpoint record links the chains back to the begin checkpoint record.

**Release identifier**

Identifies in which release the log was written.

**Log record header length**

The total length of the header of the log record.

**Undo next LSN**

Identifies the log RBA of the next log record to be undone during backwards (UNDO processing) recovery.

**STCK, or LRSN+member ID**

In a non-data-sharing environment, this is a 6-byte store clock value (STCK) reflecting the date and time the record was placed in the output buffer. The last 2 bytes contain zeros.

In a data sharing environment, this contains a 6-byte log record sequence number (LRSN) followed by a 2-byte member ID.

**Data** Data associated with the log record. The contents of the data field depend on the type and subtype of the recovery log record.

**Log record type codes**

The type code of a log record tells what kind of DB2 event the record describes:

| Code         | Type of event            |
|--------------|--------------------------|
| 0002         | Page set control         |
| 0004         | SYSCOPY utility          |
| 0010         | System event             |
| 0020         | Unit of recovery control |
| 0100         | Checkpoint               |
| 0200         | Unit of recovery undo    |
| 0400         | Unit of recovery redo    |
| 0800         | Archive log command      |
| 1000 to 8000 | Assigned by DB2          |
| 2200         | Savepoint                |

A single record can contain multiple type codes that are combined. For example, 0600 is a combined UNDO/REDO record; F400 is a combination of four DB2-assigned types plus a REDO.

**Log record subtype codes**

The log record subtype code provides a more granular definition of the event that occurred to produce the log record. Log record subtype codes are unique only within the scope of the corresponding log record type code.

Log record type 0004 (SYSCOPY utility) has log subtype codes that correspond to the page set ID values of the table spaces that have their SYSCOPY records in the log (SYSIBM.SYSUTILX, SYSIBM.SYSCOPY and DSNDB01.DBD01).

For a description of log record types 0200 (unit of recovery undo) and 0400 (unit of recovery redo), see the SUBTYPE option of DSN1LOGP in Part 3 of *DB2 Utility Guide and Reference*.

Log record type 0800 (quiesce) does not have subtype codes.

Some log record types (1000 to 8000 assigned by DB2) can have proprietary log record subtype codes assigned.

**Subtypes for type 0002 (page set control):**

| Code | Type of event |
|------|---------------|
|------|---------------|

|      |                             |
|------|-----------------------------|
| 0001 | Page set open               |
| 0002 | Data set open               |
| 0003 | Page set close              |
| 0004 | Data set close              |
| 0005 | Page set control checkpoint |
| 0006 | Page set write              |
| 0007 | Page set write I/O          |
| 0008 | Page set reset write        |
| 0009 | Page set status             |

*Subtypes for type 0010 (system event):*

| <b>Code</b> | <b>Type of event</b>                  |
|-------------|---------------------------------------|
| 0001        | Begin checkpoint                      |
| 0002        | End checkpoint                        |
| 0003        | Begin current status rebuild          |
| 0004        | Begin historic status rebuild         |
| 0005        | Begin active unit of recovery backout |
| 0006        | Pacing record                         |

*Subtypes for type 0020 (unit of recovery control):*

| <b>Code</b> | <b>Type of event</b>                        |
|-------------|---------------------------------------------|
| 0001        | Begin unit of recovery                      |
| 0002        | Begin commit phase 1 (Prepare)              |
| 0004        | End commit phase 1 (Prepare)                |
| 0008        | Begin commit phase 2                        |
| 000C        | Commit phase 1 to commit phase 2 transition |
| 0010        | End commit phase 2                          |
| 0020        | Begin abort                                 |
| 0040        | End abort                                   |
| 0081        | End undo                                    |

## Interpreting data change log records

DB2 provides the mapping and description of specific log record types that allow you to interpret data changes made to DB2 tables from the log. The macros are contained in the data set library *prefix.SDSNMACS* and are documented by comments in the macros themselves.

Log record formats for the record types and subtypes that are listed in “Log record subtype codes” on page 1124 are detailed in the mapping macro DSNDQJ00. DSNDQJ00 provides the mapping of specific data change log records, UR control

log records, and page set control log records that you need to interpret data changes by the UR. DSNDQJ00 also explains the content and usage of the log records.

---

## Reading log records with IFI

You can write a program that uses IFI to capture log records while DB2 is running. You can read the records asynchronously, by starting a trace that reads the log records into a buffer and then issuing an IFI call to read those records out of the buffer. Alternatively, you can read those log records synchronously, by using an IFI call that returns those log records directly to your IFI program.

This section describes both methods, in the following topics:

“Reading log records into a buffer”

“Reading specific log records (IFCID 0129)”

“Reading complete log data (IFCID 0306)” on page 1127

Either the primary or one of the secondary authorization IDs must have MONITOR2 privilege. For details on how to code an IFI program, see Appendix E, “Programming for the Instrumentation Facility Interface (IFI),” on page 1157.

### Reading log records into a buffer

To begin gathering active log records into a buffer, issue the following command in your IFI program:

```
-START TRACE(P) CLASS(30) IFCID(126) DEST(OPX)
```

where:

- P signifies to start a DB2 performance trace. Any of the DB2 trace types can be used.
- CLASS(30) is a user-defined trace class (31 and 32 are also user-defined classes).
- IFCID(126) activates DB2 log buffer recording.
- DEST(OPX) starts the trace to the next available DB2 online performance (OP) buffer. The size of this OP buffer can be explicitly controlled by the BUFSIZE keyword of the START TRACE command. Valid sizes range from 256 KB to 16 MB. The number must be evenly divisible by 4.

When the START TRACE command takes effect, from that point forward until DB2 terminates, DB2 begins writing 4-KB log buffer VSAM control intervals (CIs) to the OP buffer as well as to the active log. As part of the IFI COMMAND invocation, the application specifies an ECB to be posted and a threshold to which the OP buffer is filled when the application is posted to obtain the contents of the buffer. The IFI READA request is issued to obtain OP buffer contents.

### Reading specific log records (IFCID 0129)

IFCID 129 can be used with an IFI READS request to return a specific range of log records from the active log into the return area your program has initialized. Enter the following command into your IFI program:

```
CALL DSNWLI(READS,ifca,return_area,ifcid_area,qual_area)
```

IFCID 129 must appear in the IFCID area.

To retrieve the log control interval, your program must initialize certain fields in the qualification area:

### WQALLTYP

This is a 3-byte field in which you must specify CI (with a trailing blank), which stands for “control interval”.

### WQALLMOD

In this 1-byte field, you specify whether you want the first log CI of the restarted DB2 subsystem, or whether you want a specific control interval as specified by the value in the RBA field.

**F** The “first” option is used to retrieve the first log CI of this DB2 instance. This option ignores any value in WQALLRBA and WQALLNUM.

**P** The “partial” option is used to retrieve partial log CIs for the log capture exit which is described in Appendix B, “Writing exit routines,” on page 1055. DB2 places a value in field IFCAHLRS of the IFI communication area, as follows:

- The RBA of the log CI given to the log capture exit routine, if the last CI written to the log was not full.
- 0, if the last CI written to the log was full.

When you specify option P, DB2 ignores values in WQALLRBA and WQALLNUM.

**R** The “read” option is used to retrieve a set of up to 7 continuous log CIs. If you choose this option, you must also specify the WQALLRBA and WQALLNUM options, which the following text details.

### WQALLRBA

In this 8-byte field, you specify the starting log RBA of the control intervals to be returned. This value must end in X'000' to put the address on a valid boundary. This field is ignored when using the WQALLMOD=F option.

If you specify an RBA that is not in the active log, reason code 00E60854 is returned in the field IFCARC2, and the RBA of the first CI of the active log is returned in field IFCAFCI of the IFCA. These 6 bytes contain the IFCAFCI field.

### WQALLNUM

In this 2-byte field, specify the number of control intervals you want returned. The valid range is from X'0001' through X'0007', which means that you can request and receive up to seven 4-KB log control intervals. This field is ignored when using the WQALLMOD=F option. For a complete description of the qualification area, see Table 302 on page 1164.

If you specify a range of log CIs, but some of those records have not yet been written to the active log, DB2 returns as many log records as possible. You can find the number of CIs returned in field QWT02R1N of the self-defining section of the record. For information about interpreting trace output, see Appendix D, “Interpreting DB2 trace output,” on page 1139.

## Reading complete log data (IFCID 0306)

The major benefits for using IFCID 0306 are:

- IFCID 0306 can request DB2 to decompress log records if compressed, before passing them to the return area of your IFI program.
- In a data sharing environment, DB2 merges log records if the value of the IFI READS qualification WQALFLTR is X'00'. If WQALFLTR is X'01', log records are not merged.
- IFCID can retrieve log records from the archive data sets.

- Complete log records are always returned.

To use this IFCID, use the same call as described in “Reading specific log records (IFCID 0129)” on page 1126. IFCID 0306 must appear in the IFCID area. IFCID 0306 returns complete log records and the spanned record indicators in bytes 2 will have no meaning, if present. Multi-segmented control interval log records are combined for a complete log record.

### Specifying the return area

For IFCID 0306 requests, your program’s return area must reside in ECSA key 7 storage. The IFI application program must set the eye-catcher to ‘I306’ at offset 4 in the Return Area before making the IFCID 0306 call. There is an additional 60 byte area that must be included after the 4-byte length indicator and the ‘I306’ eye-catcher. This area is used by DB2 between successive application calls and must not be modified by the application. The return area mapping is documented later in this section.

The IFI application program needs to run in supervisor state to request the ECSA key 7 return area. The return area storage size need be a minimum of the largest DB2 log record returned plus the additional area defined in DSNDQW04. Minimize the number of IFI calls required to get all log data but do not over use ECSA by the IFI program. The other IFI storage areas can remain in user storage key 8. The IFI application must be in supervisor state and key 0 when making IFCID 0306 calls.

### Qualifying log records

To retrieve IFCID 0306 log records, your program must initialize certain fields in the qualification area mapped by DSNDWQAL. These qualification fields are described here:

#### WQALLMOD

In this 1-byte field, specify one of the following modes:

- D** Retrieves the single log record whose RBA value and member id is specified in WQALLRBA. Issuing a D request while holding a position in the log, causes the request to fail and terminates the log position held.
- F** Used as a first call to request log records beyond the LRSN or RBA specified in WQALLRBA that meet the criteria specified in WQALLCRI.
- H** Retrieves the highest LRSN or log RBA in the active log. The value is returned in field IFCAHLRS of the IFI communications area (IFCA). There is no data returned in the return area and the return code for this call will indicate that no data was returned.
- N** Used following mode F or N calls to request any remaining log records that meet the criteria specified in WQALLCRI. \* and any option specified in WQALLOPT. As many log records as fit in the program’s return area are returned.
- T** Terminates the log position that was held by any previous F or N request. This allows held resources to be released.

Mode R is not used for IFCID 0306.

For both F or N requests, each log record returned contains a record-level feedback area recorded in QW0306L. The number of log records retrieved is in QW0306CT. The ending log RBA or LRSN of the log records to be returned is in QW0306ES.

### **WQALLRBA**

In this 8-byte field, specify the starting log RBA or LRSN of the control records to be returned. For IFCID 0306, this is used on the “first” option (F) request to request log records beyond the LRSN or RBA specified in this field. Determine the RBA or LRSN value from the H request. For RBAs, the value plus one should be used. For IFCID 0306 with D request of WQALLMOD, the high-order 2 bytes must specify member id and the low order 6 bytes contain the RBA.

### **WQALLCRI**

In this 1-byte field, indicate what types of log records you want:

**X'00'**

Tells DB2 to retrieve only log records for changed data capture and unit of recovery control.

**X'FF'**

Tells DB2 to retrieve all types of log records. Use of this option can retrieve large data volumes and degrade DB2 performance.

### **WQALLOPT**

In this 1-byte field, indicate whether you want the returned log records to be decompressed.

**X'01'**

Tells DB2 to decompress the log records before they are returned.

**X'00'**

Tells DB2 to leave the log records in the compressed format.

### **A typical sequence of IFCID 0306 calls is:**

#### **WQALLMOD=H**

This is only necessary if you want to find the current position in the log. The LRSN or RBA is returned in IFCAHLRS. The return area is not used.

#### **WQALLMOD=F**

The WQALLRBA, WQALLCRI and WQALLOPT should be set. If 00E60812 is returned, you have all the data for this scope. You should wait a while before issuing another WQALLMOD=F call. In data sharing, log buffers are flushed when the F request is issued.

#### **WQALLMOD=N**

If the 00E60812 has not been returned, you issue this call until it is. You should wait a while before issuing another WQALLMOD=F call.

#### **WQALLMOD=T**

This should only be used if you do not want to continue with the WQALLMOD=N before the end is reached. It has no use if a position is not held in the log.

**IFCID 0306 return area mapping:** IFCID 0306 has a unique return area format. The first section is mapped by QW0306OF instead of the write header DSNDAQWIN. See Appendix E, “Programming for the Instrumentation Facility Interface (IFI),” on page 1157 for details.

---

## Reading log records with OPEN, GET, and CLOSE

DB2 provides three stand-alone log services that user-written application programs can use to read DB2 recovery log records and control intervals even when DB2 is not running:

- OPEN initializes stand-alone log services.
- GET returns a pointer to the next log record or log record control interval.
- CLOSE deallocates data sets and frees storage.

To invoke these services, use the assembler language macro, DSNJSLR, specifying one of the preceding functions.

These log services use a *request block*, which contains a feedback area in which information for all stand-alone log GET calls is returned. The request block is created when a stand-alone log OPEN call is made. The request block must be passed as input to all subsequent stand-alone log calls (GET and CLOSE). The request block is mapped by the DSNDSLRLB macro and the feedback area is mapped by the DSNDSLRF macro.

See Figure 158 on page 1137 for an example of an application program that includes these various stand-alone log calls.

When you issue an OPEN request, you can indicate whether you want to get log records or log record control intervals. Each GET request returns a single logical record or control interval depending on which you selected with the OPEN request. If neither is specified, the default, RECORD, is used. DB2 reads the log in the forward direction of ascending relative byte addresses or log record sequence numbers (LRSNs).

If a bootstrap data set (BSDS) is allocated before stand-alone services are invoked, appropriate log data sets are allocated dynamically by z/OS. If the bootstrap data set is not allocated before stand-alone services are invoked, the JCL for your user-written application to read a log must specify and allocate the log data sets to be read.

Table 290 lists and describes the JCL DD statements used by stand-alone services.

*Table 290. JCL DD statements for DB2 stand-alone log services*

| JCL DD statement  | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOBCAT or STEPCAT | Specifies the catalog in which the BSDS and the active log data sets are cataloged. Required if the BSDS or any active log data set is to be accessed, unless the data sets are cataloged in the system master catalog.                                                                                                                                                                                                                 |
| BSDS              | Specifies the bootstrap data set (BSDS). Optional. Another ddname can be used for allocating the BSDS, in which case the ddname must be specified as a parameter on the FUNC=OPEN (see "Stand-alone log OPEN request" on page 1133 for more information). Using the ddname in this way causes the BSDS to be used. If the ddname is omitted on the FUNC=OPEN request, the processing uses DDNAME=BSDS when attempting to open the BSDS. |
| ARCHIVE           | Specifies the archive log data sets to be read. Required if an archive data set is to be read and the BSDS is not available (the BSDS DD statement is omitted). Should not be present if the BSDS DD statement is present. If multiple data sets are to be read, specify them as concatenated data sets in ascending log RBA order.                                                                                                     |

Table 290. JCL DD statements for DB2 stand-alone log services (continued)

| JCL DD statement                            | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACTIVE $n$                                  | (Where $n$ is a number from 1 to 7). Specifies an active log data set that is to be read. Should not be present if the BSDS DD statement is present. If only one data set is to be read, use ACTIVE1 as the ddname. If multiple active data sets are to be read, use DDNAMEs ACTIVE1, ACTIVE2, ... ACTIVE $n$ to specify the data sets. Specify the data sets in ascending log RBA order with ACTIVE1 being the lowest RBA and ACTIVE $n$ being the highest.                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DD statements for data sharing users</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| GROUP                                       | <p>If you are reading logs from every member of a data sharing group in LRSN sequence, you can use this statement to locate the BSDSs and log data sets needed. You must include the data set name of one BSDS in the statement. DB2 can find the rest of the information from that one BSDS.</p> <p>All members' logs and BSDS data sets must be available. If you use this DD statement, you must also use the LRSN and RANGE parameters on the OPEN request. The GROUP DD statement overrides any MxxBSDS statements that are used.</p> <p>(DB2 searches for the BSDS DD statement first, then the GROUP statement, and then the MxxBSDS statements. If you want to use a particular member's BSDS for your own processing, you must call that DD statement something other than BSDS.)</p>                               |
| MxxBSDS                                     | <p>Names the BSDS data set of a member whose log must participate in the read operation and whose BSDS is to be used to locate its log data sets. Use a separate MxxBSDS DD statement for each DB2 member. <math>xx</math> can be any two valid characters.</p> <p>Use these statements if logs from selected members of the data sharing group are required and the BSDSs of those members are available. These statements are ignored if you use the GROUP DD statement.</p> <p>For one MxxBSDS statement, you can use either RBA or LRSN values to specify a range. If you use more than one MxxBSDS statement, you must use the LRSN to specify the range.</p>                                                                                                                                                           |
| MyyARCHV                                    | <p>Names the archive log data sets of a member to be used as input. <math>yy</math> can be any two valid characters that do not duplicate any <math>xx</math> used in an MxxBSDS DD statement.</p> <p>Concatenate all required archived log data sets of a given member in time sequence under one DD statement. Use a separate MyyARCHV DD statement for each member. You must use this statement if the BSDS data set is unavailable or if you want only some of the log data sets from selected members of the group.</p> <p>If you name the BSDS of a member by a MxxBSDS DD statement, do not name the log of the same member by an MyyARCHV statement. If both MyyARCHV and MxxBSDS identify the same log data sets, the service request fails. MyyARCHV statements are ignored if you use the GROUP DD statement.</p> |

Table 290. JCL DD statements for DB2 stand-alone log services (continued)

| JCL DD statement     | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MyyACTn</code> | <p>Names the active log data set of a member to be used as input. <i>yy</i> can be any two valid characters that do not duplicate any <i>xx</i> used in an <code>MxxBSDS</code> DD statement. Use the same characters that identify the <code>MyyARCHV</code> statement for the same member; do <i>not</i> use characters that identify the <code>MyyARCHV</code> statement for any other member. <i>n</i> is a number from 1 to 16. Assign values of <i>n</i> in the same way as for <code>ACTIVE<sub>n</sub></code> DD statements.</p> <p>You can use this statement if the BSDS data sets are unavailable or if you want only some of the log data sets from selected members of the group.</p> <p>If you name the BSDS of a member by a <code>MxxBSDS</code> DD statement, do not name the log of the same member by an <code>MyyACT<sub>n</sub></code> statement. <code>MyyACT<sub>n</sub></code> statements are ignored if you use the <code>GROUP</code> DD statement.</p> |

The DD statements must specify the log data sets in ascending order of log RBA (or LRSN) range. If both `ARCHIVE` and `ACTIVEn` DD statements are included, the first archive data set must contain the lowest log RBA or LRSN value. If the JCL specifies the data sets in a different order, the job terminates with an error return code with a GET request that tries to access the first record breaking the sequence. If the log ranges of the two data sets overlap, this is not considered an error; instead, the GET function skips over the duplicate data in the second data set and returns the next record. The distinction between out-of-order and overlap is as follows:

- **Out-of-order condition** occurs when the log RBA or LRSN of the first record in a data set is greater than that of the first record in the following data set.
- **Overlap condition** occurs when the out-of-order condition is not met but the log RBA or LRSN of the last record in a data set is greater than that of the first record in the following data set.

Gaps within the log range are permitted. A gap is created when one or more log data sets containing part of the range to be processed are not available. This can happen if the data set was not specified in the JCL or is not reflected in the BSDS. When the gap is encountered, an exception return code value is set, and the next complete record after the gap is returned.

Normally, the BSDS DD name is supplied in the JCL, rather than a series of `ACTIVE` DD names or a concatenated set of data sets for the `ARCHIVE` ddname. This is commonly referred to as “running in BSDS mode”.

## Data sharing members that participate in a read

The number of members whose logs participate in a particular read request is determined by:

- The number of members in the group, if you use the `GROUP` DD statement
- Otherwise, the number of different *xxs* and *yys* used in the `Mxx` and `Myy` type DD statements.

For example, assume you need to read log records from members S1, S2, S3, S4, S5 and S6.

- S1 and S2 locate their log data sets by their BSDSs.
- S3 and S4 need both archive and active logs.

S4 has two active log data sets.  
 S5 needs only its archive log.  
 S6 needs only one of its active logs.

Then you need the following DD statements to specify the required log data sets:

|         |         |                     |                                |          |         |
|---------|---------|---------------------|--------------------------------|----------|---------|
| MS1BSDS | MS2BSDS | MS3ARCHV<br>MS3ACT1 | MS4ARCHV<br>MS4ACT1<br>MS4ACT2 | MS5ARCHV | MS6ACT1 |
|---------|---------|---------------------|--------------------------------|----------|---------|

The order of the DD statements in the JCL stream is not important.

## Registers and return codes

The request macro invoking these services can be used by reentrant programs. The macro requires that register 13 point to an 18-word save area at invocation. In addition, registers 0, 1, 14, and 15 are used as work and linkage registers. A return code is passed back in register 15 at the completion of each request. When the return code is nonzero, a reason code is placed in register 0. Return codes identify a class of errors, while the reason code identifies a specific error condition of that class. The stand-alone log return codes are shown in Table 291.

Table 291. Stand-alone log return codes

| Return code | Explanation                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| 0           | Successful completion.                                                                                                        |
| 4           | Exception condition (for example, end of file), not an error. This return code is not applicable for OPEN and CLOSE requests. |
| 8           | Unsuccessful completion due to improper user protocol.                                                                        |
| 12          | Unsuccessful completion. Error encountered during processing of a valid request.                                              |

The stand-alone log services invoke executable macros that can execute only in 24-bit addressing mode and reference data below the 16-MB line. User-written applications should be link-edited as AMODE(24), RMODE(24).

## Stand-alone log OPEN request

Issue this request when you want to initialize the stand-alone log services. The syntax for the stand-alone log OPEN request is:

```
{label} DSNJSLR  FUNC=OPEN
                  ,LRSN=YES3NO
                  ,DDNAME= address or (Reg. 2-12) optional
                  ,RANGE= address or (Reg. 2-12) optional
                  ,PMO=CI or RECORD
```

| Keyword          | Explanation                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FUNC=OPEN</b> | Requests the stand-alone log OPEN function.                                                                                                                                             |
| <b>LRSN</b>      | Tells DB2 how to interpret the log range:<br>NO: the log range is specified as RBA values. This is the default.<br>YES: the log range is specified as LRSN values.                      |
| <b>DDNAME</b>    | Specifies the address of an 8-byte area which contains the ddname to be used as an alternate to a ddname of the BSDS when the BSDS is opened, or a register that contains that address. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RANGE</b>  | <p>Specifies the address of a 12-byte area containing the log range to be processed by subsequent GET requests against the request block generated by this request, or a register that contains that address.</p> <p>If LRSN=NO, then the range is specified as RBA values. If LRSN=YES, then the range is specified as LRSN values.</p> <p>The first 6 bytes contain the low RBA or LRSN value. The first complete log record with an RBA or LRSN value equal to or greater than this value is the record accessed by the first log GET request against the request block. The last 6 bytes contain the end of the range or high RBA or LRSN value. An end-of-data condition is returned when a GET request tries to access a record with a starting RBA or LRSN value greater than this value. A value of 6 bytes of X'FF' indicates that the log is to be read until either the end of the log (as specified by the BSDS) or the end of the data in the last JCL-specified log data set is encountered.</p> <p>If BSDS, GROUP, or MxxBSDS DD statements are used for locating the log data sets to be read, the RANGE parameter is required. If the JCL determines the log data sets to be read, the RANGE parameter is optional.</p> |
| <b>PMO</b>    | <p>Specifies the processing mode. You can use OPEN to retrieve either log records or control intervals in the same manner. Specify PMO=CI or RECORD, then use GET to return the data you have selected. The default is RECORD.</p> <p>The rules remain the same regarding control intervals and the range specified for the OPEN function. Control intervals must fall within the range specified on the RANGE parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Output</b> | <b>Explanation</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>GPR 1</b>  | <p>General-purpose register 1 contains the address of a request block on return from this request. This address must be used for subsequent stand-alone log requests. When no more log GET operations are required by the program, this request block should be used by a FUNC=CLOSE request.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>GPR 15</b> | <p>General-purpose register 15 contains a return code upon completion of a request. For nonzero return codes, a corresponding reason code is contained in register 0. The return codes are listed and explained in Table 291 on page 1133.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>GPR 0</b>  | <p>General-purpose register 0 contains a reason code associated with a nonzero return code in register 15.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

See Part 3 of *DB2 Codes* for reason codes that are issued with the return codes.

**Log control interval retrieval:** You can use the PMO option to retrieve log control intervals from archive log data sets. DSNJSLR also retrieves log control intervals from the active log if the DB2 system is not active. During OPEN, if DSNJSLR detects that the control interval range is not within the archive log range available (for example, the range purged from BSDS), an error condition is returned.

Specify CI and use GET to retrieve the control interval you have chosen. The rules remain the same regarding control intervals and the range specified for the OPEN function. Control intervals must fall within the range specified on the RANGE parameter.

*Log control interval format:* A field in the last 7 bytes of the control interval, offset 4090, contains a 7-byte timestamp. This field reflects the time at which the control interval was written to the active log data set. The timestamp is in store clock (STCK) format and is the high-order 7 bytes of the 8-byte store clock value.

## Stand-alone log GET request

This request returns a pointer to a buffer containing the next log record based on position information in the request block.

A log record is available in the area pointed to by the request block until the next GET request is issued. At that time, the record is no longer available to the requesting program. If the program requires reference to a log record's content after requesting a GET of the next record, the program must move the record into a storage area that is allocated by the program.

The first GET request, after a FUNC=OPEN request that specified a RANGE parameter, returns a pointer in the request feedback area. This points to the first record with a log RBA value greater than or equal to the low log RBA value specified by the RANGE parameter. If the RANGE parameter was not specified on the FUNC=OPEN request, then the data to be read is determined by the JCL specification of the data sets. In this case, a pointer to the first complete log record in the data set that is specified by the ARCHIVE, or by ACTIVE1 if ARCHIVE is omitted, is returned. The next GET request returns a pointer to the next record in ascending log RBA order. Subsequent GET requests continue to move forward in log RBA sequence until the function encounters the end of RANGE RBA value, the end of the last data set specified by the JCL, or the end of the log as determined by the bootstrap data set.

The syntax for the stand-alone log GET request is:

```
{label} DSNJSLR  FUNC=GET  
                ,RBR=(Reg. 1-12)
```

| Keyword | Explanation |
|---------|-------------|
|---------|-------------|

|                 |                                            |
|-----------------|--------------------------------------------|
| <b>FUNC=GET</b> | Requests the stand-alone log GET function. |
|-----------------|--------------------------------------------|

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RBR</b> | Specifies a register that contains the address of the request block this request is to use. Although you can specify any register between 1 and 12, using register 1 (RBR=(1)) avoids the generation of an unnecessary load register and is therefore more efficient. The pointer to the request block (that is passed in register <i>n</i> of the RBR=( <i>n</i> ) keyword) must be used by subsequent GET and CLOSE function requests. |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Output

| Explanation |
|-------------|
|-------------|

|               |                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GPR 15</b> | General-purpose register 15 contains a return code upon completion of a request. For nonzero return codes, a corresponding reason code is contained in register 0. Return codes are listed and explained in Table 291 on page 1133. |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|              |                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------|
| <b>GPR 0</b> | General-purpose register 0 contains a reason code associated with a nonzero return code in register 15. |
|--------------|---------------------------------------------------------------------------------------------------------|

See Part 3 of *DB2 Codes* for reason codes that are issued with the return codes.

Reason codes 00D10261 - 00D10268 reflect a damaged log. In each case, the RBA of the record or segment in error is returned in the stand-alone feedback block field (SLRFRBA). A damaged log can impair DB2 restart; special recovery procedures are required for these circumstances. For recovery from these errors, refer to Chapter 22, "Recovery scenarios," on page 521.

Information about the GET request and its results is returned in the request feedback area, starting at offset X'00'. If there is an error in the length of some record, the control interval length is returned at offset X'0C' and the address of the beginning of the control interval is returned at offset X'08'.

On return from this request, the first part of the request block contains the feedback information that this function returns. Mapping macro DSNDSLRF defines the feedback fields which are shown in Table 292. The information returned is status information, a pointer to the log record, the length of the log record, and the 6-byte log RBA value of the record.

Table 292. Stand-alone log get feedback area contents

| Field name | Hex offset | Length (bytes) | Field contents                                                                                                                      |

| SLRFRG15   | 06         | 2              | VSAM register 15 return code value.                                                                                                 |
| SLRFFRAD   | 08         | 4              | Address of area containing the log record or CI                                                                                     |
| SLRFRCLL   | 0C         | 2              | Length of the log record or RBA                                                                                                     |
| SLRFRBA    | 0E         | 6              | Log RBA of the log record                                                                                                           |
| SLRFDDNM   | 14         | 8              | ddname of data set on which activity occurred                                                                                       |

## Stand-alone log CLOSE request

This request deallocates any log data sets that were dynamically allocated by previous processing. Also, all storage that was obtained by previous functions, including the request block specified on this request, is freed.

The syntax for the stand-alone log CLOSE request is:

```
{label} DSNJSLR  FUNC=CLOSE
                    ,RBR=(Reg. 1-12)
```

### Keyword Explanation

#### **FUNC=CLOSE**

Requests the CLOSE function.

#### **RBR**

Specifies a register that contains the address of the request block that this function uses. Although you can specify any register between 1 and 12, using register 1 (RBR=(1)) avoids the generation of an unnecessary load register and is therefore more efficient.

### **Output**

#### **Explanation**

#### **GPR 15**

Register 15 contains a return code upon completion of a request.

---

## Reading log records with the log capture exit routine

You can use the log capture exit routine to capture DB2 log data in real time. This installation exit routine presents log data to a log capture exit routine when the data is written to the DB2 active log. This exit routine is not intended to be used for general purpose log auditing or tracking. The IFI interface (see “Reading log records with IFI” on page 1126) is designed (and is more appropriate) for this purpose.

The log capture exit routine executes in an area of DB2 that is critical for performance. As such, it is primarily intended as a mechanism to capture log data for recovery purposes. In addition, the log capture exit routine operates in a very restrictive z/OS environment, which severely limits its capabilities as a stand-alone routine.

To capture log records with this exit routine, you must first write an exit routine (or use the one provided by the preceding program offering) that can be loaded and called under the various processing conditions and restrictions required of this exit routine. See “Log capture routines” on page 1105 and refer to the previous sections of this appendix, “Contents of the log” on page 1115 and “The physical structure of the log” on page 1120.

---

## Appendix D. Interpreting DB2 trace output

The information in this appendix is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

When you activate a DB2 trace, it produces trace records based on the parameters you specified for the START TRACE command. Each record identifies one or more significant DB2 events. You can use OMEGAMON to format, print, and interpret DB2 trace output. If you do not have OMEGAMON, or you want to do your own analysis of the trace output, you can use the information in this appendix and the trace field descriptions that are shipped with DB2. By examining a DB2 trace record, you can determine the type of trace that produced the record (statistics, accounting, audit, performance, monitor, or global) and the event the record reports.

This appendix contains the following sections:

- “The sections of the trace output”
- “Trace field descriptions” on page 1155

When the trace output indicates a particular release level, 'xx' varies according to the actual release of DB2.

---

### The sections of the trace output

Trace records can be written to SMF or GTF. In both cases, the record contains up to four basic sections:

- An SMF or GTF writer header section
- A self-defining section
- A product section
- Zero or more data sections

Figure 159 shows the format of DB2 trace records.

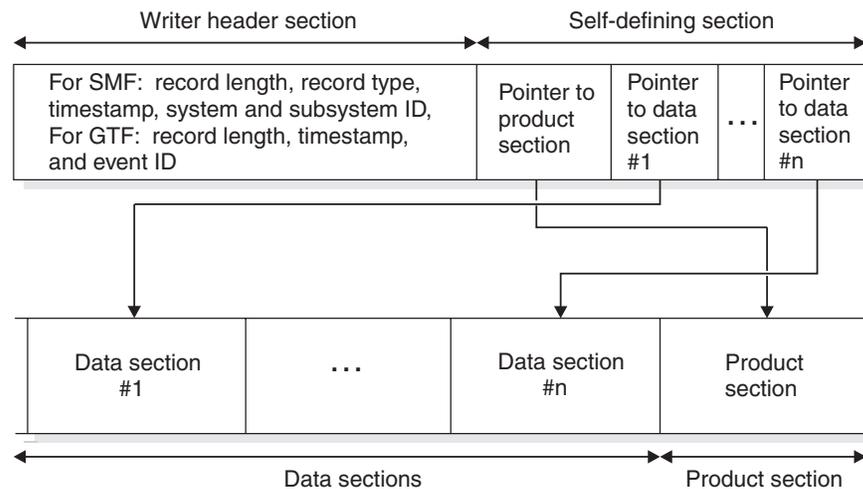

Figure 159. General format of trace records written by DB2

The writer header section begins at the first byte of the record and continues for a fixed length. (The GTF writer header is longer than the SMF writer header.)

The self-defining section follows the writer header section (both GTF and SMF) and is further described in “Self-defining section” on page 1147. The first self-defining section always points to a special data section called the product section. Among other things, the product section contains an instrumentation facility component identifier (IFCID). Descriptions of the records differ for each IFCID. For a list of records, by IFCID, for each class of a trace, see the description of the START TRACE command in *DB2 Command Reference*.

The product section also contains field QWHSNSDA, which indicates how many self-defining data sections the record contains. You can use this field to keep from trying to access data sections that do not exist. In trying to interpret the trace records, remember that the various keywords you specified when you started the trace determine whether any data is collected. If no data has been collected, field QWHSNSDA shows a data length of zero.

## SMF writer header section

In SMF, writer headers for statistics records are mapped by macro DSNDQWST, for accounting records by DSNDQWAS, and for performance, audit, and monitor records by DSNDQWSP. When these macros are assembled, they include the other macros necessary to map the remainder of the trace records sent to SMF.

The SMF writer header section begins at the first byte of the record. After establishing addressability, you can examine the header fields. The fields are described in Table 293.

Table 293. Contents of SMF writer header section

| Hex Offset | DSNDQWST | DSNDQWAS | DSNDQWSP | Description                                                                                                                                                                                                   |

## GTF writer header section

The length and content of the writer header section differs between SMF and GTF records, but the other sections of the records are the same for SMF and GTF.

The GTF writer header section begins at the first byte of the record. After establishing addressability, you can examine the fields of the header. The writer headers for trace records sent to GTF are always mapped by macro DSNDQWGT. The fields are described in Table 294 on page 1142.

Table 294. Contents of GTF writer header section

| Offset | Macro DSNDQWGT field | Description                                                |
|--------|----------------------|------------------------------------------------------------|
| 0      | QWGTLEN              | Length of Record                                           |
| 2      |                      | Reserved                                                   |
| 4      | QWGT AID             | Application identifier                                     |
| 5      | QWGT FID             | Format ID                                                  |
| 6      | QWGT TIME            | Timestamp; you must specify TIME=YES when you start GTF.   |
| 14     | QWGT EID             | Event ID: X'EFB9'                                          |
| 16     | QWGT ASCB            | ASCB address                                               |
| 20     | QWGT JOB N           | Job name                                                   |
| 28     | QWGT HDRE            | Extension to header                                        |
| 28     | QWGT DLEN            | Length of data section                                     |
| 30     | QWGT DSCC            | Segment control code<br>0=Complete 2=Last 1=First 3=Middle |
| 31     | QWGT DZZ2            | Reserved                                                   |
| 32     | QWGT SSID            | Subsystem ID                                               |
| 36     | QWGT WSEQ            | Sequence number                                            |
| 40     | QWGT END             | End of GTF header                                          |

Figure 161 on page 1143 contains trace output sent to GTF.

| <b>S</b> xx                    | Release indicator number (field QWHSRN); this varies according to the actual release level of DB2 you are using. |
| <b>T</b> E2C1D5E3...           | Local location name (16 bytes)                                                                                   |
| <b>U</b> 02                    | Last segment of the first record                                                                                 |
| <b>V</b>                       | End of first record                                                                                              |
| <b>W</b>                       | Beginning of GTF header for new record                                                                           |
| <b>X</b> 01                    | First segment of a spanned record (QWGTDS01 = QWGTDS01)                                                          |
| <b>Y</b> 03                    | Middle segment of a spanned record (QWGTDS03 = QWGTDS03)                                                         |
| <b>Z</b> 02                    | Last segment of a spanned record (QWGTDS02 = QWGTDS02)                                                           |
| <b>AA</b> 004C                 | Beginning of product section                                                                                     |

GTF records are blocked to 256 bytes. Because some of the trace records exceed the GTF limit of 256 bytes, they have been blocked by DB2. Use the following logic to process GTF records:

1. Is the GTF event ID of the record equal to the DB2 ID (that is, does QWGTID = X'x'FB9')?
  - If it is *not* equal, get another record.
  - If it is equal, continue processing.
2. Is the record spanned?
  - If it is spanned (that is, QWGTDS00 = QWGTDS00), test to determine whether it is the first, middle, or last segment of the spanned record.
    - a. If it is the *first* segment (that is, QWGTDS01 = QWGTDS01), save the entire record including the sequence number (QWGTSEQ) and the subsystem ID (QWGTSSID).
    - b. If it is a *middle* segment (that is, QWGTDS03 = QWGTDS03), find the first segment matching the sequence number (QWGTSEQ) and on the subsystem ID (QWGTSSID). Then move the data portion immediately after the GTF header to the end of the previous segment.

- c. If it is the *last* segment (that is, QWGTDS02), find the first segment matching the sequence number (QWGTSEQ) and on the subsystem ID (QWTGSSID). Then move the data portion immediately after the GTF header to the end of the previous record.

Now process the completed record.

If it is **not** spanned, process the record.

Figure 162 on page 1146 shows the same output after it has been processed by a user-written routine, which follows the logic that was outlined previously.

## Self-defining section

The self-defining section following the writer header contains pointers that enable you to find the product and data sections, which contain the actual trace data.

Each “pointer” is a descriptor that contains three fields, which are:

1. A fullword that contains the offset from the beginning of the record to the data section.
2. A halfword that contains the length of each item in the data section. If this value is zero, the length of the items are varied.
3. A halfword that contains the number of times that the data section is repeated. If the field contains “0”, the data section is not in the record. If it contains a number greater than 1, multiple data items are stored contiguously within that data section. To find the second data item, add the length of the first data item to the address of the first data item (and so forth).

Pointers occur in a fixed order, and their meanings are determined by the IFCID of the record. Different sets of pointers can occur, and each set is described by a separate DSECT. Therefore, to examine the pointers, you must first establish addressability by using the DSECT that provides the appropriate description of the self-defining section. To do this, perform the following steps:

1. Compute the address of the self-defining section.

The self-defining section begins at label “SM100END” for statistics records, “SM101END” for accounting records, and “SM102END” for performance and audit records. It does not matter which mapping DSECT you use because the length of the SMF writer header is always the same.

For GTF, use QWGTEND.

2. Determine the IFCID of the record.

Use the first field in the self-defining section; it contains the offset from the beginning of the record to the product section. The product section contains the IFCID.

The product section is mapped by DSNDQWHS; the IFCID is mapped by QWHSIID.

For statistics records that have IFCID 0001, establish addressability using label "QWS0"; for statistics records having IFCID 0002, establish addressability using label "QWS1". For accounting records, establish addressability using label "QWA0". For performance and audit records, establish addressability using label "QWT0".

After establishing addressability using the appropriate DSECT, use the pointers in the self-defining section to locate the record's data sections.

### Reading the self-defining section for same-length data items

If the length of each item in a data section is the same, the self-defining section indicates the length in a halfword that follows the fullword offset. If this value is "0", the length of the data items varies. For more information about variable-length data items, see "Reading the self-defining section for variable-length data items."

The relationship between the contents of the self-defining section "pointers" and the items in a data section for same-length data items is shown in Figure 163.

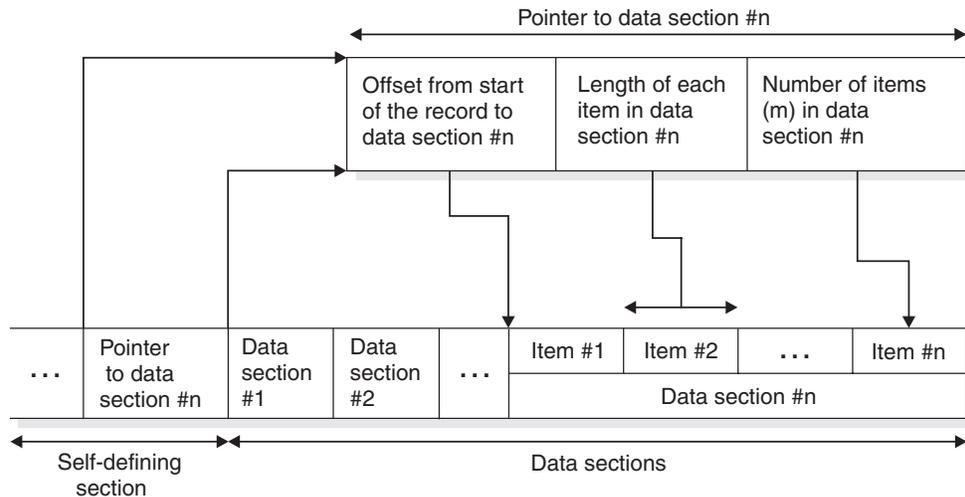

Figure 163. Relationship between self-defining section and data sections for same-length data items

### Reading the self-defining section for variable-length data items

If the length of each item in a data section varies, the self-defining section indicates the value "0" in the halfword that follows the fullword offset. The length of each variable-length data item is indicated by two bytes that precede each data item.

The relationship between the contents of the self-defining section "pointers" and the items in a data section for variable-length data items is shown in .

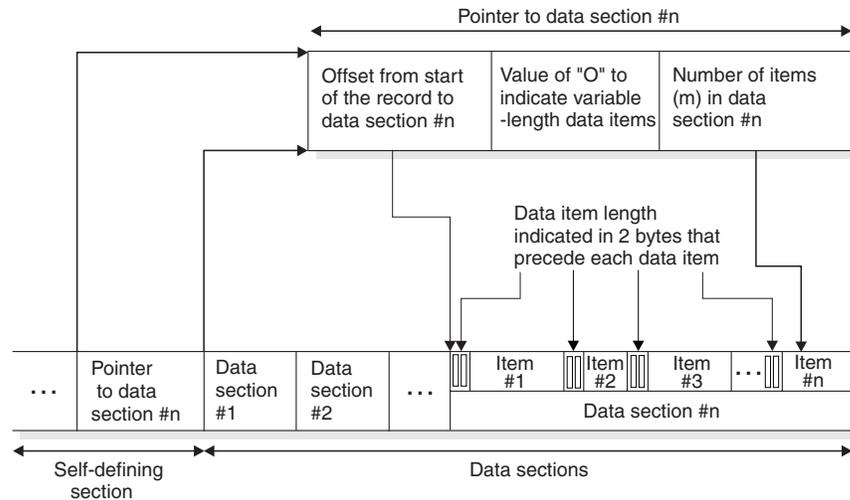

Figure 164. Relationship between self-defining section and data sections for variable-length data items

## Product section

The product section for all record types contains the standard header. The other headers (correlation, CPU, distributed, and data sharing data) might also be present. Table 295 shows the contents of the product section standard header.

Table 295. Contents of product section standard header

| Hex Offset | Macro DSNDQWHS field | Description                                 |
|------------|----------------------|---------------------------------------------|
| 0          | QWHSLEN              | Length of standard header                   |
| 2          | QWHSTYP              | Header type                                 |

| 14         | QWHAEND              | End of header                     |

The following sample shows an accounting trace for a distributed transaction sent to SMF (printed with the IMS DFSERA10 print program). In this example, one accounting record (IFCID 0003) is from the server site (SILICON\_VALLEY\_LAB). DSNDQWA0 maps the self-defining section for IFCID 0003.

| <b>P</b> 00005FC4 | Beginning of MVS/DDF accounting section (DSNDQMDA)                    |
| <b>Q</b> 00000000 | Beginning of locking accounting section (DSNDQTXA)                    |
| <b>R</b> 209501CC | Beginning of SQL accounting section (DSNDQXST)                        |
| <b>S</b> 00000000 | Beginning of buffer manager accounting section (DSNDQBAC)             |
| <b>T</b> 0052011A | Beginning of product section (DSNDQWHS); beginning of standard header |
| <b>U</b> 00020094 | Beginning of correlation header (DSNDQWHC)                            |
| <b>V</b> 00000038 | Beginning of distributed header (DSNDQWHD)                            |

---

## Trace field descriptions

If you intend to write a program to read DB2 trace records, use the assembler mapping macros in *prefix.SDSNMACS*.

You can use the TSO or ISPF browse function to look at the field descriptions in the trace record mapping macros online, even when DB2 is down. If you prefer to look at the descriptions in printed form, you can use ISPF to print a listing of the data set.

---

## Appendix E. Programming for the Instrumentation Facility Interface (IFI)

The information in this appendix is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The DB2 instrumentation facility gathers trace data that can be written to one or more destinations that you specify. The instrumentation facility interface (IFI) is designed for a program needing *online* trace information. IFI can be accessed through any of the DB2 attachment facilities.

IFI uses the standard security mechanisms that DB2 uses: connection authorization, plan authorization, and so forth. For more information about security, see Part 3, “Security and auditing,” on page 123. Security checks specifically related to IFI are included in the descriptions of the functions.

Before using IFI, you should be familiar with the material in “DB2 trace” on page 1195, which includes information on the DB2 trace facility and instrumentation facility component identifiers (IFCIDs).

Note that where the trace output indicates a particular release level, you will see 'xx' to show that this information varies according to the actual release of DB2 that you are using.

You can use IFI in a monitor program (a program or function outside of DB2 that receives information about DB2) to perform the following tasks:

- “Submitting DB2 commands through IFI”
- “Obtaining trace data through IFI” on page 1158
- “Passing data to DB2 through IFI” on page 1158

When a DB2 trace is active, internal events trigger the creation of trace records. The records, identified by *instrumentation facility component identifiers* (IFCIDs), can be written to buffers, and you can read them later with the IFI READA function. This means you are collecting the data *asynchronously*; you are not reading the data at the time it was written.

You can trigger the creation of certain types of trace records by using the IFI READS function. The records, identified as usual by IFCIDs, do not need a buffer; they are passed immediately to your monitor program through IFI. This means you are collecting the data *synchronously*. The data is collected at the time of the request for the data.

---

### Submitting DB2 commands through IFI

You can submit any DB2 command through IFI, but this capability is most useful for submitting DB2 trace commands to start, stop, display, and modify traces.

Using specified trace classes and IFCIDs, a monitor program can control the amount and type of its data. You can design your monitor program to:

- Activate and deactivate pre-defined trace classes.
- Activate and deactivate a trace record or group of records (identified by IFCIDs).

- Activate and deactivate predefined trace classes and trace records (identified by IFCIDs) restricting tracing to a set of DB2 identifiers (plan name, authorization ID, resource manager identifier (RMID), and so on).

---

## Obtaining trace data through IFI

You might want to collect trace data from DB2:

- To obtain accounting information for online billing.
- To periodically obtain system-wide information about DB2, highlight exceptional conditions, or provide throughput information.

The following illustrates the logic flow:

1. Initialize.
2. Set a timer.
3. Wait for the timer to expire.
4. Call IFI to obtain statistics data via a READS request.
5. Do delta calculations to determine activity.

This step is not necessary for IFCID 0199 because DB2 resets statistics at the beginning of every collection interval.

6. Display the information on a terminal.
  7. Loop back to the timer.
- To learn which processes have been connected to DB2 the longest, or which processes have used the most CPU time in DB2.
  - To obtain accounting records as transactions terminate.
  - To determine the access and processing methods for an SQL statement. Start a trace, issue a PREPARE statement, and then use the resulting trace data as an alternative to using EXPLAIN.
  - To capture log buffers online for use in remote recovery, as described in Appendix C, “Reading log records,” on page 1115.
  - To retrieve SQL changes synchronously from the log for processing in an application. See “Reading log records with IFI” on page 1126 for more information.

---

## Passing data to DB2 through IFI

You can use IFI to pass data to the destination of a DB2 trace. For example, you can:

- Extend accounting data collected within DB2. For example, a monitor program can collect batch file I/O counts, store them in a user-defined trace record, and process them along with standard DB2 accounting data.
- Include accounting data from QMF, IMS, or CICS.
- Permit CICS users to write the CICS accounting token and task number into the DB2 trace, assuming ACCOUNTREC in the DB2ENTRY RDO definition is neither UOW nor TASK .

---

## IFI functions

A monitor program can use the following IFI functions:

**COMMAND** To submit DB2 commands. For more information, see “COMMAND: Syntax and usage with IFI” on page 1160.

**READS** To obtain monitor trace records synchronously. The READS request

causes those records to be returned immediately to the monitor program. For more information, see “READS: Syntax and usage with IFI” on page 1162.

- READA** To obtain trace records of any trace type asynchronously. DB2 records trace events as they occur and places that information into a buffer; a READA request moves the buffered data to the monitor program. For more information, see “READA: Syntax and usage with IFI” on page 1176.
- WRITE** To write information to a DB2 trace destination that was previously activated by a START TRACE command. For more information, see “WRITE: Syntax and usage with IFI” on page 1178.

---

## Invoking IFI from your program

IFI can be used by assembler and PL/I programs. To use IFI, include a call to DSNWLI in your monitor program.

The following example depicts an IFI call in an assembler program. All examples in this appendix are given for assembler.

```
CALL DSNWLI, (function, ifca, parm-1, ... parm-n), VL
```

The parameters that are passed on the call indicate the desired function (as described in “IFI functions” on page 1158), point to communication areas used by the function, and provide other information that depends on the function specified. Because the parameter list may vary in length, the high-order bit of the last parameter must be on to signal that it is the last parameter in the list.

**Example:** To turn on the bit in assembler, use the VL option to signal a variable length parameter list.

The communication areas that are used by IFI are described in “Common communication areas for IFI calls” on page 1179.

After you insert this call in your monitor program, you must link-edit the program with the correct language interface. Each of the following language interface modules has an entry point of DSNWLI for IFI:

- CAF DSNALI
- TSO DSNELI
- CICS DSNCLI
- IMS DFSLI000
- RRSF DSNRLI

CAF DSNALI, the CAF (call attachment facility) language interface module, includes a second entry point of DSNWLI2. The monitor program that link-edits DSNALI with the program can make IFI calls directly to DSNWLI. The monitor program that loads DSNALI must also load DSNWLI2 and remember its address. When the monitor program calls DSNWLI, the program must have a dummy entry point to handle the call to DSNWLI and then call the real DSNWLI2 routine. See Part 6 of *DB2 Application Programming and SQL Guide* for additional information about using CAF.

**Considerations for writing a monitor program:** A monitor program issuing IFI requests must be connected to DB2 at the thread level. If the program contains SQL statements, you must precompile the program and create a DB2 plan using the BIND process. If the monitor program does not contain any SQL statements, it

does not have to be precompiled. However, as is the case in all the attachment environments, even though an IFI only program (one with no SQL statements) does not have a plan of its own, it can use any plan to get the thread level connection to DB2.

The monitor program can run in either 24- or 31-bit mode.

**Monitor trace classes:** Monitor trace classes 2 through 8 can be used to collect information related to DB2 resource usage. Use monitor trace class 5, for example, to find out how much time is spent processing IFI requests. Monitor trace classes 2, 3, and 5 are identical to accounting trace classes 2, 3, and 5. For more information about these traces, see “Monitor trace” on page 1198.

**Monitor authorization:** On the first READA or READS call from a user, an authorization is checked to determine if the primary authorization ID or one of the secondary authorization IDs of the plan executor has MONITOR1 or MONITOR2 privilege. If your installation uses the access control authorization exit routine, that exit routine might control the privileges that can use the monitor trace. If you have an authorization failure, an audit trace (class 1) record is generated that contains the return and reason codes from the exit. This is included in IFCID 0140. See “Access control authorization exit routine” on page 1065 for more information on the access control authorization exit routine.

---

## Using IFI from stored procedures

You can use the IFI interface from a stored procedure. The output of the trace can be returned to the client. You can also issue DB2 commands, such as “DISPLAY THREAD”, from a stored procedure and return the results to the client.

---

## COMMAND: Syntax and usage with IFI

A DB2 command resides in the output area; a monitor program can submit that command by issuing a COMMAND request to IFI. The DB2 command is processed and the output messages are returned to the monitor program in the return area.

You can submit any DB2 command, including START TRACE, STOP TRACE, DISPLAY TRACE, and MODIFY TRACE. Because the program can also issue other DB2 commands, you should be careful about which commands you use. For example, do **not** use STOP DB2.

## Authorization for DB2 commands through IFI

For an application program to submit a command, the primary authorization ID or one of the secondary authorization IDs of the process must have the appropriate DB2 command authorization. Otherwise the request is denied. An application program might have the authorization to issue DB2 commands, but not the authorization to issue READA requests. For more information about authorization, see Part 3, “Security and auditing,” on page 123.

## Syntax for DB2 commands through IFI

DB2 commands that are issued through IFI have the following syntax:  
CALL DSNWLI, ('COMMAND ', ifca, return-area, output-area, buffer-info .), VL

### *ifca*

IFCA (instrumentation facility communication area) is an area of storage that contains the return code and reason code. IFCA indicates the following information:

- The success or failure of the request
- Diagnostic information from the DB2 component that executed the command
- The number of bytes moved to the return area
- The number of bytes of the message segments that did not fit in the return area

Some commands might return valid information despite a non-zero return code or reason code. For example, the DISPLAY DATABASE command might indicate that more information could have been returned than was allowed.

If multiple errors occur, the last error is returned to the caller. For example, if the command is in error and the error message does not fit in the area, the error return code and reason code indicate that the return area is too small.

If a monitor program issues START TRACE, the ownership token (IFCAOWNER) in the IFCA determines the owner of the asynchronous buffer. The owner of the buffer is the only process that can obtain data through a subsequent READA request. See "Instrument facility communications area (IFCA)" on page 1179 for a description of the IFCA.

### *return-area*

When the issued command finishes processing, it places messages (if any) in the return area. The messages are stored as varying-length records, and the total number of bytes in the records is placed in the IFCABM (bytes moved) field of the IFCA. If the return area is too small, as many message records as will fit are placed into the return area.

The monitor program should analyze messages that are returned by the command function. See "Return area" on page 1183 for a description of the return area.

### *output-area*

Contains the varying-length command. See "Output area" on page 1184 for a description of the output area.

### *buffer-info*

This parameter is required for starting traces to an OP buffer. Otherwise, it is not needed. This parameter is used only on COMMAND requests. It points to an area that contains information about processing options when a trace is started by an IFI call to an unassigned OP $n$  destination buffer. An OP $n$  destination buffer is considered unassigned if it is not owned by a monitor program.

If the OP $n$  destination buffer is assigned, then the buffer information area is not used on a later START or MODIFY TRACE command to that OP $n$  destination. For more information about using OP $n$  buffers, see "Usage notes for READA requests through IFI" on page 1176.

When you use *buffer-info* on START TRACE, you can specify the number of bytes that can be buffered before the monitor program ECB is posted. The ECB is posted when the amount of trace data collected has reached the value that is specified in the byte count field. The byte count field is also specified in the buffer information area.

Table 301 on page 1162 summarizes the fields in the buffer information area.

Table 301. Buffer information area fields. This area is mapped by assembler mapping macro DSNDWBUF.

| Name    | Hex offset | Data type                | Description                                                                                                                                                                                 |
|---------|------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WBUFLEN | 0          | Signed two-byte integer  | Length of the buffer information area, plus 4. A zero indicates the area does not exist.                                                                                                    |
|         | 2          | Signed two-byte integer  | Reserved.                                                                                                                                                                                   |
| WBUFEYE | 4          | Character, 4 bytes       | Eye catcher for block, WBUF.                                                                                                                                                                |
| WBUFECB | 8          | Address                  | The ECB address to post when the buffer has reached the byte count specification (WBUFBC). The ECB must reside in monitor key storage.                                                      |
|         |            |                          | A zero indicates not to post the monitor program. In this case, the monitor program should use its own timer to determine when to issue a READA request.                                    |
| WBUFBC  | C          | Signed four-byte integer | The records placed into the instrumentation facility must reach this value before the ECB will be posted. If the number is zero, and an ECB exists, posting occurs when the buffer is full. |

## Example of DB2 command through IFI

This example issues a DB2 START TRACE command for MONITOR Class 1.

```
CALL DSNWLI,('COMMAND ',IFCAAREA,RETAREA,OUTAREA,BUFAREA),VL
:
:
COMMAND DC CL8 'COMMAND '
*****
* Function parameter declaration *
*****
* Storage of LENGTH(IFCA) and properly initialized *
*****
IFCAAREA DS      0CL180
:
*****
* Storage for length and returned info. *
*****
RETAREA  DS      CL608
*****
* Storage for length and DB2 Command *
*****
OUTAREA  DS      0CL42
OUTLEN   DC      X'002A0000'
OUTCMD   DC      CL37'-STA TRAC(MON) DEST(OPX) BUFSIZE(256) '
*****
* Storage of LENGTH(WBUF) and properly initialized *
*****
BUFAREA  DS      0CL16

:
```

Figure 165. Starting a trace using IFI

## READS: Syntax and usage with IFI

```
# READS allows your monitor program to read DB2 status information that is
# collected at the time of the IFI call. The records available are for IFCIDs 0001, 0002,
# 0106, 0124, 0129, 0147, 0148, 0149, 0150, 0185, 0199, 0202, 0230, 0234, 0254, 0306,
# 0316, and 0317. For a description of the data that these records provide, see
# "Synchronous data and READS requests through IFI" on page 1172. IFCID 0124,
# 0129, 0147, 148, 149, 0150, 0199, 234, 0254, 0316, and 0317 can be obtained only
# through the IFI READS interface.
```

The program that issues the READS request does not need to start monitor class 1 because no ownership of an OP buffer is involved when you obtain data from the READS interface. Data is written directly to the application program's return area, bypassing the OP buffer. This bypass is in direct contrast to the READA interface where the application that issues READA must first issue a START TRACE command to obtain ownership of an OP buffer and start the appropriate traces.

## Authorization for READS requests through IFI

On a READS request, a check is made to see if monitor class 1 is active; if it is not active, the request is denied. The primary authorization ID or one of the secondary authorization IDs of the process running the application program must have MONITOR1 or MONITOR2 privilege. If neither the primary authorization ID nor one of the secondary authorization IDs has authorization, the request is denied.

**Exception:** IFCID 185 requests do not require the MONITOR1 or MONITOR2 privilege.

READS requests are checked for authorization once for each user (ownership token) of the thread. (Several users can use the same thread, but an authorization check is performed each time the user of the thread changes.)

If you use READS to obtain your own data (IFCID 0124, 0147, 0148, or 0150 not qualified), no authorization check is performed.

## Syntax for READS requests through IFI

DB2 commands that are issued through IFI have the following syntax:

```
CALL DSNWLI, ('READS ' , ifca, return-area, ifcid-area, qual-area), VL
```

*ifca*

Contains information about the success of the call. See "Instrument facility communications area (IFCA)" on page 1179 for a description of the IFCA.

*return-area*

Contains the varying-length records that are returned by the instrumentation facility. IFI monitor programs might require large enough READS return areas to accommodate the following information:

- Larger IFCID 0147 and 0148 records that contain distributed thread data (both allied and database access).
- Additional records that are returned when database access threads exist that satisfy the specified qualifications on the READS request.
- Log record control intervals with IFCID 129. For more information about using IFI to return log records, see "Reading specific log records (IFCID 0129)" on page 1126.
- Log records based on user-specified criteria with IFCID 306. For example, the user can retrieve compressed or decompressed log records. For more information about reading log records, see Appendix C, "Reading log records," on page 1115.
- Data descriptions and changed data returned with IFCID 185.

If the return area is too small to hold all the records returned, it contains as many records as will fit. The monitor program obtains the return area for READS requests in its private address space. See "Return area" on page 1183 for a description of the return area.

*ifcid-area*

Contains the IFCIDs of the desired information. The number of IFCIDs can be

variable. If the length specification of the IFCID area is exceeded or an IFCID of X'FFFF' is encountered, the list is terminated. If an invalid IFCID is specified no data is retrieved. See "IFCID area" on page 1184 for a description of the IFCID area.

*qual-area*

This parameter is optional, and is used only on READS requests. It points to the qualification area, where a monitor program can specify constraints on the data that is to be returned. If the qualification area does not exist (length of binary zero), information is obtained from all active allied threads and database access threads. Information is not obtained for any inactive database access threads that might exist.

The length constants for the qualification area are provided in the DSNDWQAL mapping macro. If the length is not equal to the value of one of these constants, IFI considers the call invalid.

The following trace records, identified by IFCID, cannot be qualified: 0001, 0002, 0106, 0202, 217, 225, 0230. If you attempt to qualify them, the qualification is ignored.

The rest of the synchronous records can be qualified. See "Synchronous data and READS requests through IFI" on page 1172 for information about these records. However, not all the qualifications in the qualification area can be used for these IFCIDs. See "Which qualifications are used for READS requests issued through IFI?" on page 1171 for qualification restrictions. Unless the qualification area has a length of binary zero (in which case the area does not exist), the address of *qual-area* supplied by the monitor program points to an area that is formatted by the monitor program, as shown in Table 302.

Table 302. Qualification area fields. This area is mapped by the assembler mapping macro DSNDWQAL.

| Name    | Hex offset | Data type               | Description                                                                                                                                                |
|---------|------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WQALLEN | 0          | Signed two-byte integer | Length of the qualification area, plus 4. The following constants set the qualification area length field:                                                 |
|         |            | <b>WQALLN4</b>          | When specified, the location name qualifications (WQALLOCN and WQALLUWI), the group buffer pool qualifier (WQALGBP) and the read log fields are used.      |
|         |            | <b>WQALLN5</b>          | When specified, the dynamic statement cache fields (WQALFFLD, WQALFVAL, WQALSTNM, and WQALSTID) are used for READS calls for IFCID 0316 and 0317.          |
|         |            | <b>WQALLN6</b>          | When specified, the end-user identification fields (WQALEUID, WQALEUTX, and WQALEUWS) are used for READS calls for IFCID 0124, 0147, 0148, 0149, and 0150. |
|         |            | <b>WQALLN21</b>         | When specified, the location name qualifications (WQALLOCN and WQALLUWI) are ignored.                                                                      |
|         |            | <b>WQALLN22</b>         | When specified, the location name qualifications (WQALLOCN and WQALLUWI) are used.                                                                         |
|         |            | <b>WQALLN23</b>         | When specified, the log data access fields (WQALLTYP, WQALLMOD, WQALLRBA, and WQALLNUM) are used for READS calls that use IFCID 129.                       |

Table 302. Qualification area fields (continued). This area is mapped by the assembler mapping macro DSNDWQAL.

| Name       | Hex offset | Data type               | Description                                                                                                                                                                                                                                                                                                        |
|------------|------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | 2          | Signed two-byte integer | Reserved.                                                                                                                                                                                                                                                                                                          |
| WQALEYE    | 4          | Character, 4 bytes      | Eye catcher for block, WQAL.                                                                                                                                                                                                                                                                                       |
| WQALACE    | 8          | Address                 | Thread identification token value. This value indicates the specific thread wanted; binary zero if it is not to be used.                                                                                                                                                                                           |
| WQALAIT2   | C          | Address                 | Reserved.                                                                                                                                                                                                                                                                                                          |
| WQALPLAN   | 10         | Character, 8 bytes      | Plan name; binary zero if it is not to be used.                                                                                                                                                                                                                                                                    |
| WQALAUTH   | 18         | Character, 8 bytes      | The current primary authorization ID; binary zero if it is not to be used.                                                                                                                                                                                                                                         |
| WQALOPID   | 20         | Character, 8 bytes      | The original authorization ID; binary zero if it is not to be used.                                                                                                                                                                                                                                                |
| WQALCONN   | 28         | Character, 8 bytes      | Connection name; binary zero if it is not to be used.                                                                                                                                                                                                                                                              |
| WQALCORR   | 30         | Character, 12 bytes     | Correlation ID; binary zero if it is not to be used.                                                                                                                                                                                                                                                               |
| WQALREST   | 3C         | Character, 32 bytes     | Resource token for a specific lock request when IFCID 0149 is specified. The field must be set by the monitor program. The monitor program can obtain the information from a previous READS request for IFCID 0150 or from a READS request for IFCID 0147 or 0148.                                                 |
| WQALHASH   | 5C         | Hex, 4 bytes            | Resource hash value that specifies the resource token for a specific lock request when IFCID 0149 is specified. The field must be set by the monitor program. The monitor program can obtain the information from a previous READS request for IFCID 0150 or possibly from a READS request for IFCID 0147 or 0148. |
| WQALASID   | 60         | Hex, 2 bytes            | ASID that specifies the address space of the desired process.                                                                                                                                                                                                                                                      |
| WQALFOPT   | 62         | Hex, 1 byte             | Filtering options for IFCID 0150:                                                                                                                                                                                                                                                                                  |
| #          |            |                         | X'20' Return lock information for resources that have local or global waiters.                                                                                                                                                                                                                                     |
| #          |            |                         | X'40' Return lock information only for resources that have one or more interested agents.                                                                                                                                                                                                                          |

|          | 7C         | Character, 16 bytes | <p>Location name. If specified, data is returned only for distributed agents that originate at the specified location.</p> <p><b>Example:</b> If site A is located where the IFI program is running and SITE A is specified in the WQALLOCN, database access threads and distributed allied agents that execute at SITE A are reported. Local non-distributed agents are not reported.</p> <p><b>Example:</b> If site B is specified in the WQALLOCN and the IFI program is still executing at site A, information on database access threads that execute in support of a distributed allied agent at site B are reported.</p> <p><b>Example:</b> If WQALLOCN is not specified, information on all threads that execute at SITE A (the site where the IFI program executes) is returned. This includes local non-distributed threads, local database access agents, and local distributed allied agents.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| WQALLTYP | 8C         | Character, 3 bytes  | Specifies the type of log data access. 'CI' must be specified to obtain log record control intervals (CIs).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| WQALLMOD | 8F         | Character, 1 byte   | <p>The mode of log data access:</p> <p><b>'D'</b> Return the direct log record specified in WQALLRBA if the IFCID is 0306.</p> <p><b>'F'</b> Access the first log CI of the restarted DB2 system if the IFCID is 0129. One CI is returned, and the WQALLNUM and WQALLRBA fields are ignored. It indicates to return the first set of qualified log records if the IFCID is 0306.</p> <p><b>'H'</b> Return the highest LRSN or log RBA in the active log. The value is returned in the field IFCAHLRS in the IFCA.</p> <p><b>'N'</b> Return the next set of qualified log records.</p> <p><b>'P'</b> the last partial CI written to the active log is given to the Log Capture Exit. If the last CI written to the log was not full, the RBA of the log CI given to the Log Exit is returned in the IFCAHLRS field of the IFI communication area (IFCA). Otherwise, an RBA of zero is returned in IFCAHLRS. This option ignores WQALLRBA and WQALLNUM.</p> <p><b>'R'</b> Access the CIs specified by the value in the WQALLRBA field:</p> <ul style="list-style-type: none"> <li>• If the requested number of complete CIs (as specified in WQALLNUM) are currently available, those CIs are returned. If fewer than the requested number of complete CIs are available, IFI returns as many complete CIs as are available.</li> <li>• If the WQALLRBA value is beyond the end of the active log, IFI returns a return code of X'0000000C' and a reason code of X'00E60855'. No records are returned.</li> <li>• If no complete CIs exist beyond the WQALLRBA value, IFI returns a return code of X'0000000C' and a reason code of X'00E60856'. No records are returned.</li> </ul> <p><b>'T'</b> Terminate the log position that is held to anticipate a future mode 'N' call.</p> |

Table 302. Qualification area fields (continued). This area is mapped by the assembler mapping macro DSNDWQAL.

| Name     | Hex offset | Data type          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| WQALLRBA | 94         | Hex, 8 bytes       | If the IFCID is 0129, this is the starting log RBA of the CI to be returned. The CI starting log RBA value must end in X'000'. The RBA value must be right-justified.<br><br>If the IFCID is 0306, this is the log RBA or LRSN to be used in mode 'F'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| WQALGBP  | 9C         | Character, 8 bytes | Group buffer pool name for IFCID 0254. Buffer pool name for IFCID 0199. To specify a single buffer pool or group buffer pool, specify the buffer pool name in hexadecimal, followed by hexadecimal blanks.<br><br><b>Example:</b> To specify buffer pool BP1, put X'C2D7F140404040' in this field.<br><br>To specify more than one buffer pool or group buffer pool, use the pattern-matching character X'00' in any position in the buffer pool name. X'00' indicates that any character can appear in that position, and in all positions that follow.<br><br><b>Example:</b> If you put X'C2D7F10000000000' in this field, you indicate that you want data for all buffer pools whose names begin with BP1, so IFI collects data for BP1, BP10 through BP19, and BP16K0 through BP16K9.<br><br><b>Example:</b> If you put X'C2D700F100000000' in this field, you indicate that you want data for all buffer pools whose names begin with BP, so IFI collects data for all buffer pools. IFI ignores X'F1' in position four because it occurs after the first X'00'. |
| WQALLCRI | A4         | Hex, 1 byte        | Log Record Selection Criteria:<br>' <b>00</b> ' Indicates the return DB2CDC and UR control log records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| WQALLOPT | A5         | Hex, 1 byte        | Processing Options relating to decompression:<br>' <b>00</b> ' Indicates that decompression should not occur.<br>' <b>01</b> ' Indicates to decompress the log records if they are compressed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 302. Qualification area fields (continued). This area is mapped by the assembler mapping macro DSNDWQAL.

| Name     | Hex offset | Data type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WQALFLTR | A6         | Hex, 1 byte | <p>For an IFCID 0316 request, WQALFLTR identifies the filter method:</p> <p><b>X'00'</b> Indicates no filtering. This value tells DB2 to return information for as many cached statements as fit in the return area.</p> <p><b>X'01'</b> Indicates that DB2 returns information about the cached statements that have the highest values for a particular statistics field. The statistics field is specified in WQALFFLD. DB2 returns information for as many statements as fit in the return area.</p> <p><b>Example:</b> If the return is large enough for information about 10 statements, the statements with the ten highest values for the specified statistics field are reported.</p> <p><b>X'02'</b> Indicates that DB2 returns information about the cached statements that exceed a threshold value for a particular statistics field. The name of the statistics field is specified in WQALFFLD. The threshold value is specified in WQALFVAL. DB2 returns information for as many qualifying statements as fit in the return area.</p> <p><b>X'04'</b> Indicates that DB2 returns information about a single cached statement. The application provides the four-byte cached statement identifier in field WQALSTID. An IFCID 0316 request with this qualifier is intended for use with IFCID 0172 or IFCID 0196, to obtain information about the statements that are involved in a timeout or deadlock.</p> <p>For an IFCID 0317 request, WQALFLTR identifies the filter method:</p> <p><b>X'04'</b> Indicates that DB2 returns information about a single cached statement. The application provides the four-byte cached statement identifier in field WQALSTID. An IFCID 0317 request with this qualifier is intended for use with IFCID 0172 or IFCID 0196, to obtain information about the statements that are involved in a timeout or deadlock.</p> <p>For an IFCID 0306 request, WQALFLTR indicates whether DB2 merges log records in a data sharing environment:</p> <p><b>X'00'</b> Indicates that DB2 merges log records from data sharing members.</p> <p><b>X'03'</b> Indicates that DB2 does not merge log records from data sharing members.</p> |

| WQALFFLD | A7         | Character, 1 byte | <p>For an IFCID 0316 request, when WQALFLTR is X'01' or X'02', this field specifies the statistics field that is used to determine the cached statements about which DB2 reports. You can enter the following values:</p> <p>'A' The accumulated elapsed time (QW0316AE). This option is valid only when QWALFLTR=X'01'.</p> <p>'B' The number of buffer reads (QW0316NB).</p> <p>'C' The accumulated CPU time (QW0316CT). This option is valid only when QWALFLTR=X'01'.</p> <p>'E' The number of executions of the statement (QW0316NE).</p> <p>'G' The number of GETPAGE requests (QW0316NB).</p> <p>'I' The number of index scans (QW0316NI).</p> <p>'L' The number of parallel groups (QW0316NL).</p> <p>'P' The number of rows processed (QW0316NP).</p> <p>'R' The number of rows examined (QW0316NR).</p> <p>'S' The number of sorts performed (QW0316NS).</p> <p>'T' The number of table space scans (QW0316NT).</p> <p>'W' The number of buffer writes (QW0316NW).</p> <p>'X' The number of times that a RID list was not used because the number of RIDs would have exceeded one or more internal DB2 limits (QW0316RT).</p> <p>'Y' The number of times that a RID list was not used because not enough storage was available (QW0316RS).</p> <p>'1' The accumulated wait time for synchronous I/O (QW0316W1). This option is valid only when QWALFLTR=X'01'.</p> <p>'2' The accumulated wait time for lock and latch requests (QW0316W2). This option is valid only when QWALFLTR=X'01'.</p> <p>'3' The accumulated wait time for a synchronous execution unit switch (QW0316W3). This option is valid only when QWALFLTR=X'01'.</p> <p>'4' The accumulated wait time for global locks (QW0316W4). This option is valid only when QWALFLTR=X'01'.</p> <p>'5' The accumulated wait time for read activity by another thread (QW0316W5). This option is valid only when QWALFLTR=X'01'.</p> <p>'6' The accumulated wait time for write activity by another thread (QW0316W6). This option is valid only when QWALFLTR=X'01'.</p> |

Table 302. Qualification area fields (continued). This area is mapped by the assembler mapping macro DSNWQAL.

| Name     | Hex offset | Data type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| WQALFVAL | A8         | Signed 4-byte integer   | For an IFCID 0316 request, when WQALFLTR is X'02', this field and WQALFFLD determine the cached statements about which DB2 reports.<br><br>To be eligible for reporting, a cached statement must have a value for WQALFFLD that is no smaller than the value that you specify in WQALFVAL. DB2 reports information on as many eligible statements as fit in the return area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| WQALSTNM | AC         | Character, 16 bytes     | For an IFCID 0317 request, when WQALFLTR is not X'04', this field specifies the name of a cached statement about which DB2 reports. This is a name that DB2 generates when it caches the statement. To obtain this name, issue a READS request for IFCID 0316. The name is in field QW0316NM. This field and WQALSTID uniquely identify a cached statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| WQALSTID | BC         | Unsigned 4-byte integer | For an IFCID 0316 or IFCID 0317 request, this field specifies the ID of a cached statement about which DB2 reports. DB2 generates this ID when it caches the statement.<br><br>To obtain the ID, use the following options: <ul style="list-style-type: none"> <li>• For an IFCID 0317 request, when WQALFLTR is not X'04', obtain this ID by issuing a READS request for IFCID 0316. The ID is in field QW0316TK. This field and WQALSTNM uniquely identify a cached statement.</li> <li>• For an IFCID 0316 or IFCID 0317 request, when WQALFLTR is X'04', obtain this ID by issuing a READS request for IFCID 0172 or IFCID 0196. The ID is in field QW0172H9 (cached statement ID for the holder in a deadlock), QW0172W9 (cached statement ID for the waiter in a deadlock), or QW0196H9 (cached statement ID of the holder in a timeout). This field uniquely identifies a cached statement.</li> </ul> |
| WQALEUID | C0         | Character, 16 bytes     | The end user's workstation user ID. This value can be different from the authorization ID that is used to connect to DB2. This field contains binary zeroes if the client does not supply this information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| WQALEUTX | D0         | Character, 32 bytes     | The name of the transaction or application that the end user is running. This value identifies the application that is currently running, not the product that is used to run the application. This field contains binary zeroes if the client does not supply this information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| WQALEUWS | F0         | Character, 18 bytes     | The end user's workstation name. This value can be different from the authorization ID used to connect to DB2. This field contains binary zeroes if the client does not supply this information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

# **Note:** 1. The only valid filters for DDF/RRSAF 147/148 rollup records are WQALEUID, WQALEUTX, and WQALEUWN. For a 147/148 request, DDF/RRSAF records are not processed if any of the following WQAL fields are not X'00':

- # • WQALACE
- # • WQALAUTH
- # • WQALOPID
- # • WQALPLAN
- # • WQALCORR
- # • WQALLUWI
- # • WQALLOCN
- # • WQALASID
- # • WQALCONN

**Important:** If your monitor program does not initialize the qualification area, the READS request is denied.

## Which qualifications are used for READS requests issued through IFI?

Not all qualifications are used for all IFCIDs. Table 303 lists the qualification fields that are used for each IFCID.

*Table 303. Qualification fields for IFCIDs*

| These IFCIDs...        | Are allowed to use these qualification fields                                                                                                                                                                                                      |

| <b>Note:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                               |
| <ol style="list-style-type: none"> <li>DB2 allows you to partially qualify a field and fill the rest of the field with binary zero. For example, the 12-byte correlation value for a CICS thread contains the 4-character CICS transaction code in positions 5-8. Assuming a CICS transaction code of AAAA, the following hexadecimal <i>qual-area</i> correlation qualification can be used to find the first transaction with a correlation value of AAAA in positions 5-8:<br/>X'00000000C1C1C1C100000000'.</li> <li>X'00' in this field indicates a pattern-matching character. X'00' in any position of the field indicates that IFI collects data for buffer pools whose names contain any character in that position and all following positions.</li> </ol> |                                               |

## Usage notes for READS requests through IFI

Due to performance considerations, the majority of data that is obtained by a monitor program probably comes over the synchronous interface. Summarized DB2 information is easier for a monitor program to process, and the monitor program logic is simpler because a smaller number of records are processed.

Start monitor classes 2, 3, 5, 7, and 8 to collect summary and status information for later probing. In this case, an instrumentation facility trace is started and information is summarized by the instrumentation facility, but not returned to the caller until it is requested by a READS call.

The READS request can reference data that is updated during the retrieval process. You might need to do reasonability tests on data that is obtained through READS. Because the READS function does not suspend activity that takes place under referenced structures, an abend can occur. If an abend occurs, the READS function is terminated without a dump and the monitor program is notified through the return code and reason code information in the IFCA. However, the return area can contain valid trace records, even if an abend occurred; therefore, your monitor program should check for a non-zero value in the IFCABM (bytes moved) field of the IFCA.

When you use a READS request with a query parallelism task, remember that each parallel task is a separate thread. Each parallel thread has a separate READS output. See Chapter 35, "Parallel operations and query performance," on page 991 for more information on tracing the parallel tasks. A READS request might return thread information for parallel tasks on a DB2 data sharing member without the thread information for the originating task in a Sysplex query parallelism case. See *DB2 Data Sharing: Planning and Administration* for more information.

The *qual-area* parameter, mapped by DSNDWQAL, is the only means of qualifying the trace records to be returned on IFI READS requests.

## Synchronous data and READS requests through IFI

There are certain types of records that you can read synchronously. Identified by IFCID, these records are:

- |             |                                                                                                                                                                                                                                                                                                                                  |

| 0217 | Storage detail record for the DBM1 address space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0225 | Storage summary record for the DBM1 address space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0230 | Global statistics for data sharing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0234 | User authorization information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0254 | Group buffer pool usage in the data sharing group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

#

#

- 0306** Returns compressed or decompressed log records in both a data sharing or non data-sharing environment. For IFCID 306 requests, your program's return area must reside in ECSA key 7 storage with the IFI application program running in key 0 supervisor state. The IFI application program must set the eye catcher to "I306" before making the IFCID 306 call. See "Instrument facility communications area (IFCA)" on page 1179 for more information about the instrumentation facility communication area (IFCA) and what is expected of the monitor program.
- 0316** Returns information about the contents of the dynamic statement cache. The IFI application can request information for all statements in the cache, or provide qualification parameters to limit the data returned. DB2 reports the following information about a cached statement:
- A statement name and ID that uniquely identify the statement
  - If IFCID 0318 is active, performance statistics for the statement
  - The first 60 bytes of the statement text
- 0317** Returns the complete text of an SQL statement in the dynamic statement cache and the PREPARE attributes string. You must provide the statement name and statement ID from IFCID 0316 output. For more information about using IFI to obtain information about the dynamic statement cache, see "Using READS calls to monitor the dynamic statement cache."

For more information about IFCID field descriptions, see the mapping macros in *prefix.SDSNMACS*. See also "DB2 trace" on page 1195 and Appendix D, "Interpreting DB2 trace output," on page 1139 for additional information.

## Using READS calls to monitor the dynamic statement cache

You can use READS requests from an IFI application to monitor the contents of the dynamic statement cache, and optionally, to see some accumulated statistics for those statements. This strategy can help you detect and diagnose performance problems for those cached dynamic SQL statements.

An IFI program that monitors the dynamic statement cache should include these steps:

1. Acquire and initialize storage areas for common IFI communication areas.
2. Issue an IFI COMMAND call to start performance trace class 30 for IFCID 0318. This step enables statistics collection for statements in the dynamic statement cache. See "Controlling collection of dynamic statement cache statistics with IFCID 0318" on page 1175 for information on when you should start a trace for IFCID 0318.
3. Put the IFI program into a wait state. During this time, SQL applications in the subsystem execute dynamic SQL statements by using the dynamic statement cache.
4. Resume the IFI program after enough time has elapsed for a reasonable amount of activity to occur in the dynamic statement cache.
5. Set up the qualification area for a READS call for IFCID 0316 as described in Table 302 on page 1164.
6. Set up the IFCID area to request data for IFCID 0316.
7. Issue an IFI READS call to retrieve the qualifying cached SQL statements.
8. Examine the contents of the return area.

For a statement with unexpected statistics values:

- a. Obtain the statement name and statement ID from the IFCID 0316 data.
  - b. Set up the qualification area for a READS call for IFCID 0317, as described in Table 302 on page 1164.
  - c. Set up the IFCID area to request data for IFCID 0317.
  - d. Issue a READS call for IFCID 0317 to get the entire text of the statement.
  - e. Obtain the statement text from the return area.
  - f. Use the statement text to execute an SQL EXPLAIN statement.
  - g. Fetch the EXPLAIN results from the PLAN\_TABLE.
9. Issue an IFI COMMAND call to stop monitor trace class 1.
  10. Issue an IFI COMMAND call to stop performance trace class 30 for IFCID 0318.

An IFI program that monitors deadlocks and timeouts of cached statements should include these steps:

1. Acquire and initialize storage areas for common IFI communication areas.
2. Issue an IFI COMMAND call to start monitor trace class 1. This step lets you make READS calls for IFCID 0316 and IFCID 0317.
3. Issue an IFI COMMAND call to start performance trace class 30 for IFCID 0318. This step enables statistics collection for statements in the dynamic statement cache. See “Controlling collection of dynamic statement cache statistics with IFCID 0318” for information on when you should start a trace for IFCID 0318.
4. Start performance trace class 3 for IFCID 0172 to monitor deadlocks, or performance trace class 3 for IFCID 0196 to monitor timeouts.
5. Put the IFI program into a wait state. During this time, SQL applications in the subsystem execute dynamic SQL statements by using the dynamic statement cache.
6. Resume the IFI program when a deadlock or timeout occurs.
7. Issue a READA request to obtain IFCID 0172 or IFCID 0196 trace data.
8. Obtain the cached statement ID of the statement that was involved in the deadlock or timeout from the IFCID 0172 or IFCID 0196 trace data. Using the statement ID, set up the qualification area for a READS call for IFCID 0316 or IFCID 0317, as described in Table 302 on page 1164.
9. Set up the IFCID area to request data for IFCID 0316 or IFCID 0317.
10. Issue an IFI READS call to retrieve the qualifying cached SQL statement.
11. Examine the contents of the return area.
12. Issue an IFI COMMAND call to stop monitor trace class 1.
13. Issue an IFI COMMAND call to stop performance trace class 30 for IFCID 0318 and performance trace class 3 for IFCID 0172 or IFCID 0196.

## **Controlling collection of dynamic statement cache statistics with IFCID 0318**

The collection of statistics for statements in the dynamic statement cache can increase the processing cost for those statements. To minimize this increase, use IFCID 0318 to enable and disable the collection of dynamic statement cache statistics. When IFCID 0318 is inactive, DB2 does not collect those statistics. DB2 tracks the statements in the dynamic statement cache, but does not accumulate the statistics as those statements are used. When you are not actively monitoring the cache, you should turn off the trace for IFCID 0318.

If you issue a READS call for IFCID 0316 while IFCID 0318 is inactive, DB2 returns identifying information for all statements in the cache, but returns 0 in all the IFCID 0316 statistics counters.

When you stop or start the trace for IFCID 0318, DB2 resets the IFCID 0316 statistics counters for all statements in the cache to 0.

---

## READA: Syntax and usage with IFI

The READA function allows a monitor program to asynchronously read data that has accumulated in an OP $n$  buffer.

### Authorization for READA requests through IFI

On a READA request the application program must own the specified destination buffer, or the request is denied. You can obtain ownership of a storage buffer by issuing a START TRACE to an OP $n$  destination. If the primary authorization ID or one of the secondary authorization IDs of the process does not have MONITOR1 or MONITOR2 privilege, the request is denied. READA requests are checked for authorization once for each user of the thread. (Several users can use the same thread, but an authorization check is performed each time the user of the thread changes.)

### Syntax for READA requests through IFI

READA requests that are issued through IFI have the following syntax:

```
CALL DSNWLI, ('READA', ifca, return-area), VL
```

*ifca*

Contains information about the OP $n$  destination and the ownership token value (IFCAOWNER) at call initiation. After the READA call completes, the IFCA contains the return code, reason code, the number of bytes moved to the return area, the number of bytes not moved to the return area if the area was too small, and the number of records lost. See “Common communication areas for IFI calls” on page 1179 for a description of the IFCA.

*return-area*

Contains the varying-length records that are returned by the instrumentation facility. If the return area is too small, as much of the output as will fit is placed into the area (a complete varying-length record). Reason code 00E60802 is returned in cases where the monitor program's return area is not large enough to hold the returned data. See “Return area” on page 1183 for a description of the return area.

# IFI allocates up to eight OP buffers upon request from private storage in the  
# DB2 MSTR address space. IFI uses these buffers to store trace data until the  
# owning application performs a READA request to transfer the data from the  
# OP buffer to the application's return area. An application becomes the owner of  
# an OP buffer when it issues a START TRACE command and specifies a  
# destination of OP $N$  or OP $X$ . Each buffer can be of size 256 KB to 16 MB. IFI  
# allocates a maximum of 16 MB of storage for each of the eight OP buffers. The  
# default monitor buffer size is determined by the MONSIZE parameter in the  
# DSNZPARM module.

### Usage notes for READA requests through IFI

You can use a monitor trace that uses any one of eight online performance monitor destinations, OP $n$ , (where  $n$  is equal to a value from 1 to 8). Typically, the destination of OP $n$  is only used with commands issued from a monitor program.

For example, the monitor program can pass a specific online performance monitor destination (OP1, for example) on the START TRACE command to start asynchronous trace data collection.

If the monitor program passes a generic destination of OPX, the instrumentation facility assigns the next available buffer destination slot and returns the OP $n$  destination name to the monitor program. To avoid conflict with another trace or program that might be using an OP buffer, you should use the generic OPX specification when you start tracing. You can then direct the data to the destination specified by the instrumentation facility with the START or MODIFY TRACE commands.

There are times, however, when you should use a specific OP $n$  destination initially:

- When you plan to start numerous asynchronous traces to the same OP $n$  destination. To do this, you must specify the OP $n$  destination in your monitor program. The OP $n$  destination started is returned in the IFCA.
- When the monitor program specifies that a particular monitor class (defined as available) together with a particular destination (for example OP7) indicates that certain IFCIDs are started. An operator can use the DISPLAY TRACE command to determine which monitors are active and what events are being traced.

**Buffering data:** To have trace data go to the OP $n$  buffer, you must start the trace from within the monitor program. After the trace is started, DB2 collects and buffers the information as it occurs. The monitor program can then issue a read asynchronous (READA) request to move the buffered data to the monitor program. The buffering technique ensures that the data is not being updated by other users while the buffer is being read by the READA caller. For more information, see “Data integrity and IFI” on page 1188.

**Possible data loss:** You can activate all traces and have the trace data buffered. However, this plan is definitely not recommended because performance might suffer and data might be lost.

Data loss occurs when the buffer fills before the monitor program can obtain the data. DB2 does not wait for the buffer to be emptied, but, instead, informs the monitor program on the next READA request (in the IFCARLC field of the IFCA) that the data has been lost. The user must have a high enough dispatching priority that the application can be posted and then issue the READA request before significant data is lost.

## Asynchronous data and READA requests through IFI

DB2 buffers all IFCID data that is activated by the START TRACE command and passes it to a monitor program on a READA request. The IFCID events include all of the following:

- Serviceability
- Statistics
- Accounting
- Performance
- Audit data
- IFCIDs defined for the IFI write function

IFCID events are discussed in “DB2 trace” on page 1195.

Your monitor program can request an asynchronous buffer, which records trace data as trace events occur. The monitor program is then responsible for unloading

the buffer on a timely basis. One method is to set a timer to wake up and process the data. Another method is to use the buffer information area on a START TRACE command request, shown in Table 301 on page 1162, to specify an ECB address to post when a specified number of bytes have been buffered.

## Example of READA requests through IFI

The following depicts the logic flow for monitoring DB2 accounting and for displaying the information on a terminal:

1. Initialize.
2. Use GETMAIN to obtain a storage area equal to BUFSIZE.
3. Start an accounting trace by issuing a DB2 START TRACE=ACCTG DEST=OPX command through IFI indicating to wake up this routine by a POST whenever the buffer is 20% full.
4. Check the status in the IFCA to determine if the command request was successful.
5. WAIT for the buffer to be posted.
6. Clear the post flag.
7. Call IFI to obtain the buffer data via a READA request.
8. Check the status of the IFCA to determine if the READA request was successful.
9. De-block the information provided.
10. Display the information on a terminal.
11. Loop back to the WAIT.

---

## WRITE: Syntax and usage with IFI

A monitor program can write information to a DB2 trace destination by issuing a write (WRITE) request for a specific IFCID.

### Authorization for WRITE requests through IFI

WRITE requests are not checked for authorization, but a DB2 trace must be active for the IFCID being written. If the IFCID is not active, the request is denied. For a WRITE request, no other authorization checks are made.

### Syntax for WRITE requests through IFI

WRITE requests that are issued through IFI have the following syntax:

```
CALL DSNWLI,('WRITE ' ,ifca,output-area,ifcid-area),VL
```

The write function must specify an IFCID area. The data that is written is defined and interpreted by your site.

*ifca* Contains information regarding the success of the call. See “Instrument facility communications area (IFCA)” on page 1179 for a description of the IFCA.

*output-area* Contains the varying-length of the monitor program's data record to be written. See “Output area” on page 1184 for a description of the output area.

*ifcid-area* Contains the IFCID of the record to be written. Only the IFCIDs that are defined to the write function (see Table 304 on page 1179) are allowed. If

an invalid IFCID is specified or the IFCID is not active (not started by a TRACE command), no data is written. See Table 304 for IFCIDs that can be used by the write function.

Table 304. Valid IFCIDs for WRITE function

| IFCID (decimal) | IFCID (hex) | Trace type     | Class | Comment                                        |
|-----------------|-------------|----------------|-------|------------------------------------------------|
| 0146            | 0092        | Auditing       | 9     | Write to IFCID 146                             |
| 0151            | 0097        | Accounting     | 4     | Write to IFCID 151                             |
| 0152            | 0098        | Statistics     | 2     | Write to IFCID 152                             |
| 0153            | 0099        | Performance    | 1     | Background events and write to IFCID 153       |
| 0154            | 009A        | Performance    | 15    | Write to IFCID 154                             |
| 0155            | 009B        | Monitoring     | 4     | Write to IFCID 155                             |
| 0156            | 009C        | Serviceability | 6     | Reserved for user-defined serviceability trace |

See “IFCID area” on page 1184 for a description of the IFCID area.

## Usage notes for WRITE requests through IFI

A WRITE request is written to a destination that is activated by a START TRACE command.

**Recommendation:** If your site uses the IFI WRITE function, establish usage procedures and standards. Procedures ensure that the correct IFCIDs are active when DB2 is performing the WRITE function. Standards determine the records and record formats that a monitor program sends to DB2.

**Recommendation:** Because your site can use one IFCID to contain many different records, place your site's record type and sub-type in the first fields in the data record .

---

## Common communication areas for IFI calls

The following communication areas are used on all IFI calls:

- “Instrument facility communications area (IFCA)”
- “Return area” on page 1183
- “IFCID area” on page 1184
- “Output area” on page 1184

### Instrument facility communications area (IFCA)

The program's instrumentation facility communication area (IFCA) is a communications area between the monitor program and IFI. A required parameter on all IFI requests, the IFCA contains information about the success of the call in its return code and reason code fields.

**The monitor program is responsible for allocating storage for the IFCA and initializing it.** The IFCA must be initialized to binary zeros and the eye catcher, 4-byte owner field, and length field must be set by the monitor program. Failure to properly initialize the IFCA results in denying any IFI requests.

The monitor program is also responsible for checking the IFCA return code and reason code fields to determine the status of the request.

The IFCA fields are described in Table 305.

Table 305. Instrumentation facility communication area. The IFCA is mapped by assembler mapping macro DSNDFCA.

| Name     | Hex offset | Data type                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IFCALEN  | 0          | Hex, 2 bytes                        | Length of IFCA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|          | 3          | Hex, 1 byte                         | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IFCAID   | 4          | Character, 4 bytes                  | Eye catcher for block, IFCA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| IFCAOWNR | 8          | Character, 4 bytes                  | Owner field, provided by the monitor program. This value is used to establish ownership of an OP $n$ destination and to verify that a requester can obtain data from the OP $n$ destination. This is <i>not</i> the same as the owner ID of a plan.                                                                                                                                                                                                                                                                                                                                                    |
| IFCARC1  | C          | 4-byte signed integer               | Return code for the IFI call. Binary zero indicates a successful call. See Part 3 of <i>DB2 Codes</i> for information about reason codes. For a return code of 8 from a COMMAND request, the IFCAR0 and IFCAR15 values contain more information.                                                                                                                                                                                                                                                                                                                                                       |
| IFCARC2  | 10         | 4-byte signed integer               | Reason code for the IFI call. Binary zero indicates a successful call. See Part 3 of <i>DB2 Codes</i> for information about reason codes.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IFCABM   | 14         | 4-byte signed integer               | Number of bytes moved to the return area. A non-zero value in this field indicates information was returned from the call. Only complete records are moved to the monitor program area.                                                                                                                                                                                                                                                                                                                                                                                                                |
| IFCABNM  | 18         | 4-byte signed integer               | Number of bytes that did not fit in the return area and still remain in the buffer. Another READA request will retrieve that data. Certain IFI requests return a known quantity of information. Other requests will terminate when the return area is full.                                                                                                                                                                                                                                                                                                                                            |
|          | 1C         | 4-byte signed integer               | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IFCARLC  | 20         | 4-byte signed integer               | Indicates the number of records lost prior to a READA call. Records are lost when the OP buffer storage is exhausted before the contents of the buffer are transferred to the application program via an IFI READA request. Records that do not fit in the OP buffer are not written and are counted as records lost.                                                                                                                                                                                                                                                                                  |
| IFCAOPN  | 24         | Character, 4 bytes                  | Destination name used on a READA request. This field identifies the buffer requested, and is required on a READA request. Your monitor program must set this field. The instrumentation facility fills in this field on START TRACE to an OP $n$ destination from an monitor program. If your monitor program started multiple OP $n$ destination traces, the first one is placed in this field. If your monitor program did not start an OP $n$ destination trace, the field is not modified. The OP $n$ destination and owner ID are used on subsequent READA calls to find the asynchronous buffer. |
| IFCAOPNL | 28         | 2-byte signed integer               | Length of the OP $n$ destinations started. On any command entered by IFI, the value is set to X'0004'. If an OP $n$ destination is started, the length is incremented to include all OP $n$ destinations started.                                                                                                                                                                                                                                                                                                                                                                                      |
|          | 2A         | 2-byte signed integer               | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IFCAOPNR | 2C         | Character, 8 fields of 4 bytes each | Space to return 8 OP $n$ destination values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| IFCAGBM  | 9C         | Four-byte signed integer | Total length of data that was returned from other data sharing group members and fit in the return area.                                                                                                                |
| IFCAGBNM | A0         | Four-byte signed integer | Total length of data that was returned from other data sharing group members and did not fit in the return area..                                                                                                       |
| IFCADMBR | A4         | Character, 8 bytes       | Name of a single data sharing group member on which an IFI request is to be executed. Otherwise, this field is blank. If this field contains a member name, DB2 ignores field IFCAGLBL.                                 |
| IFCARMBR | AC         | Character, 8 bytes       | Name of the data sharing group member from which data is being returned. DB2 sets this field in each copy of the IFCA that it places in the return area, not in the IFCA of the application that makes the IFI request. |

## Return area

You must specify a return area on all READA, READS, and COMMAND requests. IFI uses the return area to return command responses, synchronous data, and asynchronous data to the monitor program. Table 306 describes the return area.

Table 306. Return area

| Hex offset | Data type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Signed 4-byte integer     | The length of the return area, plus 4. This must be set by the monitor program. No limit exists for the length of READA or READS return areas.                                                                                                                                                                                                                                                                                                                                                            |
| 4          | Character, varying-length | DB2 places as many varying-length records as it can fit into the area following the length field. The monitor program's length field is not modified by DB2. Each varying-length trace record has a 2-byte or 4-byte length field, depending on the high-order bit. If the high-order bit is on, the length field is 4 bytes. If the high-order bit is off, the length field is the first 2 bytes. In this case, the third byte indicates whether the record is spanned, and the fourth byte is reserved. |
|            |                           | After a COMMAND request, the last character in the return area is a new-line character (X'15').                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 307 shows the return area for IFCID 0306.

Table 307. Return area using IFCID 0306

| Hex | Data type                | Description                                                       |
|-----|--------------------------|-------------------------------------------------------------------|
| 0   | Signed four-byte integer | The length of the return area.                                    |
| 4   | Character, 4 bytes       | The eye catcher, a constant, I306. Beginning of QW0306OF mapping. |
| 8   | Character, 60 bytes      | Reserved.                                                         |
| 44  | Signed four-byte integer | The length of the returned data.                                  |

**Note:** For more information about reading log records, see Appendix C, "Reading log records," on page 1115

The destination header for data that is returned on a READA or READS request is mapped by macro DSNDQWIW or the header QW0306OF for IFCID 306 requests. Please refer to *prefix.SDSNIVPD(DSNWMSG)* for the format of the trace record

and its header. The size of the return area for READA calls should be as large the size specified with the BUFSIZE keyword on the START TRACE command.

Data returned on a COMMAND request consists of varying-length segments (X'xxxxrrrr' where the length is 2 bytes and the next 2 bytes are reserved), followed by the message text. More than one record can be returned. The last character in the return area is a new-line character (X'15').

The monitor program must compare the number of bytes moved (IFCABM in the IFCA) to the sum of the record lengths to determine when all records have been processed.

## IFCID area

You must specify the IFCID area on READS and WRITE requests. The IFCID area contains the IFCIDs to process. Table 308 shows the IFCID area.

Table 308. IFCID area

| Hex Offset | Data type                            | Description                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | Signed two-byte integer              | Length of the IFCID area, plus 4. The length can range from X'0006' to X'0044'. For WRITE requests, only one IFCID is allowed, so the length must be set to X'0006'.<br><br>For READS requests, you can specify multiple IFCIDs. If so, you must be aware that the returned records can be in a different sequence than requested and some records can be missing. |
| 2          | Signed two-byte integer              | Reserved.                                                                                                                                                                                                                                                                                                                                                          |
| 4          | Hex, <i>n</i> fields of 2 bytes each | The IFCIDs to be processed. Each IFCID is placed contiguous to the previous IFCID for a READS request. The IFCIDs start at X'0000' and progress upward. You can use X'FFFF' to signify the last IFCID in the area to process.                                                                                                                                      |

## Output area

The output area is used on command and WRITE requests. The first two bytes contain the length of the monitor program's record to write or the DB2 command to be issued, plus 4 additional bytes. The next two bytes are reserved. You can specify any length from 10 to 4096 (X'000A0000' to X'10000000'). The rest of the area is the actual command or record text.

**Example:** In an assembler program, a START TRACE command is formatted in the following way:

```
DC X'002A0000'          LENGTH INCLUDING LL00 + COMMAND
DC CL37'-STA TRACE(MON) DEST(OPX) BUFSIZE(256)'
```

## Using IFI in a data sharing group

You can use IFI READA and READS calls in an application that runs on one member of a data sharing group to gather trace data from other members of the data sharing group. You can also use an IFI COMMAND call to execute a command at another member of a data sharing group. In addition to the IFCA fields that you use for an IFI request for a single subsystem, you need to set or read the following fields for an IFI request for a data sharing group:

### IFCAGLBL

Set this flag on to indicate that the READS or READA request should be sent to all members of the data sharing group.

### IFCADMBR

If you want an IFI READS, READA, or COMMAND request to be executed at a single member of the data sharing group, assign the name of the group member to this field. If you specify a name in this field, DB2 ignores IFCAGLBL. If the name that you specify is not active when DB2 executes the IFI request, DB2 returns an error.

**Recommendation:** To issue a DB2 command that does not support SCOPE(GROUP) at another member of a data sharing group, set the IFCADMBR field and issue an IFI COMMAND.

### IFCARMBR

The name of the data sharing member that generated the data that follows the IFCA. DB2 sets this value in the copy of the IFCA that it places in the requesting program's return area.

### IFCAGRSN

A reason code that DB2 sets when not all data is returned from other data sharing group members. See Part 3 of *DB2 Codes* for specific reason codes.

### IFCAGBM

The number of bytes of data that other members of the data sharing group return and that the requesting program's return area **can** contain.

### IFCAGBNM

The number of bytes of data that members of the data sharing group return but that the requesting program's return area **cannot** contain.

As with READA or READS requests for single DB2 subsystems, you need to issue a START TRACE command before you issue the READA or READS request. You can issue START TRACE with the parameter SCOPE(GROUP) to start the trace at all members of the data sharing group. For READA requests, specify DEST(OPX) in the START TRACE command. DB2 collects data from all data sharing members and returns it to the OPX buffer for the member from which you issue the READA request.

If a new member joins a data sharing group while a trace with SCOPE(GROUP) is active, the trace starts at the new member.

After you issue a READS or READA call for all members of a data sharing group, DB2 returns data from all members in the requesting program's return area. Data from the local member is first, followed by the IFCA and data for all other members.

**Example:** If the local DB2 is called DB2A, and the other two members in the group are DB2B and DB2C, the return area looks like this:

```
Data for DB2A
IFCA for DB2B (DB2 sets IFCARMBR to DB2B)
Data for DB2B
IFCA for DB2C (DB2 sets IFCARMBR to DB2C)
Data for DB2C
```

If an IFI application requests data from a single other member of a data sharing group (IFCADMBR contains a member name), the requesting program's return area

contains the data for that member but no IFCA for the member. All information about the request is in the requesting program's IFCA.

Because a READA or READS request for a data sharing group can generate much more data than a READA or READS request for a single DB2, you need to increase the size of your return area to accommodate the additional data.

---

## Interpreting records returned by IFI

This section describes the format of the records returned by IFI as a result of READA, READS, and COMMAND requests.

### Trace data record format

Trace records that are returned from READA and READS requests contain the following sections:

- A writer header that reports the length of the entire record, whether the record was in the first, middle, or last section of data, and other specific information for the writer.

The writer header for IFI is mapped by DSNDQWIW or the header QW0306OF for IFCID 306 requests. See the mapping macros in *prefix.SDSNMACS* for the formats.

- A self-defining section
- A product section containing specific DB2 information based on the active trace
- Data areas containing the actual recorded data are mapped by multiple mapping macros described in *prefix.SDSNMACS*.

For detailed information about the format of trace records and their mapping macros, see Appendix D, "Interpreting DB2 trace output," on page 1139, or see the mapping macros in *prefix.SDSNMACS*.

Figure 166 on page 1187 shows the return area after a READS request successfully executed.

- When READS and READA requests are checked for authorization, short duration locks on the DB2 catalog are obtained. When the check is made, subsequent READS or READA requests are not checked for authorization. Remember, if you are using the access control exit routine, then that routine might be controlling the privileges that the monitor trace can use.
- When DB2 commands are submitted, each command is checked for authorization. DB2 database commands obtain additional locks on DB2 objects.

A program can issue SQL statements through an attachment facility and DB2 commands through IFI. This environment creates the potential for an application to deadlock or time-out with itself over DB2 locks acquired during the execution of SQL statements and DB2 database commands. You should ensure that all DB2 locks acquired by preceding SQL statements are no longer held when the DB2 database command is issued. You can do this by:

- Binding the DB2 plan with ACQUIRE(USE) and RELEASE(COMMIT) bind parameters
- Initiating a commit or rollback to free any locks your application is holding, before issuing the DB2 command

If you use SQL in your application, the time between commit operations should be short. For more information on locking, see Chapter 31, “Improving concurrency,” on page 813.

---

## Recovery considerations for IFI

When an application program issues an IFI call, the requested function is immediately performed. If the application program subsequently abends, the IFI request is **not** backed out. In contrast, requests that do not use IFI are committed and abended as usual. For example, if an IFI application program also issues SQL calls, a program abend causes the SQL activity to be backed out.

---

## Errors and IFI

While using IFI, you might encounter any of these types of error:

- Connection failure, because the user is not authorized to connect to DB2
- Authorization failure, because the process is not authorized to access the DB2 resources specified

Requests sent through IFI can fail for a variety of reasons, including:

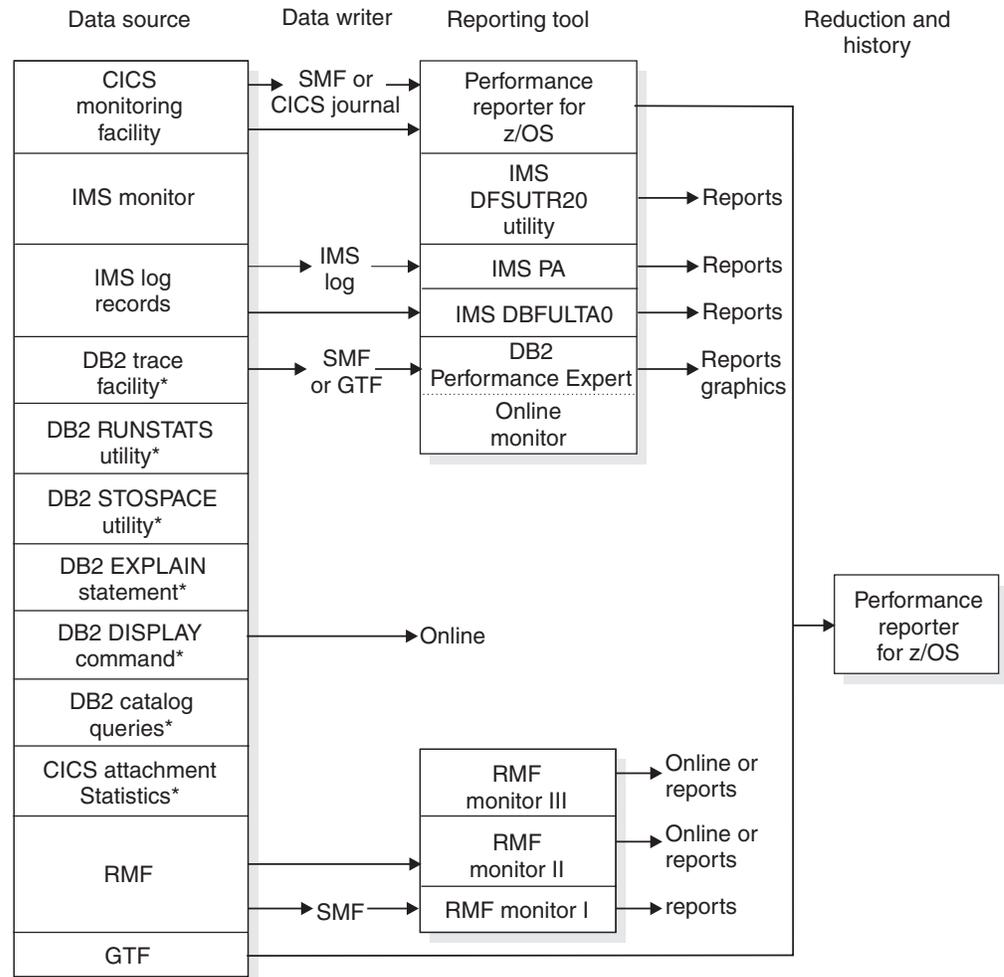

- One or more parameters are invalid.
- The IFCA area is invalid.
- The specified OP $n$  is in error.
- The requested information is not available.
- The return area is too small.

Return code and reason code information is stored in the IFCA in fields IFCARC1 and IFCARC2. Further return and reason code information is contained in Part 3 of *DB2 Codes*.

## Appendix F. Using tools to monitor performance

This appendix describes the various facilities for monitoring DB2 activity and performance. It includes information on facilities within the DB2 product as well as tools available outside of DB2. Figure 168 shows various monitoring tools that can be used in a DB2 environment.

\*Facilities available with the DB2 product

Figure 168. Monitoring tools in a DB2 environment

Table 310 describes these monitoring tools.

Table 310. Monitoring tools in a DB2 environment

| Monitoring tool                     | Description                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| CICS Attachment Facility statistics | Provide information about the use of CICS threads. This information can be displayed on a terminal or printed in a report. |

Table 310. Monitoring tools in a DB2 environment (continued)

| Monitoring tool                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CICS Monitoring Facility (CMF)               | Provides performance information about each CICS transaction executed. It can be used to investigate the resources used and the time spent processing transactions. Be aware that overhead is significant when CMF is used to gather performance information.                                                                                                                                                                                                                                                                                     |
| DB2 catalog queries                          | Help you determine when to reorganize table spaces and indexes. See the description of the REORG utility in Part 2 of <i>DB2 Utility Guide and Reference</i> .                                                                                                                                                                                                                                                                                                                                                                                    |
| DB2 Connect                                  | Can monitor and report DB2 server-elapsed time for client applications that access DB2 data. See “Reporting server-elapsed time” on page 1021.                                                                                                                                                                                                                                                                                                                                                                                                    |
| DB2 DISPLAY command                          | Gives you information about the status of threads, databases, buffer pools, traces, allied subsystems, applications, and the allocation of tape units for the archive read process. For information about the DISPLAY BUFFERPOOL command, see “Monitoring and tuning buffer pools using online commands” on page 681. For information about using the DISPLAY command to monitor distributed data activity, see “The DISPLAY command” on page 1017. For the detailed syntax of each command, refer to Chapter 2 of <i>DB2 Command Reference</i> . |
| DB2 EXPLAIN statement                        | Provides information about the access paths used by DB2. See Chapter 34, “Using EXPLAIN to improve SQL performance,” on page 931 and Chapter 5 of <i>DB2 SQL Reference</i> .                                                                                                                                                                                                                                                                                                                                                                      |
| OMEGAMON XE for DB2 Performance Expert       | A licensed program that integrates the function of DB2 Buffer Pool Analyzer and DB2 Performance Monitor. OMEGAMON provides performance monitoring, reporting, buffer pool analysis, and a performance warehouse, all in one tool. OMEGAMON monitors all subsystem instances across many different platforms in a consistent way. You can use OMEGAMON to analyze DB2 trace records and optimize buffer pool usage. See “OMEGAMON” on page 1202 for more information.                                                                              |
| OMEGAMON XE DB2 Performance Monitor (DB2 PM) | An orderable feature of DB2 that you can use to analyze DB2 trace records. As indicated previously, OMEGAMON includes the function of DB2 PM. OMEGAMON is described under “OMEGAMON” on page 1202.                                                                                                                                                                                                                                                                                                                                                |
| DB2 RUNSTATS utility                         | Can report space use and access path statistics in the DB2 catalog. See “Gathering monitor statistics and update statistics” on page 916 and Part 2 of <i>DB2 Utility Guide and Reference</i> .                                                                                                                                                                                                                                                                                                                                                   |
| DB2 STOSPACE utility                         | Provides information about the actual space allocated for storage groups, table spaces, table space partitions, index spaces, and index space partitions. See Part 2 of <i>DB2 Utility Guide and Reference</i> .                                                                                                                                                                                                                                                                                                                                  |
| DB2 trace facility                           | Provides DB2 performance and accounting information. It is described under “DB2 trace” on page 1195.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Generalized Trace Facility (GTF)             | A z/OS service aid that collects information to analyze particular situations. GTF can also be used to analyze seek times and Supervisor Call instruction (SVC) usage, and for other services. See “Recording GTF trace data” on page 1201 for more information.                                                                                                                                                                                                                                                                                  |

Table 310. Monitoring tools in a DB2 environment (continued)

| Monitoring tool                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IMS DFSUTR20 utility                          | A print utility for IMS Monitor reports.                                                                                                                                                                                                                                                                                                                                                                                              |
| IMS Fast Path Log Analysis utility (DBFULTA0) | An IMS utility that provides performance reports for IMS Fast Path transactions.                                                                                                                                                                                                                                                                                                                                                      |
| IMS Performance Analyzer (IMS PA)             | A separately licensed program that can be used to produce transit time information based on the IMS log data set. It can also be used to investigate response-time problems of IMS DB2 transactions.                                                                                                                                                                                                                                  |
| Resource Measurement Facility (RMF)           | An optional feature of z/OS that provides system-wide information on processor utilization, I/O activity, storage, and paging. There are three basic types of RMF sessions: Monitor I, Monitor II, and Monitor III. Monitor I and Monitor II sessions collect and report data primarily about specific system activities. Monitor III sessions collect and report data about overall system activity in terms of work flow and delay. |
| System Management Facility (SMF)              | A z/OS service aid used to collect information from various z/OS subsystems. This information is dumped and reported periodically, such as once a day. Refer to "Recording SMF trace data" on page 1199 for more information.                                                                                                                                                                                                         |
| Tivoli Decision Support for OS/390            | Formerly known as Tivoli Performance Reporter for OS/390, is a licensed program that collects SMF data into a DB2 database and allows you to create reports on the data. See "Tivoli Decision Support for OS/390" on page 1203.                                                                                                                                                                                                       |

## Using z/OS, CICS, and IMS tools

To monitor DB2 and CICS, you can use:

- RMF Monitor II for physical resource utilizations
- GTF for detailed I/O monitoring when needed
- Tivoli Decision Support for OS/390 for application processor utilization, transaction performance, and system statistics.

You can use RMF Monitor II to dynamically monitor system-wide physical resource utilizations, which can show queuing delays in the I/O subsystem.

In addition, the CICS attachment facility DSNB DISPLAY command allows any authorized CICS user to dynamically display statistical information related to thread usage and situations when all threads are busy. For more information about the DSNB DISPLAY command, see Chapter 2 of *DB2 Command Reference*.

Be sure that the number of threads reserved for specific transactions or for the pool is large enough to handle the actual load. You can dynamically modify the value specified in the CICS resource definition online (RDO) attribute ACCOUNTREC with the DSNB MODIFY TRANSACTION command. You might also need to modify the maximum number of threads specified for the MAX USERS field on installation panel DSNTIPE.

To monitor DB2 and IMS, you can use:

- RMF Monitor II for physical resource utilizations
- GTF for detailed I/O monitoring when needed

- IMS Performance Analyzer, or its equivalent, for response-time analysis and tracking all IMS-generated requests to DB2
- IMS Fast Path Log Analysis Utility (DBFULTA0) for performance reports for IMS Fast Path transactions.

In addition, the DB2 IMS attachment facility allows you to use the DB2 command DISPLAY THREAD command to dynamically observe DB2 performance.

## Monitoring system resources

Monitor system resources to:

- Detect resource constraints (processor, I/O, storage)
- Determine how resources are consumed
- Check processor, I/O, and paging rate to detect a bottleneck in the system
- Detect changes in resource use over comparable periods.

Figure 169 shows an example of a suggested system resources report.

```

                                SYSTEM RESOURCES REPORT
                                DATE xx/xx/xx
                                FROM xx:xx:xx
                                TO  xx:xx:xx

TOTAL CPU Busy                74.3 %

    DB2 & IRLM                 9.3 %
    IMS/CICS                   45.3 %
    QMF Users                   8.2 %
    DB2 Batch & Util            2.3 %
    OTHERS                      9.2 %

    SYSTEM AVAILABLE           98.0 %

TOTAL I/Os/sec.               75.5

TOTAL Paging/sec.             6.8

                                Short      Medium      Long
                                Transaction  Transaction  Transaction

Average Response Time         3.2 secs    8.6 secs    15.0 secs

MAJOR CHANGES:
    DB2 application DEST07 moved to production

```

Figure 169. User-created system resources report

The RMF reports used to produce the information in Figure 169 were:

- The RMF CPU activity report, which lists TOTAL CPU busy and the TOTAL I/Os per second.
- RMF paging activity report, which lists the TOTAL paging rate per second for real storage.
- The RMF work load activity report, which is used to estimate where resources are spent. Each address space or group of address spaces to be reported on separately must have different SRM reporting or performance groups. The following SRM reporting groups are considered:
  - DB2 address spaces:
    - DB2 database address space (*ssnmDBM1*)
    - DB2 system services address space (*ssnmMSTR*)
    - Distributed data facility (*ssnmDIST*)
    - IRLM (IRLMPROC)
  - IMS or CICS
  - TSO-QMF

- DB2 batch and utility jobs

The CPU for each group is obtained using the ratio  $(A/B) \times C$ , where:

A is the sum of CPU and service request block (SRB) service units for the specific group

B is the sum of CPU and SRB service units for all the groups

C is the total processor utilization.

The CPU and SRB service units must have the same coefficient.

You can use a similar approach for an I/O rate distribution.

MAJOR CHANGES shows the important environment changes, such as:

- DB2 or any related software-level change
- DB2 changes in the load module for system parameters
- New applications put into production
- Increase in the number of DB2 QMF users
- Increase in batch and utility jobs
- Hardware changes

MAJOR CHANGES is also useful for discovering the reason behind different monitoring results.

## Monitoring transaction manager throughput

Use IMS or CICS monitoring facilities to determine throughput, in terms of transactions processed, and transaction response times. Depending on the transaction manager, you can use the following reports:

- IMS Performance Analyzer
- Fast Path Log Analysis Utility (DBFULTA0)
- Tivoli Decision Support for OS/390

In these reports:

- The transactions processed include DB2 and non-DB2 transactions.
- The transaction processor time includes the DB2 processor time for IMS but not for CICS.
- The transaction transit response time includes the DB2 transit time.

A historical database is useful for saving monitoring data from different periods. Such data can help you track the evolution of your system. You can use Tivoli Decision Support for OS/390 or write your own application based on DB2 and QMF when creating this database.

---

## DB2 trace

The information under this heading, up to “Recording SMF trace data” on page 1199, is General-use Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

DB2’s instrumentation facility component (IFC) provides a trace facility that you can use to record DB2 data and events. With the IFC, however, analysis and reporting of the trace records must take place outside of DB2. You can use OMEGAMON to format, print, and interpret DB2 trace output. You can view an online snapshot from trace records by using OMEGAMON or other online monitors. For more information on OMEGAMON, see *Using IBM Tivoli OMEGAMON XE on z/OS*. For the exact syntax of the trace commands see Chapter 2 of *DB2 Command Reference*.

If you do not have OMEGAMON, or if you want to do your own analysis of the DB2 trace output, refer to Appendix D, “Interpreting DB2 trace output,” on page 1139. Also consider writing your own program using the instrumentation facility interface (IFI). Refer to Appendix E, “Programming for the Instrumentation Facility Interface (IFI),” on page 1157 for more information on using IFI.

Each *trace class* captures information on several subsystem events. These events are identified by many instrumentation facility component identifiers (IFCIDs). The IFCIDs are described by the comments in their mapping macros, contained in *prefix.SDSNMACS*, which is shipped to you with DB2.

## Types of traces

DB2 trace can record six types of data: statistics, accounting, audit, performance, monitor, and global. The description of the START TRACE command in Chapter 2 of *DB2 Command Reference* indicates which IFCIDs are activated for the different types of trace and the classes within those trace types. For details on what information each IFCID returns, see the mapping macros in *prefix.SDSNMACS*.

The trace records are written using GTF or SMF records. See “Recording SMF trace data” on page 1199 and “Recording GTF trace data” on page 1201 before starting any traces. Trace records can also be written to storage, if you are using the monitor trace class.

### Statistics trace

The statistics trace reports information about how much the DB2 system services and database services are used. It is a system-wide trace and should not be used for chargeback accounting. Use the information the statistics trace provides to plan DB2 capacity, or to tune the entire set of active DB2 programs.

Statistics trace classes 1, 3, 4, 5, and 6 are the default classes for the statistics trace if statistics is specified YES in panel DSNTIPN. If the statistics trace is started using the START TRACE command, then class 1 is the default class.

- Class 1 provides information about system services and database statistics. It also includes the system parameters that were in effect when the trace was started.
- Class 3 provides information about deadlocks and timeouts.
- Class 4 provides information about exceptional conditions.
- Class 5 provides information about data sharing.
- Class 6 provides storage statistics for the DBM1 address space.

If you specified YES in the SMF STATISTICS field on installation panel DSNTIPN, the statistics trace starts automatically when you start DB2, sending class 1, 3, 4 and 5 statistics data to SMF. SMF records statistics data in both SMF type 100 and 102 records. IFCIDs 0001, 0002, 0202, and 0230 are of SMF type 100. All other IFCIDs in statistics trace classes are of SMF type 102. From installation panel DSNTIPN, you can also control the statistics collection interval (STATISTICS TIME field).

The statistics trace is written on an interval basis, and you can control the exact time that statistics traces are taken.

### Accounting trace

The DB2 accounting trace provides information related to application programs, including such things as:

- Start and stop times
- Number of commits and aborts
- The number of times certain SQL statements are issued
- Number of buffer pool requests
- Counts of certain locking events
- Processor resources consumed
- Thread wait times for various events
- RID pool processing
- Distributed processing
- Resource limit facility statistics

DB2 trace begins collecting this data at successful thread allocation to DB2, and writes a completed record when the thread terminates or when the authorization ID changes.

During CICS thread reuse, a change in the authid or transaction code initiates the sign-on process, which terminates the accounting interval and creates the accounting record. TXIDSO=NO eliminates the sign-on process when only the transaction code changes. When a thread is reused without initiating sign-on, several transactions are accumulated into the same accounting record, which can make it very difficult to analyze a specific transaction occurrence and correlate DB2 accounting with CICS accounting. However, applications that use ACCOUNTREC(UOW) or ACCOUNTREC(TASK) in the DBENTRY RDO definition initiate a “partial sign-on”, which creates an accounting record for each transaction. You can use this data to perform program-related tuning and assess and charge DB2 costs.

Accounting data for class 1 (the default) is accumulated by several DB2 components during normal execution. This data is then collected at the end of the accounting period; it does not involve as much overhead as individual event tracing.

On the other hand, when you start class 2, 3, 7, or 8, many additional trace points are activated. Every occurrence of these events is traced internally by DB2 trace, but these traces are not written to any external destination. Rather, the accounting facility uses these traces to compute the additional total statistics that appear in the accounting record, IFCID 003, when class 2 or class 3 is activated. Accounting class 1 must be active to externalize the information.

To turn on accounting for packages and DBRMs, accounting trace classes 1 and 7 must be active. Though you can turn on class 7 while a plan is being executed, accounting trace information is only gathered for packages or DBRMs executed after class 7 is activated. Activate accounting trace class 8 with class 1 to collect information about the amount of time an agent was suspended in DB2 for each executed package. If accounting trace classes 2 and 3 are activated, there is minimal additional performance cost for activating accounting trace classes 7 and 8.

If you want information from either, or both, accounting class 2 and 3, be sure to activate class 2, class 3, or both classes before your application starts. If these classes are activated during the application, the times gathered by DB2 trace are only from the time the class was activated.

Accounting trace class 5 provides information on the amount of elapsed time and TCB time that an agent spent in DB2 processing instrumentation facility interface (IFI) requests. If an agent did not issue any IFI requests, these fields are not included in the accounting record.

If you specified YES for SMF ACCOUNTING on installation panel DSNTIPN, the accounting trace starts automatically when you start DB2, and sends IFCIDs that are of SMF type 101 to SMF. The accounting record IFCID 0003 is of SMF type 101.

### **Audit trace**

The audit trace collects information about DB2 security controls and is used to ensure that data access is allowed only for authorized purposes. On the CREATE TABLE or ALTER TABLE statements, you can specify whether or not a table is to be audited, and in what manner; you can also audit security information such as any access denials, grants, or revokes for the table. The default causes no auditing to take place. For descriptions of the available audit classes and the events they trace, see “Audit class descriptions” on page 287.

If you specified YES for AUDIT TRACE on installation panel DSNTIPN, audit trace class 1 starts automatically when you start DB2. By default, DB2 will send audit data to SMF. SMF records audit data in type 102 records. When you invoke the -START TRACE command, you can also specify GTF as a destination for audit data. Chapter 13, “Auditing,” on page 285 describes the audit trace in detail.

### **Performance trace**

The performance trace provides information about a variety of DB2 events, including events related to distributed data processing. You can use this information to further identify a suspected problem, or to tune DB2 programs and resources for individual users or for DB2 as a whole.

You cannot automatically start collecting performance data when you install or migrate DB2. To trace performance data, you must use the -START TRACE(PERFM) command. For more information about the -START TRACE(PERFM) command, refer to Chapter 2 of *DB2 Command Reference*.

The performance trace defaults to GTF.

### **Monitor trace**

The monitor trace records data for online monitoring with user-written programs. This trace type has several predefined classes; those that are used explicitly for monitoring are listed here:

- Class 1 (the default) allows any application program to issue an instrumentation facility interface (IFI) READS request to the IFI facility. If monitor class 1 is inactive, a READS request is denied. Activating class 1 has a minimal impact on performance.
- Class 2 collects processor and elapsed time information. The information can be obtained by issuing a READS request for IFCID 0147 or 0148. In addition, monitor trace class 2 information is available in the accounting record, IFCID 0003. Monitor class 2 is equivalent to accounting class 2 and results in equivalent overhead. Monitor class 2 times appear in IFCIDs 0147, 0148, and 0003 if either monitor trace class 2 or accounting class 2 is active.
- Class 3 activates DB2 wait timing and saves information about the resource causing the wait. The information can be obtained by issuing a READS request for IFCID 0147 or 0148. In addition, monitor trace class 3 information is available

in the accounting record, IFCID 0003. As with monitor class 2, monitor class 3 overhead is equivalent to accounting class 3 overhead.

When monitor trace class 3 is active, DB2 can calculate the duration of a class 3 event, such as when an agent is suspended due to an unavailable lock. Monitor class 3 times appear in IFCIDs 0147, 0148, and 0003, if either monitor class 3 or accounting class 3 is active.

- Class 5 traces the amount of time spent processing IFI requests.
- Class 7 traces the amount of time an agent spent in DB2 to process each package. If monitor trace class 2 is active, activating class 7 has minimal performance impact.
- Class 8 traces the amount of time an agent was suspended in DB2 for each package executed. If monitor trace class 3 is active, activating class 8 has minimal performance impact.

For more information on the monitor trace, refer to Appendix E, “Programming for the Instrumentation Facility Interface (IFI),” on page 1157.

## Effect on DB2 performance

The volume of data DB2 trace collects can be quite large. Consequently, the number of trace records you request will affect system performance. In particular, when you activate a performance trace, you should qualify the START TRACE command with the particular classes, plans, authorization IDs, and IFCIDs you want to trace.

The following recommendations apply:

- When starting a performance trace, be sure that you know what you want to report, for example, I/O only or SQL only. See OMEGAMON for examples of which classes produce which reports. Otherwise, you might have incomplete reports and have to rerun or collect too much data, overloading the data collector.
- When the statistics trace is active, statistics are collected by SMF at all times. Use the default statistics frequency of 30 minutes.
- Decide if the continuous collection of accounting data is needed. If a transaction manager provides enough accounting information, DB2 accounting might not be needed. In environments where the processor is heavily loaded, consider not running accounting on a continuous basis.
- When using accounting on a continuous basis, start classes 1 and 3 to SMF (SMF ACCOUNTING on installation panel DSNTIPN). You might also want to start accounting class 2 because it provides additional information that can be useful in resolving problems. Accounting class 2 does introduce some additional processor cost.
- Use the performance trace for short periods of time (START/STOP TRACE) and restrict it to certain users, applications, and classes. Use the default destination GTF to allow immediate analysis of the trace information.
- Start the global trace only if a problem is under investigation, and IBM service personnel have requested a trace.

For more detailed information about the amount of processor resources consumed by DB2 trace, see “Reducing processor resource consumption” on page 665.

---

## Recording SMF trace data

Each location is responsible for processing the SMF records produced by DB2 trace.

For example, during DB2 execution, you can use the z/OS operator command SETSMF or SS to alter SMF parameters that you specified previously. The following command records statistics (record type 100), accounting (record type 101), and performance (record type 102) data to SMF. To execute this command, specify PROMPT(ALL) or PROMPT(LIST) in the SMFPRMxx member used from SYS1.PARMLIB.

```
SETSMF SYS(TYPE(100:102))
```

If you are not using measured usage licensing, do not specify type 89 records or you will incur the overhead of collecting that data.

You can use the SMF program IFASMFDP to dump these records to a sequential data set. You might want to develop an application or use OMEGAMON to process these records. For a sample DB2 trace record sent to SMF, see Figure 160 on page 1141. For more information about SMF, refer to *z/OS JES2 Initialization and Tuning Guide*.

## Activating SMF

SMF must be running before you can send data to it. To make it operational, update member SMFPRMxx of SYS1.PARMLIB, which indicates whether SMF is active and which types of records SMF accepts. For member SMFPRMxx, xx are two user-defined alphanumeric characters appended to 'SMFPRM' to form the name of an SMFPRMxx member. To update this member, specify the ACTIVE parameter and the proper TYPE subparameter for SYS and SUBSYS.

You can also code an IEFU84 SMF exit to process the records that are produced.

## Allocating additional SMF buffers

When you specify a performance trace type, the volume of data that DB2 can collect can be quite large. If you are sending this data to SMF, you must allocate adequate SMF buffers; the default buffer settings will probably be insufficient.

If an SMF buffer shortage occurs, SMF rejects any trace records sent to it. DB2 sends a message (DSNW133I) to the MVS operator when this occurs. DB2 treats the error as temporary and remains active even though data could be lost. DB2 sends another message (DSNW123I) to the z/OS operator when the shortage has been alleviated and trace recording has resumed.

You can determine if trace data has been lost by examining the DB2 statistics records with an IFCID of 0001, as mapped by macro DSNDQWST. These records show:

- The number of trace records successfully written
- The number of trace records that could not be written
- The reason for the failure

If your location uses SMF for performance data or global trace data, be sure that:

- Your SMF data sets are large enough to hold the data.
- SMF is set up to accept record type 102. (Specify member SMFPRMxx, for which 'xx' are two user-defined alphanumeric characters.)
- Your SMF buffers are large enough.

Specify SMF buffering on the VSAM BUFSP parameter of the access method services DEFINE CLUSTER statement. Do not use the default settings if DB2 performance or global trace data is sent to SMF. Specify CISZ(4096) and

BUFSP(81920) on the DEFINE CLUSTER statement for each SMF VSAM data set. These values are the minimum required for DB2; you might have to increase them, depending on your z/OS environment.

DB2 runs above the 16MB line of virtual storage in a cross-memory environment.

## Reporting data in SMF

There are several ways to report trace records sent to SMF:

- Use Tivoli Decision Support for OS/390 to collect the data and create graphical or tabular reports.
- Write an application program to read and report information from the SMF data set. You can tailor it to fit your exact needs.
- Use OMEGAMON. See “OMEGAMON” on page 1202 for a discussion of OMEGAMON’s capabilities.

In any of those ways you can compare any report for a current day, week, or month with an equivalent sample, as far back as you want to go. The samples become more widely spaced but are still available for analysis.

---

## Recording GTF trace data

The default destination for the performance trace classes is the generalized trace facility (GTF). The z/OS operator must start GTF before you can send data to it. When starting GTF, specify TIME=YES, and then TRACE=USRP. Start GTF as indicated in Table 311 to ensure that offsets map correctly. Be sure that no GTF member exists in SYS1.PARMLIB.

*Table 311. Recording GTF trace data*

| You enter...        | System responds...                             |
|---------------------|------------------------------------------------|
| S GTF,,, (TIME=YES) | AHL100A SPECIFY TRACE OPTIONS                  |
| TRACE=USRP          | AHL101A SPECIFY TRACE EVENT KEYWORDS --USR=    |
| USR=(FB9)           | AHL102A CONTINUE TRACE DEFINITION OR REPLY END |
| END                 | AHL125A RESPECIFY TRACE OPTIONS OR REPLY U     |
| U                   | AHL031I GTF INITIALIZATION COMPLETE            |

**Note:** To make stopping GTF easier, you can name the GTF session when you start it. For example, you could specify S GTF.GTF,,, (TIME=YES).

If a GTF member exists in SYS1.PARMLIB, the GTF trace option USR might not be in effect. When no other member exists in SYS1.PARMLIB, you are sure to have only the USR option activated, and no other options that might add unwanted data to the GTF trace.

When starting GTF, if you use the JOBNAMEP option to obtain only those trace records written for a specific job, trace records written for other agents are not written to the GTF data set. This means that a trace record that is written by a system agent that is processing for an allied agent is discarded if the JOBNAMEP option is used. For example, after a DB2 system agent performs an IDENTIFY request for an allied agent, an IFCID record is written. If the JOBNAMEP keyword is used to collect trace data for a specific job, however, the record for the IDENTIFY request is not written to GTF, even if the IDENTIFY request was performed for the job named on the JOBNAMEP keyword.

You can record DB2 trace data in GTF using a GTF event ID of X'FB9'.

Trace records longer than the GTF limit of 256 bytes are spanned by DB2. For instructions on how to process GTF records, refer to Appendix D, "Interpreting DB2 trace output," on page 1139.

---

## OMEGAMON

OMEGAMON provides performance monitoring, reporting, buffer pool analysis, and a performance warehouse all in one tool:

- OMEGAMON includes the function of DB2 Performance Monitor (DB2 PM), which is also available as a stand-alone product. Both products report DB2 instrumentation in a form that is easy to understand and analyze. The instrumentation data is presented in the following ways:
  - The Batch report sets present the data you select in comprehensive reports or graphs containing system-wide and application-related information for both single DB2 subsystems and DB2 members of a data sharing group. You can combine instrumentation data from several different DB2 locations into one report.
  - The Online Monitor gives a current "snapshot" view of a running DB2 subsystem, including applications that are running. Its history function displays information about subsystem and application activity in the recent past.

Batch reports can be used to examine performance problems and trends over a period of time.

Both a host-based and Workstation Online Monitor are provided. The Workstation Online Monitor substantially improves usability, simplifies online monitoring and problem analysis, and offers significant advantages. For example, from Workstation Online Monitor, you can launch Visual Explain so you can examine the access paths and processing methods chosen by DB2 for the currently executing SQL statement.

For more information about the Workstation Online Monitor, see *OMEGAMON Monitoring Performance from Performance Expert Client* or *OMEGAMON for z/OS and Multiplatforms Monitoring Performance from Workstation for z/OS and Multiplatforms*.

In addition, OMEGAMON contains a Performance Warehouse function that lets you:

- Save DB2 trace and report data in a performance database for further investigation and trend analysis
  - Configure and schedule the report and load process from the workstation interface
  - Define and apply analysis functions to identify performance bottlenecks.
- OMEGAMON also includes the function of DB2 Buffer Pool Analyzer, which is also available as a stand-alone product. Both products help you optimize buffer pool usage by offering comprehensive reporting of buffer pool activity, including:
    - Ordering by various identifiers such as buffer pool, plan, object, and primary authorization ID
    - Sorting by getpage, sequential prefetch, and synchronous read
    - Filtering capability

In addition, you can simulate buffer pool usage for varying buffer pool sizes and analyze the results of the simulation reports to determine the impact of any changes before making those changes to your current system.

---

## Tivoli Decision Support for OS/390

Tivoli Decision Support for OS/390, formerly known as Tivoli Performance Reporter for OS/390, collects data into a DB2 database and allows you to create graphical and tabular reports to use in managing systems performance. The data can come from different sources, including SMF, the IMS log, the CICS journal, RMF, and DB2.

When considering the use of Tivoli Decision Support for OS/390, consider the following:

- Tivoli Decision Support data collection and reporting are based on user specifications. Therefore, an experienced user can produce more suitable reports than the predefined reports produced by other tools.
- Tivoli Decision Support provides historical performance data that you can use to compare a current situation with previous data.
- Tivoli Decision Support can be used very effectively for reports based on the DB2 statistics and accounting records. When using it for the performance trace consider that:
  - Because of the large number of different DB2 performance records, a substantial effort is required to define their formats to Tivoli Decision Support. Changes in the records require review of the definitions.
  - Tivoli Decision Support does not handle information from paired records, such as “start event” and “end event.” These record pairs are used by OMEGAMON to calculate elapsed times, such as the elapsed time of I/Os and lock suspensions.

The general recommendation for Tivoli Decision Support and OMEGAMON use in a DB2 subsystem is:

- If Tivoli Decision Support is already used or there is a plan to use it at the location:
  - Extend Tivoli Decision Support usage to the DB2 accounting and statistics records.
  - Use OMEGAMON for the DB2 performance trace.
- If Tivoli Decision Support is not used and there is no plan to use it:
  - Use OMEGAMON for the statistics, accounting, and performance trace.
  - Consider extending OMEGAMON with user applications based on DB2 and QMF, to provide historical performance data.

---

## Monitoring application plans and packages

The following statements identify plans and packages that:

- Possibly redo validity checks at run time; if an invalid object or missing authority is found, DB2 issues a warning and checks again for the object or authorization at run time.
- Use repeatable read.
- Are invalid (must be rebound before use), for example, the deleting an index or revoking authority can render a plan or package invalid.
- Are inoperative (require an explicit BIND or REBIND before use). A plan or package can be marked inoperative after an unsuccessful REBIND.

**General-use Programming Interface**

```
SELECT NAME, VALIDATE, ISOLATION, VALID, OPERATIVE
FROM SYSIBM.SYSPLAN
WHERE VALIDATE = 'R' OR ISOLATION = 'R'
OR VALID = 'N' OR OPERATIVE = 'N';
```

```
SELECT COLLID, NAME, VERSION, VALIDATE, ISOLATION, VALID, OPERATIVE
FROM SYSIBM.SYSPACKAGE
WHERE VALIDATE = 'R' OR ISOLATION = 'R'
OR VALID = 'N' OR OPERATIVE = 'N';
```

**End of General-use Programming Interface**

---

## Appendix G. EXPLAIN tables that are used by optimization tools

Optimization tools such as IBM Optimization Service Center for DB2 for z/OS, IBM DB2 Optimization Expert for z/OS, and the DB2 EXPLAIN function might create and use any of the following EXPLAIN tables to store performance data.

---

### DSN\_PREDICAT\_TABLE

The predicate table, DSN\_PREDICAT\_TABLE, contains information about all of the predicates in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

#### CREATE TABLE statement

The following figure shows the current format of DSN\_PREDICAT\_TABLE

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_PREDICAT_TABLE
( QUERYNO          INTEGER      NOT NULL,
  QBLOCKNO        SMALLINT    NOT NULL,
  APPLNAME        VARCHAR(24)  NOT NULL,
  PROGNAME        VARCHAR(128) NOT NULL,
  PREDNO          INTEGER      NOT NULL,
  TYPE            CHAR(8)      NOT NULL,
  LEFT_HAND_SIDE  VARCHAR(128) NOT NULL,
  LEFT_HAND_PNO   INTEGER      NOT NULL,
  LHS_TABNO       SMALLINT     NOT NULL,
  LHS_QBNO        SMALLINT     NOT NULL,
  RIGHT_HAND_SIDE VARCHAR(128) NOT NULL,
  RIGHT_HAND_PNO  INTEGER      NOT NULL,
  RHS_TABNO       SMALLINT     NOT NULL,
  RHS_QBNO        SMALLINT     NOT NULL,
  FILTER_FACTOR   FLOAT        NOT NULL,
  BOOLEAN_TERM    CHAR(1)      NOT NULL,
  SEARCHARG       CHAR(1)      NOT NULL,
  JOIN            CHAR(1)      NOT NULL,
  AFTER_JOIN      CHAR(1)      NOT NULL,
  ADDED_PRED      CHAR(1)      NOT NULL,
  REDUNDANT_PRED  CHAR(1)      NOT NULL,
  DIRECT_ACCESS   CHAR(1)      NOT NULL,
  KEYFIELD        CHAR(1)      NOT NULL,
  EXPLAIN_TIME    TIMESTAMP    NOT NULL,
  CATEGORY        SMALLINT     NOT NULL,
  CATEGORY_B      SMALLINT     NOT NULL,
  TEXT            VARCHAR(2000) NOT NULL,
  PRED_ENCODE     CHAR(1)      NOT NULL WITH DEFAULT,
  PRED_CCSID      SMALLINT     NOT NULL WITH DEFAULT,
  PRED_MCCSID     SMALLINT     NOT NULL WITH DEFAULT,
  MARKER          CHAR(1)      NOT NULL WITH DEFAULT,
  PARENT_PNO      INTEGER      NOT NULL,
```

```

        NEGATION          CHAR(1)      NOT NULL,
        LITERALS          VARCHAR(128) NOT NULL,
        CLAUSE            CHAR(8)        NOT NULL,
        GROUP_MEMBER      VARCHAR(24)   NOT NULL
    ) in database-name.table-space-name
    CCSID UNICODE;

```

Figure 170. The CREATE TABLE statement for userid.DSN\_PREDICAT\_TABLE

## Column descriptions

The following table describes the columns of the DSN\_PREDICAT\_TABLE

Table 312. DSN\_PREDICAT\_TABLE description

| Column name | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL      | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache</li> </ol>          |
| QBLOCKNO    | SMALLINT NOT NULL     | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                                  |
| APPLNAME    | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                                                                                                                                                                                                                                                                          |
| PROGNAME    | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                                  |
| PREDNO      | INTEGER NOT NULL      | The predicate number, a number used to identify a predicate within a query.                                                                                                                                                                                                                                                                                                                         |
| TYPE        | CHAR(8) NOT NULL      | A string used to indicate the type or the operation of the predicate. The possible values are: <ul style="list-style-type: none"> <li>• 'AND'</li> <li>• 'OR'</li> <li>• 'EQUAL'</li> <li>• 'RANGE'</li> <li>• 'BETWEEN'</li> <li>• 'IN'</li> <li>• 'LIKE'</li> <li>• 'NOT LIKE'</li> <li>• 'EXISTS'</li> <li>• 'NOTEXIST'</li> <li>• 'SUBQUERY'</li> <li>• 'HAVING'</li> <li>• 'OTHERS'</li> </ul> |

Table 312. DSN\_PREDICAT\_TABLE description (continued)

| Column name    | Data type                | Description                                                                                                                                                                                                                                                                                                                                             |

| TEXT         | VARCHAR(2000) | The transformed predicate text; truncated if exceeds 2000 characters.                                                                                                 |
| PRED_ENCODE  | CHAR(1)       | IBM internal use only.                                                                                                                                                |
| PRED_CCSID   | SMALLINT      | IBM internal use only.                                                                                                                                                |
| PRED_MCCSID  | SMALLINT      | IBM internal use only.                                                                                                                                                |
| MARKER       | CHAR(1)       | Whether this predicate includes host variables, parameter markers, or special registers.                                                                              |
| PARENT_PNO   | INTEGER       | The parent predicate number. If this predicate is a root predicate within a query block, then this column is 0.                                                       |
| NEGATION     | CHAR(1)       | Whether this predicate is negated via NOT.                                                                                                                            |
| LITERALS     | VARCHAR(128)  | This column indicates the literal value or literal values separated by colon symbols.                                                                                 |
| CLAUSE       | CHAR(8)       | The clause where the predicate exists:<br><br>' <b>HAVING</b> '<br>The HAVING clause<br><br>' <b>ON</b> '   The ON clause<br><br>' <b>WHERE</b> '<br>The WHERE clause |
| GROUP_MEMBER | CHAR(8)       | The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.           |

## DSN\_STRUCT\_TABLE

The structure table, DSN\_STRUCT\_TABLE, contains information about all of the query blocks in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the CREATE TABLE statement for DSN\_STRUCT\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_STRUCT_TABLE
( QUERYNO          INTEGER      NOT NULL,
  QBLOCKNO        SMALLINT    NOT NULL,
  APPLNAME        VARCHAR(24)  NOT NULL,
  PROGNAME        VARCHAR(128) NOT NULL,
  PARENT          SMALLINT    NOT NULL,
  TIMES           FLOAT        NOT NULL,
  ROWCOUNT       INTEGER      NOT NULL,
```

```

        ATOPEX          CHAR(1)      NOT NULL,
        CONTEXT        CHAR(10)     NOT NULL,
        ORDERNO        SMALLINT    NOT NULL,
        DOATOPEN_PARENT SMALLINT    NOT NULL,
        QBLOCK_TYPE     CHAR(6)      NOT NULL WITH DEFAULT,
        EXPLAIN_TIME    TIMESTAMP   NOT NULL,
        QUERY_STAGE     CHAR(8)      NOT NULL,
        GROUP_MEMBER    VARCHAR(24)  NOT NULL
    )
    IN database-name.table-space-name
    CCSID UNICODE;

```

## Column descriptions

The following table describes the columns of DSN\_STRUCT\_TABLE

Table 313. DSN\_STRUCT\_TABLE description

| Column name | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL      | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL     | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                         |
| APPLNAME    | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                                                                                                                                                                                                                                                                 |
| PROGNAME    | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                         |
| PARENT      | SMALLINT NOT NULL     | The parent query block number of the current query block in the structure of SQL text; this is the same as the PARENT_QBLOCKNO in PLAN_TABLE.                                                                                                                                                                                                                                              |
| TIMES       | FLOAT NOT NULL        | The estimated number of rows returned by Data Manager; also the estimated number of times this query block is executed.                                                                                                                                                                                                                                                                    |
| ROWCOUNT    | INTEGER NOT NULL      | The estimated number of rows returned by RDS (Query Cardinality).                                                                                                                                                                                                                                                                                                                          |
| ATOPEN      | CHAR(1) NOT NULL      | Whether the query block is moved up for do-at-open processing; 'Y' if done-at-open; 'N': otherwise.                                                                                                                                                                                                                                                                                        |
| CONTEXT     | CHAR(10) NOT NULL     | This column indicates what the context of the current query block is. The possible values are: <ul style="list-style-type: none"> <li>• 'TOP LEVEL'</li> <li>• 'UNION'</li> <li>• 'UNION ALL'</li> <li>• 'PREDICATE'</li> <li>• 'TABLE EXP'</li> <li>• 'UNKNOWN'</li> </ul>                                                                                                                |

Table 313. DSN\_STRUCT\_TABLE description (continued)

| Column name     | Data type                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORDERNO         | SMALLINT NOT NULL             | Not currently used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DOATOPEN_PARENT | SMALLINT NOT NULL             | The parent query block number of the current query block; Do-at-open parent if the query block is done-at-open, this may be different from the PARENT_QBLOCKNO in PLAN_TABLE.                                                                                                                                                                                                                                                                                                                |
| QBLOCK_TYPE     | CHAR(6) NOT NULL WITH DEFAULT | This column indicates the type of the current query block. The possible values are <ul style="list-style-type: none"> <li>• 'SELECT'</li> <li>• 'INSERT'</li> <li>• 'UPDATE'</li> <li>• 'DELETE'</li> <li>• 'SELUPD'</li> <li>• 'DELCUR'</li> <li>• 'UPDCUR'</li> <li>• 'CORSUB'</li> <li>• 'NCOSUB'</li> <li>• 'TABLEX'</li> <li>• 'TRIGGR'</li> <li>• 'UNION'</li> <li>• 'UNIONA'</li> <li>• 'CTE'</li> </ul> <p>It is equivalent to QBLOCK_TYPE column in PLAN_TABLE, except for CTE.</p> |
| EXPLAIN_TIME    | TIMESTAMP NOT NULL            | The EXPLAIN timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| QUERY_STAGE     | CHAR(8) NOT NULL              | IBM internal use only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| GROUP_MEMBER    | CHAR(8) NOT NULL              | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.                                                                                                                                                                                                                                                                                                                        |

## DSN\_PGROUP\_TABLE

The parallel group table, PGROUP\_TABLE, contains information about the parallel groups in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_PGROUP\_TABLE

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```

CREATE TABLE userid.DSN_PGROUPTABLE
( QUERYNO          INTEGER      NOT NULL,
  QBLOCKNO        SMALLINT    NOT NULL,
  PLANNAME        VARCHAR(24)   NOT NULL,
  COLLID          VARCHAR(128) NOT NULL,
  PROGNAME        VARCHAR(128) NOT NULL,
  EXPLAIN_TIME    TIMESTAMP    NOT NULL,
  VERSION         VARCHAR(122)  NOT NULL,
  GROUPID         SMALLINT     NOT NULL,
  FIRSTPLAN       SMALLINT     NOT NULL,
  LASTPLAN        SMALLINT     NOT NULL,
  CPUCOST         REAL         NOT NULL,
  IOCAST         REAL         NOT NULL,

## Column descriptions

The following table describes the columns of DSN\_PGROUPTABLE

Table 314. DSN\_PGROUPTABLE description

| Column name | Data type        | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL | <p>The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are:</p> <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache</li> </ol> |

Table 314. DSN\_PGROUP\_TABLE description (continued)

| Column name  | Data type             | Description                                                                                                                                         |
|--------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| QBLOCKNO     | SMALLINT NOT NULL     | The query block number, a number used to identify each query block within a query.                                                                  |
| PLANNAME     | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                          |
| COLLID       | VARCHAR(128) NOT NULL | The collection ID for the package.                                                                                                                  |
| PROGNAME     | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                  |
| EXPLAIN_TIME | TIMESTAMP NOT NULL    | The explain timestamp.                                                                                                                              |
| VERSION      | VARCHAR(122) NOT NULL | The version identifier for the package.                                                                                                             |
| GROUPID      | SMALLINT NOT NULL     | The parallel group identifier within the current query block.                                                                                       |
| FIRSTPLAN    | SMALLINT NOT NULL     | The plan number of the first contributing mini-plan associated within this parallel group.                                                          |
| LASTPLAN     | SMALLINT NOT NULL     | The plan number of the last mini-plan associated within this parallel group.                                                                        |
| CPUCOST      | REAL NOT NULL         | The estimated total CPU cost of this parallel group in milliseconds.                                                                                |
| IO COST      | REAL NOT NULL         | The estimated total I/O cost of this parallel group in milliseconds.                                                                                |
| BESTTIME     | REAL NOT NULL         | The estimated elapsed time for each parallel task for this parallel group.                                                                          |
| DEGREE       | SMALLINT NOT NULL     | The degree of parallelism for this parallel group determined at bind time. Max parallelism degree if the Table space is large is 255, otherwise 64. |
| MODE         | CHAR(1) NOT NULL      | The parallel mode:<br>'T' IO parallelism<br>'C' CPU parallelism<br>'X' multiple CPU Sysplex parallelism (highest level)<br>'N' No parallelism       |
| REASON       | SMALLINT NOT NULL     | The reason code for downgrading parallelism mode.                                                                                                   |
| LOCALCPU     | SMALLINT NOT NULL     | The number of CPUs currently online when preparing the query.                                                                                       |
| TOTALCPU     | SMALLINT NOT NULL     | The total number of CPUs in Sysplex. LOCALCPU and TOTALCPU are different only for the DB2 coordinator in a Sysplex.                                 |
| FIRSTBASE    | SMALLINT              | The table number of the table that partitioning is performed on.                                                                                    |
| LARGETS      | CHAR(1)               | 'Y' if the TableSpace is large in this group.                                                                                                       |
| PARTKIND     | CHAR(1)               | The partitioning type:<br>'L' Logical partitioning<br>'P' Physical partitioning                                                                     |
| GROUPTYPE    | CHAR(3)               | Determines what operations this parallel group contains: table Access, Join, or Sort 'A' 'AJ' 'AJS'                                                 |

Table 314. DSN\_PGROUPTABLE description (continued)

| Column name  | Data type        | Description                                                                                                                                                                                                                                                                                                    |
|--------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORDER        | CHAR(1)          | The ordering requirement of this parallel group :<br>'N' No order. Results need no ordering.<br>'T' Natural Order. Ordering is required but results already ordered if accessed via index.<br>'K' Key Order. Ordering achieved by sort. Results ordered by sort key. This value applies only to parallel sort. |
| STYLE        | CHAR(4)          | The Input/Output format style of this parallel group. Blank for IO Parallelism. For other modes:<br>'RIRO'<br>Records IN, Records OUT<br>'WIRO'<br>Work file IN, Records OUT<br>'WIWO'<br>Work file IN, Work file OUT                                                                                          |
| RANGEKIND    | CHAR(1)          | The range type:<br>'K' Key range<br>'P' Page range                                                                                                                                                                                                                                                             |
| NKEYCOLS     | SMALLINT         | The number of interesting key columns, that is, the number of columns that will participate in the key operation for this parallel group.                                                                                                                                                                      |
| LOWBOUND     | VARCHAR(40)      | The low bound of parallel group.                                                                                                                                                                                                                                                                               |
| HIGHBOUND    | VARCHAR(40)      | The high bound of parallel group.                                                                                                                                                                                                                                                                              |
| LOWKEY       | VARCHAR(40)      | The low key of range if partitioned by key range.                                                                                                                                                                                                                                                              |
| HIGHKEY      | VARCHAR(40)      | The high key of range if partitioned by key range.                                                                                                                                                                                                                                                             |
| FIRSTPAGE    | CHAR(4)          | The first page in range if partitioned by page range.                                                                                                                                                                                                                                                          |
| LASTPAGE     | CHAR(4)          | The last page in range if partitioned by page range.                                                                                                                                                                                                                                                           |
| GROUP_MEMBER | CHAR(8) NOT NULL | IBM internal use only.                                                                                                                                                                                                                                                                                         |
| HOST_REASON  | SMALLINT         | IBM internal use only.                                                                                                                                                                                                                                                                                         |
| PARA_TYPE    | CHAR(4)          | IBM internal use only.                                                                                                                                                                                                                                                                                         |
| PART_INNER   | CHAR(1)          | IBM internal use only.                                                                                                                                                                                                                                                                                         |
| GRNU_KEYRNG  | CHAR(1)          | IBM internal use only.                                                                                                                                                                                                                                                                                         |
| OPEN_KEYRNG  | CHAR(1)          | IBM internal use only.                                                                                                                                                                                                                                                                                         |

## DSN\_PTASK\_TABLE

The parallel tasks table, DSN\_PTASK\_TABLE, contains information about all of the parallel tasks in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_PTASK\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_PTASK_TABLE
( QUERYNO          INTEGER          NOT NULL,
  QBLOCKNO        SMALLINT         NOT NULL,
  PGDNO           SMALLINT         NOT NULL,
  APPLNAME        VARCHAR(24)      NOT NULL,
  PROGNAME        VARCHAR(128)     NOT NULL,
  LPTNO           SMALLINT         NOT NULL,
  KEYCOLID        SMALLINT         ,
  DPSI            CHAR(1)          NOT NULL,
  LPTLOKEY        VARCHAR(40)      ,
  LPTHIKEY        VARCHAR(40)      ,
  LPTLOPAG        CHAR(4)          ,
  LPTHIPAG        CHAR(4)          ,
  LPTLOPG         CHAR(4)          ,
  LPTHIPG         CHAR(4)          ,
  LPTLOPT         SMALLINT         ,
  LPTHIPT         SMALLINT         ,
  KEYCOLDT        SMALLINT         ,
  KEYCOLPREC      SMALLINT         ,
  KEYCOLSCAL      SMALLINT         ,
  EXPLAIN_TIME    TIMESTAMP        NOT NULL,
  GROUP_MEMBER    VARCHAR(24)     NOT NULL
) IN database-name.table-space-name
CCSID UNICODE;
```

## Column descriptions

The following table describes the columns of DSN\_PTASK\_TABLE.

Table 315. DSN\_PTASK\_TABLE description

| Column name | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL      | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL     | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                         |
| APPLNAME    | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                                                                                                                                                                                                                                                                 |
| PROGNAME    | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                         |
| LPTNO       | SMALLINT NOT NULL     | The parallel task number.                                                                                                                                                                                                                                                                                                                                                                  |
| KEYCOLID    | SMALLINT              | The key column ID (KEY range only).                                                                                                                                                                                                                                                                                                                                                        |

Table 315. DSN\_PTASK\_TABLE description (continued)

| Column name  | Data type            | Description                                                                                                                                                 |
|--------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DPSI         | CHAR(1) NOT NULL     | Indicates if a data partition secondary index (DPSI) is used.                                                                                               |
| LPTLOKEY     | VARCHAR(40)          | The low key value for this key column for this parallel task (KEY range only).                                                                              |
| LPTHIKEY     | VARCHAR(40)          | The high key value for this key column for this parallel task (KEY range only).                                                                             |
| LPTLOPAG     | CHAR(4)              | The low page information if partitioned by page range.                                                                                                      |
| LPTLHIPAG    | CHAR(4)              | The high page information if partitioned by page range.                                                                                                     |
| LPTLOPG      | CHAR(4)              | The lower bound page number for this parallel task (Page range or DPSI enabled only).                                                                       |
| LPTHIPG      | CHAR(4)              | The upper bound page number for this parallel task (Page range or DPSI enabled only).                                                                       |
| LPTLOPT      | SMALLINT             | The lower bound partition number for this parallel task (Page range or DPSI enabled only).                                                                  |
| LPTHIPT      | SMALLINT             | The higher bound partition number for this parallel task (Page range or DPSI enabled only).                                                                 |
| KEYCOLDT     | SMALLINT             | The data type for this key column (KEY range only).                                                                                                         |
| KEYCOLPREC   | SMALLINT             | The precision/length for this key column (KEY range only).                                                                                                  |
| KEYCOLSCAL   | SMALLINT             | The scale for this key column (KEY range with Decimal datatype only).                                                                                       |
| EXPLAIN_TIME | TIMESTAMP NOT NULL   | The EXPLAIN timestamp.                                                                                                                                      |
| GROUP_MEMBER | VARCHAR(24) NOT NULL | The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed. |

## DSN\_FILTER\_TABLE

The filter table, DSN\_FILTER\_TABLE, contains information about how predicates are used during query processing.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_FILTER\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_FILTER_TABLE
(
  QUERYNO           INTEGER      NOT NULL,
  QBLOCKNO         SMALLINT    NOT NULL,
  PLANNO           SMALLINT    NOT NULL,
```

```

        APPLNAME          VARCHAR(24) NOT NULL,
        PROGNAME         VARCHAR(128) NOT NULL,
        COLLID           VARCHAR(128) NOT NULL WITH DEFAULT,
        ORDERNO          INTEGER      NOT NULL,
        PREDNO           INTEGER      NOT NULL,
        STAGE             CHAR(9)     NOT NULL,
        ORDERCLASS       INTEGER      NOT NULL,
        EXPLAIN_TIME     TIMESTAMP   NOT NULL,
        MIXOPSEQNO       SMALLINT    NOT NULL,
        REEVAL            CHAR(1)     NOT NULL,
        GROUP_MEMBER     VARCHAR(24)  NOT NULL
    )
    IN database-name.table-space-name

CCSID UNICODE;
```

Figure 174. The CREATE TABLE statement for userid.DSN\_FILTER\_TABLE

### Column descriptions

The following table describes the columns of DSN\_FILTER\_TABLE.

Table 316. DSN\_FILTER\_TABLE description

| Column name | Data type                          | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL                   | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL                  | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                          |
| PLANNO      | SMALLINT                           | The plan number, a number used to identify each miniplan with a query block.                                                                                                                                                                                                                                                                                                                |
| APPLNAME    | VARCHAR(24) NOT NULL               | The application plan name.                                                                                                                                                                                                                                                                                                                                                                  |
| PROGNAME    | VARCHAR(128) NOT NULL WITH DEFAULT | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                          |
| COLLID      | INTEGER NOT NULL                   | The collection ID for the package.                                                                                                                                                                                                                                                                                                                                                          |
| ORDERNO     | INTEGER NOT NULL                   | The sequence number of evaluation. Indicates the order in which the predicate is applied within each stage                                                                                                                                                                                                                                                                                  |
| PREDNO      | INTEGER NOT NULL                   | The predicate number, a number used to identify a predicate within a query.                                                                                                                                                                                                                                                                                                                 |
| STAGE       | CHAR(9) NOT NULL                   | Indicates at which stage the Predicate is evaluated. The possible values are: <ul style="list-style-type: none"> <li>• 'Matching'</li> <li>• 'Screening'</li> <li>• 'Stage 1'</li> <li>• 'Stage 2'</li> </ul>                                                                                                                                                                               |

| Column name  | Data type            | Description                                                                                                                                                           |
|--------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORDERCLASS   | INTEGER NOT NULL     | IBM internal use only.                                                                                                                                                |
| EXPLAIN_TIME | TIMESTAMP NOT NULL   | The explain timestamp.                                                                                                                                                |
| MIXOPSEQ     | SMALLINT NOT NULL    | IBM internal use only.                                                                                                                                                |
| REEVAL       | CHAR(1) NOT NULL     | IBM internal use only.                                                                                                                                                |
| GROUP_MEMBER | VARCHAR(24) NOT NULL | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed. |

## DSN\_DETCOST\_TABLE

The detailed cost table, DSN\_DETCOST\_TABLE, contains information about detailed cost estimation of the mini-plans in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_DETCOST\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_DETCOST_TABLE
(
  QUERYNO           INTEGER      NOT NULL,

### Column descriptions

The following table describes the columns of `DSN_DETCOST_TABLE`.

Table 317. DSN\_DETCOST\_TABLE description

| Column name | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL      | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL     | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                          |
| APPLNAME    | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                                                                                                                                                                                                                                                                  |
| PROGNAME    | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                          |
| PLANNO      | SMALLINT NOT NULL     | The plan number, a number used to identify each mini-plan with a query block.                                                                                                                                                                                                                                                                                                               |
| OPENIO      | FLOAT(4) NOT NULL     | The Do-at-open IO cost for non-correlated subquery.                                                                                                                                                                                                                                                                                                                                         |
| OPENCPU     | FLOAT(4) NOT NULL     | The Do-at-open CPU cost for non-correlated subquery.                                                                                                                                                                                                                                                                                                                                        |
| OPENCOST    | FLOAT(4) NOT NULL     | The Do-at-open total cost for non-correlated subquery.                                                                                                                                                                                                                                                                                                                                      |

| RDSROW      | FLOAT(4) NOT NULL | The number of RDS rows returned (after all stage 1 and stage 2 predicates are applied). |
| SNCOLS      | SMALLINT NOT NULL | The number of columns as sort input for new table.                                      |
| SNROWS      | FLOAT(4) NOT NULL | The number of rows as sort input for new table.                                         |
| SNRECSZ     | INTEGER NOT NULL  | The record size for new table.                                                          |
| SNPAGES     | FLOAT(4) NOT NULL | The page size for new table.                                                            |
| SNRUNS      | FLOAT(4) NOT NULL | The number of runs generated for sort of new table.                                     |
| SNMERGES    | FLOAT(4) NOT NULL | The number of merges needed during sort.                                                |
| SNIOCOST    | FLOAT(4) NOT NULL | IBM internal use only.                                                                  |
| SNCPUCOST   | FLOAT(4) NOT NULL | IBM internal use only.                                                                  |
| SNCOST      | FLOAT(4) NOT NULL | IBM internal use only.                                                                  |
| SNCSCANIO   | FLOAT(4) NOT NULL | IBM internal use only.                                                                  |

Table 317. DSN\_DETCOST\_TABLE description (continued)

| Column name       | Data type            | Description                                              |
|-------------------|----------------------|----------------------------------------------------------|
| SNSCANCPU         | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SNCCOLS           | FLOAT(4) NOT NULL    | The number of columns as sort input for Composite table. |
| SCROWS            | FLOAT(4) NOT NULL    | The number of rows as sort input for Composite Table.    |
| SCRECSZ           | FLOAT(4) NOT NULL    | The record size for Composite table.                     |
| SCPAGES           | FLOAT(4) NOT NULL    | The page size for Composite table.                       |
| SCRUNS            | FLOAT(4) NOT NULL    | The number of runs generated during sort of composite.   |
| SCMERGES          | FLOAT(4) NOT NULL    | The number of merges needed during sort of composite.    |
| SCIOCOST          | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SCCPUCOST         | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SCCOST            | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SCSCANIO          | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SCSCANCPU         | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| SCSCANCOST        | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| COMPCARD          | FLOAT(4) NOT NULL    | The total composite cardinality.                         |
| COMPIOCOST        | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| COMPCPUCOST       | FLOAT(4) NOT NULL    | IBM internal use only.                                   |
| COMPCOST          | FLOAT(4) NOT NULL    | The total cost.                                          |
| JOINCOLS          | SMALLINT NOT NULL    | IBM internal use only.                                   |
| EXPLAIN_TIME      | TIMESTAMP NOT NULL   | The EXPLAIN timestamp.                                   |
| COSTBLK           | INTEGER NOT NULL     | IBM internal use only.                                   |
| COSTSTOR          | INTEGER NOT NULL     | IBM internal use only.                                   |
| MPBLK             | INTEGER NOT NULL     | IBM internal use only.                                   |
| MPSTOR            | INTEGER NOT NULL     | IBM internal use only.                                   |
| COMPOSITES        | INTEGER NOT NULL     | IBM internal use only.                                   |
| CLIPPED           | INTEGER NOT NULL     | IBM internal use only.                                   |
| TABREF            | VARCHAR(64) NOT NULL | IBM internal use only.                                   |
| MAX_COMPOSITES    | INTEGER NOT NULL     | IBM internal use only.                                   |
| MAX_STOR          | INTEGER NOT NULL     | IBM internal use only.                                   |
| MAX_CPU           | INTEGER NOT NULL     | IBM internal use only.                                   |
| MAX_ELAP          | INTEGER NOT NULL     | IBM internal use only.                                   |
| TBL_JOINED_THRESH | INTEGER NOT NULL     | IBM internal use only.                                   |

## DSN\_SORT\_TABLE

The sort table, DSN\_SORT\_TABLE, contains information about the sort operations required by a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_SORT\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection

IDs.

Figure 178. The CREATE TABLE statement for userid.DSN\_SORT\_TABLE

```
CREATE TABLE userid.DSN_SORT_TABLE
(
  QUERYNO           INTEGER      NOT NULL,
  QBLOCKNO         SMALLINT     NOT NULL,
  PLANNO           SMALLINT     NOT NULL,
  APPLNAME         VARCHAR(24)  NOT NULL,
  PROGNAME         VARCHAR(128) NOT NULL,
  COLLID          VARCHAR(128) NOT NULL WITH DEFAULT,
  SORTC           CHAR(5)      NOT NULL WITH DEFAULT,
  SORTN           CHAR(5)      NOT NULL WITH DEFAULT,
  SORTNO          SMALLINT     NOT NULL,
  KEYSIZE         SMALLINT     NOT NULL,
  ORDERCLASS      INTEGER      NOT NULL,
  EXPLAIN_TIME    TIMESTAMP    NOT NULL,
  GROUP_MEMBER    VARCHAR(24)  NOT NULL
)
  IN database-name.table-space-name
-name
CCSID UNICODE;
```

## Column descriptions

The following table describes the columns of DSN\_SORT\_TABLE.

Table 318. DSN\_SORT\_TABLE description

| Column name | Data type                          | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL                   | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL                  | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                          |
| PLANNO      | SMALLINT NOT NULL                  | The plan number, a number used to identify each miniplan with a query block.                                                                                                                                                                                                                                                                                                                |
| APPLNAME    | VARCHAR(24) NOT NULL               | The application name.                                                                                                                                                                                                                                                                                                                                                                       |
| PROGNAME    | VARCHAR(128) NOT NULL              | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                          |
| COLLID      | VARCHAR(128) NOT NULL WITH DEFAULT | The collection ID for the package.                                                                                                                                                                                                                                                                                                                                                          |

Table 318. DSN\_SORT\_TABLE description (continued)

| Column name  | Data type                     | Description                                                                                                                                                           |
|--------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SORTC        | CHAR(5) NOT NULL WITH DEFAULT | Indicates the reasons for sort of the Composite table. Using a bitmap of 'G','J','O','U'.<br>'G' Group By<br>'O' Order By<br>'J' Join<br>'U' Uniqueness               |
| SORTN        | CHAR(5) NOT NULL WITH DEFAULT | Indicates the reasons for sort of the Composite table. Using a bitmap of 'G','J','O','U'.<br>'G' Group By<br>'O' Order By<br>'J' Join<br>'U' Uniqueness               |
| SORTNO       | SMALLINT NOT NULL             | The sequence number of the sort.                                                                                                                                      |
| KEYSIZE      | SMALLINT NOT NULL             | The sum of the lengths of the sort keys.                                                                                                                              |
| ORDERCLASS   | INTEGER NOT NULL              | IBM internal use only.                                                                                                                                                |
| EXPLAIN_TIME | TIMESTAMP NOT NULL            | The EXPLAIN timestamp.                                                                                                                                                |
| GROUP_MEMBER | VARCHAR(24) NOT NULL          | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed. |

## DSN\_SORTKEY\_TABLE

The sort key table, DSN\_SORTKEY\_TABLE, contains information about sort keys for all of the sorts required by a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_SORTKEY\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_SORTKEY_TABLE
(
  QUERYNO           INTEGER      NOT NULL,
  QBLOCKNO         SMALLINT    NOT NULL,
  PLANNO           SMALLINT    NOT NULL,
  APPLNAME         VARCHAR(24) NOT NULL,
```

```

        PROGNAM          VARCHAR(128) NOT NULL,
        COLLID          VARCHAR(128) NOT NULL WITH DEFAULT,
        SORTNO          SMALLINT     NOT NULL,
        ORDERNO         SMALLINT     NOT NULL,
        EXPTYPE         CHAR(3)      NOT NULL,
        TEXT            VARCHAR(128) NOT NULL,
        TABNO           SMALLINT     NOT NULL,
        COLNO           SMALLINT     NOT NULL,
        DATATYPE        CHAR(18)     NOT NULL,
        LENGTH          INTEGER      NOT NULL,
        CCSID           INTEGER      NOT NULL,
        ORDERCLASS      INTEGER      NOT NULL,
        EXPLAIN_TIME    TIMESTAMP    NOT NULL,
        GROUP_MEMBER    VARCHAR(24)  NOT NULL
    )
    IN database-name.table-space-name

CCSID UNICODE;

```

## Column descriptions

The following table describes the columns of DSN\_SORTKEY\_TABLE.

Table 319. DSN\_SORTKEY\_TABLE description

| Column name | Data type                          | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL                   | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| QBLOCKNO    | SMALLINT NOT NULL                  | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                          |
| PLANNO      | SMALLINT NOT NULL                  | The plan number, a number used to identify each miniplan with a query block.                                                                                                                                                                                                                                                                                                                |
| APPLNAME    | VARCHAR(24) NOT NULL               | The application name.                                                                                                                                                                                                                                                                                                                                                                       |
| PROGNAM     | VARCHAR(128) NOT NULL              | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                          |
| COLLID      | VARCHAR(128) NOT NULL WITH DEFAULT | The collection ID for the package.                                                                                                                                                                                                                                                                                                                                                          |
| SORTNO      | SMALLINT NOT NULL                  | The sequence number of the sort                                                                                                                                                                                                                                                                                                                                                             |
| ORDERNO     | SMALLINT NOT NULL                  | The sequence number of the sort key                                                                                                                                                                                                                                                                                                                                                         |
| EXPTYPE     | CHAR(3) NOT NULL                   | The type of the sort key. The possible values are: <ul style="list-style-type: none"> <li>• 'COL'</li> <li>• 'EXP'</li> <li>• 'QRY'</li> </ul>                                                                                                                                                                                                                                              |

Table 319. DSN\_SORTKEY\_TABLE description (continued)

|--------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TEXT         | VARCHAR(128)<br>NOT NULL | The sort key text, can be a column name, an expression, or a scalar subquery, or 'Record ID'.                                                                                                                                                                                                                                                                                  |
| TABNO        | SMALLINT NOT<br>NULL     | The table number, a number which uniquely identifies the corresponding table reference within a query.                                                                                                                                                                                                                                                                         |
| COLNO        | SMALLINT NOT<br>NULL     | The column number, a number which uniquely identifies the corresponding column within a query. Only applicable when the sort key is a column.                                                                                                                                                                                                                                  |
| DATATYPE     | CHAR(18)                 | The data type of sort key. The possible values are <ul style="list-style-type: none"> <li>• 'HEXADECIMAL'</li> <li>• 'CHARACTER'</li> <li>• 'PACKED FIELD '</li> <li>• 'FIXED(31)'</li> <li>• 'FIXED(15)'</li> <li>• 'DATE'</li> <li>• 'TIME'</li> <li>• 'VARCHAR'</li> <li>• 'PACKED FLD'</li> <li>• 'FLOAT'</li> <li>• 'TIMESTAMP'</li> <li>• 'UNKNOWN DATA TYPE'</li> </ul> |
| LENGTH       | INTEGER NOT<br>NULL      | The length of sort key.                                                                                                                                                                                                                                                                                                                                                        |
| CCSID        | INTEGER NOT<br>NULL      | IBM internal use only.                                                                                                                                                                                                                                                                                                                                                         |
| ORDERCLASS   | INTEGER NOT<br>NULL      | IBM internal use only.                                                                                                                                                                                                                                                                                                                                                         |
| EXPLAIN_TIME | TIMESTAMP NOT<br>NULL    | The EXPLAIN timestamp.                                                                                                                                                                                                                                                                                                                                                         |
| GROUP_MEMBER | VARCHAR(24) NOT<br>NULL  | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.                                                                                                                                                                                                          |

## DSN\_PGRANGE\_TABLE

The page range table, DSN\_PGRANGE\_TABLE, contains information about qualified partitions for all page range scans in a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_PGRANGE\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not

limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_PGRANGE_TABLE
( QUERYNO           INTEGER           NOT NULL,
  QBLOCKNO         SMALLINT          NOT NULL,
  TABNO            SMALLINT          NOT NULL,
  RANGE            SMALLINT          NOT NULL,
  FIRSTPART        SMALLINT          NOT NULL,
  LASTPART         SMALLINT          NOT NULL,
  NUMPARTS         SMALLINT          NOT NULL,
  EXPLAIN_TIME     TIMESTAMP         NOT NULL,
  GROUP_MEMBER     VARCHAR(24)      NOT NULL
)
  IN database-name.table-space-name

CCSID UNICODE;
```

## Column descriptions

The following table describes the columns of DSN\_PGRANGE\_TABLE.

Table 320. DSN\_PGRANGE\_TABLE description

| Column name  | Data type            | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO      | INTEGER NOT NULL     | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| QBLOCKNO     | SMALLINT NOT NULL    | The query block number, a number used to identify each query block within a query.                                                                                                                                                                                                                                                                                                          |
| TABNO        | SMALLINT NOT NULL    | The table number, a number which uniquely identifies the corresponding table reference within a query.                                                                                                                                                                                                                                                                                      |
| RANGE        | SMALLINT NOT NULL    | The sequence number of the current page range.                                                                                                                                                                                                                                                                                                                                              |
| FIRSTPART    | SMALLINT NOT NULL    | The starting partition in the current page range.                                                                                                                                                                                                                                                                                                                                           |
| LASTPART     | SMALLINT NOT NULL    | The ending partition in the current page range.                                                                                                                                                                                                                                                                                                                                             |
| NUMPARTS     | SMALLINT NOT NULL    | The number of partitions in the current page range.                                                                                                                                                                                                                                                                                                                                         |
| EXPLAIN_TIME | SMALLINT NOT NULL    | The EXPLAIN timestamp.                                                                                                                                                                                                                                                                                                                                                                      |
| GROUP_MEMBER | VARCHAR(24) NOT NULL | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.                                                                                                                                                                                                                       |

## DSN\_VIEWREF\_TABLE

The view reference table, DSN\_VIEWREF\_TABLE, contains information about all of the views and materialized query tables that are used to process a query.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

## CREATE TABLE statement

The following figure shows the format of DSN\_VIEWREF\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_VIEWREF_TABLE (
  QUERYNO      INTEGER      NOT NULL WITH DEFAULT,
  APPLNAME     VARCHAR(24)  NOT NULL WITH DEFAULT,
  PROGNAME     VARCHAR(128) NOT NULL WITH DEFAULT,
  VERSION      VARCHAR(122) NOT NULL WITH DEFAULT,
  COLLID       VARCHAR(128) NOT NULL WITH DEFAULT,
  CREATOR      VARCHAR(128) NOT NULL WITH DEFAULT,
  NAME         VARCHAR(128) NOT NULL WITH DEFAULT,
  TYPE         CHAR(1)      NOT NULL WITH DEFAULT,
  MQTUSE       SMALLINT    NOT NULL WITH DEFAULT,
  EXPLAIN_TIME TIMESTAMP   NOT NULL WITH DEFAULT,
  GROUP_MEMBER VARCHAR(24)  NOT NULL
)
  IN database-name.table-space-name

CCSID UNICODE;
```

## Column descriptions

The following table describes the columns of DSN\_VIEWREF\_TABLE.

Table 321. DSN\_VIEWREF\_TABLE description

| Column name | Data type             | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO     | INTEGER NOT NULL      | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| APPLNAME    | VARCHAR(24) NOT NULL  | The application plan name.                                                                                                                                                                                                                                                                                                                                                                  |
| PROGNAME    | VARCHAR(128) NOT NULL | The program name (binding an application) or the package name (binding a package).                                                                                                                                                                                                                                                                                                          |
| VERSION     | VARCHAR(128)          | The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. Blank if not applicable.                                                                                                                                                                                          |

Table 321. DSN\_VIEWREF\_TABLE description (continued)

| Column name  | Data type                     | Description                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COLLID       | VARCHAR(128)                  | The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. Blank if not applicable. The value DSN_DYNAMICSQLCACHE indicates that the row is for a cached statement. |
| CREATOR      | VARCHAR(128)                  | Authorization ID of the owner of the object.                                                                                                                                                                                                                                          |
| NAME         | VARCHAR(128)                  | Name of the object.                                                                                                                                                                                                                                                                   |
| TYPE         | CHAR(1) NOT NULL WITH DEFAULT | The type of the object:<br>'V' View<br>'R' MQT that has been used to replace the base table for rewrite<br>'M' MQT                                                                                                                                                                    |
| MQTUSE       | SMALLINT                      | IBM internal use only.                                                                                                                                                                                                                                                                |
| EXPLAIN TIME | TIMESTAMP                     | The EXPLAIN timestamp.                                                                                                                                                                                                                                                                |
| GROUP_MEMBER | VARCHAR(24) NOT NULL          | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.                                                                                                                 |

## DSN\_QUERY\_TABLE

The query table, DSN\_QUERY\_TABLE, contains information about a SQL statement, and displays the statement before and after query transformation in XML.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and various optimization tools.

### CREATE TABLE statement

The following figure shows the format of DSN\_QUERY\_TABLE.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

```
CREATE TABLE userid.DSN_QUERY_TABLE(
  QUERYNO          INTEGER          NOT NULL,
  TYPE             CHAR(8)          NOT NULL,
  QUERY_STAGE     CHAR(8)          NOT NULL,
  SEQNO           INTEGER          NOT NULL,
  NODE_DATA       CLOB(2M)         NOT NULL,
  EXPLAIN_TIME    TIMESTAMP        NOT NULL,
  QUERY_ROWID     ROWID            NOT NULL GENERATED ALWAYS,
  GROUP_MEMBER    VARCHAR(24)      NOT NULL,
  HASHKEY         INTEGER          NOT NULL,
  HAS_PRED        CHAR(1)          NOT NULL
) IN database-name.table-space-name
```

```
CCSID UNICODE;
```

Figure 183. The CREATE TABLE statement for userid.DSN\_QUERY\_TABLE

## Column descriptions

The following table describes the columns of DSN\_QUERY\_TABLE.

Table 322. DSN\_QUERY\_TABLE description

| Column name  | Data type                       | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUERYNO      | INTEGER NOT NULL                | The query number, a number used to help identify the query being explained. It is not a unique identifier. Using negative number will cause problems. The possible sources are: <ol style="list-style-type: none"> <li>1 The statement line number in the program</li> <li>2 QUERYNO clause</li> <li>3 The EXPLAIN statement</li> <li>4 EDM unique token in the statement cache.</li> </ol> |
| TYPE         | CHAR(8) NOT NULL                | The type of the data in the NODE_DATA column.                                                                                                                                                                                                                                                                                                                                               |
| QUERY_STAGE  | CHAR(8) NOT NULL WITH DEFAULT   | The stage during query transformation when this row is populated.                                                                                                                                                                                                                                                                                                                           |
| SEQNO        | NOT NULL                        | The sequence number for this row if NODE_DATA exceeds the size of its column.                                                                                                                                                                                                                                                                                                               |
| NODE_DATA    | CLOB(2M)                        | The XML data containing the SQL statement and its query block, table, and column information.                                                                                                                                                                                                                                                                                               |
| EXPLAIN_TIME | TIMESTAMP                       | The EXPLAIN timestamp.                                                                                                                                                                                                                                                                                                                                                                      |
| QUERY_ROWID  | ROWID NOT NULL GENERATED ALWAYS | The ROWID of the statement.                                                                                                                                                                                                                                                                                                                                                                 |
| GROUP_MEMBER | VARCHAR(24) NOT NULL            | The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.                                                                                                                                                                                                                       |
| HASHKEY      | INTEGER NOT NULL                | The hash value of the contents in NODE_DATA                                                                                                                                                                                                                                                                                                                                                 |
| HAS_PRED     | CHAR(1) NOT NULL                | When NODE_DATA contains an SQL statement, this column indicates if the statement contains a parameter marker literal, non-parameter marker literal, or no predicates.                                                                                                                                                                                                                       |

---

## Appendix H. Profile tables that are used by optimization tools

Optimization tools, such as IBM Optimization Service Center for DB2 for z/OS and IBM DB2 Optimization Expert for z/OS can create and use profile tables to enable monitoring of query performance.

---

### SYSIBM.DSN\_VIRTUAL\_INDEXES

The virtual indexes table, DSN\_VIRTUAL\_INDEXES, enables optimization tools to test the effect of creating and dropping indexes on the performance of particular queries.

 The following table describes the columns in DSN\_VIRTUAL\_INDEXES.

**Recommendation:** Do not manually insert data into or delete data from this table, it is intended to be used only by optimization tools.

Table 323. SYSIBM.DSN\_VIRTUAL\_INDEXES description

| Column name | Data type    | Description                                                                                                                                                                                                                                                                                               |
|-------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TBCREATOR   | VARCHAR(128) | The schema or authorization ID of the owner of the table on which the index is being created or dropped.                                                                                                                                                                                                  |
| TBNAME      | VARCHAR(128) | The name of the table on which the index is being created or dropped.                                                                                                                                                                                                                                     |
| IXCREATOR   | VARCHAR(128) | The schema or authorization ID of the owner of the index.                                                                                                                                                                                                                                                 |
| IXNAME      | VARCHAR(128) | The index name.                                                                                                                                                                                                                                                                                           |
| ENABLE      | CHAR(1)      | Indicates whether this index should be considered in the scenario that is being tested. This column can have one of the following values:<br><br>Y      Use this index.<br>N      Do not use this index.<br><br>If this column contains 'Y', but the index definition is not valid, the index is ignored. |
| MODE        | CHAR(1)      | Indicates whether the index is being created or dropped. This column can have one of the following values:<br><br>C      This index is to be created.<br>D      This index is to be dropped.                                                                                                              |
| UNIQUERULE  | CHAR(1)      | Indicates whether the index is unique. This column can have one of the following values:<br><br>D      The index is not unique. (Duplicates are allowed.)<br>U      This index is unique.                                                                                                                 |
| COLCOUNT    | SMALLINT     | The number of columns in the key.                                                                                                                                                                                                                                                                         |

Table 323. SYSIBM.DSN\_VIRTUAL\_INDEXES description (continued)

| Column name   | Data type | Description                                                                                                                                                                                                                                                                                              |
|---------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLUSTERING    | CHAR(1)   | Indicates whether the index is clustered. This column can have one of the following values:<br><br><b>Y</b> The index is clustered.<br><br><b>N</b> The index is not clustered.                                                                                                                          |
| NLEAF         | INTEGER   | The number of active leaf pages in the index. If unknown, the value is -1.                                                                                                                                                                                                                               |
| NLEVELS       | SMALLINT  | The number of levels in the index tree. If unknown, the value is -1.                                                                                                                                                                                                                                     |
| INDEXTYPE     | CHAR(1)   | The index type. This column can have one of the following values:<br><br><b>2</b> The index is a nonpartitioned secondary index.<br><br><b>D</b> The index is a data-partitioned secondary index.                                                                                                        |
| PGSIZE        | SMALLINT  | The size, in kilobytes, of the leaf pages in the index. This column can have one of the following values: 4, 8, 16, or 32.                                                                                                                                                                               |
| FIRSTKEYCARDF | FLOAT     | The number of distinct values of the first key column. If unknown, the value is -1.                                                                                                                                                                                                                      |
| FULLKEYCARDF  | FLOAT     | The number of distinct values of the key. If unknown, the value is -1.                                                                                                                                                                                                                                   |
| CLUSTERRATIOF | FLOAT     | The percentage of rows that are in clustering order. Multiply this column value by 100 to get the percent value. For example, a value of .9125 in this column indicates that 91.25% of the rows are in clustering order. If unknown, the value is -1.                                                    |
| PADDED        | CHAR(1)   | Indicates whether keys within the index are padded for varying-length column data. This column can have one of the following values:<br><br><b>Y</b> The keys are padded.<br><br><b>N</b> The keys are not padded.                                                                                       |
| COLNO1        | SMALLINT  | The column number of the first column in the index key.                                                                                                                                                                                                                                                  |
| ORDERING1     | CHAR(1)   | Indicates the order of the first column in the index key. This column can have one of the following values:<br><br><b>A</b> Ascending<br><br><b>D</b> Descending                                                                                                                                         |
| COLNO $n$     | SMALLINT  | The column number of the $n$ th column in the index key, where $n$ is a number between 2 and 64, including 2 and 64. If the number of index keys is less than $n$ , this column is null.                                                                                                                 |
| ORDERING $n$  | CHAR(1)   | Indicates the order of the $n$ th column in the index key, where $n$ is a number between 2 and 64, including 2 and 64. This column can have one of the following values:<br><br><b>A</b> Ascending<br><br><b>D</b> Descending<br><br>If the number of index keys is less than $n$ , this column is null. |

The SQL statement to create DSN\_VIRTUAL\_INDEXES is in member DSNTESC of the SDSNSAMP library. 

---

## Appendix I. Real-time statistics tables

The information under this heading is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

DB2 collects statistics that you can use to determine when you need to perform certain maintenance functions on your table spaces and index spaces.

DB2 collects the statistics in real time. You create tables into which DB2 periodically writes the statistics. You can then write applications that query the statistics and help you decide when to run REORG, RUNSTATS, or COPY, or to enlarge your data sets. Figure 184 shows an overview of the process of collecting and using real-time statistics.

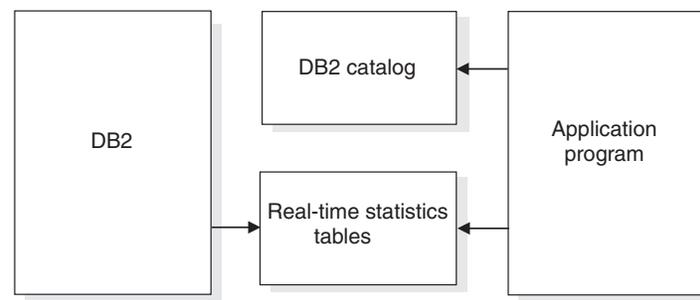

Figure 184. Real-time statistics overview

The following sections provide detailed information about the real-time statistics tables:

- “Setting up your system for real-time statistics”
- “Contents of the real-time statistics tables” on page 1237
- “Operating with real-time statistics” on page 1249

For information about a DB2-supplied stored procedure that queries the real-time statistics tables, see “The DB2 real-time statistics stored procedure” on page 1263.

---

### Setting up your system for real-time statistics

- # DB2 always generates in-memory statistics for each table space, index space,  
# including catalog objects but not the directory, in your system. For partitioned  
# spaces, DB2 generates information for each partition. However, you need to  
# perform the following steps before DB2 externalizes the statistics to DB2 tables:  
#  
# 1. Create the real-time statistics objects. See “Creating and altering the real-time  
# statistics objects” on page 1236.  
#  
# 2. Set the interval for writing statistics. See “Setting the interval for writing  
# real-time statistics” on page 1237.  
#  
# 3. Start the real-time statistics database. See “Starting the real-time statistics  
# database” on page 1237.  
#  
# 4. Establish base values for the statistics. See “Establishing base values for  
# real-time statistics” on page 1237.

## Creating and altering the real-time statistics objects

You need to create a database, table space, tables, and indexes for the real-time statistics. Those objects are listed in Table 324. Use the SQL statements in member DSNTESS of data set DSN810.SDSNSAMP as a model for creating the real-time statistics objects. You can create these objects in user-managed or DB2-managed data sets.

**Restrictions on changing the provided definitions for the real-time statistics objects:** You can change most of the attributes in the provided definitions of the real-time statistics objects. However, you cannot change the following items:

- Object names. You must use the names that are specified in DSNTESS for the database, table space, tables, indexes, and table columns.
- The CCSID parameter on the CREATE DATABASE, CREATE TABLESPACE, and CREATE TABLE statements. The CCSID must be EBCDIC.
- Number of columns or column definitions. You cannot add table columns or modify column definitions.
- The LOCKSIZE parameter on the CREATE TABLESPACE statement. The LOCKSIZE must be ROW.

# **Note:** If Real Time Statistics is active and the tablespaces are created out of order,  
 # several utilities might issue abend04E with reason code 00C90101. When you  
 # create tablespaces, always create tablespacestats before creating  
 # indexspacestats. See APAR PQ73249 for additional information.

Before you can alter an object in the real-time statistics database, you must stop the database. Otherwise, you receive an SQL error. Table 324 shows the DB2 objects for storing real-time statistics.

Table 324. DB2 objects for storing real-time statistics

| Object name               | Description                                                                  |
|---------------------------|------------------------------------------------------------------------------|
| DSNRTSDB                  | Database for real-time statistics objects                                    |
| DSNRTSTS                  | Table space for real-time statistics objects                                 |
| SYSIBM.TABLESPACESTATS    | Table for statistics on table spaces and table space partitions              |
| SYSIBM.INDEXSPACESTATS    | Table for statistics on index spaces and index space partitions              |
| SYSIBM.TABLESPACESTATS_IX | Unique index on SYSIBM.TABLESPACESTATS (columns DBID, PSID, and PARTITION)   |
| SYSIBM.INDEXSPACESTATS_IX | Unique index on SYSIBM.INDEXSPACESTATS (columns DBID, ISOBID, and PARTITION) |

To create the real-time statistics objects, you need the authority to create tables and indexes on behalf of the SYSIBM authorization ID.

DB2 inserts one row in the table for each partition or non-partitioned table space or index space. You therefore need to calculate the amount of disk space that you need for the real-time statistics tables based on the current number of table spaces and indexes in your subsystem.

To determine the amount of storage that you need for the real-time statistics when they are in memory, use the following formula:

$$\text{Max\_concurrent\_objects\_updated} * 152 \text{ bytes} = \text{Storage\_in\_bytes}$$

Where Max\_concurrent\_objects\_updated is the peak number of objects that might be updated concurrently and 152 bytes is the amount of in-memory space that DB2 uses for each object.

**Recommendation:** Place the statistics indexes and tables in their own buffer pool. When the statistics pages are in memory, the speed at which in-memory statistics are written to the tables improves.

## Setting the interval for writing real-time statistics

You can set the interval for writing real-time statistics when you install DB2, and you can subsequently update that interval online. The installation field is REAL TIME STATS on panel DSN TIPO. The default interval is 30 minutes. To update the interval, modify system parameter STATSINT.

In a data sharing environment, each member has its own interval for writing real-time statistics.

## Starting the real-time statistics database

After you create the real-time statistics database, DB2 puts it into a stopped state. After you create all the objects in the database, you need to issue START DATABASE(DSNRTSDB) to explicitly start the database.

You must start the database in read-write mode so that DB2 can externalize real-time statistics. See “When DB2 externalizes real-time statistics” on page 1250 for information about the conditions for which DB2 externalizes the statistics.

## Establishing base values for real-time statistics

Many columns in the real-time statistics tables show the number of times an operation was performed between the last time a particular utility was run and when the real-time statistics are written. For example, STATSINSERT in TABLESPACESTATS indicates the number of records or LOBs that have been inserted after the last RUNSTATS utility was run on the table space or partition. Therefore, for each object for which you want real-time statistics, run the appropriate utility (REORG, RUNSTATS, LOAD REPLACE, REBUILD INDEX, or COPY) to establish a base value from which the delta value can be calculated.

---

## Contents of the real-time statistics tables

The SYSIBM.TABLESPACESTATS table contains statistics information about table spaces and table space partitions. The SYSIBM.INDEXSPACESTATS table contains statistics information about index spaces and index space partitions.

Table 325 describes the columns of the TABLESPACESTATS table and explains how you can use them in deciding when to run REORG, RUNSTATS, or COPY.

*Table 325. Descriptions of columns in the TABLESPACESTATS table*

| Column name | Data type        | Description                                                                              |
|-------------|------------------|------------------------------------------------------------------------------------------|
| DBNAME      | CHAR(8) NOT NULL | The name of the database. This column is used to map a database to its statistics.       |
| NAME        | CHAR(8) NOT NULL | The name of the table space. This column is used to map a table space to its statistics. |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name     | Data type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PARTITION       | SMALLINT NOT NULL               | The data set number within the table space. This column is used to map a data set number in a table space to its statistics. For partitioned table spaces, this value corresponds to the partition number for a single partition. For nonpartitioned table spaces, this value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DBID            | SMALLINT NOT NULL               | The internal identifier of the database. This column is used to map a DBID to its statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PSID            | SMALLINT NOT NULL               | The internal identifier of the table space page set descriptor. This column is used to map a PSID to its statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| UPDATESTATSTIME | TIMESTAMP NOT NULL WITH DEFAULT | <p>The timestamp when the row was inserted or last updated.</p> <p>This column is updated with the current timestamp when a row in the TABLESPACESTATS table is inserted or updated. You can use this column in several ways:</p> <ul style="list-style-type: none"> <li>To determine the actions that caused the latest change to the table. Do this by selecting any of the timestamp columns and comparing them to the UPDATESTATSTIME column.</li> <li>To determine whether an analysis of data is needed. This determination might be based on a given time interval, or on a combination of the time interval and the amount of activity.</li> </ul> <p>For example, suppose that you want to analyze statistics for the last seven days. To determine whether there has been any activity in the past seven days, check whether the difference between the current date and the UPDATESTATSTIME value is less than or equal to seven:</p> $(\text{JULIAN\_DAY}(\text{CURRENT DATE}) - \text{JULIAN\_DAY}(\text{UPDATESTATSTIME})) \leq 7$ |
| TOTALROWS       | FLOAT                           | <p>The number of rows or LOBs in the table space or partition.</p> <p>If the table space contains more than one table, this value is the sum of all rows in all tables. A null value means that the number of rows is unknown or that REORG or LOAD has never been run.</p> <p>Use the TOTALROWS value with the value of any column that contains some affected rows to determine the percentage of rows that are affected by a particular action.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| NACTIVE         | INTEGER                         | <p>The number of active pages in the table space or partition.</p> <p>A null value means that the number of active pages is unknown.</p> <p>This value is equivalent to the number of preformatted pages. For multi-piece table spaces, this value is the total number of preformatted pages in all data sets.</p> <p>Use the NACTIVE value with the value of any column that contains some affected pages to determine the percentage of pages that are affected by a particular action.</p> <p>For example, suppose that your site's maintenance policies require that COPY is to be run after 20% of the pages in a table space have changed. To determine if a COPY might be required, calculate the ratio of updated pages since the last COPY to the total number of active pages. If the percentage is greater than 20, you need to run COPY:</p> $((\text{COPYUPDATEDPAGES} * 100) / \text{NACTIVE}) > 20$                                                                                                                               |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name   | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPACE         | INTEGER   | <p>The amount of space, in KB, that is allocated to the table space or partition.</p> <p>For multi-piece linear page sets, this value is the amount of space in all data sets. A null value means the amount of space is unknown.</p> <p>Use this value to monitor growth and validate design assumptions.</p>                                                                                                                                                                                                                                                                                                 |
| EXTENTS       | SMALLINT  | <p>The number of extents in the table space or partition. For multi-piece table spaces, this value is the number of extents for the last data set. For a data set that is striped across multiple volumes, the value is the number of logical extents. A null value means that the number of extents is unknown.</p> <p>Use this value to determine:</p> <ul style="list-style-type: none"> <li>• When the primary or secondary allocation value for a table space or partition needs to be altered.</li> <li>• When you are approaching the maximum number of extents and risking extend failures.</li> </ul> |
| LOADRLASTTIME | TIMESTAMP | <p>The timestamp of the last LOAD REPLACE on the table space or partition.</p> <p>A null value means that LOAD REPLACE has never been run on the table space or partition or that the timestamp of the last LOAD REPLACE is unknown.</p> <p>You can compare this timestamp to the timestamp of the last COPY on the same object to determine when a COPY is needed. If the date of the last LOAD REPLACE is more recent than the last COPY, you might need to run COPY:</p> <p><code>(JULIAN_DAY(LOADRLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</code></p>                                                        |
| REORGLASTTIME | TIMESTAMP | <p>The timestamp of the last REORG on the table space or partition.</p> <p>A null value means REORG has never been run on the table space or partition or that the timestamp of the last REORG is unknown.</p> <p>You can compare this timestamp to the timestamp of the last COPY on the same object to determine when a COPY is needed. If the date of the last REORG is more recent than the last COPY, you might need to run COPY:</p> <p><code>(JULIAN_DAY(REORGLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</code></p>                                                                                         |
| REORGINSETS   | INTEGER   | <p>The number of records or LOBs that have been inserted since the last REORG or LOAD REPLACE on the table space or partition.</p> <p>A null value means that the number of inserted records or LOBs is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                           |
| REORGDELETES  | INTEGER   | <p>The number of records or LOBs that have been deleted since the last REORG or LOAD REPLACE on the table space or partition.</p> <p>A null value means that the number of deleted records or LOBs is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                             |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name     | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REORGUPDATES    | INTEGER   | <p>The number of rows that have been updated since the last REORG or LOAD REPLACE on the table space or partition.</p> <p>This value does not include LOB updates because LOB updates are really deletions followed by insertions. A null value means that the number of updated rows is unknown.</p> <p>This value can be used with REORGDELETES and REORGINSERTS to determine if a REORG is necessary. For example, suppose that your site's maintenance policies require that REORG is run after 20 per cent of the rows in a table space have changed. To determine if a REORG is required, calculate the sum of updated, inserted, and deleted rows since the last REORG. Then calculate the ratio of that sum to the total number of rows. If the percentage is greater than 20, you might need to run REORG:<br/> <math display="block">(((\text{REORGINSERTS} + \text{REORGDELETES} + \text{REORGUPDATES}) * 100) / \text{TOTALROWS}) &gt; 20</math></p> |
| REORGDISORGL0B  | INTEGER   | <p>The number of LOBs that were inserted since the last REORG or LOAD REPLACE that are not perfectly chunked. A LOB is perfectly chunked if the allocated pages are in the minimum number of chunks. A null value means that the number of imperfectly chunked LOBs is unknown.</p> <p>Use this value to determine whether you need to run REORG. For example, you might want to run REORG if the ratio of REORGDISORGL0B to the total number of LOBs is greater than 10%:<br/> <math display="block">((\text{REORGDISORGL0B} * 100) / \text{TOTALROWS}) &gt; 10</math></p>                                                                                                                                                                                                                                                                                                                                                                                      |
| REORGUNCLUSTINS | INTEGER   | <p>The number of records that were inserted since the last REORG or LOAD REPLACE that are not well-clustered with respect to the clustering index. A record is well-clustered if the record is inserted into a page that is within 16 pages of the ideal candidate page. The clustering index determines the ideal candidate page.</p> <p>A null value means that the number of badly-clustered pages is unknown.</p> <p>You can use this value to determine whether you need to run REORG. For example, you might want to run REORG if the following comparison is true:<br/> <math display="block">((\text{REORGUNCLUSTINS} * 100) / \text{TOTALROWS}) &gt; 10</math></p>                                                                                                                                                                                                                                                                                      |
| REORGMASDELETE  | INTEGER   | <p>The number of mass deletes from a segmented or LOB table space, or the number of dropped tables from a segmented table space, since the last REORG or LOAD REPLACE.</p> <p>A null value means that the number of mass deletes is unknown.</p> <p>If this value is non-zero, a REORG might be necessary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| REORGNEARINDREF | INTEGER   | <p>The number of overflow records that were created since the last REORG or LOAD REPLACE and were relocated near the pointer record. For nonsegmented table spaces, a page is near the present page if the two page numbers differ by 16 or less. For segmented table spaces, a page is near the present page if the two page numbers differ by SEGSIZE*2 or less.</p> <p>A null value means that the number of overflow records near the pointer record is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name   | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REORGFARINDEF | INTEGER   | <p>The number of overflow records that were created since the last REORG or LOAD REPLACE and were relocated far from the pointer record. For nonsegmented table spaces, a page is far from the present page if the two page numbers differ by more than 16. For segmented table spaces, a page is far from the present page if the two page numbers differ by at least (SEGSIZE*2)+1.</p> <p>A null value means that the number of overflow records far from the pointer record is unknown.</p> <p>For example, in a non-data sharing environment, you might run REORG if the following comparison is true:<br/> <math>((\text{REORGNEARINDREF} + \text{REORGFARINDREF}) * 100) / \text{TOTALROWS} &gt; 10</math></p> <p>In a data sharing environment, you might run REORG if the following comparison is true:<br/> <math>((\text{REORGNEARINDREF} + \text{REORGFARINDREF}) * 100) / \text{TOTALROWS} &gt; 5</math></p>            |
| STATSLASTTIME | TIMESTAMP | <p>The timestamp of the last RUNSTATS on the table space or partition.</p> <p>A null value means that RUNSTATS has never been run on the table space or partition, or that the timestamp of the last RUNSTATS is unknown.</p> <p>You can compare this timestamp to the timestamp of the last REORG on the same object to determine when RUNSTATS is needed. If the date of the last REORG is more recent than the last RUNSTATS, you might need to run RUNSTATS:<br/> <math>(\text{JULIAN\_DAY}(\text{REORGLASTTIME}) &gt; \text{JULIAN\_DAY}(\text{STATSLASTTIME}))</math></p>                                                                                                                                                                                                                                                                                                                                                      |
| STATSINSERTS  | INTEGER   | <p>The number of records or LOBs that have been inserted since the last RUNSTATS on the table space or partition.</p> <p>A null value means that the number of inserted records or LOBs is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| STATSDELETES  | INTEGER   | <p>The number of records or LOBs that have been deleted since the last RUNSTATS on the table space or partition.</p> <p>A null value means that the number of deleted records or LOBs is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| STATSUPDATES  | INTEGER   | <p>The number of rows that have been updated since the last RUNSTATS on the table space or partition.</p> <p>This value does not include LOB updates because LOB updates are really deletions followed by insertions. A null value means that the number of updated rows is unknown.</p> <p>This value can be used with STATSDELETES and STATSINSERTS to determine if RUNSTATS is necessary. For example, suppose that your site's maintenance policies require that RUNSTATS is to be run after 20% of the rows in a table space have changed. To determine if RUNSTATS is required, calculate the sum of updated, inserted, and deleted rows since the last RUNSTATS. Then calculate the ratio of that sum to the total number of rows. If the percentage is greater than 20, you need to run RUNSTATS:<br/> <math>((\text{STATSINSERTS} + \text{STATSDELETES} + \text{STATSUPDATES}) * 100) / \text{TOTALROWS} &gt; 20</math></p> |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name      | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATSMASDELETE   | INTEGER   | <p>The number of mass deletes from a segmented or LOB table space, or the number of dropped tables from a segmented table space, since the last RUNSTATS.</p> <p>A null value means that the number of mass deletes is unknown.</p> <p>If this value is non-zero, RUNSTATS might be necessary.</p>                                                                                                                                                                                                                                                                                                                                     |
| COPYLASTTIME     | TIMESTAMP | <p>The timestamp of the last full or incremental image copy on the table space or partition.</p> <p>A null value means that COPY has never been run on the table space or partition, or that the timestamp of the last full image copy is unknown.</p> <p>You can compare this timestamp to the timestamp of the last REORG on the same object to determine when a COPY is needed. If the date of the last REORG is more recent than the last COPY, you might need to run COPY:<br/>(JULIAN_DAY(REORGLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</p>                                                                                        |
| COPYUPDATEDPAGES | INTEGER   | <p>The number of distinct pages that have been updated since the last COPY.</p> <p>A null value means that the number of updated pages is unknown.</p> <p>You can compare this value to the total number of pages to determine when a COPY is needed.</p> <p>For example, you might want to take an incremental image copy when 1% of the pages have changed:<br/>((COPYUPDATEDPAGES*100)/NACTIVE)&gt;1</p> <p>You might want to take a full image copy when 20% of the pages have changed:<br/>((COPYUPDATEDPAGES*100)/NACTIVE)&gt;20</p>                                                                                             |
| COPYCHANGES      | INTEGER   | <p>The number of insert, delete, and update operations since the last COPY.</p> <p>A null value means that the number of insert, delete, or update operations is unknown.</p> <p>This number indicates the approximate number of log records that DB2 needs to process to recover to the current state.</p> <p>For example, you might want to take an incremental image copy when DB2 processes more than 1% of the rows from the logs:<br/>((COPYCHANGES*100)/TOTALROWS)&gt;1</p> <p>You might want to take a full image copy when DB2 processes more than 10% of the rows from the logs:<br/>((COPYCHANGES*100)/TOTALROWS)&gt;10</p> |

Table 325. Descriptions of columns in the TABLESPACESTATS table (continued)

| Column name    | Data type            | Description                                                                                                                                                                                                                                                                                 |
|----------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COPYUPDATELRSN | CHAR(6) FOR BIT DATA | The LRSN or RBA of the first update after the last COPY.<br><br>A null value means that the LRSN or RBA is unknown.<br><br>Consider running COPY if this value is not in the active logs. To determine the oldest LRSN or RBA in the active logs, use the print log map utility (DSNJU004). |
| COPYUPDATETIME | TIMESTAMP            | The timestamp of the first update after the last COPY.<br><br>A null value means that the timestamp is unknown.                                                                                                                                                                             |

Table 326 describes the columns of the INDEXSPACESTATS table and explains how you can use them in deciding when to run REORG, RUNSTATS, or COPY.

Table 326. Descriptions of columns in the INDEXSPACESTATS table

| Column name | Data type         | Description                                                                                                                                                                                                                                                                                 |
|-------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBNAME      | CHAR(8) NOT NULL  | The name of the database. This column is used to map a database to its statistics.                                                                                                                                                                                                          |
| NAME        | CHAR(8) NOT NULL  | The name of the index space. This column is used to map an index space to its statistics.                                                                                                                                                                                                   |
| PARTITION   | SMALLINT NOT NULL | This column is used to map a data set number in an index space to its statistics. The data set number within the index space.<br><br>For partitioned index spaces, this value corresponds to the partition number for a single partition. For nonpartitioned index spaces, this value is 0. |
| DBID        | SMALLINT NOT NULL | The internal identifier of the database. This column is used to map a DBID to its statistics.                                                                                                                                                                                               |
| ISOBID      | SMALLINT NOT NULL | The internal identifier of the index space page set descriptor. This column is used to map an ISOBID to its statistics.                                                                                                                                                                     |
| PSID        | SMALLINT NOT NULL | The internal identifier of the table space page set descriptor for the table space associated with the index that is represented by this row.<br><br>This column is used to map a PSID to the statistics for the associated index.                                                          |

Table 326. Descriptions of columns in the INDEXSPACESTATS table (continued)

| Column name     | Data type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UPDATESTATSTIME | TIMESTAMP NOT NULL WITH DEFAULT | <p>The timestamp when the row was inserted or last updated.</p> <p>This column is updated with the current timestamp when a row in the INDEXSPACESTATS table is inserted or updated. You can use this column in several ways:</p> <ul style="list-style-type: none"> <li>To determine the actions that caused the latest change to the INDEXSPACESTATS table. Do this by selecting any of the timestamp columns and comparing them to the UPDATESTATSTIME column.</li> <li>To determine whether an analysis of data is needed. This determination might be based on a given time interval, or on a combination of the time interval and the amount of activity. For example, suppose that you want to analyze statistics for the last seven days. To determine whether any activity has occurred in the past seven days, check whether the difference between the current date and the UPDATESTATSTIME value is less than or equal to seven:<br/> <math>(\text{JULIAN\_DAY}(\text{CURRENT DATE}) - \text{JULIAN\_DAY}(\text{UPDATESTATSTIME})) \leq 7</math></li> </ul> |
| TOTALENTRIES    | FLOAT                           | <p>The number of entries, including duplicate entries, in the index space or partition.</p> <p>A null value means that the number of entries is unknown, or that REORG, LOAD, or REBUILD has never been run.</p> <p>Use this value with the value of any column that contains a number of affected index entries to determine the percentage of index entries that are affected by a particular action.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| NLEVELS         | SMALLINT                        | <p>The number of levels in the index tree.</p> <p>A null value means that the number of levels is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| NACTIVE         | INTEGER                         | <p>The number of active pages in the index space or partition. This value is equivalent to the number of preformatted pages.</p> <p>A null value means that the number of active pages is unknown.</p> <p>Use this value with the value of any column that contains a number of affected pages to determine the percentage of pages that are affected by a particular action.</p> <p>For example, suppose that your site's maintenance policies require that COPY is to be run after 20% of the pages in an index space have changed. To determine if a COPY is required, calculate the ratio of updated pages since the last COPY to the total number of active pages. If the percentage is greater than 20, you need to run COPY:<br/> <math>((\text{COPYUPDATEDPAGES} * 100) / \text{NACTIVE}) &gt; 20</math></p>                                                                                                                                                                                                                                                    |
| SPACE           | INTEGER                         | <p>The amount of space, in KB, that is allocated to the index space or partition. For multi-piece linear page sets, this value is the amount of space in all data sets.</p> <p>A null value means that the amount of space is unknown.</p> <p>Use this value to monitor growth and validate design assumptions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|-----------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXTENTS         | SMALLINT  | <p>The number of extents in the index space or partition. For multi-piece index spaces, this value is the number of extents for the last data set. For a data set that is striped across multiple volumes, the value is the number of logical extents.</p> <p>A null value means that the number of extents is unknown.</p> <p>Use this value to determine:</p> <ul style="list-style-type: none"> <li>• When the primary allocation value for an index space or partition needs to be altered.</li> <li>• When you are approaching the maximum number of extents and risking extend failures.</li> </ul> |
| LOADRLASTTIME   | TIMESTAMP | <p>The timestamp of the last LOAD REPLACE on the index space or partition.</p> <p>A null value means that the timestamp of the last LOAD REPLACE is unknown.</p> <p>If COPY YES was specified when the index was created (the value of COPY is Y in SYSIBM.SYSINDEXES), you can compare this timestamp to the timestamp of the last COPY on the same object to determine when a COPY is needed. If the date of the last LOAD REPLACE is more recent than the last COPY, you might need to run COPY:</p> <p><code>(JULIAN_DAY(LOADRLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</code></p>                       |
| REBUILDLASTTIME | TIMESTAMP | <p>The timestamp of the last REBUILD INDEX on the index space or partition.</p> <p>A null value means that the timestamp of the last REBUILD INDEX is unknown.</p> <p>If COPY YES was specified when the index was created (the value of COPY is Y in SYSIBM.SYSINDEXES), you can compare this timestamp to the timestamp of the last COPY on the same object to determine when a COPY is needed. If the date of the last REBUILD INDEX is more recent than the last COPY, you might need to run COPY:</p> <p><code>(JULIAN_DAY(REBUILDLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</code></p>                  |
| REORGLASTTIME   | TIMESTAMP | <p>The timestamp of the last REORG INDEX on the index space or partition.</p> <p>A null value means that the timestamp of the last REORG INDEX is unknown.</p> <p>If COPY YES was specified when the index was created (the value of COPY is Y in SYSIBM.SYSINDEXES), you can compare this timestamp to the timestamp of the last COPY on the same object to determine when a COPY is needed. If the date of the last REORG INDEX is more recent than the last COPY, you might need to run COPY:</p> <p><code>(JULIAN_DAY(REORGLASTTIME)&gt;JULIAN_DAY(COPYLASTTIME))</code></p>                          |

Table 326. Descriptions of columns in the INDEXSPACESTATS table (continued)

| Column name       | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REORGINSERTS      | INTEGER   | <p>The number of index entries that have been inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE on the index space or partition.</p> <p>A null value means that the number of inserted index entries is unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| REORGDELETES      | INTEGER   | <p>The number of index entries that have been deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE on the index space or partition.</p> <p>A null value means that the number of deleted index entries is unknown.</p> <p>This value can be used with REORGINSERTS to determine if a REORG is necessary. For example, suppose that your site's maintenance policies require that REORG is to be run after 20% of the index entries have changed. To determine if a REORG is required, calculate the sum of inserted and deleted rows since the last REORG. Then calculate the ratio of that sum to the total number of index entries. If the percentage is greater than 20, you need to run REORG:</p> $(((\text{REORGINSERTS} + \text{REORGDELETES}) * 100) / \text{TOTALENTRIES}) > 20$ |
| REORGAPPENDINSERT | INTEGER   | <p>The number of index entries that have been inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE on the index space or partition that have a key value that is greater than the maximum key value in the index or partition.</p> <p>A null value means that the number of inserted index entries is unknown.</p> <p>This value can be used with REORGINSERTS to decide when to adjust the PCTFREE specification for the index. For example, if the ratio of REORGAPPENDINSERT to REORGINSERTS is greater than 10%, you might need to run ALTER INDEX to adjust PCTFREE or to run REORG more frequently:</p> $((\text{REORGAPPENDINSERT} * 100) / \text{REORGINSERTS}) > 10$                                                                                                            |
| REORGSEUDODELETES | INTEGER   | <p>The number of index entries that have been pseudo-deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE on the index space or partition. A pseudo-delete is a RID entry that has been marked as deleted.</p> <p>A null value means that the number of pseudo-deleted index entries is unknown.</p> <p>This value can be used to determine if a REORG is necessary. For example, if the ratio of pseudo-deletes to total index entries is greater than 10%, you might need to run REORG:</p> $((\text{REORGSEUDODELETES} * 100) / \text{TOTALENTRIES}) > 10$                                                                                                                                                                                                                             |
| REORGMASDELETE    | INTEGER   | <p>The number of times that an index or index space partition was mass deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE.</p> <p>A null value means that the number of mass deletes is unknown.</p> <p>If this value is non-zero, a REORG might be necessary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Column name     | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REORGNUMLEVELS  | INTEGER   | <p>The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE.</p> <p>A null value means that the number of added or deleted levels is unknown.</p> <p>If this value has increased since the last REORG, REBUILD INDEX, or LOAD REPLACE, you need to check other values such as REORGPSEUDODELETES to determine whether to run REORG.</p> <p>If this value is less than zero, the index space contains empty pages. Running REORG can save disk space and decrease index sequential scan I/O time by eliminating those empty pages.</p>                                                                                                                                                                                                          |
| STATSLASTTIME   | TIMESTAMP | <p>The timestamp of the last RUNSTATS on the index space or partition.</p> <p>A null value means that RUNSTATS has never been run on the index space or partition, or that the timestamp of the last RUNSTATS is unknown.</p> <p>You can compare this timestamp to the timestamp of the last REORG on the same object to determine when RUNSTATS is needed. If the date of the last REORG is more recent than the last RUNSTATS, you might need to run RUNSTATS:<br/> <math>(\text{JULIAN\_DAY}(\text{REORGLASTTIME}) &gt; \text{JULIAN\_DAY}(\text{STATSLASTTIME}))</math></p>                                                                                                                                                                                                                              |
| STATSINSERTS    | INTEGER   | <p>The number of index entries that have been inserted since the last RUNSTATS on the index space or partition.</p> <p>A null value means that the number of inserted index entries unknown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| STATSDELETES    | INTEGER   | <p>The number of index entries that have been deleted since the last RUNSTATS on the index space or partition.</p> <p>A null value means that the number of deleted index entries is unknown.</p> <p>This value can be used with STATSINSERTS to determine if RUNSTATS is necessary. For example, suppose that your site's maintenance policies require that RUNSTATS is run after 20% of the rows in an index space have changed. To determine if RUNSTATS is required, calculate the sum of inserted and deleted index entries since the last RUNSTATS. Then calculate the ratio of that sum to the total number of index entries. If the percentage is greater than 20, you need to run RUNSTATS:<br/> <math>((\text{STATSINSERTS} + \text{STATSDELETES}) * 100) / \text{TOTALENTRIES} &gt; 20</math></p> |
| STATSMASSDELETE | INTEGER   | <p>The number of times that the index or index space partition was mass deleted since the last RUNSTATS.</p> <p>A null value means that the number of mass deletes is unknown.</p> <p>If this value is non-zero, RUNSTATS might be necessary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Table 326. Descriptions of columns in the INDEXSPACESTATS table (continued)

| Column name      | Data type            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COPYLASTTIME     | TIMESTAMP            | <p>The timestamp of the last full image copy on the index space or partition.</p> <p>A null value means that COPY has never been run on the index space or partition, or that the timestamp of the last full image copy is unknown.</p> <p>You can compare this timestamp to the timestamp of the last REORG on the same object to determine when a COPY is needed. If the date of the last REORG is more recent than the last COPY, you might need to run COPY:</p> $(\text{JULIAN\_DAY}(\text{REORGRLASTTIME}) > \text{JULIAN\_DAY}(\text{COPYLASTTIME}))$ |
| COPYUPDATEDPAGES | INTEGER              | <p>The number of distinct pages that have been updated since the last COPY.</p> <p>A null value means that the number of updated pages is unknown, or that the index was created with COPY NO.</p> <p>You can compare this value to the total number of pages to determine when a COPY is needed.</p> <p>For example, you might want to take a full image copy when 20% of the pages have changed:</p> $((\text{COPYUPDATEDPAGES} * 100) / \text{NACTIVE}) > 20$                                                                                             |
| COPYCHANGES      | INTEGER              | <p>The number of insert or delete operations since the last COPY.</p> <p>A null value means that the number of insert or update operations is unknown, or that the index was created with COPY NO.</p> <p>This number indicates the approximate number of log records that DB2 needs to process to recover to the current state.</p> <p>For example, you might want to take a full image copy when DB2 processes more than 10% of the index entries from the logs:</p> $((\text{COPYCHANGES} * 100) / \text{TOTALENTRIES}) > 10$                             |
| COPYUPDATELRSN   | CHAR(6) FOR BIT DATA | <p>The LRSN or RBA of the first update after the last COPY.</p> <p>A null value means that the LRSN or RBA is unknown, or that the index was created with COPY NO.</p> <p>Consider running COPY if this value is not in the active logs. To determine the oldest LRSN or RBA in the active logs, use the print log map utility (DSNJU004).</p>                                                                                                                                                                                                               |
| COPYUPDATETIME   | TIMESTAMP            | <p>The timestamp of the first update after the last COPY.</p> <p>A null value means that the timestamp is unknown, or that the index was created with COPY NO.</p>                                                                                                                                                                                                                                                                                                                                                                                           |

## Operating with real-time statistics

To use the real-time statistics effectively, you need to understand when DB2 collects and externalizes them, and what factors in your system can affect the statistics. This section contains the following topics:

- “When DB2 externalizes real-time statistics” on page 1250

- “How DB2 utilities affect the real-time statistics”
- “How non-DB2 utilities affect real-time statistics” on page 1257
- “Real-time statistics on objects in work file databases and the TEMP database” on page 1258
- “Real-time statistics on read-only or nonmodified objects” on page 1258
- “How dropping objects affects real-time statistics” on page 1258
- “How SQL operations affect real-time statistics counters” on page 1258
- “Real-time statistics in data sharing” on page 1259
- “Improving concurrency with real-time statistics” on page 1260
- “Recovering the real-time statistics tables” on page 1260
- “Statistics accuracy” on page 1260

## When DB2 externalizes real-time statistics

DB2 externalizes real-time statistics in the following circumstances:

- When you issue `STOP DATABASE(database-name) SPACENAM(space-name)`

This command externalizes statistics only for *database-name* and *space-name*. No statistics are externalized when the DSNRTSDB database is stopped.

- At the end of the time interval that you specify during installation

See “Setting the interval for writing real-time statistics” on page 1237 for information about how to set this time interval.

- When you issue `STOP DB2 MODE(QUIESCE)`

DB2 writes any statistics that are in memory when you issue this command to the statistics tables. However, if you issue `STOP DB2 MODE(FORCE)`, DB2 does not write the statistics, and you lose them.

- During utility operations

“How DB2 utilities affect the real-time statistics” gives details on how the utilities modify the statistics tables.

DB2 does not maintain real-time statistics for any objects in the real-time statistics database. Therefore, if you run a utility with a utility list, and the list contains any real-time statistics objects, DB2 does not externalize real-time statistics during the execution of that utility for any of the objects in the utility list. DB2 does not maintain interval counter real-time statistics for SYSLGRNG and its indexes during utility operation. DB2 maintains statistics for these objects only during non-utility operation.

**Recommendation:** Do not include real-time statistics objects in utility lists.

DB2 does not externalize real-time statistics at a tracker site.

## How DB2 utilities affect the real-time statistics

In general, SQL INSERT, UPDATE, and DELETE statements cause DB2 to modify the real-time statistics. However, certain DB2 utilities also affect the statistics. The following sections discuss the effect of each of those utilities on the statistics:

- “How LOAD affects real-time statistics” on page 1251
- “How REORG affects real-time statistics” on page 1253
- “How REBUILD INDEX affects real-time statistics” on page 1255
- “How RUNSTATS affects real-time statistics” on page 1255
- “How COPY affects real-time statistics” on page 1256
- “How RECOVER affects real-time statistics” on page 1257

## How LOAD affects real-time statistics

Table 327 shows how running LOAD REPLACE on a table space or table space partition affects the TABLESPACESTATS statistics.

Table 327. Changed TABLESPACESTATS values during LOAD

| Column name      | Settings for LOAD REPLACE after RELOAD phase |
|------------------|----------------------------------------------|
| TOTALROWS        | Number of loaded rows or LOBs <sup>1</sup>   |
| NACTIVE          | Actual value                                 |
| SPACE            | Actual value                                 |
| EXTENTS          | Actual value                                 |
| LOADRLASTTIME    | Current timestamp                            |
| REORGINSERTS     | 0                                            |
| REORGDELETES     | 0                                            |
| REORGUPDATES     | 0                                            |
| REORGDISORGL     | 0                                            |
| REORGUNCLUSTINS  | 0                                            |
| REORGMASDELETE   | 0                                            |
| REORGNEARINDREF  | 0                                            |
| REORGFARINDEF    | 0                                            |
| STATSLASTTIME    | Current timestamp <sup>2</sup>               |
| STATSINSERTS     | 0 <sup>2</sup>                               |
| STATSDELETES     | 0 <sup>2</sup>                               |
| STATSUPDATES     | 0 <sup>2</sup>                               |
| STATSMASDELETE   | 0 <sup>2</sup>                               |
| COPYLASTTIME     | Current timestamp <sup>3</sup>               |
| COPYUPDATEDPAGES | 0 <sup>3</sup>                               |
| COPYCHANGES      | 0 <sup>3</sup>                               |
| COPYUPDATELRSN   | Null <sup>3</sup>                            |
| COPYUPDATETIME   | Null <sup>3</sup>                            |

### Notes:

1. Under certain conditions, such as a utility restart, the LOAD utility might not have an accurate count of loaded records. In those cases, DB2 sets this value to null. Some rows that are loaded into a table space and are included in this value might later be removed during the index validation phase or the referential integrity check. DB2 includes counts of those removed records in the statistics that record deleted records.
2. DB2 sets this value only if the LOAD invocation includes the STATISTICS option.
3. DB2 sets this value only if the LOAD invocation includes the COPYDDN option.

Table 328 shows how running LOAD REPLACE affects the INDEXSPACESTATS statistics for an index space or physical index partition.

Table 328. Changed INDEXSPACESTATS values during LOAD REPLACE

| Column name  | Settings for LOAD REPLACE after BUILD phase |
|--------------|---------------------------------------------|
| TOTALENTRIES | Number of index entries added <sup>1</sup>  |

Table 328. Changed INDEXSPACESTATS values during LOAD REPLACE (continued)

| Column name       | Settings for LOAD REPLACE after BUILD phase |
|-------------------|---------------------------------------------|
| NLEVELS           | Actual value                                |
| NACTIVE           | Actual value                                |
| SPACE             | Actual value                                |
| EXTENTS           | Actual value                                |
| LOADRLASTTIME     | Current timestamp                           |
| REORGINSERTS      | 0                                           |
| REORGDELETES      | 0                                           |
| REORGAPPENDINSERT | 0                                           |
| REORGSEUDODELETES | 0                                           |
| REORGMASDELETE    | 0                                           |
| REORGLAFLNEAR     | 0                                           |
| REORGLAFLFAR      | 0                                           |
| REORGNUMLEVELS    | 0                                           |
| STATSLASTTIME     | Current timestamp <sup>2</sup>              |
| STATSINSERTS      | 0 <sup>2</sup>                              |
| STATSDELETES      | 0 <sup>2</sup>                              |
| STATSMASDELETE    | 0 <sup>2</sup>                              |
| COPYLASTTIME      | Current timestamp <sup>3</sup>              |
| COPYUPDATEDPAGES  | 0 <sup>3</sup>                              |
| COPYCHANGES       | 0 <sup>3</sup>                              |
| COPYUPDATELRN     | Null <sup>3</sup>                           |
| COPYUPDATETIME    | Null <sup>3</sup>                           |

**Notes:**

1. Under certain conditions, such as a utility restart, the LOAD utility might not have an accurate count of loaded records. In those cases, DB2 sets this value to null.
2. DB2 sets this value only if the LOAD invocation includes the STATISTICS option.
3. DB2 sets this value only if the LOAD invocation includes the COPYDDN option.

For a logical index partition:

- A LOAD operation without the REPLACE option behaves similar to a SQL INSERT operation in that the number of records loaded are counted in the incremental counters such as REORGINSERTS, REORGAPPENDINSERT, STATSINSERTS, and COPYCHANGES. A LOAD operation without the REPLACE option affects the organization of the data and can be a trigger to run REORG, RUNSTATS or COPY.
- DB2 does not reset the nonpartitioned index when it does a LOAD REPLACE on a partition. Therefore, DB2 does not reset the statistics for the index. The REORG counters from the last REORG are still correct. DB2 updates LOADRLASTTIME when the entire nonpartitioned index is replaced.
- When DB2 does a LOAD RESUME YES on a partition, after the BUILD phase, DB2 increments TOTALENTRIES by the number of index entries that were inserted during the BUILD phase.

## How REORG affects real-time statistics

Table 329 shows how running REORG on a table space or table space partition affects the TABLESPACESTATS statistics.

Table 329. Changed TABLESPACESTATS values during REORG

| Column name      | Settings for REORG SHRLEVEL NONE after RELOAD phase | Settings for REORG SHRLEVEL REFERENCE or CHANGE after SWITCH phase                                                                                                                                                                                        |
|------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTALROWS        | Number rows or LOBs loaded <sup>1</sup>             | For SHRLEVEL REFERENCE: Number of loaded rows or LOBs during RELOAD phase<br><br>For SHRLEVEL CHANGE: Number of loaded rows or LOBs during RELOAD phase plus number of rows inserted during LOG APPLY phase minus number of rows deleted during LOG phase |
| NACTIVE          | Actual value                                        | Actual value                                                                                                                                                                                                                                              |
| SPACE            | Actual value                                        | Actual value                                                                                                                                                                                                                                              |
| EXTENTS          | Actual value                                        | Actual value                                                                                                                                                                                                                                              |
| REORGLASTTIME    | Current timestamp                                   | Current timestamp                                                                                                                                                                                                                                         |
| REORGINSERTS     | 0                                                   | Actual value <sup>2</sup>                                                                                                                                                                                                                                 |

### Notes:

1. Under certain conditions, such as a utility restart, the REORG utility might not have an accurate count of loaded records. In those cases, DB2 sets this value to null. Some rows that are loaded into a table space and are included in this value might later be removed during the index validation phase or the referential integrity check. DB2 includes counts of those removed records in the statistics that record deleted records.
2. This is the actual number of inserts, updates, or deletes that are due to applying the log to the shadow copy.
3. DB2 sets this value only if the REORG invocation includes the STATISTICS option.
4. DB2 sets this value only if the REORG invocation includes the COPYDDN option.
5. This is the LRSN or timestamp for the first update that is due to applying the log to the shadow copy.

Table 330 shows how running REORG affects the INDEXSPACESTATS statistics for an index space or physical index partition.

Table 330. Changed INDEXSPACESTATS values during REORG

| Column name        | Settings for REORG SHRLEVEL NONE after RELOAD phase | Settings for REORG SHRLEVEL REFERENCE or CHANGE after SWITCH phase                                                                                                                                                                                               |

**Notes:**

1. Under certain conditions, such as a utility restart, the REORG utility might not have an accurate count of loaded records. In those cases, DB2 sets this value to null.
2. This is the actual number of inserts, updates, or deletes that are due to applying the log to the shadow copy.
3. DB2 sets this value only if the REORG invocation includes the STATISTICS option.
4. DB2 sets this value only if the REORG invocation includes the COPYDDN option.
5. Inline COPY is not allowed for SHRLEVEL CHANGE or SHRLEVEL REFERENCE.

Table 332. Changed TABLESPACESTATS values during RUNSTATS UPDATE ALL (continued)

| Column name     | During UTILINIT phase     | After RUNSTATS phase      |
|-----------------|---------------------------|---------------------------|
| STATSINSERTS    | Actual value <sup>1</sup> | Actual value <sup>2</sup> |
| STATSDELETES    | Actual value <sup>1</sup> | Actual value <sup>2</sup> |
| STATSUPDATES    | Actual value <sup>1</sup> | Actual value <sup>2</sup> |
| STATSMASSDELETE | Actual value <sup>1</sup> | Actual value <sup>2</sup> |

**Notes:**

1. DB2 externalizes the current in-memory values.
2. This value is 0 for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE.

Table 333 shows how running RUNSTATS UPDATE ALL on an index affects the INDEXSPACESTATS statistics.

Table 333. Changed INDEXSPACESTATS values during RUNSTATS UPDATE ALL

| Column name     | During UTILINIT phase          | After RUNSTATS phase                     |
|-----------------|--------------------------------|------------------------------------------|
| STATSLASTTIME   | Current timestamp <sup>1</sup> | Timestamp of the start of RUNSTATS phase |
| STATSINSERTS    | Actual value <sup>1</sup>      | Actual value <sup>2</sup>                |
| STATSDELETES    | Actual value <sup>1</sup>      | Actual value <sup>2</sup>                |
| STATSMASSDELETE | Actual value <sup>1</sup>      | Actual value <sup>2</sup>                |

**Notes:**

1. DB2 externalizes the current in-memory values.
2. This value is 0 for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE.

## How COPY affects real-time statistics

When a COPY job starts, DB2 externalizes all in-memory statistics to the real-time statistics tables. Statistics are gathered for a full image copy or an incremental copy, but not for a data set copy.

Table 334 shows how running COPY on a table space or table space partition affects the TABLESPACESTATS statistics.

Table 334. Changed TABLESPACESTATS values during COPY

| Column name      | During UTILINIT phase          | After COPY phase                     |
|------------------|--------------------------------|--------------------------------------|
| COPYLASTTIME     | Current timestamp <sup>1</sup> | Timestamp of the start of COPY phase |
| COPYUPDATEDPAGES | Actual value <sup>1</sup>      | Actual value <sup>2</sup>            |
| COPYCHANGES      | Actual value <sup>1</sup>      | Actual value <sup>2</sup>            |
| COPYUPDATELRSN   | Actual value <sup>1</sup>      | Actual value <sup>3</sup>            |
| COPYUPDATETIME   | Actual value <sup>1</sup>      | Actual value <sup>3</sup>            |

Table 334. Changed TABLESPACESTATS values during COPY (continued)

| Column name                                                                            | During UTILINIT phase | After COPY phase |
|----------------------------------------------------------------------------------------|-----------------------|------------------|
| <b>Notes:</b>                                                                          |                       |                  |
| 1. DB2 externalizes the current in-memory values.                                      |                       |                  |
| 2. This value is 0 for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE.    |                       |                  |
| 3. This value is null for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE. |                       |                  |

Table 335 shows how running COPY on an index affects the INDEXSPACESTATS statistics.

Table 335. Changed INDEXSPACESTATS values during COPY

| Column name      | During UTILINIT phase          | After COPY phase                     |
|------------------|--------------------------------|--------------------------------------|
| COPYLASTTIME     | Current timestamp <sup>1</sup> | Timestamp of the start of COPY phase |
| COPYUPDATEDPAGES | Actual value <sup>1</sup>      | Actual value <sup>2</sup>            |
| COPYCHANGES      | Actual value <sup>1</sup>      | Actual value <sup>2</sup>            |
| COPYUPDATELRSN   | Actual value <sup>1</sup>      | Actual value <sup>3</sup>            |
| COPYUPDATETIME   | Actual value <sup>1</sup>      | Actual value <sup>3</sup>            |

**Note:**

1. DB2 externalizes the current in-memory values.
2. This value is 0 for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE.
3. This value is null for SHRLEVEL REFERENCE, or the actual value for SHRLEVEL CHANGE.

### How RECOVER affects real-time statistics

After recovery to the current state, the in-memory counter fields are still valid, so DB2 does not modify them. However, after a point-in-time recovery, the statistics might not be valid. DB2 therefore sets all the REORG, STATS, and COPY counter statistics to null after a point-in-time recovery. After recovery to the current state, DB2 sets NACTIVE, SPACE, and EXTENTS to their new values. After a point-in-time recovery, DB2 sets NLEVELS, NACTIVE, SPACE, and EXTENTS to their new values.

### How non-DB2 utilities affect real-time statistics

Non-DB2 utilities do not affect real-time statistics. Therefore, an object that is the target of a non-DB2 COPY, LOAD, REBUILD, REORG, or RUNSTATS job can cause incorrect statistics to be inserted in the real-time statistics tables. Follow this process to ensure correct statistics when you run non-DB2 utilities:

1. Stop the table space or index on which you plan to run the utility. This action causes DB2 to write the in-memory statistics to the real-time statistics tables and initialize the in-memory counters. If DB2 cannot externalize the statistics, the STOP command does not fail.
2. Run the utility.
3. When the utility completes, update the statistics tables with new totals and timestamps, and put zero values in the incremental counter.

## Real-time statistics on objects in work file databases and the TEMP database

Although you cannot run utilities on objects in the work files databases and TEMP database, DB2 records the NACTIVE, SPACE, and EXTENTS statistics on table spaces in those databases.

## Real-time statistics for DEFINE NO objects

For objects that are created with DEFINE NO, no row is inserted into the real-time statistics table until the object is physically defined.

## Real-time statistics on read-only or nonmodified objects

DB2 does not externalize the NACTIVE, SPACE, or EXTENTS statistics for read-only objects or objects that are not modified.

## How dropping objects affects real-time statistics

If you drop a table space or index, DB2 deletes its statistics from the real-time statistics tables. However, if the real-time statistics database is not available when you drop a table space or index, the statistics remain in the real-time statistics tables, even though the corresponding object no longer exists. You need to use SQL DELETE statements to manually remove those rows from the real-time statistics tables.

If a row still exists in the real-time statistics tables for a dropped table space or index, and if you create a new object with the same DBID and PSID as the dropped object, DB2 reinitializes the row before it updates any values in that row.

## How SQL operations affect real-time statistics counters

SQL operations affect the counter columns in the real-time statistics tables. These are the columns that record the number of insert, delete, or update operations, as well as the total counters, TOTALROWS, and TOTALENTRIES.

**UPDATE:** When you perform an UPDATE, DB2 increments the update counters.

**INSERT:** When you perform an INSERT, DB2 increments the insert counters. DB2 keeps separate counters for clustered and unclustered INSERTs.

**DELETE:** When you perform a DELETE, DB2 increments the delete counters.

**ROLLBACK:** When you perform a ROLLBACK, DB2 increments the counters, depending on the type of SQL operation that is rolled back:

| Rolled-back SQL statement | Incremented counters |
|---------------------------|----------------------|
| UPDATE                    | Update counters      |
| INSERT                    | Delete counters      |
| DELETE                    | Insert counters      |

Notice that for INSERT and DELETE, the counter for the inverse operation is incremented. For example, if two INSERT statements are rolled back, the delete counter is incremented by 2.

**UPDATE of partitioning keys:** If an update to a partitioning key causes rows to move to a new partition, the following real-time statistics are impacted:

| Action                     | Incremented counters                                                                                                              |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| When UPDATE is executed    | Update count of old partition = +1<br>Insert count of new partition = +1                                                          |
| When UPDATE is committed   | Delete count of old partition = +1                                                                                                |
| When UPDATE is rolled back | Update count of old partition = +1<br>(compensation log record)<br>Delete count of new partition = +1<br>(remove inserted record) |

If an update to a partitioning key does not cause rows to move to a new partition, the counts are accumulated as expected:

| Action                     | Incremented counters                                                                                       |
|----------------------------|------------------------------------------------------------------------------------------------------------|
| When UPDATE is executed    | Update count of current partition = +1<br>NEAR/FAR indirect reference count = +1<br>(if overflow occurred) |
| When UPDATE is rolled back | Update count of current partition = +1<br>(compensation log record)                                        |

**Mass DELETE:** Performing a mass delete operation on a table space does not cause DB2 to reset the counter columns in the real-time statistics tables. After a mass delete operation, the value in a counter column includes the count from a time prior to the mass delete operation, as well as the count after the mass delete operation.

## Real-time statistics in data sharing

In a data sharing environment, DB2 members update their statistics serially. Each member reads the target row from the statistics table, obtains a lock, aggregates its in-memory statistics, and updates the statistics table with the new totals. Each member sets its own interval for writing real-time statistics.

DB2 does locking based on the lock size of the DSNRTSDB.DSNRTSTS table space. DB2 uses cursor stability isolation and CURRENTDATA(YES) when it reads the statistics tables.

At the beginning of a RUNSTATS job, all data sharing members externalize their statistics to the real-time statistics tables and reset their in-memory statistics. If all members cannot externalize their statistics, DB2 sets STATSLASTTIME to null. An error in gathering and externalizing statistics does not prevent RUNSTATS from running.

At the beginning of a COPY job, all data sharing members externalize their statistics to the real-time statistics tables and reset their in-memory statistics. If all members cannot externalize their statistics, DB2 sets COPYLASTTIME to null. An error in gathering and externalizing statistics does not prevent COPY from running.

Utilities that reset page sets to empty can invalidate the in-memory statistics of other DB2 members. The member that resets a page set notifies the other DB2 members that a page set has been reset to empty, and the in-memory statistics are

invalidated. If the notify process fails, the utility that resets the page set does not fail. DB2 sets the appropriate timestamp (REORGLASTTIME, STATSLASTTIME, or COPYLASTTIME) to null in the row for the empty page set to indicate that the statistics for that page set are unknown.

## Improving concurrency with real-time statistics

Follow these recommendations to reduce the risk of timeouts and deadlocks when you work with the real-time statistics tables:

- When you run COPY, RUNSTATS, or REORG on the real-time statistics objects, use SHRLEVEL CHANGE.
- When you execute SQL statements to query the real-time statistics tables, use uncommitted read isolation.

## Recovering the real-time statistics tables

When you recover a DB2 subsystem after a disaster, DB2 starts with the ACCESS(MAINT) option. No statistics are externalized in this state. Therefore, you need to perform the following actions on the real-time statistics database:

- Recover the real-time statistics objects after you recover the DB2 catalog and directory.
- Start the real-time statistics database explicitly, after DB2 restart.

## Statistics accuracy

In general, the real-time statistics are accurate values. However, several factors can affect the accuracy of the statistics:

- Certain utility restart scenarios
- Certain utility operations that leave indexes in a database restrictive state, such as RECOVER-pending (RECP)

Always consider the database restrictive state of objects before accepting a utility recommendation that is based on real-time statistics.

- A DB2 subsystem failure
- A notify failure in a data sharing environment

If you think that some statistics values might be inaccurate, you can correct the statistics by running REORG, RUNSTATS, or COPY on the objects for which DB2 generated the statistics.

---

## Appendix J. DB2-supplied stored procedures

DB2 provides several stored procedures that you can call in your application programs to perform a number of utility and application programming functions.

# **Note:** These stored procedures do not propagate the transaction identifier (XID) of  
# the thread. These stored procedures run under a new private context rather  
# than under the native context of the task that called it.

DB2 provides the following stored procedures:

- The utilities stored procedure for EBCDIC input (DSNUTILS)

This stored procedure lets you invoke utilities from a local or remote client program. See Appendix B of *DB2 Utility Guide and Reference* for information.

|  
|  
|  
|

- The utilities stored procedure for Unicode input (DSNUTILU)

This stored procedure lets you invoke utilities from a local or remote client program that generates Unicode utility control statements. See Appendix B of *DB2 Utility Guide and Reference* for information.

- The DB2 Universal Database Control Center (Control Center) table space and index information stored procedure (DSNACCQC)

This stored procedure helps you determine when utilities should be run on your databases. This stored procedure is designed primarily for use by the Control Center but can be invoked from any client program. See Appendix B of *DB2 Utility Guide and Reference* for information.

- The Control Center partition information stored procedure (DSNACCAV)

This stored procedure helps you determine when utilities should be run on your partitioned table spaces. This stored procedure is designed primarily for use by the Control Center but can be invoked from any client program. See Appendix B of *DB2 Utility Guide and Reference* for information.

- The real-time statistics stored procedure (DSNACCOR)

This stored procedure queries the DB2 real-time statistics tables to help you determine when you should run COPY, REORG, or RUNSTATS, or enlarge your DB2 data sets. See “The DB2 real-time statistics stored procedure” on page 1263 for more information.

- The WLM environment refresh stored procedure (WLM\_REFRESH)

This stored procedure lets you refresh a WLM environment from a remote workstation. See “WLM environment refresh stored procedure (WLM\_REFRESH)” on page 1285 for information.

- The CICS transaction invocation stored procedure (DSNACICS)

This stored procedure lets you invoke CICS transactions from a remote workstation. See “The CICS transaction invocation stored procedure (DSNACICS)” on page 1287 for more information.

#  
#  
#  
#  
#  
#

- The SYSIBM.USERNAMES encryption stored procedure (DSNLEUSR)

This stored procedure lets you store encrypted values in the NEWAUTHID and PASSWORD fields of the SYSIBM.USERNAMES catalog table. See “The SYSIBM.USERNAMES encryption stored procedure” on page 1295 for more information.

- The IMS transactions stored procedure (DSNAIMS)

# This stored procedure allows DB2 to invoke IMS transactions and commands easily, without maintaining their own connections to IMS. See “IMS transactions stored procedure (DSNAIMS)” on page 1298 for more information.

#

# • The IMS transactions stored procedure with multi-segment input support (DSNAIMS2)

# This stored procedure offers the same functionality as the DSNAIMS stored procedure with the addition of multi-segment input support for IMS transactions. See “IMS transactions stored procedure (DSNAIMS2)” on page 1302 for more information.

#

# • The EXPLAIN stored procedure (DSN8EXP)

# This stored procedure allows a user to perform an EXPLAIN on an SQL statement without having the authorization to execute that SQL statement. See “The DB2 EXPLAIN stored procedure” on page 1306 for more information.

#

# • The MQ XML stored procedures

# All of the MQ XML stored procedures have been deprecated.

# These stored procedures perform the following functions:

# *Table 336. MQ XML stored procedures*

| # Stored procedure name | Function                                                                                                                                                                                                                                                                                                                                  | For information, see:                            |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| # DXXMQINSERT           | Returns a message that contains an XML document from an MQ message queue, decomposes the document, and stores the data in DB2 tables that are specified by an enabled XML collection.                                                                                                                                                     | <i>DB2 Application Programming and SQL Guide</i> |

| # DXXMQRETRIEVECLOB     | Constructs XML documents from data that is stored in DB2 tables that are specified in an enabled XML collection, and sends the XML documents to an MQ message queue. DXXMQRETRIEVECLOB is intended for XML documents with a length of up to 32KB.                                                                                          | <i>DB2 Application Programming and SQL Guide</i> |

## The DB2 real-time statistics stored procedure

The information under this heading is Product-sensitive Programming Interface and Associated Guidance Information.

The DSNACCOR stored procedure is a sample stored procedure that makes recommendations to help you maintain your DB2 databases. In particular, DSNACCOR performs these actions:

- Recommends when you should reorganize, image copy, or update statistics for table spaces or index spaces
- Indicates table spaces or index spaces that have exceeded their data set
- Indicates whether objects are in a restricted state

DSNACCOR uses data from the SYSIBM.TABLESPACESTATS and SYSIBM.INDEXSPACESTATS real-time statistics tables to make its recommendations. DSNACCOR provides its recommendations in a result set.

DSNACCOR uses the set of criteria that are shown in “DSNACCOR formulas for recommending actions” on page 1273 to evaluate table spaces and index spaces. By default, DSNACCOR evaluates **all** table spaces and index spaces in the subsystem that have entries in the real-time statistics tables. However, you can override this default through input parameters.

*Important information about DSNACCOR recommendations:*

- DSNACCOR makes recommendations based on general formulas that require input from the user about the maintenance policies for a subsystem. These recommendations might not be accurate for every installation.
- If the real-time statistics tables contain information for only a small percentage of your DB2 subsystem, the recommendations that DSNACCOR makes might not be accurate for the entire subsystem.
- Before you perform any action that DSNACCOR recommends, ensure that the object for which DSNACCOR makes the recommendation is available, and that the recommended action can be performed on that object. For example, before you can perform an image copy on an index, the index must have the COPY YES attribute.

## Environment for DSNACCOR

DSNACCOR must run in a WLM-established stored procedure address space.

DSNACCOR creates and uses declared temporary tables. Therefore, before you can invoke DSNACCOR, you need to create a TEMP database and segmented table spaces in the TEMP database. For information about creating TEMP databases and table spaces, see CREATE DATABASE and CREATE TABLESPACE Chapter 5 of *DB2 SQL Reference*.

Before you can invoke DSNACCOR, the real-time statistics tables, SYSIBM.TABLESPACESTATS and SYSIBM.INDEXSPACESTATS, must exist, and the real-time statistics database must be started. See Appendix I, “Real-time statistics tables,” on page 1235 for information about the real-time statistics tables.

You should bind the package for DSNACCOR with isolation UR to avoid lock contention. You can find the installation steps for DSNACCOR in job DSNTIJSJG.

## Authorization required for DSNACCOR

To execute the CALL DSNACCOR statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNACCOR

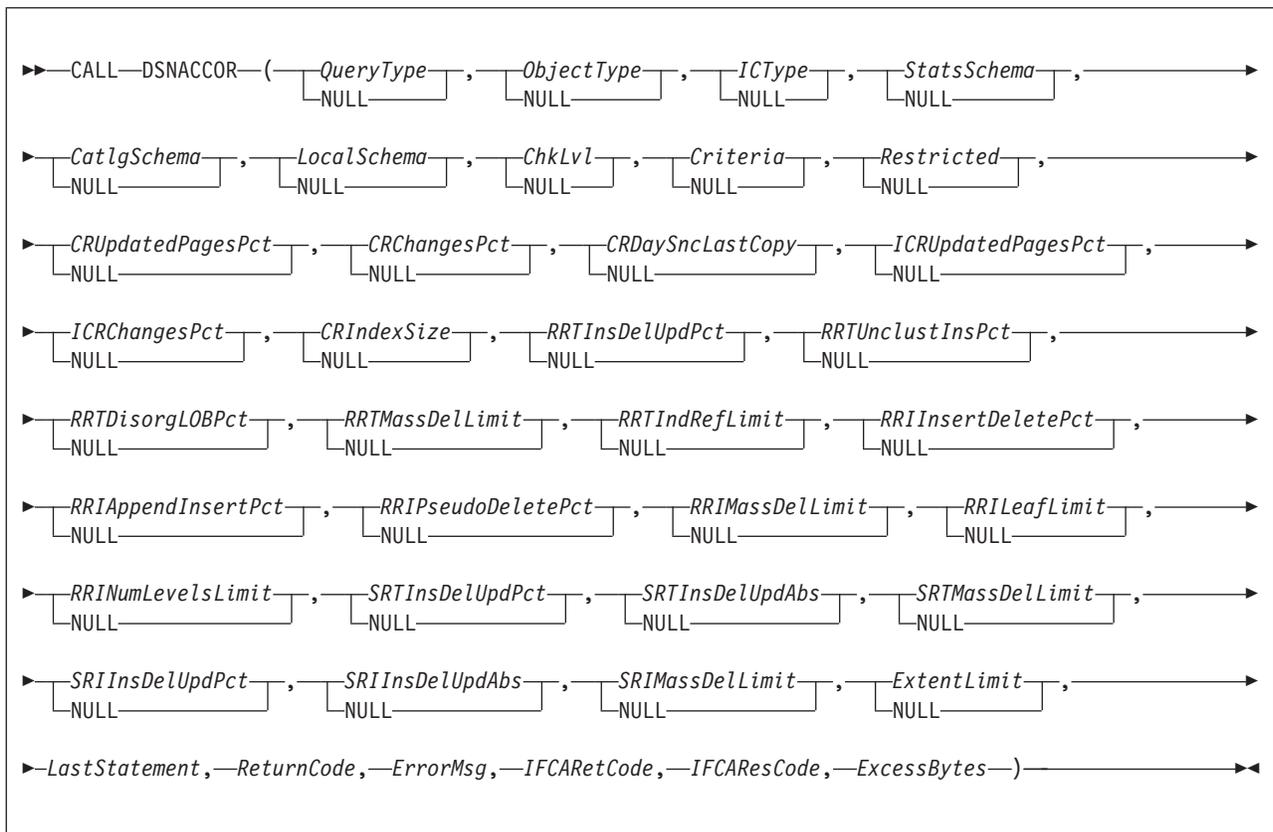

- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have:

- SELECT authority on the real-time statistics tables
- The DISPLAY system privilege

## DSNACCOR syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNACCOR. Because the linkage convention for DSNACCOR is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

## DSNACCOR option descriptions

In the following option descriptions, the default value for an input parameter is the value that DSNACCOR uses if you specify a null value.

### QueryType

Specifies the types of actions that DSNACCOR recommends. This field contains one or more of the following values. Each value is enclosed in single quotation marks and separated from other values by a space.

- |             |                                                             |
|-------------|-------------------------------------------------------------|
| <b>ALL</b>  | Makes recommendations for all of the following actions.     |
| <b>COPY</b> | Makes a recommendation on whether to perform an image copy. |

- RUNSTATS** Makes a recommendation on whether to perform RUNSTATS.
- REORG** Makes a recommendation on whether to perform REORG. Choosing this value causes DSNACCOR to process the EXTENTS value also.
- EXTENTS** Indicates when data sets have exceeded a user-specified extents limit.
- RESTRICT** Indicates which objects are in a restricted state.

*QueryType* is an input parameter of type VARCHAR(40). The default is **ALL**.

*ObjectType*

Specifies the types of objects for which DSNACCOR recommends actions:

- ALL** Table spaces and index spaces.
- TS** Table spaces only.
- IX** Index spaces only.

*ObjectType* is an input parameter of type VARCHAR(3). The default is **ALL**.

*ICType*

Specifies the types of image copies for which DSNACCOR is to make recommendations:

- F** Full image copy.
- I** Incremental image copy. This value is valid for table spaces only.
- B** Full image copy or incremental image copy.

*ICType* is an input parameter of type VARCHAR(1). The default is **B**.

*StatsSchema*

Specifies the qualifier for the real-time statistics table names. *StatsSchema* is an input parameter of type VARCHAR(128). The default is **SYSIBM**.

*CatlgSchema*

Specifies the qualifier for DB2 catalog table names. *CatlgSchema* is an input parameter of type VARCHAR(128). The default is **SYSIBM**.

*LocalSchema*

Specifies the qualifier for the names of tables that DSNACCOR creates. *LocalSchema* is an input parameter of type VARCHAR(128). The default is **DSNACC**.

*ChkLvl*

Specifies the types of checking that DSNACCOR performs, and indicates whether to include objects that fail those checks in the DSNACCOR recommendations result set. This value is the sum of any combination of the following values:

- 0** DSNACCOR performs none of the following actions.
- 1** For objects that are listed in the recommendations result set, check the SYSTABLESPACE or SYSINDEXES catalog tables to ensure that those objects have not been deleted. If value 16 is **not** also chosen, exclude rows for the deleted objects from the recommendations result set.

DSNACCOR excludes objects from the recommendations result set if those objects are not in the SYSTABLESPACE or SYSINDEXES catalog tables.

|  
|  
|

When this setting is specified, DSNACCOR does not use EXTENTS>ExtentLimit to determine whether a LOB table space should be reorganized.

- 2 For index spaces that are listed in the recommendations result set, check the SYSTABLES, SYSTABLESPACE, and SYSINDEXES catalog tables to determine the name of the table space that is associated with each index space.

Choosing this value causes DSNACCOR to also check for rows in the recommendations result set for objects that have been deleted but have entries in the real-time statistics tables (value 1). This means that if value 16 is **not** also chosen, rows for deleted objects are excluded from the recommendations result set.

- 4 Check whether rows that are in the DSNACCOR recommendations result set refer to objects that are in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.

- 8 Check whether objects that have rows in the recommendations result set are restricted. Indicate the restricted status in the OBJECTSTATUS column of the result set.

- 16 For objects that are listed in the recommendations result set, check the SYSTABLESPACE or SYSINDEXES catalog tables to ensure that those objects have not been deleted (value 1). In result set rows for deleted objects, specify the word ORPHANED in the OBJECTSTATUS column.

- 32 Exclude rows from the DSNACCOR recommendations result set for index spaces for which the related table spaces have been recommended for REORG. Choosing this value causes DSNACCOR to perform the actions for values 1 and 2.

- 64 For index spaces that are listed in the DSNACCOR recommendations result set, check whether the related table spaces are listed in the exception table. For recommendations result set rows that have corresponding exception table rows, copy the contents of the QUERYTYPE column of the exception table to the INEXCEPTTABLE column of the recommendations result set.

*ChkLvl* is an input parameter of type INTEGER. The default is 7 (values 1+2+4).

#### *Criteria*

Narrows the set of objects for which DSNACCOR makes recommendations. This value is the search condition of an SQL WHERE clause. *Criteria* is an input parameter of type VARCHAR(4096). The default is that DSNACCOR makes recommendations for all table spaces and index spaces in the subsystem. The search condition can use any column in the result set and wildcards are allowed.

#### *Restricted*

A parameter that is reserved for future use. Specify the null value for this parameter. *Restricted* is an input parameter of type VARCHAR(80).

### *CRUpdatedPagesPct*

Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOR recommends an image copy:

The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.

See item 2 in Figure 185 on page 1274. If both of the following conditions are true for an index space, DSNACCOR recommends an image copy:

- The total number of distinct updated pages, divided by the total number of preformatted pages (expressed as a percentage) is greater than *CRUpdatedPagesPct*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*. See items 2 and 3 in Figure 186 on page 1274.

*CRUpdatedPagesPct* is an input parameter of type INTEGER. The default is 20.

### *CRChangesPct*

Specifies a criterion for recommending a full image copy on a table space or index space. If the following condition is true for a table space, DSNACCOR recommends an image copy:

The total number of insert, update, and delete operations since the last image copy, divided by the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *CRChangesPct*.

See item 3 in Figure 185 on page 1274. If both of the following conditions are true for an index table space, DSNACCOR recommends an image copy:

- The total number of insert and delete operations since the last image copy, divided by the total number of entries in the index space or partition (expressed as a percentage) is greater than *CRChangesPct*.
- The number of active pages in the index space or partition is greater than *CRIndexSize*.

See items 2 and 4 in Figure 186 on page 1274. *CRChangesPct* is an input parameter of type INTEGER. The default is 10.

### *CRDaySncLastCopy*

Specifies a criterion for recommending a full image copy on a table space or index space. If the number of days since the last image copy is greater than this value, DSNACCOR recommends an image copy. (See item 1 in Figure 185 on page 1274 and item 1 in Figure 186 on page 1274.) *CRDaySncLastCopy* is an input parameter of type INTEGER. The default is 7.

### *ICRUpdatedPagesPct*

Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOR recommends an incremental image copy:

The number of distinct pages that were updated since the last image copy, divided by the total number of active pages in the table space or partition (expressed as a percentage) is greater than *ICRUpdatedPagesPct*.

(See item 1 in Figure 187 on page 1274.) *ICRUpdatedPagesPct* is an input parameter of type INTEGER. The default is 1.

### *ICRChangesPct*

Specifies a criterion for recommending an incremental image copy on a table space. If the following condition is true, DSNACCOR recommends an incremental image copy:

The ratio of the number of insert, update, or delete operations since the last image copy, to the total number of rows or LOBs in a table space or partition (expressed as a percentage) is greater than *ICRChangesPct*.

(See item 2 in Figure 187 on page 1274.) *ICRChangesPct* is an input parameter of type INTEGER. The default is 1.

#### *CRIndexSize*

Specifies, when combined with *CRUpdatedPagesPct* or *CRChangesPct*, a criterion for recommending a full image copy on an index space. (See items 2, 3, and 4 in Figure 186 on page 1274.) *CRIndexSize* is an input parameter of type INTEGER. The default is 50.

#### *RRTInsDelUpdPct*

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The sum of insert, update, and delete operations since the last REORG, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTInsDelUpdPct*

(See item 1 in Figure 188 on page 1275.) *RRTInsDelUpdPct* is an input parameter of type INTEGER. The default is 20.

#### *RRTUnclustInsPct*

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The number of unclustered insert operations, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTUnclustInsPct*.

(See item 2 in Figure 188 on page 1275.) *RRTUnclustInsPct* is an input parameter of type INTEGER. The default is 10.

#### *RRTDisorgLOBPct*

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running REORG:

The number of imperfectly chunked LOBs, divided by the total number of rows or LOBs in the table space or partition (expressed as a percentage) is greater than *RRTDisorgLOBPct*.

(See item 3 in Figure 188 on page 1275.) *RRTDisorgLOBPct* is an input parameter of type INTEGER. The default is 10.

#### *RRTMassDelLimit*

Specifies a criterion for recommending that the REORG utility is to be run on a table space. If one of the following values is greater than *RRTMassDelLimit*, DSNACCOR recommends running REORG:

- The number of mass deletes from a segmented or LOB table space since the last REORG or LOAD REPLACE
- The number of dropped tables from a nonsegmented table space since the last REORG or LOAD REPLACE

(See item 5 in Figure 188 on page 1275.) *RRTMassDelLimit* is an input parameter of type INTEGER. The default is 0.

| *RRTIndRefLimit*

| Specifies a criterion for recommending that the REORG utility is to be run on a  
| table space. If the following value is greater than *RRTIndRefLimit*, DSNACCOR  
| recommends running REORG:

|     The total number of overflow records that were created since the last  
|     REORG or LOAD REPLACE, divided by the total number of rows or LOBs  
|     in the table space or partition (expressed as a percentage)

| (See item 4 in Figure 188 on page 1275.) *RRTIndRefLimit* is an input parameter  
| of type INTEGER. The default is 10.

| *RRInsertDeletePct*

| Specifies a criterion for recommending that the REORG utility is to be run on  
| an index space. If the following value is greater than *RRInsertDeletePct*,  
| DSNACCOR recommends running REORG:

|     The sum of the number of index entries that were inserted and deleted  
|     since the last REORG, divided by the total number of index entries in the  
|     index space or partition (expressed as a percentage)

| (See item 1 in Figure 189 on page 1275.) This is an input parameter of type  
| INTEGER. The default is 20.

| *RRAppendInsertPct*

| Specifies a criterion for recommending that the REORG utility is to be run on  
| an index space. If the following value is greater than *RRAppendInsertPct*,  
| DSNACCOR recommends running REORG:

|     The number of index entries that were inserted since the last REORG,  
|     REBUILD INDEX, or LOAD REPLACE with a key value greater than the  
|     maximum key value in the index space or partition, divided by the number  
|     of index entries in the index space or partition (expressed as a percentage)

| (See item 2 in Figure 189 on page 1275.) *RRInsertDeletePct* is an input  
| parameter of type INTEGER. The default is 10.

| *RRIPseudoDeletePct*

| Specifies a criterion for recommending that the REORG utility is to be run on  
| an index space. If the following value is greater than *RRIPseudoDeletePct*,  
| DSNACCOR recommends running REORG:

|     The number of index entries that were pseudo-deleted since the last  
|     REORG, REBUILD INDEX, or LOAD REPLACE, divided by the number of  
|     index entries in the index space or partition (expressed as a percentage)

| (See item 3 in Figure 189 on page 1275.) *RRIPseudoDeletePct* is an input  
| parameter of type INTEGER. The default is 10.

| *RRIMassDelLimit*

| Specifies a criterion for recommending that the REORG utility is to be run on  
| an index space. If the number of mass deletes from an index space or partition  
| since the last REORG, REBUILD, or LOAD REPLACE is greater than this  
| value, DSNACCOR recommends running REORG.

| (See item 4 in Figure 189 on page 1275.) *RRIMassDelLimit* is an input parameter  
| of type INTEGER. The default is 0.

| *RRLeafLimit*

| Specifies a criterion for recommending that the REORG utility is to be run on  
| an index space. If the following value is greater than *RRLeafLimit*,  
| DSNACCOR recommends running REORG:

|     The number of index page splits that occurred since the last REORG,  
|     REBUILD INDEX, or LOAD REPLACE in which the higher part of the split

page was far from the location of the original page, divided by the total number of active pages in the index space or partition (expressed as a percentage)

(See item 5 in Figure 189 on page 1275.) *RRILeafLimit* is an input parameter of type INTEGER. The default is 10.

#### *RRINumLevelsLimit*

Specifies a criterion for recommending that the REORG utility is to be run on an index space. If the following value is greater than *RRINumLevelsLimit*, DSNACCOR recommends running REORG:

The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE

(See item 6 in Figure 189 on page 1275.) *RRINumLevelsLimit* is an input parameter of type INTEGER. The default is 0.

#### *SRTInsDelUpdPct*

Specifies, when combined with *SRTInsDelUpdAbs*, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of insert, update, or delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

(See items 1 and 2 in Figure 190 on page 1275.) *SRTInsDelUpdPct* is an input parameter of type INTEGER. The default is 20.

#### *SRTInsDelUpdAbs*

Specifies, when combined with *SRTInsDelUpdPct*, a criterion for recommending that the RUNSTATS utility is to be run on a table space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, divided by the total number of rows or LOBs in table space or partition (expressed as a percentage) is greater than *SRTInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRTInsDelUpdAbs*.

(See items 1 and 2 in Figure 190 on page 1275.) *SRTInsDelUpdAbs* is an input parameter of type INTEGER. The default is 0.

#### *SRTMassDelLimit*

Specifies a criterion for recommending that the RUNSTATS utility is to be run on a table space. If the following condition is true, DSNACCOR recommends running RUNSTATS:

- The number of mass deletes from a table space or partition since the last REORG or LOAD REPLACE is greater than *SRTMassDelLimit*.

(See item 3 in Figure 190 on page 1275.) *SRTMassDelLimit* is an input parameter of type INTEGER. The default is 0.

#### *SRIInsDelPct*

Specifies, when combined with *SRIInsDelAbs*, a criterion for recommending

that the RUNSTATS utility is to be run on an index space. If both of the following conditions are true, DSNACCOR recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelUpdAbs*.

(See items 1 and 2 in Figure 191 on page 1275.) *SRIInsDelPct* is an input parameter of type INTEGER. The default is 20.

#### *SRIInsDelAbs*

Specifies, when combined with *SRIInsDelPct*, specifies a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the following condition is true, DSNACCOR recommends running RUNSTATS:

- The number of inserted and deleted index entries since the last RUNSTATS on an index space or partition, divided by the total number of index entries in the index space or partition (expressed as a percentage) is greater than *SRIInsDelUpdPct*.
- The sum of the number of inserted and deleted index entries since the last RUNSTATS on an index space or partition is greater than *SRIInsDelUpdAbs*,

(See items 1 and 2 in Figure 191 on page 1275.) *SRIInsDelAbs* is an input parameter of type INTEGER. The default is 0.

#### *SRIMassDelLimit*

Specifies a criterion for recommending that the RUNSTATS utility is to be run on an index space. If the number of mass deletes from an index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE is greater than this value, DSNACCOR recommends running RUNSTATS.

(See item 3 in Figure 191 on page 1275.) *SRIMassDelLimit* is an input parameter of type INTEGER. The **default** is 0.

#### *ExtentLimit*

Specifies a criterion for recommending that the REORG utility is to be run on a table space or index space. Also specifies that DSNACCOR is to warn the user that the table space or index space has used too many extents. DSNACCOR recommends running REORG, and altering data set allocations if the following condition is true:

- The number of physical extents in the index space, table space, or partition is greater than *ExtentLimit*.

(See Figure 192 on page 1276.) *ExtentLimit* is an input parameter of type INTEGER. The default is 50.

#### *LastStatement*

When DSNACCOR returns a severe error (return code 12), this field contains the SQL statement that was executing when the error occurred. *LastStatement* is an output parameter of type VARCHAR(8012).

#### *ReturnCode*

The return code from DSNACCOR execution. Possible values are:

- 0** DSNACCOR executed successfully. The *ErrorMsg* parameter contains the approximate percentage of the total number of objects in the subsystem that have information in the real-time statistics tables.

- 4 DSNACCOR completed, but one or more input parameters might be incompatible. The *ErrorMsg* parameter contains the input parameters that might be incompatible.
- 8 DSNACCOR terminated with errors. The *ErrorMsg* parameter contains a message that describes the error.
- 12 DSNACCOR terminated with severe errors. The *ErrorMsg* parameter contains a message that describes the error. The *LastStatement* parameter contains the SQL statement that was executing when the error occurred.
- 14 DSNACCOR terminated because it could not access one or more of the real-time statistics tables. The *ErrorMsg* parameter contains the names of the tables that DSNACCOR could not access.
- 15 DSNACCOR terminated because it encountered a problem with one of the declared temporary tables that it defines and uses.
- 16 DSNACCOR terminated because it could not define a declared temporary table. No table spaces were defined in the TEMP database.
- NULL DSNACCOR terminated but could not set a return code.

*ReturnCode* is an output parameter of type INTEGER.

*ErrorMsg*

Contains information about DSNACCOR execution. If DSNACCOR runs successfully (*ReturnCode*=0), this field contains the approximate percentage of objects in the subsystem that are in the real-time statistics tables. Otherwise, this field contains error messages. *ErrorMsg* is an output parameter of type VARCHAR(1331).

*IFCARetCode*

Contains the return code from an IFI COMMAND call. DSNACCOR issues commands through the IFI interface to determine the status of objects. *IFCARetCode* is an output parameter of type INTEGER.

*IFCAResCode*

Contains the reason code from an IFI COMMAND call. *IFCAResCode* is an output parameter of type INTEGER.

*ExcessBytes*

Contains the number of bytes of information that did not fit in the IFI return area after an IFI COMMAND call. *ExcessBytes* is an output parameter of type INTEGER.

## DSNACCOR formulas for recommending actions

The following formulas specify the criteria that DSNACCOR uses for its recommendations and warnings. The variables in italics are DSNACCOR input parameters. The capitalized variables are columns of the SYSIBM.TABLESPACESTATS or SYSIBM.INDEXSPACESTATS tables. The numbers to the right of selected items are reference numbers for the option descriptions in "DSNACCOR option descriptions" on page 1265.

Figure 185 on page 1274 shows the formula that DSNACCOR uses to recommend a full image copy on a table space.

---

```

((QueryType='COPY' OR QueryType='ALL') AND
 (ObjectType='TS' OR ObjectType='ALL') AND
 IType='F') AND
 (COPYLASTTIME IS NULL OR
 REORGLASTTIME>COPYLASTTIME OR
 LOADRLASTTIME>COPYLASTTIME OR
 (CURRENT DATE-COPYLASTTIME)>CRDaySncLastCopy OR
 (COPYUPDATEDPAGES*100)/NACTIVE>CRUpdatedPagesPct OR
 (COPYCHANGES*100)/TOTALROWS>CRChangesPct)

```

---

Figure 185. DSNACCOR formula for recommending a full image copy on a table space

Figure 186 shows the formula that DSNACCOR uses to recommend a full image copy on an index space.

---

```

((QueryType='COPY' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL') AND
 (IType='F' OR IType='B')) AND
 (COPYLASTTIME IS NULL OR
 REORGLASTTIME>COPYLASTTIME OR
 LOADRLASTTIME>COPYLASTTIME OR
 REBUILDLASTTIME>COPYLASTTIME OR
 (CURRENT DATE-COPYLASTTIME)>CRDaySncLastCopy OR
 (NACTIVE>CRIndexSize AND
 ((COPYUPDATEDPAGES*100)/NACTIVE>CRUpdatedPagesPct OR
 (COPYCHANGES*100)/TOTALENTRIES>CRChangesPct)))

```

---

Figure 186. DSNACCOR formula for recommending a full image copy on an index space

Figure 187 shows the formula that DSNACCOR uses to recommend an incremental image copy on a table space.

---

```

((QueryType='COPY' OR QueryType='ALL') AND
 (ObjectType='TS' OR ObjectType='ALL') AND
 IType='I' AND
 COPYLASTTIME IS NOT NULL) AND
 (LOADRLASTTIME>COPYLASTTIME OR
 REORGLASTTIME>COPYLASTTIME OR
 (COPYUPDATEDPAGES*100)/NACTIVE>ICRUpdatedPagesPct OR
 (COPYCHANGES*100)/TOTALROWS>ICRChangesPct))

```

---

Figure 187. DSNACCOR formula for recommending an incremental image copy on a table space

Figure 188 on page 1275 shows the formula that DSNACCOR uses to recommend a REORG on a table space. If the table space is a LOB table space, and CHCKLVL=1, the formula does not include EXTENTS>ExtentLimit.

---

```

((QueryType='REORG' OR QueryType='ALL') AND
 (ObjectType='TS' OR ObjectType='ALL')) AND
 (REORGLASTTIME IS NULL OR
 ((REORGINSETS+REORGDELETES+REORGUPDATES)*100)/TOTALROWS>RRTInsDelUpdPct OR
 (REORGUNCLUSTINS*100)/TOTALROWS>RRTUnclustInsPct OR
 (REORGDISORGL0B*100)/TOTALROWS>RRTDisorgLOBPct OR
 ((REORGNEARINDREF+REORGFARINDREF)*100)/TOTALROWS>RRTIndRefLimit OR
 REORGMASDELETE>RRTMassDelLimit OR
 EXTENTS>ExtentLimit)

```

---

Figure 188. DSNACCOR formula for recommending a REORG on a table space

Figure 189 shows the formula that DSNACCOR uses to recommend a REORG on an index space.

---

```

((QueryType='REORG' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL')) AND
 (REORGLASTTIME IS NULL OR
 ((REORGINSETS+REORGDELETES)*100)/TOTALENTRIES>RRIInsertDeletePct OR
 (REORGAPPENDINSERT*100)/TOTALENTRIES>RRIAppendInsertPct OR
 (REORGPSEUDODELETES*100)/TOTALENTRIES>RRIpseudoDeletePct OR
 REORGMASDELETE>RRIMassDeleteLimit OR
 (REORGLEAFFAR*100)/NACTIVE>RRILeafLimit OR
 REORGNUMLEVELS>RRINumLevelsLimit OR
 EXTENTS>ExtentLimit)

```

---

Figure 189. DSNACCOR formula for recommending a REORG on an index space

Figure 190 shows the formula that DSNACCOR uses to recommend RUNSTATS on a table space.

---

```

((QueryType='RUNSTATS' OR QueryType='ALL') AND
 (ObjectType='TS' OR ObjectType='ALL')) AND
 (STATSLASTTIME IS NULL OR
 (((STATSINSERTS+STATSDELETES+STATSUPDATES)*100)/TOTALROWS>SRTInsDelUpdPct AND
 (STATSINSERTS+STATSDELETES+STATSUPDATES)>SRTInsDelUpdAbs) OR
 STATSMASDELETE>SRTMassDeleteLimit)

```

---

Figure 190. DSNACCOR formula for recommending RUNSTATS on a table space

Figure 191 shows the formula that DSNACCOR uses to recommend RUNSTATS on an index space.

---

```

((QueryType='RUNSTATS' OR QueryType='ALL') AND
 (ObjectType='IX' OR ObjectType='ALL')) AND
 (STATSLASTTIME IS NULL OR
 (((STATSINSERTS+STATSDELETES)*100)/TOTALENTRIES>SRIInsDelUpdPct AND
 (STATSINSERTS+STATSDELETES)>SRIInsDelPct) OR
 STATSMASDELETE>SRIInsDelAbs)

```

---

Figure 191. DSNACCOR formula for recommending RUNSTATS on an index space

Figure 192 on page 1276 shows the formula that DSNACCOR uses to that too many index space or table space extents have been used.

---

EXTENTS>ExtentLimit

---

Figure 192. DSNACCOR formula for warning that too many data set extents for a table space or index space are used

## Using an exception table

An exception table is an optional, user-created DB2 table that you can use to place information in the INEXCEPTTABLE column of the recommendations result set. You can put any information in the INEXCEPTTABLE column, but the most common use of this column is to filter the recommendations result set. Each row in the exception table represents an object for which you want to provide information for the recommendations result set.

To create the exception table, execute a CREATE TABLE statement similar to the following one. You can include other columns in the exception table, but you must include at least the columns that are shown.

```
CREATE TABLE DSNACC.EXCEPT_TBL
  (DBNAME CHAR(8) NOT NULL,
   NAME CHAR(8) NOT NULL,
   QUERYTYPE CHAR(40))
CCSID EBCDIC;
```

The meanings of the columns are:

### DBNAME

The database name for an object in the exception table.

### NAME

The table space name or index space name for an object in the exception table.

### QUERYTYPE

The information that you want to place in the INEXCEPTTABLE column of the recommendations result set.

If you put a null value in this column, DSNACCOR puts the value YES in the INEXCEPTTABLE column of the recommendations result set row for the object that matches the DBNAME and NAME values.

**Recommendation:** If you plan to put many rows in the exception table, create a nonunique index on DBNAME, NAME, and QUERYTYPE.

After you create the exception table, insert a row for each object for which you want to include information in the INEXCEPTTABLE column.

**Example:** Suppose that you want the INEXCEPTTABLE column to contain the string 'IRRELEVANT' for table space STAFF in database DSNDB04. You also want the INEXCEPTTABLE column to contain 'CURRENT' for table space DSN8S81D in database DSN8D81A. Execute these INSERT statements:

```
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSNDB04 ', 'STAFF ', 'IRRELEVANT');
INSERT INTO DSNACC.EXCEPT_TBL VALUES('DSN8D81A', 'DSN8S81D', 'CURRENT');
```

To use the contents of INEXCEPTTABLE for filtering, include a condition that involves the INEXCEPTTABLE column in the search condition that you specify in your *Criteria* input parameter.

**Example:** Suppose that you want to include all rows for database DSNDB04 in the recommendations result set, except for those rows that contain the string 'IRRELEVANT' in the INEXCEPTTABLE column. You might include the following search condition in your *Criteria* input parameter:

```
DBNAME='DSNDB04' AND INEXCEPTTABLE<>'IRRELEVANT'
```

## Example of DSNACCOR invocation

Figure 193 on page 1278 is a COBOL example that shows variable declarations and an SQL CALL for obtaining recommendations for objects in databases DSN8D81A and DSN8D81L. This example also outlines the steps that you need to perform to retrieve the two result sets that DSNACCOR returns. These result sets are described in “DSNACCOR output” on page 1281. See *DB2 Application Programming and SQL Guide* for more information about how to retrieve result sets from a stored procedure.

Figure 193. Example of DSNACCOR invocation (Part 4 of 4)

## DSNACCOR output

If DSNACCOR executes successfully, in addition to the output parameters described in “DSNACCOR option descriptions” on page 1265, DSNACCOR returns two result sets.

The first result set contains the results from IFI COMMAND calls that DSNACCOR makes. Table 337 on page 1282 shows the format of the first result set.

Table 337. Result set row for first DSNACCOR result set

| Column name | Data type | Contents                           |
|-------------|-----------|------------------------------------|
| RS_SEQUENCE | INTEGER   | Sequence number of the output line |
| RS_DATA     | CHAR(80)  | A line of command output           |

The second result set contains DSNACCOR's recommendations. This result set contains one or more rows for a table space or index space. A nonpartitioned table space or nonpartitioning index space can have at most one row in the result set. A partitioned table space or partitioning index space can have at most one row for each partition. A table space, index space, or partition has a row in the result set if both of the following conditions are true:

- If the *Criteria* input parameter contains a search condition, the search condition is true for the table space, index space, or partition.
- DSNACCOR recommends at least one action for the table space, index space, or partition.

Table 338 shows the columns of a result set row.

Table 338. Result set row for second DSNACCOR result set

| Column name  | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| REORG        | CHAR(3)   | REORG recommendation: YES or NO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Table 338. Result set row for second DSNACCOR result set (continued)

| Column name     | Data type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INEXCEPTABLE    | CHAR(40)  | A string that contains one of the following values: <ul style="list-style-type: none"> <li>Text that you specify in the QUERYTYPE column of the exception table.</li> <li>YES, if you put a row in the exception table for the object that this result set row represents, but you specify NULL in the QUERYTYPE column.</li> <li>NO, if the exception table exists but does not have a row for the object that this result set row represents.</li> <li>Null, if the exception table does not exist, or if the <i>ChkLvl</i> input parameter does not include the value 4.</li> </ul> |
| ASSOCIATEDTS    | CHAR(8)   | If OBJECTTYPE is IX and the <i>ChkLvl</i> input parameter includes the value 2, this value is the name of the table space that is associated with the index space. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                                                     |
| COPYLASTTIME    | TIMESTAMP | Timestamp of the last full image copy on the object. Null if COPY was never run, or if the last COPY execution was terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LOADRLASTTIME   | TIMESTAMP | Timestamp of the last LOAD REPLACE on the object. Null if LOAD REPLACE was never run, or if the last LOAD REPLACE execution was terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| REBUILDLASTTIME | TIMESTAMP | Timestamp of the last REBUILD INDEX on the object. Null if REBUILD INDEX was never run, or if the last REBUILD INDEX execution was terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CRUPDPGPCT      | INTEGER   | If OBJECTTYPE is TS or IX and IMAGECOPY is YES, the ratio of distinct updated pages to preformatted pages, expressed as a percentage. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CRCPYCHGPCT     | INTEGER   | If OBJECTTYPE is TS and IMAGECOPY is YES, the ratio of the total number insert, update, and delete operations since the last image copy to the total number of rows or LOBs in the table space or partition, expressed as a percentage. If OBJECTTYPE is IX and IMAGECOPY is YES, the ratio of the total number of insert and delete operations since the last image copy to the total number of entries in the index space or partition, expressed as a percentage. Otherwise null.                                                                                                   |
| CRDAYSCELSTCPY  | INTEGER   | If OBJECTTYPE is TS or IX and IMAGECOPY is YES, the number of days since the last image copy. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CRINDEXSIZE     | INTEGER   | If OBJECTTYPE is IX and IMAGECOPY is YES, the number of active pages in the index space or partition. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| REORGLASTTIME   | TIMESTAMP | Timestamp of the last REORG on the object. Null if REORG was never run, or if the last REORG execution was terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RRTINSDELUPDPCT | INTEGER   | If OBJECTTYPE is TS and REORG is YES, the ratio of the sum of insert, update, and delete operations since the last REORG to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.                                                                                                                                                                                                                                                                                                                                               |
| RRTUNCINSPCT    | INTEGER   | If OBJECTTYPE is TS and REORG is YES, the ratio of the number of unclustered insert operations to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                         |
| RRTDISORGLPCT   | INTEGER   | If OBJECTTYPE is TS and REORG is YES, the ratio of the number of imperfectly chunked LOBs to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.                                                                                                                                                                                                                                                                                                                                                                              |

Table 338. Result set row for second DSNACCOR result set (continued)

| Column name     | Data type | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RRTMASSDELETE   | INTEGER   | If OBJECTTYPE is TS, REORG is YES, and the table space is a segmented table space or LOB table space, the number of mass deletes since the last REORG or LOAD REPLACE. If OBJECTTYPE is TS, REORG is YES, and the table space is nonsegmented, the number of dropped tables since the last REORG or LOAD REPLACE. Otherwise null.                                |
| RRTINDREF       | INTEGER   | If OBJECTTYPE is TS, REORG is YES, the ratio of the total number of overflow records that were created since the last REORG or LOAD REPLACE to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.                                                                                                      |
| RRIINSDELPCT    | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the ratio of the total number of insert and delete operations since the last REORG to the total number of index entries in the index space or partition, expressed as a percentage. Otherwise null.                                                                                                                        |
| RRIAPPINSPECT   | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index entries that were inserted since the last REORG, REBUILD INDEX, or LOAD REPLACE that had a key value greater than the maximum key value in the index space or partition, to the number of index entries in the index space or partition, expressed as a percentage. Otherwise null.       |
| RRIPSDELDPCT    | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index entries that were pseudo-deleted (the RID entry was marked as deleted) since the last REORG, REBUILD INDEX, or LOAD REPLACE to the number of index entries in the index space or partition, expressed as a percentage. Otherwise null.                                                    |
| RRIMASSDELETE   | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the number of mass deletes from the index space or partition since the last REORG, REBUILD, or LOAD REPLACE. Otherwise null.                                                                                                                                                                                               |
| RRILEAF         | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the ratio of the number of index page splits that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE in which the higher part of the split page was far from the location of the original page, to the total number of active pages in the index space or partition, expressed as a percentage. Otherwise null. |
| RRINUMLEVELS    | INTEGER   | If OBJECTTYPE is IX and REORG is YES, the number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE. Otherwise null.                                                                                                                                                                                    |
| STATSLASTTIME   | TIMESTAMP | Timestamp of the last RUNSTATS on the object. Null if RUNSTATS was never run, or if the last RUNSTATS execution was terminated.                                                                                                                                                                                                                                  |
| SRTINSDELUPDPCT | INTEGER   | If OBJECTTYPE is TS and RUNSTATS is YES, the ratio of the total number of insert, update, and delete operations since the last RUNSTATS on a table space or partition, to the total number of rows or LOBs in the table space or partition, expressed as a percentage. Otherwise null.                                                                           |
| SRTINSDELUPDABS | INTEGER   | If OBJECTTYPE is TS and RUNSTATS is YES, the total number of insert, update, and delete operations since the last RUNSTATS on a table space or partition. Otherwise null.                                                                                                                                                                                        |

Table 338. Result set row for second DSNACCOR result set (continued)

| Column name   | Data type | Description                                                                                                                                                                                                                                                                      |
|---------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SRTMASSDELETE | INTEGER   | If OBJECTTYPE is TS and RUNSTATS is YES, the number of mass deletes from the table space or partition since the last REORG or LOAD REPLACE. Otherwise null.                                                                                                                      |
| SRIINSDELPCT  | INTEGER   | If OBJECTTYPE is IX and RUNSTATS is YES, the ratio of the total number of insert and delete operations since the last RUNSTATS on the index space or partition, to the total number of index entries in the index space or partition, expressed as a percentage. Otherwise null. |
| SRIINSDELABS  | INTEGER   | If OBJECTTYPE is IX and RUNSTATS is YES, the number insert and delete operations since the last RUNSTATS on the index space or partition. Otherwise null.                                                                                                                        |
| SRIMASSDELETE | INTEGER   | If OBJECTTYPE is IX and RUNSTATS is YES, the number of mass deletes from the index space or partition since the last REORG, REBUILD INDEX, or LOAD REPLACE. Otherwise, this value is null.                                                                                       |
| TOTALEXTENTS  | SMALLINT  | If EXTENTS is YES, the number of physical extents in the table space, index space, or partition. Otherwise, this value is null.                                                                                                                                                  |

## WLM environment refresh stored procedure (WLM\_REFRESH)

The WLM\_REFRESH stored procedure refreshes a WLM environment. WLM\_REFRESH can recycle the environment in which it runs, as well as any other WLM environment.

### Environment for WLM\_REFRESH

WLM\_REFRESH runs in a WLM-established stored procedures address space. The load module for WLM\_REFRESH, DSNTWR, must reside in an APF-authorized library.

### Authorization required for WLM\_REFRESH

To execute the CALL statement, the SQL authorization ID of the process must have READ access or higher to the z/OS Security Server System Authorization Facility (SAF) resource profile *ssid.WLM\_REFRESH.WLM-environment-name* in resource class DSNR. This is a different resource profile from the *ssid.WLMENV.WLM-environment-name* resource profile, which DB2 uses to determine whether a stored procedure or user-defined function is authorized to run in the specified WLM environment.

WLM\_REFRESH uses an extended MCS console to monitor the operating system response to a WLM environment refresh request. The privilege to create an extended MCS console is controlled by the resource profile MVS.MCSOPER.\* in the OPERCMDS class. If the MVS.MCSOPER.\* profile exists, or if the specific profile MVS.MCSOPER.DSNTWR exists, the task ID that is associated with the WLM environment in which WLM\_REFRESH runs must have READ access to it.

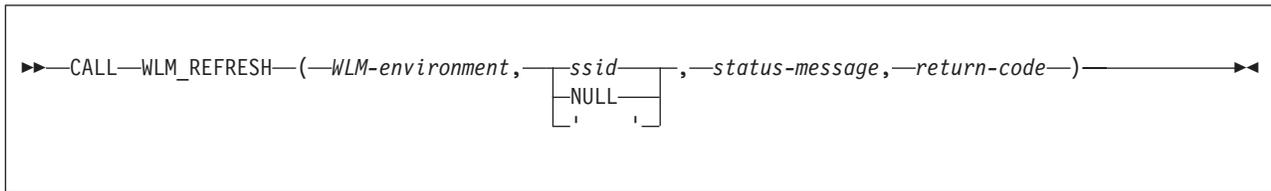

If the MVS.VARY.\* profile exists, or if the specific profile MVS.VARY.WLM exists, the task ID that is associated with the WLM environment in which WLM\_REFRESH runs must have CONTROL access to it.

See Chapter 11, “Controlling access to a DB2 subsystem,” on page 231 for information about authorizing access to SAF resource profiles. See *z/OS MVS Planning: Operations* for more information about permitting access to the extended MCS console.

## WLM\_REFRESH syntax diagram

The WLM\_REFRESH stored procedure refreshes a WLM environment. WLM\_REFRESH can recycle the environment in which it runs, as well as any other WLM environment.

The following syntax diagram shows the SQL CALL statement for invoking WLM\_REFRESH. The linkage convention for WLM\_REFRESH is GENERAL WITH NULLS.

## WLM\_REFRESH option descriptions

### *WLM-environment*

Specifies the name of the WLM environment that you want to refresh. This is an input parameter of type VARCHAR(32).

### *ssid*

Specifies the subsystem ID of the DB2 subsystem with which the WLM environment is associated. If this parameter is NULL or blank, DB2 uses one of the following values for this parameter:

- In a non-data sharing environment, DB2 uses the subsystem ID of the subsystem on which WLM\_REFRESH runs.
- In a data sharing environment, DB2 uses the group attach name for the data sharing group in which WLM\_REFRESH runs.

This is an input parameter of type VARCHAR(4).

### *status-message*

Contains an informational message about the execution of the WLM refresh. This is an output parameter of type VARCHAR(120).

### *return-code*

Contains the return code from the WLM\_REFRESH call, which is one of the following values:

- 0** WLM\_REFRESH executed successfully.
- 4** One of the following conditions exists:
  - The SAF resource profile `ssid.WLM_REFRESH.wlm-environment` is not defined in resource class DSNR.
  - The SQL authorization ID of the process (CURRENT SQLID) is not defined to SAF.
  - The wait time to obtain a response from z/OS was exceeded.
- 8** The SQL authorization ID of the process (CURRENT SQLID) is not authorized to refresh the WLM environment.

#

#  
#

- 990 DSNTWR received an unexpected SQLCODE while determining the current SQLID.
- 993 One of the following conditions exists:
- The *WLM-environment* parameter value is null, blank, or contains invalid characters.
  - The *ssid* value contains invalid characters.
- 994 The extended MCS console was not activated within the number of seconds indicated by message DSNT5461.
- 995 DSNTWR is not running as an authorized program.
- 996 DSNTWR could not activate an extended MCS console. See message DSNT533I for more information.
- 997 DSNTWR made an unsuccessful request for a message from its extended MCS console. See message DSNT533I for more information.
- 998 The extended MCS console for DSNTWR posted an alert. See message DSNT534I for more information.
- 999 The operating system denied an authorized WLM\_REFRESH request. See message DSNT545I for more information.

*return-code* is an output parameter of type INTEGER.

## Example of WLM\_REFRESH invocation

Suppose that you want to refresh WLM environment WLMENV1, which is associated with a DB2 subsystem with ID DSN. Assume that you already have READ access to the DSN.WLM\_REFRESH.WLMENV1 SAF profile. The CALL statement for WLM\_REFRESH looks like this:

```
strcpy(WLMENV,"WLMENV1");  
strcpy(SSID,"DSN");  
EXEC SQL CALL SYSPROC.WLM_REFRESH(:WLMENV, :SSID, :MSGTEXT, :RC);
```

For a complete example of setting up access to an SAF profile and calling WLM\_REFRESH, see job DSNTEJ6W, which is in data set DSN810.SDSNSAMP.

---

## The CICS transaction invocation stored procedure (DSNACICS)

The CICS transaction invocation stored procedure (DSNACICS) invokes CICS server programs. DSNACICS gives workstation applications a way to invoke CICS server programs while using TCP/IP as their communication protocol. The workstation applications use TCP/IP and DB2 Connect to connect to a DB2 UDB for z/OS subsystem, and then call DSNACICS to invoke the CICS server programs.

The DSNACICS input parameters require knowledge of various CICS resource definitions with which the workstation programmer might not be familiar. For this reason, DSNACICS invokes the DSNACICX user exit routine. The system programmer can write a version of DSNACICX that checks and overrides the parameters that the DSNACICS caller passes. If no user version of DSNACICX is provided, DSNACICS invokes the default version of DSNACICX, which does not modify any parameters.

## Environment for DSNACICS

DSNACICS runs in a WLM-established stored procedure address space and uses the Resource Recovery Services attachment facility to connect to DB2.

If you use CICS Transaction Server for OS/390 Version 1 Release 3 or later, you can register your CICS system as a resource manager with recoverable resource management services (RRMS). When you do that, changes to DB2 databases that are made by the program that calls DSNACICS and the CICS server program that DSNACICS invokes are in the same two-phase commit scope. This means that when the calling program performs an SQL COMMIT or ROLLBACK, DB2 and RRS inform CICS about the COMMIT or ROLLBACK.

If the CICS server program that DSNACICS invokes accesses DB2 resources, the server program runs under a separate unit of work from the original unit of work that calls the stored procedure. This means that the CICS server program might deadlock with locks that the client program acquires.

## Authorization required for DSNACICS

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

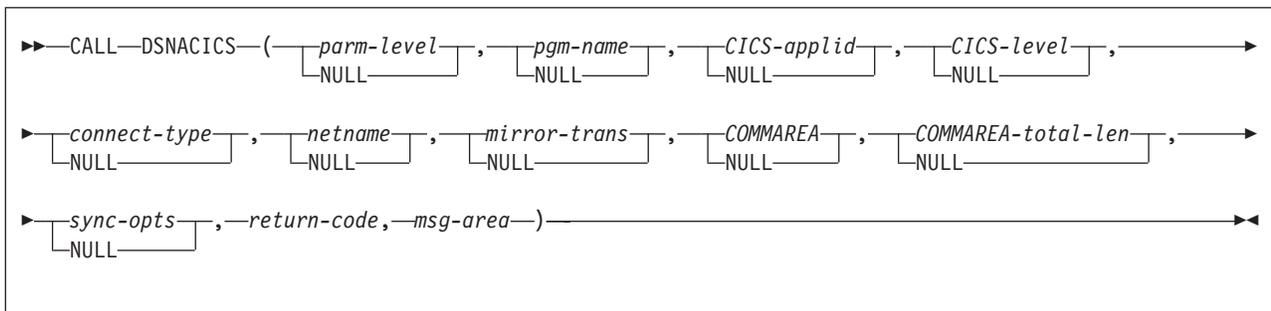

- The EXECUTE privilege on stored procedure DSNACICS
- Ownership of the stored procedure
- SYSADM authority

The CICS server program that DSNACICS calls runs under the same user ID as DSNACICS. That user ID depends on the SECURITY parameter that you specify when you define DSNACICS. See Part 2 of *DB2 Installation Guide*.

The DSNACICS caller also needs authorization from an external security system, such as RACF, to use CICS resources. See Part 2 of *DB2 Installation Guide*.

## DSNACICS syntax diagram

The following syntax diagram shows the SQL CALL statement for invoking DSNACICS. Because the linkage convention for DSNACICS is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

## DSNACICS option descriptions

*parm-level*

Specifies the level of the parameter list that is supplied to the stored procedure. This is an input parameter of type INTEGER. The value must be 1.

*pgm-name*

Specifies the name of the CICS program that DSNACICS invokes. This is the name of the program that the CICS mirror transaction calls, *not* the CICS transaction name. This is an input parameter of type CHAR(8).

*CICS-applid*

Specifies the applid of the CICS system to which DSNACICS connects. This is an input parameter of type CHAR(8).

*CICS-level*

Specifies the level of the target CICS subsystem:

- 1 The CICS subsystem is CICS for MVS/ESA Version 4 Release 1, CICS Transaction Server for OS/390 Version 1 Release 1, or CICS Transaction Server for OS/390 Version 1 Release 2.
- 2 The CICS subsystem is CICS Transaction Server for OS/390 Version 1 Release 3 or later.

This is an input parameter of type INTEGER.

*connect-type*

Specifies whether the CICS connection is generic or specific. Possible values are GENERIC or SPECIFIC. This is an input parameter of type CHAR(8).

*netname*

If the value of *connection-type* is SPECIFIC, specifies the name of the specific connection that is to be used. This value is ignored if the value of *connection-type* is GENERIC. This is an input parameter of type CHAR(8).

*mirror-trans*

Specifies the name of the CICS mirror transaction to invoke. This mirror transaction calls the CICS server program that is specified in the *pgm-name* parameter. *mirror-trans* must be defined to the CICS server region, and the CICS resource definition for *mirror-trans* must specify DFHMIRS as the program that is associated with the transaction.

If this parameter contains blanks, DSNACICS passes a mirror transaction parameter value of null to the CICS EXCI interface. This allows an installation to override the transaction name in various CICS user-replaceable modules. If a CICS user exit routine does not specify a value for the mirror transaction name, CICS invokes CICS-supplied default mirror transaction CSMI.

This is an input parameter of type CHAR(4).

COMMAREA

Specifies the communication area (COMMAREA) that is used to pass data between the DSNACICS caller and the CICS server program that DSNACICS calls. This is an input/output parameter of type VARCHAR(32704). In the length field of this parameter, specify the number of bytes that DSNACICS sends to the CICS server program.

*commarea-total-len*

Specifies the total length of the COMMAREA that the server program needs. This is an input parameter of type INTEGER. This length must be greater than or equal to the value that you specify in the length field of the COMMAREA parameter and less than or equal to 32704. When the CICS server program completes, DSNACICS passes the server program's entire COMMAREA, which is *commarea-total-len* bytes in length, to the stored procedure caller.

### *sync-opts*

Specifies whether the calling program controls resource recovery, using two-phase commit protocols that are supported by RRS. Possible values are:

- 1 The client program controls commit processing. The CICS server region does not perform a syncpoint when the server program returns control to CICS. Also, the server program cannot take any explicit syncpoints. Doing so causes the server program to abnormally terminate.
- 2 The target CICS server region takes a syncpoint on successful completion of the server program. If this value is specified, the server program can take explicit syncpoints.

When CICS has been set up to be an RRS resource manager, the client application can control commit processing using SQL COMMIT requests. DB2 UDB for z/OS ensures that CICS is notified to commit any resources that the CICS server program modifies during two-phase commit processing.

When CICS has not been set up to be an RRS resource manager, CICS forces syncpoint processing of all CICS resources at completion of the CICS server program. This commit processing is not coordinated with the commit processing of the client program.

This option is ignored when *CICS-level* is 1. This is an input parameter of type INTEGER.

### *return-code*

Return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The request to run the CICS server program failed. The *msg-area* parameter contains messages that describe the error.

This is an output parameter of type INTEGER.

### *msg-area*

Contains messages if an error occurs during stored procedure execution. The first messages in this area are generated by the stored procedure. Messages that are generated by CICS or the DSNACICX user exit routine might follow the first messages. The messages appear as a series of concatenated, viewable text strings. This is an output parameter of type VARCHAR(500).

## **DSNACICX user exit routine**

DSNACICS always calls user exit routine DSNACICX. You can use DSNACICX to change the values of DSNACICS input parameters before you pass those parameters to CICS. If you do not supply your own version of DSNACICX, DSNACICS calls the default DSNACICX, which modifies no values and does an immediate return to DSNACICS. The source code for the default version of DSNACICX is in member DSNASCIX in data set *prefix.SDSNSAMP*. The source code for a sample version of DSNACICX that is written in COBOL is in member DSNASCIO in data set *prefix.SDSNSAMP*.

### **General considerations for DSNACICX**

The DSNACICX exit routine must follow these rules:

- It can be written in assembler, COBOL, PL/I, or C.
- It must follow the Language Environment calling linkage when the caller is an assembler language program.

- The load module for DSNACICX must reside in an authorized program library that is in the STEPLIB concatenation of the stored procedure address space startup procedure.  
You can replace the default DSNACICX in the *prefix*.SDSNLOAD, library, or you can put the DSNACICX load module in a library that is ahead of *prefix*.SDSNLOAD in the STEPLIB concatenation. It is recommended that you put DSNACICX in the *prefix*.SDSNEXIT library. Sample installation job DSNTIJEX contains JCL for assembling and link-editing the sample source code for DSNACICX into *prefix*.SDSNEXIT. You need to modify the JCL for the libraries and the compiler that you are using.
- The load module must be named DSNACICX.
- The exit routine must save and restore the caller's registers. Only the contents of register 15 can be modified.
- It must be written to be reentrant and link-edited as reentrant.
- It must be written and link-edited to execute as AMODE(31),RMODE(ANY).
- DSNACICX can contain SQL statements. However, if it does, you need to change the DSNACICS procedure definition to reflect the appropriate SQL access level for the types of SQL statements that you use in the user exit routine.

### Specifying the DSNACICX exit routine

DSNACICS always calls an exit routine named DSNACICX. DSNACICS calls your DSNACICX exit routine if it finds it before the default DSNACICX exit routine. Otherwise, it calls the default DSNACICX exit routine.

### When the DSNACICX exit routine is taken

The DSNACICX exit routine is taken whenever DSNACICS is called. The exit routine is taken before DSNACICS invokes the CICS server program.

### Loading a new version of the DSNACICX exit routine

DB2 loads DSNACICX only once, when DSNACICS is first invoked. If you change DSNACICX, you can load the new version by quiescing and then resuming the WLM application environment for the stored procedure address space in which DSNACICS runs:

```
VARY WLM,APPLENV=DSNACICS-applenv-name,QUIESCE
VARY WLM,APPLENV=DSNACICS-applenv-name,RESUME
```

### Parameter list for DSNACICX

At invocation, registers are set as described in Table 339.

Table 339. Registers at invocation of DSNACICX

| Register | Contains                                             |
|----------|------------------------------------------------------|
| 1        | Address of pointer to the exit parameter list (XPL). |
| 13       | Address of the register save area.                   |
| 14       | Return address.                                      |
| 15       | Address of entry point of exit routine.              |

Table 340 on page 1292 shows the contents of the DSNACICX exit parameter list, XPL. Member DSNDXPL in data set *prefix*.SDSNMACS contains an assembler language mapping macro for XPL. Sample exit routine DSNASCIO in data set *prefix*.SDSNSAMP includes a COBOL mapping macro for XPL.

Table 340. Contents of the XPL exit parameter list

| Name            | Hex offset | Data type            | Description                                                         | Corresponding DSNACICS parameter |
|-----------------|------------|----------------------|---------------------------------------------------------------------|----------------------------------|
| XPL_EYEC        | 0          | Character, 4 bytes   | Eye-catcher: 'XPL '                                                 |                                  |
| XPL_LEN         | 4          | Character, 4 bytes   | Length of the exit parameter list                                   |                                  |
| XPL_LEVEL       | 8          | 4-byte integer       | Level of the parameter list                                         | <i>parm-level</i>                |
| XPL_PGMNAME     | C          | Character, 8 bytes   | Name of the CICS server program                                     | <i>pgm-name</i>                  |
| XPL_CICSAPPLID  | 14         | Character, 8 bytes   | CICS VTAM applid                                                    | <i>CICS-applid</i>               |
| XPL_CICSLEVEL   | 1C         | 4-byte integer       | Level of CICS code                                                  | <i>CICS-level</i>                |
| XPL_CONNECTTYPE | 20         | Character, 8 bytes   | Specific or generic connection to CICS                              | <i>connect-type</i>              |
| XPL_NETNAME     | 28         | Character, 8 bytes   | Name of the specific connection to CICS                             | <i>netname</i>                   |
| XPL_MIRRORTRAN  | 30         | Character, 8 bytes   | Name of the mirror transaction that invokes the CICS server program | <i>mirror-trans</i>              |
| XPL_COMMAREAPTR | 38         | Address, 4 bytes     | Address of the COMMAREA                                             | <sup>1</sup>                     |
| XPL_COMMINLEN   | 3C         | 4-byte integer       | Length of the COMMAREA that is passed to the server program         | <sup>2</sup>                     |
| XPL_COMMTOTLEN  | 40         | 4-byte integer       | Total length of the COMMAREA that is returned to the caller         | <i>commarea-total-len</i>        |
| XPL_SYNCOPTS    | 44         | 4-byte integer       | Syncpoint control option                                            | <i>sync-opts</i>                 |
| XPL_RETCODE     | 48         | 4-byte integer       | Return code from the exit routine                                   | <i>return-code</i>               |
| XPL_MSGLLEN     | 4C         | 4-byte integer       | Length of the output message area                                   | <i>return-code</i>               |
| XPL_MSGAREA     | 50         | Character, 256 bytes | Output message area                                                 | <i>msg-area</i> <sup>3</sup>     |

**Note:**

1. The area that this field points to is specified by DSNACICS parameter *COMMAREA*. This area does not include the length bytes.
2. This is the same value that the DSNACICS caller specifies in the length bytes of the *COMMAREA* parameter.
3. Although the total length of *msg-area* is 500 bytes, DSNACICX can use only 256 bytes of that area.

## Example of DSNACICS invocation

The following PL/I example shows the variable declarations and SQL CALL statement for invoking the CICS transaction that is associated with program CICSPGM1.

```

/*****
/* DSNACICS PARAMETERS */

                     :MSG_AREA            :IND_MSG_AREA);

```

## DSNACICS output

DSNACICS places the return code from DSNACICS execution in the *return-code* parameter. If the value of the return code is non-zero, DSNACICS puts its own error messages and any error messages that are generated by CICS and the DSNACICX user exit routine in the *msg-area* parameter.

The *COMMAREA* parameter contains the *COMMAREA* for the CICS server program that DSNACICS calls. The *COMMAREA* parameter has a *VARCHAR* type. Therefore, if the server program puts data other than character data in the *COMMAREA*, that data can become corrupted by code page translation as it is passed to the caller. To avoid code page translation, you can change the *COMMAREA* parameter in the *CREATE PROCEDURE* statement for DSNACICS to *VARCHAR(32704) FOR BIT DATA*. However, if you do so, the client program might need to do code page translation on any character data in the *COMMAREA* to make it readable.

## DSNACICS restrictions

Because DSNACICS uses the distributed program link (DPL) function to invoke CICS server programs, server programs that you invoke through DSNACICS can contain only the CICS API commands that the DPL function supports. The list of supported commands is documented in *CICS Transaction Server for z/OS Application Programming Reference*.

```
# DSNACICS does not propagate the transaction identifier (XID) of the thread. The
# stored procedure runs under a new private context rather than under the native
# context of the task that called it.
```

## DSNACICS debugging

If you receive errors when you call DSNACICS, ask your system administrator to add a *DSNDUMP DD* statement in the startup procedure for the address space in which DSNACICS runs. The *DSNDUMP DD* statement causes DB2 to generate an *SVC* dump whenever DSNACICS issues an error message.

---

## # The SYSIBM.USERNAMES encryption stored procedure

# The DSNLEUSR stored procedure is a sample stored procedure that lets you store encrypted values in the following fields of the SYSIBM.USERNAMES table.  
#  
# • The translated authorization ID (NEWAUTHID)  
# • The password (PASSWORD)

# You provide all the values for a SYSIBM.USERNAMES row as input to DSNLEUSR. DSNLEUSR encrypts the translated authorization ID and password values before it inserts the row into SYSIBM.USERNAMES.

## # Environment for DSNLEUSR

DSNLEUSR has the following requirements:

- The DB2 subsystem needs to be in DB2 Version 8 new-function mode.
- DSNLEUSR runs in a WLM-established stored procedure address space.
- z/OS Integrated Cryptographic Service Facility (ICSF) must be installed, configured, and active. The services that ICSF calls that are used by this stored procedure are CSNBCKM and CSNBENC. See *Integrated Cryptographic Service Facility System Programmer's Guide* for more information.

## # Authorization required for DSNLEUSR

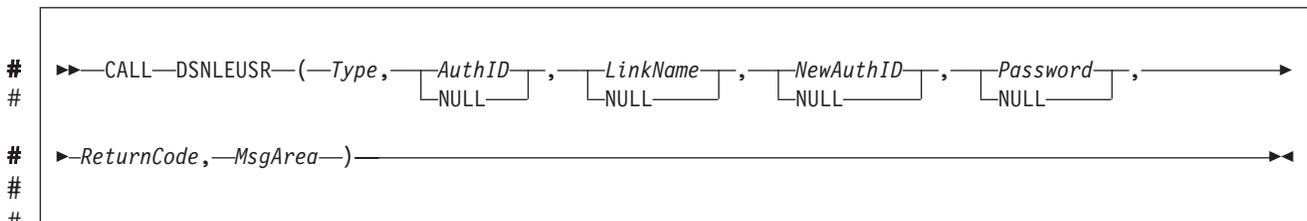

To execute the CALL DSNLEUSR statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the package for DSNLEUSR
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have INSERT authority on SYSIBM.USERNAMES.

## # DSNLEUSR syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNLEUSR. Because the linkage convention for DSNLEUSR is GENERAL WITH NULLS, if you pass parameters in host variables, you need to include a null indicator with every host variable. Null indicators for input host variables must be initialized before you execute the CALL statement.

## # DSNLEUSR option descriptions

*Type*

Specifies the value that is to be inserted into the TYPE column of SYSIBM.USERNAMES. *Type* is an input parameter of type CHAR(1).

*AuthID*

Specifies the value that is to be inserted into the AUTHID column of

# SYSIBM.USERNAMES. *AuthID* is an input parameter of type VARCHAR(128).  
# If you specify a null value, DSNLEUSR does not insert a value for *AuthID*.

# *LinkName*  
# Specifies the value that is to be inserted into the LINKNAME column of  
# SYSIBM.USERNAMES. *LinkName* is an input parameter of type CHAR(8).  
# Although the LINKNAME field of SYSIBM.USERNAMES is VARCHAR(24),  
# this value is restricted to a maximum of 8 bytes. If you specify a null value,  
# DSNLEUSR does not insert a value for *LinkName*.

# *NewAuthID*  
# Specifies the value that is to be inserted into the NEWAUTHID column of  
# SYSIBM.USERNAMES. *NewAuthID* is an input parameter of type  
# VARCHAR(54). The NEWAUTHID field is type VARCHAR(54) to allow for  
# expansion during encryption.  
# If you specify a null value, DSNLEUSR does not insert a value for *NewAuthID*.

# *Password*  
# Specifies the value that is to be inserted into the PASSWORD column of  
# SYSIBM.USERNAMES. *Password* is an input parameter of type CHAR(8).  
# Although the PASSWORD field of SYSIBM.USERNAMES is VARCHAR(24),  
# your input value is restricted to 8 or fewer bytes.  
# If you specify a null value, DSNLEUSR does not insert a value for *Password*.

# *ReturnCode*  
# The return code from DSNLEUSR execution. Possible values are:  
# 0 DSNLEUSR executed successfully.  
# 8 The request to encrypt the translated authorization ID or password  
# failed. *MsgArea* contains the following fields:  
# • An unformatted SQLCA that describes the error. See Appendix D of  
# *DB2 SQL Reference* for the description of the SQLCA.  
# • A string that contains a DSNL045I message with the ICSF return  
# code, the ICSF reason code, and the ICSF function that failed. The  
# string immediately follows the SQLCA field and does not begin with  
# a length field.  
# 12 The insert operation for the SYSIBM.USERNAMES row failed. *MsgArea*  
# contains an SQLCA that describes the error.  
# 16 DSNLEUSR terminated because the DB2 subsystem is not in DB2  
# Version 8 new-function mode. *MsgArea* contains an SQLCA that  
# describes the error.

# *ReturnCode* is an output parameter of type INTEGER.

# *MsgArea*  
# Contains information about DSNLEUSR execution. The information that is  
# returned is described in the *ReturnCode* description. *MsgArea* is an output  
# parameter of type VARCHAR(500).

## # Example of DSNLEUSR invocation

# Figure 194 on page 1297 is a COBOL example that shows variable declarations and  
# an SQL CALL for inserting a row into SYSIBM.USERNAMES with an encrypted  
# translated authorization ID and an encrypted password.  
#

---

## # IMS transactions stored procedure (DSNAIMS)

# DSNAIMS is a stored procedure that allows DB2 applications to invoke IMS  
# transactions and commands easily, without maintaining their own connections to  
# IMS. DSNAIMS uses the IMS Open Transaction Manager Access (OTMA) API to  
# connect to IMS and execute the transactions.

### # Environment for DSNAIMS

# DSNAIMS runs in a WLM-established stored procedures address space. DSNAIMS  
# requires DB2 with RRSAPF enabled and IMS version 7 or later with OTMA Callable  
# Interface enabled.

# To use a two-phase commit process, you must have IMS Version 8 with UQ70789  
# or later.

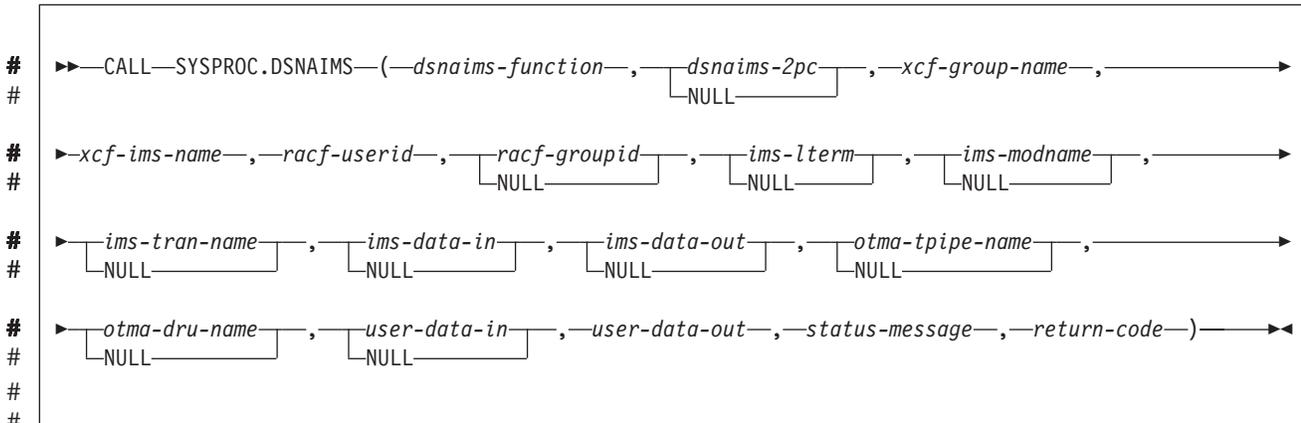

### # Authorization required for DSNAIMS

# To set up and run DSNAIMS, you must be authorized the perform the following  
# steps:

- # 1. Use the job DSNTIJIM to issue the CREATE PROCEDURE statement for  
# DSNAIMS and to grant the execution of DSNAIMS to PUBLIC. DSNTIJIM is  
# provided in the SDSNSAMP data set. You need to customize DSNTIJIM to fit  
# the parameters of your system.
- # 2. Ensure that OTMA C/I is initialized. Refer to IMS Open Transaction Manager  
# Access Guide and Reference for an explanation of the C/I initialization.

### # DSNAIMS syntax diagram

# The following syntax diagram shows the SQL CALL statement for invoking  
# DSNAIMS.

### # DSNAIMS option descriptions

# *dsnaims-function*  
# A string that indicates whether the transaction is send-only, receive-only, or  
# send-and-receive:

# **SENDRECV**  
# Sends and receives IMS data. SENDRECV invokes an IMS transaction  
# or command and returns the result to the caller. The transaction can be

```

#           an IMS full function or a fast path. SENDRECV does not support
#           multiple iterations of a conversational transaction
#
#           SEND Sends IMS data. SEND invokes an IMS transaction or command, but
#           does not receive IMS data. If result data exists, it can be retrieved with
#           the RECEIVE function. A send-only transaction cannot be an IMS fast
#           path transaction or a conversations transaction.
#
#           RECEIVE
#           Receives IMS data. The data can be the result of a transaction or
#           command initiated by the SEND function or an unsolicited output
#           message from an IMS application. The RECEIVE function does not
#           initiate an IMS transaction or command.
#
#           dsnaims-2pc
#
#           Specifies whether to use a two-phase commit process to perform the
#           transaction syncpoint service. Possible values are Y or N. For N, commits and
#           rollbacks that are issued by the IMS transaction do not affect commit and
#           rollback processing in the DB2 application that invokes DSNAIMS.
#           Furthermore, IMS resources are not affected by commits and rollbacks that are
#           issued by the calling DB2 application. If you specify Y, you must also specify
#           SENDRECV. To use a two-phase commit process, you must set the IMS control
#           region parameter (RRS) to Y.
#
#           This parameter is optional. The default is N.
#
#           xcf-group-name
#           Specifies the XCF group name that the IMS OTMA joins. You can obtain this
#           name by viewing the GRNAME parameter in IMS PROCLIB member
#           DFSPBxxx or by using the IMS command /DISPLAY OTMA.
#
#           xcf-ims-name
#           Specifies the XCF member name that IMS uses for the XCF group. If IMS is not
#           using the XRF or RSR feature, you can obtain the XCF member name from the
#           OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the
#           XRF or RSR feature, you can obtain the XCF member name from the USERVAR
#           parameter in IMS PROCLIB member DFSPBxxx.
#
#           racf-userid
#           Specifies the RACF user ID that is used for IMS to perform the transaction or
#           command authorization checking. This parameter is required if DSNAIMS is
#           running APF-authorized. If DSNAIMS is running unauthorized, this parameter
#           is ignored and the EXTERNAL SECURITY setting for the DSNAIMS stored
#           procedure definition determines the user ID that is used by IMS.
#
#           racf-groupid
#           Specifies the RACF group ID that is used for IMS to perform the transaction or
#           command authorization checking. racf_groupid is used for stored procedures
#           that are APF-authorized. It is ignored for other stored procedures.
#
#           ims-lterm
#           Specifies an IMS LTERM name that is used to override the LTERM name in the
#           I/O program communication block of the IMS application program. This field
#           is used as an input and an output field:
#
#           • For SENDRECV, the value is sent to IMS on input and can be updated by
#             IMS on output.
#
#           • For SEND, the parameter is IN only.
#
#           • For RECEIVE, the parameter is OUT only.
#
#           An empty or NULL value tells IMS to ignore the parameter.

```

```

#
# ims-modname
# Specifies the formatting map name that is used by the server to map output
# data streams, such as 3270 streams. Although this invocation does not have
# IMS MFS support, the input MODNAME can be used as the map name to
# define the output data stream. This name is an 8-byte message output
# descriptor name that is placed in the I/O program communication block.
# When the message is inserted, IMS places this name in the message prefix with
# the map name in the program communication block of the IMS application
# program.
#
# For SENDRECV, the value is sent to IMS on input, and can be updated on
# output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS
# ignores the parameter when it is an empty or NULL value.
#
# ims-tran-name
# Specifies the name of an IMS transaction or command that is sent to IMS. If
# the IMS command is longer than eight characters, specify the first eight
# characters (including the "/" of the command). Specify the remaining
# characters of the command in the ims-tran-name parameter. If you use an empty
# or NULL value, you must specify the full transaction name or command in the
# ims-data-in parameter.
#
# ims-data-in
# Specifies the data that is sent to IMS. This parameter is required in each of the
# following cases:
#
# • Input data is required for IMS
#
# • No transaction name or command is passed in ims-tran-name
#
# • The command is longer than eight characters
#
# This parameter is ignored when for RECEIVE functions.
#
# ims-data-out
# Data returned after successful completion of the transaction. This parameter is
# required for SENDRECV and RECEIVE functions. The parameter is ignored for
# SEND functions.
#
# otma-tpipe-name
# Specifies an 8-byte user-defined communication session name that IMS uses for
# the input and output data for the transaction or the command in a SEND or a
# RECEIVE function. If the otma_tpipe_name parameter is used for a SEND
# function to generate an IMS output message, the same otma_pipe_name must
# be used to retrieve output data for the subsequent RECEIVE function.
#
# otma-dru-name
# Specifies the name of an IMS user-defined exit routine, OTMA destination
# resolution user exit routine, if it is used. This IMS exit routine can format part
# of the output prefix and can determine the output destination for an IMS
# ALT_PCB output. If an empty or null value is passed, IMS ignores this
# parameter.
#
# user-data-in
# This optional parameter contains any data that is to be included in the IMS
# message prefix, so that the data can be accessed by IMS OTMA user exit
# routines (DFSYIOE0 and DFSYDRU0) and can be tracked by IMS log records.
# IMS applications that run in dependent regions do not access this data. The
# specified user data is not included in the output message prefix. You can use
# this parameter to store input and output correlator tokens or other information.
# This parameter is ignored for RECEIEVE functions.
#

```

```

#          user-data-out
#          On output, this field contains the user-data-in in the IMS output prefix. IMS
#          user exit routines (DFSYIOE0 and DFSYDRU0) can also create user-data-out for
#          SENDRECV and RECEIVE functions. The parameter is not updated for SEND
#          functions.
#
#          status-message
#          Indicates any error message that is returned from the transaction or command,
#          OTMA, RRS, or DSNAIMS.
#
#          return-code
#          Indicates the return code that is returned for the transaction or command,
#          OTMA, RRS, or DSNAIMS.

```

## Examples of DSNAIMS invocation

The following examples show how to call DSNAIMS.

**Example 1:** Sample parameters for executing an IMS command:

```

CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCCLNM", "", "", "", "", "",
                    "/LOG Hello World.", ims_data_out, "", "", "",
                    user_out, error_message, rc)

```

**Example 2:** Sample parameters for executing an IMS IVTNO transaction:

```

CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCCLNM", "", "", "", "", "",
                    "IVTNO DISPLAY LAST1      ", ims_data_out
                    "", "", "", user_out, error_message, rc)

```

**Example 3:** Sample parameters for send-only IMS transaction:

```

CALL SYSPROC.DSNAIMS("SEND", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCCLNM", "", "", "", "", "",
                    "IVTNO DISPLAY LAST1      ", ims_data_out,
                    "DSNAIPIPE", "", "", user_out, error_message, rc)

```

**Example 4:** Sample parameters for receive-only IMS transaction:

```

CALL SYSPROC.DSNAIMS("RECEIVE", "N", "IMS7GRP", "IMS7TMEM",
                    "IMSCCLNM", "", "", "", "", "",
                    "IVTNO DISPLAY LAST1      ", ims_data_out,
                    "DSNAIPIPE", "", "", user_out, error_message, rc)

```

## Connecting to multiple IMS subsystems with DSNAIMS

By default DSNAIMS connects to only one IMS subsystem at a time. The first request to DSNAIMS determines to which IMS subsystem the stored procedure connects. DSNAIMS attempts to reconnect to IMS only in the following cases:

- IMS is restarted and the saved connection is no longer valid
- WLM loads another DSNAIMS task

To connect to multiple IMS subsystems simultaneously, perform the following steps:

1. Make a copy of the DB2-supplied job DSNTIJIM and customize it to your environment.
2. Change the procedure name from SYSPROCC.DSNAIMS to another name, such as DSNAIMSB.
3. Do not change the EXTERNAL NAME option. Leave it as DSNAIMS.
4. Run the new job to create a second instance of the stored procedure.

# 5. To ensure that you connect to the intended IMS target, consistently use the XFC  
# group and member names that you associate with each stored procedure  
# instance.

# **Example:**

```
# CALL SYSPROC.DSNAIMS("SENDRECV", "N", "IMS7GRP", "IMS7TMEM", ...)  
# CALL SYSPROC.DSNAIMSB("SENDRECV", "N", "IMS8GRP", "IMS8TMEM", ...)
```

---

## # **IMS transactions stored procedure (DSNAIMS2)**

# DSNAIMS2 is a stored procedure that allows DB2 applications to invoke IMS  
# transactions and commands easily, without maintaining their own connections to  
# IMS. DSNAIMS2 includes multi-segment input support for IMS transactions.

# DSNAIMS2 uses the IMS Open Transaction Manager Access (OTMA) API to  
# connect to IMS and execute the transactions.

# When you define the DSNAIMS2 stored procedure to your DB2 subsystem, you  
# can use the name DSNAIMS in your application if you prefer. Customize DSNTIJI2  
# to define the stored procedure to your DB2 subsystem as DSNAIMS; however, the  
# EXTERNAL NAME option must still be DSNAIMS2.

## # **Environment for DSNAIMS2**

# DSNAIMS2 runs in a WLM-established stored procedures address space.  
# DSNAIMS2 requires DB2 with RRSF enabled and IMS version 7 or later with  
# OTMA Callable Interface enabled.

# To use a two-phase commit process, you must have IMS Version 8 with UQ70789  
# or later.

## # **Authorization required for DSNAIMS2**

# To set up and run DSNAIMS2, you must be authorized to perform the following  
# steps:

- # 1. Use the job DSNTIJI2 to issue the CREATE PROCEDURE statement for  
# DSNAIMS2 and to grant the execution of DSNAIMS2 to PUBLIC. DSNTIJI2 is  
# provided in the SDSNSAMP data set. You need to customize DSNTIJI2 to fit  
# the parameters of your system.
- # 2. Ensure that OTMA C/I is initialized. Refer to IMS Open Transaction Manager  
# Access Guide and Reference for an explanation of the C/I initialization.

## # **DSNAIMS2 syntax diagram**

# The following syntax diagram shows the SQL CALL statement for invoking  
# DSNAIMS2.

```

# ►►CALL—SYSPROC.DSNAIMS2—(—dsnaims-function—, —dsnaims-2pc—, —xcf-group-name—, —————►

#

```

## DSNAIMS2 option descriptions

### *dsnaims-function*

A string that indicates whether the transaction is send-only, receive-only, or send-and-receive:

#### **SENDRECV**

Sends and receives IMS data. SENDRECV invokes an IMS transaction or command and returns the result to the caller. The transaction can be an IMS full function or a fast path. SENDRECV does not support multiple iterations of a conversational transaction

**SEND** Sends IMS data. SEND invokes an IMS transaction or command, but does not receive IMS data. If result data exists, it can be retrieved with the RECEIVE function. A send-only transaction cannot be an IMS fast path transaction or a conversational transaction.

#### **RECEIVE**

Receives IMS data. The data can be the result of a transaction or command initiated by the SEND function or an unsolicited output message from an IMS application. The RECEIVE function does not initiate an IMS transaction or command.

### *dsnaims-2pc*

Specifies whether to use a two-phase commit process to perform the transaction syncpoint service. Possible values are Y or N. For N, commits and rollbacks that are issued by the IMS transaction do not affect commit and rollback processing in the DB2 application that invokes DSNAIMS2. Furthermore, IMS resources are not affected by commits and rollbacks that are issued by the calling DB2 application. If you specify Y, you must also specify SENDRECV. To use a two-phase commit process, you must set the IMS control region parameter (RRS) to Y.

This parameter is optional. The default is N.

### *xcf-group-name*

Specifies the XCF group name that the IMS OTMA joins. You can obtain this name by viewing the GRNAME parameter in IMS PROCLIB member DFSPBxxx or by using the IMS command /DISPLAY OTMA.

### *xcf-ims-name*

Specifies the XCF member name that IMS uses for the XCF group. If IMS is not

# using the XRF or RSR feature, you can obtain the XCF member name from the  
# OTMANM parameter in IMS PROCLIB member DFSPBxxx. If IMS is using the  
# XRF or RSR feature, you can obtain the XCF member name from the USERVAR  
# parameter in IMS PROCLIB member DFSPBxxx.

# *racf-userid*

# Specifies the RACF user ID that is used for IMS to perform the transaction or  
# command authorization checking. This parameter is required if DSNAIMS2 is  
# running APF-authorized. If DSNAIMS2 is running unauthorized, this  
# parameter is ignored and the EXTERNAL SECURITY setting for the  
# DSNAIMS2 stored procedure definition determines the user ID that is used by  
# IMS.

# *racf-groupid*

# Specifies the RACF group ID that is used for IMS to perform the transaction or  
# command authorization checking. *racf\_groupid* is used for stored procedures  
# that are APF-authorized. It is ignored for other stored procedures.

# *ims-lterm*

# Specifies an IMS LTERM name that is used to override the LTERM name in the  
# I/O program communication block of the IMS application program. This field  
# is used as an input and an output field:

- # • For SENDRECV, the value is sent to IMS on input and can be updated by  
# IMS on output.
- # • For SEND, the parameter is IN only.
- # • For RECEIVE, the parameter is OUT only.

# An empty or NULL value tells IMS to ignore the parameter.

# *ims-modname*

# Specifies the formatting map name that is used by the server to map output  
# data streams, such as 3270 streams. Although this invocation does not have  
# IMS MFS support, the input MODNAME can be used as the map name to  
# define the output data stream. This name is an 8-byte message output  
# descriptor name that is placed in the I/O program communication block.  
# When the message is inserted, IMS places this name in the message prefix with  
# the map name in the program communication block of the IMS application  
# program.

# For SENDRECV, the value is sent to IMS on input, and can be updated on  
# output. For SEND, the parameter is IN only. For RECEIVE it is OUT only. IMS  
# ignores the parameter when it is an empty or NULL value.

# *ims-tran-name*

# Specifies the name of an IMS transaction or command that is sent to IMS. If  
# the IMS command is longer than eight characters, specify the first eight  
# characters (including the "/" of the command). Specify the remaining  
# characters of the command in the *ims-tran-name* parameter. If you use an empty  
# or NULL value, you must specify the full transaction name or command in the  
# *ims-data-in* parameter.

# *ims-data-in*

# Specifies the data that is sent to IMS. This parameter is required in each of the  
# following cases:

- # • Input data is required for IMS
- # • No transaction name or command is passed in *ims-tran-name*
- # • The command is longer than eight characters

# This parameter is ignored when for RECEIVE functions.

```

#           ims-data-out
#           Data returned after successful completion of the transaction. This parameter is
#           required for SENDRECV and RECEIVE functions. The parameter is ignored for
#           SEND functions.

#           otma-tpipe-name
#           Specifies an 8-byte user-defined communication session name that IMS uses for
#           the input and output data for the transaction or the command in a SEND or a
#           RECEIVE function. If the otma_tpipe_name parameter is used for a SEND
#           function to generate an IMS output message, the same otma_pipe_name must
#           be used to retrieve output data for the subsequent RECEIVE function.

#           otma-dru-name
#           Specifies the name of an IMS user-defined exit routine, OTMA destination
#           resolution user exit routine, if it is used. This IMS exit routine can format part
#           of the output prefix and can determine the output destination for an IMS
#           ALT_PCB output. If an empty or null value is passed, IMS ignores this
#           parameter.

#           user-data-in
#           This optional parameter contains any data that is to be included in the IMS
#           message prefix, so that the data can be accessed by IMS OTMA user exit
#           routines (DFSYIOE0 and DFSYDRU0) and can be tracked by IMS log records.
#           IMS applications that run in dependent regions do not access this data. The
#           specified user data is not included in the output message prefix. You can use
#           this parameter to store input and output correlator tokens or other information.
#           This parameter is ignored for RECEIVE functions.

#           user-data-out
#           On output, this field contains the user-data-in in the IMS output prefix. IMS
#           user exit routines (DFSYIOE0 and DFSYDRU0) can also create user-data-out for
#           SENDRECV and RECEIVE functions. The parameter is not updated for SEND
#           functions.

#           status-message
#           Indicates any error message that is returned from the transaction or command,
#           OTMA, RRS, or DSNAIMS2.

#           otma-data-inseg
#           Specifies the number of segments followed by the lengths of the segments to
#           be sent to IMS. All values should be separated by semicolons. This field is
#           required to send multi-segment input to IMS. For single-segment transactions
#           and commands, set the field to NULL, "0" or "0;".

#           return-code
#           Indicates the return code that is returned for the transaction or command,
#           OTMA, RRS, or DSNAIMS2.

```

## Examples of DSNAIMS2 invocation

The following examples show how to call DSNAIMS2.

**Example 1:** Sample parameters for executing a multi-segment IMS transaction:

```

CALL SYSPROC.DSNAIMS2("SEND","N","IMS7GRP","IMS7TMEM",
                     "IMSCLNM","","","","","","",
                     "PART 1ST SEGMENT FROM CI 2ND SEGMENT FROM CI ",
                     ims_data_out,"","","",user_out, error_message,
                     "2;25;20",rc)

```

```

#           Example 2: Sample parameters for executing a single-segment IMS IVTNO
#           transaction:
#           CALL SYSPROC.DSNAIMS2("SEND", "N", "IMS7GRP", "IMS7TMEM",
#           "IMSCLNM", "", "", "", "", "IVTNO",
#           "DISPLAY LAST1", ims_data_out, "", "", "",
#           user_out, error_message, NULL, rc)

```

## Connecting to multiple IMS subsystems with DSNAIMS2

```

#           By default DSNAIMS2 connects to only one IMS subsystem at a time. The first
#           request to DSNAIMS2 determines to which IMS subsystem the stored procedure
#           connects. DSNAIMS2 attempts to reconnect to IMS only in the following cases:
#           • IMS is restarted and the saved connection is no longer valid
#           • WLM loads another DSNAIMS2 task

```

```

#           To connect to multiple IMS subsystems simultaneously, perform the following
#           steps:

```

1. Make a copy of the DB2-supplied job DSNTIJI2 and customize it to your environment.
2. Change the procedure name from SYSPROCC.DSNAIMS2 to another name, such as DSNAIMS2B.
3. Do not change the EXTERNAL NAME option. Leave it as DSNAIMS2.
4. Change the name of the stored procedure in the grant statement in job DSNTIJI2.
5. Run the new job to create a second instance of the stored procedure.
6. To ensure that you connect to the intended IMS target, consistently use the XFC group and member names that you associate with each stored procedure instance.

```

#           Example:

```

```

#           CALL SYSPROC.DSNAIMS2("SENDRECV", "N", "IMS7GRP", "IMS7TMEM", ...)
#           CALL SYSPROC.DSNAIMS2B("SENDRECV", "N", "IMS8GRP", "IMS8TMEM", ...)

```

---

## The DB2 EXPLAIN stored procedure

The information under this heading is Product-sensitive Programming Interface and Associated Guidance Information, as defined in “Notices” on page 1437.

The DSNAEXP stored procedure is a sample stored procedure that lets users perform an EXPLAIN on an SQL statement without having the authorization to execute that SQL statement.

**Note:** The DSNAEXP stored procedure replaces the DSN8EXP stored procedure for DB2 Version 8 new function mode. In DB2 Version 8 compatibility mode you must use the DSN8EXP stored procedure.

## Environment

DSNAEXP must run in a WLM-established stored procedure address space.

Before you can invoke DSNAEXP, table *sqlid*.PLAN\_TABLE must exist. *sqlid* is the value that you specify for the *sqlid* input parameter when you call DSNAEXP.

Job DSNTESC in DSN8810.SDSNSAMP contains a sample CREATE TABLE statement for the PLAN\_TABLE.

## Authorization required

To execute the CALL DSN8.DSNAEXP statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

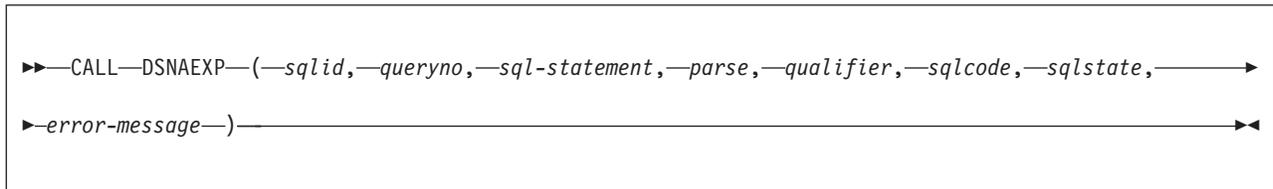

- The EXECUTE privilege on the package for DSNAEXP
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

In addition:

- The SQL authorization ID of the process in which DSNAEXP is called must have the authority to execute SET CURRENT SQLID=*sqlid*.
- The SQL authorization ID of the process must also have one of the following characteristics:
  - Be the owner of a plan table named PLAN\_TABLE
  - Have an alias on a plan table named *owner*.PLAN\_TABLE and have SELECT and INSERT privileges on the table

## DSNAEXP syntax diagram

The following syntax diagram shows the CALL statement for invoking DSNAEXP. Because the linkage convention for DSNAEXP is GENERAL, you cannot pass null values to the stored procedure.

## DSNAEXP option descriptions

*sqlid*

Specifies:

- The authorization ID under which the EXPLAIN statement is to be executed
- The qualifier for the table into which EXPLAIN output is written:  
*sqlid*.PLAN\_TABLE
- The implicit qualifier for unqualified objects in the SQL statement on which EXPLAIN is executed, if the value of *parse* is 'N'

*sqlid* is an input parameter of type CHAR(8).

*queryno*

Specifies a number that is to be used to identify *sql-statement* in the EXPLAIN output. This number appears in the QUERYNO column in the PLAN\_TABLE.

*queryno* is an input parameter of type INTEGER.

*sql-statement*

Specifies the SQL statement on which EXPLAIN is to be executed. *sql-statement* is an input parameter of type CLOB(2M).

*parse*

Specifies whether DSNAEXP adds a qualifier for unqualified table or view

names in the input SQL statement. Valid values are 'Y' and 'N'. If the value of *parse* is 'Y', *qualifier* must contain a valid SQL qualifier name.

If *sql-statement* is insert-within-select and common table expressions, you need to disable the parsing functionality, and add the qualifier manually.

*parse* is an input parameter of type CHAR(1).

#### *qualifier*

Specifies the qualifier that DSNAEXP adds to unqualified table or view names in the input SQL statement. If the value of *parse* is 'N', *qualifier* is ignored.

If the statement on which EXPLAIN is run contains an INSERT within a SELECT or a common table expression, *parse* must be 'N', and table and view qualifiers must be explicitly specified.

*qualifier* is an input parameter of type CHAR(8).

#### *sqlcode*

Contains the SQLCODE from execution of the EXPLAIN statement. *sqlcode* is an output parameter of type INTEGER.

#### *sqlstate*

Contains the SQLSTATE from execution of the EXPLAIN statement. *sqlstate* is an output parameter of type CHAR(5).

#### *error-message*

Contains information about DSNAEXP execution. If the SQLCODE from execution of the EXPLAIN statement is not 0, *error-message* contains the error message for the SQLCODE. *error-message* is an output parameter of type VARCHAR(960).

## Example of DSNAEXP invocation

The following C example shows how to call DSNAEXP to execute an EXPLAIN statement.

```
EXEC SQL BEGIN DECLARE SECTION;
char      hvsqlid[9];           /* Qualifier for PLAN_TABLE */
long int  hvqueryno;           /* QUERYNO to give the SQL */
struct {
    short int hvsql_stmt_len;   /* Input SQL statement length */
    char      hvsql_stmt_txt SQL TYPE IS CLOB 2M;
                                /* SQL statement text */
}         hvsql_stmt ;        /* SQL statement to EXPLAIN */
char      hvparse[1];          /* Qualify object names */
char      hvqualifier[9];      /* indicator */
char      hvqualifier[9];      /* Qualifier for unqualified */
                                /* objects */
long int  hvsqlcode;           /* SQLCODE from CALL DSNAEXP */
char      hvsqlstate[6];       /* SQLSTATE from CALL DSNAEXP */
struct {
    short int hvmsg_len;        /* Error message length */
    char      hvmsg_text[961];  /* Error message text */
}         hvmsg;              /* Error message from failed */
                                /* CALL DSNAEXP */

EXEC SQL END DECLARE SECTION;
short int i;
:
:
/* Set the input parameters */
strcpy(hvsqlid,"ADMFO01 ");
hvqueryno=320;
strcpy(hvsql_stmt.hvsql_stmt_text,"SELECT CURRENT DATE FROM SYSDDUMMY1");
hvsql_stmt.hvsql_stmt_len=strlen(hvsql_stmt.hvsql_stmt_text);
hvparse[0]='Y';
strcpy(hvqualifier,"SYSIBM");
```

```

/* Initialize the output parameters */
hvsqlcode=0;
for (i = 0; i < 5; i++) hvsqlstate[i] = '0';
hvsqlstate[5]='\0';
hvmsg.hvmsg_len=0;
for (i = 0; i < 960; i++) hvmsg.hvmsg_text[i] = ' ';
hvmsg.hvmsg_text[960] = '\0';
/* Call DSNAXP to do EXPLAIN and put output in ADMF001.PLAN_TABLE */
EXEC SQL
    CALL DSN8.DSNAEXP(:hvsqlid,
                     :hvqueryno,
                     :hvsql_stmt,
                     :hvparse,
                     :hvqualifier,
                     :hvsqlcode,
                     :hvsqlstate,
                     :hvmsg);

```

## DSNAEXP output

If DSNAXP executes successfully, *sqlid.PLAN\_TABLE* contains the EXPLAIN output. A user with SELECT authority on *sqlid.PLAN\_TABLE* can obtain the results of the EXPLAIN that was executed by DSNAXP by executing this query:

```
SELECT * FROM sqlid.PLAN_TABLE WHERE QUERYNO='queryno';
```

If DSNAXP does not execute successfully, *sqlcode*, *sqlstate*, and *error-message* contain error information.

---

## ADMIN\_COMMAND\_DB2 stored procedure

The SYSPROC.ADMIN\_COMMAND\_DB2 stored procedure executes one or more DB2 commands on a connected DB2 subsystem or on a DB2 data sharing group member and returns the command output messages.

**GUPI**

### Environment

ADMIN\_COMMAND\_DB2 must run in a WLM-established stored procedure address space.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCD
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

To execute the DB2 command, you must use a privilege set that includes the authorization to execute the DB2 command, as described in the *DB2 Command Reference*.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_COMMAND_DB2(—DB2-command,—command-length,—parse-type,—
—DB2-member,—commands-executed,—IFI-return-code,—IFI-reason-code,—excess-bytes,—
NULL,—
—group-IFI-reason-code,—group-excess-bytes,—return-code,—message—)
```

## Option descriptions

### *DB2-command*

Specifies any DB2 command such as `-DISPLAY THREAD(*)`, or multiple DB2 commands. With multiple DB2 commands, use `'\0'` to delimit the commands. The DB2 command is executed using the authorization ID of the user who invoked the stored procedure.

This is an input parameter of type `VARCHAR(32704)` and cannot be null.

### *command-length*

Specifies the length of the DB2 command or commands. When multiple DB2 commands are specified in *DB2-command*, *command-length* is the sum of all of those commands, including the `'\0'` command delimiters.

This is an input parameter of type `INTEGER` and cannot be null.

### *parse-type*

Identifies the type of output message parsing requested.

If you specify a parse type, `ADMIN_COMMAND_DB2` parses the command output messages and provides the formatted result in a global temporary table. Possible values are:

- BP** Parse `"-DISPLAY BUFFERPOOL"` command output messages.
- DB** Parse `"-DISPLAY DATABASE"` command output messages and return database information.
- TS** Parse `"-DISPLAY DATABASE(...) SPACENAM(...)"` command output messages and return table spaces information.
- IX** Parse `"-DISPLAY DATABASE(...) SPACENAM(...)"` command output messages and return index spaces information.
- THD** Parse `"-DISPLAY THREAD"` command output messages.
- UT** Parse `"-DISPLAY UTILITY"` command output messages.
- GRP** Parse `"-DISPLAY GROUP"` command output messages.
- DDF** Parse `"-DISPLAY DDF"` command output messages.

### **Any other value**

Do not parse any command output messages.

This is an input parameter of type `VARCHAR(3)` and cannot be null.

| *DB2-member*

| Specifies the name of a single data sharing group member on which an IFI  
| request is to be executed

| This is an input parameter of type VARCHAR(8).

| *commands-executed*

| Provides the number of commands that were executed

| This is an output parameter of type INTEGER.

| *IFI-return-code*

| Provides the IFI return code

| This is an output parameter of type INTEGER.

| *IFI-reason-code*

| Provides the IFI reason code

| This is an output parameter of type INTEGER.

| *excess-bytes*

| Indicates the number of bytes that did not fit in the return area

| This is an output parameter of type INTEGER.

| *group-IFI-reason-code*

| Provides the reason code for the situation in which an IFI call requests data  
| from members of a data sharing group, and not all the data is returned from  
| group members.

| This is an output parameter of type INTEGER.

| *group-excess-bytes*

| Indicates the total length of data that was returned from other data sharing  
| group members and did not fit in the return area

| This is an output parameter of type INTEGER.

| *return-code*

| Provides the return code from the stored procedure. Possible values are:

| **0** The stored procedure did not encounter an SQL error during  
| processing. Check the *IFI-return-code* value to determine whether the  
| DB2 command issued using the instrumentation facility interface (IFI)  
| was successful or not.

| **12** The stored procedure encountered an SQL error during processing. The  
| *message* output parameter contains messages describing the SQL error.

| This is an output parameter of type INTEGER.

| *message*

| Contains messages describing the SQL error encountered by the stored  
| procedure. If no SQL error occurred, then no message is returned.

| The first messages in this area are generated by the stored procedure. Messages  
| that are generated by DB2 might follow the first messages.

| This is an output parameter of type VARCHAR(1331).

| **Example**

| The following C language sample shows how to invoke  
| ADMIN\_COMMAND\_DB2:

```

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/

}
return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1310:

- *commands-executed*
- *IFI-return-code*
- *IFI-reason-code*
- *excess-bytes*
- *group-IFI-reason-code*
- *group-excess-bytes*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns two result sets.

The first result set is returned in the created global temporary table SYSIBM.DB2\_CMD\_OUTPUT and contains the DB2 command output messages that were not parsed.

The following table shows the format of the first result set:

*Table 341. Result set row for first ADMIN\_COMMAND\_DB2 result set*

| Column name | Data type | Contents                                             |
|-------------|-----------|------------------------------------------------------|
| ROWNUM      | INTEGER   | Sequence number of the table row, from 1 to <i>n</i> |
| TEXT        | CHAR(80)  | DB2 command output message line                      |

The format of the second result set varies, depending on the DB2 command issued and the *parse-type* value.

- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = “BP”)
- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = “THD”)
- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = “UT”)
- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = “DB” or “TS” or “IX”)

- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = "GRP")
- Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = "DDF")

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BUFFERPOOL\_STATUS when *parse-type* = "BP":

Table 342. Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = "BP")

| Column name | Data type | Contents                                                                                            |
|-------------|-----------|-----------------------------------------------------------------------------------------------------|
| ROWNUM      | INTEGER   | Sequence number of the table row, from 1 to <i>n</i>                                                |
| BPNAME      | CHAR(6)   | Buffer pool name                                                                                    |
| VPSIZE      | INTEGER   | Buffer pool size                                                                                    |
| VPSEQT      | INTEGER   | Sequential steal threshold for the buffer pool                                                      |
| VPPSEQT     | INTEGER   | Parallel sequential threshold for the buffer pool                                                   |
| VPXPSEQT    | INTEGER   | Assisting parallel sequential threshold for the buffer pool                                         |
| DWQT        | INTEGER   | Deferred write threshold for the buffer pool                                                        |
| PCT_VDWQT   | INTEGER   | Vertical deferred write threshold for the buffer pool (as a percentage of virtual buffer pool size) |
| ABS_VDWQT   | INTEGER   | Vertical deferred write threshold for the buffer pool (as absolute number of buffers)               |
| PGSTEAL     | CHAR(4)   | Page-stealing algorithm that DB2 uses for the buffer pool                                           |
| ID          | INTEGER   | Buffer pool internal identifier                                                                     |
| USE_COUNT   | INTEGER   | Number of open table spaces or index spaces that reference this buffer pool                         |
| PGFIX       | CHAR(3)   | Specifies whether the buffer pool should be fixed in real storage when it is used                   |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB2\_THREAD\_STATUS when *parse-type* = "THD":

Table 343. Result set row for second ADMIN\_COMMAND\_DB2 result set (*parse-type* = "THD")

| Column name | Data type | Contents                                             |
|-------------|-----------|------------------------------------------------------|
| ROWNUM      | INTEGER   | Sequence number of the table row, from 1 to <i>n</i> |

Table 343. Result set row for second ADMIN\_COMMAND\_DB2 result set (parse-type = "THD") (continued)

| Column name | Data type     | Contents                                                                                             |
|-------------|---------------|------------------------------------------------------------------------------------------------------|
| TYPE        | INTEGER       | Thread type:<br>0 Unknown<br>1 Active<br>2 Inactive<br>3 Indoubt<br>4 Postponed                      |
| NAME        | CHAR(8)       | Connection name used to establish the thread                                                         |
| STATUS      | CHAR(11)      | Status of the conversation or socket                                                                 |
| ACTIVE      | CHAR(1)       | Indicates whether a thread is active or not. An asterisk means that the thread is active within DB2. |
| REQ         | CHAR(5)       | Current number of DB2 requests on the thread                                                         |
| ID          | CHAR(12)      | Recovery correlation ID associated with the thread                                                   |
| AUTHID      | CHAR(8)       | Authorization ID associated with the thread                                                          |
| PLAN        | CHAR(8)       | Plan name associated with the thread                                                                 |
| ASID        | CHAR(4)       | Address space identifier                                                                             |
| TOKEN       | CHAR(6)       | Unique thread identifier                                                                             |
| COORDINATOR | CHAR(46)      | Name of the two-phase commit coordinator                                                             |
| RESET       | CHAR(5)       | Indicates whether or not the thread needs to be reset to purge info from the indoubt thread report   |
| URID        | CHAR(12)      | Unit of recovery identifier                                                                          |
| LUWID       | CHAR(35)      | Logical unit of work ID of the thread                                                                |
| WORKSTATION | CHAR(18)      | Client workstation name                                                                              |
| USERID      | CHAR(16)      | Client user ID                                                                                       |
| APPLICATION | CHAR(32)      | Client application name                                                                              |
| ACCOUNTING  | CHAR(247)     | Client accounting information                                                                        |
| LOCATION    | VARCHAR(4050) | Location name of the remote system                                                                   |
| DETAIL      | VARCHAR(4050) | Additional thread information                                                                        |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY\_JOB\_STATUS when *parse-type* = "UT":

Table 344. Result set row for second ADMIN\_COMMAND\_DB2 result set (parse-type = "UT")

| Column name | Data type     | Contents                                                                 |
|-------------|---------------|--------------------------------------------------------------------------|
| ROWNUM      | INTEGER       | Sequence number of the table row, from 1 to <i>n</i>                     |
| CSECT       | CHAR(8)       | Name of the command program CSECT that issued the message                |
| USER        | CHAR(8)       | User ID of the person running the utility                                |
| MEMBER      | CHAR(8)       | Utility job is running on this member                                    |
| UTILID      | CHAR(16)      | Utility job identifier                                                   |
| STATEMENT   | INTEGER       | Utility statement number                                                 |
| UTILITY     | CHAR(20)      | Utility name                                                             |
| PHASE       | CHAR(20)      | Utility restart from the beginning of this phase                         |
| COUNT       | INTEGER       | Number of pages or records processed in a utility phase                  |
| STATUS      | CHAR(18)      | Utility status                                                           |
| DETAIL      | VARCHAR(4050) | Additional utility information                                           |
| NUM_OBJ     | INTEGER       | Total number of objects in the list of objects the utility is processing |
| LAST_OBJ    | INTEGER       | Last object that started                                                 |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DB\_STATUS when *parse-type* = "DB" or "TS" or "IX":

Table 345. Result set row for second ADMIN\_COMMAND\_DB2 result set (parse-type = "DB" or "TS" or "IX")

| Column name | Data type | Contents                                                                       |
|-------------|-----------|--------------------------------------------------------------------------------|

| MEMBER_IPV6ADDR | CHAR(39)  | IPV6 address associated with the specific member of a data sharing group. Always null. |

## ADMIN\_COMMAND\_DSN stored procedure

The SYSPROC.ADMIN\_COMMAND\_DSN stored procedure executes a BIND, REBIND, or FREE DSN subcommand and returns the output from the DSN subcommand execution.

### Environment

ADMIN\_COMMAND\_DSN runs in a WLM-established stored procedures address space. TCB=1 is also required.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_COMMAND\_DSN stored procedure
- Ownership of the stored procedure
- SYSADM authority

To execute the DSN subcommand, you must use a privilege set that includes the authorization to execute the DSN subcommand as described in the *DB2 Command Reference*.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
►—CALL—SYSPROC.ADMIN_COMMAND_DSN—(—DSN-subcommand,—message—)—————►
```

## Option descriptions

### *DSN-subcommand*

Specifies the DSN subcommand to be executed. If the DSN subcommand passed to the stored procedure is not BIND, REBIND, or FREE, an error message is returned. The DSN subcommand is performed using the authorization ID of the user who invoked the stored procedure.

This is an input parameter of type VARCHAR(32704) and cannot be null.

### *message*

Contains messages if an error occurs during stored procedure execution.

A blank *message* does not mean that the DSN subcommand completed successfully. The calling application must read the result set to determine if the DSN subcommand was successful or not.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_COMMAND\_DSN:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_COMMAND_DSN parameters */
  char subcmd[32705]; /* BIND, REBIND or FREE DSN */
}
```

```

char          errmsg[1332];          /* subcommand          */
/* Error message          */

/* Result set locators          */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

/* Result set row          */
long int      rownum;                /* Sequence number of the */
/* table row          */
char          text[256];             /* DSN subcommand output row */
EXEC SQL END DECLARE SECTION;

/*****
/* Set input parameter to execute a REBIND PLAN DSN subcommand */
*****/
strcpy(subcmd, "REBIND PLAN (DSNACCOB) FLAG(W)");

/*****
/* Call stored procedure SYSPROC.ADMIN_COMMAND_DSN          */
*****/
EXEC SQL CALL SYSPROC.ADMIN_COMMAND_DSN (:subcmd, :errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446, */
/* which indicates that result sets were returned          */
*****/
if (SQLCODE == +446)          /* Result sets were returned */
{
    /* Establish a link between the result set and its locator */
    EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_COMMAND_DSN;

    /* Associate a cursor with the result set          */
    EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

    /* Perform fetches using C1 to retrieve all rows from the */
    /* result set          */
    EXEC SQL FETCH C1 INTO :rownum, :text;
    while(SQLCODE==0)
    {
        EXEC SQL FETCH C1 INTO :rownum, :text;
    }
}

return;
}

```

## Output

This stored procedure returns an error message, *message*, if an error occurs.

The stored procedure returns one result set that contains the DSN sub-command output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DSN\_SUBCMD\_OUTPUT:

*Table 348. Result set row for ADMIN\_COMMAND\_DSN result set*

| Column name | Data type    | Contents                                             |
|-------------|--------------|------------------------------------------------------|
| ROWNUM      | INTEGER      | Sequence number of the table row, from 1 to <i>n</i> |
| TEXT        | VARCHAR(255) | DSN subcommand output message line                   |

## ADMIN\_COMMAND\_UNIX stored procedure

The SYSPROC.ADMIN\_COMMAND\_UNIX stored procedure executes a z/OS UNIX System Services command and returns the output.

### Environment

ADMIN\_COMMAND\_UNIX runs in a WLM-established stored procedures address space.

The load module for ADMIN\_COMMAND\_UNIX, DSNADMCU, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMCU to program control, see installation job DSNTIJRA.

### Authorization

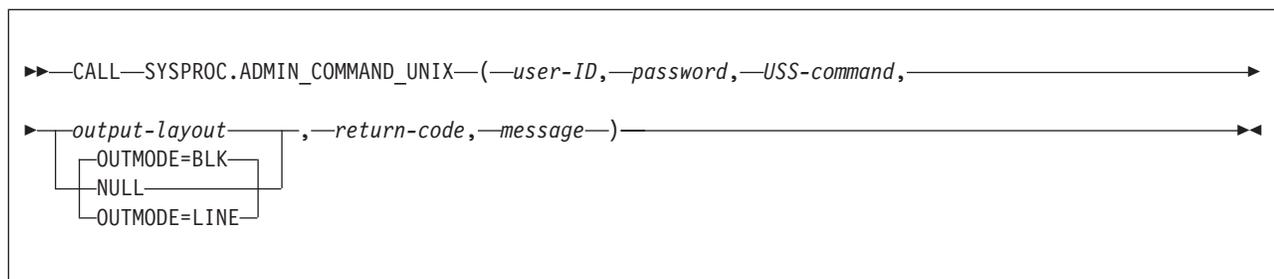

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMCU
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user specified in the *user-ID* input parameter of the SQL CALL statement must have the appropriate authority to execute the z/OS UNIX System Services command.

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

### Option descriptions

#### *user-ID*

Specifies the user ID under which the z/OS UNIX System Services command is issued.

This is an input parameter of type VARCHAR(128) and cannot be null.

#### *password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

This is an input parameter of type VARCHAR(24) and cannot be null.

#### *USS-command*

Specifies the z/OS UNIX System Services command to be executed.

This is an input parameter of type VARCHAR(32704) and cannot be null.

#### *output-layout*

Specifies how the output from the z/OS UNIX System Services command is returned. The output from the z/OS UNIX System Services command is a multi-line message. Possible values are:

##### **OUTMODE=LINE**

Each line is returned as a row in the result set.

##### **OUTMODE=BLK**

The lines are blocked into 32677 blocks and each block is returned as a row in the result set.

If a null or empty string is provided, then the default option OUTMODE=BLK is used.

This is an input parameter of type VARCHAR(1024).

#### *return-code*

Provides the return code from the stored procedure. Possible values are:

**0** The call completed successfully.

**12** The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

#### *message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## **Example**

The following C language sample shows how to invoke ADMIN\_COMMAND\_UNIX:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_COMMAND_UNIX parameters */
    char    userid[129];          /* User ID */
    short int ind_userid;        /* Indicator variable */
```

```

char      password[25];          /* Password */
short int ind_password;         /* Indicator variable */
char      command[32705];       /* USS command */
short int ind_command;         /* Indicator variable */
char      layout[1025];        /* Command output layout */
short int ind_layout;          /* Indicator variable */
long int  retcd;               /* Return code */
short int ind_retcd;           /* Indicator variable */
char      errmsg[1332];        /* Error message */
short int ind_errmsg;          /* Indicator variable */

/* Result set locators */
volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

/* Result set row */
long int  rownum;              /* Sequence number of the
                               /* table row
char      text[32678];         /* A row in USS command output*/
EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to execute a USS command */
/* Set the indicator variables to 0 for non-null input parameters */
/* Set the indicator variables to -1 for null input parameters */
*****/
strcpy(userid, "USRT001");
ind_userid = 0;
strcpy(password, "NICETEST");
ind_password = 0;
strcpy(command, "ls");
ind_command = 0;
ind_layout = -1;

/*****
/* Call stored procedure SYSPROC.ADMIN_COMMAND_UNIX */
*****/
EXEC SQL CALL SYSPROC.ADMIN_COMMAND_UNIX
              (:userid   :ind_userid,
              :password  :ind_password,
              :command   :ind_command,
              :layout    :ind_layout,
              :retcd     :ind_retcd,
              :errmsg    :ind_errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446,
/* which indicates that result sets were returned */
*****/
if (SQLCODE == +446)          /* Result sets were returned */
{
  /* Establish a link between the result set and its locator */
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_COMMAND_UNIX;

  /* Associate a cursor with the result set */
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Perform fetches using C1 to retrieve all rows from the
  /* result set
  EXEC SQL FETCH C1 INTO :rownum, :text;
  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1 INTO :rownum, :text;
  }
}

```

```

    }
    return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1324:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the z/OS UNIX System Services command output messages.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.USS\_CMD\_OUTPUT:

*Table 349. Result set row for ADMIN\_COMMAND\_UNIX result set*

| Column name | Data type      | Contents                                                                                  |
|-------------|----------------|-------------------------------------------------------------------------------------------|
| ROWNUM      | INTEGER        | Sequence number of the table row, from 1 to <i>n</i>                                      |
| TEXT        | VARCHAR(32677) | A block of text or a line from the output messages of a z/OS UNIX System Services command |

## ADMIN\_DS\_BROWSE stored procedure

The SYSPROC.ADMIN\_DS\_BROWSE stored procedure returns either text or binary records from a physical sequential (PS) data set, generation data set, or partitioned data set (PDS) or partitioned data set extended (PDSE) member. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

### Environment

The load module for ADMIN\_DS\_BROWSE, DSNADMDB, must reside in an APF-authorized library. ADMIN\_DS\_BROWSE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDB
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN\_DS\_BROWSE caller also needs authorization from an external security system, such as RACF, in order to browse or view an z/OS data set resource.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_DS_BROWSE ( data-type, data-set-name, member-name, dump-option,  
return-code, message )
```

## Option descriptions

### *data-type*

Specifies the type of data to be browsed. Possible values are:

- 1 Text data
- 2 Binary data

This is an input parameter of type INTEGER and cannot be null.

### *data-set-name*

Specifies the name of the data set, or of the library that contains the member to be browsed. Possible values are:

#### **PS data set name**

If reading from a PS data set, the *data-set-name* contains the name of the PS data set.

#### **PDS or PDSE name**

If reading from a member that belongs to this PDS or PDSE, the *data-set-name* contains the name of the PDS or PDSE.

#### **GDS name**

If reading from a generation data set, the *data-set-name* contains the name of the generation data set, such as USERGDG.FILE.G0001V00.

This is an input parameter of type CHAR(44) and cannot be null.

### *member-name*

Specifies the name of the PDS or PDSE member, if reading from a PDS or PDSE member. Otherwise, a blank character.

This is an input parameter of type CHAR(8) and cannot be null.

### *dump-option*

Specifies whether to use the DB2 standard dump facility to dump the information necessary for problem diagnosis when an SQL error occurred or when a call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

Possible values are:

- Y Generate a dump.
- N Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

### *return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

### Example

The following C language sample shows how to invoke ADMIN\_DS\_BROWSE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_DS_BROWSE parameters */
  long int datatype; /* Data type */
  char dsname[45]; /* Data set name */
  char mbrname[9]; /* Library member name */
  char dumpopt[2]; /* Dump option */
  long int retcd; /* Return code */
  char errmsg[1332]; /* Error message */

  /* Result set locators */
  volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

  /* Result set row */
  long int rownum; /* Sequence number of the */
  /* table row */
  char text_rec[81]; /* A data set record */
  EXEC SQL END DECLARE SECTION;

  /***** Assign values to input parameters to browse a library member *****/
  datatype = 1;
  strcpy(dsname, "USER.DATASET.PDS");
  strcpy(mbrname, "MEMBER0A");
  strcpy(dumpopt, "N");

  /***** Call stored procedure SYSPROC.ADMIN_DS_BROWSE *****/
  EXEC SQL CALL SYSPROC.ADMIN_DS_BROWSE
              (:datatype, :dsname, :mbrname, :dumpopt,
              :retcd, :errmsg);

  /***** Retrieve result set when the SQLCODE from the call is +446, *****/
  /* which indicates that result sets were returned */
}
```

```

/*****
if (SQLCODE == +466)          /* Result sets were returned */
{
  /* Establish a link between the result set and its locator */
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_DS_BROWSE;

  /* Associate a cursor with the result set */
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Perform fetches using C1 to retrieve all rows from the */
  /* result set */
  EXEC SQL FETCH C1 INTO :rownum, :text_rec;
  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1 INTO :rownum, :text_rec;
  }
}

return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1328:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the text or binary records read.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.TEXT\_REC\_OUTPUT containing text records read:

*Table 350. Result set row for ADMIN\_DS\_BROWSE result set (text records)*

| Column name | Data type   | Contents                                               |
|-------------|-------------|--------------------------------------------------------|
| ROWNUM      | INTEGER     | Sequence number of the table row, from 1 to <i>n</i> . |
| TEXT_REC    | VARCHAR(80) | Record read (text format).                             |

The following table shows the format of the result set returned in the created global temporary table SYSIBM.BIN\_REC\_OUTPUT containing binary records read:

*Table 351. Result set row for ADMIN\_DS\_BROWSE result set (binary records)*

| Column name | Data type                | Contents                                               |
|-------------|--------------------------|--------------------------------------------------------|
| ROWNUM      | INTEGER                  | Sequence number of the table row, from 1 to <i>n</i> . |
| BINARY_REC  | VARCHAR(80) FOR BIT DATA | Record read (binary format).                           |

## ADMIN\_DS\_DELETE stored procedure

The SYSPROC.ADMIN\_DS\_DELETE stored procedure deletes a physical sequential (PS) data set, a partitioned data set (PDS) or partitioned data set extended (PDSE), a generation data set (GDS), or a member of a PDS or PDSE.

## Environment

The load module for ADMIN\_DS\_DELETE, DSNADMDD, must reside in an APF-authorized library. ADMIN\_DS\_DELETE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_DS\_DELETE stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN\_DS\_DELETE caller also needs authorization from an external security system, such as RACF, in order to delete an z/OS data set resource.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_DELETE—(—data-set-type,—data-set-name,—parent-data-set-name,—————▶▶  
▶—dump-option,—return-code,—message—)—————▶▶
```

## Option descriptions

### *data-set-type*

Specifies the type of data set to delete. Possible values are:

- 1 Partitioned data set (PDS)
- 2 Partitioned data set extended (PDSE)
- 3 Member of a PDS or PDSE
- 4 Physical sequential data set (PS)
- 6 Generation data set (GDS)

This is an input parameter of type INTEGER and cannot be null.

### *data-set-name*

Specifies the name of the data set, library member, or GDS absolute generation number to be deleted. Possible values are:

#### **PS, PDS, or PDSE name**

If *data-set-type* is 1, 2, or 4, the *data-set-name* contains the name of the PS, PDS, or PDSE to be deleted.

#### **PDS or PDSE member name**

If *data-set-type* is 3, the *data-set-name* contains the name of the PDS or PDSE member to be deleted.

| **absolute generation number**

| If *data-set-type* is 6, the *data-set-name* contains the absolute generation  
| number of the GDS to be deleted, such as G0001V00.

| This is an input parameter of type CHAR(44) and cannot be null.

| *parent-data-set-name*

| Specifies the name of the library that contains the member to be deleted, or of  
| the GDG that contains the GDS to be delete. Otherwise blank. Possible values  
| are:

| **blank** If *data-set-type* is 1, 2, or 4, the *parent-data-set-name* is left blank.

| **PDS or PDSE name**

| If *data-set-type* is 3, the *parent-data-set-name* contains the name of the  
| PDS or PDSE whose member is to be deleted.

| **GDG name**

| If *data-set-type* is 6, the *parent-data-set-name* contains the name of the  
| GDG that the GDS to be deleted belongs to.

| This is an input parameter of type CHAR(44) and cannot be null.

| *dump-option*

| Specifies whether to use the DB2 standard dump facility to dump the  
| information necessary for problem diagnosis when a call to the IBM routine  
| IEFDB476 to get messages about an unsuccessful SVC 99 call failed.

| Possible values are:

| **Y** Generate a dump.

| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| *return-code*

| Provides the return code from the stored procedure. Possible values are:

| **0** Data set, PDS member, PDSE member, or GDS was deleted  
| successfully.

| **12** The call did not complete successfully. The *message* output parameter  
| contains messages describing the error.

| This is an output parameter of type INTEGER.

| *message*

| Contains messages describing the error encountered by the stored procedure. If  
| no error occurred, then no message is returned.

| The first messages in this area are generated by the stored procedure. Messages  
| that are generated by z/OS might follow the first messages.

| This is an output parameter of type VARCHAR(1331).

| **Example**

| The following C language sample shows how to invoke ADMIN\_DS\_DELETE:

| #include <stdio.h>  
| #include <stdlib.h>  
| #include <string.h>  
|  
| /\*\*\*\*\* DB2 SQL Communication Area \*\*\*\*\*/  
| EXEC SQL INCLUDE SQLCA;

```

int main( int argc, char *argv[] )    /* Argument count and list */
{
  /****** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_DS_DELETE parameters */
  long int  dstype;                    /* Data set type */
  char      dsname[45];                /* Data set name ,
                                        /* member name, or
                                        /* generation # (G0001V00)
  char      parentds[45];              /* PDS, PDSE, GDG or blank
  char      dumpopt[2];                /* Dump option
  long int  retcd;                     /* Return code
  char      errmsg[1332];              /* Error message
  EXEC SQL END DECLARE SECTION;

  /****** Assign values to input parameters to delete a data set *****/
  dstype = 4;
  strcpy(dsname, "USER.DATASET.PDS");
  strcpy(parentds, " ");
  strcpy(dumpopt, "N");

  /****** Call stored procedure SYSPROC.ADMIN_DS_DELETE *****/
  EXEC SQL CALL SYSPROC.ADMIN_DS_DELETE
              (:dstype, :dsname, :parentds, :dumpopt,
              :retcd, :errmsg);

  return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1331:

- *return-code*
- *message*

---

## ADMIN\_DS\_LIST stored procedure

The SYSPROC.ADMIN\_DS\_LIST stored procedure returns a list of data set names, generation data group (GDG), partitioned data set (PDS) or partitioned data set extended (PDSE) members, or generation data sets of a GDG.

### Environment

The load module for ADMIN\_DS\_LIST, DSNADM DL, must reside in an APF-authorized library. ADMIN\_DS\_LIST runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADM DL

- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN\_DS\_LIST caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```

▶▶CALLSYSPROC.ADMIN_DS_LIST(—data-set-name,—list-members,—list-generations,—
▶max-results,—dump-option,—return-code,—message—)▶▶

```

## Option descriptions

### *data-set-name*

Specifies the data set name. You can use masking characters. For example:  
USER.\*

If no masking characters are used, only one data set will be listed.

This is an input parameter of type CHAR(44) and cannot be null.

### *list-members*

Specifies whether to list PDS or PDSE members. Possible values are:

**Y** List members. Only set to Y when *data-set-name* is a fully qualified PDS or PDSE.

**N** Do not list members.

This is an input parameter of type CHAR(1) and cannot be null.

### *list-generations*

Specifies whether to list generation data sets. Possible values are:

**Y** List generation data sets. Only set to Y when *data-set-name* is a fully qualified GDG.

**N** Do not list generation data sets.

This is an input parameter of type CHAR(1) and cannot be null.

### *max-results*

Specifies the maximum number of result set rows. This option is applicable only when both list-members and list-generations are 'N'.

This is an input parameter of type INTEGER and cannot be null.

### *dump-option*

Specifies whether to use the DB2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occur:

- SQL error.

- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load Catalog Search Interface module error.

Possible values are:

- Y**      Generate a dump.
- N**      Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

*return-code*

Provides the return code from the stored procedure. Possible values are:

- 0**      The call completed successfully.
- 12**     The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 or by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_DS\_LIST:

```
#pragma csect(CODE,"SAMDLPGM")
#pragma csect(STATIC,"PGMDLSAM")
#pragma runopts(plist(os))

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/

EXEC SQL CALL SYSPROC.ADMIN_DS_LIST
              (:dsname, :listmbr, :listgds, :maxresult,
              :dumpopt, :retcd, :errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446,
/* which indicates that result sets were returned
*****/
if (SQLCODE == +446)          /* Result sets were returned */
{
  /* Establish a link between the result set and its locator
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
              WITH PROCEDURE SYSPROC.ADMIN_DS_LIST;

  /* Associate a cursor with the result set
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Perform fetches using C1 to retrieve all rows from the
  /* result set
  EXEC SQL FETCH C1 INTO :dsnamer, :createyr, :createday,
                        :type, :volume, :primaryext,
                        :secondext, :measure, :extinuse,
                        :dasduse, :harba, :hurba;

  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1 INTO :dsnamer, :createyr, :createday,
                          :type, :volume, :primaryext,
                          :secondext, :measure, :extinuse,
                          :dasduse, :harba, :hurba;
  }
}
return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1334:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the list of data sets, GDGs, PDS or PDSE members, or generation data sets that were requested.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.DSLIST:

*Table 352. Result set row for ADMIN\_DS\_LIST result set*

| Column name | Data type   | Contents                                                                                                                                                                                                                                                                                                                 |

Possible values are:<br>• BLOCKS<br>• BYTES<br>• CYLINDERS<br>• KB<br>• MB<br>• TRACKS<br>Not applicable for member and VSAM cluster.                                                                                                 |
| EXTENTS_IN_USE   | INTEGER              | Current allocated extents. Not applicable for member and VSAM cluster.                                                                                                                                                                                                                           |
| DASD_USAGE       | CHAR(8) FOR BIT DATA | Disk usage. For VSAM data and VSAM index only.                                                                                                                                                                                                                                                   |
| HARBA            | CHAR(6) FOR BIT DATA | High allocated RBA. For VSAM data and VSAM index only.                                                                                                                                                                                                                                           |
| HURBA            | CHAR(6) FOR BIT DATA | High used RBA. For VSAM data and VSAM index only.                                                                                                                                                                                                                                                |

When a data set spans more than one volume, one row is returned for each volume that contains a piece of the data set. The VOLUME, EXTENTS\_IN\_USE, DASD\_USAGE, HARBA, and HURBA columns reflect information for the specified volume.

---

## ADMIN\_DS\_RENAME stored procedure

The SYSPROC.ADMIN\_DS\_RENAME stored procedure renames a physical sequential (PS) data set, a partitioned data set (PDS) or partitioned data set extended (PDSE), or a member of a PDS or PDSE.

### Environment

The load module for ADMIN\_DS\_RENAME, DSNADMDR, must reside in an APF-authorized library. ADMIN\_DS\_RENAME runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_DS\_RENAME stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN\_DS\_RENAME caller also needs authorization from an external security system, such as RACF, in order to rename an z/OS data set resource.

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_RENAME—(—data-set-type,—data-set-name,—parent-data-set-name,—————▶▶  
▶—new-data-set-name,—dump-option,—return-code,—message—)—————▶▶
```

### Option descriptions

*data-set-type*

Specifies the type of data set to rename. Possible values are:

- 1 Partitioned data set (PDS)
- 2 Partitioned data set extended (PDSE)
- 3 Member of a PDS or PDSE
- 4 Physical sequential data set (PS)

This is an input parameter of type INTEGER and cannot be null.

| *data-set-name*

| Specifies the data set or member to be renamed. Possible values are:

| **PS, PDS, or PDSE name**

| If *data-set-type* is 1, 2, or 4, the *data-set-name* contains the name of the  
| PS, PDS, or PDSE to be renamed.

| **PDS or PDSE member name**

| If *data-set-type* is 3, the *data-set-name* contains the name of the PDS or  
| PDSE member to be renamed.

| This is an input parameter of type CHAR(44) and cannot be null.

| *parent-data-set-name*

| Specifies the name of the PDS or PDSE, if renaming a PDS or PDSE member.  
| Otherwise, a blank character. Possible values are:

| **blank** If *data-set-type* is 1, 2, or 4, the *parent-data-set-name* is left blank.

| **PDS or PDSE name**

| If *data-set-type* is 3, the *parent-data-set-name* contains the name of the  
| PDS or PDSE whose member is to be renamed.

| This is an input parameter of type CHAR(44) and cannot be null.

| *new-data-set-name*

| Specifies the new data set or member name. Possible values are:

| **new data set name**

| If *data-set-type* is 1, 2, or 4, the *new-data-set-name* contains the new data  
| set name.

| **new member name**

| If *data-set-type* is 3, the *new-data-set-name* contains the new member  
| name.

| This is an input parameter of type CHAR(44) and cannot be null.

| *dump-option*

| Specifies whether to use the DB2 standard dump facility to dump the  
| information necessary for problem diagnosis when any of the following errors  
| occurred:

- | • A call to the IBM routine IEFDB476 to get messages about an unsuccessful  
| SVC 99 call failed.
- | • Load IDCAMS program error.

| Possible values are:

| **Y** Generate a dump.

| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| *return-code*

| Provides the return code from the stored procedure. Possible values are:

| **0** The data set, PDS member, or PDSE member was renamed  
| successfully.

| **12** The call did not complete successfully. The *message* output parameter  
| contains messages describing the error.

| This is an output parameter of type INTEGER.

*message*

Contains messages based on *return-code* and *data-set-type* combinations.

| <i>return-code</i> | <i>data-set-type</i> | <b>Content</b>                                                                                                                                                                                                                                                    |
|--------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                  | 1, 2, or 4           | Contains IDCAMS messages.                                                                                                                                                                                                                                         |
| 0                  | 3                    | No message is returned.                                                                                                                                                                                                                                           |
| Not 0              | not applicable       | Contains messages describing the error encountered by the stored procedure. The first messages are generated by the stored procedure and messages that are generated by z/OS might follow these first messages. The first messages can also be generated by z/OS. |

This is an output parameter of type VARCHAR(1331).

### Example

The following C language sample shows how to invoke ADMIN\_DS\_RENAME:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_RENAME parameters */
    long int  dstype; /* Data set type */
    char      dsname[45]; /* Data set or member name */
    char      parentds[45]; /* Parent data set (PDS or
    /* PDSE) name or blank */
    char      newdsname[45]; /* New data set or member name*/
    char      dumpopt[2]; /* Dump option */
    long int  retcd; /* Return code */
    char      ermmsg[1332]; /* Error message */
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to rename a library member *****/
    dstype = 3;
    strcpy(dsname, "MEMBER01");
    strcpy(parentds, "USER.DATASET.PDS");
    strcpy(newdsname, "MEMBER0A");
    strcpy(dumpopt, "N");

    /***** Call stored procedure SYSPROC.ADMIN_DS_RENAME *****/
    EXEC SQL CALL SYSPROC.ADMIN_DS_RENAME
        (:dstype, :dsname, :parentds, :newdsname,
```

```

|                                     :dumpopt, :retcd, :errmsg);
|
|                                     return(retcd);
|                                     }
|

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1339:

- *return-code*
- *message*

---

## ADMIN\_DS\_SEARCH stored procedure

The SYSPROC.ADMIN\_DS\_SEARCH stored procedure determines if a physical sequential (PS) data set, partitioned data set (PDS), partitioned data set extended (PDSE), generation data group (GDG), generation data set (GDS) is cataloged, or if a library member of a cataloged PDS or PDSE exists.

### Environment

The load module for ADMIN\_DS\_SEARCH, DSNADMDE, must reside in an APF-authorized library. ADMIN\_DS\_SEARCH runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_DS\_SEARCH stored procedure
- Ownership of the stored procedure
- SYSADM authority

The ADMIN\_DS\_SEARCH caller also needs authorization from an external security system, such as RACF, in order to perform the requested operation on an z/OS data set resource.

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```

| ►►—CALL—SYSPROC.ADMIN_DS_SEARCH—(—data-set-name,—member-name,—dump-option,—►►
| ►—data-set-exists,—return-code,—message—)—►►

```

### Option descriptions

*data-set-name*

Specifies the name of a PS data set, PDS, PDSE, GDG or GDS.

This is an input parameter of type CHAR(44) and cannot be null.

*member-name*

Specifies the name of a PDS or PDSE member. Set this parameter to a blank character if you only want to check the existence of the PDS or PDSE.

This is an input parameter of type CHAR(8) and cannot be null.

*dump-option*

Specifies whether to use the DB2 standard dump facility to dump the information necessary for problem diagnosis when any of the following errors occurred:

- A call to the IBM routine IEFDB476 to get messages about an unsuccessful SVC 99 call failed.
- Load IDCAMS program error.

Possible values are:

**Y**      Generate a dump.

**N**      Do not generate a dump.

This is an input parameter of type CHAR(1) and cannot be null.

*data-set-exists*

Indicates whether a data set or library member exists or not. Possible values are:

**-1**      Call did not complete successfully. Unable to determine if data set or member exists.

**0**      Data set or member was found

**1**      Data set not found

**2**      PDS or PDSE member not found

This is an output parameter of type INTEGER.

*return-code*

Provides the return code from the stored procedure. Possible values are:

**0**      The call completed successfully.

**12**      The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains IDCAMS messages if *return-code* is 0. Otherwise, contains messages describing the error encountered by the stored procedure. The first messages are generated by the stored procedure and messages that are generated by z/OS might follow these first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_DS\_SEARCH:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
```

```
/****** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;
```

```

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_DS_SEARCH parameters */
  char dsname[45]; /* Data set name or GDG */
  char mbrname[9]; /* Library member name */
  char dumpopt[2]; /* Dump option */
  long int exist; /* Data set or library member */
  /* existence indicator */
  long int retcd; /* Return code */
  char errmsg[1332]; /* Error message */
  EXEC SQL END DECLARE SECTION;

  /***** Assign values to input parameters to determine whether a
  /* library member exists or not *****/
  strcpy(dsname, "USER.DATASET.PDS");
  strcpy(mbrname, "MEMBER0A");
  strcpy(dumpopt, "N");

  /***** Call stored procedure SYSPROC.ADMIN_DS_SEARCH *****/
  EXEC SQL CALL SYSPROC.ADMIN_DS_SEARCH
              (:dsname, :mbrname, :dumpopt,
              :exist, :retcd, :errmsg);

  return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1342:

- *data-set-exists*
- *return-code*
- *message*

---

## ADMIN\_DS\_WRITE stored procedure

The SYSPROC.ADMIN\_DS\_WRITE stored procedure writes either text or binary records passed in a global temporary table to either a physical sequential (PS) data set, partitioned data set (PDS) or partitioned data set extended (PDSE) member, or generation data set (GDS). It can either append or replace an existing PS data set, PDS or PDSE member, or GDS. It can create a new PS data set, PDS or PDSE data set or member, or a new GDS for an existing generation data group (GDG) as needed. This stored procedure supports only data sets with LRECL=80 and RECFM=FB.

### Environment

The load module for ADMIN\_DS\_WRITE, DSNADMDW, must reside in an APF-authorized library. ADMIN\_DS\_WRITE runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMDW
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The ADMIN\_DS\_WRITE caller also needs authorization from an external security system, such as RACF, in order to write to an z/OS data set resource.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_DS_WRITE—(—data-type,—data-set-name,—member-name,—processing-option,—  
▶—dump-option,—return-code,—message—)————▶▶
```

## Option descriptions

This stored procedure takes the following input options:

### *data-type*

Specifies the type of data to be saved. Possible values are:

- 1 Text data
- 2 Binary data

This is an input parameter of type INTEGER and cannot be null.

### *data-set-name*

Specifies the name of the data set, GDG that contains the GDS, or library that contains the member, to be written to. Possible values are:

#### **PS data set name**

Name of the PS data set, if writing to a PS data set.

#### **GDG name**

Name of the GDG, if writing to a GDS within this GDG.

#### **PDS or PDSE name**

Name of the PDS or PDSE, if writing to a member that belongs to this library.

This is an input parameter of type CHAR(44) and cannot be null.

### *member-name*

Specifies the relative generation number of the GDS, if writing to a GDS, or the name of the PDS or PDSE member, if writing to a PDS or PDSE member. Otherwise, a blank character. Possible values are:

| **GDS relative generation number**

| Relative generation number of a GDS, if writing to a GDS. For  
| example: -1, 0, +1

| **PDS or PDSE member name**

| Name of the PDS or PDSE member, if writing to a library member.

| **blank** In all other cases, blank.

| This is an input parameter of type CHAR(8) and cannot be null.

| *processing-option*

| Specifies the type of operation. Possible values are:

| **R** Replace

| **A** Append

| **NM** New member

| **ND** New PS, PDS, PDSE, or GDS data set

| This is an input parameter of type CHAR(2) and cannot be null.

| *dump-option*

| Specifies whether to use the DB2 standard dump facility to dump the  
| information necessary for problem diagnosis when an SQL error has occurred  
| or when a call to the IBM routine IEFDB476 to get messages about an  
| unsuccessful SVC 99 call failed.

| Possible values are:

| **Y** Generate a dump.

| **N** Do not generate a dump.

| This is an input parameter of type CHAR(1) and cannot be null.

| *return-code*

| Provides the return code from the stored procedure. Possible values are:

| **0** The call completed successfully.

| **12** The call did not complete successfully. The *message* output parameter  
| contains messages describing the error.

| This is an output parameter of type INTEGER.

| *message*

| Contains messages describing the error encountered by the stored procedure. If  
| no error occurred, then no message is returned.

| The first messages in this area are generated by the stored procedure. Messages  
| that are generated by DB2 or by z/OS might follow the first messages.

| This is an output parameter of type VARCHAR(1331).

| **Additional input**

| In addition to the input parameters, the stored procedure reads records to be  
| written to a file from a created global temporary table. If the data to be written is  
| text data, then the stored procedure reads records from  
| SYSIBM.TEXT\_REC\_INPUT. If the data is binary data, then the stored procedure  
| reads records from the created global temporary table SYSIBM.BIN\_REC\_INPUT.

The following table shows the format of the created global temporary table SYSIBM.TEXT\_REC\_INPUT containing text records to be saved:

*Table 353. Additional input for text data for the ADMIN\_DS\_WRITE stored procedure*

| Column name | Data type | Contents                                               |
|-------------|-----------|--------------------------------------------------------|
| ROWNUM      | INTEGER   | Sequence number of the table row, from 1 to <i>n</i> . |
| TEXT_REC    | CHAR(80)  | Text record to be saved.                               |

The following table shows the format of the created global temporary table SYSIBM.BIN\_REC\_INPUT containing binary records to be saved:

*Table 354. Additional input for binary data for the ADMIN\_DS\_WRITE stored procedure*

| Column name | Data type                | Contents                                               |
|-------------|--------------------------|--------------------------------------------------------|
| ROWNUM      | INTEGER                  | Sequence number of the table row, from 1 to <i>n</i> . |
| BINARY_REC  | VARCHAR(80) FOR BIT DATA | Binary record to be saved.                             |

## Example

The following C language sample shows how to invoke ADMIN\_DS\_WRITE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_DS_WRITE parameters */
    long int datatype; /* Data type */
    char dsname[45]; /* Data set name or GDG */
    char mbrname[9]; /* Library member name,
                    /* generation # (-1, 0, +1),
                    /* or blank
    char procopt[3]; /* Processing option
    char dumpopt[2]; /* Dump option
    long int retcd; /* Return code
    char errmsg[1332]; /* Error message

    /* Temporary table SYSIBM.TEXT_REC_INPUT columns */
    long int rownum; /* Sequence number of the
                    /* table row
    char textrec[81]; /* Text record
    EXEC SQL END DECLARE SECTION;

    /*****
    /* Create the records to be saved
    /*****
    char dsrecord[12][50] = {
    "///IEBCOPY JOB ,CLASS=K,MSGCLASS=H,MSGLEVEL=(1,1)",
    "///STEP010 EXEC PGM=IEBCOPY",
    "///SYSPRINT DD SYSOUT=*",
    "///SYSUT3 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
```

```

        //SYSUT4 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
        /*",
        //DDI1 DD DSN=USER.DEV.LOADLIB1,DISP=SHR",
        //DDO1 DD DSN=USER.DEV.LOADLIB2,DISP=SHR",
        //SYSIN DD *,
        " COPY OUTDD=DDO1,INDD=DDI1",
        /*",
        /*"
    };
    int i = 0;                                /* Loop counter          */

    /******
    /* Assign the values to input parameters to create a new          */
    /* partitioned data set and member                                */
    /******
    datatype = 1;
    strcpy(dsname, "USER.DATASET.PDS");
    strcpy(mbrname, "MEMBER01");
    strcpy(procopt, "ND");
    strcpy(dumpopt, "N");

    /******
    /* Clear temporary table SYSIBM.TEXT_REC_INPUT                    */
    /******
    EXEC SQL DELETE FROM SYSIBM.TEXT_REC_INPUT;

    /******
    /* Insert the records to be saved in the new library member      */
    /* into the temporary table SYSIBM.TEXT_REC_INPUT                */
    /******
    for (i = 0; i < 12; i++)
    {
        rownum = i+1;
        strcpy(textrec, dsrecord[i]);
        EXEC SQL INSERT INTO SYSIBM.TEXT_REC_INPUT
            ( ROWNUM, TEXT_REC )
            VALUES (:rownum, :textrec);
    };

    /******
    /* Call stored procedure SYSPROC.ADMIN_DS_WRITE                  */
    /******
    EXEC SQL CALL SYSPROC.ADMIN_DS_WRITE
        (:datatype, :dsname, :mbrname, :procopt,
         :dumpopt, :retcd, :errmsg );

    return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 1345:

- *return-code*
- *message*

---

## ADMIN\_INFO\_HOST stored procedure

The SYSPROC.ADMIN\_INFO\_HOST stored procedure returns the host name of a connected DB2 subsystem or the host name of every member of a data sharing group.

## Environment

ADMIN\_INFO\_HOST runs in a WLM-established stored procedures address space.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIH
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

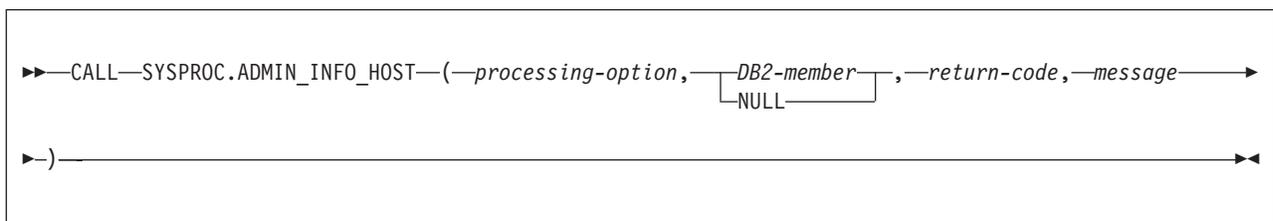

The ADMIN\_INFO\_HOST stored procedure internally calls the ADMIN\_COMMAND\_DB2 stored procedure to execute the following DB2 commands:

- -DISPLAY DDF
- -DISPLAY GROUP

The owner of the package or plan that contains the CALL ADMIN\_INFO\_HOST statement must also have the authorization required to execute the stored procedure ADMIN\_COMMAND\_DB2 and the specified DB2 commands. To determine the privilege or authority required to issue a DB2 command, see *DB2 Command Reference*.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

## Option descriptions

### *processing-option*

Specifies processing option. Possible values are:

- 1 Return the host name of the connected DB2 subsystem or the host name of a specified DB2 data sharing group member.  
For a data sharing group member, you must specify *DB2-member*.
- 2 Return the host name of every DB2 member of the same data sharing group.

This is an input parameter of type INTEGER and cannot be null.

### *DB2-member*

Specifies the DB2 data sharing group member name.

This parameter must be null if *processing-option* is 2.

This is an input parameter of type CHAR(8).

#### *return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 Unable to list the host name of the connected DB2 subsystem or of every DB2 member of the same data sharing group due to one of the following reasons:
  - The IPADDR field returned when the -DISPLAY DDF command is executed on the connected DB2 subsystem or DB2 member contains the value -NONE
  - One of the DB2 members is down
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

#### *message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_INFO\_HOST:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_INFO_HOST parameters */

    short int ind_procopt; /* Indicator variable */
    char      db2mbr[9]; /* Data sharing group member */
                                /* name */
    short int ind_db2mbr; /* Indicator variable */
    long int  retcd; /* Return code */
    short int ind_retcd; /* Indicator variable */
    char      errmsg[1332]; /* Error message */
    short int ind_errmsg; /* Indicator variable */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int rownum; /* Sequence number of the */
                                /* table row */
    char      db2member[9]; /* DB2 data sharing group */
                                /* member name */
}
```

```

char          hostname[256];          /* Host name of the connected */
                                           /* DB2 subsystem or DB2      */
                                           /* member name                */

EXEC SQL END DECLARE SECTION;

/*****
/* Assign values to input parameters to find the host name of      */
/* the connected DB2 subsystem                                     */
/* Set the indicator variables to 0 for non-null input parameters */
/* Set the indicator variables to -1 for null input parameters    */
*****/
procopt = 1;
ind_procopt = 0;
ind_db2mbr = -1;

/*****
/* Call stored procedure SYSPROC.ADMIN_INFO_HOST                    */
*****/
EXEC SQL CALL SYSPROC.ADMIN_INFO_HOST
           (:procopt   :ind_procopt,
           :db2mbr    :ind_db2mbr,
           :retcd     :ind_retcd,
           :errmsg    :ind_errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446,     */
/* which indicates that result sets were returned                 */
*****/
if (SQLCODE == +446)          /* Result sets were returned */
{
  /* Establish a link between the result set and its locator      */
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
        WITH PROCEDURE SYSPROC.ADMIN_INFO_HOST;

  /* Associate a cursor with the result set                        */
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Use C1 to fetch the only row from the result set            */
  EXEC SQL FETCH C1 INTO :rownum, :db2mbr, :hostname;
}

return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1349:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the host names.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.SYSTEM\_HOSTNAME:

*Table 355. Result set row for ADMIN\_INFO\_HOST result set*

| Column name | Data type | Contents                                               |
|-------------|-----------|--------------------------------------------------------|
| ROWNUM      | INTEGER   | Sequence number of the table row, from 1 to <i>n</i> . |

Table 355. Result set row for ADMIN\_INFO\_HOST result set (continued)

| Column name | Data type    | Contents                                                                                                                                                                                                                        |
|-------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB2_MEMBER  | CHAR(8)      | DB2 data sharing group member name.                                                                                                                                                                                             |
| HOSTNAME    | VARCHAR(255) | Host name of the connected DB2 subsystem if the <i>processing-option</i> input parameter is 1 and the <i>DB2-member</i> input parameter is null. Otherwise, the host name of the DB2 member specified in the DB2_MEMBER column. |

## ADMIN\_INFO\_SSID stored procedure

The SYSPROC.ADMIN\_INFO\_SSID stored procedure returns the name of the connected DB2 subsystem.

### GUPI

### Environment

ADMIN\_INFO\_SSID must run in a WLM-established stored procedure address space.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_INFO\_SSID stored procedure
- Ownership of the stored procedure
- SYSADM authority

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_INFO_SSID—(—subsystem-ID,—return-code,—message—)————▶▶
```

### Option descriptions

#### *subsystem-ID*

Identifies the subsystem ID of the connected DB2 subsystem

This is an output parameter of type VARCHAR(4).

#### *return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.

12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_INFO\_SSID:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_INFO_SSID PARAMETERS */
  char      ssid[5];           /* DB2 subsystem identifier */
  long int  retcd;            /* Return code */
  char      errmsg[1332];     /* Error message */
  EXEC SQL END DECLARE SECTION;

  /***** Call stored procedure SYSPROC.ADMIN_INFO_SSID *****/
  EXEC SQL CALL SYSPROC.ADMIN_INFO_SSID
              (:ssid, :retcd, :errmsg);

  return(retcd);
}
```

## Output

The output of this stored procedure is the following output parameters, which are described in “Option descriptions” on page 1352:

- *subsystem-ID*
- *return-code*
- *message*

---

## ADMIN\_INFO\_SYSPARM stored procedure

The SYSPROC.ADMIN\_INFO\_SYSPARM stored procedure returns the system parameters, DSNHDECP parameters, and IRLM parameters of a connected DB2 subsystem, or member of its data sharing group.

This stored procedure functions the same as the SYSPROC.DSNWZP stored procedure, except that the ADMIN\_INFO\_SYSPARM stored procedure returns IRLM parameters, accepts a DB2 member as input, and returns the parameter settings in a result set.

## Environment

ADMIN\_INFO\_SYSPARM runs in a WLM-established stored procedures address space, where NUMTCB=1 is required.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMIZ
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The user who calls this stored procedure must have MONITOR1 privilege.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_INFO_SYSPARM ( ( DB2-member , -return-code , -message- ) )
```

The diagram shows a SQL CALL statement for the stored procedure ADMIN\_INFO\_SYSPARM. The statement is enclosed in a rectangular box with double arrowheads at both ends. The syntax is: CALL SYSPROC.ADMIN\_INFO\_SYSPARM ( ( DB2-member , -return-code , -message- ) ). A bracket underlines the DB2-member parameter, with the word NULL written below it, indicating that NULL is an acceptable value for this parameter.

## Option descriptions

### *DB2-member*

Specifies the name of the DB2 data sharing group member that you want to get the system parameters, DSNHDECP values, and IRLM parameters from.

Specify NULL for this parameter if you are retrieving the system parameters, DSNHDECP values, and IRLM parameters from the connected DB2 subsystem.

This is an input parameter of type VARCHAR(8).

### *return-code*

Provides the return code from the stored procedure. The following values are possible:

- 0** The call completed successfully.
- 12** The call did not complete successfully. The *message* output parameter contains messages that describe the IFI error or SQL error that is encountered by the stored procedure.

This is an output parameter of type INTEGER.

*message*

Contains messages that describe the IFI error or SQL error that was encountered by the stored procedure. If an error did not occur, a message is not returned.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_INFO\_SYSPARM:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_INFO_SYSPARM parameters */
  char db2_member[9]; /* Data sharing group member */
  short int ind_db2_member; /* Indicator variable */
  long int retcd; /* Return code */
  short int ind_retcd; /* Indicator variable */

        WITH PROCEDURE SYSPROC.ADMIN_INFO_SYSPARM;
  /* Associate a cursor with the result set */
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;
  /* Perform fetches using C1 to retrieve all rows from the */
  /* result set */
  EXEC SQL FETCH C1
        INTO :rownum, :macro, :parameter,
            :install_panel :ind_install_panel,
            :install_field :ind_install_field,
            :install_location :ind_install_location,
            :value,
            :additional_info :ind_additional_info;
  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1
          INTO :rownum, :macro, :parameter,
              :install_panel :ind_install_panel,
              :install_field :ind_install_field,
              :install_location :ind_install_location,
              :value,
              :additional_info :ind_additional_info;
  }
}
return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1354:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the parameter settings.

The following table shows the format of the result set that is returned in the created global temporary table SYSIBM.DB2\_SYSPARM:

*Table 356. Result set row for ADMIN\_INFO\_SYSPARM result set*

| Column name | Data type           | Contents                                               |
|-------------|---------------------|--------------------------------------------------------|
| ROWNUM      | INTEGER<br>NOT NULL | Sequence number of the table row, from 1 to <i>n</i> . |

Table 356. Result set row for ADMIN\_INFO\_SYSPARM result set (continued)

| Column name      | Data type                 | Contents                                                                                                                                                       |
|------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MACRO            | VARCHAR(8)<br>NOT NULL    | Macro that contains the system parameter, the DSNHDECP parameter, or the name of the IRLM procedure that z/OS invokes if IRLM is started automatically by DB2. |
| PARAMETER        | VARCHAR(40)<br>NOT NULL   | Name of the system parameter, DSNHDECP parameter, or IRLM parameter.                                                                                           |
| INSTALL_PANEL    | VARCHAR(8)                | Name of the installation panel where the parameter value can be changed when installing or migrating DB2.                                                      |
| INSTALL_FIELD    | VARCHAR(40)               | Name of the parameter on the installation panel.                                                                                                               |
| INSTALL_LOCATION | VARCHAR(12)               | Location of the parameter on the installation panel.                                                                                                           |
| VALUE            | VARCHAR(2048)<br>NOT NULL | The value of the parameter.                                                                                                                                    |
| ADDITIONAL_INFO  | VARCHAR(200)              | Reserved for future use.                                                                                                                                       |

## ADMIN\_JOB\_CANCEL stored procedure

The SYSPROC.ADMIN\_JOB\_CANCEL stored procedure purges or cancels a job.

### Environment

The load module for ADMIN\_JOB\_CANCEL, DSNADMJP, must reside in an APF-authorized library. ADMIN\_JOB\_CANCEL runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN\_JOB\_CANCEL, DSNADMJP, must be program controlled if the BPX.DAEMON.HFCTL FACILITY class profile has not been set up. For information on how to define DSNADMJP to program control, see installation job DSNTIJRA.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_JOB\_CANCEL stored procedure
- Ownership of the stored procedure
- SYSADM authority

The user specified in the *user-ID* input parameter of the SQL CALL statement also needs authorization from an external security system, such as RACF, in order to perform the requested operation.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
CALL SYSPROC.ADMIN_JOB_CANCEL(—user-ID,—password,—processing-option,—job-ID,—  
return-code,—message—)
```

## Option descriptions

### *user-ID*

Specifies the user ID under which the job is canceled or purged.

This is an input parameter of type VARCHAR(128) and cannot be null.

### *password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

This is an input parameter of type VARCHAR(24) and cannot be null.

### *processing-option*

Identifies the type of command to invoke. Possible values are:

- 1 Cancel a job.
- 2 Purge a job.

This is an input parameter of type INTEGER and cannot be null.

### *job-ID*

Specifies the job ID of the job to be canceled or purged. Acceptable formats are:

- Jnnnnnnn
- JOBnnnnnn

where *n* is a digit between 0 and 9. For example: JOB01035

Both Jnnnnnnn and JOBnnnnnn must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

### *return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

### *message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by z/OS might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_JOB\_CANCEL:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_JOB_CANCEL parameters */
  char      userid[129];          /* User ID */
  short int ind_userid;          /* Indicator variable */
  char      password[25];        /* Password */
  short int ind_password;        /* Indicator variable */
  long int  procopt;             /* Processing option */
  short int ind_procopt;         /* Indicator variable */
  char      jobid[9];            /* Job ID */
  short int ind_jobid;           /* Indicator variable */
  long int  retcd;               /* Return code */
  short int ind_retcd;           /* Indicator variable */
  char      errmsg[1332];        /* Error message */
  short int ind_errmsg;          /* Indicator variable */
  EXEC SQL END DECLARE SECTION;

  /***** Assign values to input parameters to purge a job */
  /* Set the indicator variables to 0 for non-null input parameters */
  strcpy(userid, "USRT001");
  ind_userid = 0;
  strcpy(password, "NICETEST");
  ind_password = 0;
  procopt = 2;
  ind_procopt = 0;
  strcpy(jobid, "JOB00105");
  ind_jobid = 0;

  /***** Call stored procedure SYSPROC.ADMIN_JOB_CANCEL *****/
  EXEC SQL CALL SYSPROC.ADMIN_JOB_CANCEL
              (:userid   :ind_userid,
               :password :ind_password,
               :procopt  :ind_procopt,
               :jobid    :ind_jobid,
               :retcd    :ind_retcd,
               :errmsg   :ind_errmsg);

  return(retcd);
}
```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1358:

- *return-code*

- *message*

---

## ADMIN\_JOB\_FETCH stored procedure

The SYSPROC.ADMIN\_JOB\_FETCH stored procedure retrieves SYSOUT from JES spool and returns the SYSOUT.

### Environment

The load module for ADMIN\_JOB\_FETCH, DSNADMJF, must reside in an APF-authorized library. ADMIN\_JOB\_FETCH runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN\_JOB\_FETCH, DSNADMJF, must be program controlled if the BPX.DAEMON.HFCTL FACILITY class profile has not been set up. For information on how to define DSNADMJF to program control, see installation job DSNTIJRA.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMJF
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_JOB_FETCH—(—user-ID,—password,—job-ID,—return-code,—message—)————▶▶
```

### Option descriptions

*user-ID*

Specifies the user ID under which SYSOUT is retrieved.

This is an input parameter of type VARCHAR(128) and cannot be null.

*password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

This is an input parameter of type VARCHAR(24) and cannot be null.

*job-ID*

Specifies the JES2 or JES3 job ID whose SYSOUT data sets are to be retrieved.

This is an input parameter of type CHAR(8) and cannot be null.

*return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_JOB\_FETCH:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_FETCH parameters */
    char      userid[129];          /* User ID */
    short int ind_userid;          /* Indicator variable */
    char      password[25];        /* Password */
    short int ind_password;        /* Indicator variable */
    char      jobid[9];            /* Job ID */
    short int ind_jobid;           /* Indicator variable */
    long int  retcd;               /* Return code */
    short int ind_retcd;           /* Indicator variable */
    char      errmsg[1332];        /* Error message */
    short int ind_errmsg;          /* Indicator variable */

    /* Result set locators */
    volatile SQL TYPE IS RESULT_SET_LOCATOR *rs_loc1;

    /* Result set row */
    long int  rownum;              /* Sequence number of the */
    char      text[4097];          /* table row */
    EXEC SQL END DECLARE SECTION;

    /***** Assign values to input parameters to fetch the SYSOUT of a job */
    /* Set the indicator variables to 0 for non-null input parameters */
    strcpy(userid, "USRT001");
    ind_userid = 0;
    strcpy(password, "NICETEST");
    ind_password = 0;
    strcpy(jobid, "JOB00100");
```

```

ind_jobid = 0;

/*****
/* Call stored procedure SYSPROC.ADMIN_JOB_FETCH
*****/
EXEC SQL CALL SYSPROC.ADMIN_JOB_FETCH
              (:userid   :ind_userid,
              :password  :ind_password,
              :jobid     :ind_jobid,
              :retcd     :ind_retcd,
              :errmsg    :ind_errmsg);

/*****
/* Retrieve result set when the SQLCODE from the call is +446,
/* which indicates that result sets were returned
*****/
if (SQLCODE == +466)          /* Result sets were returned */
{
  /* Establish a link between the result set and its locator
  EXEC SQL ASSOCIATE LOCATORS (:rs_loc1)
  WITH PROCEDURE SYSPROC.ADMIN_JOB_FETCH;

  /* Associate a cursor with the result set
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :rs_loc1;

  /* Perform fetches using C1 to retrieve all rows from the
  /* result set
  EXEC SQL FETCH C1 INTO :rownum, :text;
  while(SQLCODE==0)
  {
    EXEC SQL FETCH C1 INTO :rownum, :text;
  }
}

return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1360:

- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the data from the JES-managed SYSOUT data set that belong to the job ID specified in the input parameter *job-ID*.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.JES\_SYSOUT:

*Table 357. Result set row for ADMIN\_JOB\_FETCH result set*

| Column name | Data type     | Contents                         |
|-------------|---------------|----------------------------------|
| ROWNUM      | INTEGER       | Sequence number of the table row |
| TEXT        | VARCHAR(4096) | A record in the SYSOUT data set  |

---

## ADMIN\_JOB\_QUERY stored procedure

The SYSPROC.ADMIN\_JOB\_QUERY stored procedure displays the status and completion information of a job.

### Environment

The load module for ADMIN\_JOB\_QUERY, DSNADMJQ, must reside in an APF-authorized library. ADMIN\_JOB\_QUERY runs in a WLM-established stored procedures address space, and all libraries in this WLM procedure STEPLIB DD concatenation must be APF-authorized.

The load module for ADMIN\_JOB\_QUERY, DSNADMJQ, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJQ to program control, see installation job DSNTIJRA.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges:

- The EXECUTE privilege on the ADMIN\_JOB\_QUERY stored procedure
- Ownership of the stored procedure
- SYSADM authority

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```
▶▶—CALL—SYSPROC.ADMIN_JOB_QUERY—(—user-ID,—password,—job-ID,—status,—max-RC,—  
▶—completion-type,—system-abend-code,—user-abend-code,—return-code,—message—)▶▶
```

### Option descriptions

#### *user-ID*

Specifies the user ID under which the job is queried.

This is an input parameter of type VARCHAR(128) and cannot be null.

#### *password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

This is an input parameter of type VARCHAR(24) and cannot be null.

#### *job-ID*

Specifies the job ID of the job being queried. Acceptable formats are:

- Jnnnnnnnn
- JOBnnnnnn

where *n* is a digit between 0 and 9. For example: JOB01035

Both *Jnnnnnnnn* and *JOBnnnnnn* must be exactly 8 characters in length.

This is an input parameter of type CHAR(8) and cannot be null.

*status*

Identifies the current status of the job. Possible values are:

- 1 Job received, but not yet run (INPUT).
- 2 Job running (ACTIVE).
- 3 Job finished and has output to be printed or retrieved (OUTPUT).
- 4 Job not found.
- 5 Job in an unknown phase.

This is an output parameter of type INTEGER.

*max-RC*

Provides the job completion code.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

*completion-type*

Identifies the job's completion type. Possible values are:

- 0 No completion information is available.
- 1 Job ended normally.
- 2 Job ended by completion code.
- 3 Job had a JCL error.
- 4 Job was canceled.
- 5 Job terminated abnormally.
- 6 Converter terminated abnormally while processing the job.
- 7 Job failed security checks.
- 8 Job failed in end-of-memory .

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

The *completion-type* information is the last six bits in the field STTRMXRC of the IAZSSST mapping macro. This information is returned via SSI 80. For additional information, see the discussion of the SSST macro in *z/OS MVS Data Areas*.

This is an output parameter of type INTEGER.

*system-abend-code*

Returns the system abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

*user-abend-code*

Returns the user abend code if an abnormal termination occurs.

This parameter is always null if querying in a JES3 z/OS Version 1.7 or earlier system. For JES3, this feature is only supported for z/OS Version 1.8 or higher.

This is an output parameter of type INTEGER.

*return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 The call completed successfully.
- 4 The job was not found, or the job status is unknown.
- 12 The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

This is an output parameter of type VARCHAR(1331).

## Example

The following C language sample shows how to invoke ADMIN\_JOB\_QUERY:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
  /***** DB2 Host Variables *****/
  EXEC SQL BEGIN DECLARE SECTION;

  /* SYSPROC.ADMIN_JOB_QUERY parameters */
  char      userid[129];          /* User ID */
  short int ind_userid;          /* Indicator variable */
  char      password[25];        /* Password */
  short int ind_password;        /* Indicator variable */
  char      jobid[9];            /* Job ID */
  short int ind_jobid;           /* Indicator variable */
  long int  stat;                /* Job status */
  short int ind_stat;            /* Indicator variable */
  long int  maxrc;               /* Job maxcc */
  short int ind_maxrc;           /* Indicator variable */
  long int  comptype;            /* Job completion type */
  short int ind_comptype;        /* Indicator variable */
  long int  sabndcd;             /* System abend code */
  short int ind_sabndcd;         /* Indicator variable */
  long int  uabndcd;             /* User abend code */
  short int ind_uabndcd;         /* Indicator variable */
  long int  retcd;               /* Return code */
  short int ind_retcd;           /* Indicator variable */
  char      errmsg[1332];        /* Error message */
  short int ind_errmsg;          /* Indicator variable */
  EXEC SQL END DECLARE SECTION;

  /*****
  /* Assign values to input parameters to query the status and
  /* completion code of a job
  /* Set the indicator variables to 0 for non-null input parameters */
  *****/
```

```

|         strcpy(userid, "USRT001");
|         ind_userid = 0;
|         strcpy(password, "NICETEST");
|         ind_password = 0;
|         strcpy(jobid, "JOB00111");
|         ind_jobid = 0;
|
|         /*****
|         /* Call stored procedure SYSPROC.ADMIN_JOB_QUERY          */
|         /*****
|         EXEC SQL CALL SYSPROC.ADMIN_JOB_QUERY
|                (:userid   :ind_userid,
|                 :password :ind_password,
|                 :jobid    :ind_jobid,
|                 :stat     :ind_stat,
|                 :maxrc    :ind_maxrc,
|                 :comptype :ind_comptype,
|                 :sabndcd  :ind_sabndcd,
|                 :uabndcd  :ind_uabndcd,
|                 :retcd    :ind_retcd,
|                 :errmsg   :ind_errmsg);
|
|         return(retcd);
|     }

```

## Output

This stored procedure returns the following output parameters, which are described in "Option descriptions" on page 1363:

- *status*
- *max-RC*
- *completion-type*
- *system-abend-code*
- *user-abend-code*
- *return-code*
- *message*

---

## ADMIN\_JOB\_SUBMIT stored procedure

The SYSPROC.ADMIN\_JOB\_SUBMIT stored procedure submits a job to a JES2 or JES3 system.

### Environment

ADMIN\_JOB\_SUBMIT runs in a WLM-established stored procedures address space.

The load module for ADMIN\_JOB\_SUBMIT, DSNADMJS, must be program controlled if the BPX.DAEMON.HFSCCTL FACILITY class profile has not been set up. For information on how to define DSNADMJS to program control, see installation job DSNTIJRA.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMJS

- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```

▶▶—CALL—SYSPROC.ADMIN_JOB_SUBMIT—(—user-ID,—password,—job-ID,—return-code,—message—)————▶▶

```

## Option descriptions

### *user-ID*

Specifies the user ID under which the job is submitted.

This is an input parameter of type VARCHAR(128) and cannot be null.

### *password*

Specifies the password associated with the input parameter *user-ID*.

The value of *password* is passed to the stored procedure as part of payload, and is not encrypted. It is not stored in dynamic cache when parameter markers are used.

This is an input parameter of type VARCHAR(24) and cannot be null.

### *job-ID*

Identifies the JES2 or JES3 job ID of the submitted job.

This is an output parameter of type CHAR(8).

### *return-code*

Provides the return code from the stored procedure. Possible values are:

**0**      The call completed successfully.

**12**     The call did not complete successfully. The *message* output parameter contains messages describing the error.

This is an output parameter of type INTEGER.

### *message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## Additional input

In addition to the input parameters, the stored procedure submits the job's JCL from the created global temporary table SYSIBM.JOB\_JCL for execution.

The following table shows the format of the created global temporary table SYSIBM.JOB\_JCL:

Table 358. Additional input for the ADMIN\_JOB\_SUBMIT stored procedure

| Column name | Data type   | Contents                                             |
|-------------|-------------|------------------------------------------------------|
| ROWNUM      | INTEGER     | Sequence number of the table row, from 1 to <i>n</i> |
| STMT        | VARCHAR(80) | A JCL statement                                      |

## Example

The following C language sample shows how to invoke ADMIN\_JOB\_SUBMIT:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_JOB_SUBMIT parameters */
    char    userid[129];          /* User ID */
    short int ind_userid;        /* Indicator variable */
    char    password[25];        /* Password */
    short int ind_password;     /* Indicator variable */
    char    jobid[9];            /* Job ID */
    short int ind_jobid;        /* Indicator variable */
    long int retcd;              /* Return code */
    short int ind_retcd;        /* Indicator variable */
    char    errmsg[1332];        /* Error message */
    short int ind_errmsg;       /* Indicator variable */

    /* Temporary table SYSIBM.JOB_JCL columns */
    long int rownum;             /* Sequence number of the */
                                /* table row */
    char    stmt[81];            /* JCL statement */
    EXEC SQL END DECLARE SECTION;

    /***** */
    /* Create the JCL job to be submitted for execution */
    /***** */
    char jclstmt[12][50] = {
        " //IEBCOPY JOB ,CLASS=K,MSGCLASS=H,MSGLEVEL=(1,1)",
        " //STEP010 EXEC PGM=IEBCOPY",
        " //SYSPRINT DD SYSOUT=*",
        " //SYSUT3 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
        " //SYSUT4 DD SPACE=(TRK,(1,1)),UNIT=SYSDA",
        " /*",
        " //DDI1 DD DSN=USER.DEV.LOADLIB1,DISP=SHR",
        " //DDO1 DD DSN=USER.DEV.LOADLIB2,DISP=SHR",
        " //SYSIN DD *",
        " COPY OUTDD=DDO1,INDD=DDI1",
        " /*",
        " /*"
    };
    int i = 0; /* loop counter */

    /***** */
    /* Assign values to input parameters */
    /* Set the indicator variables to 0 for non-null input parameters */
    /***** */
    strcpy(userid, "USRT001");
```

```

ind_userid = 0;
strcpy(password, "NICETEST");
ind_password = 0;

/*****
/* Clear temporary table SYSIBM.JOB_JCL */
/*****
EXEC SQL DELETE FROM SYSIBM.JOB_JCL;

/*****
/* Insert the JCL job into the temporary table SYSIBM.JOB_JCL */
/*****
for (i = 0; i < 12; i++)
{
    rownum = i+1;
    strcpy(stmt, jclstmt[i]);
    EXEC SQL INSERT INTO SYSIBM.JOB_JCL
        ( ROWNUM, STMT)
        VALUES (:rownum, :stmt);
};

/*****
/* Call stored procedure SYSPROC.ADMIN_JOB_SUBMIT */
/*****
EXEC SQL CALL SYSPROC.ADMIN_JOB_SUBMIT
        (:userid :ind_userid,
         :password :ind_password,
         :jobid :ind_jobid,
         :retcd :ind_retcd,
         :errmsg :ind_errmsg);

return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1367:

- *job-ID*
- *return-code*
- *message*

---

## ADMIN\_UTL\_SCHEDULE stored procedure

The SYSPROC.ADMIN\_UTL\_SCHEDULE stored procedure executes parallel utility execution.

### Environment

ADMIN\_UTL\_SCHEDULE runs in a WLM-established stored procedures address space.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

- The EXECUTE privilege on the package for DSNADMUM
- Ownership of the package
- PACKADM authority for the package collection

- SYSADM authority

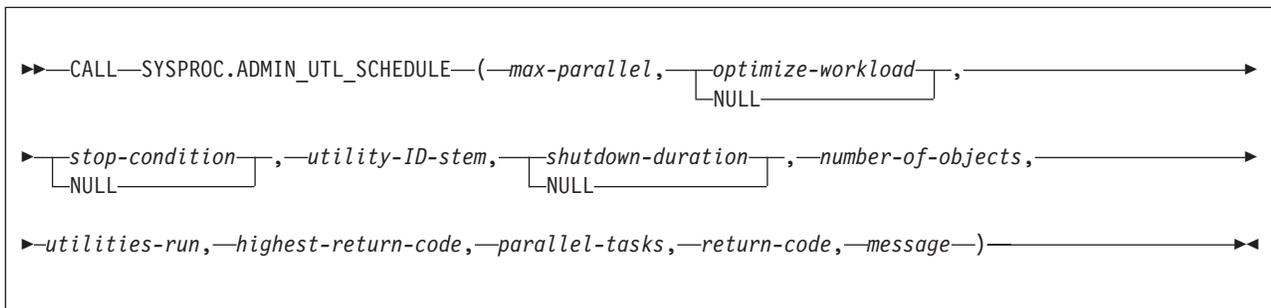

The ADMIN\_UTL\_SCHEDULE stored procedure internally calls the following stored procedures:

- ADMIN\_COMMAND\_DB2, to execute the DB2 DISPLAY UTILITY command
- ADMIN\_INFO\_SSID, to obtain the subsystem ID of the connected DB2 subsystem
- ADMIN\_UTL\_SORT, to sort objects into parallel execution units
- DSNUTILU, to run the requested utilities

The owner of the package or plan that contains the CALL ADMIN\_UTL\_SCHEDULE statement must also have the authorization required to execute these stored procedures and run the requested utilities. To determine the privilege or authority required to call DSNUTILU, see *DB2 Utility Guide and Reference*.

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

## Option descriptions

### *max-parallel*

Specifies the maximum number of parallel threads that may be started. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

### *optimize-workload*

Specifies whether the parallel utility executions should be sorted to achieve shortest overall execution time. Possible values are:

#### **NO or null**

The workload is not to be sorted.

**YES** The workload is to be sorted.

This is an input parameter of type VARCHAR(8). The default value is NO.

### *stop-condition*

Specifies the utility execution condition after which ADMIN\_UTL\_SCHEDULE will not continue starting new utility executions in parallel, but will wait until all currently running utilities have completed and will then return to the caller. Possible values are:

| **AUTHORIZ or null**

| No new utility executions will be started after one of the currently  
| running utilities has encountered a return code from DSNUTILU of 12  
| or higher.

| **WARNING**

| No new utility executions will be started after one of the currently  
| running utilities has encountered a return code from DSNUTILU of 4  
| or higher.

| **ERROR**

| No new utility executions will be started after one of the currently  
| running utilities has encountered a return code from DSNUTILU of 8  
| or higher.

| This is an input parameter of type VARCHAR(8). The default value is  
| AUTHORIZ.

| *utility-ID-stem*

| Specifies the first part of the utility ID of a utility execution in a parallel  
| thread. The complete utility ID is dynamically created in the form  
| *utility-ID-stem* followed by *TT* followed by *NNNNNN*, where:

| *TT* The zero-padded number of the subtask executing the utility

| *NNNNNN*

| A consecutive number of utilities executed in a subtask.

| For example, utilityidstem02000005 is the fifth utility execution that has been  
| processed by the second subtask.

| This is an input parameter of type VARCHAR(8) and cannot be null.

| *shutdown-duration*

| Specifies the number of seconds that ADMIN\_UTL\_SCHEDULE will wait for a  
| utility execution to complete before a shutdown is initiated. When a shutdown  
| is initiated, current utility executions can run to completion, and no new utility  
| will be started. Possible values are:

| **null** A shutdown will not be performed

| **1 to 999999999999999**

| A shutdown will be performed after this many seconds

| This is an input parameter of type FLOAT(8). The default value is null.

| *number-of-objects*

| As an input parameter, this specifies the number of utility executions and their  
| sorting objects that were passed in the SYSIBM.UTILITY\_OBJECTS table.  
| Possible values are 1 to 999999.

| As an output parameter, this specifies the number of objects that were passed  
| in SYSIBM.UTILITY\_OBJECTS table that are found in the DB2 catalog.

| This is an input and output parameter of type INTEGER and cannot be null.

| *utilities-run*

| Indicates the number of actual utility executions.

| This is an output parameter of type INTEGER.

| *highest-return-code*

| Indicates the highest return code from DSNUTILU for all utility executions.

| This is an output parameter of type INTEGER.

*parallel-tasks*

Indicates the actual number of parallel tasks that were started to execute the utility in parallel.

This is an output parameter of type SMALLINT.

*return-code*

Provides the return code from the stored procedure. Possible values are:

- 0 All parallel utility executions ran successfully.
- 4 The statistics for one or more sorting objects have not been gathered in the catalog.
- 12 An ADMIN\_UTL\_SCHEDULE error occurred or all the objects passed in the SYSIBM.UTILITY\_OBJECTS table are not found in the DB2 catalog. The *message* parameter contains details.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

### Additional input

In addition to the input parameters, the stored procedure reads from the created global temporary tables SYSIBM.UTILITY\_OBJECTS and SYSIBM.UTILITY\_STMT.

The stored procedure reads objects for utility execution from SYSIBM.UTILITY\_OBJECTS. The following table shows the format of the created global temporary table SYSIBM.UTILITY\_OBJECTS:

*Table 359. Format of the input objects*

| Column name | Data type   | Contents                                                                                                                                                                      |
|-------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OBJECTID    | INTEGER     | A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert. |
| STMTID      | INTEGER     | A statement row in SYSIBM.UTILITY_STMT                                                                                                                                        |
| TYPE        | VARCHAR(10) | Object type: <ul style="list-style-type: none"> <li>• TABLESPACE</li> <li>• INDEXSPACE</li> <li>• TABLE</li> <li>• INDEX</li> <li>• STOGROUP</li> </ul>                       |

Table 359. Format of the input objects (continued)

| Column name | Data type    | Contents                                                                                                                                                                                                                                                                                                       |
|-------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QUALIFIER   | VARCHAR(128) | Qualifier (database or creator) of the object in NAME, empty or null for STOGROUP. If the qualifier is not provided and the type of the object is TABLESPACE or INDEXSPACE, then the default database is DSNDB04. If the object is of the type TABLE or INDEX, the schema is the current SQL authorization ID. |
| NAME        | VARCHAR(128) | Unqualified name of the object. NAME cannot be null. If the object no longer exists, it will be ignored and the corresponding utility will not be executed.                                                                                                                                                    |
| PART        | SMALLINT     | Partition number of the object for which the utility will be invoked. Null or 0 if the object is not partitioned.                                                                                                                                                                                              |
| RESTART     | VARCHAR(8)   | Restart parameter of DSNUTILU                                                                                                                                                                                                                                                                                  |

Table 359. Format of the input objects (continued)

| Column name  | Data type   | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UTILITY_NAME | VARCHAR(20) | <p>Utility name.<br/>UTILITY_NAME cannot be null.</p> <p><b>Recommendation:</b> Sort objects for the same utility.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• CHECK DATA</li> <li>• CHECK INDEX</li> <li>• CHECK LOB</li> <li>• COPY</li> <li>• COPYTOCOPY</li> <li>• DIAGNOSE</li> <li>• LOAD</li> <li>• MERGECOPY</li> <li>• MODIFY RECOVERY</li> <li>• MODIFY STATISTICS</li> <li>• QUIESCE</li> <li>• REBUILD INDEX</li> <li>• RECOVER</li> <li>• REORG INDEX</li> <li>• REORG LOB</li> <li>• REORG TABLESPACE</li> <li>• REPAIR</li> <li>• REPORT RECOVERY</li> <li>• REPORT TABLESPACESET</li> <li>• RUNSTATS INDEX</li> <li>• RUNSTATS TABLESPACE</li> <li>• STOSPACE</li> <li>• UNLOAD</li> </ul> |

The stored procedure reads the corresponding utility statements from SYSIBM.UTILITY\_STMT. The following table shows the format of the created global temporary table SYSIBM.UTILITY\_STMT:

Table 360. Format of the utility statements

| Column name | Data type | Contents                                                              |
|-------------|-----------|-----------------------------------------------------------------------|
| STMTID      | INTEGER   | A unique positive identifier for a single utility execution statement |

Table 360. Format of the utility statements (continued)

| Column name | Data type     | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STMTSEQ     | INTEGER       | If a utility statement exceeds 4000 characters, it can be split up and inserted into SYSIBM.UTILITY_STMT with the sequence starting at 0, and then being incremented with every insert. During the actual execution, the statement pieces are concatenated without any separation characters or blanks in between.                                                                                                                                  |
| UTSTMT      | VARCHAR(4000) | A utility statement or part of a utility statement. A placeholder &OBJECT. can be used to be replaced by the object name passed in SYSIBM.UTILITY_OBJECTS. A placeholder &THDINDEX. can be used to be replaced by the current thread index (01-99) of the utility being executed. You can use this when running REORG with SHRLEVEL CHANGE in parallel, so that you can specify a different mapping table for each thread of the utility execution. |

## Example

The following C language sample shows how to invoke ADMIN\_UTL\_SCHEDULE:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

/***** DB2 SQL Communication Area *****/
EXEC SQL INCLUDE SQLCA;

int main( int argc, char *argv[] ) /* Argument count and list */
{
    /***** DB2 Host Variables *****/
    EXEC SQL BEGIN DECLARE SECTION;

    /* SYSPROC.ADMIN_UTL_SCHEDULE parameters */
    short int maxparallel; /* Max parallel */
    short int ind_maxparallel; /* Indicator variable */
    char optimizeworkload[9]; /* Optimize workload */
    short int ind_optimizeworkload; /* Indicator variable */
    char stoponcond[9]; /* Stop on condition */
    short int ind_stoponcond; /* Indicator variable */
    char utilityidstem[9]; /* Utility ID stem */
    short int ind_utilityidstem; /* Indicator variable */
    float shutdownduration; /* Shutdown duration */
    short int ind_shutdownduration; /* Indicator variable */
    long int numberofobjects; /* Number of objects */
}
```

```

short int ind_numberofobjects;      /* Indicator variable      */
long int utilitiesexec;             /* Utilities executed      */
short int ind_utilitiesexec;        /* Indicator variable      */
long int highestretcd;              /* DSNUTILU highest ret code */
short int ind_highestretcd;         /* Indicator variable      */
long int paralleltasks;             /* Parallel tasks          */
short int ind_paralleltasks;        /* Indicator variable      */
long int retcd;                     /* Return code             */
short int ind_retcd;                /* Indicator variable      */
char errmsg[1332];                  /* Error message           */
short int ind_errmsg;               /* Indicator variable      */

/* Temporary table SYSIBM.UTILITY_OBJECTS columns */

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1370:

- *number-of-objects*
- *utilities-run*
- *highest-return-code*
- *parallel-tasks*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns two results sets.

The first result set is returned in the created global temporary table SYSIBM.UTILITY\_SYSPRINT and contains the output from the individual utility executions. The following table shows the format of the created global temporary table SYSIBM.UTILITY\_SYSPRINT:

*Table 361. Result set row for first ADMIN\_UTL\_SCHEDULE result set*

| Column name | Data type    | Contents                                                                                                                          |
|-------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------|
| OBJECTID    | INTEGER      | A unique positive identifier for the object the utility execution is associated with                                              |
| TEXTSEQ     | INTEGER      | Sequence number of utility execution output statements for the object whose unique identifier is specified in the OBJECTID column |
| TEXT        | VARCHAR(254) | A utility execution output statement                                                                                              |

The second result set is returned in the created global temporary table SYSIBM.UTILITY\_RETCODE and contains the return code for each of the individual DSNUTILU executions. The following table shows the format of the output created global temporary table SYSIBM.UTILITY\_RETCODE:

*Table 362. Result set row for second ADMIN\_UTL\_SCHEDULE result set*

| Column name | Data type | Contents                                                                             |
|-------------|-----------|--------------------------------------------------------------------------------------|
| OBJECTID    | INTEGER   | A unique positive identifier for the object the utility execution is associated with |
| RETCODE     | INTEGER   | Return code from DSNUTILU for this utility execution                                 |

## ADMIN\_UTL\_SORT stored procedure

The SYSPROC.ADMIN\_UTL\_SORT stored procedure sorts objects for parallel utility execution using JCL or the ADMIN\_UTL\_SCHEDULE stored procedure.

### Environment

ADMIN\_UTL\_SORT runs in a WLM-established stored procedures address space.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have one or more of the following privileges on each package that the stored procedure uses:

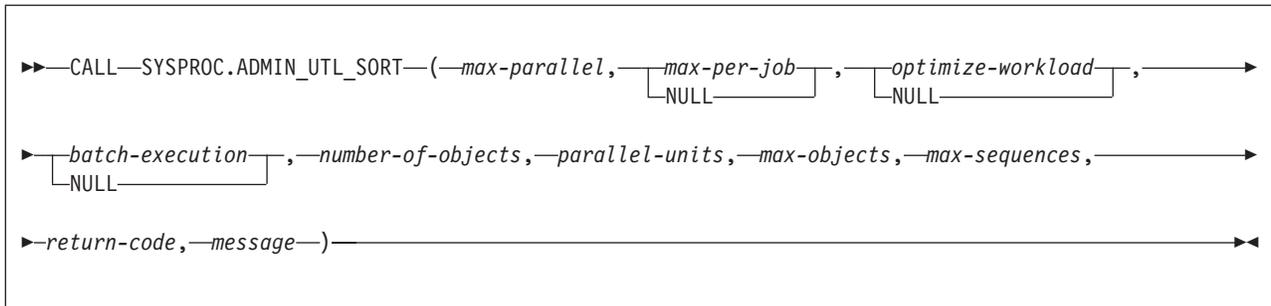

- The EXECUTE privilege on the package for DSNADMUS
- Ownership of the package
- PACKADM authority for the package collection
- SYSADM authority

The owner of the package or plan that contains the CALL statement must also have SELECT authority on the following catalog tables:

- SYSIBM.SYSTABLEPART
- SYSIBM.SYSINDEXPART
- SYSIBM.SYSINDEXES
- SYSIBM.SYSTABLES

## Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

## Option descriptions

### *max-parallel*

Specifies the maximum number of parallel units. The actual number may be lower than the requested number based on the optimizing sort result. Possible values are: 1 to 99.

This is an input parameter of type SMALLINT and cannot be null.

### *max-per-job*

Specifies the maximum number of steps per job for batch execution. Possible values are:

#### **1 to 255**

Steps per job for batch execution

#### **null** Online execution

This is an input parameter of type SMALLINT. This parameter cannot be null if *batch-execution* is YES.

### *optimize-workload*

Specifies whether the parallel units should be sorted to achieve shortest overall execution time. Possible values are:

#### **NO or null**

The workload is not to be sorted.

#### **YES** The workload is to be sorted.

This is an input parameter of type VARCHAR(8). The default value is NO.

### *batch-execution*

Indicates whether the objects should be sorted for online or batch (JCL) execution.

#### **NO or null**

The workload is for online execution.

#### **YES** The workload is for batch execution.

This is an input parameter of type VARCHAR(8). The default value is NO.

*number-of-objects*

As an input parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY\_SORT\_OBJ. Possible values are: 1 to 999999.

As an output parameter, this specifies the number of objects that were passed in SYSIBM.UTILITY\_SORT\_OBJ table that are found in the DB2 catalog.

This is an input and output parameter of type INTEGER and cannot be null.

*parallel-units*

Indicates the number of recommended parallel units.

This is an output parameter of type SMALLINT.

*max-objects*

Indicates the maximum number of objects in any parallel unit.

This is an output parameter of type INTEGER.

*max-sequences*

Indicates the number of jobs in any parallel unit.

This is an output parameter of type INTEGER.

*return-code*

Provides the return code from the stored procedure. Possible values are:

**0** Sort ran successfully.

**4** The statistics for one or more sorting objects have not been gathered in the catalog or the object no longer exists.

**12** An ADMIN\_UTL\_SORT error occurred. The *message* parameter will contain details.

This is an output parameter of type INTEGER.

*message*

Contains messages describing the error encountered by the stored procedure. If no error occurred, then no message is returned.

The first messages in this area are generated by the stored procedure. Messages that are generated by DB2 might follow the first messages.

This is an output parameter of type VARCHAR(1331).

## **Additional input**

In addition to the input parameters, this stored procedure reads the objects for sorting and the corresponding utility names from the created global temporary table SYSIBM.UTILITY\_SORT\_OBJ.

The following table shows the format of the created global temporary table SYSIBM.UTILITY\_SORT\_OBJ:

Table 363. Input for the ADMIN\_UTL\_SORT stored procedure

| Column name | Data type    | Contents                                                                                                                                                                                                                                                                                                                                                           |
|-------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OBJECTID    | INTEGER      | A unique positive identifier for the object the utility execution is associated with. When you insert multiple rows, increment OBJECTID by 1, starting at 0 for every insert.                                                                                                                                                                                      |
| TYPE        | VARCHAR(10)  | Object type: <ul style="list-style-type: none"> <li>• TABLESPACE</li> <li>• INDEXSPACE</li> <li>• TABLE</li> <li>• INDEX</li> <li>• STOGROUP</li> </ul>                                                                                                                                                                                                            |
| QUALIFIER   | VARCHAR(128) | Qualifier (database or creator) of the object in NAME, empty or null for STOGROUP. If the qualifier is not provided and the type of the object is TABLESPACE or INDEXSPACE, then the default database is DSNDB04. If the object is of the type TABLE or INDEX, the schema is the current SQL authorization ID. If the object no longer exists, it will be ignored. |
| NAME        | VARCHAR(128) | Unqualified name of the object.<br><br>NAME cannot be null.                                                                                                                                                                                                                                                                                                        |
| PART        | SMALLINT     | Partition number of the object for which the utility will be invoked. Null or 0 if the object is not partitioned.                                                                                                                                                                                                                                                  |

Table 363. Input for the ADMIN\_UTL\_SORT stored procedure (continued)

| Column name  | Data type   | Contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

        EXEC SQL FETCH C1 INTO :resobjectid, :unit,
            :unitseq, :unitseqpos, :exclusive;
    }
}
return(retcd);
}

```

## Output

This stored procedure returns the following output parameters, which are described in “Option descriptions” on page 1380:

- *number-of-objects*
- *parallel-units*
- *max-objects*
- *max-sequences*
- *return-code*
- *message*

In addition to the preceding output, the stored procedure returns one result set that contains the objects sorted into parallel execution units.

The following table shows the format of the result set returned in the created global temporary table SYSIBM.UTILITY\_SORT\_OUT:

*Table 364. Result set row for ADMIN\_UTL\_SORT result set*

| Column name  | Data type | Contents                                            |
|--------------|-----------|-----------------------------------------------------|
| OBJECTID     | INTEGER   | A unique positive identifier for the object         |
| UNIT         | SMALLINT  | Number of parallel execution unit                   |
| UNIT_SEQ     | INTEGER   | Job sequence within parallel execution unit         |
| UNIT_SEQ_POS | INTEGER   | Step within job                                     |
| EXCLUSIVE    | CHAR(1)   | Requires execution with nothing running in parallel |

## Common SQL API stored procedures

Common SQL API stored procedures implement a cross-database and cross-operating system SQL API that is portable across IBM data servers, including DB2 for Linux, UNIX, and Windows.

The Common SQL API is a solution-level API that supports common tooling across IBM data servers. This Common SQL API ensures that tooling does not break when a data server is upgraded, and it notifies the caller when an upgrade to tooling is available to capitalize on new data server functionality. Applications that support more than one IBM data server will benefit from using the Common SQL API, as it lowers the complexity of implementation. Such applications typically perform a variety of common administrative functions. For example, you can use these stored procedures to retrieve data server configuration information, return system information about the data server, and return the short message text for an SQLCODE.

These stored procedures use version-stable XML documents as parameters. These XML parameter documents adhere to a single, common document type definition (DTD). This DTD is flexible enough to represent hierarchical structures and binary data. The XML parameter documents can be parsed by using the Apache Commons Configuration component.

Each of the three XML parameter documents has a name and a version, and is typically associated with one stored procedure. The three types of XML parameter documents are:

- XML input document
- XML output document
- XML message document

The XML input document is passed as input to the stored procedure. The XML output document is returned as output, and the XML message document returns messages. If the structure, attributes, or types in an XML parameter document change, the version of the XML parameter document changes. The version of all three of these documents remains in sync when you call a stored procedure. For example, if you call the `GET_SYSTEM_INFO` stored procedure and specify the *major\_version* parameter as 1 and the *minor\_version* parameter as 1, the XML input, XML output, and XML message documents will be Version 1.1 documents.

## Versioning of XML documents

Common SQL API stored procedures support multiple versions of the three XML parameter documents: XML input documents, XML output documents, and XML message documents.

If the structure, attributes, or types in an XML parameter document change, the version of the XML parameter document changes. Therefore, the content of an XML parameter document varies depending on the version that you specify.

The version of all three of these documents remains in sync when you call a stored procedure. For example, if you call the `GET_SYSTEM_INFO` stored procedure and specify the *major\_version* parameter as 1 and the *minor\_version* parameter as 1, the XML input, XML output, and XML message documents will be Version 1.1 documents.

Version information in an XML parameter document is expressed as key and value pairs for **Document Type Major Version** and **Document Type Minor Version**. For example, an XML output document might define the following keys and values in a dictionary element:

```
<key>Document Type Name</key><string>Data Server Configuration Output</string>  
<key>Document Type Major Version</key><integer>2</integer>  
<key>Document Type Minor Version</key><integer>0</integer>
```

To determine the highest supported document version for a stored procedure, specify NULL for the *major\_version* parameter, the *minor\_version* parameter, and all other required parameters. The stored procedure returns the highest supported document version as values in the *major\_version* and *minor\_version* output parameters, and sets the *xml\_output* and *xml\_message* output parameters to NULL.

If you specify non-null values for the *major\_version* and *minor\_version* parameters, you must specify a document version that is supported. If the version is invalid, the stored procedure returns an error (-20457).

If the XML input document in the *xml\_input* parameter specifies the **Document Type Major Version** and **Document Type Minor Version** keys, the value for those keys must be equal to the values that you specified in the *major\_version* and *minor\_version* parameters, or an error (+20458) is raised.

## XML input documents

The XML input document is passed as input to common SQL API stored procedures and adheres to a single, common document type definition (DTD).

The XML input document consists of a set of entries that are common to all stored procedures, and a set of entries that are specific to each stored procedure. The XML input document has the following general structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <!-- Document type specific data appears here. -->
</dict>
</plist>
```

The **Document Type Name** key varies depending on the stored procedure. This example shows an XML input document for the GET\_MESSAGE stored procedure. In addition, the values of the **Document Type Major Version** and **Document Type Minor Version** keys depend on the values that you specified in the *major\_version* and *minor\_version* parameters for the stored procedure.

If the stored procedure is not running in Complete mode, you must specify the **Document Type Name** key, the required parameters, and any optional parameters that you want to specify. Specifying the **Document Type Major Version** and **Document Type Minor Version** keys are optional. If you specify the **Document Type Major Version** and **Document Type Minor Version** keys, the values must be the same as the values that you specified in the *major\_version* and *minor\_version* parameters. You must either specify both or omit both of the **Document Type Major Version** and **Document Type Minor Version** keys. Specifying the **Document Locale** key is optional. If you specify the **Document Locale** key, the value is ignored.

**Important:** XML input documents must be encoded in UTF-8 and contain only English characters.

### Complete mode for returning valid XML input documents

You can use *Complete mode* to create a valid XML input document for the common SQL API stored procedures. Then, you can customize the XML input document and pass it back to the procedure.

If the **Complete** key is included and you set the value to true, the stored procedure will run in Complete mode, and all other entries in the XML input document will be ignored. The following example shows the minimal XML input document that is required for the stored procedure to run in Complete mode:

```

| <?xml version="1.0" encoding="UTF-8"?>
| <plist version="1.0">
| <dict>
|   <key>Complete</key><true/>
| </dict>
| </plist>

```

If the stored procedure runs in Complete mode, a complete input document is returned by the *xml\_output* parameter of the stored procedure. The returned XML document is a full XML input document that includes a **Document Type** and sections for all possible required and optional parameters. The returned XML input document also includes entries for **Display Name**, **Hint**, and the **Document Locale**. Although these entries are not required (and will be ignored) in the XML input document, they are usually needed when rendering the document in a client application.

All entries in the returned XML input document can be rendered and changed in ways that are independent of the operating system or data server. Subsequently, the modified XML input document can be passed in the *xml\_input* parameter in a new call to the same stored procedure. This enables you to programmatically create valid *xml\_input* documents.

## XML output documents

The XML output documents that are returned as output from common SQL API stored procedures share a common set of entries.

At a minimum, the XML output documents that are returned in the *xml\_output* parameter include the following key and value pairs, followed by information that is specific to each stored procedure:

```

| <?xml version="1.0" encoding="UTF-8"?>
| <plist version="1.0">
| <dict>
|   <key>Document Type Name</key>
|   <string>Data Server Configuration Output</string>
|   <key>Document Type Major Version</key><integer>1</integer>
|   <key>Document Type Minor Version</key><integer>0</integer>
|   <key>Data Server Product Name</key><string>DSN</string>
|   <key>Data Server Product Version</key><string>8.1.5</string>
|   <key>Data Server Major Version</key><integer>8</integer>
|   <key>Data Server Minor Version</key><integer>1</integer>
|   <key>Data Server Platform</key><string>z/OS</string>
|   <key>Document Locale</key><string>en_US</string>
|   <!-- Document type specific data appears here. -->
| </dict>
| </plist>

```

The **Document Type Name** key varies depending on the stored procedure. This example shows an XML output document for the GET\_CONFIG stored procedure. In addition, the values of the **Document Type Major Version** and **Document Type Minor Version** keys depend on the values that you specified in the *major\_version* and *minor\_version* parameters for the stored procedure.

Entries in the XML output document are grouped by using nested dictionaries. Each entry in the XML output document describes a single piece of information. In general, an XML output document is comprised of **Display Name**, **Value**, and **Hint**, as shown in the following example:

```

| <key>SQL Domain</key>
| <dict>
|   <key>Display Name</key>

```

```

|         <string>SQL Domain</string>
|         <key>Value</key>
|         <string>v33ec059.svl.ibm.com</string>
|         <key>Hint</key>
|         <string />
|     </dict>

```

XML output documents are generated in UTF-8 and contain only English characters.

### XPath expressions for filtering output

You can use an XPath expression to filter the XML output that is returned by the GET\_CONFIG, GET\_MESSAGE, and GET\_SYSTEM\_INFO stored procedures.

To filter the output, specify a valid XPath query string in the *xml\_filter* parameter of the stored procedure.

The following restrictions apply to the XPath expression that you specify:

- The XPath expression must reference a single value.
- The XPath expression must always be absolute from the root node. For example, the following path expressions are allowed: /, *nodename*, ., and ... The following expressions are not allowed: // and @
- The only predicates allowed are [*path*='value'] and [*n*].
- The only axis allowed is following-sibling.
- The XPath expression must end with one of the following, and, if necessary, be appended with the predicate [1]: following-sibling::string, following-sibling::data, following-sibling::date, following-sibling::real, or following-sibling::integer.
- Unless the axis is found at the end of the XPath expression, it must be followed by a ::dict, ::string, ::data, ::date, ::real, or ::integer, and if necessary, be appended with the predicate [1].
- The only supported XPath operator is =.
- The XPath expression cannot contain a function, namespace, processing instruction, or comment.

**Tip:** If the stored procedure operates in complete mode, do not apply filtering, or an SQLCODE (+20458) is raised.

**Example:** The following XPath expression selects the value for the Data Server Product Version key from an XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

The stored procedure returns the string 8.1.5 in the *xml\_output* parameter if the value of the Data Server Product Version is 8.1.5. Therefore, the stored procedure call returns a single value rather than an XML document.

## XML message documents

An XML message document provides detailed information about an SQL warning condition.

When a common SQL API stored procedure encounters an internal processing error or invalid parameter, the data server returns an SQLCODE and the

corresponding SQL message to the caller. When this occurs, the procedure returns an XML message document in the *xml\_message* parameter that contains additional information about the warning.

An XML message document contains key and value pairs followed by details about an SQL warning condition. The general structure of an XML message document is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>8.1.5</string>
  <key>Data Server Major Version</key><integer>8</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>
  --- Details about an SQL warning condition are included here. ---
</dict>
</plist>
```

The details about an SQL warning will be encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**, as shown in the following example:

```
<key>Short Message Text</key>
<dict>
  <key>Display Name</key><string>Short Message Text</string>
  <key>Value</key>
  <string>DSNA630I DSNADMGC A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
    The XML input document must be empty or NULL.</string>
  <key>Hint</key><string />
</dict>
```

XML message documents are generated in UTF-8 and contain only English characters.

## GET\_CONFIG stored procedure

The GET\_CONFIG stored procedure retrieves data server configuration information.

This data server configuration information includes:

- Data sharing group information
- DB2 subsystem status information
- DB2 subsystem parameters, DSNHDECP parameters, and the IRLM parameters that are found in IFCID 106 section 5
- DB2 distributed access information
- Active log data set information
- The time of the last restart of DB2
- Resource limit facility information
- Connected DB2 subsystems information

## Environment

The GET\_CONFIG stored procedure runs in a WLM-established stored procedures address space.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET\_CONFIG stored procedure.

## Syntax

```
CALL GET_CONFIG ( [major_version], [minor_version],  
                 [requested_locale], [xml_input], [xml_filter], [xml_output], [xml_message] )
```

The schema is SYSPROC.

## Option descriptions

### *major\_version*

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters in the stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest major document version that is supported is 2. Major document version 1 is also supported.

This parameter is used in conjunction with the *minor\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

### *minor\_version*

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

This parameter is used in conjunction with the *major\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### *requested\_locale*

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml\_output* and *xml\_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested\_locale* are en\_US and NULL. If you specify a null value, the result is the same as specifying en\_US.

#### *xml\_input*

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Configuration Input in UTF-8 that contains input values for the stored procedure.

To pass an XML input document to the stored procedure, you must specify the *major\_version* parameter as 2 and the *minor\_version* parameter as 0 (zero).

For a non-data sharing system, a sample of a Version 2.0 XML input document is as follows:

```
<plist version="1.0">
<?xml version="1.0" encoding="UTF-8" ?>
<dict>
  <key>Document Type Name</key>
  <string>Data Server Configuration Input</string>
  <key>Document Type Major Version</key>
  <integer>2</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>DB2 Subsystem Status Information</string>
        <string>DB2 Subsystem Parameters</string>
        <string>DB2 Distributed Access Information</string>
        <string>Active Log Data Set Information</string>
        <string>Time of Last DB2 Restart</string>
        <string>Resource Limit Facility Information</string>
        <string>Connected DB2 Subsystem</string>
      </array>
    </dict>
  </dict>
</dict>
</plist>
```

For a data sharing system, a sample of a Version 2.0 XML input document is as follows:

```

<plist version="1.0">
<?xml version="1.0" encoding="UTF-8" ?>
<dict>
  <key>Document Type Name</key>
  <string>Data Server Configuration Input</string>
  <key>Document Type Major Version</key>
  <integer>2</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>Common Data Sharing Group Information</string>
        <string>DB2 Subsystem Status Information</string>
        <string>DB2 Subsystem Parameters</string>
        <string>DB2 Distributed Access Information</string>
        <string>Active Log Data Set Information</string>
        <string>Time of Last DB2 Restart</string>
        <string>Resource Limit Facility Information</string>
        <string>Connected DB2 Subsystem</string>
      </array>
    </dict>
    <key>DB2 Data Sharing Group Members</key>
    <dict>
      <key>Value</key>
      <array>
        <string>DB2A</string>
        <string>DB2B</string>
      </array>
    </dict>
  </dict>
</dict>
</plist>

```

When passing an XML input document to the stored procedure, you must specify the **Document Type Name** key. In a non-data sharing system, you must specify the **Include** parameter. In a data sharing system, you must specify at least one of the following parameters:

- **Include**
- **DB2 Data Sharing Group Members**

If no XML input document is passed to the stored procedure, and you specified the *major\_version* parameter as 2 and the *minor\_version* parameter as 0 (zero), the stored procedure returns the following parameters for a non-data sharing system in a Version 2.0 XML output document by default:

- **DB2 Subsystem Status Information**
- **DB2 Subsystem Parameters**
- **DB2 Distributed Access Information**
- **Active Log Data Set Information**
- **Time of Last DB2 Restart**
- **Resource Limit Facility Information**
- **Connected DB2 Subsystem**

For a data sharing system, the same information is returned for each member of a data sharing group, plus the **Common Data Sharing Group Information** parameter.

If you passed a Version 2.0 XML input document to the stored procedure, the stored procedure returns the information in a Version 2.0 XML output document. The information returned is dependent on what you specified in the **Include** array and in the **DB2 Data Sharing Group Members** array (if applicable). For a non-data sharing system, the items that are specified in the **Include** array are returned. For a data sharing system, the following information is returned:

- The items that are specified in the **Include** array for each DB2 member that is specified in the **DB2 Data Sharing Group Members** array, if both the **Include** parameter and the **DB2 Data Sharing Group Members** parameter are specified.
- The items that are specified in the **Include** array for every DB2 member in the data sharing group, if only the **Include** parameter is specified.
- The **Common Data Sharing Group Information** and the following items for each member that is specified in the **DB2 Data Sharing Group Members** array, if only the **DB2 Data Sharing Group Members** parameter is specified:
  - **DB2 Subsystem Status Information**
  - **DB2 Subsystem Parameters**
  - **DB2 Distributed Access Information**
  - **Active Log Data Set Information**
  - **Time of Last DB2 Restart**
  - **Resource Limit Facility Information**
  - **Connected DB2 Subsystem**

**Note:** If the **Common Data Sharing Group Information** item is specified in the **Include** array, this information is returned only once for the data sharing group. This information is not returned repeatedly for every DB2 member that is processed.

**Complete mode:** For an example of a Version 2.0 XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode in a non-data sharing system, see Example 4 in the Examples section. For an example of a Version 2.0 XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode in a data sharing system with two DB2 members, DB2A and DB2B, see Example 5.

#### *xml\_filter*

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see “XPath expressions for filtering output” on page 1390.

The following example selects the value for the Data Server Product Version from the XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

#### *xml\_output*

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Configuration Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is

unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The *xml\_output* parameter can return either a Version 1.0 or Version 2.0 XML output document depending on the *major\_version* and *minor\_version* parameters that you specify. For information about the content of a Version 2.0 XML output document, see the option description for the *xml\_input* parameter.

For a sample Version 1.0 XML output document, see Example 1 in the Examples section.

For a sample Version 2.0 XML output document in a non-data sharing system, see Example 6.

For a sample Version 2.0 XML output document in a data sharing system, see Example 7.

#### *xml\_message*

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the stored procedure results in an SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The *xml\_message* parameter can return either a Version 1.0 or Version 2.0 XML message document depending on the *major\_version* and *minor\_version* parameters that you specify.

For an example of an XML message document, see Example 2.

If the GET\_CONFIG stored procedure is processing more than one DB2 member in a data sharing system and an error is encountered when processing one of the DB2 members, the stored procedure specifies the name of the DB2 member that is causing the error as the value of the **DB2 Object** key in the XML message document. The value of the **Short Message Text** key applies to the DB2 member that is specified.

The following example shows a fragment of a Version 2.0 XML message document with the **DB2 Object** key specified:

```
<key>Short Message Text</key>
  <dict>
    <key>Display Name</key>
    <string>Short Message Text</string>
    <key>Value</key>
    <string>DSNA6xxI DSNADMGC .....</string>
    <key>DB2 Object</key>
    <string>DB2B</string>
    <key>Hint</key>
    <string />
  </dict>
```

## Examples

**Example 1:** The following example shows a fragment of a Version 1.0 XML output document for the GET\_CONFIG stored procedure for a data sharing member. For a non-data sharing member, the following entries in the **DB2 Distributed Access Information** item are not included: **Resynchronization Domain**, **Alias List**, **Member IPv4 Address**, and **Location Server List**.

The two major sections that the XML output document always contains are **Common Data Sharing Group Information** and **DB2 Subsystem Specific Information**. In this example, the ellipsis ( . . . ) represent a dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, such as:

```

<dict>
  <key>Display Name</key>

```

**Example 2:** The following example shows a sample XML message document for the GET\_CONFIG stored procedure. Similar to an XML output document, the details about an SQL warning condition are encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**.

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>8.1.5</string>
  <key>Data Server Major Version</key><integer>8</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>
  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Value</key>
    <string>DSNA630I DSNADMGC A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
      The XML input document must be empty or NULL.</string>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>

```

**Example 3:** This example shows a simple and static Java program that calls the GET\_CONFIG stored procedure with an XPath that queries the value of the data server's IP address. The XPath is statically created as a string object by the program, and then converted to a BLOB to serve as input for the *xml\_filter* parameter. After the stored procedure is called, the *xml\_output* parameter contains only a single string and no XML document. This output is materialized as a file called *xml\_output.xml* that is in the same directory where the *GetConfDriver* class resides.

```

**Example 7:** This example shows a fragment of a Version 2.0 XML output document for the GET\_CONFIG stored procedure in a data sharing system with two DB2 members, DB2A and DB2B. An XML input document is not passed to the stored procedure. The ellipsis (. . .) represent a dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, as in the following example, or an entry that is the same as the corresponding entry in a Version 1.0 XML output document:

```

<dict>
  <key>Display Name</key>
  <string>DDF Status</string>
  <key>Value</key>
  <string>STARTD</string>
  <key>Hint</key>
  <string />
</dict>
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>

## GET\_MESSAGE stored procedure

The GET\_MESSAGE stored procedure returns the short message text for an SQLCODE.

### Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET\_MESSAGE stored procedure.

### Syntax

The following syntax diagram shows the SQL CALL statement for invoking this stored procedure:

```

CALL GET_MESSAGE (
  [major_version], [minor_version],
  [requested_locale], [xml_input], [xml_filter], [xml_output], [xml_message]
)

```

The schema is SYSPROC.

### Option descriptions

#### *major\_version*

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents that are passed as parameters

in the stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only major document version that is supported is 1.

If the XML document in the *xml\_input* parameter specifies the Document Type Major Version key, the value for that key must be equal to the value provided in the *major\_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### *minor\_version*

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents that are passed as parameters for this stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and only minor document version that is supported is 0 (zero).

If the XML document in the *xml\_input* parameter specifies the Document Type Minor Version key, the value for that key must be equal to the value provided in the *minor\_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### *requested\_locale*

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml\_output* and *xml\_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested\_locale* are en\_US and NULL. If you specify a null value, the result is the same as specifying en\_US.

#### *xml\_input*

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server Message Input in UTF-8 that contains input values for the stored procedure.

The general structure of an XML input document is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Required Parameters</key>
  <dict>
    <key>SQLCODE</key>
    <dict>
      <key>Value</key><integer>sqlcode</integer>
    </dict>
  </dict>
  <key>Optional Parameters</key>
  <dict>
    <key>Message Tokens</key>
    <dict>
      <key>Value</key>
      <array>
        <string>token1 in SQLCA</string>
        <string>token2 in SQLCA</string>
      </array>
    </dict>
  </dict>
</dict>
</plist>
```

For an example of an XML input document that will not run in Complete mode, see Example 2 in the Examples section.

**Complete mode:** For an example of an XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode, see Example 1 in the Examples section.

#### *xml\_filter*

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see “XPath expressions for filtering output” on page 1390.

The following example selects the value for the short message text from the XML output document:

```
/plist/dict/key[.='Short Message Text']/following-sibling::dict[1]/key
[.='Value']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

#### *xml\_output*

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server Message Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

For an example of an XML output document, see Example 3.

#### *xml\_message*

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about an SQL warning condition. This document is returned when a call to the procedure results in an SQL warning, and the warning message

indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

For an example of an XML message document, see Example 4.

## Example

**Example 1:** The following example shows an XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode.

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message Input</string>
  <key>Document Type Major Version</key>
  <integer>1</integer>
  <key>Document Type Minor Version</key>
  <integer>0</integer>
  <key>Document Locale</key>
  <string>en_US</string>
  <key>Required Parameters</key>
  <dict>
    <key>Display Name</key>
    <string>Required Parameters</string>
    <key>SQLCODE</key>
    <dict>
      <key>Display Name</key>
      <string>SQLCODE</string>
      <key>Value</key>
      <integer />
      <key>Hint</key>
      <string />
    </dict>
    <key>Hint</key>
    <string />
  </dict>
  <key>Optional Parameters</key>
  <dict>
    <key>Display Name</key>
    <string>Optional Parameters</string>
    <key>Message Tokens</key>
    <dict>
      <key>Display Name</key>
      <string>Message Tokens</string>
      <key>Value</key>
      <array>
        <string />
      </array>
      <key>Hint</key>
      <string />
    </dict>
    <key>Hint</key>
    <string />
  </dict>
</dict>
</plist>
```

**Example 2:** The following example shows a complete sample of an XML input document for the GET\_MESSAGE stored procedure.

```
<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
```

```

    <key>Document Type Name</key>
    <string>Data Server Message Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Required Parameters</key>
    <dict>
      <key>SQLCODE</key>
      <dict>
        <key>Value</key><integer>-104</integer>
      </dict>
    </dict>
    <key>Optional Parameters</key>
    <dict>
      <key>Message Tokens</key>
      <dict>
        <key>Value</key>
        <array>
          <string>X</string>
          <string>( . LIKE AS</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>

```

**Example 3:** The following example shows a complete sample of an XML output document for the GET\_MESSAGE stored procedure. The short message text for an SQLCODE will be encapsulated in a dictionary entry, which is comprised of **Display Name, Value, and Hint**.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key>
  <string>Data Server Message Output</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>
  <key>Data Server Product Version</key><string>8.1.5</string>
  <key>Data Server Major Version</key><integer>8</integer>
  <key>Data Server Minor Version</key><integer>1</integer>
  <key>Data Server Platform</key><string>z/OS</string>
  <key>Document Locale</key><string>en_US</string>

  <key>Short Message Text</key>
  <dict>
    <key>Display Name</key><string>Short Message Text</string>
    <key>Hint</key><string />
  </dict>
</dict>
</plist>

```

**Example 4:** The following example shows a sample XML message document for the GET\_MESSAGE stored procedure. Similar to an XML output document, the details about an SQL warning condition will be encapsulated in a dictionary entry, which is comprised of **Display Name, Value, and Hint**.

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server Message</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Data Server Product Name</key><string>DSN</string>

```

```

<key>Data Server Product Version</key><string>8.1.5</string>
<key>Data Server Major Version</key><integer>8</integer>
<key>Data Server Minor Version</key><integer>1</integer>
<key>Data Server Platform</key><string>z/OS</string>
<key>Document Locale</key><string>en_US</string>
<key>Short Message Text</key>
<dict>
  <key>Display Name</key><string>Short Message Text</string>
  <key>Value</key>
  <string>DSNA630I DSNADMGM A PARAMETER FORMAT OR CONTENT ERROR WAS FOUND.
    The value for key 'Document Type Minor Version' is '2'. It does
    not match the value '0', which was specified for parameter 2 of
    the stored procedure. Both values must be equal.</string>
  <key>Hint</key><string />
</dict>
</dict>
</plist>

```

**Example 5:** This example shows a simple and static Java program that calls the GET\_MESSAGE stored procedure with an XML input document and an XPath that queries the short message text of an SQLCODE.

The XML input document is initially saved as a file called `xml_input.xml` that is in the same directory where the `GetMessageDriver` class resides. This sample program uses the following `xml_input.xml` file:

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server Message Input</string>
    <key>Document Type Major Version</key>
    <integer>1</integer>
    <key>Document Type Minor Version</key>
    <integer>0</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Complete</key>
    <false />
    <key>Required Parameters</key>
    <dict>
      <key>SQLCODE</key>
      <dict>
        <key>Value</key>
        <integer>-204</integer>
      </dict>
    </dict>
    <key>Optional Parameters</key>
    <dict>
      <key>Message Tokens</key>
      <dict>
        <key>Value</key>
        <array>
          <string>SYSIBM.DDF_CONFIG</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>

```

The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the `xml_filter` parameter. After the stored procedure is called, the `xml_output` parameter contains only a single string and no XML document. This output is materialized as a file called `xml_output.xml` that is in the same directory where the `GetMessageDriver` class resides.

*Sample invocation of the GET\_MESSAGE stored procedure with a valid XML input document and a valid XPath:*

```

}
}

```

## GET\_SYSTEM\_INFO stored procedure

The GET\_SYSTEM\_INFO stored procedure returns system information about the data server.

This system information includes:

- Operating system information
- Product information
- DB2 MEPL
- SYSMOD APPLY status

- Workload Manager (WLM) classification rules that apply to DB2 Workload for subsystem types DB2 and DDF

## Environment

The load module for the GET\_SYSTEM\_INFO stored procedure, DSNADMGS, must reside in an APF-authorized library. The GET\_SYSTEM\_INFO stored procedure runs in a WLM-established stored procedures address space, and all of the libraries that are specified in the STEPLIB DD statement must be APF-authorized. TCB=1 is also required.

## Authorization

To execute the CALL statement, the owner of the package or plan that contains the CALL statement must have EXECUTE privilege on the GET\_SYSTEM\_INFO stored procedure.

In addition, because the GET\_SYSTEM\_INFO stored procedure queries the SMPCSI data set for the status of the SYSMODs, the authorization ID that is associated with the stored procedure address space where the GET\_SYSTEM\_INFO stored procedure is running must have at least RACF read authority to the SMPCSI data set.

## Syntax

```
CALL GET_SYSTEM_INFO ( ( major_version , minor_version ,
                        [ NULL ] , [ NULL ] ,
requested_locale , xml_input , xml_filter , xml_output , xml_message ) )
```

The schema is SYSPROC.

## Option descriptions

### *major\_version*

An input and output parameter of type INTEGER that indicates the major document version. On input, this parameter indicates the major document version that you support for the XML documents passed as parameters in the stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter specifies the highest major document version that is supported by the stored procedure. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. Currently, the highest and the only major document version that is supported is 1.

If the XML document in the *xml\_input* parameter specifies a Document Type Major Version key, the value for that key must be equal to the value that is provided in the *major\_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *minor\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### *minor\_version*

An input and output parameter of type INTEGER that indicates the minor document version. On input, this parameter specifies the minor document version that you support for the XML documents passed as parameters for this stored procedure (*xml\_input*, *xml\_output*, and *xml\_message*). The stored procedure processes all XML documents in the specified version, or returns an error (-20457) if the version is invalid.

On output, this parameter indicates the highest minor document version that is supported for the highest supported major version. To determine the highest supported document version, specify NULL for this input parameter and all other required parameters. The highest minor document version that is supported is 1. Minor document version 0 (zero) is also supported.

If the XML document in the *xml\_input* parameter specifies a Document Type Minor Version key, the value for that key must be equal to the value that is provided in the *minor\_version* parameter, or an error (+20458) is raised.

This parameter is used in conjunction with the *major\_version* parameter. Therefore, you must specify both parameters together. For example, you must specify both as either NULL, or non-NULL.

#### *requested\_locale*

An input parameter of type VARCHAR(33) that specifies a locale. If the specified language is supported on the server, translated content is returned in the *xml\_output* and *xml\_message* parameters. Otherwise, content is returned in the default language. Only the language and possibly the territory information is used from the locale. The locale is not used to format numbers or influence the document encoding. For example, key names are not translated. The only translated portion of the XML output and XML message documents are **Display Name**, **Display Unit**, and **Hint**. The value might be globalized where applicable. You should always compare the requested language to the language that is used in the XML output document (see the **Document Locale** entry in the XML output document).

Currently, the supported values for *requested\_locale* are en\_US and NULL. If you specify a null value, the result is the same as specifying en\_US.

#### *xml\_input*

An input parameter of type BLOB(2G) that specifies an XML input document of type Data Server System Input in UTF-8 that contains input values for the stored procedure.

This XML input document is optional. If the XML input document is not passed to the stored procedure, the stored procedure returns the following information by default:

- Operating system information
- Product information
- DB2 MEPL
- Workload Manager (WLM) classification rules for DB2 Workload

This stored procedure supports two types of XML input documents, Version 1.0 or Version 1.1.

For Version 1.0, the general structure of an XML input document is as follows:

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>0</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>SMPCSI Data Set</key>
    <dict>
      <key>Value</key><string>SMPCSI data set name</string>
    </dict>
  <key>SYSMOD</key>
  <dict>
    <key>Value</key>
    <array>
      <string>SYSMOD number</string>
      <string>SYSMOD number</string>
    </array>
  </dict>
</dict>
</plist>

```

For Version 1.1, the general structure of an XML input document is as follows:

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
  <key>Document Type Name</key><string>Data Server System Input</string>
  <key>Document Type Major Version</key><integer>1</integer>
  <key>Document Type Minor Version</key><integer>1</integer>
  <key>Document Locale</key><string>en_US</string>
  <key>Complete</key><false/>
  <key>Optional Parameters</key>
  <dict>
    <key>Include</key>
    <dict>
      <key>Value</key>
      <array>
        <string>Operating System Information</string>
        <string>Product Information</string>
        <string>DB2 MEPL</string>
        <string>Workload Manager (WLM) Classification Rules for
          DB2 Workload</string>
      </array>
    </dict>
    <key>SMPCSI Data Set</key>
    <dict>
      <key>Value</key><string>SMPCSI data set name</string>
    </dict>
    <key>SYSMOD</key>
    <dict>
      <key>Value</key>
      <array>
        <string>SYSMOD number</string>
        <string>SYSMOD number</string>
      </array>
    </dict>
  </dict>
</dict>
</plist>

```

**Version 1.0:** When a Version 1.0 XML input document is passed to the stored procedure, the stored procedure returns the following information in a Version 1.0 XML output document:

- Operating system information
- Product information
- DB2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for DB2 Workload

To use Version 1.0 of the XML input document you must specify the *major\_version* parameter as 1 and the *minor\_version* parameter as 0 (zero). You must also specify the **Document Type Name** key, the SMPCSI data set, and the list of SYSMODs.

For an example of a complete Version 1.0 XML input document for the GET\_SYSTEM\_INFO stored procedure, see Example 3 in the Examples section.

**Version 1.1:** A Version 1.1 XML input document supports the **Include** parameter, in addition to the **SMPCSI Data Set** and **SYSMOD** parameters that are supported by a Version 1.0 XML input document.

You can use the Version 1.1 XML input document in the following ways:

- To specify which items to include in the XML output document by specifying these items in the **Include** array
- To specify the SMPCSI data set and list of SYSMODs so that the stored procedure returns their APPLY status

To use Version 1.1 of the XML input document, you must specify the *major\_version* parameter as 1 and the *minor\_version* parameter as 1. You must also specify the **Document Type Name** key, and at least one of the following parameters:

- **Include**
- **SMPCSI Data Set** and **SYSMOD**

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include**, **SMPCSI Data Set**, and **SYSMOD** parameters, the stored procedure will return the items that you specified in the **Include** array, and the SYSMOD status of the SYSMODs that you specified in the **SYSMOD** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify the **Include** parameter only, the stored procedure will return only the items that you specified in the **Include** array.

If you pass a Version 1.1 XML input document to the stored procedure and specify only the **SMPCSI Data Set** and **SYSMOD** parameters, the stored procedure returns the following information in a Version 1.1 XML output document:

- Operating system information
- Product information
- DB2 MEPL
- SYSMOD status (APPLY status for the SYSMODs that are listed in the XML input document)
- Workload Manager (WLM) classification rules for DB2 Workload

For an example of a complete Version 1.1 XML input document for the GET\_SYSTEM\_INFO stored procedure, see Example 4.

**Complete mode:** For examples of Version 1.0 and Version 1.1 XML input documents that are returned by the *xml\_output* parameter when the stored procedure is running in Complete mode, see Example 1 and Example 2 respectively.

#### *xml\_filter*

An input parameter of type BLOB(4K) in UTF-8 that specifies a valid XPath query string. Use a filter when you want to retrieve a single value from an XML output document. For more information, see “XPath expressions for filtering output” on page 1390.

The following example selects the value for the Data Server Product Version from the XML output document:

```
/plist/dict/key[.='Data Server Product Version']/following-sibling::string[1]
```

If the key is not followed by the specified sibling, an error is returned.

#### *xml\_output*

An output parameter of type BLOB(2G) that returns a complete XML output document of type Data Server System Output in UTF-8. If a filter is specified, this parameter returns a string value. If the stored procedure is unable to return a complete output document (for example, if a processing error occurs that results in an SQL warning or error), this parameter is set to NULL.

The *xml\_output* parameter can return either a Version 1.0 or Version 1.1 XML output document depending on the *major\_version* and *minor\_version* parameters that you specify. For more information about the content differences between the Version 1.0 and Version 1.1 XML output documents, see the option description for the *xml\_input* parameter.

A complete XML output document provides the following system information:

- Operating system information
- Product information
- DB2 MEPL
- The APPLY status of SYSMODs
- Workload Manager (WLM) classification rules for DB2 Workload for subsystem types DB2 and DDF

For an example of an XML output document, see Example 5.

#### *xml\_message*

An output parameter of type BLOB(64K) that returns a complete XML output document of type Data Server Message in UTF-8 that provides detailed information about a SQL warning condition. This document is returned when a call to the stored procedure results in a SQL warning, and the warning message indicates that additional information is returned in the XML message output document. If the warning message does not indicate that additional information is returned, then this parameter is set to NULL.

The *xml\_message* parameter can return either a Version 1.0 or Version 1.1 XML message document, depending on the *major\_version* and *minor\_version* parameters that you specify. The format of a Version 1.0 or Version 1.1 XML message document is similar. For an example of an XML message document, see Example 6.

## Examples

**Example 1:** The following example shows a Version 1.0 XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode.

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Display Name</key><string>Optional Parameters</string>
      <key>SMPCSI Data Set</key>
      <dict>
        <key>Display Name</key><string>SMPCSI Data Set</string>
        <key>Value</key><string />
        <key>Hint</key><string />
      </dict>
      <key>SYSMOD</key>
      <dict>
        <key>Display Name</key><string>SYSMOD</string>
        <key>Value</key>
        <array>
          <string />
        </array>
        <key>Hint</key><string />
      </dict>
      <key>Hint</key><string />
    </dict>
  </dict>
</plist>
```

**Example 2:** The following example shows a Version 1.1 XML input document that is returned by the *xml\_output* parameter when the stored procedure is running in Complete mode.

```
<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>1</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Display Name</key><string>Optional Parameters</string>
      <key>Include</key>
      <dict>
        <key>Display Name</key><string>Include</string>
        <key>Value</key>
        <array>
          <string>Operating System Information</string>
          <string>Product Information</string>
          <string>DB2 MEPL</string>
          <string>Workload Manager (WLM) Classification Rules for
            DB2 Workload</string>
        </array>
        <key>Hint</key><string />
      </dict>
      <key>SMPCSI Data Set</key>
      <dict>
        <key>Display Name</key><string>SMPCSI Data Set</string>
        <key>Value</key><string />
      </dict>
    </dict>
  </dict>
</plist>
```

```

        <key>Hint</key><string />
    </dict>
    <key>SYSMOD</key>
    <dict>
        <key>Display Name</key><string>SYSMOD</string>
        <key>Value</key>
        <array>
            <string />
        </array>
        <key>Hint</key><string />
    </dict>
    <key>Hint</key><string />
</dict>
</dict>
</plist>

```

**Example 3:** The following example shows a complete sample of a Version 1.0 XML input document for the GET\_SYSTEM\_INFO stored procedure.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
    <key>Document Type Name</key>
    <string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>0</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
        <key>SMPCSI Data Set</key>
        <dict>
            <key>Value</key><string>IXM180.GLOBAL.CSI</string>
        </dict>
        <key>SYSMOD</key>
        <dict>
            <key>Value</key>
            <array>
                <string>UK20028</string>
                <string>UK20030</string>
            </array>
        </dict>
    </dict>
</dict>
</plist>

```

You must specify the SMPCSI data set and one or more SYSMODs. SYSMOD status information will be returned for only the SYSMODs that are listed in the **Optional Parameters** section, provided that the SMPCSI data set that you specify is valid.

**Example 4:** The following example shows a complete sample of a Version 1.1 XML input document for the GET\_SYSTEM\_INFO stored procedure.

```

<?xml version="1.0" encoding="UTF-8"?>
<plist version="1.0">
<dict>
    <key>Document Type Name</key><string>Data Server System Input</string>
    <key>Document Type Major Version</key><integer>1</integer>
    <key>Document Type Minor Version</key><integer>1</integer>
    <key>Document Locale</key><string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
        <key>Include</key>
        <dict>
            <key>Value</key>
            <array>

```

```

        <string>Operating System Information</string>
        <string>Product Information</string>
        <string>DB2 MEPL</string>
        <string>Workload Manager (WLM) Classification Rules for
            DB2 Workload</string>
    </array>
</dict>
<key>SMPCSI Data Set</key>
<dict>
    <key>Value</key><string>IXM180.GLOBAL.CSI</string>
</dict>
<key>SYSMOD</key>
<dict>
    <key>Value</key>
    <array>
        <string>UK24596</string>
        <string>UK24709</string>
    </array>
</dict>
</dict>
</dict>
</plist>

```

**Example 5:** The following example shows a fragment of an XML output document for the GET\_SYSTEM\_INFO stored procedure. In this example, the ellipsis (. . .) represent a dictionary entry that is comprised of **Display Name**, **Value**, and **Hint**, such as:

```

<dict>
    <key>Display Name</key>
    <string>Name</string>
    <key>Value</key>
    <string>JES2</string>
    <key>Hint</key>

</dict>
</plist>

```

**Example 6:** The following example shows a sample XML message document for the GET\_SYSTEM\_INFO stored procedure. Similar to an XML output document, the details about an SQL warning condition will be encapsulated in a dictionary entry, which is comprised of **Display Name**, **Value**, and **Hint**.

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
<dict>
<key>Document Type Name</key><string>Data Server Message</string>
<key>Document Type Major Version</key><integer>1</integer>
<key>Document Type Minor Version</key><integer>1</integer>
<key>Data Server Product Name</key><string>DSN</string>
<key>Data Server Product Version</key><string>8.1.5</string>
<key>Data Server Major Version</key><integer>8</integer>
<key>Data Server Minor Version</key><integer>1</integer>
<key>Data Server Platform</key><string>z/OS</string>
<key>Document Locale</key><string>en_US</string>
<key>Short Message Text</key>
<dict>
<key>Display Name</key><string>Short Message Text</string>
<key>Value</key>
<string>DSNA647I DSNADMGS INVOCATION OF GIMAPI FAILED. Error processing
command: QUERY . RC=12 CC=50504. GIM54701W ALLOCATION FAILED FOR
SMPCSI - IKJ56228I DATA SET IXM180.GLOBAL.CSI NOT IN CATALOG OR
CATALOG CAN NOT BE ACCESSED. GIM44232I GIMMPVIA - DYNAMIC
ALLOCATION FAILED FOR THE GLOBAL ZONE, DATA SET IXM180.GLOBAL.CSI.
GIM50504S ** OPEN PROCESSING FAILED FOR THE GLOBAL ZONE.</string>
<key>Hint</key><string />
</dict>
</dict>
</plist>

```

**Example 7:** This example shows a simple and static Java program that calls the GET\_SYSTEM\_INFO stored procedure with an XML input document and an XPath that queries the value of the operating system name and release.

The XML input document is initially saved as a file called xml\_input.xml that is in the same directory where the GetSystemDriver class resides. This sample program uses the following xml\_input.xml file:

```

<?xml version="1.0" encoding="UTF-8" ?>
<plist version="1.0">
  <dict>
    <key>Document Type Name</key>
    <string>Data Server System Input</string>
    <key>Document Type Major Version</key>
    <integer>1</integer>
    <key>Document Type Minor Version</key>
    <integer>1</integer>
    <key>Document Locale</key>
    <string>en_US</string>
    <key>Optional Parameters</key>
    <dict>
      <key>Include</key>
      <dict>
        <key>Value</key>
        <array>
          <string>Operating System Information</string>
        </array>
      </dict>
    </dict>
  </dict>
</plist>

```

The XPath is statically created as a string object by the program and then converted to a BLOB to serve as input for the *xml\_filter* parameter. After the stored procedure is called, the *xml\_output* parameter contains only a single string and no XML document. This output is materialized as a file called *xml\_output.xml* that is in the same directory where the *GetSystemDriver* class resides.

*Sample invocation of the GET\_SYSTEM\_INFO stored procedure with a valid XML input document and a valid XPath:*

```

## Appendix K. How to use the DB2 library

Titles of books in the library begin with DB2 Universal Database for z/OS Version 8. However, references from one book in the library to another are shortened and do not include the product name, version, and release. Instead, they point directly to the section that holds the information. For a complete list of books in the library, and the sections in each book, see the bibliography at the back of this book.

The most rewarding task associated with a database management system is asking questions of it and getting answers, the task called *end use*. Other tasks are also necessary—defining the parameters of the system, putting the data in place, and so on. The tasks that are associated with DB2 are grouped into the following major categories (but supplemental information relating to all of the following tasks for new releases of DB2 can be found in *DB2 Release Planning Guide*).

**Installation:** If you are involved with DB2 only to install the system, *DB2 Installation Guide* might be all you need.

If you will be using data sharing capabilities you also need *DB2 Data Sharing: Planning and Administration*, which describes installation considerations for data sharing.

If you want to set up a DB2 subsystem to meet the requirements of the Common Criteria, you need *DB2 Common Criteria Guide*, which contains information that supersedes other information in the DB2 UDB for z/OS library regarding Common Criteria.

**End use:** End users issue SQL statements to retrieve data. They can also insert, update, or delete data, with SQL statements. They might need an introduction to SQL, detailed instructions for using SPUFI, and an alphabetized reference to the types of SQL statements. This information is found in *DB2 Application Programming and SQL Guide*, and *DB2 SQL Reference*.

End users can also issue SQL statements through the DB2 Query Management Facility (QMF) or some other program, and the library for that licensed program might provide all the instruction or reference material they need. For a list of the titles in the DB2 QMF library, see the bibliography at the end of this book.

**Application programming:** Some users access DB2 without knowing it, using programs that contain SQL statements. DB2 application programmers write those programs. Because they write SQL statements, they need the same resources that end users do.

Application programmers also need instructions on many other topics:

- How to transfer data between DB2 and a host program—written in Java, C, or COBOL, for example
- How to prepare to compile a program that embeds SQL statements
- How to process data from two systems simultaneously, say DB2 and IMS or DB2 and CICS
- How to write distributed applications across operating systems
- How to write applications that use Open Database Connectivity (ODBC) to access DB2 servers

- How to write applications in the Java programming language to access DB2 servers

The material needed for writing a host program containing SQL is in *DB2 Application Programming and SQL Guide* and in *DB2 Application Programming Guide and Reference for Java*. The material needed for writing applications that use DB2 ODBC or ODBC to access DB2 servers is in *DB2 ODBC Guide and Reference*. For handling errors, see *DB2 Codes*.

If you will be working in a distributed environment, you will need *DB2 Reference for Remote DRDA Requesters and Servers*.

Information about writing applications across operating systems can be found in *IBM DB2 Universal Database SQL Reference for Cross-Platform Development*.

**System and database administration:** *Administration* covers almost everything else.

If you will be using the RACF access control module for DB2 authorization checking, you will need *DB2 RACF Access Control Module Guide*.

If you are involved with DB2 only to design the database, or plan operational procedures, you need *DB2 Administration Guide*. If you also want to carry out your own plans by creating DB2 objects, granting privileges, running utility jobs, and so on, you also need:

- *DB2 SQL Reference*, which describes the SQL statements you use to create, alter, and drop objects and grant and revoke privileges
- *DB2 Utility Guide and Reference*, which explains how to run utilities
- *DB2 Command Reference*, which explains how to run commands

If you will be using data sharing, you need *DB2 Data Sharing: Planning and Administration*, which describes how to plan for and implement data sharing.

Additional information about system and database administration can be found in *DB2 Messages* and *DB2 Codes*, which list messages and codes issued by DB2, with explanations and suggested responses.

**Diagnosis:** Diagnosticians detect and describe errors in the DB2 program. They might also recommend or apply a remedy. The documentation for this task is in *DB2 Diagnosis Guide and Reference*, *DB2 Messages*, and *DB2 Codes*.

## Programming Interface Information

This book is intended to help you to plan for and administer DB2 Universal Database for z/OS (DB2 UDB for z/OS).

This book also documents General-use Programming Interface and Associated Guidance Information and Product-sensitive Programming Interface and Associated Guidance Information provided by DB2 Universal Database for z/OS.

General-use Programming Interfaces allow the customer to write programs that obtain the services of DB2 UDB for z/OS.

General-use Programming Interface and Associated Guidance Information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking:

```
_____ General-use Programming Interface _____  
General-use Programming Interface and Associated Guidance Information ...  
_____ End of General-use Programming Interface _____
```

Product-sensitive Programming Interfaces allow the customer installation to perform tasks such as diagnosing, modifying, monitoring, repairing, tailoring, or tuning of this IBM software product. Use of such interfaces creates dependencies on the detailed design or implementation of the IBM software product. Product-sensitive Programming Interfaces should be used only for these specialized purposes. Because of their dependencies on detailed design and implementation, it is to be expected that programs written to such interfaces may need to be changed in order to run with new product releases or versions, or as a result of service.

Product-sensitive Programming Interface and Associated Guidance Information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking:

```
_____ Product-sensitive Programming Interface _____  
Product-sensitive Programming Interface and Associated Guidance Information ...  
_____ End of Product-sensitive Programming Interface _____
```

---

## Trademarks

IBM, the IBM logo, and [ibm.com](http://www.ibm.com)<sup>®</sup> are trademarks or registered marks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at <http://www.ibm.com/legal/copytrade.shtml>.

Microsoft<sup>®</sup>, Windows, Windows NT<sup>®</sup>, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks of Sun Microsystems, Inc. in the United States, other countries, or both.

---

## Glossary

The following terms and abbreviations are defined as they are used in the DB2 library.

### A

**abend.** Abnormal end of task.

**abend reason code.** A 4-byte hexadecimal code that uniquely identifies a problem with DB2.

**abnormal end of task (abend).** Termination of a task, job, or subsystem because of an error condition that recovery facilities cannot resolve during execution.

**access method services.** The facility that is used to define and reproduce VSAM key-sequenced data sets.

**access path.** The path that is used to locate data that is specified in SQL statements. An access path can be indexed or sequential.

**active log.** The portion of the DB2 log to which log records are written as they are generated. The active log always contains the most recent log records, whereas the archive log holds those records that are older and no longer fit on the active log.

**active member state.** A state of a member of a data sharing group. The cross-system coupling facility identifies each active member with a group and associates the member with a particular task, address space, and z/OS system. A member that is not active has either a failed member state or a quiesced member state.

**address space.** A range of virtual storage pages that is identified by a number (ASID) and a collection of segment and page tables that map the virtual pages to real pages of the computer's memory.

**address space connection.** The result of connecting an allied address space to DB2. Each address space that contains a task that is connected to DB2 has exactly one address space connection, even though more than one task control block (TCB) can be present. See also *allied address space* and *task control block*.

| **address space identifier (ASID).** A unique  
| system-assigned identifier for and address space.

**administrative authority.** A set of related privileges that DB2 defines. When you grant one of the administrative authorities to a person's ID, the person has all of the privileges that are associated with that administrative authority.

**after trigger.** A trigger that is defined with the trigger activation time AFTER.

**agent.** As used in DB2, the structure that associates all processes that are involved in a DB2 unit of work. An *allied agent* is generally synonymous with an *allied thread*. *System agents* are units of work that process tasks that are independent of the allied agent, such as prefetch processing, deferred writes, and service tasks.

# **aggregate function.** An operation that derives its  
# result by using values from one or more rows. Contrast  
# with *scalar function*.

**alias.** An alternative name that can be used in SQL statements to refer to a table or view in the same or a remote DB2 subsystem.

**allied address space.** An area of storage that is external to DB2 and that is connected to DB2. An allied address space is capable of requesting DB2 services.

**allied thread.** A thread that originates at the local DB2 subsystem and that can access data at a remote DB2 subsystem.

**allocated cursor.** A cursor that is defined for stored procedure result sets by using the SQL ALLOCATE CURSOR statement.

**already verified.** An LU 6.2 security option that allows DB2 to provide the user's verified authorization ID when allocating a conversation. With this option, the user is not validated by the partner DB2 subsystem.

| **ambiguous cursor.** A database cursor that is in a plan  
| or package that contains either PREPARE or EXECUTE  
| IMMEDIATE SQL statements, and for which the  
| following statements are true: the cursor is not defined  
| with the FOR READ ONLY clause or the FOR UPDATE  
| OF clause; the cursor is not defined on a read-only  
| result table; the cursor is not the target of a WHERE  
| CURRENT clause on an SQL UPDATE or DELETE  
| statement.

**American National Standards Institute (ANSI).** An organization consisting of producers, consumers, and general interest groups, that establishes the procedures by which accredited organizations create and maintain voluntary industry standards in the United States.

**ANSI.** American National Standards Institute.

**APAR.** Authorized program analysis report.

**APAR fix corrective service.** A temporary correction of an IBM software defect. The correction is temporary,

because it is usually replaced at a later date by a more permanent correction, such as a program temporary fix (PTF).

**APF.** Authorized program facility.

**API.** Application programming interface.

**APPL.** A VTAM network definition statement that is used to define DB2 to VTAM as an application program that uses SNA LU 6.2 protocols.

**application.** A program or set of programs that performs a task; for example, a payroll application.

**application-directed connection.** A connection that an application manages using the SQL CONNECT statement.

**application plan.** The control structure that is produced during the bind process. DB2 uses the application plan to process SQL statements that it encounters during statement execution.

**application process.** The unit to which resources and locks are allocated. An application process involves the execution of one or more programs.

**application programming interface (API).** A functional interface that is supplied by the operating system or by a separately orderable licensed program that allows an application program that is written in a high-level language to use specific data or functions of the operating system or licensed program.

**application requester.** The component on a remote system that generates DRDA requests for data on behalf of an application. An application requester accesses a DB2 database server using the DRDA application-directed protocol.

**application server.** The target of a request from a remote application. In the DB2 environment, the application server function is provided by the distributed data facility and is used to access DB2 data from remote applications.

**archive log.** The portion of the DB2 log that contains log records that have been copied from the active log.

**ASCII.** An encoding scheme that is used to represent strings in many environments, typically on PCs and workstations. Contrast with *EBCDIC* and *Unicode*.

| **ASID.** Address space identifier.

**attachment facility.** An interface between DB2 and TSO, IMS, CICS, or batch address spaces. An attachment facility allows application programs to access DB2.

**attribute.** A characteristic of an entity. For example, in database design, the phone number of an employee is one of that employee's attributes.

**authorization ID.** A string that can be verified for connection to DB2 and to which a set of privileges is allowed. It can represent an individual, an organizational group, or a function, but DB2 does not determine this representation.

**authorized program analysis report (APAR).** A report of a problem that is caused by a suspected defect in a current release of an IBM supplied program.

**authorized program facility (APF).** A facility that permits the identification of programs that are authorized to use restricted functions.

| **automatic query rewrite.** A process that examines an  
| SQL statement that refers to one or more base tables,  
| and, if appropriate, rewrites the query so that it  
| performs better. This process can also determine  
| whether to rewrite a query so that it refers to one or  
| more materialized query tables that are derived from  
| the source tables.

**auxiliary index.** An index on an auxiliary table in which each index entry refers to a LOB.

**auxiliary table.** A table that stores columns outside the table in which they are defined. Contrast with *base table*.

## B

**backout.** The process of undoing uncommitted changes that an application process made. This might be necessary in the event of a failure on the part of an application process, or as a result of a deadlock situation.

**backward log recovery.** The fourth and final phase of restart processing during which DB2 scans the log in a backward direction to apply UNDO log records for all aborted changes.

**base table.** (1) A table that is created by the SQL CREATE TABLE statement and that holds persistent data. Contrast with *result table* and *temporary table*.

(2) A table containing a LOB column definition. The actual LOB column data is not stored with the base table. The base table contains a row identifier for each row and an indicator column for each of its LOB columns. Contrast with *auxiliary table*.

**base table space.** A table space that contains base tables.

**basic predicate.** A predicate that compares two values.

**basic sequential access method (BSAM).** An access method for storing or retrieving data blocks in a continuous sequence, using either a sequential-access or a direct-access device.

| **batch message processing program.** In IMS, an  
| application program that can perform batch-type  
| processing online and can access the IMS input and  
| output message queues.

**before trigger.** A trigger that is defined with the  
trigger activation time BEFORE.

**binary integer.** A basic data type that can be further  
classified as small integer or large integer.

# **binary large object (BLOB).** A sequence of bytes in  
# which the size of the value ranges from 0 bytes to  
# 2 GB-1. Such a string has a CCSID value of 65535.

**binary string.** A sequence of bytes that is not  
associated with a CCSID. For example, the BLOB data  
type is a binary string.

**bind.** The process by which the output from the SQL  
precompiler is converted to a usable control structure,  
often called an access plan, application plan, or  
package. During this process, access paths to the data  
are selected and some authorization checking is  
performed. The types of bind are:

**automatic bind.** (More correctly, *automatic rebind*) A  
process by which SQL statements are bound  
automatically (without a user issuing a BIND  
command) when an application process begins  
execution and the bound application plan or  
package it requires is not valid.

**dynamic bind.** A process by which SQL statements  
are bound as they are entered.

**incremental bind.** A process by which SQL  
statements are bound during the execution of an  
application process.

**static bind.** A process by which SQL statements are  
bound after they have been precompiled. All static  
SQL statements are prepared for execution at the  
same time.

# **bit data.** Data that is character type CHAR or  
# VARCHAR and has a CCSID value of 65535.

**BLOB.** Binary large object.

**block fetch.** A capability in which DB2 can retrieve, or  
fetch, a large set of rows together. Using block fetch can  
significantly reduce the number of messages that are  
being sent across the network. Block fetch applies only  
to cursors that do not update data.

**BMP.** Batch Message Processing (IMS). See *batch  
message processing program*.

**bootstrap data set (BSDS).** A VSAM data set that  
contains name and status information for DB2, as well  
as RBA range specifications, for all active and archive  
log data sets. It also contains passwords for the DB2  
directory and catalog, and lists of conditional restart  
and checkpoint records.

**BSAM.** Basic sequential access method.

**BSDS.** Bootstrap data set.

**buffer pool.** Main storage that is reserved to satisfy  
the buffering requirements for one or more table spaces  
or indexes.

**built-in data type.** A data type that IBM supplies.  
Among the built-in data types for DB2 UDB for z/OS  
are string, numeric, ROWID, and datetime. Contrast  
with *distinct type*.

**built-in function.** A function that DB2 supplies.  
Contrast with *user-defined function*.

**business dimension.** A category of data, such as  
products or time periods, that an organization might  
want to analyze.

## C

**cache structure.** A coupling facility structure that  
stores data that can be available to all members of a  
Sysplex. A DB2 data sharing group uses cache  
structures as group buffer pools.

**CAF.** Call attachment facility.

**call attachment facility (CAF).** A DB2 attachment  
facility for application programs that run in TSO or  
z/OS batch. The CAF is an alternative to the DSN  
command processor and provides greater control over  
the execution environment.

**call-level interface (CLI).** A callable application  
programming interface (API) for database access, which  
is an alternative to using embedded SQL. In contrast to  
embedded SQL, DB2 ODBC (which is based on the CLI  
architecture) does not require the user to precompile or  
bind applications, but instead provides a standard set  
of functions to process SQL statements and related  
services at run time.

**cascade delete.** The way in which DB2 enforces  
referential constraints when it deletes all descendent  
rows of a deleted parent row.

**CASE expression.** An expression that is selected based  
on the evaluation of one or more conditions.

**cast function.** A function that is used to convert  
instances of a (source) data type into instances of a  
different (target) data type. In general, a cast function  
has the name of the target data type. It has one single  
argument whose type is the source data type; its return  
type is the target data type.

**castout.** The DB2 process of writing changed pages  
from a group buffer pool to disk.

**castout owner.** The DB2 member that is responsible  
for casting out a particular page set or partition.

**catalog.** In DB2, a collection of tables that contains descriptions of objects such as tables, views, and indexes.

**catalog table.** Any table in the DB2 catalog.

**CCSID.** Coded character set identifier.

**CDB.** Communications database.

**CDRA.** Character Data Representation Architecture.

**CEC.** Central electronic complex. See *central processor complex*.

**central electronic complex (CEC).** See *central processor complex*.

**central processor (CP).** The part of the computer that contains the sequencing and processing facilities for instruction execution, initial program load, and other machine operations.

**central processor complex (CPC).** A physical collection of hardware (such as an ES/3090™) that consists of main storage, one or more central processors, timers, and channels.

| **CFRM.** Coupling facility resource management.

**CFRM policy.** A declaration by a z/OS administrator regarding the allocation rules for a coupling facility structure.

**character conversion.** The process of changing characters from one encoding scheme to another.

**Character Data Representation Architecture (CDRA).** An architecture that is used to achieve consistent representation, processing, and interchange of string data.

**character large object (CLOB).** A sequence of bytes representing single-byte characters or a mixture of single- and double-byte characters where the size of the value can be up to 2 GB-1. In general, character large object values are used whenever a character string might exceed the limits of the VARCHAR type.

**character set.** A defined set of characters.

**character string.** A sequence of bytes that represent bit data, single-byte characters, or a mixture of single-byte and multibyte characters.

**check constraint.** A user-defined constraint that specifies the values that specific columns of a base table can contain.

**check integrity.** The condition that exists when each row in a table conforms to the check constraints that are defined on that table. Maintaining check integrity requires DB2 to enforce check constraints on operations that add or change data.

| **check pending.** A state of a table space or partition that prevents its use by some utilities and by some SQL statements because of rows that violate referential constraints, check constraints, or both.

**checkpoint.** A point at which DB2 records internal status information on the DB2 log; the recovery process uses this information if DB2 abnormally terminates.

| **child lock.** For explicit hierarchical locking, a lock that is held on either a table, page, row, or a large object (LOB). Each child lock has a parent lock. See also *parent lock*.

**CI.** Control interval.

| **CICS.** Represents (in this publication): CICS Transaction Server for z/OS: Customer Information Control System Transaction Server for z/OS.

**CICS attachment facility.** A DB2 subcomponent that uses the z/OS subsystem interface (SSI) and cross-storage linkage to process requests from CICS to DB2 and to coordinate resource commitment.

**CIDE.** Control interval definition field.

**claim.** A notification to DB2 that an object is being accessed. Claims prevent drains from occurring until the claim is released, which usually occurs at a commit point. Contrast with *drain*.

**claim class.** A specific type of object access that can be one of the following isolation levels:  
Cursor stability (CS)  
Repeatable read (RR)  
Write

**claim count.** A count of the number of agents that are accessing an object.

**class of service.** A VTAM term for a list of routes through a network, arranged in an order of preference for their use.

**class word.** A single word that indicates the nature of a data attribute. For example, the class word PROJ indicates that the attribute identifies a project.

**clause.** In SQL, a distinct part of a statement, such as a SELECT clause or a WHERE clause.

**CLI.** Call- level interface.

**client.** See *requester*.

**CLIST.** Command list. A language for performing TSO tasks.

**CLOB.** Character large object.

**closed application.** An application that requires exclusive use of certain statements on certain DB2

objects, so that the objects are managed solely through the application's external interface.

**CLPA.** Create link pack area.

| **clustering index.** An index that determines how rows  
| are physically ordered (*clustered*) in a table space. If a  
| clustering index on a partitioned table is not a  
| partitioning index, the rows are ordered in cluster  
| sequence within each data partition instead of spanning  
| partitions. Prior to Version 8 of DB2 UDB for z/OS, the  
| partitioning index was required to be the clustering  
| index.

**coded character set.** A set of unambiguous rules that establish a character set and the one-to-one relationships between the characters of the set and their coded representations.

**coded character set identifier (CCSID).** A 16-bit number that uniquely identifies a coded representation of graphic characters. It designates an encoding scheme identifier and one or more pairs consisting of a character set identifier and an associated code page identifier.

**code page.** (1) A set of assignments of characters to code points. In EBCDIC, for example, the character 'A' is assigned code point X'C1' (2), and character 'B' is assigned code point X'C2'. Within a code page, each code point has only one specific meaning.

**code point.** In CDRA, a unique bit pattern that represents a character in a code page.

# **code unit.** The fundamental binary width in a  
# computer architecture that is used for representing  
# character data, such as 7 bits, 8 bits, 16 bits, or 32 bits.  
# Depending on the character encoding form that is used,  
# each code point in a coded character set can be  
# represented internally by one or more code units.

**coexistence.** During migration, the period of time in which two releases exist in the same data sharing group.

**cold start.** A process by which DB2 restarts without processing any log records. Contrast with *warm start*.

**collection.** A group of packages that have the same qualifier.

**column.** The vertical component of a table. A column has a name and a particular data type (for example, character, decimal, or integer).

# **column function.** See *aggregate function*.

**"come from" checking.** An LU 6.2 security option that defines a list of authorization IDs that are allowed to connect to DB2 from a partner LU.

**command.** A DB2 operator command or a DSN subcommand. A command is distinct from an SQL statement.

**command prefix.** A one- to eight-character command identifier. The command prefix distinguishes the command as belonging to an application or subsystem rather than to MVS.

**command recognition character (CRC).** A character that permits a z/OS console operator or an IMS subsystem user to route DB2 commands to specific DB2 subsystems.

**command scope.** The scope of command operation in a data sharing group. If a command has *member scope*, the command displays information only from the one member or affects only non-shared resources that are owned locally by that member. If a command has *group scope*, the command displays information from all members, affects non-shared resources that are owned locally by all members, displays information on sharable resources, or affects sharable resources.

**commit.** The operation that ends a unit of work by releasing locks so that the database changes that are made by that unit of work can be perceived by other processes.

**commit point.** A point in time when data is considered consistent.

**committed phase.** The second phase of the multisite update process that requests all participants to commit the effects of the logical unit of work.

**common service area (CSA).** In z/OS, a part of the common area that contains data areas that are addressable by all address spaces.

**communications database (CDB).** A set of tables in the DB2 catalog that are used to establish conversations with remote database management systems.

**comparison operator.** A token (such as =, >, or <) that is used to specify a relationship between two values.

**composite key.** An ordered set of key columns of the same table.

**compression dictionary.** The dictionary that controls the process of compression and decompression. This dictionary is created from the data in the table space or table space partition.

**concurrency.** The shared use of resources by more than one application process at the same time.

**conditional restart.** A DB2 restart that is directed by a user-defined conditional restart control record (CRCR).

**connection.** In SNA, the existence of a communication path between two partner LUs that allows information

to be exchanged (for example, two DB2 subsystems that are connected and communicating by way of a conversation).

**connection context.** In SQLJ, a Java object that represents a connection to a data source.

**connection declaration clause.** In SQLJ, a statement that declares a connection to a data source.

**connection handle.** The data object containing information that is associated with a connection that DB2 ODBC manages. This includes general status information, transaction status, and diagnostic information.

**connection ID.** An identifier that is supplied by the attachment facility and that is associated with a specific address space connection.

**consistency token.** A timestamp that is used to generate the version identifier for an application. See also *version*.

**constant.** A language element that specifies an unchanging value. Constants are classified as string constants or numeric constants. Contrast with *variable*.

**constraint.** A rule that limits the values that can be inserted, deleted, or updated in a table. See *referential constraint*, *check constraint*, and *unique constraint*.

**context.** The application's logical connection to the data source and associated internal DB2 ODBC connection information that allows the application to direct its operations to a data source. A DB2 ODBC context represents a DB2 thread.

**contracting conversion.** A process that occurs when the length of a converted string is smaller than that of the source string. For example, this process occurs when an EBCDIC mixed-data string that contains DBCS characters is converted to ASCII mixed data; the converted string is shorter because of the removal of the shift codes.

**control interval (CI).** A fixed-length area or disk in which VSAM stores records and creates distributed free space. Also, in a key-sequenced data set or file, the set of records that an entry in the sequence-set index record points to. The control interval is the unit of information that VSAM transmits to or from disk. A control interval always includes an integral number of physical records.

**control interval definition field (CIDF).** In VSAM, a field that is located in the 4 bytes at the end of each control interval; it describes the free space, if any, in the control interval.

**conversation.** Communication, which is based on LU 6.2 or Advanced Program-to-Program Communication (APPC), between an application and a remote

transaction program over an SNA logical unit-to-logical unit (LU-LU) session that allows communication while processing a transaction.

**coordinator.** The system component that coordinates the commit or rollback of a unit of work that includes work that is done on one or more other systems.

| **copy pool.** A named set of SMS storage groups that  
| contains data that is to be copied collectively. A copy  
| pool is an SMS construct that lets you define which  
| storage groups are to be copied by using FlashCopy  
| functions. HSM determines which volumes belong to a  
| copy pool.

| **copy target.** A named set of SMS storage groups that  
| are to be used as containers for copy pool volume  
| copies. A copy target is an SMS construct that lets you  
| define which storage groups are to be used as  
| containers for volumes that are copied by using  
| FlashCopy functions.

| **copy version.** A point-in-time FlashCopy copy that is  
| managed by HSM. Each copy pool has a version  
| parameter that specifies how many copy versions are  
| maintained on disk.

**correlated columns.** A relationship between the value of one column and the value of another column.

**correlated subquery.** A subquery (part of a WHERE or HAVING clause) that is applied to a row or group of rows of a table or view that is named in an outer subselect statement.

**correlation ID.** An identifier that is associated with a specific thread. In TSO, it is either an authorization ID or the job name.

**correlation name.** An identifier that designates a table, a view, or individual rows of a table or view within a single SQL statement. It can be defined in any FROM clause or in the first clause of an UPDATE or DELETE statement.

**cost category.** A category into which DB2 places cost estimates for SQL statements at the time the statement is bound. A cost estimate can be placed in either of the following cost categories:

- A: Indicates that DB2 had enough information to make a cost estimate without using default values.
- B: Indicates that some condition exists for which DB2 was forced to use default values for its estimate.

The cost category is externalized in the COST\_CATEGORY column of the DSN\_STATEMENT\_TABLE when a statement is explained.

**coupling facility.** A special PR/SM LPAR logical partition that runs the coupling facility control program and provides high-speed caching, list processing, and locking functions in a Parallel Sysplex.

| **coupling facility resource management.** A component  
| of z/OS that provides the services to manage coupling  
| facility resources in a Parallel Sysplex. This  
| management includes the enforcement of CFRM  
| policies to ensure that the coupling facility and  
| structure requirements are satisfied.

**CP.** Central processor.

**CPC.** Central processor complex.

**C++ member.** A data object or function in a structure,  
union, or class.

**C++ member function.** An operator or function that is  
declared as a member of a class. A member function  
has access to the private and protected data members  
and to the member functions of objects in its class.  
Member functions are also called methods.

**C++ object.** (1) A region of storage. An object is  
created when a variable is defined or a new function is  
invoked. (2) An instance of a class.

**CRC.** Command recognition character.

**CRCR.** Conditional restart control record. See also  
*conditional restart*.

**create link pack area (CLPA).** An option that is used  
during IPL to initialize the link pack pageable area.

**created temporary table.** A table that holds temporary  
data and is defined with the SQL statement CREATE  
GLOBAL TEMPORARY TABLE. Information about  
created temporary tables is stored in the DB2 catalog,  
so this kind of table is persistent and can be shared  
across application processes. Contrast with *declared  
temporary table*. See also *temporary table*.

**cross-memory linkage.** A method for invoking a  
program in a different address space. The invocation is  
synchronous with respect to the caller.

**cross-system coupling facility (XCF).** A component of  
z/OS that provides functions to support cooperation  
between authorized programs that run within a  
Sysplex.

**cross-system extended services (XES).** A set of z/OS  
services that allow multiple instances of an application  
or subsystem, running on different systems in a Sysplex  
environment, to implement high-performance,  
high-availability data sharing by using a coupling  
facility.

**CS.** Cursor stability.

**CSA.** Common service area.

**CT.** Cursor table.

**current data.** Data within a host structure that is  
current with (identical to) the data within the base  
table.

**current SQL ID.** An ID that, at a single point in time,  
holds the privileges that are exercised when certain  
dynamic SQL statements run. The current SQL ID can  
be a primary authorization ID or a secondary  
authorization ID.

**current status rebuild.** The second phase of restart  
processing during which the status of the subsystem is  
reconstructed from information on the log.

**cursor.** A named control structure that an application  
program uses to point to a single row or multiple rows  
within some ordered set of rows of a result table. A  
cursor can be used to retrieve, update, or delete rows  
from a result table.

**cursor sensitivity.** The degree to which database  
updates are visible to the subsequent FETCH  
statements in a cursor. A cursor can be sensitive to  
changes that are made with positioned update and  
delete statements specifying the name of that cursor. A  
cursor can also be sensitive to changes that are made  
with searched update or delete statements, or with  
cursors other than this cursor. These changes can be  
made by this application process or by another  
application process.

**cursor stability (CS).** The isolation level that provides  
maximum concurrency without the ability to read  
uncommitted data. With cursor stability, a unit of work  
holds locks only on its uncommitted changes and on  
the current row of each of its cursors.

**cursor table (CT).** The copy of the skeleton cursor  
table that is used by an executing application process.

**cycle.** A set of tables that can be ordered so that each  
table is a descendent of the one before it, and the first  
table is a descendent of the last table. A self-referencing  
table is a cycle with a single member.

## D

| **DAD.** See *Document access definition*.

| **disk.** A direct-access storage device that records data  
| magnetically.

**database.** A collection of tables, or a collection of table  
spaces and index spaces.

**database access thread.** A thread that accesses data at  
the local subsystem on behalf of a remote subsystem.

**database administrator (DBA).** An individual who is  
responsible for designing, developing, operating,  
safeguarding, maintaining, and using a database.

| **database alias.** The name of the target server if  
| different from the location name. The database alias  
| name is used to provide the name of the database  
| server as it is known to the network. When a database  
| alias name is defined, the location name is used by the  
| application to reference the server, but the database  
| alias name is used to identify the database server to be  
| accessed. Any fully qualified object names within any  
| SQL statements are not modified and are sent  
| unchanged to the database server.

| **database descriptor (DBD).** An internal representation  
| of a DB2 database definition, which reflects the data  
| definition that is in the DB2 catalog. The objects that  
| are defined in a database descriptor are table spaces,  
| tables, indexes, index spaces, relationships, check  
| constraints, and triggers. A DBD also contains  
| information about accessing tables in the database.

**database exception status.** An indication that  
something is wrong with a database. All members of a  
data sharing group must know and share the exception  
status of databases.

| **database identifier (DBID).** An internal identifier of  
| the database.

**database management system (DBMS).** A software  
system that controls the creation, organization, and  
modification of a database and the access to the data  
that is stored within it.

**database request module (DBRM).** A data set  
member that is created by the DB2 precompiler and  
that contains information about SQL statements.  
DBRMs are used in the bind process.

**database server.** The target of a request from a local  
application or an intermediate database server. In the  
DB2 environment, the database server function is  
provided by the distributed data facility to access DB2  
data from local applications, or from a remote database  
server that acts as an intermediate database server.

**data currency.** The state in which data that is retrieved  
into a host variable in your program is a copy of data  
in the base table.

**data definition name (ddname).** The name of a data  
definition (DD) statement that corresponds to a data  
control block containing the same name.

**data dictionary.** A repository of information about an  
organization's application programs, databases, logical  
data models, users, and authorizations. A data  
dictionary can be manual or automated.

**data-driven business rules.** Constraints on particular  
data values that exist as a result of requirements of the  
business.

**Data Language/I (DL/I).** The IMS data manipulation  
language; a common high-level interface between a  
user application and IMS.

**data mart.** A small data warehouse that applies to a  
single department or team. See also *data warehouse*.

**data mining.** The process of collecting critical business  
information from a data warehouse, correlating it, and  
uncovering associations, patterns, and trends.

**data partition.** A VSAM data set that is contained  
within a partitioned table space.

**data-partitioned secondary index (DPSI).** A secondary  
index that is partitioned. The index is partitioned  
according to the underlying data.

**data sharing.** The ability of two or more DB2  
subsystems to directly access and change a single set of  
data.

**data sharing group.** A collection of one or more DB2  
subsystems that directly access and change the same  
data while maintaining data integrity.

**data sharing member.** A DB2 subsystem that is  
assigned by XCF services to a data sharing group.

**data source.** A local or remote relational or  
non-relational data manager that is capable of  
supporting data access via an ODBC driver that  
supports the ODBC APIs. In the case of DB2 UDB for  
z/OS, the data sources are always relational database  
managers.

| **data space.** In releases prior to DB2 UDB for z/OS,  
| Version 8, a range of up to 2 GB of contiguous virtual  
| storage addresses that a program can directly  
| manipulate. Unlike an address space, a data space can  
| hold only data; it does not contain common areas,  
| system data, or programs.

**data type.** An attribute of columns, literals, host  
variables, special registers, and the results of functions  
and expressions.

**data warehouse.** A system that provides critical  
business information to an organization. The data  
warehouse system cleanses the data for accuracy and  
currency, and then presents the data to decision makers  
so that they can interpret and use it effectively and  
efficiently.

**date.** A three-part value that designates a day, month,  
and year.

**date duration.** A decimal integer that represents a  
number of years, months, and days.

**datetime value.** A value of the data type DATE, TIME,  
or TIMESTAMP.

**DBA.** Database administrator.

**DBCLOB.** Double-byte character large object.

**DBCS.** Double-byte character set.

**DBD.** Database descriptor.

**DBID.** Database identifier.

**DBMS.** Database management system.

**DBRM.** Database request module.

**DB2 catalog.** Tables that are maintained by DB2 and contain descriptions of DB2 objects, such as tables, views, and indexes.

**DB2 command.** An instruction to the DB2 subsystem that a user enters to start or stop DB2, to display information on current users, to start or stop databases, to display information on the status of databases, and so on.

**DB2 for VSE & VM.** The IBM DB2 relational database management system for the VSE and VM operating systems.

**DB2I.** DB2 Interactive.

**DB2 Interactive (DB2I).** The DB2 facility that provides for the execution of SQL statements, DB2 (operator) commands, programmer commands, and utility invocation.

**DB2I Kanji Feature.** The tape that contains the panels and jobs that allow a site to display DB2I panels in Kanji.

**DB2 PM.** DB2 Performance Monitor.

**DB2 thread.** The DB2 structure that describes an application's connection, traces its progress, processes resource functions, and delimits its accessibility to DB2 resources and services.

**DCLGEN.** Declarations generator.

**DDF.** Distributed data facility.

**ddname.** Data definition name.

**deadlock.** Unresolvable contention for the use of a resource, such as a table or an index.

**declarations generator (DCLGEN).** A subcomponent of DB2 that generates SQL table declarations and COBOL, C, or PL/I data structure declarations that conform to the table. The declarations are generated from DB2 system catalog information. DCLGEN is also a DSN subcommand.

**declared temporary table.** A table that holds temporary data and is defined with the SQL statement DECLARE GLOBAL TEMPORARY TABLE. Information about declared temporary tables is not stored in the DB2 catalog, so this kind of table is not persistent and

can be used only by the application process that issued the DECLARE statement. Contrast with *created temporary table*. See also *temporary table*.

**default value.** A predetermined value, attribute, or option that is assumed when no other is explicitly specified.

**deferred embedded SQL.** SQL statements that are neither fully static nor fully dynamic. Like static statements, they are embedded within an application, but like dynamic statements, they are prepared during the execution of the application.

**deferred write.** The process of asynchronously writing changed data pages to disk.

**degree of parallelism.** The number of concurrently executed operations that are initiated to process a query.

**delete-connected.** A table that is a dependent of table P or a dependent of a table to which delete operations from table P cascade.

**delete hole.** The location on which a cursor is positioned when a row in a result table is refetched and the row no longer exists on the base table, because another cursor deleted the row between the time the cursor first included the row in the result table and the time the cursor tried to refetch it.

**delete rule.** The rule that tells DB2 what to do to a dependent row when a parent row is deleted. For each relationship, the rule might be CASCADE, RESTRICT, SET NULL, or NO ACTION.

**delete trigger.** A trigger that is defined with the triggering SQL operation DELETE.

**delimited identifier.** A sequence of characters that are enclosed within double quotation marks ("). The sequence must consist of a letter followed by zero or more characters, each of which is a letter, digit, or the underscore character (\_).

**delimiter token.** A string constant, a delimited identifier, an operator symbol, or any of the special characters that are shown in DB2 syntax diagrams.

**denormalization.** A key step in the task of building a physical relational database design. Denormalization is the intentional duplication of columns in multiple tables, and the consequence is increased data redundancy. Denormalization is sometimes necessary to minimize performance problems. Contrast with *normalization*.

**dependent.** An object (row, table, or table space) that has at least one parent. The object is also said to be a dependent (row, table, or table space) of its parent. See also *parent row*, *parent table*, *parent table space*.

**dependent row.** A row that contains a foreign key that matches the value of a primary key in the parent row.

**dependent table.** A table that is a dependent in at least one referential constraint.

**DES-based authenticator.** An authenticator that is generated using the DES algorithm.

**descendent.** An object that is a dependent of an object or is the dependent of a descendent of an object.

**descendent row.** A row that is dependent on another row, or a row that is a descendent of a dependent row.

**descendent table.** A table that is a dependent of another table, or a table that is a descendent of a dependent table.

**deterministic function.** A user-defined function whose result is dependent on the values of the input arguments. That is, successive invocations with the same input values produce the same answer. Sometimes referred to as a *not-variant* function. Contrast this with an *nondeterministic function* (sometimes called a *variant function*), which might not always produce the same result for the same inputs.

**DFP.** Data Facility Product (in z/OS).

**DFSMS.** Data Facility Storage Management Subsystem (in z/OS). Also called *Storage Management Subsystem (SMS)*.

| **DFSMSdss.** The data set services (dss) component of  
| DFSMS (in z/OS).

| **DFSMSHsm.** The hierarchical storage manager (hsm)  
| component of DFSMS (in z/OS).

**dimension.** A data category such as time, products, or markets. The elements of a dimension are referred to as members. Dimensions offer a very concise, intuitive way of organizing and selecting data for retrieval, exploration, and analysis. See also *dimension table*.

**dimension table.** The representation of a dimension in a star schema. Each row in a dimension table represents all of the attributes for a particular member of the dimension. See also *dimension*, *star schema*, and *star join*.

**directory.** The DB2 system database that contains internal objects such as database descriptors and skeleton cursor tables.

# **distinct predicate.** In SQL, a predicate that ensures  
# that two row values are not equal, and that both row  
# values are not null.

**distinct type.** A user-defined data type that is internally represented as an existing type (its source type), but is considered to be a separate and incompatible type for semantic purposes.

**distributed data.** Data that resides on a DBMS other than the local system.

**distributed data facility (DDF).** A set of DB2 components through which DB2 communicates with another relational database management system.

**Distributed Relational Database Architecture (DRDA).** A connection protocol for distributed relational database processing that is used by IBM's relational database products. DRDA includes protocols for communication between an application and a remote relational database management system, and for communication between relational database management systems. See also *DRDA access*.

**DL/I.** Data Language/I.

**DNS.** Domain name server.

| **document access definition (DAD).** Used to define  
| the indexing scheme for an XML column or the  
| mapping scheme of an XML collection. It can be used  
| to enable an XML Extender column of an XML  
| collection, which is XML formatted.

**domain.** The set of valid values for an attribute.

**domain name.** The name by which TCP/IP applications refer to a TCP/IP host within a TCP/IP network.

**domain name server (DNS).** A special TCP/IP network server that manages a distributed directory that is used to map TCP/IP host names to IP addresses.

**double-byte character large object (DBCLOB).** A sequence of bytes representing double-byte characters where the size of the values can be up to 2 GB. In general, DBCLOB values are used whenever a double-byte character string might exceed the limits of the VARCHAR type.

**double-byte character set (DBCS).** A set of characters, which are used by national languages such as Japanese and Chinese, that have more symbols than can be represented by a single byte. Each character is 2 bytes in length. Contrast with *single-byte character set* and *multibyte character set*.

**double-precision floating point number.** A 64-bit approximate representation of a real number.

**downstream.** The set of nodes in the syncpoint tree that is connected to the local DBMS as a participant in the execution of a two-phase commit.

| **DPSI.** Data-partitioned secondary index.

**drain.** The act of acquiring a locked resource by quiescing access to that object.

**drain lock.** A lock on a claim class that prevents a claim from occurring.

**DRDA.** Distributed Relational Database Architecture.

**DRDA access.** An open method of accessing distributed data that you can use to connect to another database server to execute packages that were previously bound at the server location. You use the SQL CONNECT statement or an SQL statement with a three-part name to identify the server. Contrast with *private protocol access*.

**DSN.** (1) The default DB2 subsystem name. (2) The name of the TSO command processor of DB2. (3) The first three characters of DB2 module and macro names.

**duration.** A number that represents an interval of time. See also *date duration*, *labeled duration*, and *time duration*.

| **dynamic cursor.** A named control structure that an application program uses to change the size of the result table and the order of its rows after the cursor is opened. Contrast with *static cursor*.

**dynamic dump.** A dump that is issued during the execution of a program, usually under the control of that program.

**dynamic SQL.** SQL statements that are prepared and executed within an application program while the program is executing. In dynamic SQL, the SQL source is contained in host language variables rather than being coded into the application program. The SQL statement can change several times during the application program's execution.

| **dynamic statement cache pool.** A cache, located above the 2-GB storage line, that holds dynamic statements.

## E

**EA-enabled table space.** A table space or index space that is enabled for extended addressability and that contains individual partitions (or pieces, for LOB table spaces) that are greater than 4 GB.

| **EB.** See *exabyte*.

**EBCDIC.** Extended binary coded decimal interchange code. An encoding scheme that is used to represent character data in the z/OS, VM, VSE, and iSeries® environments. Contrast with *ASCII* and *Unicode*.

**e-business.** The transformation of key business processes through the use of Internet technologies.

| **EDM pool.** A pool of main storage that is used for database descriptors, application plans, authorization cache, application packages.

**EID.** Event identifier.

**embedded SQL.** SQL statements that are coded within an application program. See *static SQL*.

**enclave.** In Language Environment, an independent collection of routines, one of which is designated as the main routine. An enclave is similar to a program or run unit.

**encoding scheme.** A set of rules to represent character data (ASCII, EBCDIC, or Unicode).

**entity.** A significant object of interest to an organization.

**enumerated list.** A set of DB2 objects that are defined with a LISTDEF utility control statement in which pattern-matching characters (\*, %, \_ or ?) are not used.

**environment.** A collection of names of logical and physical resources that are used to support the performance of a function.

**environment handle.** In DB2 ODBC, the data object that contains global information regarding the state of the application. An environment handle must be allocated before a connection handle can be allocated. Only one environment handle can be allocated per application.

**EOM.** End of memory.

**EOT.** End of task.

**equijoin.** A join operation in which the join-condition has the form *expression = expression*.

**error page range.** A range of pages that are considered to be physically damaged. DB2 does not allow users to access any pages that fall within this range.

**escape character.** The symbol that is used to enclose an SQL delimited identifier. The escape character is the double quotation mark ("), except in COBOL applications, where the user assigns the symbol, which is either a double quotation mark or an apostrophe (').

**ESDS.** Entry sequenced data set.

**ESMT.** External subsystem module table (in IMS).

**EUR.** IBM European Standards.

| **exabyte.** For processor, real and virtual storage capacities and channel volume:  
| 1 152 921 504 606 846 976 bytes or 2<sup>60</sup>.

**exception table.** A table that holds rows that violate referential constraints or check constraints that the CHECK DATA utility finds.

**exclusive lock.** A lock that prevents concurrently executing application processes from reading or changing data. Contrast with *share lock*.

**executable statement.** An SQL statement that can be embedded in an application program, dynamically prepared and executed, or issued interactively.

**execution context.** In SQLJ, a Java object that can be used to control the execution of SQL statements.

**exit routine.** A user-written (or IBM-provided default) program that receives control from DB2 to perform specific functions. Exit routines run as extensions of DB2.

**expanding conversion.** A process that occurs when the length of a converted string is greater than that of the source string. For example, this process occurs when an ASCII mixed-data string that contains DBCS characters is converted to an EBCDIC mixed-data string; the converted string is longer because of the addition of shift codes.

**explicit hierarchical locking.** Locking that is used to make the parent-child relationship between resources known to IRLM. This kind of locking avoids global locking overhead when no inter-DB2 interest exists on a resource.

**exposed name.** A correlation name or a table or view name for which a correlation name is not specified. Names that are specified in a FROM clause are exposed or non-exposed.

**expression.** An operand or a collection of operators and operands that yields a single value.

**extended recovery facility (XRF).** A facility that minimizes the effect of failures in z/OS, VTAM, the host processor, or high-availability applications during sessions between high-availability applications and designated terminals. This facility provides an alternative subsystem to take over sessions from the failing subsystem.

**Extensible Markup Language (XML).** A standard metalanguage for defining markup languages that is a subset of Standardized General Markup Language (SGML). The less complex nature of XML makes it easier to write applications that handle document types, to author and manage structured information, and to transmit and share structured information across diverse computing environments.

**external function.** A function for which the body is written in a programming language that takes scalar argument values and produces a scalar result for each invocation. Contrast with *sourced function*, *built-in function*, and *SQL function*.

**external procedure.** A user-written application program that can be invoked with the SQL CALL statement, which is written in a programming language. Contrast with *SQL procedure*.

**external routine.** A user-defined function or stored procedure that is based on code that is written in an external programming language.

**external subsystem module table (ESMT).** In IMS, the table that specifies which attachment modules must be loaded.

## F

**failed member state.** A state of a member of a data sharing group. When a member fails, the XCF permanently records the failed member state. This state usually means that the member's task, address space, or z/OS system terminated before the state changed from active to quiesced.

**fallback.** The process of returning to a previous release of DB2 after attempting or completing migration to a current release.

**false global lock contention.** A contention indication from the coupling facility when multiple lock names are hashed to the same indicator and when no real contention exists.

**fan set.** A direct physical access path to data, which is provided by an index, hash, or link; a fan set is the means by which the data manager supports the ordering of data.

**federated database.** The combination of a DB2 Universal Database server (in Linux, UNIX, and Windows environments) and multiple data sources to which the server sends queries. In a federated database system, a client application can use a single SQL statement to join data that is distributed across multiple database management systems and can view the data as if it were local.

**fetch orientation.** The specification of the desired placement of the cursor as part of a FETCH statement (for example, BEFORE, AFTER, NEXT, PRIOR, CURRENT, FIRST, LAST, ABSOLUTE, and RELATIVE).

**field procedure.** A user-written exit routine that is designed to receive a single value and transform (encode or decode) it in any way the user can specify.

**filter factor.** A number between zero and one that estimates the proportion of rows in a table for which a predicate is true.

**fixed-length string.** A character or graphic string whose length is specified and cannot be changed. Contrast with *varying-length string*.

**FlashCopy.** A function on the IBM Enterprise Storage Server that can create a point-in-time copy of data while an application is running.

**foreign key.** A column or set of columns in a dependent table of a constraint relationship. The key must have the same number of columns, with the same descriptions, as the primary key of the parent table.

Each foreign key value must either match a parent key value in the related parent table or be null.

| **forest.** An ordered set of subtrees of XML nodes.

**forget.** In a two-phase commit operation, (1) the vote that is sent to the prepare phase when the participant has not modified any data. The forget vote allows a participant to release locks and forget about the logical unit of work. This is also referred to as the read-only vote. (2) The response to the *committed* request in the second phase of the operation.

**forward log recovery.** The third phase of restart processing during which DB2 processes the log in a forward direction to apply all REDO log records.

**free space.** The total amount of unused space in a page; that is, the space that is not used to store records or control information is free space.

**full outer join.** The result of a join operation that includes the matched rows of both tables that are being joined and preserves the unmatched rows of both tables. See also *join*.

**fullselect.** A subselect, a values-clause, or a number of both that are combined by set operators. *Fullselect* specifies a result table. If UNION is not used, the result of the fullselect is the result of the specified subselect.

| **fully escaped mapping.** A mapping from an SQL identifier to an XML name when the SQL identifier is a column name.

# **function.** A mapping, which is embodied as a program (the function body) that is invocable by means of zero or more input values (arguments) to a single value (the result). See also *aggregate function* and *scalar function*.

# Functions can be user-defined, built-in, or generated by DB2. (See also *built-in function*, *cast function*, *external function*, *sourced function*, *SQL function*, and *user-defined function*.)

**function definer.** The authorization ID of the owner of the schema of the function that is specified in the CREATE FUNCTION statement.

**function implementer.** The authorization ID of the owner of the function program and function package.

**function package.** A package that results from binding the DBRM for a function program.

**function package owner.** The authorization ID of the user who binds the function program's DBRM into a function package.

**function resolution.** The process, internal to the DBMS, by which a function invocation is bound to a particular function instance. This process uses the function name, the data types of the arguments, and a

list of the applicable schema names (called the *SQL path*) to make the selection. This process is sometimes called *function selection*.

**function selection.** See *function resolution*.

**function signature.** The logical concatenation of a fully qualified function name with the data types of all of its parameters.

## G

**GB.** Gigabyte (1 073 741 824 bytes).

**GBP.** Group buffer pool.

**GBP-dependent.** The status of a page set or page set partition that is dependent on the group buffer pool. Either read/write interest is active among DB2 subsystems for this page set, or the page set has changed pages in the group buffer pool that have not yet been cast out to disk.

**generalized trace facility (GTF).** A z/OS service program that records significant system events such as I/O interrupts, SVC interrupts, program interrupts, or external interrupts.

**generic resource name.** A name that VTAM uses to represent several application programs that provide the same function in order to handle session distribution and balancing in a Sysplex environment.

**getpage.** An operation in which DB2 accesses a data page.

**global lock.** A lock that provides concurrency control within and among DB2 subsystems. The scope of the lock is across all DB2 subsystems of a data sharing group.

**global lock contention.** Conflicts on locking requests between different DB2 members of a data sharing group when those members are trying to serialize shared resources.

**governor.** See *resource limit facility*.

**graphic string.** A sequence of DBCS characters.

**gross lock.** The *shared*, *update*, or *exclusive* mode locks on a table, partition, or table space.

**group buffer pool (GBP).** A coupling facility cache structure that is used by a data sharing group to cache data and to ensure that the data is consistent for all members.

**group buffer pool duplexing.** The ability to write data to two instances of a group buffer pool structure: a *primary group buffer pool* and a *secondary group buffer*

*pool*. z/OS publications refer to these instances as the "old" (for primary) and "new" (for secondary) structures.

**group level.** The release level of a data sharing group, which is established when the first member migrates to a new release.

**group name.** The z/OS XCF identifier for a data sharing group.

**group restart.** A restart of at least one member of a data sharing group after the loss of either locks or the shared communications area.

**GTF.** Generalized trace facility.

## H

**handle.** In DB2 ODBC, a variable that refers to a data structure and associated resources. See also *statement handle*, *connection handle*, and *environment handle*.

**help panel.** A screen of information that presents tutorial text to assist a user at the workstation or terminal.

**heuristic damage.** The inconsistency in data between one or more participants that results when a heuristic decision to resolve an indoubt LUW at one or more participants differs from the decision that is recorded at the coordinator.

**heuristic decision.** A decision that forces indoubt resolution at a participant by means other than automatic resynchronization between coordinator and participant.

| **hole.** A row of the result table that cannot be accessed  
| because of a delete or an update that has been  
| performed on the row. See also *delete hole* and *update hole*.  
|

**home address space.** The area of storage that z/OS currently recognizes as *dispatched*.

**host.** The set of programs and resources that are available on a given TCP/IP instance.

**host expression.** A Java variable or expression that is referenced by SQL clauses in an SQLJ application program.

**host identifier.** A name that is declared in the host program.

**host language.** A programming language in which you can embed SQL statements.

**host program.** An application program that is written in a host language and that contains embedded SQL statements.

**host structure.** In an application program, a structure that is referenced by embedded SQL statements.

**host variable.** In an application program, an application variable that is referenced by embedded SQL statements.

| **host variable array.** An array of elements, each of  
| which corresponds to a value for a column. The  
| dimension of the array determines the maximum  
| number of rows for which the array can be used.

**HSM.** Hierarchical storage manager.

**HTML.** Hypertext Markup Language, a standard method for presenting Web data to users.

**HTTP.** Hypertext Transfer Protocol, a communication protocol that the Web uses.

## I

**ICF.** Integrated catalog facility.

**IDCAMS.** An IBM program that is used to process access method services commands. It can be invoked as a job or jobstep, from a TSO terminal, or from within a user's application program.

**IDCAMS LISTCAT.** A facility for obtaining information that is contained in the access method services catalog.

**identify.** A request that an attachment service program in an address space that is separate from DB2 issues thorough the z/OS subsystem interface to inform DB2 of its existence and to initiate the process of becoming connected to DB2.

**identity column.** A column that provides a way for DB2 to automatically generate a numeric value for each row. The generated values are unique if cycling is not used. Identity columns are defined with the AS IDENTITY clause. Uniqueness of values can be ensured by defining a unique index that contains only the identity column. A table can have no more than one identity column.

**IFCID.** Instrumentation facility component identifier.

**IFI.** Instrumentation facility interface.

**IFI call.** An invocation of the instrumentation facility interface (IFI) by means of one of its defined functions.

**IFP.** IMS Fast Path.

**image copy.** An exact reproduction of all or part of a table space. DB2 provides utility programs to make full image copies (to copy the entire table space) or incremental image copies (to copy only those pages that have been modified since the last image copy).

**implied forget.** In the presumed-abort protocol, an implied response of *forget* to the second-phase *committed* request from the coordinator. The response is implied when the participant responds to any subsequent request from the coordinator.

**IMS.** Information Management System.

**IMS attachment facility.** A DB2 subcomponent that uses z/OS subsystem interface (SSI) protocols and cross-memory linkage to process requests from IMS to DB2 and to coordinate resource commitment.

**IMS DB.** Information Management System Database.

**IMS TM.** Information Management System Transaction Manager.

**in-abort.** A status of a unit of recovery. If DB2 fails after a unit of recovery begins to be rolled back, but before the process is completed, DB2 continues to back out the changes during restart.

**in-commit.** A status of a unit of recovery. If DB2 fails after beginning its phase 2 commit processing, it "knows," when restarted, that changes made to data are consistent. Such units of recovery are termed *in-commit*.

**independent.** An object (row, table, or table space) that is neither a parent nor a dependent of another object.

**index.** A set of pointers that are logically ordered by the values of a key. Indexes can provide faster access to data and can enforce uniqueness on the rows in a table.

| **index-controlled partitioning.** A type of partitioning  
| in which partition boundaries for a partitioned table are  
| controlled by values that are specified on the CREATE  
| INDEX statement. Partition limits are saved in the  
| LIMITKEY column of the SYSIBM.SYSINDEXPART  
| catalog table.

**index key.** The set of columns in a table that is used to determine the order of index entries.

**index partition.** A VSAM data set that is contained within a partitioning index space.

**index space.** A page set that is used to store the entries of one index.

**indicator column.** A 4-byte value that is stored in a base table in place of a LOB column.

**indicator variable.** A variable that is used to represent the null value in an application program. If the value for the selected column is null, a negative value is placed in the indicator variable.

**indoubt.** A status of a unit of recovery. If DB2 fails after it has finished its phase 1 commit processing and before it has started phase 2, only the commit coordinator knows if an individual unit of recovery is

to be committed or rolled back. At emergency restart, if DB2 lacks the information it needs to make this decision, the status of the unit of recovery is *indoubt* until DB2 obtains this information from the coordinator. More than one unit of recovery can be *indoubt* at restart.

**indoubt resolution.** The process of resolving the status of an *indoubt* logical unit of work to either the committed or the rollback state.

**inflight.** A status of a unit of recovery. If DB2 fails before its unit of recovery completes phase 1 of the commit process, it merely backs out the updates of its unit of recovery at restart. These units of recovery are termed *inflight*.

**inheritance.** The passing downstream of class resources or attributes from a parent class in the class hierarchy to a child class.

**initialization file.** For DB2 ODBC applications, a file containing values that can be set to adjust the performance of the database manager.

**inline copy.** A copy that is produced by the LOAD or REORG utility. The data set that the inline copy produces is logically equivalent to a full image copy that is produced by running the COPY utility with read-only access (SHRLEVEL REFERENCE).

**inner join.** The result of a join operation that includes only the matched rows of both tables that are being joined. See also *join*.

**inoperative package.** A package that cannot be used because one or more user-defined functions or procedures that the package depends on were dropped. Such a package must be explicitly rebound. Contrast with *invalid package*.

| **insensitive cursor.** A cursor that is not sensitive to  
| inserts, updates, or deletes that are made to the  
| underlying rows of a result table after the result table  
| has been materialized.

**insert trigger.** A trigger that is defined with the triggering SQL operation INSERT.

**install.** The process of preparing a DB2 subsystem to operate as a z/OS subsystem.

**installation verification scenario.** A sequence of operations that exercises the main DB2 functions and tests whether DB2 was correctly installed.

**instrumentation facility component identifier (IFCID).** A value that names and identifies a trace record of an event that can be traced. As a parameter on the START TRACE and MODIFY TRACE commands, it specifies that the corresponding event is to be traced.

**instrumentation facility interface (IFI).** A programming interface that enables programs to obtain online trace data about DB2, to submit DB2 commands, and to pass data to DB2.

**Interactive System Productivity Facility (ISPF).** An IBM licensed program that provides interactive dialog services in a z/OS environment.

**inter-DB2 R/W interest.** A property of data in a table space, index, or partition that has been opened by more than one member of a data sharing group and that has been opened for writing by at least one of those members.

**intermediate database server.** The target of a request from a local application or a remote application requester that is forwarded to another database server. In the DB2 environment, the remote request is forwarded transparently to another database server if the object that is referenced by a three-part name does not reference the local location.

**internationalization.** The support for an encoding scheme that is able to represent the code points of characters from many different geographies and languages. To support all geographies, the Unicode standard requires more than 1 byte to represent a single character. See also *Unicode*.

**internal resource lock manager (IRLM).** A z/OS subsystem that DB2 uses to control communication and database locking.

| **International Organization for Standardization.** An international body charged with creating standards to facilitate the exchange of goods and services as well as cooperation in intellectual, scientific, technological, and economic activity.

**invalid package.** A package that depends on an object (other than a user-defined function) that is dropped. Such a package is implicitly rebound on invocation. Contrast with *inoperative package*.

**invariant character set.** (1) A character set, such as the syntactic character set, whose code point assignments do not change from code page to code page. (2) A minimum set of characters that is available as part of all character sets.

**IP address.** A 4-byte value that uniquely identifies a TCP/IP host.

**IRLM.** Internal resource lock manager.

**ISO.** International Organization for Standardization.

**isolation level.** The degree to which a unit of work is isolated from the updating operations of other units of work. See also *cursor stability*, *read stability*, *repeatable read*, and *uncommitted read*.

**ISPF.** Interactive System Productivity Facility.

**ISPF/PDF.** Interactive System Productivity Facility/Program Development Facility.

**iterator.** In SQLJ, an object that contains the result set of a query. An iterator is equivalent to a cursor in other host languages.

**iterator declaration clause.** In SQLJ, a statement that generates an iterator declaration class. An iterator is an object of an iterator declaration class.

## J

| **Japanese Industrial Standard.** An encoding scheme that is used to process Japanese characters.

| **JAR.** Java Archive.

**Java Archive (JAR).** A file format that is used for aggregating many files into a single file.

**JCL.** Job control language.

**JDBC.** A Sun Microsystems database application programming interface (API) for Java that allows programs to access database management systems by using callable SQL. JDBC does not require the use of an SQL preprocessor. In addition, JDBC provides an architecture that lets users add modules called *database drivers*, which link the application to their choice of database management systems at run time.

**JES.** Job Entry Subsystem.

**JIS.** Japanese Industrial Standard.

**job control language (JCL).** A control language that is used to identify a job to an operating system and to describe the job's requirements.

**Job Entry Subsystem (JES).** An IBM licensed program that receives jobs into the system and processes all output data that is produced by the jobs.

**join.** A relational operation that allows retrieval of data from two or more tables based on matching column values. See also *equijoin*, *full outer join*, *inner join*, *left outer join*, *outer join*, and *right outer join*.

## K

**KB.** Kilobyte (1024 bytes).

**Kerberos.** A network authentication protocol that is designed to provide strong authentication for client/server applications by using secret-key cryptography.

**Kerberos ticket.** A transparent application mechanism that transmits the identity of an initiating principal to its target. A simple ticket contains the principal's

identity, a session key, a timestamp, and other information, which is sealed using the target's secret key.

**key.** A column or an ordered collection of columns that is identified in the description of a table, index, or referential constraint. The same column can be part of more than one key.

**key-sequenced data set (KSDS).** A VSAM file or data set whose records are loaded in key sequence and controlled by an index.

**keyword.** In SQL, a name that identifies an option that is used in an SQL statement.

**KSDS.** Key-sequenced data set.

## L

**labeled duration.** A number that represents a duration of years, months, days, hours, minutes, seconds, or microseconds.

**large object (LOB).** A sequence of bytes representing bit data, single-byte characters, double-byte characters, or a mixture of single- and double-byte characters. A LOB can be up to 2 GB-1 byte in length. See also *BLOB*, *CLOB*, and *DBCLOB*.

**last agent optimization.** An optimized commit flow for either presumed-nothing or presumed-abort protocols in which the last agent, or final participant, becomes the commit coordinator. This flow saves at least one message.

**latch.** A DB2 internal mechanism for controlling concurrent events or the use of system resources.

**LCID.** Log control interval definition.

**LDS.** Linear data set.

**leaf page.** A page that contains pairs of keys and RIDs and that points to actual data. Contrast with *nonleaf page*.

**left outer join.** The result of a join operation that includes the matched rows of both tables that are being joined, and that preserves the unmatched rows of the first table. See also *join*.

**limit key.** The highest value of the index key for a partition.

**linear data set (LDS).** A VSAM data set that contains data but no control information. A linear data set can be accessed as a byte-addressable string in virtual storage.

**linkage editor.** A computer program for creating load modules from one or more object modules or load

modules by resolving cross references among the modules and, if necessary, adjusting addresses.

**link-edit.** The action of creating a loadable computer program using a linkage editor.

**list.** A type of object, which DB2 utilities can process, that identifies multiple table spaces, multiple index spaces, or both. A list is defined with the LISTDEF utility control statement.

**list structure.** A coupling facility structure that lets data be shared and manipulated as elements of a queue.

**LLE.** Load list element.

**L-lock.** Logical lock.

| **load list element.** A z/OS control block that controls  
| the loading and deleting of a particular load module  
| based on entry point names.

**load module.** A program unit that is suitable for loading into main storage for execution. The output of a linkage editor.

**LOB.** Large object.

**LOB locator.** A mechanism that allows an application program to manipulate a large object value in the database system. A LOB locator is a fullword integer value that represents a single LOB value. An application program retrieves a LOB locator into a host variable and can then apply SQL operations to the associated LOB value using the locator.

**LOB lock.** A lock on a LOB value.

**LOB table space.** A table space in an auxiliary table that contains all the data for a particular LOB column in the related base table.

**local.** A way of referring to any object that the local DB2 subsystem maintains. A *local table*, for example, is a table that is maintained by the local DB2 subsystem. Contrast with *remote*.

**locale.** The definition of a subset of a user's environment that combines a CCSID and characters that are defined for a specific language and country.

**local lock.** A lock that provides intra-DB2 concurrency control, but not inter-DB2 concurrency control; that is, its scope is a single DB2.

**local subsystem.** The unique relational DBMS to which the user or application program is directly connected (in the case of DB2, by one of the DB2 attachment facilities).

| **location.** The unique name of a database server. An  
| application uses the location name to access a DB2

| database server. A database alias can be used to  
| override the location name when accessing a remote  
| server.

| **location alias.** Another name by which a database  
| server identifies itself in the network. Applications can  
| use this name to access a DB2 database server.

**lock.** A means of controlling concurrent events or access to data. DB2 locking is performed by the IRLM.

**lock duration.** The interval over which a DB2 lock is held.

**lock escalation.** The promotion of a lock from a row, page, or LOB lock to a table space lock because the number of page locks that are concurrently held on a given resource exceeds a preset limit.

**locking.** The process by which the integrity of data is ensured. Locking prevents concurrent users from accessing inconsistent data.

**lock mode.** A representation for the type of access that concurrently running programs can have to a resource that a DB2 lock is holding.

**lock object.** The resource that is controlled by a DB2 lock.

**lock promotion.** The process of changing the size or mode of a DB2 lock to a higher, more restrictive level.

**lock size.** The amount of data that is controlled by a DB2 lock on table data; the value can be a row, a page, a LOB, a partition, a table, or a table space.

**lock structure.** A coupling facility data structure that is composed of a series of lock entries to support shared and exclusive locking for logical resources.

**log.** A collection of records that describe the events that occur during DB2 execution and that indicate their sequence. The information thus recorded is used for recovery in the event of a failure during DB2 execution.

| **log control interval definition.** A suffix of the  
| physical log record that tells how record segments are  
| placed in the physical control interval.

**logical claim.** A claim on a logical partition of a nonpartitioning index.

**logical data modeling.** The process of documenting the comprehensive business information requirements in an accurate and consistent format. Data modeling is the first task of designing a database.

**logical drain.** A drain on a logical partition of a nonpartitioning index.

**logical index partition.** The set of all keys that reference the same data partition.

**logical lock (L-lock).** The lock type that transactions use to control intra- and inter-DB2 data concurrency between transactions. Contrast with *physical lock (P-lock)*.

**logically complete.** A state in which the concurrent copy process is finished with the initialization of the target objects that are being copied. The target objects are available for update.

**logical page list (LPL).** A list of pages that are in error and that cannot be referenced by applications until the pages are recovered. The page is in *logical error* because the actual media (coupling facility or disk) might not contain any errors. Usually a connection to the media has been lost.

**logical partition.** A set of key or RID pairs in a nonpartitioning index that are associated with a particular partition.

**logical recovery pending (LRECP).** The state in which the data and the index keys that reference the data are inconsistent.

**logical unit (LU).** An access point through which an application program accesses the SNA network in order to communicate with another application program.

**logical unit of work (LUW).** The processing that a program performs between synchronization points.

**logical unit of work identifier (LUWID).** A name that uniquely identifies a thread within a network. This name consists of a fully-qualified LU network name, an LUW instance number, and an LUW sequence number.

**log initialization.** The first phase of restart processing during which DB2 attempts to locate the current end of the log.

**log record header (LRH).** A prefix, in every logical record, that contains control information.

**log record sequence number (LRSN).** A unique identifier for a log record that is associated with a data sharing member. DB2 uses the LRSN for recovery in the data sharing environment.

**log truncation.** A process by which an explicit starting RBA is established. This RBA is the point at which the next byte of log data is to be written.

**LPL.** Logical page list.

**LRECP.** Logical recovery pending.

**LRH.** Log record header.

**LRSN.** Log record sequence number.

**LU.** Logical unit.

**LU name.** Logical unit name, which is the name by which VTAM refers to a node in a network. Contrast with *location name*.

**LUW.** Logical unit of work.

**LUWID.** Logical unit of work identifier.

## M

**mapping table.** A table that the REORG utility uses to map the associations of the RIDs of data records in the original copy and in the shadow copy. This table is created by the user.

**mass delete.** The deletion of all rows of a table.

**master terminal.** The IMS logical terminal that has complete control of IMS resources during online operations.

**master terminal operator (MTO).** See *master terminal*.

**materialize.** (1) The process of putting rows from a view or nested table expression into a work file for additional processing by a query.

(2) The placement of a LOB value into contiguous storage. Because LOB values can be very large, DB2 avoids materializing LOB data until doing so becomes absolutely necessary.

| **materialized query table.** A table that is used to  
| contain information that is derived and can be  
| summarized from one or more source tables.

**MB.** Megabyte (1 048 576 bytes).

**MBCS.** Multibyte character set. UTF-8 is an example of an MBCS. Characters in UTF-8 can range from 1 to 4 bytes in DB2.

**member name.** The z/OS XCF identifier for a particular DB2 subsystem in a data sharing group.

**menu.** A displayed list of available functions for selection by the operator. A menu is sometimes called a *menu panel*.

| **metalanguage.** A language that is used to create other  
| specialized languages.

**migration.** The process of converting a subsystem with a previous release of DB2 to an updated or current release. In this process, you can acquire the functions of the updated or current release without losing the data that you created on the previous release.

**mixed data string.** A character string that can contain both single-byte and double-byte characters.

**MLPA.** Modified link pack area.

**MODEENT.** A VTAM macro instruction that associates a logon mode name with a set of parameters representing session protocols. A set of MODEENT macro instructions defines a logon mode table.

**modeling database.** A DB2 database that you create on your workstation that you use to model a DB2 UDB for z/OS subsystem, which can then be evaluated by the Index Advisor.

**mode name.** A VTAM name for the collection of physical and logical characteristics and attributes of a session.

**modify locks.** An L-lock or P-lock with a MODIFY attribute. A list of these active locks is kept at all times in the coupling facility lock structure. If the requesting DB2 subsystem fails, that DB2 subsystem's modify locks are converted to retained locks.

**MPP.** Message processing program (in IMS).

**MTO.** Master terminal operator.

**multibyte character set (MBCS).** A character set that represents single characters with more than a single byte. Contrast with *single-byte character set* and *double-byte character set*. See also *Unicode*.

**multidimensional analysis.** The process of assessing and evaluating an enterprise on more than one level.

**Multiple Virtual Storage.** An element of the z/OS operating system. This element is also called the Base Control Program (BCP).

**multisite update.** Distributed relational database processing in which data is updated in more than one location within a single unit of work.

**multithreading.** Multiple TCBs that are executing one copy of DB2 ODBC code concurrently (sharing a processor) or in parallel (on separate central processors).

**must-complete.** A state during DB2 processing in which the entire operation must be completed to maintain data integrity.

**mutex.** Pthread mutual exclusion; a lock. A Pthread mutex variable is used as a locking mechanism to allow serialization of critical sections of code by temporarily blocking the execution of all but one thread.

| **MVS.** See *Multiple Virtual Storage*.

## N

**negotiable lock.** A lock whose mode can be downgraded, by agreement among contending users, to be compatible to all. A physical lock is an example of a negotiable lock.

**nested table expression.** A fullselect in a FROM clause (surrounded by parentheses).

**network identifier (NID).** The network ID that is assigned by IMS or CICS, or if the connection type is RRSAF, the RRS unit of recovery ID (URID).

**NID.** Network identifier.

**nonleaf page.** A page that contains keys and page numbers of other pages in the index (either leaf or nonleaf pages). Nonleaf pages never point to actual data.

| **nonpartitioned index.** An index that is not physically  
| partitioned. Both partitioning indexes and secondary  
| indexes can be nonpartitioned.

**nonscrollable cursor.** A cursor that can be moved only in a forward direction. Nonscrollable cursors are sometimes called forward-only cursors or serial cursors.

**normalization.** A key step in the task of building a logical relational database design. Normalization helps you avoid redundancies and inconsistencies in your data. An entity is normalized if it meets a set of constraints for a particular normal form (first normal form, second normal form, and so on). Contrast with *denormalization*.

**nondeterministic function.** A user-defined function whose result is not solely dependent on the values of the input arguments. That is, successive invocations with the same argument values can produce a different answer. This type of function is sometimes called a *variant* function. Contrast this with a *deterministic function* (sometimes called a *not-variant function*), which always produces the same result for the same inputs.

**not-variant function.** See *deterministic function*.

| **NPSI.** See *nonpartitioned secondary index*.

**NRE.** Network recovery element.

**NUL.** The null character ('\0'), which is represented by the value X'00'. In C, this character denotes the end of a string.

**null.** A special value that indicates the absence of information.

**NULLIF.** A scalar function that evaluates two passed expressions, returning either NULL if the arguments are equal or the value of the first argument if they are not.

**null-terminated host variable.** A varying-length host variable in which the end of the data is indicated by a null terminator.

**null terminator.** In C, the value that indicates the end of a string. For EBCDIC, ASCII, and Unicode UTF-8 strings, the null terminator is a single-byte value (X'00').

For Unicode UCS-2 (wide) strings, the null terminator is a double-byte value (X'0000').

## O

**OASN (origin application schedule number).** In IMS, a 4-byte number that is assigned sequentially to each IMS schedule since the last cold start of IMS. The OASN is used as an identifier for a unit of work. In an 8-byte format, the first 4 bytes contain the schedule number and the last 4 bytes contain the number of IMS sync points (*commit points*) during the current schedule. The OASN is part of the NID for an IMS connection.

**ODBC.** Open Database Connectivity.

**ODBC driver.** A dynamically-linked library (DLL) that implements ODBC function calls and interacts with a data source.

**OBID.** Data object identifier.

**Open Database Connectivity (ODBC).** A Microsoft database application programming interface (API) for C that allows access to database management systems by using callable SQL. ODBC does not require the use of an SQL preprocessor. In addition, ODBC provides an architecture that lets users add modules called *database drivers*, which link the application to their choice of database management systems at run time. This means that applications no longer need to be directly linked to the modules of all the database management systems that are supported.

**ordinary identifier.** An uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character. An ordinary identifier must not be a reserved word.

**ordinary token.** A numeric constant, an ordinary identifier, a host identifier, or a keyword.

**originating task.** In a parallel group, the primary agent that receives data from other execution units (referred to as *parallel tasks*) that are executing portions of the query in parallel.

**OS/390.** Operating System/390®.

**outer join.** The result of a join operation that includes the matched rows of both tables that are being joined and preserves some or all of the unmatched rows of the tables that are being joined. See also *join*.

**overloaded function.** A function name for which multiple function instances exist.

## P

**package.** An object containing a set of SQL statements that have been statically bound and that is available for processing. A package is sometimes also called an *application package*.

**package list.** An ordered list of package names that may be used to extend an application plan.

**package name.** The name of an object that is created by a BIND PACKAGE or REBIND PACKAGE command. The object is a bound version of a database request module (DBRM). The name consists of a location name, a collection ID, a package ID, and a version ID.

**page.** A unit of storage within a table space (4 KB, 8 KB, 16 KB, or 32 KB) or index space (4 KB). In a table space, a page contains one or more rows of a table. In a LOB table space, a LOB value can span more than one page, but no more than one LOB value is stored on a page.

**page set.** Another way to refer to a table space or index space. Each page set consists of a collection of VSAM data sets.

**page set recovery pending (PSRCP).** A restrictive state of an index space. In this case, the entire page set must be recovered. Recovery of a logical part is prohibited.

**panel.** A predefined display image that defines the locations and characteristics of display fields on a display surface (for example, a *menu panel*).

**parallel complex.** A cluster of machines that work together to handle multiple transactions and applications.

**parallel group.** A set of consecutive operations that execute in parallel and that have the same number of parallel tasks.

**parallel I/O processing.** A form of I/O processing in which DB2 initiates multiple concurrent requests for a single user query and performs I/O processing concurrently (in *parallel*) on multiple data partitions.

**parallelism assistant.** In Sysplex query parallelism, a DB2 subsystem that helps to process parts of a parallel query that originates on another DB2 subsystem in the data sharing group.

**parallelism coordinator.** In Sysplex query parallelism, the DB2 subsystem from which the parallel query originates.

**Parallel Sysplex.** A set of z/OS systems that communicate and cooperate with each other through certain multisystem hardware components and software services to process customer workloads.

**parallel task.** The execution unit that is dynamically created to process a query in parallel. A parallel task is implemented by a z/OS service request block.

**parameter marker.** A question mark (?) that appears in a statement string of a dynamic SQL statement. The question mark can appear where a host variable could appear if the statement string were a static SQL statement.

| **parameter-name.** An SQL identifier that designates a  
| parameter in an SQL procedure or an SQL function.

**parent key.** A primary key or unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the referential constraint.

| **parent lock.** For explicit hierarchical locking, a lock  
| that is held on a resource that might have child locks  
| that are lower in the hierarchy. A parent lock is usually  
| the table space lock or the partition intent lock. See also  
| *child lock*.

**parent row.** A row whose primary key value is the foreign key value of a dependent row.

**parent table.** A table whose primary key is referenced by the foreign key of a dependent table.

**parent table space.** A table space that contains a parent table. A table space containing a dependent of that table is a dependent table space.

**participant.** An entity other than the commit coordinator that takes part in the commit process. The term participant is synonymous with *agent* in SNA.

**partition.** A portion of a page set. Each partition corresponds to a single, independently extendable data set. Partitions can be extended to a maximum size of 1, 2, or 4 GB, depending on the number of partitions in the partitioned page set. All partitions of a given page set have the same maximum size.

**partitioned data set (PDS).** A data set in disk storage that is divided into partitions, which are called members. Each partition can contain a program, part of a program, or data. The term partitioned data set is synonymous with program library.

| **partitioned index.** An index that is physically  
| partitioned. Both partitioning indexes and secondary  
| indexes can be partitioned.

**partitioned page set.** A partitioned table space or an index space. Header pages, space map pages, data pages, and index pages reference data only within the scope of the partition.

**partitioned table space.** A table space that is subdivided into parts (based on index key range), each of which can be processed independently by utilities.

**partitioning index.** An index in which the leftmost columns are the partitioning columns of the table. The index can be partitioned or nonpartitioned.

**partition pruning.** The removal from consideration of inapplicable partitions through setting up predicates in a query on a partitioned table to access only certain partitions to satisfy the query.

**partner logical unit.** An access point in the SNA network that is connected to the local DB2 subsystem by way of a VTAM conversation.

**path.** See *SQL path*.

**PCT.** Program control table (in CICS).

**PDS.** Partitioned data set.

**piece.** A data set of a nonpartitioned page set.

**physical claim.** A claim on an entire nonpartitioning index.

**physical consistency.** The state of a page that is not in a partially changed state.

**physical drain.** A drain on an entire nonpartitioning index.

**physical lock (P-lock).** A type of lock that DB2 acquires to provide consistency of data that is cached in different DB2 subsystems. Physical locks are used only in data sharing environments. Contrast with *logical lock (L-lock)*.

**physical lock contention.** Conflicting states of the requesters for a physical lock. See also *negotiable lock*.

**physically complete.** The state in which the concurrent copy process is completed and the output data set has been created.

**plan.** See *application plan*.

**plan allocation.** The process of allocating DB2 resources to a plan in preparation for execution.

**plan member.** The bound copy of a DBRM that is identified in the member clause.

**plan name.** The name of an application plan.

**plan segmentation.** The dividing of each plan into sections. When a section is needed, it is independently brought into the EDM pool.

**P-lock.** Physical lock.

**PLT.** Program list table (in CICS).

**point of consistency.** A time when all recoverable data that an application accesses is consistent with other data. The term point of consistency is synonymous with *sync point* or *commit point*.

**policy.** See *CFRM policy*.

**Portable Operating System Interface (POSIX).** The IEEE operating system interface standard, which defines the Pthread standard of threading. See also *Pthread*.

**POSIX.** Portable Operating System Interface.

**postponed abort UR.** A unit of recovery that was inflight or in-abort, was interrupted by system failure or cancellation, and did not complete backout during restart.

**PPT.** (1) Processing program table (in CICS). (2) Program properties table (in z/OS).

**precision.** In SQL, the total number of digits in a decimal number (called the *size* in the C language). In the C language, the number of digits to the right of the decimal point (called the *scale* in SQL). The DB2 library uses the SQL terms.

**precompilation.** A processing of application programs containing SQL statements that takes place before compilation. SQL statements are replaced with statements that are recognized by the host language compiler. Output from this precompilation includes source code that can be submitted to the compiler and the database request module (DBRM) that is input to the bind process.

**predicate.** An element of a search condition that expresses or implies a comparison operation.

**prefix.** A code at the beginning of a message or record.

**preformat.** The process of preparing a VSAM ESDS for DB2 use, by writing specific data patterns.

**prepare.** The first phase of a two-phase commit process in which all participants are requested to prepare for commit.

**prepared SQL statement.** A named object that is the executable form of an SQL statement that has been processed by the PREPARE statement.

**presumed-abort.** An optimization of the presumed-nothing two-phase commit protocol that reduces the number of recovery log records, the duration of state maintenance, and the number of messages between coordinator and participant. The optimization also modifies the indoubt resolution responsibility.

**presumed-nothing.** The standard two-phase commit protocol that defines coordinator and participant responsibilities, relative to logical unit of work states, recovery logging, and indoubt resolution.

**primary authorization ID.** The authorization ID that is used to identify the application process to DB2.

**primary group buffer pool.** For a duplexed group buffer pool, the structure that is used to maintain the coherency of cached data. This structure is used for page registration and cross-invalidation. The z/OS equivalent is *old* structure. Compare with *secondary group buffer pool*.

**primary index.** An index that enforces the uniqueness of a primary key.

**primary key.** In a relational database, a unique, nonnull key that is part of the definition of a table. A table cannot be defined as a parent unless it has a unique key or primary key.

**principal.** An entity that can communicate securely with another entity. In Kerberos, principals are represented as entries in the Kerberos registry database and include users, servers, computers, and others.

**principal name.** The name by which a principal is known to the DCE security services.

**private connection.** A communications connection that is specific to DB2.

**private protocol access.** A method of accessing distributed data by which you can direct a query to another DB2 system. Contrast with *DRDA access*.

**private protocol connection.** A DB2 private connection of the application process. See also *private connection*.

**privilege.** The capability of performing a specific function, sometimes on a specific object. The types of privileges are:

**explicit privileges,** which have names and are held as the result of SQL GRANT and REVOKE statements. For example, the SELECT privilege.

**implicit privileges,** which accompany the ownership of an object, such as the privilege to drop a synonym that one owns, or the holding of an authority, such as the privilege of SYSADM authority to terminate any utility job.

**privilege set.** For the installation SYSADM ID, the set of all possible privileges. For any other authorization ID, the set of all privileges that are recorded for that ID in the DB2 catalog.

**process.** In DB2, the unit to which DB2 allocates resources and locks. Sometimes called an *application process*, a process involves the execution of one or more programs. The execution of an SQL statement is always associated with some process. The means of initiating and terminating a process are dependent on the environment.

**program.** A single, compilable collection of executable statements in a programming language.

**program temporary fix (PTF).** A solution or bypass of a problem that is diagnosed as a result of a defect in a

current unaltered release of a licensed program. An authorized program analysis report (APAR) fix is corrective service for an existing problem. A PTF is preventive service for problems that might be encountered by other users of the product. A PTF is *temporary*, because a permanent fix is usually not incorporated into the product until its next release.

**protected conversation.** A VTAM conversation that supports two-phase commit flows.

**PSRCP.** Page set recovery pending.

**PTF.** Program temporary fix.

**Pthread.** The POSIX threading standard model for splitting an application into subtasks. The Pthread standard includes functions for creating threads, terminating threads, synchronizing threads through locking, and other thread control facilities.

## Q

**QMF.** Query Management Facility.

**QSAM.** Queued sequential access method.

**query.** A component of certain SQL statements that specifies a result table.

**query block.** The part of a query that is represented by one of the FROM clauses. Each FROM clause can have multiple query blocks, depending on DB2's internal processing of the query.

**query CP parallelism.** Parallel execution of a single query, which is accomplished by using multiple tasks. See also *Sysplex query parallelism*.

**query I/O parallelism.** Parallel access of data, which is accomplished by triggering multiple I/O requests within a single query.

**queued sequential access method (QSAM).** An extended version of the basic sequential access method (BSAM). When this method is used, a queue of data blocks is formed. Input data blocks await processing, and output data blocks await transfer to auxiliary storage or to an output device.

**quiesce point.** A point at which data is consistent as a result of running the DB2 QUIESCE utility.

**quiesced member state.** A state of a member of a data sharing group. An active member becomes quiesced when a STOP DB2 command takes effect without a failure. If the member's task, address space, or z/OS system fails before the command takes effect, the member state is failed.

## R

| **RACF.** Resource Access Control Facility, which is a component of the z/OS Security Server.

**RAMAC.** IBM family of enterprise disk storage system products.

**RBA.** Relative byte address.

**RCT.** Resource control table (in CICS attachment facility).

**RDB.** Relational database.

**RDBMS.** Relational database management system.

**RDBNAM.** Relational database name.

**RDF.** Record definition field.

**read stability (RS).** An isolation level that is similar to repeatable read but does not completely isolate an application process from all other concurrently executing application processes. Under level RS, an application that issues the same query more than once might read additional rows that were inserted and committed by a concurrently executing application process.

**rebind.** The creation of a new application plan for an application program that has been bound previously. If, for example, you have added an index for a table that your application accesses, you must rebind the application in order to take advantage of that index.

**rebuild.** The process of reallocating a coupling facility structure. For the shared communications area (SCA) and lock structure, the structure is repopulated; for the group buffer pool, changed pages are usually cast out to disk, and the new structure is populated only with changed pages that were not successfully cast out.

**RECFM.** Record format.

**record.** The storage representation of a row or other data.

**record identifier (RID).** A unique identifier that DB2 uses internally to identify a row of data in a table. Compare with *row ID*.

| **record identifier (RID) pool.** An area of main storage that is used for sorting record identifiers during list-prefetch processing.

**record length.** The sum of the length of all the columns in a table, which is the length of the data as it is physically stored in the database. Records can be fixed length or varying length, depending on how the columns are defined. If all columns are fixed-length

columns, the record is a fixed-length record. If one or more columns are varying-length columns, the record is a varying-length column.

**Recoverable Resource Manager Services attachment facility (RRSAF).** A DB2 subcomponent that uses Resource Recovery Services to coordinate resource commitment between DB2 and all other resource managers that also use RRS in a z/OS system.

**recovery.** The process of rebuilding databases after a system failure.

**recovery log.** A collection of records that describes the events that occur during DB2 execution and indicates their sequence. The recorded information is used for recovery in the event of a failure during DB2 execution.

**recovery manager.** (1) A subcomponent that supplies coordination services that control the interaction of DB2 resource managers during commit, abort, checkpoint, and restart processes. The recovery manager also supports the recovery mechanisms of other subsystems (for example, IMS) by acting as a participant in the other subsystem's process for protecting data that has reached a point of consistency. (2) A coordinator or a participant (or both), in the execution of a two-phase commit, that can access a recovery log that maintains the state of the logical unit of work and names the immediate upstream coordinator and downstream participants.

**recovery pending (RECP).** A condition that prevents SQL access to a table space that needs to be recovered.

**recovery token.** An identifier for an element that is used in recovery (for example, NID or URID).

**RECP.** Recovery pending.

**redo.** A state of a unit of recovery that indicates that changes are to be reapplied to the disk media to ensure data integrity.

**reentrant.** Executable code that can reside in storage as one shared copy for all threads. Reentrant code is not self-modifying and provides separate storage areas for each thread. Reentrancy is a compiler and operating system concept, and reentrancy alone is not enough to guarantee logically consistent results when multithreading. See also *threadsafe*.

**referential constraint.** The requirement that nonnull values of a designated foreign key are valid only if they equal values of the primary key of a designated table.

**referential integrity.** The state of a database in which all values of all foreign keys are valid. Maintaining referential integrity requires the enforcement of referential constraints on all operations that change the data in a table on which the referential constraints are defined.

**referential structure.** A set of tables and relationships that includes at least one table and, for every table in the set, all the relationships in which that table participates and all the tables to which it is related.

**refresh age.** The time duration between the current time and the time during which a materialized query table was last refreshed.

**registry.** See *registry database*.

**registry database.** A database of security information about principals, groups, organizations, accounts, and security policies.

**relational database (RDB).** A database that can be perceived as a set of tables and manipulated in accordance with the relational model of data.

**relational database management system (RDBMS).** A collection of hardware and software that organizes and provides access to a relational database.

**relational database name (RDBNAM).** A unique identifier for an RDBMS within a network. In DB2, this must be the value in the LOCATION column of table SYSIBM.LOCATIONS in the CDB. DB2 publications refer to the name of another RDBMS as a LOCATION value or a location name.

**relationship.** A defined connection between the rows of a table or the rows of two tables. A relationship is the internal representation of a referential constraint.

**relative byte address (RBA).** The offset of a data record or control interval from the beginning of the storage space that is allocated to the data set or file to which it belongs.

**remigration.** The process of returning to a current release of DB2 following a fallback to a previous release. This procedure constitutes another migration process.

**remote.** Any object that is maintained by a remote DB2 subsystem (that is, by a DB2 subsystem other than the local one). A *remote view*, for example, is a view that is maintained by a remote DB2 subsystem. Contrast with *local*.

**remote attach request.** A request by a remote location to attach to the local DB2 subsystem. Specifically, the request that is sent is an SNA Function Management Header 5.

**remote subsystem.** Any relational DBMS, except the *local subsystem*, with which the user or application can communicate. The subsystem need not be remote in any physical sense, and might even operate on the same processor under the same z/OS system.

**reoptimization.** The DB2 process of reconsidering the access path of an SQL statement at run time; during

reoptimization, DB2 uses the values of host variables, parameter markers, or special registers.

**REORG pending (REORP).** A condition that restricts SQL access and most utility access to an object that must be reorganized.

**REORP.** REORG pending.

**repeatable read (RR).** The isolation level that provides maximum protection from other executing application programs. When an application program executes with repeatable read protection, rows that the program references cannot be changed by other programs until the program reaches a commit point.

**repeating group.** A situation in which an entity includes multiple attributes that are inherently the same. The presence of a repeating group violates the requirement of first normal form. In an entity that satisfies the requirement of first normal form, each attribute is independent and unique in its meaning and its name. See also *normalization*.

**replay detection mechanism.** A method that allows a principal to detect whether a request is a valid request from a source that can be trusted or whether an untrustworthy entity has captured information from a previous exchange and is replaying the information exchange to gain access to the principal.

**request commit.** The vote that is submitted to the prepare phase if the participant has modified data and is prepared to commit or roll back.

**requester.** The source of a request to access data at a remote server. In the DB2 environment, the requester function is provided by the distributed data facility.

**resource.** The object of a lock or claim, which could be a table space, an index space, a data partition, an index partition, or a logical partition.

**resource allocation.** The part of plan allocation that deals specifically with the database resources.

**resource control table (RCT).** A construct of the CICS attachment facility, created by site-provided macro parameters, that defines authorization and access attributes for transactions or transaction groups.

**resource definition online.** A CICS feature that you use to define CICS resources online without assembling tables.

**resource limit facility (RLF).** A portion of DB2 code that prevents dynamic manipulative SQL statements from exceeding specified time limits. The resource limit facility is sometimes called the governor.

**resource limit specification table (RLST).** A site-defined table that specifies the limits to be enforced by the resource limit facility.

**resource manager.** (1) A function that is responsible for managing a particular resource and that guarantees the consistency of all updates made to recoverable resources within a logical unit of work. The resource that is being managed can be physical (for example, disk or main storage) or logical (for example, a particular type of system service). (2) A participant, in the execution of a two-phase commit, that has recoverable resources that could have been modified. The resource manager has access to a recovery log so that it can commit or roll back the effects of the logical unit of work to the recoverable resources.

**restart pending (RESTP).** A restrictive state of a page set or partition that indicates that restart (backout) work needs to be performed on the object. All access to the page set or partition is denied except for access by the:

- RECOVER POSTPONED command
- Automatic online backout (which DB2 invokes after restart if the system parameter LBACKOUT=AUTO)

**RESTP.** Restart pending.

**result set.** The set of rows that a stored procedure returns to a client application.

**result set locator.** A 4-byte value that DB2 uses to uniquely identify a query result set that a stored procedure returns.

**result table.** The set of rows that are specified by a SELECT statement.

**retained lock.** A MODIFY lock that a DB2 subsystem was holding at the time of a subsystem failure. The lock is retained in the coupling facility lock structure across a DB2 failure.

**RID.** Record identifier.

**RID pool.** Record identifier pool.

**right outer join.** The result of a join operation that includes the matched rows of both tables that are being joined and preserves the unmatched rows of the second join operand. See also *join*.

**RLF.** Resource limit facility.

**RLST.** Resource limit specification table.

**RMID.** Resource manager identifier.

**RO.** Read-only access.

**rollback.** The process of restoring data that was changed by SQL statements to the state at its last commit point. All locks are freed. Contrast with *commit*.

**root page.** The index page that is at the highest level (or the beginning point) in an index.

**routine.** A term that refers to either a user-defined function or a stored procedure.

**row.** The horizontal component of a table. A row consists of a sequence of values, one for each column of the table.

**ROWID.** Row identifier.

**row identifier (ROWID).** A value that uniquely identifies a row. This value is stored with the row and never changes.

**row lock.** A lock on a single row of data.

| **rowset.** A set of rows for which a cursor position is established.

| **rowset cursor.** A cursor that is defined so that one or more rows can be returned as a rowset for a single FETCH statement, and the cursor is positioned on the set of rows that is fetched.

| **rowset-positioned access.** The ability to retrieve multiple rows from a single FETCH statement.

| **row-positioned access.** The ability to retrieve a single row from a single FETCH statement.

**row trigger.** A trigger that is defined with the trigger granularity FOR EACH ROW.

**RRE.** Residual recovery entry (in IMS).

**RRSAF.** Recoverable Resource Manager Services attachment facility.

**RS.** Read stability.

**RTT.** Resource translation table.

**RURE.** Restart URE.

## S

**savepoint.** A named entity that represents the state of data and schemas at a particular point in time within a unit of work. SQL statements exist to set a savepoint, release a savepoint, and restore data and schemas to the state that the savepoint represents. The restoration of data and schemas to a savepoint is usually referred to as *rolling back to a savepoint*.

**SBCS.** Single-byte character set.

**SCA.** Shared communications area.

# **scalar function.** An SQL operation that produces a single value from another value and is expressed as a function name, followed by a list of arguments that are enclosed in parentheses. Contrast with *aggregate function*.

**scale.** In SQL, the number of digits to the right of the decimal point (called the *precision* in the C language). The DB2 library uses the SQL definition.

| **schema.** (1) The organization or structure of a  
| database. (2) A logical grouping for user-defined  
| functions, distinct types, triggers, and stored  
| procedures. When an object of one of these types is  
| created, it is assigned to one schema, which is  
| determined by the name of the object. For example, the  
| following statement creates a distinct type T in schema  
| C:  
| CREATE DISTINCT TYPE C.T ...

**scrollability.** The ability to use a cursor to fetch in either a forward or backward direction. The FETCH statement supports multiple fetch orientations to indicate the new position of the cursor. See also *fetch orientation*.

**scrollable cursor.** A cursor that can be moved in both a forward and a backward direction.

**SDWA.** System diagnostic work area.

**search condition.** A criterion for selecting rows from a table. A search condition consists of one or more predicates.

**secondary authorization ID.** An authorization ID that has been associated with a primary authorization ID by an authorization exit routine.

**secondary group buffer pool.** For a duplexed group buffer pool, the structure that is used to back up changed pages that are written to the primary group buffer pool. No page registration or cross-invalidation occurs using the secondary group buffer pool. The z/OS equivalent is *new* structure.

| **secondary index.** A nonpartitioning index on a  
| partitioned table.

**section.** The segment of a plan or package that contains the executable structures for a single SQL statement. For most SQL statements, one section in the plan exists for each SQL statement in the source program. However, for cursor-related statements, the DECLARE, OPEN, FETCH, and CLOSE statements reference the same section because they each refer to the SELECT statement that is named in the DECLARE CURSOR statement. SQL statements such as COMMIT, ROLLBACK, and some SET statements do not use a section.

**segment.** A group of pages that holds rows of a single table. See also *segmented table space*.

**segmented table space.** A table space that is divided into equal-sized groups of pages called segments. Segments are assigned to tables so that rows of different tables are never stored in the same segment.

**self-referencing constraint.** A referential constraint that defines a relationship in which a table is a dependent of itself.

**self-referencing table.** A table with a self-referencing constraint.

| **sensitive cursor.** A cursor that is sensitive to changes  
| that are made to the database after the result table has  
| been materialized.

| **sequence.** A user-defined object that generates a  
| sequence of numeric values according to user  
| specifications.

**sequential data set.** A non-DB2 data set whose records are organized on the basis of their successive physical positions, such as on magnetic tape. Several of the DB2 database utilities require sequential data sets.

**sequential prefetch.** A mechanism that triggers consecutive asynchronous I/O operations. Pages are fetched before they are required, and several pages are read with a single I/O operation.

**serial cursor.** A cursor that can be moved only in a forward direction.

**serialized profile.** A Java object that contains SQL statements and descriptions of host variables. The SQLJ translator produces a serialized profile for each connection context.

**server.** The target of a request from a remote requester. In the DB2 environment, the server function is provided by the distributed data facility, which is used to access DB2 data from remote applications.

**server-side programming.** A method for adding DB2 data into dynamic Web pages.

**service class.** An eight-character identifier that is used by the z/OS Workload Manager to associate user performance goals with a particular DDF thread or stored procedure. A service class is also used to classify work on parallelism assistants.

**service request block.** A unit of work that is scheduled to execute in another address space.

**session.** A link between two nodes in a VTAM network.

**session protocols.** The available set of SNA communication requests and responses.

**shared communications area (SCA).** A coupling facility list structure that a DB2 data sharing group uses for inter-DB2 communication.

**share lock.** A lock that prevents concurrently executing application processes from changing data, but not from reading data. Contrast with *exclusive lock*.

**shift-in character.** A special control character (X'0F') that is used in EBCDIC systems to denote that the subsequent bytes represent SBCS characters. See also *shift-out character*.

**shift-out character.** A special control character (X'0E') that is used in EBCDIC systems to denote that the subsequent bytes, up to the next shift-in control character, represent DBCS characters. See also *shift-in character*.

**sign-on.** A request that is made on behalf of an individual CICS or IMS application process by an attachment facility to enable DB2 to verify that it is authorized to use DB2 resources.

**simple page set.** A nonpartitioned page set. A simple page set initially consists of a single data set (page set piece). If and when that data set is extended to 2 GB, another data set is created, and so on, up to a total of 32 data sets. DB2 considers the data sets to be a single contiguous linear address space containing a maximum of 64 GB. Data is stored in the next available location within this address space without regard to any partitioning scheme.

**simple table space.** A table space that is neither partitioned nor segmented.

**single-byte character set (SBCS).** A set of characters in which each character is represented by a single byte. Contrast with *double-byte character set* or *multibyte character set*.

**single-precision floating point number.** A 32-bit approximate representation of a real number.

**size.** In the C language, the total number of digits in a decimal number (called the *precision* in SQL). The DB2 library uses the SQL term.

**SMF.** System Management Facilities.

**SMP/E.** System Modification Program/Extended.

**SMS.** Storage Management Subsystem.

**SNA.** Systems Network Architecture.

**SNA network.** The part of a network that conforms to the formats and protocols of Systems Network Architecture (SNA).

**socket.** A callable TCP/IP programming interface that TCP/IP network applications use to communicate with remote TCP/IP partners.

**sourced function.** A function that is implemented by another built-in or user-defined function that is already known to the database manager. This function can be a scalar function or a column (aggregating) function; it returns a single value from a set of values (for example, MAX or AVG). Contrast with *built-in function*, *external function*, and *SQL function*.

**source program.** A set of host language statements and SQL statements that is processed by an SQL precompiler.

| **source table.** A table that can be a base table, a view, a  
| table expression, or a user-defined table function.

**source type.** An existing type that DB2 uses to internally represent a distinct type.

**space.** A sequence of one or more blank characters.

**special register.** A storage area that DB2 defines for an application process to use for storing information that can be referenced in SQL statements. Examples of special registers are USER and CURRENT DATE.

**specific function name.** A particular user-defined function that is known to the database manager by its specific name. Many specific user-defined functions can have the same function name. When a user-defined function is defined to the database, every function is assigned a specific name that is unique within its schema. Either the user can provide this name, or a default name is used.

**SPUFI.** SQL Processor Using File Input.

**SQL.** Structured Query Language.

**SQL authorization ID (SQL ID).** The authorization ID that is used for checking dynamic SQL statements in some situations.

**SQLCA.** SQL communication area.

**SQL communication area (SQLCA).** A structure that is used to provide an application program with information about the execution of its SQL statements.

**SQL connection.** An association between an application process and a local or remote application server or database server.

**SQLDA.** SQL descriptor area.

**SQL descriptor area (SQLDA).** A structure that describes input variables, output variables, or the columns of a result table.

**SQL escape character.** The symbol that is used to enclose an SQL delimited identifier. This symbol is the double quotation mark ("). See also *escape character*.

**SQL function.** A user-defined function in which the CREATE FUNCTION statement contains the source code. The source code is a single SQL expression that evaluates to a single value. The SQL user-defined function can return only one parameter.

**SQL ID.** SQL authorization ID.

**SQLJ.** Structured Query Language (SQL) that is embedded in the Java programming language.

**SQL path.** An ordered list of schema names that are used in the resolution of unqualified references to user-defined functions, distinct types, and stored procedures. In dynamic SQL, the current path is found in the CURRENT PATH special register. In static SQL, it is defined in the PATH bind option.

**SQL procedure.** A user-written program that can be invoked with the SQL CALL statement. Contrast with *external procedure*.

**SQL processing conversation.** Any conversation that requires access of DB2 data, either through an application or by dynamic query requests.

**SQL Processor Using File Input (SPUFI).** A facility of the TSO attachment subcomponent that enables the DB2I user to execute SQL statements without embedding them in an application program.

**SQL return code.** Either SQLCODE or SQLSTATE.

**SQL routine.** A user-defined function or stored procedure that is based on code that is written in SQL.

**SQL statement coprocessor.** An alternative to the DB2 precompiler that lets the user process SQL statements at compile time. The user invokes an SQL statement coprocessor by specifying a compiler option.

**SQL string delimiter.** A symbol that is used to enclose an SQL string constant. The SQL string delimiter is the apostrophe ('), except in COBOL applications, where the user assigns the symbol, which is either an apostrophe or a double quotation mark (").

**SRB.** Service request block.

**SSI.** Subsystem interface (in z/OS).

**SSM.** Subsystem member (in IMS).

**stand-alone.** An attribute of a program that means that it is capable of executing separately from DB2, without using DB2 services.

**star join.** A method of joining a dimension column of a fact table to the key column of the corresponding dimension table. See also *join*, *dimension*, and *star schema*.

**star schema.** The combination of a fact table (which contains most of the data) and a number of dimension tables. See also *star join*, *dimension*, and *dimension table*.

**statement handle.** In DB2 ODBC, the data object that contains information about an SQL statement that is managed by DB2 ODBC. This includes information such as dynamic arguments, bindings for dynamic arguments and columns, cursor information, result values, and status information. Each statement handle is associated with the connection handle.

**statement string.** For a dynamic SQL statement, the character string form of the statement.

**statement trigger.** A trigger that is defined with the trigger granularity FOR EACH STATEMENT.

| **static cursor.** A named control structure that does not  
| change the size of the result table or the order of its  
| rows after an application opens the cursor. Contrast  
| with *dynamic cursor*.

**static SQL.** SQL statements, embedded within a program, that are prepared during the program preparation process (before the program is executed). After being prepared, the SQL statement does not change (although values of host variables that are specified by the statement might change).

**storage group.** A named set of disks on which DB2 data can be stored.

**stored procedure.** A user-written application program that can be invoked through the use of the SQL CALL statement.

**string.** See *character string* or *graphic string*.

**strong typing.** A process that guarantees that only user-defined functions and operations that are defined on a distinct type can be applied to that type. For example, you cannot directly compare two currency types, such as Canadian dollars and U.S. dollars. But you can provide a user-defined function to convert one currency to the other and then do the comparison.

**structure.** (1) A name that refers collectively to different types of DB2 objects, such as tables, databases, views, indexes, and table spaces. (2) A construct that uses z/OS to map and manage storage on a coupling facility. See also *cache structure*, *list structure*, or *lock structure*.

**Structured Query Language (SQL).** A standardized language for defining and manipulating data in a relational database.

**structure owner.** In relation to group buffer pools, the DB2 member that is responsible for the following activities:

- Coordinating rebuild, checkpoint, and damage assessment processing
- Monitoring the group buffer pool threshold and notifying castout owners when the threshold has been reached

**subcomponent.** A group of closely related DB2 modules that work together to provide a general function.

**subject table.** The table for which a trigger is created. When the defined triggering event occurs on this table, the trigger is activated.

**subpage.** The unit into which a physical index page can be divided.

**subquery.** A SELECT statement within the WHERE or HAVING clause of another SQL statement; a nested SQL statement.

**subselect.** That form of a query that does not include an ORDER BY clause, an UPDATE clause, or UNION operators.

**substitution character.** A unique character that is substituted during character conversion for any characters in the source program that do not have a match in the target coding representation.

**subsystem.** A distinct instance of a relational database management system (RDBMS).

**surrogate pair.** A coded representation for a single character that consists of a sequence of two 16-bit code units, in which the first value of the pair is a high-surrogate code unit in the range U+D800 through U+DBFF, and the second value is a low-surrogate code unit in the range U+DC00 through U+DFFF. Surrogate pairs provide an extension mechanism for encoding 917 476 characters without requiring the use of 32-bit characters.

**SVC dump.** A dump that is issued when a z/OS or a DB2 functional recovery routine detects an error.

**sync point.** See *commit point*.

**syncpoint tree.** The tree of recovery managers and resource managers that are involved in a logical unit of work, starting with the recovery manager, that make the final commit decision.

**synonym.** In SQL, an alternative name for a table or view. Synonyms can be used to refer only to objects at the subsystem in which the synonym is defined.

**syntactic character set.** A set of 81 graphic characters that are registered in the IBM registry as character set 00640. This set was originally recommended to the programming language community to be used for syntactic purposes toward maximizing portability and interchangeability across systems and country boundaries. It is contained in most of the primary registered character sets, with a few exceptions. See also *invariant character set*.

**Sysplex.** See *Parallel Sysplex*.

**Sysplex query parallelism.** Parallel execution of a single query that is accomplished by using multiple tasks on more than one DB2 subsystem. See also *query CP parallelism*.

**system administrator.** The person at a computer installation who designs, controls, and manages the use of the computer system.

**system agent.** A work request that DB2 creates internally such as prefetch processing, deferred writes, and service tasks.

**system conversation.** The conversation that two DB2 subsystems must establish to process system messages before any distributed processing can begin.

**system diagnostic work area (SDWA).** The data that is recorded in a SYS1.LOGREC entry that describes a program or hardware error.

**system-directed connection.** A connection that a relational DBMS manages by processing SQL statements with three-part names.

**System Modification Program/Extended (SMP/E).** A z/OS tool for making software changes in programming systems (such as DB2) and for controlling those changes.

**Systems Network Architecture (SNA).** The description of the logical structure, formats, protocols, and operational sequences for transmitting information through and controlling the configuration and operation of networks.

**SYS1.DUMPxx data set.** A data set that contains a system dump (in z/OS).

**SYS1.LOGREC.** A service aid that contains important information about program and hardware errors (in z/OS).

## T

**table.** A named data object consisting of a specific number of columns and some number of unordered rows. See also *base table* or *temporary table*.

| **table-controlled partitioning.** A type of partitioning in  
| which partition boundaries for a partitioned table are  
| controlled by values that are defined in the CREATE  
| TABLE statement. Partition limits are saved in the  
| LIMITKEY\_INTERNAL column of the  
| SYSIBM.SYSTABLEPART catalog table.

**table function.** A function that receives a set of arguments and returns a table to the SQL statement that references the function. A table function can be referenced only in the FROM clause of a subselect.

**table locator.** A mechanism that allows access to trigger transition tables in the FROM clause of SELECT statements, in the subselect of INSERT statements, or from within user-defined functions. A table locator is a fullword integer value that represents a transition table.

**table space.** A page set that is used to store the records in one or more tables.

**table space set.** A set of table spaces and partitions that should be recovered together for one of these reasons:

- Each of them contains a table that is a parent or descendent of a table in one of the others.
- The set contains a base table and associated auxiliary tables.

A table space set can contain both types of relationships.

**task control block (TCB).** A z/OS control block that is used to communicate information about tasks within an address space that are connected to DB2. See also *address space connection*.

**TB.** Terabyte (1 099 511 627 776 bytes).

**TCB.** Task control block (in z/OS).

**TCP/IP.** A network communication protocol that computer systems use to exchange information across telecommunication links.

**TCP/IP port.** A 2-byte value that identifies an end user or a TCP/IP network application within a TCP/IP host.

**template.** A DB2 utilities output data set descriptor that is used for dynamic allocation. A template is defined by the TEMPLATE utility control statement.

**temporary table.** A table that holds temporary data. Temporary tables are useful for holding or sorting intermediate results from queries that contain a large number of rows. The two types of temporary table, which are created by different SQL statements, are the created temporary table and the declared temporary table. Contrast with *result table*. See also *created temporary table* and *declared temporary table*.

**Terminal Monitor Program (TMP).** A program that provides an interface between terminal users and command processors and has access to many system services (in z/OS).

**thread.** The DB2 structure that describes an application's connection, traces its progress, processes resource functions, and delimits its accessibility to DB2 resources and services. Most DB2 functions execute under a thread structure. See also *allied thread* and *database access thread*.

**threadsafe.** A characteristic of code that allows multithreading both by providing private storage areas for each thread, and by properly serializing shared (global) storage areas.

**three-part name.** The full name of a table, view, or alias. It consists of a location name, authorization ID, and an object name, separated by a period.

**time.** A three-part value that designates a time of day in hours, minutes, and seconds.

**time duration.** A decimal integer that represents a number of hours, minutes, and seconds.

**timeout.** Abnormal termination of either the DB2 subsystem or of an application because of the unavailability of resources. Installation specifications are set to determine both the amount of time DB2 is to wait for IRLM services after starting, and the amount of time IRLM is to wait if a resource that an application requests is unavailable. If either of these time specifications is exceeded, a timeout is declared.

**Time-Sharing Option (TSO).** An option in MVS that provides interactive time sharing from remote terminals.

**timestamp.** A seven-part value that consists of a date and time. The timestamp is expressed in years, months, days, hours, minutes, seconds, and microseconds.

**TMP.** Terminal Monitor Program.

**to-do.** A state of a unit of recovery that indicates that the unit of recovery's changes to recoverable DB2 resources are indoubt and must either be applied to the disk media or backed out, as determined by the commit coordinator.

**trace.** A DB2 facility that provides the ability to monitor and collect DB2 monitoring, auditing, performance, accounting, statistics, and serviceability (global) data.

**transaction lock.** A lock that is used to control concurrent execution of SQL statements.

**transaction program name.** In SNA LU 6.2 conversations, the name of the program at the remote logical unit that is to be the other half of the conversation.

| **transient XML data type.** A data type for XML values  
| that exists only during query processing.

**transition table.** A temporary table that contains all the affected rows of the subject table in their state before or after the triggering event occurs. Triggered SQL statements in the trigger definition can reference the table of changed rows in the old state or the new state.

**transition variable.** A variable that contains a column value of the affected row of the subject table in its state before or after the triggering event occurs. Triggered SQL statements in the trigger definition can reference the set of old values or the set of new values.

| **tree structure.** A data structure that represents entities  
| in nodes, with a most one parent node for each node,  
| and with only one root node.

**trigger.** A set of SQL statements that are stored in a DB2 database and executed when a certain event occurs in a DB2 table.

**trigger activation.** The process that occurs when the trigger event that is defined in a trigger definition is executed. Trigger activation consists of the evaluation of the triggered action condition and conditional execution of the triggered SQL statements.

**trigger activation time.** An indication in the trigger definition of whether the trigger should be activated before or after the triggered event.

**trigger body.** The set of SQL statements that is executed when a trigger is activated and its triggered action condition evaluates to true. A trigger body is also called *triggered SQL statements*.

**trigger cascading.** The process that occurs when the triggered action of a trigger causes the activation of another trigger.

**triggered action.** The SQL logic that is performed when a trigger is activated. The triggered action consists of an optional triggered action condition and a set of triggered SQL statements that are executed only if the condition evaluates to true.

**triggered action condition.** An optional part of the triggered action. This Boolean condition appears as a WHEN clause and specifies a condition that DB2 evaluates to determine if the triggered SQL statements should be executed.

**triggered SQL statements.** The set of SQL statements that is executed when a trigger is activated and its triggered action condition evaluates to true. Triggered SQL statements are also called the *trigger body*.

**trigger granularity.** A characteristic of a trigger, which determines whether the trigger is activated:

- Only once for the triggering SQL statement
- Once for each row that the SQL statement modifies

**triggering event.** The specified operation in a trigger definition that causes the activation of that trigger. The triggering event is comprised of a triggering operation (INSERT, UPDATE, or DELETE) and a subject table on which the operation is performed.

**triggering SQL operation.** The SQL operation that causes a trigger to be activated when performed on the subject table.

**trigger package.** A package that is created when a CREATE TRIGGER statement is executed. The package is executed when the trigger is activated.

**TSO.** Time-Sharing Option.

**TSO attachment facility.** A DB2 facility consisting of the DSN command processor and DB2I. Applications

that are not written for the CICS or IMS environments can run under the TSO attachment facility.

**typed parameter marker.** A parameter marker that is specified along with its target data type. It has the general form:

CAST(? AS data-type)

**type 1 indexes.** Indexes that were created by a release of DB2 before DB2 Version 4 or that are specified as type 1 indexes in Version 4. Contrast with *type 2 indexes*. As of Version 8, type 1 indexes are no longer supported.

**type 2 indexes.** Indexes that are created on a release of DB2 after Version 7 or that are specified as type 2 indexes in Version 4 or later.

## U

**UCS-2.** Universal Character Set, coded in 2 octets, which means that characters are represented in 16-bits per character.

**UDF.** User-defined function.

**UDT.** User-defined data type. In DB2 UDB for z/OS, the term *distinct type* is used instead of user-defined data type. See *distinct type*.

**uncommitted read (UR).** The isolation level that allows an application to read uncommitted data.

**underlying view.** The view on which another view is directly or indirectly defined.

**undo.** A state of a unit of recovery that indicates that the changes that the unit of recovery made to recoverable DB2 resources must be backed out.

**Unicode.** A standard that parallels the ISO-10646 standard. Several implementations of the Unicode standard exist, all of which have the ability to represent a large percentage of the characters that are contained in the many scripts that are used throughout the world.

**uniform resource locator (URL).** A Web address, which offers a way of naming and locating specific items on the Web.

**union.** An SQL operation that combines the results of two SELECT statements. Unions are often used to merge lists of values that are obtained from several tables.

**unique constraint.** An SQL rule that no two values in a primary key, or in the key of a unique index, can be the same.

**unique index.** An index that ensures that no identical key values are stored in a column or a set of columns in a table.

**unit of recovery.** A recoverable sequence of operations within a single resource manager, such as an instance of DB2. Contrast with *unit of work*.

**unit of recovery identifier (URID).** The LOGRBA of the first log record for a unit of recovery. The URID also appears in all subsequent log records for that unit of recovery.

**unit of work.** A recoverable sequence of operations within an application process. At any time, an application process is a single unit of work, but the life of an application process can involve many units of work as a result of commit or rollback operations. In a *multisite update* operation, a single unit of work can include several *units of recovery*. Contrast with *unit of recovery*.

**Universal Unique Identifier (UUID).** An identifier that is immutable and unique across time and space (in z/OS).

**unlock.** The act of releasing an object or system resource that was previously locked and returning it to general availability within DB2.

**untyped parameter marker.** A parameter marker that is specified without its target data type. It has the form of a single question mark (?).

**updatability.** The ability of a cursor to perform positioned updates and deletes. The updatability of a cursor can be influenced by the SELECT statement and the cursor sensitivity option that is specified on the DECLARE CURSOR statement.

**update hole.** The location on which a cursor is positioned when a row in a result table is fetched again and the new values no longer satisfy the search condition. DB2 marks a row in the result table as an update hole when an update to the corresponding row in the database causes that row to no longer qualify for the result table.

**update trigger.** A trigger that is defined with the triggering SQL operation UPDATE.

**upstream.** The node in the syncpoint tree that is responsible, in addition to other recovery or resource managers, for coordinating the execution of a two-phase commit.

**UR.** Uncommitted read.

**URE.** Unit of recovery element.

**URID .** Unit of recovery identifier.

**URL.** Uniform resource locator.

**user-defined data type (UDT).** See *distinct type*.

**user-defined function (UDF).** A function that is defined to DB2 by using the CREATE FUNCTION

statement and that can be referenced thereafter in SQL statements. A user-defined function can be an *external function*, a *sourced function*, or an *SQL function*. Contrast with *built-in function*.

**user view.** In logical data modeling, a model or representation of critical information that the business requires.

**UTF-8.** Unicode Transformation Format, 8-bit encoding form, which is designed for ease of use with existing ASCII-based systems. The CCSID value for data in UTF-8 format is 1208. DB2 UDB for z/OS supports UTF-8 in mixed data fields.

**UTF-16.** Unicode Transformation Format, 16-bit encoding form, which is designed to provide code values for over a million characters and a superset of UCS-2. The CCSID value for data in UTF-16 format is 1200. DB2 UDB for z/OS supports UTF-16 in graphic data fields.

**UUID.** Universal Unique Identifier.

## V

**value.** The smallest unit of data that is manipulated in SQL.

**variable.** A data element that specifies a value that can be changed. A COBOL elementary data item is an example of a variable. Contrast with *constant*.

**variant function.** See *nondeterministic function*.

**varying-length string.** A character or graphic string whose length varies within set limits. Contrast with *fixed-length string*.

**version.** A member of a set of similar programs, DBRMs, packages, or LOBs.

**A version of a program** is the source code that is produced by precompiling the program. The program version is identified by the program name and a timestamp (consistency token).

**A version of a DBRM** is the DBRM that is produced by precompiling a program. The DBRM version is identified by the same program name and timestamp as a corresponding program version.

**A version of a package** is the result of binding a DBRM within a particular database system. The package version is identified by the same program name and consistency token as the DBRM.

**A version of a LOB** is a copy of a LOB value at a point in time. The version number for a LOB is stored in the auxiliary index entry for the LOB.

**view.** An alternative representation of data from one or more tables. A view can include all or some of the columns that are contained in tables on which it is defined.

**view check option.** An option that specifies whether every row that is inserted or updated through a view must conform to the definition of that view. A view check option can be specified with the WITH CASCADED CHECK OPTION, WITH CHECK OPTION, or WITH LOCAL CHECK OPTION clauses of the CREATE VIEW statement.

**Virtual Storage Access Method (VSAM).** An access method for direct or sequential processing of fixed- and varying-length records on disk devices. The records in a VSAM data set or file can be organized in logical sequence by a key field (key sequence), in the physical sequence in which they are written on the data set or file (entry-sequence), or by relative-record number (in z/OS).

**Virtual Telecommunications Access Method (VTAM).** An IBM licensed program that controls communication and the flow of data in an SNA network (in z/OS).

| **volatile table.** A table for which SQL operations choose index access whenever possible.

**VSAM.** Virtual Storage Access Method.

**VTAM.** Virtual Telecommunication Access Method (in z/OS).

## W

**warm start.** The normal DB2 restart process, which involves reading and processing log records so that data that is under the control of DB2 is consistent. Contrast with *cold start*.

**WLM application environment.** A z/OS Workload Manager attribute that is associated with one or more stored procedures. The WLM application environment determines the address space in which a given DB2 stored procedure runs.

**write to operator (WTO).** An optional user-coded service that allows a message to be written to the system console operator informing the operator of errors and unusual system conditions that might need to be corrected (in z/OS).

**WTO.** Write to operator.

**WTOR.** Write to operator (WTO) with reply.

## X

**XCF.** See *cross-system coupling facility*.

**XES.** See *cross-system extended services*.

| **XML.** See *Extensible Markup Language*.

| **XML attribute.** A name-value pair within a tagged XML element that modifies certain features of the element.

# **XML element.** A logical structure in an XML document that is delimited by a start and an end tag. # Anything between the start tag and the end tag is the # content of the element.

| **XML node.** The smallest unit of valid, complete structure in a document. For example, a node can represent an element, an attribute, or a text string.

| **XML publishing functions.** Functions that return XML values from SQL values.

**X/Open.** An independent, worldwide open systems organization that is supported by most of the world's largest information systems suppliers, user organizations, and software companies. X/Open's goal is to increase the portability of applications by combining existing and emerging standards.

**XRF.** Extended recovery facility.

## Z

| **z/OS.** An operating system for the eServer™ product line that supports 64-bit real and virtual storage.

**z/OS Distributed Computing Environment (z/OS DCE).** A set of technologies that are provided by the Open Software Foundation to implement distributed computing.

---

## Bibliography

### DB2 Universal Database for z/OS Version 8 product information:

- *DB2 Administration Guide*, SC18-7413
- *DB2 Application Programming and SQL Guide*, SC18-7415
- *DB2 Application Programming Guide and Reference for Java*, SC18-7414
- *DB2 Codes*, GC18-9603
- *DB2 Command Reference*, SC18-7416
- *DB2 Common Criteria Guide*, SC18-9672
- *DB2 Data Sharing: Planning and Administration*, SC18-7417
- *DB2 Diagnosis Guide and Reference*, LY37-3201
- *DB2 Diagnostic Quick Reference Card*, LY37-3202
- *DB2 Image, Audio, and Video Extenders Administration and Programming*, SC26-9947
- *DB2 Installation Guide*, GC18-7418
- *DB2 Licensed Program Specifications*, GC18-7420
- *DB2 Management Clients Package Program Directory*, GI10-8567
- *DB2 Messages*, GC18-9602
- *DB2 ODBC Guide and Reference*, SC18-7423
- *The Official Introduction to DB2 UDB for z/OS*
- *DB2 Program Directory*, GI10-8566
- *DB2 RACF Access Control Module Guide*, SC18-7433
- *DB2 Reference for Remote DRDA Requesters and Servers*, SC18-7424
- *DB2 Reference Summary*, SX26-3853
- *DB2 Release Planning Guide*, SC18-7425
- *DB2 SQL Reference*, SC18-7426
- *DB2 Text Extender Administration and Programming*, SC26-9948
- *DB2 Utility Guide and Reference*, SC18-7427
- *DB2 What's New?*, GC18-7428
- *DB2 XML Extender for z/OS Administration and Programming*, SC18-7431

### Books and resources about related products:

#### APL2®

- *APL2 Programming Guide*, SH21-1072
- *APL2 Programming: Language Reference*, SH21-1061

- *APL2 Programming: Using Structured Query Language (SQL)*, SH21-1057

#### BookManager® READ/MVS

- *BookManager READ/MVS V1R3: Installation Planning & Customization*, SC38-2035

#### C language: IBM C/C++ for z/OS

- *z/OS C/C++ Programming Guide*, SC09-4765
- *z/OS C/C++ Run-Time Library Reference*, SA22-7821

#### Character Data Representation Architecture

- *Character Data Representation Architecture Overview*, GC09-2207
- *Character Data Representation Architecture Reference and Registry*, SC09-2190

#### CICS Transaction Server for z/OS

The publication order numbers below are for Version 2 Release 2 and Version 2 Release 3 (with the release 2 number listed first).

- *CICS Transaction Server for z/OS Information Center*, SK3T-6903 or SK3T-6957.
- *CICS Transaction Server for z/OS Application Programming Guide*, SC34-5993 or SC34-6231
- *CICS Transaction Server for z/OS Application Programming Reference*, SC34-5994 or SC34-6232
- *CICS Transaction Server for z/OS CICS-RACF Security Guide*, SC34-6011 or SC34-6249
- *CICS Transaction Server for z/OS CICS Supplied Transactions*, SC34-5992 or SC34-6230
- *CICS Transaction Server for z/OS Customization Guide*, SC34-5989 or SC34-6227
- *CICS Transaction Server for z/OS Data Areas*, LY33-6100 or LY33-6103
- *CICS Transaction Server for z/OS DB2 Guide*, SC34-6014 or SC34-6252
- *CICS Transaction Server for z/OS External Interfaces Guide*, SC34-6006 or SC34-6244
- *CICS Transaction Server for z/OS Installation Guide*, GC34-5985 or GC34-6224
- *CICS Transaction Server for z/OS Intercommunication Guide*, SC34-6005 or SC34-6243
- *CICS Transaction Server for z/OS Messages and Codes*, GC34-6003 or GC34-6241
- *CICS Transaction Server for z/OS Operations and Utilities Guide*, SC34-5991 or SC34-6229

- *CICS Transaction Server for z/OS Performance Guide*, SC34-6009 or SC34-6247
- *CICS Transaction Server for z/OS Problem Determination Guide*, SC34-6002 or SC34-6239
- *CICS Transaction Server for z/OS Release Guide*, GC34-5983 or GC34-6218
- *CICS Transaction Server for z/OS Resource Definition Guide*, SC34-5990 or SC34-6228
- *CICS Transaction Server for z/OS System Definition Guide*, SC34-5988 or SC34-6226
- *CICS Transaction Server for z/OS System Programming Reference*, SC34-5595 or SC34-6233

#### **CICS Transaction Server for OS/390**

- *CICS Transaction Server for OS/390 Application Programming Guide*, SC33-1687
- *CICS Transaction Server for OS/390 DB2 Guide*, SC33-1939
- *CICS Transaction Server for OS/390 External Interfaces Guide*, SC33-1944
- *CICS Transaction Server for OS/390 Resource Definition Guide*, SC33-1684

#### **COBOL:**

- *IBM COBOL Language Reference*, SC27-1408
- *Enterprise COBOL for z/OS Programming Guide*, SC27-1412

#### **Database Design**

- *DB2 for z/OS and OS/390 Development for Performance Volume I* by Gabrielle Wiorkowski, Gabrielle & Associates, ISBN 0-96684-605-2
- *DB2 for z/OS and OS/390 Development for Performance Volume II* by Gabrielle Wiorkowski, Gabrielle & Associates, ISBN 0-96684-606-0
- *Handbook of Relational Database Design* by C. Fleming and B. Von Halle, Addison Wesley, ISBN 0-20111-434-8

#### **DB2 Administration Tool**

- *DB2 Administration Tool for z/OS User's Guide and Reference*, available on the Web at [www.ibm.com/software/data/db2imstools/library.html](http://www.ibm.com/software/data/db2imstools/library.html)

#### **DB2 Buffer Pool Analyzer for z/OS**

- *DB2 Buffer Pool Tool for z/OS User's Guide and Reference*, available on the Web at [www.ibm.com/software/data/db2imstools/library.html](http://www.ibm.com/software/data/db2imstools/library.html)

#### **DB2 Connect**

- *IBM DB2 Connect Quick Beginnings for DB2 Connect Enterprise Edition*, GC09-4833

- *IBM DB2 Connect Quick Beginnings for DB2 Connect Personal Edition*, GC09-4834
- *IBM DB2 Connect User's Guide*, SC09-4835

#### **DB2 DataPropagator**

- *DB2 Universal Database Replication Guide and Reference*, SC27-1121

#### **DB2 Performance Expert for z/OS, Version 1**

The following books are part of the DB2 Performance Expert library. Some of these books include information about the following tools: IBM DB2 Performance Expert for z/OS; IBM DB2 Performance Monitor for z/OS; and DB2 Buffer Pool Analyzer for z/OS.

- *OMEGAMON Buffer Pool Analyzer User's Guide*, SC18-7972
- *OMEGAMON Configuration and Customization*, SC18-7973
- *OMEGAMON Messages*, SC18-7974
- *OMEGAMON Monitoring Performance from ISPF*, SC18-7975
- *OMEGAMON Monitoring Performance from Performance Expert Client*, SC18-7976
- *OMEGAMON Program Directory*, GI10-8549
- *OMEGAMON Report Command Reference*, SC18-7977
- *OMEGAMON Report Reference*, SC18-7978
- *Using IBM Tivoli OMEGAMON XE on z/OS*, SC18-7979

#### **DB2 Query Management Facility (QMF) Version 8.1**

- *DB2 Query Management Facility: DB2 QMF High Performance Option User's Guide for TSO/CICS*, SC18-7450
- *DB2 Query Management Facility: DB2 QMF Messages and Codes*, GC18-7447
- *DB2 Query Management Facility: DB2 QMF Reference*, SC18-7446
- *DB2 Query Management Facility: Developing DB2 QMF Applications*, SC18-7651
- *DB2 Query Management Facility: Getting Started with DB2 QMF for Windows and DB2 QMF for WebSphere*, SC18-7449
- *DB2 Query Management Facility: Getting Started with DB2 QMF Query Miner*, GC18-7451
- *DB2 Query Management Facility: Installing and Managing DB2 QMF for TSO/CICS*, GC18-7444
- *DB2 Query Management Facility: Installing and Managing DB2 QMF for Windows and DB2 QMF for WebSphere*, GC18-7448

- *DB2 Query Management Facility: Introducing DB2 QMF*, GC18-7443
- *DB2 Query Management Facility: Using DB2 QMF*, SC18-7445
- *DB2 Query Management Facility: DB2 QMF Visionary Developer's Guide*, SC18-9093
- *DB2 Query Management Facility: DB2 QMF Visionary Getting Started Guide*, GC18-9092

### DB2 Redbooks®

For access to all IBM Redbooks about DB2, see the IBM Redbooks Web page at [www.ibm.com/redbooks](http://www.ibm.com/redbooks)

### DB2 Server for VSE & VM

- *DB2 Server for VM: DBS Utility*, SC09-2983

### DB2 Universal Database Cross-Platform information

- *IBM DB2 Universal Database SQL Reference for Cross-Platform Development*, available at [www.ibm.com/software/data/developer/cpsqlref/](http://www.ibm.com/software/data/developer/cpsqlref/)

### DB2 Universal Database for iSeries

The following books are available at [www.ibm.com/series/infocenter](http://www.ibm.com/series/infocenter)

- *DB2 Universal Database for iSeries Performance and Query Optimization*
- *DB2 Universal Database for iSeries Database Programming*
- *DB2 Universal Database for iSeries SQL Programming Concepts*
- *DB2 Universal Database for iSeries SQL Programming with Host Languages*
- *DB2 Universal Database for iSeries SQL Reference*
- *DB2 Universal Database for iSeries Distributed Data Management*
- *DB2 Universal Database for iSeries Distributed Database Programming*

### DB2 Universal Database for Linux, UNIX, and Windows:

- *DB2 Universal Database Administration Guide: Planning*, SC09-4822
- *DB2 Universal Database Administration Guide: Implementation*, SC09-4820
- *DB2 Universal Database Administration Guide: Performance*, SC09-4821
- *DB2 Universal Database Administrative API Reference*, SC09-4824
- *DB2 Universal Database Application Development Guide: Building and Running Applications*, SC09-4825

- *DB2 Universal Database Call Level Interface Guide and Reference, Volumes 1 and 2*, SC09-4849 and SC09-4850
- *DB2 Universal Database Command Reference*, SC09-4828
- *DB2 Universal Database SQL Reference Volume 1*, SC09-4844
- *DB2 Universal Database SQL Reference Volume 2*, SC09-4845

### Device Support Facilities

- *Device Support Facilities User's Guide and Reference*, GC35-0033

### DFSMS

These books provide information about a variety of components of DFSMS, including z/OS DFSMS, z/OS DFSMSdfp, z/OS DFSMSdss, z/OS DFSMSshsm, and z/OS DFP.

- *z/OS DFSMS Access Method Services for Catalogs*, SC26-7394
- *z/OS DFSMSdss Storage Administration Guide*, SC35-0423
- *z/OS DFSMSdss Storage Administration Reference*, SC35-0424
- *z/OS DFSMSshsm Managing Your Own Data*, SC35-0420
- *z/OS DFSMSdfp: Using DFSMSdfp in the z/OS Environment*, SC26-7473
- *z/OS DFSMSdfp Diagnosis Reference*, GY27-7618
- *z/OS DFSMS: Implementing System-Managed Storage*, SC27-7407
- *z/OS DFSMS: Macro Instructions for Data Sets*, SC26-7408
- *z/OS DFSMS: Managing Catalogs*, SC26-7409
- *z/OS MVS: Program Management User's Guide and Reference*, SA22-7643
- *z/OS MVS Program Management: Advanced Facilities*, SA22-7644
- *z/OS DFSMSdfp Storage Administration Reference*, SC26-7402
- *z/OS DFSMS: Using Data Sets*, SC26-7410
- *DFSMSdfp Advanced Services*, SC26-7400
- *DFSMS/MVS: Utilities*, SC26-7414

### DFSORT™

- *DFSORT Application Programming: Guide*, SC33-4035
- *DFSORT Installation and Customization*, SC33-4034

### Distributed Relational Database Architecture

- *Open Group Technical Standard*; the Open Group presently makes the following DRDA books available through its Web site at [www.opengroup.org](http://www.opengroup.org)
  - *Open Group Technical Standard, DRDA Version 3 Vol. 1: Distributed Relational Database Architecture*
  - *Open Group Technical Standard, DRDA Version 3 Vol. 2: Formatted Data Object Content Architecture*
  - *Open Group Technical Standard, DRDA Version 3 Vol. 3: Distributed Data Management Architecture*

### Domain Name System

- *DNS and BIND, Third Edition, Paul Albitz and Cricket Liu, O'Reilly, ISBN 0-59600-158-4*

### Education

- Information about IBM educational offerings is available on the Web at <http://www.ibm.com/software/sw-training/>
- A collection of glossaries of IBM terms is available on the IBM Terminology Web site at [www.ibm.com/ibm/terminology/index.html](http://www.ibm.com/ibm/terminology/index.html)

### eServer zSeries

- *IBM eServer zSeries Processor Resource/System Manager Planning Guide, SB10-7033*

### Fortran: VS Fortran

- *VS Fortran Version 2: Language and Library Reference, SC26-4221*
- *VS Fortran Version 2: Programming Guide for CMS and MVS, SC26-4222*

### High Level Assembler

- *High Level Assembler for MVS and VM and VSE Language Reference, SC26-4940*
- *High Level Assembler for MVS and VM and VSE Programmer's Guide, SC26-4941*

### ICSF

- *z/OS ICSF Overview, SA22-7519*
- *Integrated Cryptographic Service Facility Administrator's Guide, SA22-7521*

### IMS Version 8

IMS product information is available on the IMS Library Web page, which you can find at [www.ibm.com/ims](http://www.ibm.com/ims)

- *IMS Administration Guide: System, SC27-1284*
- *IMS Administration Guide: Transaction Manager, SC27-1285*

- *IMS Application Programming: Database Manager, SC27-1286*
- *IMS Application Programming: Design Guide, SC27-1287*
- *IMS Application Programming: Transaction Manager, SC27-1289*
- *IMS Command Reference, SC27-1291*
- *IMS Customization Guide, SC27-1294*
- *IMS Install Volume 1: Installation Verification, GC27-1297*
- *IMS Install Volume 2: System Definition and Tailoring, GC27-1298*
- *IMS Messages and Codes Volumes 1 and 2, GC27-1301 and GC27-1302*
- *IMS Open Transaction Manager Access Guide and Reference, SC18-7829*
- *IMS Utilities Reference: System, SC27-1309*

General information about IMS Batch Terminal Simulator for z/OS is available on the Web at [www.ibm.com/software/data/db2imstools/library.html](http://www.ibm.com/software/data/db2imstools/library.html)

### IMS DataPropagator

- *IMS DataPropagator for z/OS Administrator's Guide for Log, SC27-1216*
- *IMS DataPropagator: An Introduction, GC27-1211*
- *IMS DataPropagator for z/OS Reference, SC27-1210*

### ISPF

- *z/OS ISPF Dialog Developer's Guide, SC23-4821*
- *z/OS ISPF Messages and Codes, SC34-4815*
- *z/OS ISPF Planning and Customizing, GC34-4814*
- *z/OS ISPF User's Guide Volumes 1 and 2, SC34-4822 and SC34-4823*

### Language Environment

- *Debug Tool User's Guide and Reference, SC18-7171*
- *Debug Tool for z/OS and OS/390 Reference and Messages, SC18-7172*
- *z/OS Language Environment Concepts Guide, SA22-7567*
- *z/OS Language Environment Customization, SA22-7564*
- *z/OS Language Environment Debugging Guide, GA22-7560*
- *z/OS Language Environment Programming Guide, SA22-7561*
- *z/OS Language Environment Programming Reference, SA22-7562*

### MQSeries

- *MQSeries Application Messaging Interface, SC34-5604*

- *MQSeries for OS/390 Concepts and Planning Guide*, GC34-5650
- *MQSeries for OS/390 System Setup Guide*, SC34-5651

### **National Language Support**

- *National Language Design Guide Volume 1*, SE09-8001
- *IBM National Language Support Reference Manual Volume 2*, SE09-8002

### **NetView**

- *Tivoli NetView for z/OS Installation: Getting Started*, SC31-8872
- *Tivoli NetView for z/OS User's Guide*, GC31-8849

### **Microsoft ODBC**

Information about Microsoft ODBC is available at <http://msdn.microsoft.com/library/>

### **Parallel Sysplex Library**

- *System/390 9672 Parallel Transaction Server, 9672 Parallel Enterprise Server, 9674 Coupling Facility System Overview For R1/R2/R3 Based Models*, SB10-7033
- *z/OS Parallel Sysplex Application Migration*, SA22-7662
- *z/OS Parallel Sysplex Overview: An Introduction to Data Sharing and Parallelism*, SA22-7661
- *z/OS Parallel Sysplex Test Report*, SA22-7663

The *Parallel Sysplex Configuration Assistant* is available at [www.ibm.com/s390/pso/psotool](http://www.ibm.com/s390/pso/psotool)

### **PL/I: Enterprise PL/I for z/OS**

- *IBM Enterprise PL/I for z/OS Language Reference*, SC27-1460
- *IBM Enterprise PL/I for z/OS Programming Guide*, SC27-1457

### **PL/I: PL/I for MVS & VM**

- *PL/I for MVS & VM Programming Guide*, SC26-3113

### **SMP/E**

- *SMP/E for z/OS and OS/390 Reference*, SA22-7772
- *SMP/E for z/OS and OS/390 User's Guide*, SA22-7773

### **Storage Management**

- *z/OS DFSMS: Implementing System-Managed Storage*, SC26-7407
- *MVS/ESA Storage Management Library: Managing Data*, SC26-7397

- *MVS/ESA Storage Management Library: Managing Storage Groups*, SC35-0421
- *MVS Storage Management Library: Storage Management Subsystem Migration Planning Guide*, GC26-7398

### **System Network Architecture (SNA)**

- *SNA Formats*, GA27-3136
- *SNA LU 6.2 Peer Protocols Reference*, SC31-6808
- *SNA Transaction Programmer's Reference Manual for LU Type 6.2*, GC30-3084
- *SNA/Management Services Alert Implementation Guide*, GC31-6809

### **TCP/IP**

- *IBM TCP/IP for MVS: Customization & Administration Guide*, SC31-7134
- *IBM TCP/IP for MVS: Diagnosis Guide*, LY43-0105
- *IBM TCP/IP for MVS: Messages and Codes*, SC31-7132
- *IBM TCP/IP for MVS: Planning and Migration Guide*, SC31-7189

### **TotalStorage® Enterprise Storage Server**

- *RAMAC Virtual Array: Implementing Peer-to-Peer Remote Copy*, SG24-5680
- *Enterprise Storage Server Introduction and Planning*, GC26-7444
- *IBM RAMAC Virtual Array*, SG24-6424

### **Unicode**

- *z/OS Support for Unicode: Using Conversion Services*, SA22-7649

Information about Unicode, the Unicode consortium, the Unicode standard, and standards conformance requirements is available at [www.unicode.org](http://www.unicode.org)

### **VTAM**

- *Planning for NetView, NCP, and VTAM*, SC31-8063
- *VTAM for MVS/ESA Diagnosis*, LY43-0078
- *VTAM for MVS/ESA Messages and Codes*, GC31-8369
- *VTAM for MVS/ESA Network Implementation Guide*, SC31-8370
- *VTAM for MVS/ESA Operation*, SC31-8372
- *z/OS Communications Server SNA Programming*, SC31-8829
- *z/OS Communications Server SNA Programmer's LU 6.2 Reference*, SC31-8810
- *VTAM for MVS/ESA Resource Definition Reference*, SC31-8377

## **WebSphere family**

- *WebSphere MQ Integrator Broker: Administration Guide, SC34-6171*
- *WebSphere MQ Integrator Broker for z/OS: Customization and Administration Guide, SC34-6175*
- *WebSphere MQ Integrator Broker: Introduction and Planning, GC34-5599*
- *WebSphere MQ Integrator Broker: Using the Control Center, SC34-6168*

## **z/Architecture**

- *z/Architecture Principles of Operation, SA22-7832*

## **z/OS**

- *z/OS C/C++ Programming Guide, SC09-4765*
- *z/OS C/C++ Run-Time Library Reference, SA22-7821*
- *z/OS C/C++ User's Guide, SC09-4767*
- *z/OS Communications Server: IP Configuration Guide, SC31-8875*
- *z/OS Communications Server: IP and SNA Codes, SC31-8791*
- *z/OS DCE Administration Guide, SC24-5904*
- *z/OS DCE Introduction, GC24-5911*
- *z/OS DCE Messages and Codes, SC24-5912*
- *z/OS Information Roadmap, SA22-7500*
- *z/OS Introduction and Release Guide, GA22-7502*
- *z/OS JES2 Initialization and Tuning Guide, SA22-7532*
- *z/OS JES3 Initialization and Tuning Guide, SA22-7549*
- *z/OS Language Environment Concepts Guide, SA22-7567*
- *z/OS Language Environment Customization, SA22-7564*
- *z/OS Language Environment Debugging Guide, GA22-7560*
- *z/OS Language Environment Programming Guide, SA22-7561*
- *z/OS Language Environment Programming Reference, SA22-7562*
- *z/OS Managed System Infrastructure for Setup User's Guide, SC33-7985*
- *z/OS MVS Diagnosis: Procedures, GA22-7587*
- *z/OS MVS Diagnosis: Reference, GA22-7588*
- *z/OS MVS Diagnosis: Tools and Service Aids, GA22-7589*
- *z/OS MVS Initialization and Tuning Guide, SA22-7591*
- *z/OS MVS Initialization and Tuning Reference, SA22-7592*
- *z/OS MVS Installation Exits, SA22-7593*
- *z/OS MVS JCL Reference, SA22-7597*
- *z/OS MVS JCL User's Guide, SA22-7598*
- *z/OS MVS Planning: Global Resource Serialization, SA22-7600*
- *z/OS MVS Planning: Operations, SA22-7601*
- *z/OS MVS Planning: Workload Management, SA22-7602*
- *z/OS MVS Programming: Assembler Services Guide, SA22-7605*
- *z/OS MVS Programming: Assembler Services Reference, Volumes 1 and 2, SA22-7606 and SA22-7607*
- *z/OS MVS Programming: Authorized Assembler Services Guide, SA22-7608*
- *z/OS MVS Programming: Authorized Assembler Services Reference Volumes 1-4, SA22-7609, SA22-7610, SA22-7611, and SA22-7612*
- *z/OS MVS Programming: Callable Services for High-Level Languages, SA22-7613*
- *z/OS MVS Programming: Extended Addressability Guide, SA22-7614*
- *z/OS MVS Programming: Sysplex Services Guide, SA22-7617*
- *z/OS MVS Programming: Sysplex Services Reference, SA22-7618*
- *z/OS MVS Programming: Workload Management Services, SA22-7619*
- *z/OS MVS Recovery and Reconfiguration Guide, SA22-7623*
- *z/OS MVS Routing and Descriptor Codes, SA22-7624*
- *z/OS MVS Setting Up a Sysplex, SA22-7625*
- *z/OS MVS System Codes SA22-7626*
- *z/OS MVS System Commands, SA22-7627*
- *z/OS MVS System Messages Volumes 1-10, SA22-7631, SA22-7632, SA22-7633, SA22-7634, SA22-7635, SA22-7636, SA22-7637, SA22-7638, SA22-7639, and SA22-7640*
- *z/OS MVS Using the Subsystem Interface, SA22-7642*
- *z/OS Planning for Multilevel Security and the Common Criteria, SA22-7509*
- *z/OS RMF User's Guide, SC33-7990*
- *z/OS Security Server Network Authentication Server Administration, SC24-5926*
- *z/OS Security Server RACF Auditor's Guide, SA22-7684*
- *z/OS Security Server RACF Command Language Reference, SA22-7687*
- *z/OS Security Server RACF Macros and Interfaces, SA22-7682*
- *z/OS Security Server RACF Security Administrator's Guide, SA22-7683*
- *z/OS Security Server RACF System Programmer's Guide, SA22-7681*
- *z/OS Security Server RACROUTE Macro Reference, SA22-7692*

- *z/OS Support for Unicode: Using Conversion Services*, SA22-7649
- *z/OS TSO/E CLISTs*, SA22-7781
- *z/OS TSO/E Command Reference*, SA22-7782
- *z/OS TSO/E Customization*, SA22-7783
- *z/OS TSO/E Messages*, SA22-7786
- *z/OS TSO/E Programming Guide*, SA22-7788
- *z/OS TSO/E Programming Services*, SA22-7789
