

DB2 Version 9.1 for z/OS

*SQL Reference*

DB2 Version 9.1 for z/OS

*SQL Reference*

**Note**

Before using this information and the product it supports, be sure to read the general information under "Notices" at the end of this information.

**Eleventh edition (March 2011)**

This edition applies to DB2 Version 9.1 for z/OS (DB2 V9.1 for z/OS, product number 5635-DB2), DB2 9 for z/OS Value Unit Edition (product number 5697-P12), and to any subsequent releases until otherwise indicated in new editions. Make sure you are using the correct edition for the level of the product.

Specific changes are indicated by a vertical bar to the left of a change. A vertical bar to the left of a figure caption indicates that the figure has changed. Editorial changes that have no technical significance are not noted.

## About this information

This book is a reference for Structured Query Language (SQL) for DB2 Universal Database™ for z/OS®. Unless otherwise stated, references to SQL in this book imply SQL for DB2® UDB for z/OS, and all objects described in this book are objects of DB2 UDB for z/OS.

This information assumes that your DB2 subsystem is running in Version 9.1 new-function mode. Generally, new functions that are described, including changes to existing functions, statements, and limits, are available only in new-function mode. Two exceptions to this general statement are new and changed utilities and optimization enhancements, which are also available in conversion mode unless stated otherwise.

The syntax and semantics of most SQL statements are essentially the same in all IBM® relational database products, and the language elements common to the products provide a base for the definition of IBM SQL. Consult IBM DB2 Universal Database SQL Reference for Cross-Platform Development if you intend to develop applications that adhere to IBM SQL.

---

## Who should read this information

This information is intended for end users, application programmers, system and database administrators, and for persons involved in error detection and diagnosis.

This information is a reference rather than a tutorial. It assumes that you are already familiar with SQL programming concepts.

When you first use this information, consider reading Chapters 1 and 2 sequentially. These chapters describe the basic concepts of relational databases and SQL, the basic syntax of SQL, and the language elements that are common to many SQL statements. The rest of the chapters and appendixes are designed for the quick location of answers to specific SQL questions. They provide you with query forms, SQL statements, SQL procedure statements, DB2 limits, SQLCA, SQLDA, catalog tables, and SQL reserved words.

---

## DB2 Utilities Suite

**Important:** In this version of DB2 for z/OS, the DB2 Utilities Suite is available as an optional product. You must separately order and purchase a license to such utilities, and discussion of those utility functions in this publication is not intended to otherwise imply that you have a license to them.

The DB2 Utilities Suite can work with DB2 Sort and the DFSORT program, which you are licensed to use in support of the DB2 utilities even if you do not otherwise license DFSORT for general use. If your primary sort product is not DFSORT, consider the following informational APARs mandatory reading:

- II14047/II14213: USE OF DFSORT BY DB2 UTILITIES
- II13495: HOW DFSORT TAKES ADVANTAGE OF 64-BIT REAL ARCHITECTURE

These informational APARs are periodically updated.

## Terminology and citations

In this information, DB2 Version 9.1 for z/OS is referred to as "DB2 for z/OS." In cases where the context makes the meaning clear, DB2 for z/OS is referred to as "DB2." When this information refers to titles of DB2 for z/OS books, a short title is used. (For example, "See *DB2 SQL Reference*" is a citation to *IBM DB2 Version 9.1 for z/OS SQL Reference*.)

When referring to a DB2 product other than DB2 for z/OS, this information uses the product's full name to avoid ambiguity.

The following terms are used as indicated:

**DB2** Represents either the DB2 licensed program or a particular DB2 subsystem.

**OMEGAMON®**

Refers to any of the following products:

- IBM Tivoli® OMEGAMON XE for DB2 Performance Expert on z/OS
- IBM Tivoli OMEGAMON XE for DB2 Performance Monitor on z/OS
- IBM DB2 Performance Expert for Multiplatforms and Workgroups
- IBM DB2 Buffer Pool Analyzer for z/OS

**C, C++, and C language**

Represent the C or C++ programming language.

**CICS®** Represents CICS Transaction Server for z/OS.

**IMS™** Represents the IMS Database Manager or IMS Transaction Manager.

**MVS™** Represents the MVS element of the z/OS operating system, which is equivalent to the Base Control Program (BCP) component of the z/OS operating system.

**RACF®**

Represents the functions that are provided by the RACF component of the z/OS Security Server.

---

## Accessibility features for DB2 Version 9.1 for z/OS

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

### Accessibility features

The following list includes the major accessibility features in z/OS products, including DB2 Version 9.1 for z/OS. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers and screen magnifiers.
- Customization of display attributes such as color, contrast, and font size

**Tip:** The Information Management Software for z/OS Solutions Information Center (which includes information for DB2 Version 9.1 for z/OS) and its related publications are accessibility-enabled for the IBM Home Page Reader. You can operate all features using the keyboard instead of the mouse.

## Keyboard navigation

You can access DB2 Version 9.1 for z/OS ISPF panel functions by using a keyboard or keyboard shortcut keys.

For information about navigating the DB2 Version 9.1 for z/OS ISPF panels using TSO/E or ISPF, refer to the *z/OS TSO/E Primer*, the *z/OS TSO/E User's Guide*, and the *z/OS ISPF User's Guide*. These guides describe how to navigate each interface, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

## Related accessibility information

Online documentation for DB2 Version 9.1 for z/OS is available in the Information Management Software for z/OS Solutions Information Center, which is available at the following website: <http://publib.boulder.ibm.com/infocenter/imzic>

## IBM and accessibility

See the *IBM Accessibility Center* at <http://www.ibm.com/able> for more information about the commitment that IBM has to accessibility.

---

## How to send your comments

Your feedback helps IBM to provide quality information. Please send any comments that you have about this book or other DB2 for z/OS documentation. You can use the following methods to provide comments:

- Send your comments by email to [db2zinfo@us.ibm.com](mailto:db2zinfo@us.ibm.com) and include the name of the product, the version number of the product, and the number of the book. If you are commenting on specific text, please list the location of the text (for example, a chapter and section title or a help topic title).
- You can send comments from the web. Visit the DB2 for z/OS - Technical Resources website at:

<http://www.ibm.com/support/docview.wss?rs=64&uid=swg27011656>

This website has an online reader comment form that you can use to send comments.

- You can also send comments by using the **Feedback** link at the footer of each page in the Information Management Software for z/OS Solutions Information Center at <http://publib.boulder.ibm.com/infocenter/imzic>.

## How to read syntax diagrams

Certain conventions apply to the syntax diagrams that are used in IBM documentation.

Apply the following rules when reading the syntax diagrams that are used in DB2 for z/OS documentation:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

The ►— symbol indicates the beginning of a statement.

The —→ symbol indicates that the statement syntax is continued on the next line.

The ►— symbol indicates that a statement is continued from the previous line.

The —→◀ symbol indicates the end of a statement.

- Required items appear on the horizontal line (the main path).

- Optional items appear below the main path.

If an optional item appears above the main path, that item has no effect on the execution of the statement and is used only for readability.

- If you can choose from two or more items, they appear vertically, in a stack.

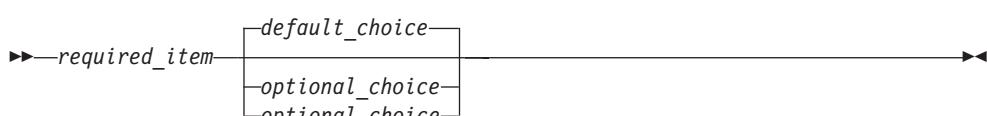

If you *must* choose one of the items, one item of the stack appears on the main path.

If choosing one of the items is optional, the entire stack appears below the main path.

If one of the items is the default, it appears above the main path and the remaining choices are shown below.

- An arrow returning to the left, above the main line, indicates an item that can be repeated.

If the repeat arrow contains a comma, you must separate repeated items with a comma.

A repeat arrow above a stack indicates that you can repeat the items in the stack.

- Sometimes a diagram must be split into fragments. The syntax fragment is shown separately from the main syntax diagram, but the contents of the fragment should be read as if they are on the main path of the diagram.

#### **fragment-name:**

- With the exception of XPath keywords, keywords appear in uppercase (for example, FROM). Keywords must be spelled exactly as shown. XPath keywords are defined as lowercase names, and must be spelled exactly as shown. Variables appear in all lowercase letters (for example, `column-name`). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

---

## Conventions for describing mixed data values

When mixed data values are shown in examples, certain conventions are used to represent these values.

At sites using a double-byte character set (DBCS), character strings can include a mixture of single-byte and double-byte characters. When mixed data values are shown in the examples, the conventions shown in the following example apply:

Convention	Representation
$\text{S}_0$	"shift-out" control character (X'0E'), used only for EBCDIC data
$\text{S}_1$	"shift-in" control character (X'0F'), used only for EBCDIC data
sbcsv-string	SBCS string of zero or more single-byte characters
dbcsv-string	DBCS string of zero or more double-byte characters
'	DBCS apostrophe
G	DBCS uppercase G

*Figure 1. Conventions used when mixed data values are shown in examples*

---

## Industry standards

DB2 for z/OS is developed based on specific industry standards for SQL.

- ISO/IEC FCD 9075-1:2003, *Information technology - Database languages - SQL - Part 1: Framework (SQL/Framework)*
- ISO/IEC FCD 9075-2:2003, *Information technology - Database languages - SQL - Part 2: Foundation (SQL/Foundation)*
- ISO/IEC FCD 9075-3:2003, *Information technology - Database languages - SQL - Part 3: Call-Level Interface (SQL/CLI)*
- ISO/IEC FCD 9075-4:2003, *Information technology - Database languages - SQL - Part 4: Persistent Stored Modules (SQL/PSM)*
- ISO/IEC FCD 9075-5:2003, *Information technology - Database languages - SQL- Part 5: Host Language Bindings (SQL/Bindings)*
- ISO/IEC FCD 9075-9:2003, *Information technology - Database languages - SQL - Part 9: Management of External Data (SQL/MED)*
- ISO/IEC FCD 9075-10:2003, *Information technology - Database languages - SQL - Part 10: Object Language Bindings (SQL/OLB)*
- ISO/IEC FCD 9075-11:2003, *Information technology - Database languages - SQL - Part 11: Information and Definition Schemas (SQL/Schemata)*
- ISO/IEC FCD 9075-13:2003, *Information technology - Database languages - SQL - Part 13: Java Routines and Types (SQL/JRT)*
- ISO/IEC FCD 9075-14:2006, *Information technology - Database languages - SQL - Part 14: XML-Related Specifications (SQL/XML)*
- ANSI (American National Standards Institute) X3.135-1999, *Database Language - SQL*

# Chapter 1. DB2 concepts

Certain DB2 concepts are important to understand when using Structured Query Language (SQL).

The following topics provide information on these concepts:

- “Structured query language”
- “DB2 schemas and schema qualifiers” on page 10
- “DB2 tables” on page 5
- “DB2 indexes” on page 5
- “DB2 keys” on page 6
- “Constraints” on page 20
- “Triggers” on page 24
- “Storage structures” on page 14
- “DB2 storage groups” on page 11
- “DB2 databases” on page 12
- “DB2 catalog” on page 16
- “DB2 views” on page 8
- “Sequences” on page 30
- “Routines” on page 28
- “Application processes, concurrency, and recovery” on page 25
- “Packages and application plans” on page 27
- “Distributed data” on page 31
- “Character conversion” on page 38

---

## Structured query language

The language that you use to access the data in DB2 tables is the *structured query language* (SQL). SQL is a standardized language for defining and manipulating data in a relational database.

The language consists of SQL statements. SQL statements let you accomplish the following actions:

- Define, modify, or drop data objects, such as tables.
- Retrieve, insert, update, or delete data in tables.

Other SQL statements let you authorize users to access specific resources, such as tables or views.

When you write an SQL statement, you specify what you want done, not how to do it. To access data, for example, you need only to name the tables and columns that contain the data. You do not need to describe how to get to the data.

In accordance with the relational model of data:

- The database is perceived as a set of tables.
- Relationships are represented by values in tables.

- Data is retrieved by using SQL to specify a *result table* that can be derived from one or more tables.

DB2 transforms each SQL statement, that is, the specification of a result table, into a sequence of operations that optimize data retrieval. This transformation occurs when the SQL statement is *prepared*. This transformation is also known as *binding*.

All executable SQL statements must be prepared before they can run. The result of preparation is the executable or *operational form* of the statement.

As the following example illustrates, SQL is generally intuitive. 

**Example:** Assume that you are shopping for shoes and you want to know what shoe styles are available in size 8. The SQL query that you need to write is similar to the question that you would ask a salesperson, "What shoe styles are available in size 8?" Just as the salesperson checks the shoe inventory and returns with an answer, DB2 retrieves information from a table (SHOES) and returns a result table. The query looks like this:

```
SELECT STYLE
      FROM SHOES
     WHERE SIZE = 8;
```

Assume that the answer to your question is that two shoe styles are available in a size 8: loafers and sandals. The result table looks like this:

STYLE
=====
LOAFERS
SANDALS

You can send an SQL statement to DB2 in several ways. One way is interactively, by entering SQL statements at a keyboard. Another way is through an application program. The program can contain SQL statements that are statically embedded in the application. Alternatively the program can create its SQL statements dynamically, for example, in response to information that a user provides by filling in a form. In this information, you can read about each of these methods.

## Static SQL

The source form of a *static* SQL statement is embedded within an application program written in a host language such as COBOL. The statement is prepared before the program is executed and the operational form of the statement persists beyond the execution of the program.

Static SQL statements in a source program must be processed before the program is compiled. This processing can be accomplished through the DB2 precompiler or the DB2 coprocessor. The DB2 precompiler or the coprocessor checks the syntax of the SQL statements, turns them into host language comments, and generates host language statements to invoke DB2.

The preparation of an SQL application program includes precompilation, the preparation of its static SQL statements, and compilation of the modified source program.

## **Dynamic SQL**

Programs that contain embedded *dynamic* SQL statements must be precompiled like those that contain static SQL, but unlike static SQL, the dynamic statements are constructed and prepared at run time.

The source form of a dynamic statement is a character string that is passed to DB2 by the program using the static SQL PREPARE or EXECUTE IMMEDIATE statement. A statement that is prepared using the PREPARE statement can be referenced in a DECLARE CURSOR, DESCRIBE, or EXECUTE statement. Whether the operational form of the statement is persistent depends on whether dynamic statement caching is enabled.

SQL statements embedded in a REXX application are dynamic SQL statements. SQL statements submitted to an interactive SQL facility and to the CALL Level Interface (CLI) are also dynamic SQL.

## **Deferred embedded SQL**

A *deferred embedded* SQL statement is neither fully static nor fully dynamic.

Like a static statement, it is embedded within an application, but like a dynamic statement, it is prepared during the execution of the application. Although prepared at run time, a deferred embedded SQL statement is processed with bind-time rules such that the authorization ID and qualifier determined at bind time for the plan or package owner are used. Deferred embedded SQL statements are used for DB2 private protocol access to remote data.

## **Interactive SQL**

*Interactive SQL* refers to SQL statements submitted using SPUFI (SQL processor using file input) or the command line processor.

SPUFI and the command line processor prepares and executes these statements dynamically.

## **SQL Call Level Interface and Open Database Connectivity**

The DB2 Call Level Interface (CLI) is an application programming interface in which functions are provided to application programs to process dynamic SQL statements.

DB2 CLI allows users to access SQL functions directly through a call interface. CLI programs can also be compiled using an Open Database Connectivity (ODBC) Software Developer's Kit, available from Microsoft or other vendors, enabling access to ODBC data sources. Unlike using embedded SQL, no precompilation is required. Applications developed using this interface can be executed on a variety of databases without being compiled against each of databases. Through the interface, applications use procedure calls at execution time to connect to databases, to issue SQL statements, and to get returned data and status information.

## **Java database connectivity and embedded SQL for Java**

DB2 provides two standards-based Java programming APIs: Java Database Connectivity (JDBC) and embedded SQL for Java (SQL/OLB or SQLJ). Both can be used to create Java applications and applets that access DB2.

Static SQL cannot be used by JDBC. SQLJ applications use JDBC as a foundation for such tasks as connecting to databases and handling SQL errors, but can contain embedded static SQL statements in the SQLJ source files. An SQLJ file has to be translated with the SQLJ translator before the resulting Java source code can be compiled.

## DB2 data structures

Data structures are elements that are required to use DB2. You can access and use these elements to organize your data. Examples of data structures include tables, table spaces, indexes, index spaces, keys, views, and databases.

The brief descriptions here show how the structures fit into an overall view of DB2. The following figure shows how some DB2 structures contain others. To some extent, the notion of “containment” provides a hierarchy of structures.

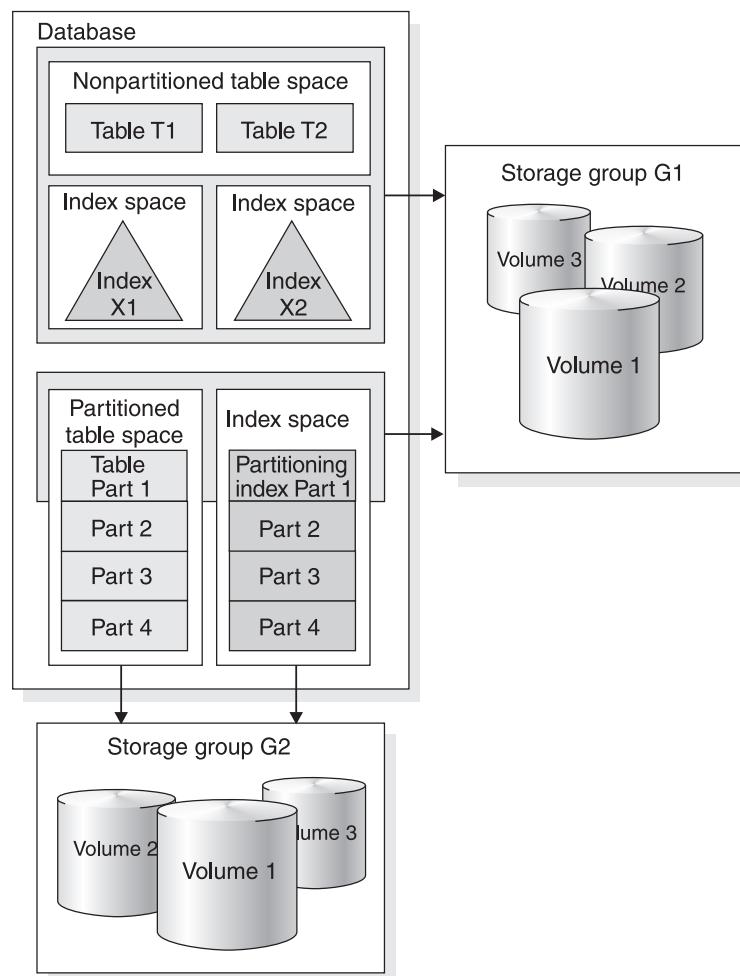

Figure 2. A hierarchy of DB2 structures

The DB2 structures from the most to the least inclusive are:

### Databases

A set of DB2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside.

### **Storage groups**

A set of volumes on disks that hold the data sets in which tables and indexes are stored.

### **Table spaces**

A set of volumes on disks that hold the data sets in which tables and indexes are stored.

**Tables** All data in a DB2 database is presented in *tables*, which are collections of rows all having the same columns. A table that holds persistent user data is a *base table*. A table that stores data temporarily is a *temporary table*.

**Views** A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

### **Indexes**

An *index* is an ordered set of pointers to the data in a DB2 table. The index is stored separately from the table.

## **DB2 tables**

*Tables* are logical structures that DB2 maintains. DB2 supports several different types of tables.

Tables are made up of columns and rows. The rows of a relational table have no fixed order. The order of the columns, however, is always the order in which you specified them when you defined the table.

At the intersection of every column and row is a specific data item called a *value*. A *column* is a set of values of the same type. A *row* is a sequence of values such that the *n*th value is a value of the *n*th column of the table. Every table must have one or more columns, but the number of rows can be zero.

DB2 accesses data by referring to its content instead of to its location or organization in storage.

DB2 supports several different types of tables:

- Auxiliary tables
- Base tables
- Clone tables
- Empty tables
- Materialized query tables
- Result tables
- Temporary tables
- XML tables

## **DB2 indexes**

An *index* is an ordered set of pointers to rows of a table. DB2 can use indexes to improve performance and ensure uniqueness. Understanding the structure of DB2 indexes can help you achieve the best performance for your system.

Conceptually, you can think of an index to the rows of a DB2 table like you think of an index to the pages of a book. Each index is based on the values of data in one or more columns of a table.

DB2 can use indexes to ensure uniqueness and to improve performance by clustering data, partitioning data, and providing efficient access paths to data for

queries. In most cases, access to data is faster with an index than with a scan of the data. For example, you can create an index on the DEPTNO column of the sample DEPT table to easily locate a specific department and avoid reading through each row of, or *scanning*, the table.

An index is stored separately from the data in the table. Each index is physically stored in its own index space. When you define an index by using the CREATE INDEX statement, DB2 builds this structure and maintains it automatically. However, you can perform necessary maintenance such as reorganizing it or recovering the index.

The main purposes of indexes are:

- To improve performance. Access to data is often faster with an index than without.
- To ensure that a row is unique. For example, a unique index on the employee table ensures that no two employees have the same employee number.
- To cluster the data.
- To determine which partition the data goes into.
- To provide index-only access to data.

Except for changes in performance, users of the table are unaware that an index is in use. DB2 decides whether to use the index to access the table. Some techniques enable you to influence how indexes affect performance when you calculate the storage size of an index and determine what type of index to use.

An index can be either partitioning or nonpartitioning, and either type can be clustered. For example, you can apportion data by last names, possibly using one partition for each letter of the alphabet. Your choice of a partitioning scheme is based on how an application accesses data, how much data you have, and how large you expect the total amount of data to grow.

Be aware that indexes have both benefits and disadvantages. A greater number of indexes can simultaneously improve the access performance of a particular transaction and require additional processing for inserting, updating, and deleting index keys. After you create an index, DB2 maintains the index, but you can perform necessary maintenance, such as reorganizing it or recovering it, as necessary.

## DB2 keys

A *key* is a column or an ordered collection of columns that is identified in the description of a table, an index, or a referential constraint. Keys are crucial to the table structure in a relational database.

Keys are important in a relational database because they ensure that each record in a table is uniquely identified, they help establish and enforce referential integrity, and they establish relationships between tables. The same column can be part of more than one key.

A *composite key* is an ordered set of two or more columns of the same table. The ordering of the columns is not constrained by their actual order within the table. The term *value*, when used with respect to a composite key, denotes a composite value. For example, consider this rule: "The value of the foreign key must be equal

to the value of the primary key." This rule means that each component of the value of the foreign key must be equal to the corresponding component of the value of the primary key.

DB2 supports several types of keys.

## Unique keys

A *unique constraint* is a rule that the values of a key are valid only if they are unique. A key that is constrained to have unique values is a *unique key*. DB2 uses a *unique index* to enforce the constraint during the execution of the LOAD utility and whenever you use an INSERT, UPDATE, or MERGE statement to add or modify data. Every unique key is a key of a unique index. You can define a unique key by using the UNIQUE clause of either the CREATE TABLE or the ALTER TABLE statement. A table can have any number of unique keys.

The columns of a unique key cannot contain null values.

## Primary keys

A *primary key* is a special type of unique key and cannot contain null values. For example, the DEPTNO column in the DEPT table is a primary key.

A table can have no more than one primary key. Primary keys are optional and can be defined in CREATE TABLE or ALTER TABLE statements.

The unique index on a primary key is called a *primary index*. When a primary key is defined in a CREATE TABLE statement or ALTER TABLE statement, DB2 automatically creates the primary index if one of the following conditions is true:

- DB2 is operating in new-function mode, and the table space is implicitly created.
- DB2 is operating in new-function mode, the table space is explicitly created, and the schema processor is running.
- DB2 is operating in conversion mode, and the schema processor is running.

If a unique index already exists on the columns of the primary key when it is defined in the ALTER TABLE statement, this unique index is designated as the primary index when DB2 is operating in new-function mode and implicitly created the table space.

## Parent keys

A *parent key* is either a primary key or a unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the constraint.

## Foreign keys

A *foreign key* is a key that is specified in the definition of a referential constraint in a CREATE or ALTER TABLE statement. A foreign key refers to or is related to a specific parent key.

Unlike other types of keys, a foreign key does not require an index on its underlying column or columns. A table can have zero or more foreign keys. The value of a composite foreign key is null if any component of the value is null.

The following figure shows the relationship between some columns in the DEPT table and the EMP table.

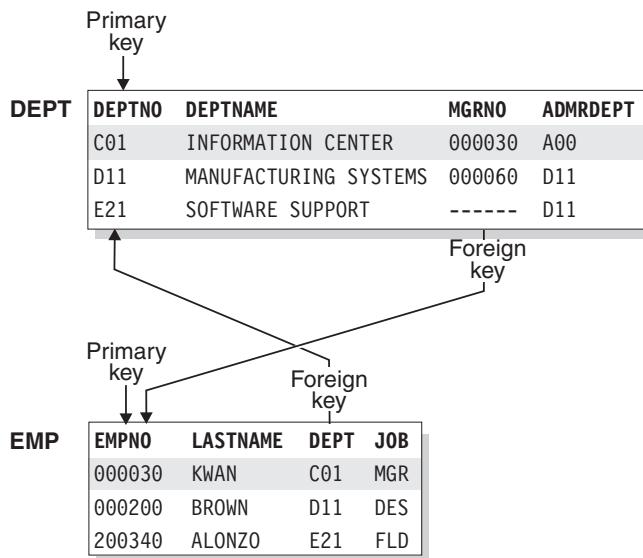

Figure 3. Relationship between DEPT and EMP tables

**Figure notes:** Each table has a primary key:

- DEPTNO in the DEPT table
- EMPNO in the EMP table

Each table has a foreign key that establishes a relationship between the tables:

- The values of the foreign key on the DEPT column of the EMP table match values in the DEPTNO column of the DEPT table.
- The values of the foreign key on the MGRNO column of the DEPT table match values in the EMPNO column of the EMP table when an employee is a manager.

To see a specific relationship between rows, notice how the shaded rows for department C01 and employee number 000030 share common values.

## DB2 views

A *view* is an alternative way of representing data that exists in one or more tables. A view can include all or some of the columns from one or more base tables.

A view is a named specification of a result table. Conceptually, creating a view is somewhat like using binoculars. You might look through binoculars to see an entire landscape or to look at a specific image within the landscape, such as a tree.

You can create a view that:

- Combines data from different base tables
- Is based on other views or on a combination of views and tables
- Omits certain data, thereby shielding some table data from users

In fact, these are common underlying reasons to use a view. Combining information from base tables and views simplifies retrieving data for a user, and limiting the data that a user can see is useful for security. You can use views for a number of different purposes. A view can:

- Control access to a table
- Make data easier to use
- Simplify authorization by granting access to a view without granting access to the table
- Show only portions of data in the table
- Show summary data for a given table
- Combine two or more tables in meaningful ways
- Show only the selected rows that are pertinent to the process that uses the view

To define a view, you use the CREATE VIEW statement and assign a name (up to 128 characters in length) to the view. Specifying the view in other SQL statements is effectively like running an SQL SELECT statement. At any time, the view consists of the rows that would result from the SELECT statement that it contains. You can think of a view as having columns and rows just like the base table on which the view is defined.

**Example 1:** The following figure shows a view of the EMP table that omits sensitive employee information and renames some of the columns.

Base table, **EMP**:

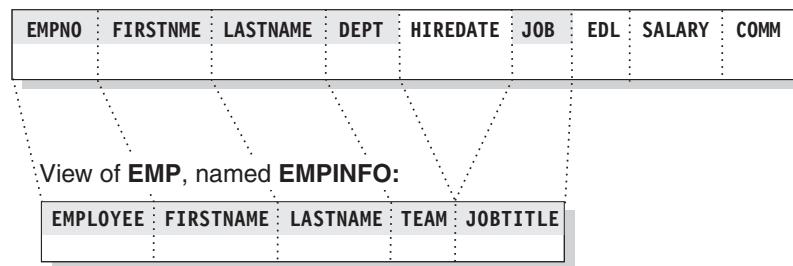

Figure 4. A view of the EMP table

**Figure note:** The EMPINFO view represents a table that includes columns named EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, and JOBTITLE. The data in the view comes from the columns EMPNO, FIRSTNME, LASTNAME, DEPT, and JOB of the EMP table.

**Example 2:** The following CREATE VIEW statement defines the EMPINFO view that is shown in the preceding figure:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
  AS SELECT EMPNO, FIRSTNME, LASTNAME, DEPT, JOB
    FROM EMP;
```

When you define a view, DB2 stores the definition of the view in the DB2 catalog. However, DB2 does not store any data for the view itself, because the data exists in the base table or tables.

**Example 3:** You can narrow the scope of the EMPINFO view by limiting the content to a subset of rows and columns that includes departments A00 and C01 only:

```
CREATE VIEW EMPINFO (EMPLOYEE, FIRSTNAME, LASTNAME, TEAM, JOBTITLE)
  AS SELECT EMPNO, FIRSTNME, LASTNAME, DEPT, JOB
    WHERE DEPT = 'A00' OR DEPT = 'C01'
      FROM EMP;
```

In general, a view inherits the attributes of the object from which it is derived. Columns that are added to the tables after the view is defined on those tables do not appear in the view.

**Restriction:** You cannot create an index for a view. In addition, you cannot create any form of a key or a constraint (referential or otherwise) on a view. Such indexes, keys, or constraints must be built on the tables that the view references.

To retrieve or access information from a view, you use views like you use base tables. You can use a SELECT statement to show the information from the view. The SELECT statement can name other views and tables, and it can use the WHERE, GROUP BY, and HAVING clauses. It cannot use the ORDER BY clause or name a host variable.

Whether a view can be used in an insert, update, or delete operation depends on its definition. For example, if a view includes a foreign key of its base table, INSERT and UPDATE operations that use the view are subject to the same referential constraint as the base table. Likewise, if the base table of a view is a parent table, DELETE operations that use the view are subject to the same rules as DELETE operations on the base table. *Read-only* views cannot be used for insert, update, and delete operations.

## DB2 schemas and schema qualifiers

The objects in a relational database are organized into sets called schemas. A *schema* is a collection of named objects that provides a logical classification of objects in the database. The first part of a schema name is the qualifier.

A schema provides a logical classification of objects in the database. The objects that a schema can contain include tables, indexes, table spaces, distinct types, functions, stored procedures, and triggers. An object is assigned to a schema when it is created.

The *schema name* of the object determines the schema to which the object belongs. A user object, such as a distinct type, function, procedure, sequence, or trigger should not be created in a *system schema*, which is any one of a set of schemas that are reserved for use by the DB2 subsystem.

When a table, index, table space, distinct type, function, stored procedure, or trigger is created, it is given a qualified two-part name. The first part is the schema name (or the qualifier), which is either implicitly or explicitly specified. The default schema is the authorization ID of the owner of the plan or package. The second part is the name of the object.

In previous versions, CREATE statements had certain restrictions when the value of CURRENT SCHEMA was different from CURRENT SQLID value. Although those restrictions no longer exist, you now must consider how to determine the qualifier and owner when CURRENT SCHEMA and CURRENT SQLID contain different values. The rules for how the owner is determined depend on the type of object being created.

CURRENT SCHEMA and CURRENT SQLID effect only dynamic SQL statements. Static CREATE statements are not affected by either CURRENT SCHEMA or CURRENT SQLID.

The following table summarizes the affect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- Alias
- Auxiliary table
- Created global temporary table
- Table
- View

*Table 1. Schema qualifier and owner for objects*

Specification of name for new object being created	Schema qualifier of new object	Owner of new object
<i>name</i> (no qualifier)	value of CURRENT SCHEMA	value of CURRENT SQLID
<i>abc.name</i> (single qualifier)	abc	abc
..... <i>abc.name</i> (multiple qualifiers)	abc	abc

The following table summarizes the affect of CURRENT SCHEMA in determining the schema qualifier and owner for these objects:

- User-defined distinct type
- User-defined function
- Procedure
- Sequence
- Trigger

*Table 2. Schema qualifier and owner for additional objects*

Specification of name for new object being created	Schema qualifier of new object	Owner of new object
<i>name</i> (no qualifier)	value of CURRENT SCHEMA	value of CURRENT SQLID
<i>abc.name</i> (single qualifier)	abc	value of CURRENT SQLID
..... <i>abc.name</i> (multiple qualifiers)	abc	value of CURRENT SQLID

## DB2 storage groups

DB2 *storage groups* are a set of volumes on disks that hold the data sets in which tables and indexes are stored.

The description of a storage group names the group and identifies its volumes and the VSAM (Virtual Storage Access Method) catalog that records the data sets. The default storage group, SYSDEFLT, is created when you install DB2.

Within the storage group, DB2 does the following actions:

- Allocates storage for table spaces and indexes
- Defines the necessary VSAM data sets
- Extends and deletes VSAM data sets
- Alters VSAM data sets

All volumes of a given storage group must have the same device type. However, parts of a single database can be stored in different storage groups.

DB2 can manage the auxiliary storage requirements of a database by using DB2 storage groups. Data sets in these DB2 storage groups are called *DB2-managed data sets*.

These DB2 storage groups are not the same as storage groups that are defined by the DFSMS storage management subsystem (DFSMSsms).

You have several options for managing DB2 data sets:

- Let DB2 manage the data sets. This option means less work for DB2 database administrators.

After you define a DB2 storage group, DB2 stores information about it in the DB2 catalog. (This catalog is not the same as the integrated catalog facility catalog that describes DB2 VSAM data sets). The catalog table SYSIBM.SYSSTOGROUP has a row for each storage group, and SYSIBM.SYSVOLUMES has a row for each volume. With the proper authorization, you can retrieve the catalog information about DB2 storage groups by using SQL statements.

When you create table spaces and indexes, you name the storage group from which space is to be allocated. You can also assign an entire database to a storage group. Try to assign frequently accessed objects (indexes, for example) to fast devices, and assign seldom-used tables to slower devices. This approach to choosing storage groups improves performance.

If you are authorized and do not take specific steps to manage your own storage, you can still define tables, indexes, table spaces, and databases. A default storage group, SYSDEFLT, is defined when DB2 is installed. DB2 uses SYSDEFLT to allocate the necessary auxiliary storage. Information about SYSDEFLT, as with any other storage group, is kept in the catalog tables SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES.

For both user-managed and DB2-managed data sets, you need at least one integrated catalog facility (ICF) catalog; this catalog can be either a user catalog or a master catalog. These catalogs are created with the ICF. You must identify the catalog of the ICF when you create a storage group or when you create a table space that does not use storage groups.

- Let SMS manage some or all the data sets, either when you use DB2 storage groups or when you use data sets that you have defined yourself. This option offers a reduced workload for DB2 database administrators and storage administrators. You can specify SMS classes when you create or alter a storage group.
- Define and manage your own data sets using VSAM Access Method Services. This option gives you the most control over the physical storage of tables and indexes.

**Recommendation:** Use DB2 storage groups and whenever you can, either specifically or by default. Also use SMS managed DB2 storage groups whenever you can.

## DB2 databases

DB2 *databases* are a set of DB2 structures that include a collection of tables, their associated indexes, and the table spaces in which they reside. You define a database by using the CREATE DATABASE statement.

Whenever a table space is created, it is explicitly or implicitly assigned to an existing database. If you create a table space and do not specify a database name, the table space is created in the default database, DSNDB04. In this case, DB2

implicitly creates a database or uses an existing implicitly created database for the table. All users who have the authority to create table spaces or tables in database DSNDB04 have authority to create tables and table spaces in an implicitly created database. If the table space is implicitly created, and you do not specify the IN clause in the CREATE TABLE statement, DB2 implicitly creates the database to which the table space is assigned.

A single database, for example, can contain all the data that is associated with one application or with a group of related applications. Collecting that data into one database allows you to start or stop access to all the data in one operation. You can also grant authorization for access to all the data as a single unit. Assuming that you are authorized to access data, you can access data that is stored in different databases.

**Recommendation:** Keep only a minimal number of table spaces in each database, and a minimal number of tables in each tablespace. Excessive numbers of table spaces and tables in a database can cause decreases in performance and manageability issues. If you reduce the number of table spaces and tables in a database, you improve performance, minimize maintenance, increase concurrency, and decrease log volume.

The following figure shows how the main DB2 data structures fit together. Two databases, A and B, are represented as squares. Database A contains a table space and two index spaces. The table space is segmented and contains tables A1 and A2. Each index space contains one index, an index on table A1 and an index on table A2. Database B contains one table space and one index space. The table space is partitioned and contains table B1, partitions 1 through 4. The index space contains one partitioning index, parts 1 - 4.

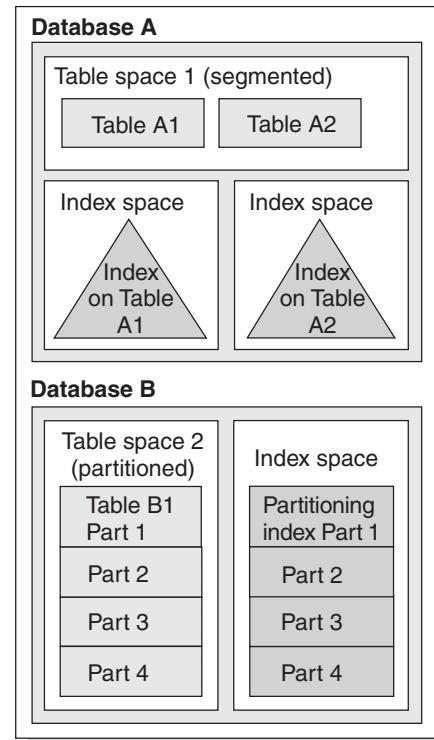

Figure 5. Data structures in a DB2 database

When you migrate to the current version, DB2 adopts the default database and default storage group that you used in the previous version. You have the same authority for the current version as you did in the previous version.

Declared global temporary tables are now stored in the WORKFILE database. The TEMP database is no longer used.

## Reasons to define a database

In DB2 for z/OS, a database is a logical collection of table spaces and index spaces. Consider the following factors when deciding whether to define a new database for a new set of objects:

- You can start and stop an entire database as a unit; you can display the statuses of all its objects by using a single command that names only the database. Therefore, place a set of tables that are used together into the same database. (The same database holds all indexes on those tables.)
- Some operations lock an entire database. For example, some phases of the LOAD utility prevent some SQL statements (CREATE, ALTER, and DROP) from using the same database concurrently. Therefore, placing many unrelated tables in a single database is often inconvenient.

When one user is executing a CREATE, ALTER, or DROP statement for a table, no other user can access the database that contains that table. QMF<sup>TM</sup> users, especially, might do a great deal of data definition; the QMF operations SAVE DATA and ERASE *data-object* are accomplished by creating and dropping DB2 tables. For maximum concurrency, create a separate database for each QMF user.

- The internal database descriptors (DBDs) might become inconveniently large. DBDs grow as new objects are defined, but they do not immediately shrink when objects are dropped; the DBD space for a dropped object is not reclaimed until the MODIFY RECOVERY utility is used to delete records of obsolete copies from SYSIBM.SYSCOPY. DBDs occupy storage and are the objects of occasional input and output operations. Therefore, limiting the size of DBDs is another reason to define new databases.

---

## Storage structures

In DB2, a *storage structure* is a set of one or more VSAM data sets that hold DB2 tables or indexes. A storage structure is also called a *page set*.

The two primary types of storage structures in DB2 for z/OS are table spaces and index spaces.

## DB2 table spaces

A DB2 *table space* is a set of volumes on disks that hold the data sets in which tables are actually stored. All tables are kept in table spaces. A table space can have one or more tables.

A table space can consist of a number of VSAM data sets. Data sets are VSAM linear data sets (LDSs). Table spaces are divided into equal-sized units, called *pages*, which are written to or read from disk in one operation. You can specify page sizes (4 KB, 8 KB, 16 KB, or 32 KB in size) for the data; the default page size is 4 KB. As a general rule, you should have only one table in each tablespace. It is also best to keep only one tablespace in each database. If you must have more than one tablespace in a database, keep no more than 20 tablespaces in that database.

Data in most table spaces can be compressed, which can allow you to store more data on each data page.

You can explicitly define a table space by using the CREATE TABLESPACE statement, which can specify the database to which the table space belongs and the storage group that it uses.

Alternatively, you can let DB2 implicitly create a table space for you by issuing a CREATE TABLE statement that does not specify an existing table space. In this case, DB2 assigns the table space to the default database and the default storage group. If DB2 is operating in conversion mode, a segmented table space is created. In new-function mode, DB2 creates a partition-by-growth table space.

When you create a table space, you can specify what type of table space is created. DB2 supports different types of table spaces:

#### **Universal table spaces**

Provide better space management (for varying-length rows) and improved mass delete performance by combining characteristics of partitioned and segmented table space schemes. A universal table space can hold one table.

#### **Partitioned table spaces**

Divide the available space into separate units of storage called *partitions*. Each partition contains one data set of one table.

#### **Segmented table spaces**

Divide the available space into groups of pages called *segments*. Each segment is the same size. A segment contains rows from only one table.

#### **Large object table spaces**

Hold large object data such as graphics, video, or very large text strings. A LOB table space is always associated with the table space that contains the logical LOB column values.

#### **Simple table spaces**

Can contain more than one table. The rows of different tables are not kept separate (unlike segmented table spaces).

**Restriction:** Starting in DB2 Version 9.1, you cannot create a simple table space. Simple table spaces that were created with an earlier version of DB2 are still supported.

#### **XML table spaces**

Hold XML data. An XML table space is always associated with the table space that contains the logical XML column value.

## **DB2 index spaces**

An *index space* is a DB2 storage structure that contains a single index.

When you create an index by using the CREATE INDEX statement, an index space is automatically defined in the same database as the table. You can define a unique name for the index space, or DB2 can derive a unique name for you. Under certain circumstances, DB2 implicitly creates index spaces.

## **DB2 system objects**

Unlike the DB2 data structures that users create and access, DB2 controls and accesses system objects.

DB2 has a comprehensive infrastructure that enables it to provide data integrity, performance, and the ability to recover user data. In addition, Parallel Sysplex® data sharing uses shared system objects.

## DB2 catalog

DB2 maintains a set of tables that contain information about the data that DB2 controls. These tables are collectively known as the *catalog*.

The catalog tables contain information about DB2 objects such as tables, views, and indexes. When you create, alter, or drop an object, DB2 inserts, updates, or deletes rows of the catalog that describe the object.

The DB2 catalog consists of tables of data about everything defined to the DB2 system, including table spaces, indexes, tables, copies of table spaces and indexes, and storage groups. The system database DSNDB06 contains the DB2 catalog.

When you create, alter, or drop any structure, DB2 inserts, updates, or deletes rows of the catalog that describe the structure and tell how the structure relates to other structures. For example, SYSIBM.SYSTABLES is one catalog table that records information when a table is created. DB2 inserts a row into SYSIBM.SYSTABLES that includes the table name, its owner, its creator, and the name of its table space and its database.

To understand the role of the catalog, consider what happens when the EMP table is created. DB2 records the following data:

### Table information

To record the table name and the name of its owner, its creator, its type, the name of its table space, and the name of its database, DB2 inserts a row into the catalog.

### Column information

To record information about each column of the table, DB2 inserts the name of the table to which the column belongs, its length, its data type, and its sequence number by inserting a row into the catalog for each column of the table.

### Authorization information

To record that the owner of the table has authorization to create the table, DB2 inserts a row into the catalog.

Tables in the catalog are like any other database tables with respect to retrieval. If you have authorization, you can use SQL statements to look at data in the catalog tables in the same way that you retrieve data from any other table in the DB2 database. DB2 ensures that the catalog contains accurate object descriptions. If you are authorized to access the specific tables or views on the catalog, you can SELECT from the catalog, but you cannot use INSERT, UPDATE, DELETE, TRUNCATE, or MERGE statements on the catalog.

The *communications database* (CDB) is part of the DB2 catalog. The CDB consists of a set of tables that establish conversations with remote database management systems (DBMSs). The distributed data facility (DDF) uses the CDB to send and receive distributed data requests.

## DB2 directory

The DB2 directory contains information that DB2 uses during normal operation.

You cannot access the directory by using SQL, although much of the same information is contained in the DB2 catalog, for which you can submit queries. The structures in the directory are not described in the DB2 catalog.

The directory consists of a set of DB2 tables that are stored in table spaces in system database DSNDB01. Each of the table spaces that are listed in the following table is contained in a VSAM linear data set.

*Table 3. Directory table spaces*

Table space name	Description
SCT02	Contains the internal form of SQL statements that are contained in an application. When you bind a plan, DB2 creates a structure in SCT02.
SPT01 Skeleton package	Contains the internal form of SQL statements that are contained in a package.
SYSSPUXA	Contains the contents of a package selection.
SYSSPUXB	Contains the contents of a package explain block.
SYSLGRNX Log range	Tracks the opening and closing of table spaces, indexes, or partitions. By tracking this information and associating it with relative byte addresses (RBAs) as contained in the DB2 log, DB2 can reduce recovery time by reducing the amount of log that must be scanned for a particular table space, index, or partition.
SYSUTILX System utilities	Contains a row for every utility job that is running. The row persists until the utility is finished. If the utility terminates without completing, DB2 uses the information in the row when you restart the utility.
DBD01 Database descriptor (DBD)	Contains internal information, called <i>database descriptors</i> (DBDs), about the databases that exist within the DB2 subsystem.
	Each database has exactly one corresponding DBD that describes the database, table spaces, tables, table check constraints, indexes, and referential relationships. A DBD also contains other information about accessing tables in the database. DB2 creates and updates DBDs whenever their corresponding databases are created or updated.

## Active and archive logs

DB2 records all data changes and other significant events in a log.

If you keep these logs, DB2 can re-create those changes for you in the event of a failure or roll the changes back to a previous point in time.

DB2 writes each log record to a disk data set called the *active log*. When the active log is full, DB2 copies the contents of the active log to a disk or magnetic tape data set called the *archive log*.

You can choose either single logging or dual logging.

- A single active log contains up to 93 active log data sets.

- With dual logging, the active log has twice the capacity for active log data sets, because two identical copies of the log records are kept.

Each DB2 subsystem manages multiple active logs and archive logs. The following facts are true about each DB2 active log:

- Each log can be duplexed to ensure high availability.
- Each active log data set is a VSAM linear data set (LDS).
- DB2 supports striped active log data sets.

## Bootstrap data set

The *bootstrap data set (BSDS)* is a VSAM key-sequenced data set (KSDS). This KSDS contains information that is critical to DB2, such as the names of the logs. DB2 uses information in the BSDS for system restarts and for any activity that requires reading the log.

Specifically, the BSDS contains:

- An inventory of all active and archive log data sets that are known to DB2. DB2 uses this information to track the active and archive log data sets. DB2 also uses this information to locate log records to satisfy log read requests during normal DB2 system activity and during restart and recovery processing.
- A wrap-around inventory of all recent DB2 checkpoint activity. DB2 uses this information during restart processing.
- The distributed data facility (DDF) communication record, which contains information that is necessary to use DB2 as a distributed server or requester.
- Information about buffer pools.

Because the BSDS is essential to recovery in the event of subsystem failure, during installation DB2 automatically creates two copies of the BSDS and, if space permits, places them on separate volumes.

The BSDS can be duplexed to ensure availability.

## Buffer pools

*Buffer pools* are areas of virtual storage in which DB2 temporarily stores pages of table spaces or indexes. Access to data in this temporary storage is faster than accessing data on a disk.

When an application program accesses a row of a table, DB2 retrieves the page that contains the row and places the page in a buffer. If the required data is already in a buffer, the application program does not need to wait for it to be retrieved from disk, so the time and cost of retrieving the page is reduced.

Buffer pools require monitoring and tuning. The size of buffer pools is critical to the performance characteristics of an application or group of applications that access data in those buffer pools.

DB2 lets you specify default buffer pools for user data and for indexes. A special type of buffer pool that is used only in Parallel Sysplex data sharing is the *group buffer pool*, which resides in the coupling facility. Group buffer pools reside in a special PR/SM™ LPAR logical partition called a *coupling facility*, which enables several DB2 subsystems to share information and control the coherency of data.

Buffer pools reside in the DB2 DBM1 primary address space. This option offers the best performance. The maximum size of a buffer pool is 1 TB.

## Data definition control support database

The *data definition control support* (DDCS) database refers to a user-maintained collection of tables that are used by data definition control support to restrict the submission of specific DB2 DDL (data definition language) statements to selected application identifiers (plans or collections of packages).

This database is automatically created during installation. After this database is created, you must populate the tables to use this facility. The system name for this database is DSNRGFDB.

## Resource limit facility database

The *resource limit facility database* (DSNRLST) is a facility that lets you control the amount of processor resources that are used by dynamic SELECT statements.

**GUPI** For example, you might choose to disable bind operations during critical times of day to avoid contention with the DB2 catalog.

You can establish a single limit for all users, different limits for individual users, or both. You can choose to have these limits applied before the statement is executed (this is called *predictive governing*), or while a statement is running (sometimes called *reactive governing*). You can even use both modes of governing. You define these limits in one or more resource limit specification tables (RLST). **GUPI**

## Work file database

Use the *work file database* as storage for processing SQL statements that require working space, such as that required for a sort.

The work file database is used as storage for DB2 work files for processing SQL statements that require working space (such as the space that is required for a sort), and as storage for created global temporary tables and declared global temporary tables.

DB2 creates a work file database and some table spaces in it for you at installation time. You can create additional work file table spaces at any time. You can drop, re-create, and alter the work file database or the table spaces in it, or both, at any time.

In a non-data-sharing environment, the work file database is named DSNDDB07. In a data sharing environment, each DB2 member in the data sharing group has its own work file database.

You can also use the work file database for all temporary tables.

---

## DB2 and data integrity

Referential integrity ensures data integrity by enforcing rules with referential constraints, check constraints, and triggers. You can rely on constraints and triggers to ensure the integrity and validity of your data, rather than relying on individual applications to do that work.

## Constraints

*Constraints* are rules that control values in columns to prevent duplicate values or set restrictions on data added to a table.

Constraints fall into the following three types:

- Unique constraints
- Referential constraints
- Check constraints

### Unique constraints

A *unique constraint* is a rule that the values of a key are valid only if they are unique in a table.

Unique constraints are optional and can be defined in the CREATE TABLE or ALTER TABLE statements with the PRIMARY KEY clause or the UNIQUE clause. The columns specified in a unique constraint must be defined as NOT NULL. A unique index enforces the uniqueness of the key during changes to the columns of the unique constraint.

A table can have an arbitrary number of unique constraints, with at most one unique constraint defined as a primary key. A table cannot have more than one unique constraint on the same set of columns.

A unique constraint that is referenced by the foreign key of a referential constraint is called the *parent key*.

### Referential constraints

DB2 ensures referential integrity between your tables when you define referential constraints.

Referential integrity is the state in which all values of all foreign keys are valid. Referential integrity is based on *entity integrity*. Entity integrity requires that each entity have a unique key. For example, if every row in a table represents relationships for a unique entity, the table should have one column or a set of columns that provides a unique identifier for the rows of the table. This column (or set of columns) is called the parent key of the table. To ensure that the parent key does not contain duplicate values, a unique index must be defined on the column or columns that constitute the parent key. Defining the parent key is called entity integrity.

A *referential constraint* is the rule that the nonnull values of a foreign key are valid only if they also appear as values of a parent key. The table that contains the parent key is called the *parent table* of the referential constraint, and the table that contains the foreign key is a *dependent* of that table.

The relationship between some rows of the DEPT and EMP tables, shown in the following figure, illustrates referential integrity concepts and terminology. For example, referential integrity ensures that every foreign key value in the DEPT column of the EMP table matches a primary key value in the DEPTNO column of the DEPT table.

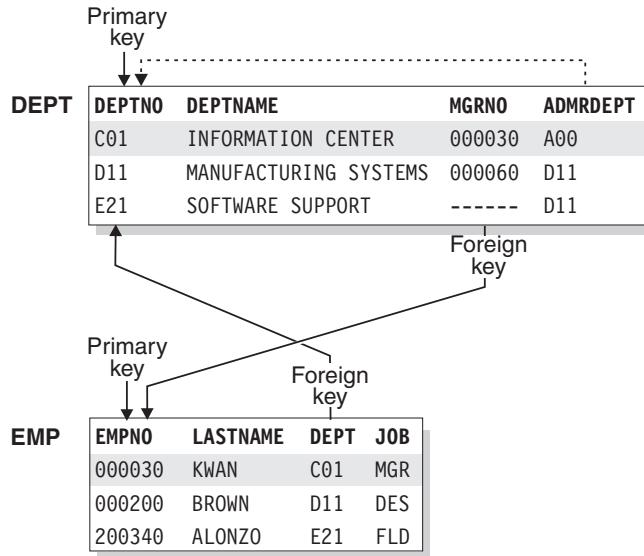

Figure 6. Referential integrity of DEPT and EMP tables

Two parent and dependent relationships exist between the DEPT and EMP tables.

- The foreign key on the DEPT column establishes a parent and dependent relationship. The DEPT column in the EMP table depends on the DEPTNO in the DEPT table. Through this foreign key relationship, the DEPT table is the parent of the EMP table. You can assign an employee to no department (by specifying a null value), but you cannot assign an employee to a department that does not exist.
- The foreign key on the MGRNO column also establishes a parent and dependent relationship. Because MGRNO depends on EMPNO, EMP is the parent table of the relationship, and DEPT is the dependent table.

You can define a primary key on one or more columns. A primary key that includes two or more columns is called a *composite key*. A foreign key can also include one or more columns. When a foreign key contains multiple columns, the corresponding primary key must be a composite key. The number of foreign key columns must be the same as the number of columns in the parent key, and the data types of the corresponding columns must be compatible. (The sample project activity table, DSN8910.PROJACT, is an example of a table with a primary key on multiple columns, PROJNO, ACTNO, and ACSTDATE.)

A table can be a dependent of itself; this is called a *self-referencing table*. For example, the DEPT table is self-referencing because the value of the administrative department (ADMRDEPT) must be a department ID (DEPTNO). To enforce the self-referencing constraint, DB2 requires that a foreign key be defined.

Similar terminology applies to the rows of a parent-and-child relationship. A row in a dependent table, called a *dependent row*, refers to a row in a parent table, called a *parent row*. But a row of a parent table is not always a parent row—perhaps nothing refers to it. Likewise, a row of a dependent table is not always a dependent row—the foreign key can allow null values, which refer to no other rows.

Referential constraints are optional. You define referential constraints by using CREATE TABLE and ALTER TABLE statements.

DB2 enforces referential constraints when the following actions occur:

- An INSERT statement is applied to a dependent table.
- An UPDATE statement is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A MERGE statement that includes an insert operation is applied to a dependent table.
- A MERGE statement that includes an update operation is applied to a foreign key of a dependent table or to the parent key of a parent table.
- A DELETE statement is applied to a parent table. All affected referential constraints and all delete rules of all affected relationships must be satisfied in order for the delete operation to succeed.
- The LOAD utility with the ENFORCE CONSTRAINTS option is run on a dependent table.
- The CHECK DATA utility is run.

Another type of referential constraint is an *informational referential constraint*. This type of constraint is not enforced by DB2 during normal operations. An application process should verify the data in the referential integrity relationship. An informational referential constraint allows queries to take advantage of materialized query tables.

The order in which referential constraints are enforced is undefined. To ensure that the order does not affect the result of the operation, there are restrictions on the definition of delete rules and on the use of certain statements. The restrictions are specified in the descriptions of the SQL statements CREATE TABLE, ALTER TABLE, INSERT, UPDATE, MERGE, and DELETE.

The rules of referential integrity involve the following concepts and terminology:

**parent key**

A primary key or a unique key of a referential constraint.

**parent table**

A table that is a parent in at least one referential constraint. A table can be defined as a parent in an arbitrary number of referential constraints.

**dependent table**

A table that is a dependent in at least one referential constraint. A table can be defined as a dependent in an arbitrary number of referential constraints.  
A dependent table can also be a parent table.

**descendent table**

A table that is a dependent of another table or a table that is a dependent of a descendent table.

**referential cycle**

A set of referential constraints in which each associated table is a descendent of itself.

**parent row**

A row that has at least one dependent row.

**dependent row**

A row that has at least one parent row.

**descendent row**

A row that is dependent on another row or a row that is a dependent of a descendent row.

### **self-referencing row**

A row that is a parent of itself.

### **self-referencing table**

A table that is both parent and dependent in the same referential constraint. The constraint is called a *self-referencing constraint*.

The following rules provide referential integrity:

#### **insert rule**

A nonnull insert value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is null if any component of the value is null.

#### **update rule**

A nonnull update value of the foreign key must match some value of the parent key of the parent table. The value of a composite foreign key is treated as null if any component of the value is null.

#### **delete rule**

Controls what happens when a row of the parent table is deleted. The choices of action, made when the referential constraint is defined, are RESTRICT, NO ACTION, CASCADE, or SET NULL. SET NULL can be specified only if some column of the foreign key allows null values.

More precisely, the delete rule applies when a row of the parent table is the object of a delete or propagated delete operation and that row has dependents in the dependent table of the referential constraint. A *propagated delete* refers to the situation where dependent rows are deleted when parent rows are deleted. Let  $P$  denote the parent table, let  $D$  denote the dependent table, and let  $p$  denote a parent row that is the object of a delete or propagated delete operation. If the delete rule is:

- RESTRICT or NO ACTION, an error occurs and no rows are deleted.
- CASCADE, the delete operation is propagated to the dependent rows of  $p$  in  $D$ .
- SET NULL, each nullable column of the foreign key of each dependent row of  $p$  in  $D$  is set to null.

Each referential constraint in which a table is a parent has its own delete rule, and all applicable delete rules are used to determine the result of a delete operation. Thus, a row cannot be deleted if it has dependents in a referential constraint with a delete rule of RESTRICT or NO ACTION or the deletion cascades to any of its descendants that are dependents in a referential constraint with the delete rule of RESTRICT or NO ACTION.

The deletion of a row from parent table  $P$  involves other tables and can affect rows of these tables:

- If  $D$  is a dependent of  $P$  and the delete rule is RESTRICT or NO ACTION,  $D$  is involved in the operation but is not affected by the operation and the deletion from the parent table  $P$  does not take place.
- If  $D$  is a dependent of  $P$  and the delete rule is SET NULL,  $D$  is involved in the operation and rows of  $D$  might be updated during the operation.
- If  $D$  is a dependent of  $P$  and the delete rule is CASCADE,  $D$  is involved in the operation and rows of  $D$  might be deleted during the operation. If rows of  $D$  are deleted, the delete operation on  $P$  is said to be propagated to  $D$ . If  $D$  is also a parent table, the actions described in this list apply, in turn, to the dependents of  $D$ .

Any table that can be involved in a delete operation on  $P$  is said to be *delete-connected* to  $P$ . Thus, a table is delete-connected to table  $P$  if it is a dependent of  $P$  or a dependent of a table to which delete operations from  $P$  cascade.

## Check constraints

A *check constraint* is a rule that specifies the values that are allowed in one or more columns of every row of a base table.

Like referential constraints, check constraints are optional and you define them by using the CREATE TABLE and ALTER TABLE statements. The definition of a check constraint restricts the values that a specific column of a base table can contain.

A table can have any number of check constraints. DB2 enforces a check constraint by applying the restriction to each row that is inserted, loaded, or updated. One restriction is that a column name in a check constraint on a table must identify a column of that table.

**Example:** You can create a check constraint to ensure that all employees earn a salary of \$30 000 or more:

```
CHECK (SALARY>= 30000)
```

## Triggers

A *trigger* defines a set of actions that are executed when a delete, insert, or update operation occurs on a specified table or view. When an SQL operation is executed, the trigger is *activated*. You can use triggers with referential constraints and check constraints to enforce data integrity rules.

When an insert, load, update, or delete is executed, the trigger is *activated*.

You can use triggers along with referential constraints and check constraints to enforce data integrity rules. Triggers are more powerful than constraints because you can use them to do the following things:

- Update other tables
- Automatically generate or transform values for inserted or updated rows
- Invoke functions that perform operations both inside and outside of DB2

For example, assume that you need to prevent an update to a column when a new value exceeds a certain amount. Instead of preventing the update, you can use a trigger. The trigger can substitute a valid value and invoke a procedure that sends a notice to an administrator about the attempted invalid update.

You can define triggers with the CREATE TRIGGER statement.

INSTEAD OF triggers are triggers that execute instead of the INSERT, UPDATE, or DELETE statement that activates the trigger. Unlike other triggers, which are defined on tables only, INSTEAD OF triggers are defined on views only. INSTEAD OF triggers are particularly useful when the triggered actions for INSERT, UPDATE, or DELETE statements on views need to be different from the actions for SELECT statements. For example, an INSTEAD OF trigger can be used to facilitate an update through a join query or to encode or decode data in a view.

Triggers move the business rule application logic into the database, which results in faster application development and easier maintenance. The business rule is no longer repeated in several applications, and the rule is centralized to the trigger.

DB2 checks the validity of the changes that any application makes to the salary column, and you are not required to change application programs when the logic changes.

---

## Application processes, concurrency, and recovery

All SQL programs execute as part of an *application process*. An application process involves the execution of one or more programs, and it is the unit to which DB2 allocates resources and locks.

Different application processes might involve the execution of different programs, or different executions of the same program. The means of initiating and terminating an application process are dependent on the environment.

### Locking, commit, and rollback

More than one application process might request access to the same data at the same time. Furthermore, under certain circumstances, an SQL statement can execute concurrently with a utility on the same table space. *Locking* is used to maintain data integrity under such conditions, preventing, for example, two application processes from updating the same row of data simultaneously.

DB2 implicitly acquires locks to prevent uncommitted changes made by one application process from being perceived by any other. DB2 will implicitly release all locks it has acquired on behalf of an application process when that process ends, but an application process can also explicitly request that locks be released sooner. A *commit* operation releases locks acquired by the application process and commits database changes made by the same process.

DB2 provides a way to *back out* uncommitted changes made by an application process. This might be necessary in the event of a failure on the part of an application process, or in a *deadlock* situation. An application process, however, can explicitly request that its database changes be backed out. This operation is called *rollback*.

The interface used by an SQL program to explicitly specify these commit and rollback operations depends on the environment. If the environment can include recoverable resources other than DB2 databases, the SQL COMMIT and ROLLBACK statements cannot be used. Thus, these statements cannot be used in an IMS, CICS, or WebSphere® environment.

### Unit of work

A *unit of work* is a recoverable sequence of operations within an application process. A unit of work is sometimes called a *logical unit of work*.

At any time, an application process has a single unit of work, but the life of an application process can involve many units of work as a result of commit or full rollback operations.

A unit of work is initiated when an application process is initiated. A unit of work is also initiated when the previous unit of work is ended by something other than the end of the application process. A unit of work is ended by a commit operation, a full rollback operation, or the end of an application process. A commit or rollback operation affects only the database changes made within the unit of work it ends. While these changes remain uncommitted, other application processes are unable to perceive them unless they are running with an isolation level of uncommitted

read. The changes can still be backed out. Once committed, these database changes are accessible by other application processes and can no longer be backed out by a rollback. Locks acquired by DB2 on behalf of an application process that protects uncommitted data are held at least until the end of a unit of work.

The initiation and termination of a unit of work define *points of consistency* within an application process. A point of consistency is a claim by the application that the data is consistent. For example, a banking transaction might involve the transfer of funds from one account to another. Such a transaction would require that these funds be subtracted from the first account, and added to the second. Following the subtraction step, the data is inconsistent. Only after the funds have been added to the second account is consistency reestablished. When both steps are complete, the commit operation can be used to end the unit of work, thereby making the changes available to other application processes. The following figure illustrates this concept.

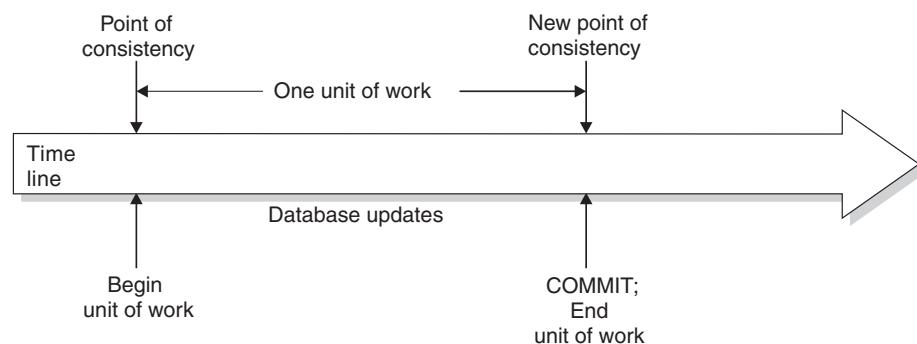

Figure 7. Unit of work with a commit operation

## Unit of recovery

A DB2 *unit of recovery* is a recoverable sequence of operations executed by DB2 for an application process.

If a unit of work involves changes to other recoverable resources, the unit of work will be supported by other units of recovery. If relational databases are the only recoverable resources used by the application process, then the scope of the unit of work and the unit of recovery are the same and either term can be used.

## Rolling back work

DB2 can back out all changes made in a unit of recovery or only selected changes. Only backing out all changes results in a point of consistency.

### Rolling back all changes

The SQL ROLLBACK statement without the TO SAVEPOINT clause specified causes a full rollback operation. If such a rollback operation is successfully executed, DB2 backs out uncommitted changes to restore the data consistency that existed when the unit of work was initiated.

That is, DB2 undoes the work, as shown in the following figure:

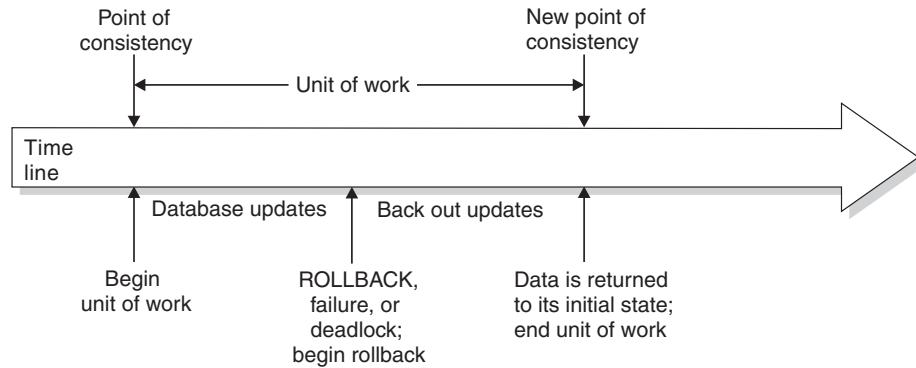

Figure 8. Rolling back all changes from a unit of work

### Rolling back selected changes using savepoints

A *savepoint* represents the state of data at some particular time during a unit of work. An application process can set savepoints within a unit of work, and then as logic dictates, roll back only the changes that were made after a savepoint was set.

For example, part of a reservation transaction might involve booking an airline flight and then a hotel room. If a flight gets reserved but a hotel room cannot be reserved, the application process might want to undo the flight reservation without undoing any database changes made in the transaction prior to making the flight reservation. SQL programs can use the SQL SAVEPOINT statement to set savepoints, the SQL ROLLBACK statement with the TO SAVEPOINT clause to undo changes to a specific savepoint or the last savepoint that was set, and the SQL RELEASE SAVEPOINT statement to delete a savepoint. The following figure illustrates this concept.

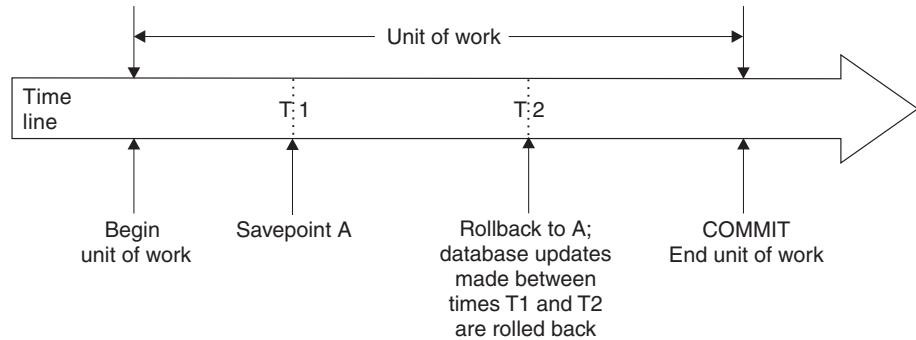

Figure 9. Rolling back changes to a savepoint within a unit of work

### Packages and application plans

A *package* contains control structures that DB2 uses when it runs SQL statements. An *application plan* relates an application process to a local instance of DB2 and specifies processing options.

Packages are produced during program preparation. You can think of the control structures as the bound or operational form of SQL statements. All control structures in a package are derived from the SQL statements that are embedded in a single source program.

An application plan contains one or both of the following elements:

- A list of package names
- The bound form of SQL statements

Most DB2 applications require an application plan. Packages make application programs more flexible and easier to maintain. For example, when you use packages, you do not need to bind the entire plan again when you change one SQL statement.

**Example:** The following figure shows an application plan that contains two packages. Suppose that you decide to change the SELECT statement in package AA to select data from a different table. In this case, you need to bind only package AA again and not package AB. 

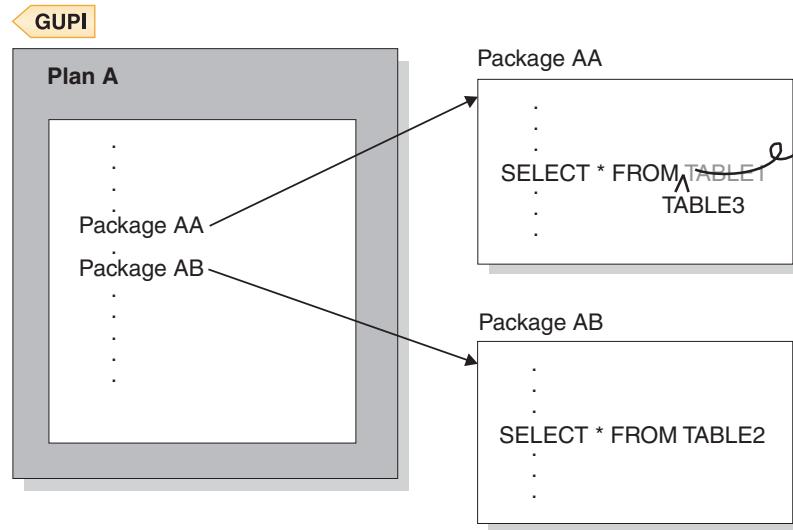

Figure 10. Application plan and packages

In general, you create plans and packages by using the DB2 commands BIND PLAN and BIND PACKAGE.

A *trigger package* is a special type of package that is created when you execute a CREATE TRIGGER statement. A trigger package executes only when the trigger with which it is associated is activated.

Packages for JDBC, SQLJ, and ODBC applications serve different purposes that you can read more about later in this information.

## Routines

A *routine* is an executable SQL object. The two types of routines are functions and stored procedures.

### Functions

A *function* is a routine that can be invoked from within other SQL statements and that returns a value or a table.

Functions are classified as either SQL functions or external functions. SQL functions are written using SQL statements, which are also known collectively as SQL procedural language. External functions reference a host language program. The host language program can contain SQL, but does not require SQL.

You define functions by using the CREATE FUNCTION statement. You can classify functions as built-in functions, user-defined functions, or cast functions that are generated for distinct types. Functions can also be classified as aggregate, scalar, or table functions, depending on the input data values and result values.

A *table function* can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table that is created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

## Stored procedures

A *procedure*, also known as a stored procedure, is a routine that you can call to perform operations that can include SQL statements.

Procedures are classified as either SQL procedures or external procedures. SQL procedures contain only SQL statements. External procedures reference a host language program that might or might not contain SQL statements.

DB2 for z/OS supports the following two types of SQL procedures:

### External SQL procedures

External SQL procedures are procedures whose body is written in SQL. DB2 supports them by generating an associated C program for each procedure. All SQL procedures that were created prior to Version 9.1 are external SQL procedures. Starting in Version 9.1, you can create an external SQL procedure by specifying FENCED or EXTERNAL in the CREATE PROCEDURE statement.

### Native SQL procedures

Native SQL procedures are procedures whose body is written in SQL. For native SQL procedures, DB2 does not generate an associated C program. Starting in Version 9.1, all SQL procedures that are created without the FENCED or EXTERNAL options in the CREATE PROCEDURE statement are native SQL procedures. You can create native SQL procedures in one step. Native SQL statements support more functions and usually provide better performance than external SQL statements.

SQL control statements are supported in SQL procedures. Control statements are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL procedures provide the same benefits as procedures in a host language. That is, a common piece of code needs to be written and maintained only once and can be called from several programs.

SQL procedures provide additional benefits when they contain SQL statements. In this case, SQL procedures can reduce or eliminate network delays that are associated with communication between the client and server and between each SQL statement. SQL procedures can improve security by providing a user the ability to invoke only a procedure instead of providing them with the ability to execute the SQL that the procedure contains.

You define procedures by using the CREATE PROCEDURE statement.

## Sequences

A *sequence* is a stored object that simply generates a sequence of numbers in a monotonically ascending (or descending) order. A sequence provides a way to have DB2 automatically generate unique integer primary keys and to coordinate keys across multiple rows and tables.

A sequence can be used to exploit parallelization, instead of programmatically generating unique numbers by locking the most recently used value and then incrementing it.

Sequences are ideally suited to the task of generating unique key values. One sequence can be used for many tables, or a separate sequence can be created for each table requiring generated keys. A sequence has the following properties:

- Guaranteed, unique values, assuming that the sequence is not reset and does not allow the values to cycle
- Monotonically increasing or decreasing values within a defined range
- Can increment with a value other than 1 between consecutive values (the default is 1).
- Recoverable. If DB2 should fail, the sequence is reconstructed from the logs so that DB2 guarantees that unique sequence values continue to be generated across a DB2 failure.

Values for a given sequence are automatically generated by DB2. Use of DB2 sequences avoids the performance bottleneck that results when an application implements sequences outside the database. The counter for the sequence is incremented (or decremented) independently of the transaction. In some cases, gaps can be introduced in a sequence. A gap can occur when a given transaction increments a sequence two times. The transaction might see a gap in the two numbers that are generated because there can be other transactions concurrently incrementing the same sequence. A user might not realize that other users are drawing from the same sequence. Furthermore, it is possible that a given sequence can appear to have generated gaps in the numbers, because a transaction that might have generated a sequence number might have rolled back or the DB2 subsystem might have failed. Updating a sequence is not part of a transaction's unit of recovery.

A sequence is created with a CREATE SEQUENCE statement. A sequence can be referenced using a *sequence-reference*. A sequence reference can appear most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value, or the previously generated value.

Although there are similarities, a sequence is different than an identity column. A sequence is an object, whereas an identity column is a part of a table. A sequence can be used with multiple tables, but an identity column is tied to a single table.

## User-defined types

A *user-defined type* is a data type that is defined to the database using a CREATE statement.

A *distinct type* is a user-defined type that shares its internal representation with a built-in data type (its source type), but is considered to be a separate and

incompatible data type for most operations. A distinct type is created with an SQL CREATE TYPE statement. A distinct type can be used to define a column of a table, or a parameter of a routine.

For more information, see “CREATE TYPE” on page 1177 and “Distinct types” on page 94.

## Distributed data

The database managers in a distributed relational database communicate and cooperate with each other in a way that allows a DB2 application program to use SQL to access data at any of the interconnected computer systems.

A *distributed relational database* consists of a set of tables and other objects that are spread across different, but interconnected, computer systems. Each computer system has a relational database manager, such as DB2, that manages the tables in its environment. The database managers communicate and cooperate with each other in a way that allows a DB2 application program to use SQL to access data at any of the computer systems. The DB2 subsystem where the application plan is bound is known as the *local DB2 subsystem*. Any database server other than the local DB2 subsystem is considered a *remote database server*, and access to its data is a distributed operation.

Distributed relational databases are built on formal requester-server protocols and functions. An *application requester* component supports the application end of a connection. It transforms an application's database request into communication protocols that are suitable for use in the distributed database network. These requests are received and processed by an *application server* component at the database server end of the connection. Working together, the application requester and application server handle the communication and location considerations so that the application is isolated from these considerations and can operate as if it were accessing a local database.

For more information on Distributed Relational Database Architecture<sup>TM</sup> (DRDA<sup>®</sup>) communication protocols, see *Open Group Technical Standard, DRDA Version 3 Vol. 1: Distributed Relational Database Architecture*.

## Connections

A *connection* is an association between an application process and a local or remote database server. Connections are managed by applications.

An application process must be connected to the application server facility of a database manager before SQL statements that reference tables or views can be executed. An application can use the CONNECT statement to establish a connection to a database server and make that database server the current server of the application process.

**Commit processing:** When DB2 for z/OS acts as a requester, it negotiates with the database server during the connection process to determine how to perform commits. If the remote server does not support two-phase commit protocol, DB2 downgrades to perform one-phase commits. Otherwise, DB2 always performs two-phase commits, which allow applications to update one or more databases in a single unit of work and are more reliable than one-phase commits. Two-phase commit is a two-step process:

1. First, all database managers involved in the same unit of work are pooled to determine whether they are ready to commit.
2. Then, if all database managers respond positively, they are directed to execute commit processing. If all database managers do not respond positively, they are directed to execute backout processing.

DB2 can also provide coordination for transactions that include both two-phase commit resources and one-phase commit resources. If an application has multiple connections to several different database servers, and if any of the connections are one-phase commit connections, then only one database that is involved in the transaction can be updated. The connections to all the other databases that are involved in the transaction are read-only.

**Supported SQL statements and clauses:** For the most part, an application can use the statements and clauses that are supported by the database manager of the current server, even though that application might be running via the application requester of a database manager that does not support some of those statements and clauses. Restrictions to this general rule for DB2 for z/OS are documented in *IBM DB2 SQL Reference for Cross-Platform Development*.

To execute a static SQL statement that references tables or views, the bound form of the statement is taken from a package that the database manager previously created through a bind operation or when a version of a native SQL procedure was defined.

## Distributed unit of work

The *distributed unit of work facility* provides for the remote preparation and execution of SQL statements.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server. Any number of database servers can participate in the same unit of work, and any number of connections can exist between an application process and a database server. A commit or rollback operation that does not specify a savepoint ends the unit of work.

## Connection management

How connections are managed depends on what states the SQL connection and the application process are in.

At any time:

- An SQL connection is in one of the following states:
  - Current and held
  - Current and release-pending
  - Dormant and held
  - Dormant and release-pending
- An application process is in the connected or unconnected state, and has a set of zero or more SQL connections. Each SQL connection is uniquely identified by the name of the database server at the other end of the connection. Only one SQL connection is active (current) at a time.

**Initial state of an application process:** An application process is initially in the connected state, and it has exactly one SQL connection. The server of that connection is the local DB2 subsystem.

**Initial state of an SQL connection:** An SQL connection is initially in the current and held state.

The following figure shows the state transitions:

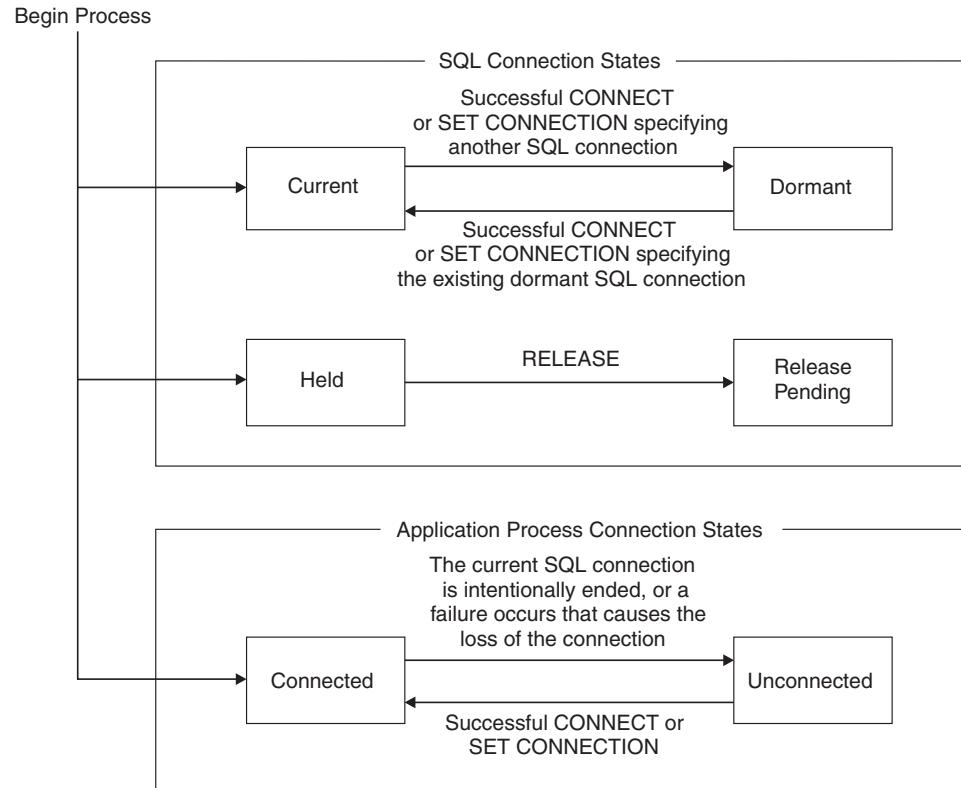

Figure 11. State transitions for an SQL connection and an application process connection in a distributed unit of work

## SQL connection states

If an application process successfully executes a CONNECT statement, the SQL connection states of the connections change.

If an application process successfully executes a CONNECT statement:

- The current connection is placed in the dormant and held state.
- The new connection is placed in the current and held state.
- The location name is added to the set of existing connections.

If the location name is already in the set of existing connections, an error is returned.

An SQL connection in the dormant state is placed in the current state using:

- The SET CONNECTION statement, or
- The CONNECT statement, if the SQLRULES(DB2) bind option is in effect.

When an SQL connection is placed in the current state, the previously-current SQL connection, if any, is placed in the dormant state. No more than one SQL

connection in the set of existing connections of an application process can be current at any time. Changing the state of an SQL connection from current to dormant or from dormant to current has no effect on its held or release-pending state.

An SQL connection is placed in the release-pending state by the RELEASE statement. When an application process executes a commit operation, every release-pending connection of the process is ended. Changing the state of an SQL connection from held to release-pending has no effect on its current or dormant state. Thus, an SQL connection in the release-pending state can still be used until the next commit operation. No way exists to change the state of a connection from release-pending to held.

## Application process connection states

In a distributed unit of work, an application process can be in a connected or unconnected state. Depending on the state, the application process can execute only certain SQL statements successfully.

A connection to a different database server can be established by the explicit or implicit execution of a CONNECT statement. The following rules apply:

- An application process cannot have more than one SQL connection to the same database server at the same time.
- When an application process executes a SET CONNECTION statement, the specified location name must be in the set of existing connections of the application process.
- When an application process executes a CONNECT statement and the SQLRULES(STD) bind option is in effect, the specified location must not be in the set of existing connections of the application process.

If an application process has a current SQL connection, the application process is in a *connected* state. The CURRENT SERVER special register contains the name of the database server of the current SQL connection. The application process can execute SQL statements that refer to objects managed by that server. If the server is a DB2 subsystem, the application process can also execute certain SQL statements that refer to objects managed by a DB2 subsystem with which that server can establish a connection.

An application process in an unconnected state enters a connected state when it successfully executes a CONNECT or SET CONNECTION statement.

If an application process does not have a current SQL connection, the application process is in an *unconnected* state. The CURRENT SERVER special register contains blanks. The only SQL statements that can be executed successfully are CONNECT, RELEASE, COMMIT, ROLLBACK, and any of the following local SET statements.

- SET CONNECTION
- SET CURRENT APPLICATION ENCODING SCHEME
- SET CURRENT PACKAGE PATH
- SET CURRENT PACKAGESET
- SET *host-variable* = CURRENT APPLICATION ENCODING SCHEME
- SET *host-variable* = CURRENT PACKAGESET
- SET *host-variable* = CURRENT SERVER

Because the application process is in an unconnected state, a COMMIT or ROLLBACK statement is processed by the local DB2 subsystem.

An application process in a connected state enters an unconnected state when its current SQL connection is intentionally ended, or the execution of an SQL statement is unsuccessful because of a failure that causes a rollback operation at the current server and loss of the SQL connection. SQL connections are intentionally ended when an application process successfully executes a commit operation and either of the following are true:

- The SQL connection is in the release-pending state.
- The SQL connection is not in the release-pending state, but it is a remote connection and either of the following are true:
  - The DISCONNECT(AUTOMATIC) bind option is in effect
  - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection

**An implicit CONNECT to a default DB2 subsystem is executed** when an application process executes an SQL statement other than COMMIT, CONNECT TO, CONNECT RESET, SET CONNECTION, RELEASE, or ROLLBACK, and if all of the following conditions apply:

- The CURRENTSERVER bind option was specified when creating the application plan of the application process and the identified server is not the local DB2.
- An explicit CONNECT statement has not already been successfully or unsuccessfully executed by the application process.
- An implicit connection has not already been successfully or unsuccessfully executed by the application process. An implicit connection occurs as the result of execution of an SQL statement that contains a three-part name in a package that is bound with the DBPROTOCOL(DRDA) option.

If the implicit CONNECT fails, the application process is placed in an *unconnected* state.

**When a connection is ended**, all resources that were acquired by the application process through the connection and all resources that were used to create and maintain the connection are returned to the connection pool. For example, if application process *P* placed the connection to application server *X* in the release-pending state, all cursors of *P* at *X* are closed and returned to the connection pool when the connection is ended during the next commit operation.

When a connection is ended as a result of a communications failure, the application process is placed in an unconnected state.

All connections of an application process are ended when the process ends.

## Remote unit of work

The *remote unit of work facility* also provides for the remote preparation and execution of SQL statements, but in a much more restricted fashion than the distributed unit of work facility.

An application process at computer system A can connect to a database server at computer system B and, within one or more units of work, execute any number of static or dynamic SQL statements that reference objects at B. All objects referenced in a single SQL statement must be managed by the same database server, and all SQL statements in the same unit of work must be executed by the same database server. However, unlike a distributed unit of work, an application process can have only one connection at a time. The process cannot connect to a new server until it

executes a commit or rollback operation on the current server to end that unit of work. This restricts the situations in which a CONNECT statement can be executed.

## Connection management

How connections are managed depends on what states the SQL connection and the application process are in.

An application process is in one of four states at any time:

- Connectable and connected
- Unconnectable and connected
- Connectable and unconnected
- Unconnectable and unconnected

**Initial state of an application process:** An application process is initially in the connectable and connected state. The database server to which the application process is connected is determined by a product-specific option that might involve an implicit CONNECT operation. An implicit connect operation cannot occur if an implicit or explicit connect operation has already successfully or unsuccessfully occurred. Thus, an application process cannot be implicitly connected to a database server more than once. Other rules for implicit connect operations are product-specific.

Figure 12 shows the state transitions:

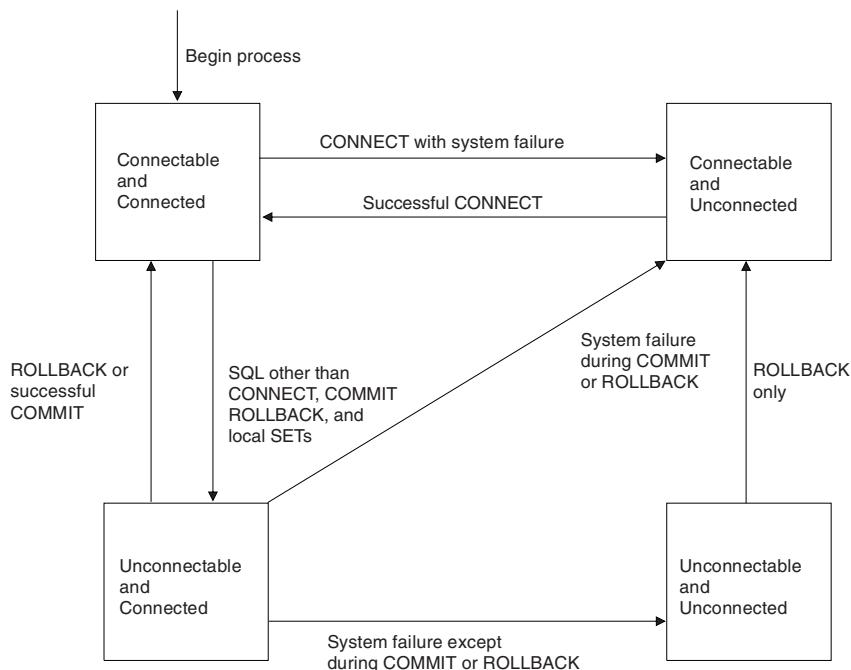

Figure 12. State transitions for an application process connection in a remote unit of work

In the following descriptions of application process connections, CONNECT can mean:

- CONNECT TO
- CONNECT RESET
- CONNECT *authorization*

It cannot mean CONNECT with no operand, which is used to return information about the current server.

Consecutive CONNECT statements can be executed successfully because CONNECT does not remove an application process from the connectable state. A CONNECT statement does not initiate a new unit of work; a unit of work is initiated by the first SQL statement that accesses data. CONNECT cannot execute successfully when it is preceded by any SQL statement other than CONNECT, COMMIT, RELEASE, ROLLBACK, or SET CONNECTION. To avoid an error, execute a commit or rollback operation before a CONNECT statement is executed.

**Connectable and connected state:** In the connectable and connected state, an application process is connected to a database server, and CONNECT statements that target the current server can be executed. An application process re-enters this state when either of the following is true:

- The process completes a rollback or a successful commit from an unconnectable and connected state.
- The process successfully executes a CONNECT statement from a connectable and unconnected state.

**Unconnectable and connected state:** In the unconnectable and connected state, an application process is connected to a database server, and only a CONNECT statement with no operands can be executed. An application process enters this state from a connectable and connected state when it executes any SQL statement other than CONNECT, COMMIT, or ROLLBACK.

**Connectable and unconnected state:** In the connectable and unconnected state, an application process is not connected to a database server. The only SQL statement that can be executed is CONNECT. An application process enters this state if any of the following is true:

- The process does not successfully execute a CONNECT statement from a connectable and connected state.
- The process executes a COMMIT statement when the SQL connection is in a release-pending state.
- A system failure occurs during a COMMIT or ROLLBACK from an unconnectable and connected state.
- The process executes a ROLLBACK statement from an unconnectable and unconnected state.

Other product-specific reasons can also cause an application process to enter the connectable and unconnected state.

**Unconnectable and unconnected state:** In the unconnectable and unconnected state, an application process is not connected to a database server and CONNECT statements cannot be executed. The only SQL statement that can be executed is ROLLBACK. An application process enters this state from an unconnectable and connected state as a result of a system failure, except during a COMMIT or ROLLBACK, at the server.

## Character conversion

A *string* is a sequence of bytes that can represent characters. Within a string, all the characters are represented by a common encoding representation. In some cases, it might be necessary to convert these characters to a different encoding representation. The process of conversion is known as *character conversion*.

Character conversion, when required, is automatic, and when successful, it is transparent to the application.

In client/server environments, character conversion can occur when an SQL statement is executed remotely. Consider, for example, the following two cases. In either case, the data could have a different representation at the sending and receiving systems.

- The values of data sent from the requester to the current server
- The values of data sent from the current server to the requester

Conversion can also occur during string operations on the same system, as in the following examples:

- An overriding CCSID is specified.

For example, an SQL statement with a descriptor, which requires an SQLDA. In the SQLDA, the CCSID is in the SQLNAME field for languages other than REXX, and in the SQLCCSID field for REXX. (For more information, see “SQL descriptor area (SQLDA)” on page 1656). A DECLARE VARIABLE statement can also be issued to associate a CCSID with the host variables into which data is retrieved from a table.

- The value of the ENCODING bind option or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure (static SQL statements) or the CURRENT APPLICATION ENCODING SCHEME special register (for dynamic SQL) is different than encoding scheme of the data being retrieved.
- A mixed character string is assigned to an SBCS column or host variable.
- An SQL statement refers to data that is defined with different CCSIDs.

The text of an SQL statement is also subject to character conversion because it is a character string.

The following list defines some of the terms used for character conversion.

**ASCII** Acronym for American Standard Code for Information Interchange, an encoding scheme used to represent characters. The term ASCII is used throughout this information to refer to IBM-PC Data or ISO 8-bit data.

### character set

A defined set of characters, a character being the smallest component of written language that has semantic value. For example, the following character set appears in several code pages:

- 26 nonaccented letters A through Z
- 26 nonaccented letters a through z
- digits 0 through 9
- . , : ; ? ( ) ' " / - \_ & + % \* = < >

### code page

A set of assignments of characters to code points. For example, in EBCDIC, “A” is assigned code point X'C1', and “B” is assigned code point X'C2'. In

Unicode UTF-8, "A" is assigned code point X'41', and "B" is assigned code point X'42'. Within a code page, each code point has only one specific meaning.

#### **code point**

A unique bit pattern that represents a character. It is a numerical index or position in an encoding table used for encoding characters.

#### **coded character set**

A set of unambiguous rules that establishes a character set and the one-to-one relationships between the characters of the set and their coded representations. It is the assignment of each character in a character set to a unique numeric code value.

#### **coded character set identifier (CCSID)**

A two-byte, unsigned binary integer that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

#### **EBCDIC**

Acronym for Extended Binary-Coded Decimal Interchange Code, an encoding scheme used to represent character data, a group of coded character sets that consist of 8 bit coded characters. EBCDIC coded character sets use the first 64 code positions (X'00' to X'3F') for control codes. The range X'41' to X'FE' is used for single-byte characters. For double-byte characters, the first byte is in the range X'41' to X'FE' and the second byte is also in the range X'41' to X'FE', while X'4040' represents a double-byte space.

#### **encoding scheme**

A set of rules used to represent character data. All string data stored in a table must use the same encoding scheme and all tables within a table space must use the same encoding scheme, except for global temporary tables, declared temporary tables, and work file table spaces. DB2 supports these encoding schemes:

- ASCII
- EBCDIC
- Unicode

#### **substitution character**

A unique character that is substituted during character conversion for any characters in the source encoding representation that do not have a match in the target encoding representation.

#### **Unicode**

A universal encoding scheme for written characters and text that enables the exchange of data internationally. It provides a character set standard that can be used all over the world. It provides the ability to encode all characters used for the written languages of the world and treats alphabetic characters, ideographic characters, and symbols equivalently because it specifies a numeric value and a name for each of its characters. It includes punctuation marks, mathematical symbols, technical symbols, geometric shapes, and dingbats. DB2 supports these two encoding forms:

- UTF-8: Unicode Transformation Format, a 8 bit encoding form designed for ease of use with existing ASCII-based systems. UTF-8 can encode any of the Unicode characters. A UTF-8 character is 1,2,3, or 4 bytes in length. A UTF-8 data string can contain any combination of SBCS and MBCS data, including supplementary characters. The CCSID value for data in UTF-8 format is 1208.

|

- UTF-16: Unicode Transformation Format, a 16 bit encoding form designed to provide code values for over a million characters and a superset of UCS-2. UTF-16 can encode any of the Unicode characters. In UTF-16 encoding, characters are 2 bytes in length, except for supplementary characters, which take two 2 byte string units per character. The CCSID value for data in UTF-16 format is 1200.

Character data (CHAR, VARCHAR, and CLOB) is encoded in Unicode UTF-8. Character strings are also used for mixed data (that is a mixture of single-byte characters and multi-byte characters) and for data that is not associated with any character set (called bit data). Graphic data (GRAPHIC, VARGRAPHIC, and DBCLOB) is encoded in Unicode UTF-16. For a comparison of some UTF-8 and UTF-16 code points for some sample characters, see Figure 15 on page 42. This table shows how a UTF-8 character can be 1 to 4 bytes in length, a non-supplementary UTF-16 character is 2 bytes in length, and how a supplementary character in either UTF-8 or UTF-16 takes two 2 byte code points.

Character conversion can affect the results of several SQL operations. In this information, the effects are described in:

["Conversion rules for string assignment" on page 111](#)

["Conversion rules for operations that combine strings" on page 122](#)

["Character conversion in set operations and concatenations" on page 666](#)

## Character sets and code pages

Even with the same encoding scheme, different CCSIDs exist, and the same code point can represent a different character in different CCSIDs. Furthermore, a byte in a character string does not necessarily represent a character from a single-byte character set (SBCS).

The following figure shows how a typical character set might map to different code points in two different code pages.

code page: pp1 (ASCII)

	0	1	2	3	4	5		E	F
0				0	@	P		Å	
1				1	A	Q		À	α
2			†	2	B	R		Å	β
3				3	C	S		Á	γ
4				4	D	T		Ā	σ
5			%	5	E	U		Ä	ε
E			.	>	N			¼	Ö
F			/	*	O			®	

code point: 2F

character set ss1  
(in code page pp1)

code page: pp2 (EBCDIC)

	0	1		A	B	C	D	E	F
0				#					0
1				\$	A	J			1
2				s	%	B	K	S	2
3				t	—	C	L	T	3
4				u	*	D	M	U	4
5				v	(	E	N	V	5
E				!	:	Å		}	
F				À	¢	;	Á	{	

character set ss1  
(in code page pp2)

Figure 13. Code page mappings for character set ss1 in ASCII and EBCDIC

For Unicode, there is only one CCSID for UTF-8 and only one CCSID for UTF-16. The following figure shows how the first 127 single code points for UTF-8 are the same as ASCII with a CCSID of 367. For example, in both UTF-8 and ASCII CCSID 367, an A is X'41' and a 1 is X'31'.

## First 127 code points for UTF-8 code page

	0	1	2	3	4	5	6	7
0			(SP)	0	@	P	`	p
1			!	1	A	Q	a	q
2			"	2	B	R	b	r
3			#	3	C	S	c	s
4			\$	4	D	T	d	t
5			%	5	E	U	e	u
6			&	6	F	V	f	v
7			'	7	G	W	g	w
8			(	8	H	X	h	x
9			)	9	I	Y	i	y
A			*	:	J	Z	j	z
B			+	;	K	[	k	{

D			-	=	M	]	m	}
E			.	>	N	^	n	~
F			/	?	O	_	o	

code point: 2F

Figure 14. Code point mapping for the first 127 code points for UTF-8 single-byte characters (CCSID 1208)

The following figure shows a comparison of how some UTF-16 and UTF-8 code points map to some sample characters. The character for the eighth note musical symbol takes two 2 byte code points because it is a supplementary character.

Character glyph	UTF-8 code point	UTF-16 code point
M	4D	004D
Ä	C384	00C4
☰	E4BA8B	4E8B
♪	F09D85A0	D834DD60

Figure 15. A comparison of how some UTF-8 and UTF-16 code points map to some sample characters

Character encoding for IBM systems is described in *Character Data Representation Architecture Reference and Registry*. For more information on Unicode, see the Unicode standards web site at <http://www.unicode.org>.

## Coded character sets and CCSIDs

IBM's character data representation architecture (CDRA) deals with the differences in string representation and encoding. The *Coded Character Set Identifier (CCSID)* is a key element of this architecture. A CCSID is a 2 byte (unsigned) binary number that uniquely identifies an encoding scheme and one or more pairs of character sets and code pages.

A CCSID is an attribute of strings, just as length is an attribute of strings. All values of the same string column have the same CCSID.

Character conversion is described in terms of CCSIDs of the source and target. With DB2 for z/OS, two methods are used to identify valid source and target combinations and to perform the conversion from one coded character set to another:

- DB2 catalog table SYSIBM.SYSSTRINGS

Each row in the catalog table describes a conversion from one coded character set to another.

- z/OS support for Unicode

For more information about the conversion services that are provided, including a complete list of the IBM-supplied conversion tables, see *z/OS Support for Unicode: Using Conversion Services*.

In some cases, no conversion is necessary even though the strings involved have different CCSIDs.

Different types of conversions might be supported by each database manager. Round-trip conversions attempt to preserve characters in one CCSID that are not defined in the target CCSID so that if the data is subsequently converted back to the original CCSID, the same original characters result. Enforced subset match conversions do not attempt to preserve such characters. Which type of conversion is used for a specific source and target CCSID is product-specific.

For more information on character conversion, see *DB2 Installation Guide*.

## Determining the encoding scheme and CCSID of a string

An encoding scheme and a CCSID are attributes of strings, just as length is an attribute of strings. All values of the same string column have the same encoding scheme and CCSID.

Every string has an encoding scheme and a CCSID that identifies the manner in which the characters in the string are encoded. Strings can be encoded in ASCII, EBCDIC, or Unicode.

The CCSID that is associated with a string value depends on the SQL statement in which the data is referenced and the type of expression. Table 4 on page 44 describes the rules for determining the CCSID that is associated with a string value. Use the Type 1 rules when the SQL statement meets the following conditions:

- The SQL statement operates with a single set of CCSIDs (SBCS, mixed, and graphic). An SQL statement that does not contain any of the following items operates with a single set of CCSIDs:
  - References to columns from multiple tables or views that are defined with CCSIDs from more than one set of CCSIDs (SBCS, mixed, and graphic)

- Graphic hexadecimal (GX) or hexadecimal Unicode (UX) string constants
- References to the XMLCLOB built-in function
- Cast specifications with a CCSID clause
- User-defined table functions
- The SQL statement is not one of the following statements:
  - CALL statement
  - SET assignment statement
  - SET special register
  - VALUE statement
  - VALUES INTO statement

Use the Type 2 rules when the statement does not meet the conditions for Type 1 rules.

*Table 4. Rules for determining the CCSID that is associated with string data*

Source of the string data	Type 1 rules	Type 2 rules
String constant	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant.  Otherwise, the default EBCDIC encoding scheme is used for the string constant.  The CCSID is the appropriate character string CCSID for the encoding scheme.	The CCSID is the appropriate character string CCSID for the application encoding scheme. <sup>1</sup>
Hexadecimal string constant (X'...')	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the string constant.  Otherwise, the default EBCDIC encoding scheme is used for the string constant.  The CCSID is the appropriate graphic string CCSID for the encoding scheme.	The CCSID is the appropriate character string CCSID for the application encoding scheme. <sup>1</sup>
Graphic string constant (G'...')	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the graphic string constant.  Otherwise, the default EBCDIC encoding scheme is used for the graphic string constant.  The CCSID is the graphic string CCSID for the encoding scheme.	The CCSID is the graphic string CCSID for the application encoding scheme. <sup>1</sup>
Graphic hexadecimal constant (GX'...')	Not applicable.	The CCSID is the graphic string CCSID for the application encoding scheme, which must be ASCII or EBCDIC.
Hexadecimal Unicode string constant (UX'....')	Not applicable.	The CCSID is 1200 (UTF-16).

*Table 4. Rules for determining the CCSID that is associated with string data (continued)*

Source of the string data	Type 1 rules	Type 2 rules
Special register	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the special register.  Otherwise, the default EBCDIC encoding scheme is used for the special register.  The CCSID is the appropriate character string CCSID for the encoding scheme.	The CCSID is the appropriate CCSID for the application encoding scheme. <sup>1</sup>
Column of a table	The CCSID is the CCSID that is associated with the column of the table.	The CCSID is the CCSID that is associated with the column of the table.
Column of a view	The CCSID is the CCSID of the column of the result table of the fullselect of the view definition.	The CCSID is the CCSID of the column of the result table of the fullselect of the view definition.
Expression	The CCSID is the CCSID of the result of the expression.	The CCSID is the CCSID of the result of the expression.
Result of a built-in function	If the description of the function, in Chapter 3, "Functions," on page 259, indicates what the CCSID of the result is, the CCSID is that CCSID.  Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the CCSID set that is used by the statement for the data type of the result.	If the description of the function, in Chapter 3, "Functions," on page 259, indicates what the CCSID of the result is, the CCSID is that CCSID.  Otherwise, if the description of the function refers to this table for the CCSID, the CCSID is the appropriate CCSID of the application encoding scheme for the data type of the result. <sup>1</sup>
Parameter of a user-defined routine	The CCSID is the CCSID that was determined when the function or procedure was created.	The CCSID is the CCSID that was determined when the function or procedure was created.
The expression in the RETURN statement of a CREATE statement for a user-defined SQL scalar function	If the expression in the RETURN statement is string data, the encoding scheme is the same as for the parameters of the function. The CCSID is determined from the encoding scheme and the attributes of the data.	The CCSID is determined from the CCSID of the result of the expression specified in the RETURN statement.
String host variable	If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the host variable.  Otherwise, the default EBCDIC encoding scheme is used for the host variable.  The CCSID is the appropriate CCSID for the data type of the host variable.	At package prepare time, the CCSID is the appropriate CCSID for the data type of the host variable for the application encoding scheme.  At run time, the CCSID specified in the declare variable statement, or as an override in the SQLDA. Otherwise, the CCSID is the appropriate CCSID for the data type of the host variable for the application encoding scheme.

**Note:** If the context is within a check constraint or trigger package, the CCSID is the appropriate CCSID for Unicode instead of the application encoding scheme.

The following examples show how these rules are applied.

*Example 1:* Assume that the default encoding scheme for the installation is EBCDIC and that the installation does not support mixed and graphic data. The following

statement conforms to the rules for Type 1 in Table 4 on page 44. Therefore, the X'40' is interpreted as EBCDIC SBCS data because the statement references a table that is in EBCDIC. The CCSID for X'40' is the default EBCDIC SBCS CCSID for the installation.

```
SELECT * FROM EBCDIC_TABLE WHERE COL1 = X'40';
```

the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank.

*Example 2:* The following statement references data from two different tables that use different encoding schemes. This statement does not conform to the rules for Type 1 statements in Table 4 on page 44. Therefore, the rules for Type 2 statements are used. The CCSID for X'40' is dependent on the current application encoding scheme. Assuming that the current application encoding scheme is EBCDIC, X'40' represents a single EBCDIC blank.

```
SELECT * FROM EBCDIC_TABLE, UNICODE_TABLE WHERE COL1 = X'40';
```

as with Example 1, the result of the query includes each row that has a value in column COL1 that is equal to a single EBCDIC blank. If the current application encoding scheme were ASCII or Unicode, X'40' would represent something different and the results of the query would be different.

## Expanding conversions

An *expanding conversion* occurs when the length of the converted string is greater than that of the source string.

For example, an expanding conversion occurs when an ASCII mixed data string that contains DBCS characters is converted to EBCDIC mixed data. To prevent the loss of data on expanding conversions, use a varying-length string variable with a maximum length that is sufficient to contain the expansion.

Expanding conversions also can occur when string data is converted to or from Unicode. It can also occur between UTF-8 and UTF-16, depending on the data being converted. UTF-8 uses 1, 2, 3, or 4 bytes per character. UTF-16 uses 2 bytes per character, except for supplementary characters, which use two 2 byte code points for each character. If UTF-8 were being converted to UTF-16, a 1 byte character would be expanded to 2 bytes.

## Contracting conversions

A *contracting conversion* occurs when the length of the converted string is smaller than that of the source string.

For example, a contracting conversion occurs when an EBCDIC mixed data string that contains DBCS characters is converted to ASCII mixed data due to the removal of shift codes.

Contracting conversions also can occur when string data is converted to or from Unicode data. It can also occur between UTF-8 and UTF-16, depending on the data being converted.

---

## Chapter 2. Language elements

An understanding of the basic syntax of SQL and language elements that are common to many SQL statements can be helpful in using SQL with DB2 for z/OS.

The following topics provide information about these language elements:

- “Characters”
- “Tokens” on page 48
- “Identifiers” on page 49
- “Naming conventions” on page 51
- “SQL path” on page 56
- “Qualification of unqualified object names” on page 57
- “Aliases and synonyms” on page 59
- “Authorization IDs, roles, and authorization names” on page 62
- “Data types” on page 69
- “Promotion of data types” on page 95
- “Casting between data types” on page 96
- “Assignment and comparison” on page 102
- “Rules for result data types” on page 119
- “Constants” on page 126
- “Special registers” on page 131
- “Column names” on page 153
- “References to variables” on page 159
- “Host structures in PL/I, C, and COBOL” on page 171
- “Host-variable-arrays in PL/I, C, C++, and COBOL” on page 172
- “Functions” on page 173
- “Expressions” on page 180
- “Predicates” on page 222
- “Search conditions” on page 247
- “Options affecting SQL” on page 248
- “Mappings from SQL to XML” on page 257

---

### Characters

The basic symbols of keywords and operators in the SQL language are *characters* that are classified as letters, digits, or special characters.

- A *letter* is any of the 26 uppercase (A through Z) and 26 lowercase (a through z) letters of the English alphabet.<sup>1</sup>
- A *digit* is any one of the characters 0 through 9.
- A *special character* is any character other than a letter or a digit.

---

1. Letters also include three code points reserved as alphabetic extenders for national languages (\$, #, and @ in the United States). These three code points (X'5B', X'7B', and X'7C') should be avoided because they represent different characters depending on the CCSID.

## Tokens

The basic syntactical units of the SQL language are called *tokens*. A token consists of one or more characters of which none are blanks, control characters, or characters within a string constant or delimited identifier.

Tokens are classified as *ordinary* or *delimiter* tokens:

- An *ordinary token* is a numeric constant, an ordinary identifier, a host identifier, or a keyword.

*Examples:*

1 .1 +2 SELECT E 3

- A *delimiter token* is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark (?) is also a delimiter token when it serves as a parameter marker, as explained in "PREPARE" on page 1405.

*Examples:*

, 'string' "fld1" = .

**Spaces:** A space is a sequence of one or more blank characters.

**Control characters:** A *control character* is a special character that is used for string alignment. Treated similar to a space, a control character does not cause a particular action to occur. The following table shows the control characters that DB2 recognizes and their hexadecimal values.

In an SQL procedure, a *new line control character* is a special character that is used for a new line. The carriage return, new line or next line, and line feed (new line) characters, or the combination of carriage return followed by new line characters, and the combination of carriage return followed by line feed characters, as shown in the following table, are the new line control characters for SQL procedures.

*Table 5. Hexadecimal values for the control characters that DB2 recognizes*

Control character	EBCDIC hex value	Unicode hex value
Tab	05	09
Form feed	0C	0C
Carriage return	0D	0D
New line or next line	15	C285
Line feed (new line)	25	0A

Tokens, other than string constants and certain delimited identifiers, must not include a control character or space. A control character or space can follow a token. A delimiter token, control character, or a space must follow every ordinary token. If the syntax does not allow a delimiter token to follow an ordinary token, a control character or a space must follow that ordinary token.

**Comments:** Dynamic SQL statements can include SQL comments. Static SQL statements can include host language comments or SQL comments. Comments can be specified wherever a space can be specified, except within a delimiter token or between the keywords EXEC and SQL. In Java, SQL comments are not allowed within embedded Java expressions. There are two types of SQL comments:

### simple comments

Simple comments are introduced with two consecutive hyphens (--) .

Simple comments cannot continue past the end of the line. For additional information, see “SQL comments” on page 695.

#### **bracketed comments**

Bracketed comments are introduced with /\* and end with \*/. A bracketed comment can continue past the end of the line. For additional information, see “SQL comments” on page 695.

**Uppercase and lowercase:** A token in an SQL statement can include lowercase letters, but lowercase letters in an ordinary token are folded to uppercase. However, lowercase letters are folded to uppercase in a C or Java program only if the appropriate precompiler option is specified. Delimiter tokens are never folded to uppercase.

*Example:* The following two statements, after folding, are equivalent:

```
select * from DSN8910.EMP where lastname = 'Smith';
SELECT * FROM DSN8910.EMP WHERE LASTNAME = 'Smith';
```

---

## **Identifiers**

An *identifier* is a token used to form a name. An identifier in an SQL statement is an SQL identifier or a host identifier.

See “Limits in DB2 for z/OS” on page 1588 for the identifier length limits that DB2 imposes.

### **SQL identifiers**

SQL identifiers can be *ordinary identifiers* or *delimited identifiers*.

#### **Ordinary identifiers**

An *ordinary identifier* is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character.

An ordinary identifier should not be a reserved word. If a reserved word is used as an identifier in SQL, it must be specified in uppercase and must be a delimited identifier or specified in a host variable. For a list of reserved words, see “Reserved schema names and reserved words” on page 1594.

SQL ordinary identifiers can contain DBCS characters unless otherwise specified. However, an SQL ordinary identifier cannot contain a mixture of SBCS and DBCS characters.

The following list shows the rules for forming SQL ordinary identifiers:

- The UTF-8 representation of the name must not exceed 128 bytes.
- Continuation to the next line is not allowed.

If the SQL ordinary identifier contains DBCS characters, the following additional rules apply:

- The identifier, if encoded in EBCDIC, must start with a shift-out (X'0E') and end with a shift-in (X'0F'). There must be an even number of bytes between the shift-out and the shift-in. An odd-numbered byte between those shifts must not be a shift-out. DBCS blanks (X'4040' in EBCDIC) are not acceptable between the shift-out and the shift-in.
- The identifiers are not folded to uppercase or changed in any other way.

*Example:* The following example is an ordinary identifier:

SALARY

### Delimited identifiers

A *delimited identifier* is a sequence of one or more characters enclosed within escape characters.

The escape character is the quotation mark (")<sup>2</sup> except for:

- Dynamic SQL when the field SQL STRING DELIMITER on installation panel DSNTIPF is set to the quotation mark ("") and either of these conditions is true:
  - DYNAMICRULES run behavior applies. For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.
  - DYNAMICRULES bind, define, or invoke behavior applies and installation panel field USE FOR DYNAMIC RULES is YES.

In this case, the escape character is the apostrophe (').

However, for COBOL application programs, if DYNAMICRULES run behavior does not apply and installation panel field USE FOR DYNAMICRULES is NO, a COBOL compiler option specifies whether the escape character is the quotation mark or apostrophe.

- Static SQL in COBOL application programs. A COBOL compiler option specifies whether the escape character is the quotation mark ("") or the apostrophe (').

A delimited identifier can be used when the sequence of characters does not qualify as an ordinary identifier. Such a sequence, for example, could be an SQL reserved word, or it could begin with a digit. Two consecutive escape characters are used to represent one escape character within the delimited identifier. A delimited identifier that contains EBCDIC DBCS characters also must contain the necessary shift characters.

Leading and embedded blanks in the sequence are significant. Trailing blanks in the sequence are not significant. The length of a delimited identifier does not include the starting and ending escape characters. Embedded escape characters (that appear as two characters) are counted in the length as a single character.

*Example:* If the escape character is the quotation mark, the following example is a delimited identifier:

"VIEW"

### Host identifiers

A *host identifier* is a name declared in the host program.

The rules for forming a host identifier are the rules of the host language. In non-Java programs, do not use names beginning with 'DB2', 'SQ'<sup>3</sup>, 'SQL', 'sql', 'RDI', or 'DSN' because precompilers generate host variable names that begin with these characters. In Java, do not use names beginning with '\_\_sJT\_\_'.

---

2. In CCSID 1026 and CCSID 1155, the code point for the quotation mark can be X'7F' or X'FC'. However, if the beginning delimiter is X'7F', the ending delimiter must also be X'7F'. If the beginning delimiter is X'FC', ending delimiter must also be X'FC'.

3. 'SQ' is allowed in C, COBOL, and REXX.

## Restrictions for distributed access

To use certain identifiers in distributed access, those identifiers need to be restricted to certain characters.

DB2's internal processing of distributed access must sometimes convert the identifiers for *authorization-name*, *procedure-name*, and *schema-name* between CCSIDs. If there is any possibility that these identifiers will be used in distributed access, restrict the identifiers to characters whose representation in Unicode UTF-8 have code points in the range 0 through 127. You do not need to enter the identifiers in Unicode; this restriction refers to conversion that DB2 performs internally.

---

## Naming conventions

The rules for forming a name depend on the type of the object designated by the name.

The syntax diagrams use different terms for different types of names. The following list defines these terms.

### **alias-name**

A qualified or unqualified name that designates an alias, table, or view. The unqualified form of *alias-name* is an SQL identifier. An unqualified *alias-name* in an SQL statement is implicitly qualified by the default schema. The qualified form is a *schema-name* followed by a period and an SQL identifier.

See “Aliases and synonyms” on page 59 for additional information about aliases.

### **authorization-name**

An SQL identifier that designates a set of privileges. It can also designate a user, a group of users, or a role. For a user or a group of users, DB2 does not control this property. For a role, DB2 does control this property. See “Authorization IDs, roles, and authorization names” on page 62 for the distinction between an authorization name and an authorization ID.

### **aux-table-name**

A qualified or unqualified name that designates an auxiliary table. The rules for the name are the same as the rules for *table-name*. See *table-name*.

### **bpname**

A name that identifies a buffer pool. The following list shows the names of the different buffer pool sizes.

**4KB** BP0, BP1, BP2, ..., BP49

**8KB** BP8K0, BP8K1, BP8K2, ..., BP8K9

**16KB** BP16K0, BP16K1, BP16K2, ..., BP16K9

**32KB** BP32K, BP32K1, BP32K2, ..., BP32K9

### **built-in-type**

A qualified or unqualified name that identifies an IBM-supplied data type. A qualified name is SYSIBM followed by a period and the name of the built-in data type. An unqualified name has an implicit qualifier, the schema name, which is determined by the rules in “Qualification of unqualified object names” on page 57.

### **catalog-name**

An SQL identifier that designates an integrated catalog facility catalog. The identifier must start with a letter and must not include special characters.

<b>clone-table-name</b>	A qualified or unqualified name that designates the name of a clone table. See the definition of <i>table-name</i> for more information about qualification of table names.
<b>collection-id</b>	An SQL identifier that identifies a collection of packages, such as a collection ID as a qualifier for a package ID. Refer to <i>DB2 Command Reference</i> for naming conventions.
<b>column-name</b>	A qualified or unqualified name that designates a column of a table or view.  A qualified column name is a qualifier followed by a period and an SQL identifier. The qualifier is a table name, a view name, a synonym, an alias, or a correlation name. The unqualified column name is an SQL identifier.
<b>constraint-name</b>	An SQL identifier that designates a primary key, check, referential, or unique constraint on a table.
<b>correlation-name</b>	An SQL identifier that designates a table, a view, or individual rows of a table or view.
<b>context-name</b>	An unqualified SQL identifier that designates a trusted context.
<b>cursor-name</b>	An SQL identifier that designates an SQL cursor. In SQLJ, <i>cursor-name</i> is a host variable (with no indicator variable) that identifies an instance of an iterator.
<b>database-name</b>	An SQL identifier that designates a database. The identifier must start with a letter and must not include special characters.
<b>descriptor-name</b>	A host identifier that designates an SQL descriptor area (SQLDA). See “References to host variables” on page 160 for a description of a host identifier. A descriptor name never includes an indicator variable.
<b>distinct-type-name</b>	A qualified or unqualified name that designates a distinct type.  A qualified distinct type name is a two-part name. The first part is the schema name of the distinct type. The second part is an SQL identifier. A period must separate each of the parts.  An unqualified distinct type name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the distinct type appears as described by the rules in “Qualification of unqualified object names” on page 57.
<b>external-program-name</b>	A name that specifies the program that runs when the function is invoked or the procedure name is specified in a CALL statement.
<b>function-name</b>	A qualified or unqualified name that designates a user-defined function, a cast function that was generated when a distinct type was created, or a built-in function.

A qualified function name is a two-part name. The first part is the schema name of the function. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified function name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

**host-label**

A token that designates a label in a host program.

**host-variable**

A sequence of tokens that designates a host variable. A host variable includes at least one host identifier, as explained in “References to host variables” on page 160.

**index-name**

A qualified or unqualified name that designates an index.

A qualified index name is an authorization ID or schema name followed by a period and an SQL identifier.

An unqualified index name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

For an index on a declared temporary table, the qualifier must be SESSION.

**label**

An SQL identifier that designates a label in an SQL procedure. A label must not be a delimited identifier that includes lowercase letters or special characters.

**location-name**

An SQL identifier that designates the name of a location. A location name is 1 to 16 bytes, does not include alphabetic extenders, lowercase letters, or Katakana characters. The characters allowed in the delimited form are the same as those allowed in the ordinary form.

**package-name**

A qualified or unqualified name that designates a package. The unqualified form of a *package-name* is an SQL identifier. A *package-name* must not be a delimited identifier that includes lowercase letters or special characters. A *package-name* in an SQL statement must be qualified. In some contexts outside of SQL, a package name can be specified as an unqualified name.

**parameter-name**

An SQL identifier that designates a parameter in a procedure or function. A *parameter-name* in an SQL procedure must not be SQLCODE or SQLSTATE.

**plan-name**

An SQL identifier that designates an application plan. The identifier must not be a delimited identifier that includes lowercase letters or special characters.

**procedure-name**

A qualified or unqualified name that designates a stored procedure.

A fully qualified procedure name is a three-part name. The first part is a location name that identifies the DBMS at which the procedure is stored.

The second part is the schema name of the stored procedure. The third part is an SQL identifier. A period must separate each of the parts in a qualified name.

A two-part procedure name is implicitly qualified with the location name of the current server. The first part is the schema name of the stored procedure. The second part is an SQL identifier. A period must separate the two parts.

A one part, or unqualified, procedure name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears, as described by the rules in “Qualification of unqualified object names” on page 57.

The SQL identifier in a qualified or unqualified name must not be an asterisk (\*).

| **profile-name**

| An SQL identifier that corresponds to a RACF profile name.

| **program-name**

| An SQL identifier that designates an exit routine.

| **role-name**

| An unqualified SQL identifier that designates a role. The identifier cannot be SYSADM, SYSCTRL, or PUBLIC.

| **routine-version-id**

| An SQL identifier of up to 64 EBCDIC bytes that designates a version of a routine. The UTF-8 representation of the name must not exceed 122 bytes.

| **savepoint-name**

| An unqualified SQL identifier that designates a savepoint.

| **schema-name**

| An SQL identifier that provides a logical grouping for SQL objects. A *schema-name* is used as a qualifier of the name of SQL objects.

| **seclabel-name**

| A string that corresponds to the value of the RACF security label. It is recommended that name not include national characters (@ (X'7C'), # (X'7B'), or \$ (X'5B')), as an error can occur for some conversions from Unicode.

| **sequence-name**

| A qualified or unqualified name that designates a sequence.

| A qualified sequence name is a two-part name. The first part is the schema name. The second part is an SQL identifier. A period must separate each of the parts.

| A one-part or unqualified sequence name is an SQL identifier with an implicit qualifier. The implicit qualifier is an authorization ID, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

| **server-name**

| An SQL identifier that designates an application server. The identifier must start with a letter and must not include lowercase letters or special characters.

**specific-name**

A qualified or unqualified name that designates a unique name for a user-defined function.

A qualified specific name is a two-part name. The first part is the schema name. The second part is an SQL identifier, and it must not be an asterisk (\*). A period must separate each of the parts.

An unqualified specific name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

A specific name can be used to identify a function to alter, comment on, drop, grant privileges on, revoke privileges from, or be the source function for another function. A specific name cannot be used to invoke a function. In addition to being used in certain SQL statements, a specific name must be used in DB2 commands to uniquely identify a function.

**SQL-condition-name**

An SQL identifier that designates a condition in an SQL procedure.

**SQL-label**

An SQL identifier that designates a label in an SQL procedure.

**SQL-parameter-name**

A qualified or unqualified name that designates a parameter in the SQL routine body of an SQL function or SQL procedure. The unqualified form of an *SQL-parameter-name* is an SQL identifier. The qualified form is a *function-name* or *procedure-name* followed by a period and an SQL identifier.

**SQL-variable-name**

A qualified or unqualified name that designates a variable in an SQL routine body. The unqualified form of an *SQL-variable-name* is an SQL identifier. The qualified form is a *function-name* or *procedure-name* followed by a period and an SQL identifier.

**statement-name**

An SQL identifier that designates a prepared SQL statement.

**stogroup-name**

An SQL identifier that designates a storage group.

**synonym**

An SQL identifier that designates a synonym, a table, or a view. The table or view must exist at the current server. A qualified name is never interpreted as a synonym.

See “Aliases and synonyms” on page 59 for additional information about synonyms.

**table-name**

A qualified or unqualified name that designates a table.

A fully qualified table name is a three-part name. The first part is a location name that designates the DBMS at which the table is stored. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part table name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified table name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the rules set forth in “Qualification of unqualified object names” on page 57. For a declared temporary table, the qualifier (the second part in a three-part name and the first part in a two-part name) must be SESSION. For complete details on specifying a name when a declared temporary table is defined and then later referring to that declared temporary table in other SQL statements, see “DECLARE GLOBAL TEMPORARY TABLE” on page 1202.

#### **table-space-name**

An SQL identifier that designates a table space of an identified database. The identifier must start with a letter and must not include special characters. If a database is not identified, DSNDB04 is implicit.

#### **trigger-name**

A qualified or unqualified name that designates a trigger.

A qualified trigger name is a two-part name. The first part is the schema name of the trigger. The second part is an SQL identifier. A period must separate each of the parts.

An unqualified trigger name is an SQL identifier with an implicit qualifier. The implicit qualifier is the schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

#### **view-name**

A qualified or unqualified name that designates a view.

A fully qualified view name is a three-part name. The first part is a location name that designates the DBMS where the view is defined. The second part is a schema name. The third part is an SQL identifier. A period must separate each of the parts.

A two-part view name is implicitly qualified by the location name of the current server. The first part is a schema name. The second part is an SQL identifier. A period must separate the two parts.

A one-part or unqualified view name is an SQL identifier with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second is a schema name, which is determined by the context in which the unqualified name appears as described by the rules in “Qualification of unqualified object names” on page 57.

#### **XML-attribute-name**

An identifier that is used as an XML attribute name.

#### **XML-element-name**

An identifier that is used as an XML element name.

---

## **SQL path**

The *SQL path* is an ordered list of schema names. DB2 uses the path to resolve the schema name for unqualified data type names (both built-in types and distinct types), function names, and stored procedure names that appear in any context other than as the main object of an ALTER, CREATE, DROP, COMMENT, GRANT, RENAME, or REVOKE statement.

Searching through the path from left to right, DB2 implicitly qualifies the object name with the first schema name in the SQL path that contains the same object with the same unqualified name for which the user has appropriate authorization. For functions, DB2 uses a process called function resolution in conjunction with the SQL path to determine which function to choose because several functions with the same name and number of parameters but different parameter data types might be defined in the same schema or other schemas in the SQL path. (For details, see “Function resolution” on page 175.) For procedures, DB2 selects a matching procedure name only if the number of parameters is also the same.

The SQL path does not apply to unqualified procedure names in ASSOCIATE LOCATOR and DESCRIBE PROCEDURE statements. For these statements, an implicit schema name is not generated.

For an example of how DB2 uses the SQL path to resolve the schema name, assume that the SQL path is SMITH, XGRAPHIC, SYSIBM, and that an unqualified distinct type name MYTYPE was specified. DB2 looks for MYTYPE first in schema SMITH, then XGRAPHIC, and then SYSIBM.

The PATH option establishes the SQL path used to resolve:

- Unqualified data type and function names in static SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name as an identifier token (CALL *procedure-name*)

If the PATH option was not specified when the plan or package was created or last rebound or when native SQL procedure was defined or last changed, the default value of the SQL path is: SYSIBM, SYSFUN, SYSPROC, *plan or package qualifier*.

The CURRENT PATH special register determines the SQL path used to resolve:

- Unqualified data type and function names in dynamic SQL statements
- Unqualified procedure names in SQL CALL statements that specify the procedure name in a host variable (CALL *host-variable*)

Generally, the initial value of the CURRENT PATH special register is one of the following:

- The value of the PATH option
- SYSIBM, SYSFUN, SYSPROC, *value of CURRENT SQLID special register* if the PATH option was not specified.

If schema SYSIBM, SYSPROC, or SYSFUN is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path; if all are not specified, they are assumed in the order of SYSIBM, SYSPROC, and SYSFUN. For example, assume that the SQL path is explicitly specified as SYSIBM, GEORGIA, SMITH. As implicitly assumed schemas, SYSPROC and SYSFUN are added to the beginning of the explicit path effectively making the path:

SYSPROC, SYSFUN, SYSIBM, GEORGIA, SMITH

For more information about the SQL path for dynamic SQL, see “CURRENT PATH” on page 142 and “SET PATH” on page 1507.

## Qualification of unqualified object names

Unqualified object names are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

## Unqualified alias, index, JAR file, sequence, table, trigger, and view names

Unqualified alias, index, JAR file, sequence, table, trigger, and view names are implicitly qualified by the default schema.

The default schema is determined as follows:

- For static SQL statements, the default schema is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE PROCEDURE or ALTER PROCEDURE statement (for a native SQL procedure). If this option is not in effect for the plan, package, or native SQL procedure, the default schema is the authorization ID of the owner of the plan, package, or native SQL procedure.
- For dynamic SQL statements, the behavior as specified by the combination of the DYNAMICRULES option and the run-time environment determines the default schema. (For a list of these behaviors and the DYNAMICRULES values that determine them, see Table 6 on page 64).
  - If *DYNAMICRULES run behavior* applies, the default schema is the schema in the CURRENT SCHEMA special register. Run behavior is the default.
  - If *bind behavior* applies, the default schema is the identifier that is implicitly or explicitly specified in the QUALIFIER option, as explained for static SQL statements.
  - If *define behavior* applies, the default schema is the owner of the function or stored procedure (the owner is the definer).
  - If *invoke behavior* applies, the default schema is the authorization ID of the invoker of the function or stored procedure.

**Exception:** For bind, define, and invoke behavior, the default schema of PLAN\_TABLE, DSN\_STATEMNT\_TABLE, and DSN\_FUNCTION\_TABLE (output from the EXPLAIN statement) is always the value in special register CURRENT SQLID.

## Unqualified distinct type, function, procedure, and specific names

The qualification of unqualified distinct type, function, stored procedure, and specific names depends on the SQL statement in which the unqualified name appears.

- If an unqualified name is the main object of an ALTER, CREATE, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified with a schema name as follows:
  - In a static statement, the implicit schema name is the identifier specified in the QUALIFIER option of the BIND subcommand or the CREATE PROCEDURE or ALTER PROCEDURE statement (for a native SQL procedure). If this option is not in effect for the plan, package, or procedure, the implicit qualifier is the authorization ID of the owner of the plan, package, or procedure.
  - In a dynamic statement, the implicit schema name is the schema in the CURRENT SCHEMA special register.
- Otherwise, the implicit schema name for the unqualified name is determined as follows:
  - For distinct type names, DB2 searches the SQL path and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the distinct type.

- For function names, DB2 uses the SQL path in conjunction with function resolution, as described in “Function resolution” on page 175.
- For stored procedure names in CALL statements, DB2 searches the SQL path and selects the first schema in the path such that the schema contains a procedure with the same name and number of parameters and the user has authorization to use the procedure.
- For stored procedure names in ASSOCIATE LOCATORS and DESCRIBE PROCEDURE statements, DB2 does not use the SQL path because an implicit schema name is not generated for these statements.

For information about the SQL path, see “SQL path” on page 56.

## Aliases and synonyms

A table or view can be referred to in an SQL statement by its name, by an alias that has been defined for its name, or by a synonym that has been defined for its name. Thus, aliases and synonyms can be thought of as alternative names for tables and views.

An alias can be defined at a local server and can refer to a table or view that is at the current server or a remote server. The alias name can be used wherever the table name or view name can be used to refer to the table or view in an SQL statement. The rules for forming an alias name are the same as the rules for forming a table name or a view name, as explained below. A fully qualified alias name (a three-part name) can refer to an alias at a remote server. However, the table or view identified by the alias at the remote server must exist at the remote server.

An alias name designates an alias when it is preceded by the keyword ALIAS, as in CREATE ALIAS, DROP ALIAS, COMMENT ON ALIAS, and LABEL ON ALIAS. In all other contexts, an alias name designates a table or view. For example, COMMENT ON ALIAS A specifies a comment about the alias A, whereas COMMENT ON TABLE A specifies a comment about the table or view designated by A.

A synonym designates a synonym when it is preceded by the keyword SYNONYM, as in CREATE SYNONYM and DROP SYNONYM. In all other contexts, a synonym designates a local table or view and can be used wherever the name of a table or view can be used in an SQL statement.

Statements that use three-part names and refer to distributed data result in either DRDA access to the remote site or DB2 private protocol access. DRDA access for three-part names is used when the plan or package that contains the query to distributed data is bound with bind option DBPROTOCOL(DRDA), or the value of field DATABASE PROTOCOL on installation panel DSNTIP5 is DRDA and bind option DBPROTOCOL(PRIVATE) was not specified when the plan or package was bound. When an application program uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names. Also, each alias needs to be defined at the local site. An alias at a remote site can refer to yet another server as long as a referenced alias eventually refers to a table or view.

The option of referencing a table or view by an alias or a synonym is not explicitly shown in the syntax diagrams or mentioned in the description of SQL statements. But they can be referred to in an SQL statement, with two exceptions: a local alias cannot be used in the CREATE ALIAS statement, and a synonym cannot be used

in the CREATE SYNONYM statement. If an alias is used in the CREATE SYNONYM statement, it must identify a table or view at the current server. The synonym is defined on the name of that table or view. If a synonym is used in the CREATE ALIAS statement, the alias is defined on the name of the table or view identified by the synonym.

The effect of using an alias or a synonym in an SQL statement is that of text substitution. For example, if A is an alias for table Q.T, one of the steps involved in the preparation of SELECT \* FROM A is the replacement of 'A' by 'Q.T'. Likewise, if S is a synonym for Q.T, one of the steps involved in the preparation of SELECT \* FROM S is the replacement of 'S' by 'Q.T'.

The differences between aliases and synonyms are as follows:

- Authorization or the CREATE ALIAS privilege is required to define an alias. No authorization is required to define a synonym.
- An alias can be defined on the name of a table or view, including tables and views that are not at the current server. A synonym can only be defined on the name of a table or view at the current server.
- An alias can be defined on an undefined name. A synonym can only be defined on the name of an existing table or view.
- Dropping a table or view has no effect on its aliases. But dropping a table or view does drop its synonyms.
- An alias is a qualified name that can be used by any authorization ID. A synonym is an unqualified name that can only be used by the authorization ID that created it.
- An alias defined at one DB2 subsystem can be used at another DB2 subsystem. A synonym can only be used at the DB2 subsystem where it is defined.
- When an alias is used, an error occurs if the name that it designates is undefined or is the name of an alias at the current server. (The alias can represent another alias at a different server, which can represent yet another alias at yet another server as long as eventually a referenced alias represents a table or view.) When a synonym is used, this error cannot occur.

---

## Authorization, privileges, and object ownership

Users (as identified by an authorization ID) can successfully execute SQL statements only if they have the authority to perform the specified operation. For example, to create a table, a user must be authorized to create tables.

The two forms of authorization are administrative authority and privileges.

### Administrative authority

The holder of administrative authority is charged with the task of controlling DB2 and is responsible for the safety and integrity of the data.

Those with SYSADM authority implicitly have all privileges on all objects and control who will have access to DB2 and the extent of this access.

### Privileges

Privileges are those activities that a user is allowed to perform. Authorized users can create objects, have access to objects that they own, and can pass on privileges on the objects that they own to other users by using the GRANT statement. Privileges can be granted to specific users or to PUBLIC. PUBLIC specifies that a privilege is granted to all users (including to future users).

The REVOKE statement can be used to revoke previously granted privileges.

### Object ownership

When an object is created, one authorization ID is assigned ownership of the object. Ownership means that the user is authorized to reference the object in any applicable SQL statement. The privileges on the object can be granted by the owner, and cannot be revoked from the owner. Owners of views only receive the level of privileges that they have on the underlying table or view. The owner of the object that is being created is determined as follows:

- If the schema qualifier is not explicitly specified, the owner depends on how the CREATE statement is issued:
  - If the CREATE statement is embedded in a program, the owner of the object that is being created is the authorization ID that serves as the implicit qualifier for unqualified object names. This is the authorization ID that is in the QUALIFIER option when the plan, package, or native SQL procedure (that contains the CREATE statement) is created or last changed. If the QUALIFIER option is not used, the owner of the object is the authorization ID in the OWNER option when the plan, package, or native SQL procedure is created or last changed. If the OWNER option is not used, the owner is the owner of the plan, package, or native SQL procedure. If the plan or package was last bound in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, a role is the owner.
  - If the CREATE statement is dynamically prepared, the owner of the object that is being created is the authorization ID of the process.
  - If the CREATE statement is execute in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the role of the primary authorization ID is the owner.
- If the schema qualifier is explicitly specified, the owner depends on the type of object that is being created unless the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause. When the CREATE statement is executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the object is determined as follows:
  - If the CREATE statement is embedded in a program, the role that owns the plan or package is the owner of the object.
  - If the CREATE statement is dynamically prepared, the primary authorization ID is the owner.

If the schema qualifier is explicitly specified, and the CREATE statement is not executed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner depends on the type of object that is being created: :

- For an alias, auxiliary table, created global temporary table, table, or view, the owner of the object that is being created is the same as the explicit schema name.
- For a user-defined distinct type, user-defined function, procedure, sequence, JAR files, or trigger, the owner of the object that is being created is the authorization ID of the process.

## Authorization IDs, roles, and authorization names

Processes can successfully execute SQL statements only if they have the necessary authority. A process derives this authority from its authorization IDs. An authorization ID can also designate a user, a group of users, or a role.

An *authorization ID* is a character string that is associated with a process that is checked to determine the authority to perform a specified operation.

DB2 does not control the association of users to user groups. However, DB2 does control the association between users and roles when a trusted context is defined.

DB2 uses authorization IDs to provide authorization checking of SQL statements.

Whenever a connection is established between DB2 and a process, DB2 obtains an authorization ID and passes it to the authorization connection or sign-on exit routine. The list of one or more authorization IDs that is returned by the exit routine are used as the authorization IDs of the process. If the process is running in a trusted context with a role, the authorization IDs of the process includes this role.

Every process has exactly one primary authorization ID. Any other authorization IDs of a process are secondary authorization IDs. The use of these authorization IDs depends on the type of process (bind process, application process, or process involved in the creation of objects).

A *role* is a database entity that groups together one or more privileges. A role is available only when the process is run in a trusted context. Users are associated with a role in the definition of a trusted context.

A trusted context can have a default role, specific roles for individual users, or no roles at all. A user in a trusted context can have only one active role. This is the role that is specifically defined for the user or the default role of the trusted context. The following restrictions apply to roles:

- A role cannot be a primary authorization ID.
- A role cannot be set by using a SET CURRENT SQLID statement.
- A role can be the schema qualifier of an object. However, when it is used as a schema qualifier, a role is considered to be a character string and does not add any implicit schema privileges (ALTERIN, CREATEIN, or DROPIN) to this role.
- A role must already exist for privileges to be granted to it.

The role that is in effect for a user is considered to be one of the secondary authorization IDs of the user.

Do not confuse an *authorization-name* that is specified in an SQL statement with an authorization ID of a process.

**Example:** Assume that SMITH is your TSO logon, DYNAMICRULES run behavior is in effect, and you execute the following statements interactively:

```
CREATE TABLE TDEPT LIKE DSN8910.DEPT;
GRANT SELECT ON TDEPT TO KEENE;
```

Also assume that your site has not replaced the default exit routine for connection authorization and that you have not executed the SET CURRENT SQLID

statement. Thus, when the GRANT statement is prepared and executed by SPUFI, the SQL authorization ID is SMITH. KEENE is an authorization name that is specified in the GRANT statement.

Authorization to execute the GRANT statement is checked against SMITH. The authorization rule is that the privilege set that is designated by SMITH must include the SELECT privilege with the GRANT option on SMITH.TDEPT. No check that involves KEENE is performed. If the GRANT statement specifies a role, the existence of the role is checked.

## Authorization IDs and schema names

An authorization ID that has the same name as the name of a schema implicitly has certain privileges for that schema.

If an authorization ID is not a role and has the same name as the name of a schema, that authorization ID implicitly has the following privileges for that schema:

- CREATEIN privilege
- ALTERIN privilege
- DROPIN privilege

## Authorization IDs and statement preparation

The authorization ID that is specified as the owner of the plan or package must be one of the authorization IDs of the bind process. The owner can be set to any value if one of the authorization IDs of the bind process has SYSADM or SYSCTRL authority.

A process that creates a plan or package is called a *bind process*. The connection with DB2 is the result of the execution of a BIND or REBIND subcommand. Both subcommands allow for the specification of the authorization ID of the owner of the plan or package.

BINDAGENT can specify an owner other than himself (or one of his representatives), but it has to be someone that granted him BINDAGENT. The default owner for BIND is the primary authorization ID. The default owner for REBIND is the previous owner of the plan or package (ownership is unchanged if an owner is not explicitly specified). If the BIND or REBIND is performed in a trusted context that is defined with the ROLE AS OBJECT OWNER clause, the owner of the plan or package is a role. If the OWNER bind option is specified, the role that is specified in it is the owner, otherwise the role that performs the bind or rebind becomes the owner.

The authorization ID that is used for the authorization checking of embedded SQL statements is that of the owner of the plan or package. If the application is bound in a trusted context using the ROLE AS OBJECT OWNER clause, the authorization ID that is used for authorization checking is the role that owns the plan or package, otherwise the authorization ID is the authorization ID of the owner of the plan or package. If an embedded SQL statement refers to tables or views at a DB2 subsystem other than the one at which the plan or package is bound, the authorization checking is deferred until run time. For more information on this, see “Authorization IDs and remote execution” on page 67.

If VALIDATE(BIND) is specified, the privileges required to use or manipulate objects at the DB2 subsystem at which the plan or package is bound must exist at

bind time. If the privileges or the referenced objects do not exist and SQLERROR(NOPACKAGE) is in effect, the bind operation is unsuccessful. If SQLERROR(CONTINUE) is specified, then the bind is successful and any statements in error are flagged. If any statements in error are flagged, an error will occur when you attempt to execute them at run time.

If a plan or package is bound with VALIDATE(RUN), authorization checking is still performed at bind time, but the referenced objects and the privileges required to use these objects need not exist at this time. If any privilege required for a statement does not exist at bind time, an authorization check is performed whenever the statement is first executed within a unit of work, and all privileges required for the statement must exist at that time. If any privilege does not exist, execution of the statement is unsuccessful. When the authorization check is performed at run time, it is performed against the plan or package owner, not the SQL authorization ID. For the effect of this option on cursors, see “DECLARE CURSOR” on page 1191.

## Authorization IDs and dynamic SQL

The bind option DYNAMICRULES determines the authorization ID that is used for checking authorization when dynamic SQL statements are processed. The set of values for the authorization ID and other dynamic SQL attributes is called the *dynamic SQL statement behavior*. The four possible behaviors are run, bind, define, and invoke.

This discussion applies to dynamic SQL statements that refer to objects at the current server. For those that refer to objects elsewhere, see “Authorization IDs and remote execution” on page 67.

In addition to determining the authorization ID, DYNAMICRULES also controls other dynamic SQL attributes such as the implicit qualifier that is used for unqualified alias, index, sequence, table, trigger, and view names; the source for application programming options; and whether certain SQL statements can be invoked dynamically.

As the following table shows, the combination of the value of the DYNAMICRULES option and the run-time environment determines which of the four SQL statement behavior is used. DYNAMICRULES(RUN), which implies run behavior, is the default.

*Table 6. How DYNAMICRULES and the run-time environment determine dynamic SQL statement behavior*

DYNAMICRULES value	Behavior of dynamic SQL statements	
	Stand-alone program environment	User-defined function or stored procedure environment
RUN	Run behavior	Run behavior
BIND	Bind behavior	Bind behavior
DEFINERUN	Run behavior	Define behavior
DEFINEBIND	Bind behavior	Define behavior
INVOKERUN	Run behavior	Invoke behavior

*Table 6. How DYNAMICRULES and the run-time environment determine dynamic SQL statement behavior (continued)*

DYNAMICRULES value	Behavior of dynamic SQL statements	
	Stand-alone program environment	User-defined function or stored procedure environment
INVOKEBIND	Bind behavior	Invoke behavior

**Note:** BIND and RUN values can be specified for packages, plans, and native SQL procedures. The other values can be specified for packages and native SQL procedures but not for plans.

In the following behavior descriptions, a package that *runs under* a user-defined function or stored procedure package is a package whose associated program meets one of the following conditions:

- The program is called by a user-defined function or stored procedure.
- The program is in a series of nested calls that start with a user-defined function or stored procedure.

#### Run behavior

DB2 uses the authorization IDs of the application process and the SQL authorization ID (the value of special register CURRENT SQLID) for authorization checking of dynamic SQL statements. If the process is running in a trusted context with a role associated with the primary authorization ID, the authorization IDs of the application process include this role.

A process that uses a plan and its associated packages is called an *application process*. At any time, the SQL authorization ID is the value of CURRENT SQLID. This SQL special register can be initialized by the connection or sign-on exit routine. If the exit routine does not set a value, the initial value of CURRENT SQLID is the primary authorization ID of the process. You can use the SQL statement SET CURRENT SQLID to change the value of CURRENT SQLID. Unless some authorization ID of the process has SYSADM authority, the new value must be one of the authorization IDs of the process. Thus, CURRENT SQLID usually contains either the primary authorization ID of the process or one of its secondary authorization IDs. The CURRENT SQLID cannot contain a role.

**Privilege set:** If the dynamically prepared statement is other than an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, each privilege required for the statement can be a privilege designated by any authorization ID of the process. Therefore, the privilege set is the union of the set of privileges held by each authorization ID of the process. When the process is running in a trusted context with a role, the authorization IDs of the process include this role.

If the dynamic SQL statement is an ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, or REVOKE statement, the only authorization ID that is used for authorization checking is the SQL authorization ID. Therefore, the privilege set is the privileges held by that single authorization ID of the process. If the process is running in a trusted context using the ROLE AS OBJECT OWNER clause for the a CREATE, GRANT, or REVOKE statement, the single authorization ID of the process that is checked is the role that is in effect.

**Implicit qualification:** As explained under “Qualification of unqualified object names” on page 57, when an SQL statement is dynamically prepared, the values of the CURRENT SCHEMA special register is used as the implicit qualifier. For example, it is used as the implicit qualifier for all unqualified tables, aliases, views, indexes, and sequences.

#### Bind behavior

The same rules that are used to determine the authorization ID for static (embedded) statements are used for dynamic statements. DB2 uses the authorization ID of the owner of the package or plan for authorization checking of dynamic SQL statements, as explained in detail under “Authorization IDs and statement preparation” on page 63.

**Privilege set:** The privilege set is the privileges that are held by the owner of the package or plan.

**Implicit qualification:** The identifier specified in the QUALIFIER option of the bind command that is used to bind the SQL statements, or the CREATE PROCEDURE or ALTER PROCEDURE statement that is used to create a version of an SQL procedure is the implicit qualifier for all unqualified tables, views, aliases, indexes, and sequences. If the QUALIFIER option was not used when the plan, package, or native SQL procedure was created or last changed, the implicit qualifier is the owner of the plan, package, or native SQL procedure.

#### Define behavior

Define behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(DEFINEBIND) or DYNAMICRULES(DEFINERUN). DB2 uses the authorization ID of the stored procedure or user-defined function owner (the definer) for authorization checking of dynamic SQL statements in the application package.

**Privilege set:** The privilege set is the privileges that are held by the authorization ID of the owner.

**Implicit qualification:** The stored procedure or user-defined function owner is also the implicit qualifier. For example, the owner is the implicit qualifier for unqualified table, view, alias, index, and sequence names.

#### Invoke behavior

Invoke behavior applies only if the dynamic SQL statement is in a package that is run as a stored procedure or user-defined function (or *runs under* a stored procedure or user-defined function package), and the package was bound with DYNAMICRULES(INVOKEBIND) or DYNAMICRULES(INVOKERUN). DB2 uses the stored procedure or user-defined function invoker for authorization checking of dynamic SQL statements in the application package. The invoker can also be a role.

**Privilege set:** The privilege set is the privileges that are held by the invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked. This includes the role of the primary authorization ID, if running in a trusted context with a role. In that case, the privilege set is the union of the set of privileges held by each authorization ID of the process.

**Implicit qualification:** The stored procedure or user-defined function invoker is also the implicit qualifier. For example, it is the implicit qualifier for unqualified table, view, alias, index, and sequence names. The invoker can also be a role.

**Restricted statements when run behavior does not apply:** When bind, define, or invoke behavior is in effect, you cannot use the following dynamic SQL statements: ALTER, CREATE, COMMENT, DROP, GRANT, RENAME, and REVOKE.

## Authorization IDs and remote execution

The authorization rules for remote execution depend on whether the distributed operation is DRDA access with a DB2 for z/OS server and requester. DRDA access with a server and requester other than DB2, or DB2 private protocol access can also effect the authorization rules for remote execution.

### DRDA access with DB2 for z/OS only

To prepare and execute SQL statements using DRDA access, certain privileges are required by the package owner and additional privileges are required by the user who invokes the application.

Any static statement executed using DRDA access is in a package bound at a server other than the local DB2. Before the package can be bound, its owner must have the BINDADD privilege and the CREATE IN privilege for the package's collection. Also required are enough privileges to execute the package's static SQL statements that refer to data on that server. All these privileges are recorded in the DB2 catalog of the server, not in the catalog of the local DB2. Such privileges must be granted by GRANT statements executed at the server. This allows the server to control the creation and use of packages that are run from other DBMSs.

A user who invokes an application that has a plan at the local DB2 must have the EXECUTE privilege on the plan recorded in the DB2 catalog of the requester. If the application uses a package bound at a server other than the local DB2 and the package is not a user-defined function, stored procedure, or trigger package, the plan owner must have the EXECUTE privilege on the package recorded in the DB2 catalog of the server. The plan needs no other privilege to execute the package. EXECUTE authority is also required to use a package that is a user-defined function, stored procedure, or trigger package; however, the plan owner is not the required holder of the privilege, as explained in *DB2 Administration Guide*. In the case of trigger packages, the authorization ID of the SQL statement that activates the trigger must have the EXECUTE privilege on the trigger. Again, all these privileges must be recorded in the DB2 catalog of the server.

Having the appropriate privileges recorded as described above allows the execution of the static SQL statements in the package, and the execution of dynamic SQL statements if DYNAMICRULES bind, define, or invoke behavior is in effect. If DYNAMICRULES run behavior is in effect, the authorization rules for dynamic SQL statements is different. Authorization for the execution of dynamic SQL statements must come from the set of authorization IDs that are derived during connection processing, and, if the process is running in a trusted connection, the role that is in effect. An application goes through connection

processing when it first connects to a server or when it reuses a CICS or IMS thread that has a different primary authorization ID. For details on connection processing, see *DB2 Administration Guide*.

If an application uses Recoverable Resources Manager Services attachment facility (RRSAF) and has no plan, authority to execute the package is determined in the same way as when the requester is not DB2 for z/OS, which is described next under "DRDA access with a server or requester other than DB2."

## DRDA access with a server or requester other than DB2

Specific privileges are required depending on whether DB2 is the server or the requester involved in DRDA access.

*DB2 for z/OS as the server:* If the requester is not a DB2 for z/OS subsystem, there is no DB2 application plan involved. In this case, the privilege set of the authorization ID, which is determined by the DYNAMICRULES behavior, must have the EXECUTE privilege on the package. Dynamic SQL statements in the package are executed according to the DYNAMICRULES behavior, as described in "Authorization IDs and dynamic SQL" on page 64.

*DB2 for z/OS as the requester:* The authorization rules for remote execution are those of the server.

## DB2 private protocol access

Any statement that refers to a table or view at a DB2 subsystem other than the current server and is bound with bind option DBPROTOCOL(PRIVATE) is executed using DB2 private protocol access.

Such statements are processed as deferred embedded SQL statements. The additional cost of the dynamic bind occurs once for every unit of work where the statement is executed. Authorization to execute such statements is checked against the owner of a plan or package. Authorization IDs for executing dynamic statements are handled just as they are for DRDA access. In either case, the pertinent privileges must be recorded in the catalog of the DBMS that executes the statement.

## Authorization ID translations

When certain authorization IDs are sent to a remote DBMS, those authorization IDs might undergo translation before being used.

Translation can occur for a primary authorization ID, the authorization ID of the owner of an application plan, or the authorization ID of the owner of a package. For example, a user known as SMITH at the local DBMS could be known, after translation, as JONES at the server. Likewise, a package owner known as GRAY could be known as WINTERS at the server. If so, JONES or WINTERS would be used, instead of SMITH or GRAY, to determine the authorization ID for dynamic SQL statements in the package. If the DYNAMICRULES run behavior applies, JONES, who is executing the dynamic statement at the server, is used. If DYNAMICRULES bind behavior applies, WINTERS, the package owner at the server, is used.

Two sets of communications database (CDB) catalog tables control the translations. One set is at the local DB2, and the other set is at the remote DB2. Translation can take place at either or both sites.

## Other security measures

Even if DB2 authority requirements are satisfied, other security measures can be in effect when distributed data is accessed.

The fact that DB2 authority requirements are satisfied does not guarantee that a user has access to a given server. Other security measures can also come into play. For example, requests to execute remote SQL statements could be denied based on Resource Access Control Facility (RACF) considerations. Developing such security measures is discussed in *DB2 Administration Guide*.

---

## Data types

DB2 supports both IBM-supplied data types (built-in data types) and user-defined data types (distinct types).

The smallest unit of data that can be manipulated in SQL is called a *value*. How values are interpreted depends on the data type of their source. The sources of values are:

- Columns
- Constants
- Expressions
- Functions
- Special registers
- Variables (such as host variables, SQL variables, parameter markers, and parameters of routines)

The following topics describes the built-in data types and distinct types.

Figure 16 on page 70 shows the built-in data types that DB2 supports.

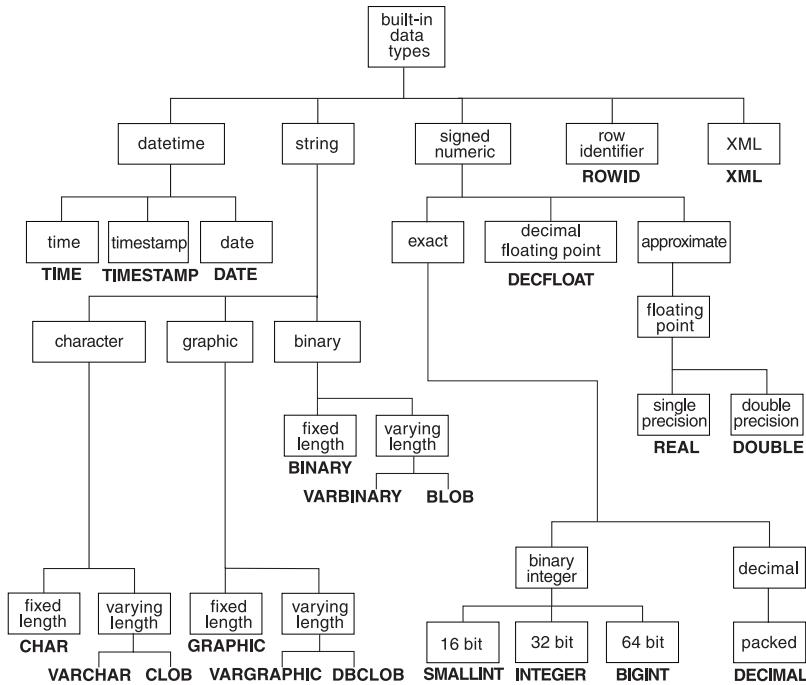

Figure 16. Built-in data types supported by DB2

## Nulls

All data types include the null value. Distinct from all nonnull values, the null value is a special value that denotes the absence of a (nonnull) value.

Although all data types include the null value, some sources of values cannot provide the null value. For example, constants, columns that are defined as NOT NULL, and special registers cannot contain null values; the COUNT and COUNT\_BIG functions cannot return a null value; and ROWID columns cannot store a null value although a null value can be returned for a ROWID column as the result of a query.

## Numbers

The numeric data types are categorized as exact numerics: binary integer and decimal; decimal floating point; and approximate numerics: floating-point

Binary integer includes small integer, large integer, and big integer. Binary numbers are exact representations of integers. Decimal numbers are exact representations of real numbers. Binary and decimal numbers are considered exact numeric types. Decimal floating point numbers include DECFLOAT(16) and DECFLOAT(34), which are capable of representing either 16 or 34 significant digits. Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers and are considered approximate numeric types.

All numbers have a sign, a precision, and a scale. If a column value is zero, the sign is positive. Decimal floating point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of binary or decimal digits excluding the

sign. The scale is the total number of binary or decimal digits to the right of the decimal point. If there is no decimal point, the scale is zero.

### **Small integer (SMALLINT)**

A *small integer* is a binary integer with a precision of 15 bits. The range of small integers is -32768 to +32767.

### **Large integer (INTEGER)**

A *large integer* is a binary integer with a precision of 31 bits.

The range of large integers is -2147483648 to +2147483647.

### **Big integer (BIGINT)**

A *big integer* is a binary integer with a precision of 63 bits.

The range of big integers is -9223372036854775808 to +9223372036854775807.

### **Single precision floating-point (REAL)**

A *single precision floating-point* number is a short (32 bits) floating-point number.

The range of single precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

### **Double precision floating-point (DOUBLE or FLOAT)**

A *double precision floating-point* number is a long (64 bits) floating-point number.

The range of double precision floating-point numbers is about -7.2E+75 to 7.2E+75. In this range, the largest negative value is about -5.4E-79, and the smallest positive value is about 5.4E-079.

### **Decimal (DECIMAL or NUMERIC)**

A *decimal* number is a packed decimal number with an implicit decimal point.

The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits.

All values of a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is  $-n$  to  $+n$ , where  $n$  is the largest positive number that can be represented with the applicable precision and scale. The maximum range is  $1 - 10^{31}$  to  $10^{31} - 1$ .

### **Decimal floating-point (DECFLOAT)**

A *decimal floating-point* value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value.

The maximum precision is 34 digits.

The range of a decimal floating point number is either 16 or 34 digits of precision, and an exponent range of respectively  $10^{-383}$  to  $10^{+384}$  or  $10^{-6143}$  to  $10^{+6144}$ .

In addition to the finite numbers, decimal floating point numbers are able to represent one of the following named special values:

- Infinity - a value that represents a number whose magnitude is infinitely large.

- Quiet NaN - a value that represents undefined results which does not cause an invalid number condition.
- Signaling NaN - a value that represents undefined results which will cause an invalid number condition if used in any numerical operation.

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity is significant (that is, it is possible to have both positive and negative infinity). The sign of a NaN has no meaning for arithmetic operations. INF can be used in place of INFINITY.

## Numeric host variables

Numeric host variables can be defined in all languages with a few exceptions.

Binary integer variables can be defined in all host languages.

Floating-point variables can be defined in all host languages. All languages, except Java, support System/390® floating-point format. Assembler, C, C++, PL/I, and Java also support IEEE floating-point format. In assembler, C, C++, and PL/I programs, the precompiler option FLOAT tells DB2 whether floating-point variables contain data in System/390 floating-point format or IEEE floating-point format. The contents of floating-point host variables must match the format that is specified with the FLOAT SQL processing option.

Decimal variables can be defined in all host languages except Fortran.

In COBOL, decimal numbers can be represented in the following formats:

- Packed decimal format, denoted by USAGE PACKED-DECIMAL or COMP-3
- External decimal format, denoted by USAGE DISPLAY with SIGN LEADING SEPARATE
- NATIONAL decimal format denoted by USAGE NATIONAL and SIGN LEADING SEPARATE

Decimal floating-point variables can be defined in Java.

## String representations of numeric values

String representations of numeric values can be used in some contexts. A valid string representation of a numeric value must conform to the rules for numeric constants.

The encoding scheme in use determines what type of strings can be used for string representation of numeric values. For ASCII and EBCDIC, a string representation of a numeric value must be a character string. For UNICODE, a string representation of a numeric value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a numeric value is when the encoding scheme is UNICODE.

When a decimal, decimal floating-point, or floating-point number is cast to a string (for example, using a CAST specification), the implicit decimal point is replaced by the default decimal separator character that is in effect when the statement is prepared. When a string is cast to a decimal, decimal floating-point, or floating-point value (for example, using a CAST specification), the default decimal separator character in effect when the statement was prepared is used to interpret the string.

For more information, see “Constants” on page 126.

## Subnormal numbers and underflow

The decimal floating-point data type has a set of non-zero numbers that fall outside the range of normal decimal floating-point values. These numbers are called subnormal.

Non-zero numbers whose adjusted exponents are less than  $E_{\min}$ <sup>4</sup> are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and can result from any operation. If a result is subnormal before any rounding occurs, the subnormal condition is returned.

For a subnormal result, the minimum values of the exponent becomes  $E_{\min} - (\text{precision}-1)$ , called  $E_{\text{tiny}}$ , where precision is the working precision. If necessary, the result will be rounded to ensure that the exponent is no smaller than  $E_{\text{tiny}}$ . If the result becomes inexact during rounding, an underflow condition is returned. A subnormal result does not always return the underflow condition but will always return the subnormal condition.

When a number underflows to zero during a calculation, its exponent will be  $E_{\text{tiny}}$ . The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent which can arise during operations that do not result in subnormal numbers. This occurs where the length of the coefficient in decimal digits is equal to the precision.

## Character strings

A *character string* is a sequence of bytes. The length of the string is the number of bytes in the sequence. If the length is zero, the value is called the *empty string*. The empty string should not be confused with the null value.

### Default CCSIDs

The value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

The following table shows how the value of the field MIXED DATA (on installation panel DSNTIPF) determines the default CCSIDs for a character string.

Table 7. Default CCSIDs for character strings

Encoding scheme	Value of MIXED DATA field	Default attribute
ASCII or EBCDIC	NO	Character: SBCS  The value of the ASCII CODED CHAR SET or EBCDIC CODED CHAR SET field on installation panel determines the system CCSID for SBCS data.
ASCII or EBCDIC	YES	Character: MIXED  The value of the ASCII CODED CHAR SET or EBCDIC CODED CHAR SET field on installation panel DSNTIPF determines the system CCSID for SBCS data, MIXED, and graphic data.

*Table 7. Default CCSIDs for character strings (continued)*

Encoding scheme	Value of MIXED DATA field	Default attribute
Unicode	Not applicable	Character: MIXED  The CCSIDs are: <ul style="list-style-type: none"><li>• 367 for SBCS data</li><li>• 1208 for MIXED data</li><li>• 1200 for graphic data</li></ul>

## Fixed-length character strings

When fixed-length character string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length character string, the length attribute must be between 1 and 255 inclusive.

## Varying-length character strings

The types of varying-length character strings are VARCHAR and *character large object (CLOB)*. A CLOB is a type of LOB. A CLOB column is useful for storing large amounts of character data, such as documents written with a single character set.

When varying-length character strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute except for C NUL-terminated strings. Actual values might have a smaller value. For varying-length character strings, the length specifies the number of bytes.

For a VARCHAR string, the length attribute must be between 1 and 32704. For a VARCHAR column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in Maximum record size in the description of the CREATE TABLE statement. For a CLOB string, the length attribute must be between 1 and 2 147 483 647 inclusive. (2 147 483 647 is 2 gigabytes minus 1 byte.) For more information about CLOBS, see “Large objects (LOBs)” on page 85.

## Character string variables

Character string variables follow specific rules for use in host languages.

- Fixed-length character string variables can be used in all languages except REXX and Java. In C, CHAR string variables are limited to a length of 1.
- Varying-length character string variables can be used in all host languages with the following exceptions:
  - Fortran: varying-length non-LOB character strings cannot be used.
  - Assembler, C, and COBOL: varying-length non-LOB strings are simulated as described in *DB2 Application Programming and SQL Guide*. In C, NUL-terminated strings can also be used.
  - REXX: CLOBs and DBCLOBs cannot be used.

## Character string encoding schemes

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

Each character string is further defined as one of the following subtypes:

### **Bit data**

Data that is not associated with a coded character set and, therefore, is never converted. The CCSID for bit data is X'FFFF' (65535). The bytes do not represent characters.

Bit data is a form of character data. The pad character is a blank for assignments to bit data; the pad character is X'00' for assignments to binary data. It is recommended that binary data be used instead of character for bit data.

If both operands in a predicate are EBCDIC, both operands are padded with X'40'. Otherwise, both operands are padded with X'20'. For example, if both operands are ASCII, or if one operand is ASCII and the other operand is EBCDIC, both are padded with X'20'.

### **SBCS data**

Data in which every character is represented by a single byte. Each SBCS string has an associated CCSID. If necessary, an SBCS string is converted before it is used in an operation with a character string that has a different CCSID.

### **Mixed data**

Data that can contain a mixture of characters from a single-byte character set (SBCS) and a multiple-byte character set (MBCS). Each mixed string has an associated CCSID. If necessary, a mixed string is converted before an operation with a character string that has a different CCSID. If a mixed data string contains an MBCS character, it cannot be converted to SBCS data.

EBCDIC mixed data can contain shift characters, which are not MBCS data.

When the encoding scheme is Unicode or the DB2 installation is defined to support mixed data, DB2 recognizes MBCS sequences within mixed data string when performing character sensitive operations. These operations include parsing, character conversion, and the pattern matching specified by the LIKE predicate.

Character strings with a CLOB data type can only be SBCS or MIXED. BLOB should be used for binary strings.

The method of representing DBCS and MBCS characters within a mixed string differs among the encoding schemes.

- ASCII reserves a set of code points for SBCS characters and another set as the first half of DBCS characters. When it encounters the first half of a DBCS character, the system reads the next byte in order to obtain the complete character.
- EBCDIC makes use of two special code points:
  - A shift-out character (X'0E') to introduce a string of DBCS characters.
  - A shift-in character (X'0F') to end a string of DBCS characters.

DBCS sequences within mixed data strings are recognized as the string is read from left to right. At any time, the reading of the string is in SBCS mode or DBCS mode. In SBCS mode, which is the initial mode, any byte other than a shift-out is interpreted as an SBCS character. When a shift-out is read, the mode switches to DBCS mode. In DBCS mode, the next byte and every second byte after that byte is interpreted as the first byte of a DBCS character unless it is a shift character. If the byte is a shift-out, an error occurs. If the byte is a shift-in, the mode returns to SBCS mode. An error occurs if the mode is still DBCS mode

after processing the last byte of the string. Because of the shift characters, EBCDIC mixed data requires more storage than ASCII mixed data.

- UTF-8 is a varying-length encoding of byte sequences. The high bits indicate the part of the sequence to which a byte belongs. The first byte indicates the number of bytes to follow in a byte sequence.

## Examples

The same mixed date character string can be represented as character and hexadecimal data in different encoding schemes.

For the same mixed data character string, the following table shows character and hexadecimal representations of the character string in different encoding schemes. In EBCDIC, the shift-out and shift-in characters are needed to delineate the double-byte characters.

*Table 8. Example of a character string in different encoding schemes*

Data type and encoding scheme	Character representation	Hexadecimal representation (with spaces separating each character)
9 bytes in ASCII	π gen 𩶏 ki	8CB3 67 65 6E 8B43 6B 69
13 bytes in EBCDIC	s <sub>0</sub> π s <sub>1</sub> gen s <sub>0</sub> 𩶏 s <sub>1</sub> ki	0E 4695 0F 87 85 95 0E 45B9 0F 92 89
11 bytes in Unicode UTF-8	π gen 𩶏 ki	E58583 67 65 6E E6B097 6B 69

Because of the differences of the representation of mixed data strings in ASCII, EBCDIC, and Unicode, mixed data is not transparently portable. To minimize the effects of these differences, use varying-length strings in applications that require mixed data and operate on ASCII, EBCDIC, and Unicode data.

## String unit specifications

The ability to specify string units for certain built-in functions and on the CAST specification allows you to process string data in a more "character-based manner" than a "byte-based manner". The string unit determines the length in which the operation is to occur. You can specify CODEUNITS32, CODEUNITS16, or OCTETS as the units for the operation.

### CODEUNITS32

Specifies that Unicode UTF-32 is the units for the operation.

CODEUNITS32 is useful when an application wants to process data in a simple fixed-length format and needs the same answer regardless of the storage format of the data (ASCII, EBCDIC, UTF-8, or UTF-16). Although the answers are in terms of CODEUNITS32, the data is not converted to UTF-32 to perform the function.

### CODEUNITS16

Specifies that Unicode UTF-16 is the units for the operation.

CODEUNITS16 is useful when an application wants to know how many double-byte characters are in a string.

### OCTETS

Specifies that bytes are the units for the operation. OCTETS is often used when an application is interested in allocation buffer space or when operations need to use simple byte processing.

Determining the length of a string by counting in string units (CODEUNITS16 or CODEUNITS32) or bytes (OCTETS) can result in different answers. When OCTETS is specified, the length of a string is determined by simply counting the number of bytes in the string. Counting by CODEUNITS16 or CODEUNITS32 gives the same answer unless the data contains supplementary characters. For information about the difference between CODEUNITS16 and CODEUNITS32 when the data contains supplementary characters, see “Difference between CODEUNITS16 and CODEUNITS32” on page 78.

*Example:* Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The first two queries, which count the length of the string in CODEUNITS32 and CODEUNITS16, returns the same value, 6. The third query, which counts the length of the string in OCTETS, returns the value 7. These values are the length of the string as expressed in the string units that are specified.

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS32)
      FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME,CODEUNITS16)
      FROM T1 WHERE NAME = 'Jürgen';
SELECT CHARACTER_LENGTH(NAME,OCTETS)
      FROM T1 WHERE NAME = 'Jürgen';
```

The following table shows the UTF-8, UTF-16, and UTF-32 representations of 'Jürgen'.

Format	Representation of the name 'Jürgen'
UTF-8	x'4AC3BC7267656E'
UTF-16	x'004A00FC007200670065006E'
UTF-32	x'000004A000000FC0000007200000067000000650000006E'

The bold highlighting in the table demonstrates how the representation of the character *ü* in 'Jürgen' differs between the three string units:

- The UTF-8 representation of the character ü is X'C3BC'. In UTF-8, characters that are not in the Latin-1 subset (essentially a through z, A through Z, and 0 through 9), such as accented characters or Japanese characters, are represented by multiple bytes.
- The UTF-16 representation of the character ü is X'00FC'. In UTF-16, each character is represented in 2 bytes. UTF-16 supplementary characters take two 2-byte code points.
- The UTF-32 representation of the character ü is X'000000FC'. In UTF-32, each character is represented in 4 bytes.

Specifying the string units on a built-in function does not affect the data type or the CCSID of the result of the function. If necessary, DB2 converts the data to Unicode for evaluation when CODEUNITS32 or CODEUNITS16 is specified. DB2 always evaluates the data in the encoding scheme of the output data when OCTETS is specified. For more information about the data types and CCSIDs of the results of functions, see the description of each function.

Differences between the way that characters are represented in ASCII, EBCDIC, and Unicode can affect the results of your queries.

*Example:* Assume that NAME is a VARCHAR(128) column, encoded in EBCDIC (CCSID 37), that contains the value 'Mit freundlichen Grüßen, Jürgen'. The following query returns the string 'Mit freundlichen Grüß':

```
SELECT SUBSTRING(C1,1,21,CODEUNITS16)
  FROM T1 WHERE C1 = 'Mit freundlichen Grüßen, Jürgen';
```

The following table shows the result data in more detail:

Format	Representation of 'Mit freundlichen Grüß'
EBCDIC	D489A340869985A4958493898388859540C799 <b>DC59</b>
UTF-8	4D697420667265756E646C696368656E204772 <b>C3BCC39F</b>
UTF-16	004D006900740020006007200650075006E0064006C0069006300680 065006E002000470072 <b>00FC00DF</b>

The bold highlighting in the table shows that the representation of the characters *i* and *ß* in UTF-8 and UTF-16 each require two bytes. If OCTETS had been specified on the SUBSTRING function to have the string evaluated in UTF-8 bytes instead of EBCDIC OCTETS or CODEUNITS16, the result would have been 'Mit freundlichen Grü'. The character *ß* would have been lost.

#### Difference between CODEUNITS16 and CODEUNITS32:

CODEUNITS16 and CODEUNITS32 return the same answer unless the data contains supplementary characters.

A supplementary character is represented as two UTF-16 code units or one UTF-32 code unit. In UTF-8, a non-supplementary character is represented by 1 to 3 bytes and a supplementary character is represented by 4 bytes. In UTF-16, a non-supplementary character is represented by one CODEUNIT16 code unit or 2 bytes, and a supplementary character is represented by two CODEUNIT16 code units or 4 bytes. In UTF-32, a character is represented by one CODEUNIT32 code unit or 4 bytes. Thus, CODEUNITS16 and CODEUNITS32 return different answers when the data contains supplementary characters.

*Example 1:* The following table shows the hexadecimal values for the mathematical bold capital A and the Latin capital letter A. The mathematical bold capital A is a supplementary character that is represented by 4 bytes in UTF-8, UTF-16, and UTF-32.

Character	UTF-8 representation	UTF-16 representation	UTF-32 representation
Unicode value \u1D400 - 'A'	X'F09D9080'	X'D835DC00'	X'0001D400'
<b>MATHEMATICAL BOLD CAPITAL A</b>			
Unicode value \u0041 - 'A'	X'41'	X'0041'	X'00000041'
<b>LATIN CAPITAL LETTER A</b>			

Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers:

```
-- Query:                                     -- Returns the value:
SELECT CHARACTER_LENGTH(C1,CODEUNITS32) FROM T1;    -- 1
SELECT CHARACTER_LENGTH(C1,CODEUNITS16) FROM T1;    -- 2
SELECT CHARACTER_LENGTH(C1,OCTETS) FROM T1;        -- 4
```

*Example 2:* Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following similar queries return different answers.

```
-- Query:                                -- Returns the value:  
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS32)) FROM T1;    -- X'F09D9080'  
SELECT HEX(SUBSTRING(C1,1,1,CODEUNITS16)) FROM T1;    -- X'20'  
SELECT HEX(SUBSTRING(C1,1,2,CODEUNITS16)) FROM T1;    -- X'F09D9080'  
SELECT HEX(SUBSTRING(C1,1,1,OCTETS)) FROM T1;        -- X'20'  
SELECT HEX(SUBSTR(C1,1,1)) FROM T1;                  -- X'F0'
```

The value X'20' is the pad (blank) character.

#### Determining the length attribute of the final result:

When CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying specific formulas depending on which function is specified.

To determine the final result of a function or the CAST specification, DB2 might need to use an intermediate result string if CODEUNITS32 or CODEUNITS16 is specified, depending on the encoding scheme of the data:

- ASCII and EBCDIC data require the use of a UTF-16 intermediate result string when either CODEUNITS32 or CODEUNITS16 is specified.
- UTF-8 data requires the use of a UTF-16 intermediate result string only when CODEUNITS16 is specified.

Regardless of whether an intermediate string is used, when CODEUNITS32, CODEUNITS16, or OCTETS is specified for a function or the CAST specification, the length attribute of the final result string is calculated by applying the formulas that are described in the following table. The length attributes that are calculated at each step in the formulas are measured in bytes, unless indicated otherwise.

Table 9. Formulas for the length attribute of the final result string

Function	Determination of the length attribute of the string <sup>1</sup>
CAST specification	Follow these three steps to determine the length attribute of the final result:
CHAR	<b>1. Length of the intermediate string (IML)</b> When CODEUNITS32 or CODEUNITS16 is specified: <ul style="list-style-type: none"><li>• If the source string is not in Unicode CCSID 1200, 1208, or 367, convert the source string to CCSID 1200, using the formulas in Table 35 on page 126 to determine the result length of the intermediate string (IML).</li><li>• If source string is in Unicode CCSID 1208 or 367, and CODEUNITS16 is specified, convert the source string to CCSID 1200, using the formulas in Table 35 on page 126 to determine the result length of the intermediate string (IML).</li><li>• Otherwise, the intermediate string is the same as the source string.</li></ul>
CLOB	
DBCLOB	
GRAPHIC	
VARCHAR	
VARGRAPHIC	When OCTETS is specified: <ul style="list-style-type: none"><li>• If the CCSID of the source string is different from the CCSID of the result of the function, convert the source string to the CCSID of the result of the function, using the formulas in Table 35 on page 126 to determine the result length of the intermediate string (IML).</li><li>• Otherwise, the intermediate string is the same as the source string.</li></ul> <p><b>Exception:</b> For the GRAPHIC and VARGRAPHIC function, if the source string is EBCDIC, the source is widened with prefix X'42' before the source string is converted to CCSID 1200 and the length of the intermediate string is determined.</p>
	<b>2. Result length attribute of the intermediate string (rl)</b> The result length (rl) of the intermediate string depends on whether a <i>length</i> argument was explicitly specified. If <i>length</i> was not specified, the result length (rl) attribute is: $rl = IML$
	If <i>length</i> was specified, the result length (rl) attribute is: <pre>IF (ol * n) &lt; r_IML THEN     rl = ol * n ELSE     IF intermediate string is in CCSID 1200         (UTF-16) THEN             rl = MIN( ol * n , IML + ( r * 2 ) )     ELSE         rl = MIN( ol * n , IML + r )</pre>
	Where: <ul style="list-style-type: none"><li>• ol = original <i>length</i> argument, expressed in the specified string units</li><li>• n = 4 bytes for CODEUNITS32 2 bytes for CODEUNITS16</li><li>• IML = length of the intermediate string</li><li>• r_IML = IML rounded up to next multiple of n</li><li>• r = ol - (r_IML/n), expressed in the specified string units</li></ul> The calculation for r is an estimate of the difference between the <i>length</i> argument and the estimated number of characters of the input argument, expressed in the specified string units.
	<b>3. Length of the final result string (the result of the function)</b> The result length attribute of the final string is determined by converting the result length (rl) of the intermediate string to the CCSID of the result of the function, using the formulas in Table 35 on page 126, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is rl.

Table 9. Formulas for the length attribute of the final result string (continued)

Function	Determination of the length attribute of the string <sup>1</sup>
CHARACTER_LENGTH	<p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li><b>Length of the intermediate string (IML)</b> The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)</li> </ol>
LOCATE LOCATE_IN_STRING IN_STRING POSITION	<p>For the LOCATE, LOCATE_IN_STRING, and POSITION functions, this applies to both the <i>source-string</i> and <i>search-string</i>. If the CCSIDs of intermediate strings for the converted <i>source-string</i> and <i>search-string</i> differ, the intermediate string for the <i>search-string</i> is converted to the CCSID of intermediate string for the <i>source-string</i>.</p> <ol style="list-style-type: none"> <li><b>Result length attribute of the intermediate string (rl)</b> The result length (rl) attribute is always 4 (the length of an integer):  <math display="block">rl = 4</math></li> <li><b>Length of the final result string (the result the function)</b> The length of the final result of the function is always an integer.</li> </ol>
INSERT OVERLAY	<p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li><b>Length of the intermediate string (IML)</b> The length of the intermediate string (IML) for both the <i>source-string</i> and the <i>insert-string</i> is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)  If the CCSIDs of the intermediate strings for the converted <i>source-string</i> and <i>insert-string</i> differ, the intermediate string for the <i>insert-string</i> is converted to the CCSID of the intermediate string for the <i>source-string</i>.</li> <li><b>Result length attribute of the intermediate string (rl)</b> The result length (rl) attribute of the intermediate string depends on whether the start and length arguments are constants.  If the <i>start</i> and <i>length</i> arguments are both constants, the result length attribute is:  <math display="block">rl = L1 - \text{MIN}(\text{MAX}(0, L1 - (V2 - 1) * n), V3 * m) + L4</math></li> <li>If at least one argument (the <i>start</i> or <i>length</i> argument) is not a constant, the result length attribute is:  <math display="block">rl = L1 + L4</math></li> </ol> <p>Where:</p> <ul style="list-style-type: none"> <li>L1 and L4 are the length attributes of the intermediate strings of the <i>source-string</i> and <i>insert-string</i>, respectively.</li> <li>V2 and V3 are the <i>start</i> and <i>length</i> values, respectively, expressed in the specified string units.</li> </ul> <p><b>m=</b></p> <ul style="list-style-type: none"> <li>1 if the intermediate string of the <i>source-string</i> is not CCSID 1200 (UTF-16)</li> <li>2 if the intermediate string of the <i>source-string</i> is CCSID 1200 (UTF-16)</li> </ul> <p><b>n=</b></p> <ul style="list-style-type: none"> <li>4 bytes for CODEUNITS32</li> <li>2 bytes for CODEUNITS16</li> </ul> <ol style="list-style-type: none"> <li><b>Length of the final result string (the result the function)</b> The length of the final result is the same as the length of the final result for the CAST specification. (See Length attribute of the final result string (the result of the function).)</li> </ol>

Table 9. Formulas for the length attribute of the final result string (continued)

Function	Determination of the length attribute of the string <sup>1</sup>
LEFT	<p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li><b>Length of the intermediate string (IML)</b> The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)</li> </ol>
RIGHT	<ol style="list-style-type: none"> <li><b>Result length attribute of the intermediate string (rl)</b> The result length (rl) attribute is the same as the length of the intermediate string: <math display="block">rl = IML</math></li> <li><b>Length of the final result string (the result of the function)</b> The result length attribute of the final string is determined by converting the result length (rl) of the intermediate string to the CCSID of the result of the function, using the formulas in Table 35 on page 126, if CCSID conversion is necessary. Otherwise, the result length attribute of the final string is rl.</li> </ol> <p>The result length attribute of the final string is:</p> $\text{MIN}(\text{length of source string, length of CCSID converted string})$
SUBSTRING	<p>Follow these three steps to determine the length attribute of the final result:</p> <ol style="list-style-type: none"> <li><b>Length of the intermediate string (IML)</b> The length of the intermediate string (IML) is determined the same way as for the CAST specification. (See Length of the intermediate string (IML).)</li> <li><b>Result length attribute of the intermediate string (rl)</b> The result length (rl) of the intermediate string depends on whether a <i>length</i> argument was explicitly specified. If <i>length</i> was not specified, the result length (rl) attribute is: <math display="block">rl = IML</math></li> <li>If <i>length</i> was specified, the result length (rl) attribute is: <math display="block">rl = \text{MIN}(ol * n, IML)</math> Where:<ul style="list-style-type: none"> <li>• <i>ol</i> = original <i>length</i> argument, expressed in the specified string units  <ul style="list-style-type: none"> <li><b>n</b> = 4 bytes for CODEUNITS32</li> <li>2 bytes for CODEUNITS16</li> </ul> </li> <li>• IML = length of the intermediate string</li> </ul></li> </ol> <p><b>3. Length of the final result string (the result of the function)</b> The length of the final result string is the same as for LEFT built-in function.</p>

**Note:**

1. The final value of the calculation for each length attribute (IML, rl, and the final result of the function) is limited by the maximum length of the function or by the maximum length of the corresponding data type of the result, whichever is applicable. Each length attribute is expressed in terms of bytes.

*Example 1:* Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,10,CODEUNITS32) as COL1 FROM T1;
```

DB2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Table 35 on page 126,  $X * 2$ ) is  $26 * 2$ . Thus, the length of the intermediate string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 10 UTF-32 characters in this string. The result length attribute is 40 bytes ( $r1 = o1 * n$  or  $10 * 4$ ) because  $o1 * n < r\_IML$  or  $40 < 52$ .
3. The 40 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Table 35 on page 126,  $X * .5$ ) is  $40 * .5$ . Thus, the length of the final result of the functions is 20 bytes.

*Example 2:* This example is similar to the first example, except that the specified length for the function is 20 instead of 10. Assume that T1 is a table encoded in EBCDIC and C1 is a CHAR(26) column (SBCS data with EBCDIC CCSID 37). The CHAR function is invoked in the following statement:

```
SELECT CHAR(C1,20,CODEUNITS32) as COL1 FROM T1;
```

DB2 uses an intermediate string to evaluate the function and determines the intermediate and final result string lengths using these steps:

1. C1, which is SBCS EBCDIC 37 data, is converted to Unicode 1200 (UTF-16). The result length of the conversion (using the formula from Table 35 on page 126,  $X * 2$ ) is  $26 * 2$ . Thus, the length of the intermediate result string is 52 bytes (IML = 52).
2. The CHAR function is evaluated against the first 20 UTF-32 characters in this intermediate string. However, because the estimated number of characters in the intermediate string, as expressed in the specified string units, is only 13 characters ( $r\_IML/n$  or  $52/4$ ), the intermediate string must be padded with 7 padding characters to satisfy the 20 characters that are requested ( $r = o1 - (r\_IML/n)$  or  $20 - 13$ ). In Unicode 1200 (UTF-16), each padding character takes 2 bytes.

The result length attribute is then calculated to be 66 bytes ( $r1 = \text{MIN}(o1 * n, IML + (r * 2))$  or  $\text{MIN}(20 * 4, 52 + 14)$ ) because  $o1 * n < r\_IML$  or  $80 < 52$  is not true.

3. The 66 bytes of the string are converted back to SBCS EBCDIC 37. The result length of the conversion (using the formula from Table 35 on page 126,  $X * .5$ ) is  $66 * .5$ . Thus, the length of the final result of the function is 33 bytes.

## Graphic strings

A *graphic string* is a sequence of double-byte characters.

The length of the string is the number of characters in the sequence. Like character strings, graphic strings can be empty. An empty string should not be confused with the null value.

### Fixed-length graphic strings

When fixed-length graphic string distinct types, columns, and variables are defined, the length attribute is specified and all values have the same length. For a fixed-length graphic string, the length attribute must be between 1 and 127 inclusive. A fixed-length graphic string column can also be called a GRAPHIC column.

### Varying-length graphic strings

The types of varying-length graphic strings are VARGRAPHIC and *double-byte character large object (DBCLOB)*. DBCLOB is a type of LOB. A DBCLOB column is

useful for storing large amounts of double-byte character data, such as documents written with a single double-byte character set.

When varying-length graphic strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual values might have a smaller value. For a varying-length graphic string, the length attribute must be between 1 and 16352.

For a varying-length graphic string column, the maximum for the length attribute is determined by the record size associated with the table, as described Maximum record size in the description of the CREATE TABLE statement. For a DBCLOB string, the length attribute must be between 1 and 1 073 741 823 inclusive. In UTF-16, although supplementary characters use two 2-byte code points, supplementary characters are still considered double-byte characters. For more information about DBCLOBS, see “Large objects (LOBs)” on page 85.

## Graphic string variables

Graphic string variables must follow certain rules.

Variables with a graphic string type cannot be defined in Fortran. In addition, graphic string variables follow these rules:

- Fixed-length graphic string host variables can be defined in all host languages, except REXX and Java. In C, fixed-length graphic-string variables are limited to a length of 1.
- Varying-length graphic string variables can be defined in all host languages, with the exception of DBCLOBS which cannot be used in REXX.

## Graphic string encoding schemes

Each graphic string can be further defined as either double-byte data or Unicode data.

### Double-byte data

Data in which every character is represented by a character from the double-byte character set (DBCS) that does not include shift-out or shift-in characters. Each double-byte graphic string has an associated ASCII or EBCDIC CCSID.

### Unicode data

Data that contains characters represented by two bytes, except supplementary characters, which take two 2-byte code points per character. Each Unicode graphic string is encoded using UTF-16. The CCSID for UTF-16 is 1200.

## String units in built-in functions

When working with graphic strings, you can specify the string unit in which the operation is to take place for certain built-in functions and the CAST specification. The string unit determines the length in which the operation is to occur.

For more information about string units, see “String unit specifications” on page 76.

## Binary strings

A *binary string* is a sequence of bytes.

The length of a binary string is the number of bytes in the sequence. Binary strings are not associated with any CCSID. There are three binary string data types: BINARY, VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT).

### Fixed-length binary strings

The type of fixed-length binary strings is BINARY. When fixed-length binary string distinct types, columns, and variables are defined, the length attribute is specified, and all values have the same length. For a fixed-length binary string, the length attribute must be between 1 and 255 inclusive.

### Varying-length binary strings

The types of varying-length binary strings are VARBINARY (BINARY VARYING) and BLOB (BINARY LARGE OBJECT)

When varying-length binary strings, distinct types, columns, and variables are defined, the maximum length is specified and this length becomes the length attribute. Actual length values might have a smaller value than the length attribute value. For varying-length binary strings, the actual length specifies the number of bytes in the string.

For a VARBINARY string, the length attribute must be between 1 and 32704. For a VARBINARY string column, the maximum for the length attribute is determined by the record size that is associated with the table, as described in "Maximum record size" on the description of the CREATE TABLE statement. Like a varying-length character string, varying-length binary string could be an empty string.

A binary string column is useful for storing non-character data, such as encoded or compressed data, pictures, voice, and mixed media. Another use is to hold structured data for exploitation by distinct types, user-defined functions, and stored procedures. Note, that although binary strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BINARY, BLOB, VARBINARY built-in functions and CAST specification can be used to change a FOR BIT DATA character string into a binary string.

## Large objects (LOBs)

The term *large object (LOB)* refers to any of the following data types: CLOB, DBCLOB, or BLOB.

**CLOB** A *character large object (CLOB)* is a varying-length string with a maximum length of 2 147 483 647 bytes (2 gigabytes minus 1 byte). A CLOB is designed to store large SBCS data or mixed data, such as lengthy documents. For example, you can store information such as an employee resume, the script of a play, or the text of novel in a CLOB. Alternatively, you can store such information in UTF-8 in a mixed CLOB. A CLOB is a varying-length character string.

### DBCLOB

A *double-byte character large object (DBCLOB)* is a varying-length string with a maximum length of 1 073 741 823 double-byte characters. A DBCLOB is designed to store large DBCS data. For example, you could store the information mentioned for CLOB (an employee resume, the script for a play, or the text of a novel) in UTF-16 in a DBCLOB. A DBCLOB is a varying-length graphic string.

**BLOB** A *binary large object (BLOB)* is a varying-length string with a maximum

length of 2 147 483 647 bytes (2 gigabytes minus 1 byte). A BLOB is designed to store non-traditional data such as pictures, voice, and mixed media. BLOBs can also store structured data for use by distinct types and user-defined functions. A BLOB is a binary string.

Although BLOB strings and FOR BIT DATA character strings might be used for similar purposes, the two data types are not compatible. The BLOB function can be used to change a FOR BIT DATA character string into a BLOB string.

## Restrictions using LOBs

With a few exceptions, you can use LOBs in the same contexts in which you can use other varying-length strings.

The following table shows the contexts in which LOBs cannot be used.

Table 10. Contexts in which LOBs cannot be used

Context of usage	LOB (CLOB, DBCLOB, or BLOB)
A GROUP BY clause	Not allowed
An ORDER BY clause	Not allowed
A CREATE INDEX statement	Not allowed
A SELECT DISTINCT statement	Not allowed
I A subselect of a set operation except UNION ALL	Not allowed
Predicates	Cannot be used in any predicate except EXISTS, LIKE, and NULL. This restriction includes a <i>simple-when-clause</i> in a CASE expression. <i>expression WHEN expression</i> in a <i>simple-when-clause</i> is equivalent to a predicate with <i>expression=expression</i> .
The definition of primary, unique, and foreign keys	Not allowed
Check constraints	Not allowed

## Manipulating LOBs using locators

A LOB locator is a host variable with a value that represents a single LOB value in the database server. LOB locators provide a mechanism for you to easily manipulate very large objects in application programs without having to store the entire LOB value on the client machine where the application program might be running.

Because LOB values can be very large, the transfer of these values from the database server to host variables in client application programs can be time consuming. Also, application programs typically process LOB values a piece at a time, rather than as a whole. For these cases, the application can use a *large object locator* (LOB locator) to reference the LOB value.

For example, when selecting a LOB value, an application program could handle the value in either of these two ways:

- Select the entire LOB value and place it into an equally large host variable. This method is acceptable if the application program is going to process the entire LOB value at once.
- Select the LOB value into a LOB locator. Then, using the LOB locator, the application program can issue subsequent database operations on the LOB value (such as using it as a parameter to the scalar functions SUBSTR, CONCAT, COALESCE, LENGTH, doing an assignment, searching the LOB value with

LIKE or POSSTR, or using it as a parameter to a user-defined function or procedure) by supplying the LOB locator value as input. The resulting output of the LOB locator operation, for example, the amount of data that is assigned to a client host variable, would then typically be a small subset of the input LOB value.

LOB locators can also represent more than just base values; they can also represent the value associated with a LOB expression. For example, a LOB locator might represent the value associated with:

```
SUBSTR(lob_value_1 CONCAT lob_value_2 CONCAT lob_value_3 , 42, 6000000)
```

For non-locator-based host variables in an application program, when a null value is selected into that host variable, the indicator variable is set to -1, signifying that the value is null. For LOB locators, however, the meaning of indicator variables is slightly different. Because a LOB locator host variable itself can never be null, a negative indicator variable value indicates that the LOB value represented by the LOB locator is null. The null information is kept local to the client by virtue of the indicator variable value (the server does not track null values with valid LOB locators).

A LOB locator represents a value, not a row or location in the database. Therefore, after a value is selected into a LOB locator, no action that is subsequently performed on the original row or table will affect the value that is referenced by the LOB locator. The value associated with a LOB locator is valid until the transaction ends, or until the LOB locator is explicitly freed, whichever comes first.

A LOB locator is also not a database type, and it is never stored in the database. As a result, it cannot participate in views or check constraints. However, values for the SQLTYPE field of the SQLDA exist for LOB locators so that they can be described within an SQLDA structure that is used by FETCH, OPEN, CALL and EXECUTE statements.

For more information about manipulating LOBs with LOB locators, see *DB2 Application Programming and SQL Guide*.

## Datetime values

Datetime values are neither strings nor numbers. Nevertheless, datetime values can be used in certain arithmetic and string operations and are compatible with certain strings.

Moreover, strings can represent datetime values, as discussed in “String representations of datetime values” on page 89.

### Date

A *date* is a three-part value (year, month, and day) designating a point in time using the Gregorian calendar, which is assumed to have been in effect from the year 1 A.D.

<sup>4</sup> The range of the year part is 0001 to 9999. The range of the month part is 1 to 12. The range of the day part is 1 to 28, 29, 30, or 31, depending on the month and year.

---

4. Historical dates do not always follow the Gregorian calendar. Dates between 1582-10-04 and 1582-10-15 are accepted as valid dates although they never existed in the Gregorian calendar.

The internal representation of a date is a string of 4 bytes. Each byte consists of two packed decimal digits. The first 2 bytes represent the year, the third byte the month, and the last byte the day.

The length of a DATE column as described in the catalog is the internal length, which is 4 bytes. The length of a DATE column as described in the SQLDA is the external length, which is 10 bytes unless a date exit routine was specified when your DB2 subsystem was installed. (Writing a date exit routine is described in *DB2 Administration Guide*.) In that case, the string format of a date can be up to 255 bytes in length. Accordingly, DCLGEN<sup>5</sup> defines fixed-length string variables for DATE columns with a length equal to the value of the field LOCAL DATE LENGTH on installation panel DSNTIP4, or a length of 10 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

### Time

A *time* is a three-part value (hour, minute, and second) designating a time of day using a 24-hour clock. The range of the hour part is 0 to 24. The range of the minute and second parts is 0 to 59. If the hour is 24, the minute and second parts are both zero.

The internal representation of a time is a string of 3 bytes. Each byte consists of two packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column as described in the catalog is the internal length which is 3 bytes. The length of a TIME column as described in the SQLDA is the external length which is 8 bytes unless a time exit routine was specified when the DB2 subsystem was installed. (Writing a time exit routine is described in *DB2 Administration Guide*.) In that case, the string format of a time can be up to 255 bytes in length. Accordingly, DCLGEN<sup>5</sup> defines fixed-length string variables for TIME columns with a length equal to the value of the field LOCAL TIME LENGTH on installation panel DSNTIP4, or a length of 8 bytes if a value for the field was not specified.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

### Timestamp

A *timestamp* is a seven-part value (year, month, day, hour, minute, second, and microsecond) that represents a date and time. The time portion of a timestamp includes a fractional specification of microseconds.

The internal representation of a timestamp is a string of 10 bytes, each of which consists of two packed decimal digits. The first 4 bytes represent the date, the next 3 bytes the time, and the last 3 bytes the microseconds.

The length of a TIMESTAMP column as described in the catalog is the internal length which is 10 bytes. The length of a TIMESTAMP column as described in the SQLDA is the external length which is 26 bytes. DCLGEN therefore defines 26-byte, fixed-length string variables for TIMESTAMP columns.

---

5. DCLGEN is a DB2 DSN subcommand for generating table declarations for designated tables or views. The declarations are stored in z/OS data sets, for later inclusion in DB2 source programs.

A character-string representation must have an actual length that is not greater than 255 bytes and must not be a CLOB or DBCLOB.

## Datetime host variables

Character-string host variables are normally used to contain date, time, and timestamp values. However, date, time, and timestamp host variables can also be specified in Java as java.sql.Date, java.sql.Time, and java.sql.Timestamp, respectively.

## String representations of datetime values

Dates, times, and timestamp values can be represented by strings. For many host languages, there are no special SQL constants for datetime values and, except for Java, no host variables with a data type of date, time, or timestamp. Thus, to be retrieved, a datetime value must be assigned to a string variable.

Values whose data types are date, time, or timestamp are represented in an internal form that is transparent to the user of SQL. But dates, times, and timestamps can also be represented by strings. These representations directly concern the SQL user because for many host languages there are no special SQL constants for datetime values and, except for Java, no host variables with a data type of date, time, or timestamp. Thus, to be retrieved, a datetime value must be assigned to a string variable.

Each datetime value is assigned an encoding scheme. This encoding scheme is used when the datetime value is converted from its internal form to the string representation in the form of the mixed CCSID if the field MIXED DATA is YES on installation panel DSNTIPF. Otherwise the SBCS CCSID of the assigned encoding scheme is used. For Unicode, the mixed CCSID is always used. The following table shows how the encoding scheme is determined:

*Table 11. The encoding scheme of datetime values*

Datetime expression	Result encoding scheme
Columns	The same encoding scheme as the table that contains the column
Host variables	If the statement references: <ul style="list-style-type: none"><li>• A single encoding scheme - The same encoding scheme</li><li>• Multiple encoding schemes - The application encoding scheme</li></ul>
Special registers	If the statement references: <ul style="list-style-type: none"><li>• A single encoding scheme - The same encoding scheme</li><li>• Multiple encoding schemes - The application encoding scheme</li></ul>
Expressions	If the statement references: <ul style="list-style-type: none"><li>• A single encoding scheme - The same encoding scheme</li><li>• Multiple encoding schemes - The application encoding scheme</li></ul>

For ASCII and EBCDIC, a string representation of a datetime value must be a character string. For Unicode, a string representation of a datetime value can be either a character string or a graphic string. Thus, the only time a graphic string can be used for a datetime value is when the encoding scheme is Unicode.

In host languages other than Java, a datetime value must be assigned to a string variable. When a date or time is assigned to a string variable, the string format is determined by a precompiler option or subsystem parameter. When a string representation of a datetime value is used in other operations, it is converted to a datetime value. However, this can be done only if the string representation is recognized by DB2 or an exit provided by the installation and the other operand is a compatible datetime value. An input string representation of a date or time with LOCAL specified must have an actual length that is not greater than 255 bytes.

Datetime values that are represented by strings can appear in contexts requiring values whose data types are date, time, or timestamp. A string representation of a date, time or timestamp can be passed as an argument to the DATE, TIME, or TIMESTAMP function to obtain a datetime value. A CAST specification can also be used to turn a character representation of a date, time, or timestamp into a datetime value.

#### Date strings:

A string representation of a date is a string that starts with a digit and has a length of at least 8 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the month and day portions.

The following table shows the valid string formats for dates. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. For an installation-defined date string format, the format and length must have been specified when DB2 was installed. They cannot be listed here.

*Table 12. Formats for string representations of dates*

Format name	Abbreviation	Date format	Example
International Standards Organization	ISO	yyyy-mm-dd	1987-10-12
IBM USA standard	USA	mm/dd/yyyy	10/12/1987
IBM European standard	EUR	dd.mm.yyyy	12.10.1987
Japanese industrial standard Christian era	JIS	yyyy-mm-dd	1987-10-12
Installation-defined	LOCAL	Any installation- defined form	—

#### Time strings:

A string representation of a time is a string that starts with a digit, and has a length of at least 4 characters. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the hour part of the time; seconds can be omitted entirely. If you choose to omit seconds, an implicit specification of 0 seconds is assumed. Thus 13.30 is equivalent to 13.30.00.

The following table shows the valid string formats for times. Each format is identified by name and includes an associated abbreviation (for use by the CHAR function) and an example of its use. In the case of an installation-defined time string format, the format and length must have been specified when your DB2 subsystem was installed. They cannot be listed here.

*Table 13. Formats for string representations of times*

Format name	Abbreviation	Time format	Example
International Standards Organization 1	ISO <sup>1</sup>	hh.mm.ss	13.30.05
IBM USA standard	USA	hh:mm AM or PM	1:30 PM
IBM European standard	EUR	hh.mm.ss	13.30.05
Japanese industrial standard Christian era	JIS	hh:mm:ss	13:30:05
Installation-defined	LOCAL	Any installation-defined form	—

**Note:** 1. This is an earlier version of the ISO format. JIS can be used to get the current ISO format.

In the USA format:

- The minutes can be omitted, thereby specifying 00 minutes. For example, 1 PM is equivalent to 1:00 PM.
- The letters A, M, and P can be lowercase.
- A single blank must precede the AM or PM.
- The hour must not be greater than 12 and cannot be 0 except for the special case of 00:00 AM.

Using the ISO format of the 24-hour clock, the correspondence between the USA format and the 24-hour clock is as follows:

- 12:01 AM through 12:59 AM correspond to 00.01.00 through 00.59.00
- 01:00 AM through 11:59 AM correspond to 01.00.00 through 11.59.00
- 12:00 PM (noon) through 11:59 PM correspond to 12.00.00 through 23.59.00
- 12:00 AM (midnight) corresponds to 24.00.00
- 00:00 AM (midnight) corresponds to 00.00.00

#### Timestamp strings:

A string representation of a timestamp is a string that starts with a digit and has a length of at least 16 characters. The complete string representation of a timestamp has the form *yyyy-mm-dd-hh.mm.ss.nnnnnn*. Trailing blanks can be included, leading blanks are not allowed, and leading zeros can be omitted in the month, day, and hour part of the timestamp; trailing zeros can be truncated or omitted entirely from microseconds. If you choose to omit any digit of the microseconds portion, an implicit specification of 0 is assumed. Thus, '1990-3-2-8.30.00.10' is equivalent to '1990-03-02-08.30.00.100000'. A timestamp whose time part is '24.00.00.000000' is also accepted.

SQL statements also support the ODBC or JDBC string representation of a timestamp as an input value only. The ODBC and JDBC string representation of a timestamp has the form *yyyy-mm-dd hh:mm:ss.nnnnnn*.

**LOCAL date and time exits:** For LOCAL, the date exit for ASCII data is DSNXVDTA, the date exit for EBCDIC is DSNXVDTX, and the date exit for Unicode is DSNXVDTU. For LOCAL, the time exit for ASCII data is DSNXVTMA, the time exit for EBCDIC is DSNXVTMX, and the time exit for Unicode is DSNXVTMU.

## Restrictions on the use of local datetime formats

Certain restrictions apply on the use of date and time values as input, as output, and for use in binding a package.

The following rules apply to the character-string representation of dates and times:

**For input:** In distributed operations, DB2 as a server uses its local date or time routine to evaluate host variables and constants. This means that character-string representation of dates and times can be:

- One of the standard formats
- A format recognized by the server's local date/time exit

**For output:** With DRDA access, DB2 as a server returns date and time host variables in the format defined at the server. With DB2 private protocol access, DB2 as a server returns date and time host variables in the format defined at the requesting system. To have date and time host variables returned in another format, use CHAR(*date-expression*, XXXX) where XXXX is JIS, EUR, USA, ISO, or LOCAL to explicitly specify the specific format.

**For BIND PACKAGE COPY:** When binding a package using the COPY option, DB2 uses the ISO format for output values unless the SQL statement explicitly specifies a different format. Input values can be specified in the format described previously.

## Row ID values

A *row ID* is a value that uniquely identifies a row in a table. A column or a host variable can have a row ID data type.

A ROWID column enables queries to be written that navigate directly to a row in the table because the column implicitly contains the location of the row. Each value in a ROWID column must be unique. Although the location of the row might change, for example across a table space reorganization, DB2 maintains the internal representation of the row ID value permanently. When a row is inserted into the table, DB2 generates a value for the ROWID column unless one is supplied. If a value is supplied, it must be a valid row ID value that was previously generated by DB2 and the column must be defined as GENERATED BY DEFAULT. Users cannot update the value of a ROWID column.

The internal representation of a row ID value is transparent to the user. The value is never subject to character conversion because it is considered to contain BIT data. The length of a ROWID column as described in the LENGTH column of catalog table SYSCOLUMNS is the internal length, which is 17 bytes. The length as described in the LENGTH2 column of catalog table SYSCOLUMNS is the external length, which is 40 bytes.

A ROWID column can be either user-defined or implicitly generated by DB2. You can use the CREATE TABLE statement or the ALTER TABLE statement to define a ROWID column. If you define a LOB column in a table and the table does not have a ROWID column, DB2 implicitly generates a ROWID column. DB2:

- Creates the column with a name of DB2\_GENERATED\_ROWID\_FOR\_LOBS $nn$ . DB2 appends  $nn$  only if the column name already exists in the table, replacing  $nn$  with '00' and incrementing by '1' until the name is unique within the row.
- Defines the column as GENERATED ALWAYS.
- Appends the column to the end of the row after all the other explicitly defined columns.

An implicitly hidden ROWID column is called *a hidden ROWID column*. A hidden ROWID column is not visible in SQL statements unless you refer to the column directly by name. For example, assume that DB2 generated a hidden ROWID column named DB2\_GENERATED\_ROWID\_FOR\_LOBS for table MYTABLE. The result table for a SELECT \* statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2\_GENERATED\_ROWID\_FOR\_LOBS would include the hidden ROWID column.

If you add a ROWID column to a table that already has a hidden ROWID column, DB2 ensures that the corresponding values in each column are identical. If the ROWID column that you add is defined as GENERATED BY DEFAULT, DB2 changes the attribute of the hidden ROWID column to GENERATED BY DEFAULT.

In a distributed data environment, the row ID data type is not supported for DB2 private protocol access. For information about using row IDs, see *DB2 Application Programming and SQL Guide*.

## XML values

An XML value represents well-formed XML in the form of an XML document, XML content, or a sequence of XML nodes.

An XML value that is stored in a table as the value of a column that is defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value. The only predicates that can be applied to the XML data type are the XMLEXISTS predicate and the NULL predicate.

An XML value can be transformed into a serialized string value that represents the XML document by using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed to an XML value by using the XMLPARSE function.

The XML data type has a variable length and allows for a wide range of sizes. Although data of this type has no defined maximum length, it does have an effective maximum length limit when treated as a serialized string value that represents XML. The maximum effective length is the same as the DB2 limit for a LOB data value. DB2 treats XML string data in a similar manner as LOB data to accommodate very large XML values. Thus, XML values are constrained by the same maximum length limit as LOB data. Unlike the LOB data type which has a LOB locator type, there is no XML locator type.

**Restrictions when using XML values:** With a few exceptions, you can use XML values in the same contexts in which you can use other data type. XML values cannot be used in the following contexts:

- SELECT lists that are preceded by the DISTINCT clause
- GROUP BY clauses
- ORDER BY clauses
- A subselect of a fullselect with a set operator that is not UNION ALL
- Basic predicates, quantified predicates, BETWEEN predicates, DISTINCT predicates, IN predicates, or LIKE predicates
- Aggregate functions with the DISTINCT keyword
- Primary, unique, or foreign keys

- CREATE TYPE statements
- | No host languages have any built-in support for an XML data type.

## Distinct types

A *distinct type* is a user-defined data type that shares its internal representation with a built-in data type (its *source type*), but is considered to be a separate and incompatible data type for most operations.

For example, the semantics for a picture type, a text type, and an audio type that all use the built-in data type BLOB for their internal representation are quite different. A distinct type is created with the SQL statement CREATE TYPE.

For example, the following statement creates a distinct type named AUDIO:

```
CREATE TYPE AUDIO AS BLOB (1M);
```

Although AUDIO has the same representation as the built-in data type BLOB, it is a separate data type that is not comparable to a BLOB or to any other data type. This inability to compare AUDIO to other data types allows functions to be created specifically for AUDIO and assures that these functions cannot be applied to other data types.

The name of a distinct type is qualified with a schema name. The implicit schema name for an unqualified name depends on the context in which the distinct type appears. If an unqualified distinct type name is used:

- In a CREATE TYPE statement or the object of DROP, COMMENT, GRANT, or REVOKE statement, DB2 uses the normal process of qualification by authorization ID to determine the schema name.
- In any other context, DB2 uses the SQL path to determine the schema name. DB2 searches the schemas in the path, in sequence, and selects the first schema in the path such that the distinct type exists in the schema and the user has authorization to use the data type. For a description of the SQL path, see “SQL path” on page 56.

A distinct type does not automatically acquire the functions and operators of its source type because they might not be meaningful. (For example, it might make sense for a “length” function of the AUDIO type to return the length in seconds rather than in bytes.) Instead, distinct types support *strong typing*. Strong typing ensures that only the functions and operators that are explicitly defined on a distinct type can be applied to that distinct type. However, a function or operator of the source type can be applied to the distinct type by creating an appropriate user-defined function. The user-defined function must be sourced on the existing function that has the source type as a parameter. For example, the following series of SQL statements shows how to create a distinct type named MONEY based on data type DECIMAL(9,2), how to define the + operator for the distinct type, and how the operator might be applied to the distinct type:

```
CREATE TYPE MONEY AS DECIMAL(9,2);
CREATE FUNCTION "+"(MONEY,MONEY)
RETURNS MONEY
SOURCE SYSIBM.+"(DECIMAL(9,2),DECIMAL(9,2));
CREATE TABLE SALARY_TABLE
(SALARY MONEY,
 COMMISSION MONEY);
SELECT SALARY + COMMISSION FROM SALARY_TABLE;
```

A distinct type is subject to the same restrictions as its source type. For example, if a CLOB value is not allowed as input to a function, you cannot specify a distinct type that is based on a CLOB as input.

The comparison operators are automatically generated for distinct types, except those that are based on a CLOB, DBCLOB, or BLOB. In addition, DB2 automatically generates functions for every distinct type that support casting from the source type to the distinct type and from the distinct type to the source type. For example, for the AUDIO type created above, these are generated cast functions:

```
FUNCTION schema-name.BLOB (schema-name.AUDIO) RETURNS SYSIBM.BLOB (1M)
FUNCTION schema-name.AUDIO (SYSIBM.BLOB (1M)) RETURNS schema-name.AUDIO
```

In a distributed data environment, distinct types are not supported for DB2 private protocol access.

## Promotion of data types

Data types can be classified into groups of related data types. Within such groups, an order of precedence exists in which one data type is considered to precede another data type. This precedence enables DB2 to support the *promotion* of one data type to another data type that appears later in the precedence order.

For example, DB2 can promote the data type CHAR to VARCHAR and the data type INTEGER to DOUBLE PRECISION; however, DB2 cannot promote a CLOB to a VARCHAR.

DB2 considers the promotion of data types when:

- Performing function resolution (see “Function resolution” on page 175)
- Casting distinct types (see “Casting between data types” on page 96)
- Assigning built-in data types to distinct types (see “Distinct type assignments” on page 113)

For each data type, the following table shows the precedence list (in order) that DB2 uses to determine the data types to which the data type can be promoted. The table indicates that the best choice is the same data type and not promotion to another data type. The table also shows data types that are considered equivalent during the promotion process. For example, CHARACTER and GRAPHIC are considered to be equivalent data types.

*Table 14. Precedence of data types*

Data type <sup>1,2</sup>	Data type precedence list (in best-to-worst order)
SMALLINT <sup>3</sup>	SMALLINT, INTEGER, BIGINT, decimal, real, double, DECFLOAT
INTEGER <sup>3</sup>	INTEGER, BIGINT, decimal, real, double, DECFLOAT
BIGINT <sup>3</sup>	BIGINT, decimal, real, double, DECFLOAT
decimal <sup>3</sup>	decimal, real, double, DECFLOAT
real	real, double, DECFLOAT
double	double, DECFLOAT
DECFLOAT	DECFLOAT
CHAR or GRAPHIC	CHAR or GRAPHIC, VARCHAR or VARGRAPHIC, CLOB or DBCLOB
VARCHAR or VARGRAPHIC	VARCHAR or VARGRAPHIC, CLOB or DBCLOB

Table 14. Precedence of data types (continued)

Data type <sup>1,2</sup>	Data type precedence list (in best-to-worst order)
CLOB or DBCLOB	CLOB or DBCLOB
BINARY	BINARY, VARBINARY, BLOB
VARBINARY	VARBINARY, BLOB
BLOB	BLOB
DATE	DATE
TIME	TIME
TIMESTAMP	TIMESTAMP
ROWID	ROWID
XML	XML
A distinct type	The same distinct type

**Notes:**

1. The data types in lowercase letters represent the following data types:

**decimal**

DECIMAL(*p,s*) or NUMERIC(*p,s*)

**real** REAL or FLOAT(*n*) where *n* is not greater than 21

**double** DOUBLE, DOUBLE PRECISION, FLOAT or FLOAT(*n*) where *n* is greater than 21

2. Other synonyms for the listed data types are considered to be the same as the synonym listed.
3. Real and double are checked for function resolution purposes only. Additionally, the number of significant digits (even for DECFLOAT(16)), and the exponent range of DECFLOAT exceeds that of real and double (double has 16 significant digits). Therefore, DECFLOAT values will not be promoted to real or double.

## Casting between data types

There are many occasions when a value with a given data type needs to be *cast* (changed) to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion is one example where the promotion of one data type to another data type requires that the value be cast to the new data type. A data type that can be changed to another data type is *castable* from the source data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. You can use the function notation syntax or CAST specification syntax to explicitly cast a data type. DB2 might implicitly cast data types during assignments that involve a distinct type (see “Distinct type assignments” on page 113). In addition, when you create a sourced user-defined function, the data types of the parameters of the source function must be castable to the data types of the function that you are creating (see “CREATE FUNCTION” on page 915).

If truncation occurs when a character or graphic string is cast to another data type, a warning occurs if any non-blank characters are truncated. This truncation behavior is similar to retrieval assignment of character or graphic strings. See “Retrieval assignment” on page 110.

- If truncation occurs when casting to a binary string, an error is returned.
- For casts that involve a distinct type as either the data type to be cast to or from, Table 15 shows the supported casts.
- For casting a parameter marker or NULL value to the XML data type, the CAST specification can be used. XML input can also be specified for the CAST specification when the result data type is XML.

*Table 15. Supported casts when a distinct type is involved*

Data type ...	Is castable to data type ...
Distinct type <i>DT</i>	Source data type of distinct type <i>DT</i>
Source data type of distinct type <i>DT</i>	Distinct type <i>DT</i>
Distinct type <i>DT</i>	Distinct type <i>DT</i>
Data type <i>A</i>	Distinct type <i>DT</i> where <i>A</i> is promotable to the source data type of distinct type <i>DT</i> (see “Promotion of data types” on page 95)
INTEGER	Distinct type <i>DT</i> if <i>DT</i> 's source data type is SMALLINT
DOUBLE	Distinct type <i>DT</i> if <i>DT</i> 's source data type is REAL
VARCHAR	Distinct type <i>DT</i> if <i>DT</i> 's source data type is CHAR or GRAPHIC
VARGRAPHIC	Distinct type <i>DT</i> if <i>DT</i> 's source data type is GRAPHIC or CHAR
VARBINARY	Distinct type <i>DT</i> if <i>DT</i> 's source data type is BINARY

When a distinct type is involved in a cast, a cast function that was generated when the distinct type was created is used. How DB2 chooses the function depends on whether function notation or CAST specification syntax is used. (For details, see “Function resolution” on page 175 and “CAST specification” on page 202, respectively.) Function resolution is similar for both. However, in CAST specification, when an unqualified distinct type is specified as the target data type, DB2 first resolves the schema name of the distinct type and then uses that schema name to locate the cast function.

For casts between built-in data types, the following table shows the supported casts.

*Table 16. Supported casts between built-in data types*

Cast from data type -		To data type <sup>1</sup>																			
		S	I	D	E	V	G	A	R	A	V	T	I	M	E	S	R	O	X	W	X
N	E	N	A	A	A	L	A	A	O	I	I	O	R	R	O	T	M	M	I	M	
T	R	T	L	T	L	E	R	R	B	C	C	B	Y	Y	B	E	E	P	D	L	
SMALLINT	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y										
INTEGER	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y										
BIGINT	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y										
DECIMAL	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y										

Table 16. Supported casts between built-in data types (continued)

		To data type <sup>1</sup>									
		S	I	D	E	V	G	R	A	V	T
Cast from data type -	M	N	B	E	C	D	A	R	R	A	I
	A	L	T	I	C	F	O	R	A	B	M
	L	E	G	I	L	R	U	C	A	I	E
	I	G	I	M	O	E	B	H	H	L	S
	N	E	N	A	A	A	L	A	A	A	R
	T	R	T	L	T	L	E	R	O	L	O
	DECFLOAT	Y	Y	Y	Y	Y	Y	Y	Y	Y	X
	REAL	Y	Y	Y	Y	Y	Y	Y	Y	Y	M
	DOUBLE	Y	Y	Y	Y	Y	Y	Y	Y	Y	I
	CHAR	Y	Y	Y	Y	Y	Y	Y	Y	Y	M
	VARCHAR	Y	Y	Y	Y	Y	Y	Y	Y	Y	M
	CLOB					Y	Y	Y	Y	Y	L
	GRAPHIC	Y	Y	Y	Y	Y	Y	Y <sup>2</sup>	Y <sup>2</sup>	Y	Y
	VARGRAPHIC	Y	Y	Y	Y	Y	Y	Y <sup>2</sup>	Y <sup>2</sup>	Y	Y
	DBCLOB					Y <sup>2</sup>	Y <sup>2</sup>	Y <sup>2</sup>	Y	Y	Y
	BINARY									Y	Y
	VARBINARY									Y	Y
	BLOB									Y	Y
	DATE					Y	Y				Y
	TIME					Y	Y				Y
	TIMESTAMP					Y	Y			Y	Y
	ROWID					Y	Y		Y	Y	Y
	XML										Y

**Note:**

1. Other synonyms for the listed data types are considered to be the same as the synonym listed. Some exceptions exist when the cast involves character string data if the subtype is FOR BIT DATA.
2. The result length for these casts is  $3 * \text{LENGTH}(\text{graphic string})$ .
3. These data types are castable between each other only if the data is Unicode.

Table 17 shows where to find information about the rules that apply when casting to the identified target data types.

Table 17. Rules for casting to a data type

Target data type	Rules
SMALLINT	"SMALLINT" on page 505
INTEGER	"INTEGER or INT" on page 392
BIGINT	"BIGINT" on page 295
DECIMAL	"DECIMAL or DEC" on page 344
NUMERIC	"DECIMAL or DEC" on page 344

*Table 17. Rules for casting to a data type (continued)*

Target data type	Rules
REAL	"REAL" on page 478
DOUBLE	"DOUBLE_PRECISION or DOUBLE" on page 353
DECFLOAT	"DECFLOAT" on page 340
CHAR	"CHAR" on page 302
VARCHAR	"VARCHAR" on page 558
CLOB	"CLOB" on page 312
GRAPHIC	"GRAPHIC" on page 376
VARGRAPHIC	"VARGRAPHIC" on page 569
DBCLOB	"DBCLOB" on page 336
BINARY	"BINARY" on page 297
VARBINARY	"VARBINARY" on page 556
BLOB	"BLOB" on page 299
DATE	"DATE" on page 328
TIME	"TIME" on page 524
TIMESTAMP	See "TIMESTAMP" on page 525, where one operand is specified.
ROWID	"ROWID" on page 493

## Casting non-XML values to XML values

*Table 18. Supported Casts from Non-XML Values to XML Values*

Source Data Type	Target Data Type	
	XML	Resulting XML Schema Type
SMALLINT	Y	xs:short
INTEGER	Y	xs:int
BIGINT	Y	xs:long
DECIMAL	Y	xs:decimal
DECFLOAT	N	
REAL	N	
FLOAT	Y	xs:double
DOUBLE	Y	xs:double
CHAR	Y	xs:string
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string
BINARY	N	
VARBINARY	N	
BLOB	N	
character type FOR BIT DATA	N	

*Table 18. Supported Casts from Non-XML Values to XML Values (continued)*

Source Data Type	Target Data Type	
	XML	Resulting XML Schema Type
DATE	N	
TIME	N	
TIMESTAMP	N	
ROWID	N	
distinct type	N	

When character string values are cast to XML values, the resulting xs:string atomic value cannot contain illegal XML characters. If the input character string is not in Unicode, the input characters are converted to Unicode.

## Casting XML values to non-XML values

An XMLCAST from an XML value to a non-XML value can be described as two casts: an XQuery cast that converts the source XML value to a target XQuery data type that corresponds to the SQL target type, followed by a cast from the corresponding XQuery data type to the actual SQL type. The target XQuery data type is an XML schema data type like xs:decimal or xs:string, as shown in the follow table.

An XMLCAST is supported if the target type has a corresponding XQuery target type that is supported, and if there is a supported XQuery cast from the type of the source value to the corresponding XQuery target type. The target type that is used in the XQuery cast is based on the corresponding XQuery target type and might contain some additional restrictions.

The following table lists the XQuery types that result from such conversion.

*Table 19. Supported Casts from XML Values to Non-XML Values*

Target Data Type	Source Data Type	
	XML	Corresponding XQuery Target Type
SMALLINT	Y	xs:integer
INTEGER	Y	xs:integer
BIGINT	Y	xs:integer
DECIMAL	Y	xs:decimal
DECFLOAT	Y	xs:double
REAL	Y	xs:double
FLOAT	Y	xs:double
DOUBLE	Y	xs:double
CHAR	Y	xs:string
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string

*Table 19. Supported Casts from XML Values to Non-XML Values (continued)*

Target Data Type	Source Data Type	
	XML	Corresponding XQuery Target Type
BINARY	N	
VARBINARY	N	
BLOB	N	
character type FOR BIT DATA	N	
DATE	Y	xs:date
TIME	Y	xs:time
TIMESTAMP	Y	xs:dateTime
ROWID	N	
distinct type	N	

The following restrictions are in effect when a value is cast from an XQuery target data type to a target SQL data type:

- If the target type is one of the character or graphic string types, the resulting XML value is converted, if necessary, to the CCSID of the target data type using the rules described in “Conversion rules for string assignment” on page 111, before it is converted to the target type with a limited length. Truncation occurs if the specified length limit is smaller than the length of the resulting string after CCSID conversion. A warning occurs if any non-blank characters are truncated. If the target type is a fixed-length string type (CHAR or GRAPHIC) and the specified length of the target type is greater than the length of the resulting string from CCSID conversion, blanks are padded at the end. This truncation and padding behavior is similar to retrieval assignment of character or graphic strings.
- If the target type is DOUBLE or REAL and the source XML value after the XQuery cast is an xs:double value of INF, -INF, or NaN, an error is returned. If the source value is an xs:double negative zero, the value is converted to positive zero. If the source value is beyond the range of the target data type, an overflow error is returned. If the source value contains more significant digits than the precision of the target data type, the source value is rounded to the precision of the target data type.
- If the target type is DECFLOAT and the source XML value is an xs:double value of INF, -INF, or NaN, the result will be the corresponding special DECFLOAT values INF, -INF, or NaN. If the source value is an xs:double negative zero, the result is negative zero. If the target type is DECFLOAT(16) and the source value is beyond the range of DECFLOAT(16), an overflow error is returned. If the source value has more than 16 significant digits, the value is rounded according to the ROUNDING mode that is in effect. This rounding behavior is the same as what is used during the cast of DECFLOAT(34) to DECFLOAT(16).
- If the target type is DECIMAL, the resulting xs:decimal value is converted, if necessary, to the precision and scale of the target data type. The necessary number of leading zeros is added or removed. In the fractional part of the number, the necessary number of trailing zeros is added or the necessary number of digits is eliminated. This truncation behavior is similar to the behavior of the cast from DECIMAL to DECIMAL.
- If the target type is DATE, TIME, or TIMESTAMP, the resulting XML value is adjusted to UTC time and the time zone component is removed. If the target type is TIME and the resulting XML value contains a seconds component with

non-zero digits after the decimal point, those digits are truncated. If the target type is DATE or TIMESTAMP, the year part of the resulting xs:date or xs:dateTime value must be in the range of 0001 to 9999. If the target type is TIMESTAMP, the fractional second part of the xs:dateTime value must have six or fewer digits.

## Assignment and comparison

The basic operations of SQL are assignment and comparison.

Assignment operations are performed during the execution of statements such as CALL, INSERT, UPDATE, MERGE FETCH, SELECT INTO, SET *host-variable* or SET *assignment-statement*, and VALUES INTO statements. In addition, when a function is invoked or a stored procedure is called, the arguments of the function or stored procedure are assigned. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

The basic rule for both operations is that data types of the operands must be compatible. The compatibility rule also applies to other operations that are described under “Rules for result data types” on page 119. The following table shows the compatibility of data types for assignments and comparisons.

*Table 20. Compatibility of data types for assignments and comparisons with numeric data types.* Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

Operand	Binary integer	Decimal number	Floating point	Decimal floating point
Binary integer	Y	Y	Y	Y
Decimal number	Y	Y	Y	Y
Floating point	Y	Y	Y	Y
Decimal floating point	Y	Y	Y	Y
Character string	N	N	N	N
Graphic string	N	N	N	N
Binary string	N	N	N	N
Date	N	N	N	N
Time	N	N	N	N
Timestamp	N	N	N	N
Row ID	N	N	N	N
Distinct type	1	1	1	1
XML <sup>2</sup>	N	N	N	N

**Notes:**

1. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 113.
2. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

*Table 21. Compatibility of data types for assignments and comparisons with string data types.* Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

Operand	Character string	Graphic string	Binary string
Binary integer	N	N	N
Decimal number	N	N	N
Floating point	N	N	N
Decimal floating point	N	N	N
Character string	Y	Y <sup>4,5</sup>	N <sup>3</sup>
Graphic string	Y <sup>4,5</sup>	Y	N
Binary string	N <sup>3</sup>	N	Y
Date	1	1,4	N
Time	1	1,4	N
Timestamp	1	1,4	N
Row ID	N	N	N
Distinct type	2	2	2
XML <sup>6</sup>	N	N	N

**Notes:**

1. The compatibility of datetime values is limited to assignment and comparison:
  - Datetime values can be assigned to string columns and to string variables that are not LOB values, as explained in “Datetime assignments” on page 112.
  - A valid string representation of a date can be assigned to a date column or compared to a date.
  - A valid string representation of a time can be assigned to a time column or compared to a time.
  - A valid string representation of a timestamp can be assigned to a timestamp column or compared to a timestamp.
2. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 113.
3. All character strings, even those with subtype FOR BIT DATA, are not compatible with binary strings.
4. On assignment and comparison from Graphic to Character, the resulting length in bytes is  $3 * (\text{LENGTH}(\text{graphic-string}))$ , depending on the CCSIDs.
5. Character strings with subtype FOR BIT DATA are not compatible with Graphic Data.
6. Character and graphic strings, including LOBs, can be assigned to XML columns. However, XML cannot be assigned to a character or graphic string column. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

*Table 22. Compatibility of data types for assignments and comparisons with date, time, and timestamp data types.* Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

Operand	Date	Time	Timestamp
Binary integer	N	N	N
Decimal number	N	N	N
Floating point	N	N	N
Decimal floating point	N	N	N
Character string	1	1	1
Graphic string	1,3	1,3	1,3
Binary string	N	N	N

*Table 22. Compatibility of data types for assignments and comparisons with date, time, and timestamp data types (continued).* Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

Operand	Date	Time	Timestamp
Date	Y	N	N
Time	N	Y	N
Timestamp	N	N	Y
Row ID	N	N	N
Distinct type	2	2	2
XML <sup>4</sup>	N	N	N

**Notes:**

1. The compatibility of datetime values is limited to assignment and comparison:
  - Datetime values can be assigned to string columns and to string variables that are not LOB values, as explained in “Datetime assignments” on page 112.
  - A valid string representation of a date can be assigned to a date column or compared to a date.
  - A valid string representation of a time can be assigned to a time column or compared to a time.
  - A valid string representation of a timestamp can be assigned to a timestamp column or compared to a timestamp.
2. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 113.
3. On assignment and comparison from Graphic to Character, the resulting length in bytes is  $3 * (\text{LENGTH}(\text{graphic-string}))$ , depending on the CCSIDs.
4. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

*Table 23. Compatibility of data types for assignments and comparisons with row ID, XML, and distinct data types.* Y indicates that the data types are compatible. N indicates no compatibility. For any number in a column, read the corresponding note at the bottom of the table.

Operand	Row ID	XML <sup>2</sup>	Distinct type
Binary integer	N	N	1
Decimal number	N	N	1
Floating point	N	N	1
Decimal floating point	N	N	1
Character string	N	N	1
Graphic string	N	N	1
Binary string	N	N	1
Date	N	N	1
Time	N	N	1
Timestamp	N	N	1
Row ID	Y	N	1
Distinct type	1	N	Y <sup>1</sup>
XML <sup>2</sup>	N	Y	N

**Notes:**

1. A value with a distinct type is comparable only to a value that is defined with the same distinct type. In general, DB2 supports assignments between a distinct type value and its source data type. For additional information, see “Distinct type assignments” on page 113.
2. For comparison, XML can only be compared using the XMLEXISTS and NULL predicates.

Compatibility with a column that has a field procedure is determined by the data type of the column, which applies to the decoded form of its values.

A basic rule for assignment operations is that a null value cannot be assigned to:

- A column that cannot contain null values

- A non-Java host variable that does not have an associated indicator variable

For a host variable that does have an associated indicator variable, a null value is assigned by setting the indicator variable to a negative value. See “References to host variables” on page 160 for a discussion of indicator variables.

- A Java host variable that is a primitive type

For a Java host variable that is not a primitive type, the value of that variable is set to a Java null value.

## Numeric assignments

The basic rule for numeric assignments is that the whole part of a decimal or integer number cannot be truncated. If necessary, the fractional part of a decimal number is truncated.

### Decimal or integer to floating-point

Because floating-point numbers are only approximations of real numbers, the result of assigning a decimal or integer number to a floating-point column or variable might not be identical to the original number.

### Floating-point or decimal to integer

When a single precision floating-point number is converted to integer, rounding occurs on the seventh significant digit, zeros are added to the end of the number, if necessary, starting from the seventh significant digit, and the fractional part of the number is eliminated. When a double precision floating-point or decimal number is converted to integer, the fractional part of the number is eliminated.

*Example 1:* The following example shows single precision floating-point numbers converted to an integer:

Floating-point number:	Results when assigned to an integer column or host variable:
2.0000045E6	2000000
2.00000555E8	200001000

*Example 2:* The following example shows a double precision floating-point number converted to an integer:

Floating-point number:	Results when assigned to an integer column or host variable:
2.0000045E6	2000004
2.00000555E8	200000555

*Example 3:* The following example shows a decimal number converted to an integer:

Decimal number:	Results when assigned to an integer column or host variable:
2000004.5	2000004
200000555.0	200000555

### Decimal to decimal

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target.

The necessary number of leading zeros is added or eliminated, and, in the fractional part of the number, the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

### **Decimal to DECFLOAT**

When a decimal number is assigned to a DECFLOAT column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated.

Depending on the precision and scale of the decimal number, and the precision of the target, the value might be rounded to fit.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

### **Integer to decimal**

When an integer is assigned to a decimal column or variable, the number is converted first to a temporary decimal number and then, if necessary, to the precision and scale of the target.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer.

### **Integer to DECFLOAT**

When an integer is assigned to a DECFLOAT column or variable, the number is converted first to a temporary decimal number and then to DECFLOAT.

The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer. The decimal number is then converted to DECFLOAT using the rules for "Decimal to DECFLOAT."

### **Floating-point to floating-point**

When a single precision floating-point number is assigned to a double precision floating-point column or variable, the single precision data is padded with eight hex zeros. When a double precision floating-point number is assigned to a single precision floating-point column or variable, the double precision data is converted and rounded up on the seventh hex digit.

In assembler, C, or C++ applications that are precompiled with the FLOAT(IEEE) option, floating-point constants and values in host variables are assumed to have IEEE floating-point format. All floating-point data is stored in DB2 in System/390 floating-point format. Therefore, when the FLOAT(IEEE) precompiler option is in effect, DB2 performs the following conversions:

- When a number in short or long IEEE floating-point format is assigned to a single-precision or double-precision floating-point column, DB2 converts the number to System/390 floating-point format.
- When a single-precision or double-precision floating-point column value is assigned to a short or long floating-point host variable, DB2 converts the column value to IEEE floating-point format.

## Floating-point to decimal

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number.

When a single precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 6 by rounding on the seventh decimal digit. Twenty five zeros are then appended to the number to bring the precision to 31. Because of rounding, a number less than  $0.5 \times 10^{-6}$  is reduced to 0.

When a double precision floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 15, and then, if necessary, truncated to the precision and scale of the target. In this conversion, zeros are added to the end of the number, if necessary, to bring the precision to 16. The number is then rounded (using floating-point arithmetic) on the sixteenth decimal digit to produce a 15-digit number. Because of rounding, a number less in magnitude than  $0.5 \times 10^{-15}$  is reduced to 0. If the decimal number requires more than 15 digits to the left of the decimal point, an error is reported. Otherwise, the scale is given the largest possible value that allows the whole part of the number to be represented without loss of significance.

The following examples show the effect of converting a double precision floating-point number to decimal:

*Example 1:* The floating-point number, .123456789098765E-05 in decimal notation is, .00000123456789098765. Rounding adds 5 in the 16th position, so the number becomes .00000123456789148765 and truncates the result to .000001234567891. Zeros are then added to the end of a 31-digit result, and the number becomes .00000123456789100000000000000000.

*Example 2:* The floating-point number, 1.2339999999999E+01 in decimal notation is, 12.3399999999990. Rounding adds 5 in the 16th position, so the number becomes 12.33999999999905 and truncates the result to 12.3399999999990. Zeros are then added to the end of a 31-digit result and the number becomes 12.3399999999990000000000000000000.

## Floating point to DECFLOAT

When a single or double precision floating-point number is assigned to a DECFLOAT column or variable, the number is first converted to a temporary string representation of the floating point number. The string representation of the number is then converted to DECFLOAT.

## DECFLOAT to integer

When a DECFLOAT is assigned to a binary integer column or variable, the fractional part of the number is lost.

*Example 1:* The following example shows decimal floating-point numbers converted to an integer:

Decimal floating-point number:	Results when assigned to an integer column or host variable:
2.0000045E6	2000004
2.00000555E8	200000555

## **DECFLOAT to decimal**

When a DECFLOAT value is assigned to a decimal column or variable, the DECFLOAT value is converted, if necessary, to the precision and the scale of the target.

During the assignment, the necessary number of leading zeros is added and, in the fractional part of the number, the necessary number of trailing zeros is added, or rounding occurs.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

*Example 1:* The following example shows decimal floating-point numbers converted to a decimal value:

Decimal floating-point number:	Results when assigned to an decimal(15,0) column or host variable:
2.0000045E6	2000005
Decimal floating-point number:	Results when assigned to an decimal(15,2) column or host variable:
2.0000045E6	2000004.50
2.00000555E8	200000555.00

## **DECFLOAT to floating-point**

Because floating-point numbers are only approximations of real numbers, the result of assigning a DECFLOAT value to a floating-point column or variable might not be identical to the original number.

The DECFLOAT value is first converted to a string representation, and is then converted to floating-point number.

## **DECFLOAT(16) to DECFLOAT(34)**

When a DECFLOAT(16) is assigned to a DECFLOAT(34) column or variable, the exponent of the source is converted to the corresponding exponent in the result format, and the coefficient is extended by appending zeros on the left.

## **DECFLOAT(34) to DECFLOAT(16)**

When a DECFLOAT(34) is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format.

The source coefficient is rounded to the precision of the target.

For static SQL statements, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

## To COBOL integers

Assignment to COBOL integer variables uses the full size of the integer.

Thus, the value placed in the COBOL data item might be out of the range of values.

*Example 1:* If COL1 contains a value of 12345, the following statements cause the value 12345 to be placed in A, even though A has been defined with only 4 digits:

```
01 A PIC S9999 BINARY.  
EXEC SQL SELECT COL1  
      INTO :A  
      FROM TABLEX  
END-EXEC.
```

*Example 2:* The following COBOL statement results in 2345 being placed in A:

```
MOVE 12345 TO A.
```

## String assignments

There are two types of string assignments; storage assignment and retrieval assignment.

- *Storage assignment* is when a value is assigned to a column or a parameter of a function or stored procedure.
- *Retrieval assignment* is when a value is assigned to a host variable.

The rules differ for storage and retrieval assignment.

### Binary string assignment

Binary string assignment involves assignment at both the storage and the retrieval of binary strings.

**Storage assignment:** The length of a string that is assigned to a column or parameter of a function or procedure must not be greater than the length attribute of the column or parameter. If the string is longer than the length attribute of that column or parameter, an error is returned.

When the string is assigned to a fixed-length binary string column or parameter of a function or procedure, and the length of the string is less than the length attribute of that column or parameter, the string is padded to the right with the necessary number of binary zeros.

**Retrieval assignment:** The length of a string that is assigned to a host variable can be greater than the length attribute of the host variable. When a string is assigned to a host variable and the string is longer than the length attribute of the host variable, the string is truncated on the right by the necessary number of bytes. When this occurs, a warning is returned.

### Character and graphic string assignment

The rules for storage and retrieval assignment apply when both the source and the target are strings.

When a datetime data type is involved, see “Datetime assignments” on page 112. For the special considerations that apply when a distinct type is involved in an assignment, especially to a host variable, see “Distinct type assignments” on page 113.

### **Storage assignment:**

The basic rule for character storage assignment is that the length of a string that is assigned to a column or parameter of a function or stored procedure must not be greater than the length attribute of the column or the parameter.

Trailing blanks are included in the length of the string. When the length of the string is greater than the length attribute of the column or the parameter, the following actions occur:

- If all of the trailing characters that must be truncated to make a string fit the target are blanks and the string is a character or graphic string, the string is truncated and assigned without warning.
- Otherwise, the string is not assigned and an error occurs to indicate that at least one of the excess characters is non-blank.

When a string is assigned to a fixed-length column or parameter and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of SBCS or DBCS blanks. The pad character is always a blank even for columns or parameters that are defined with the FOR BIT DATA attribute.

### **Retrieval assignment:**

The length of a string that is assigned to a host variable can be greater than the length attribute of the host variable. When the length of the string is greater than the length of the host variable, the string is truncated on the right by the necessary number of SBCS or DBCS characters.

When truncation occurs, the value W is assigned to the SQLWARN1 field of the SQLCA. Furthermore, if an indicator variable is provided and the source of the value is not a LOB, the indicator variable is set to the original length of the string. The truncation result of an improperly formed mixed string is unpredictable.

When a character string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of blanks. The pad character is always a blank even for strings defined with the FOR BIT DATA attribute.

When a string of length  $n$  is assigned to a varying-length string variable with a maximum length greater than  $n$ , the characters after the  $n$ th character of the variable are undefined.

### **Assignments involving mixed data strings**

A mixed data string that contains MBCS characters cannot be assigned to an SBCS column, SBCS parameter, or SBCS host variable.

The following rules apply when a mixed data string is assigned to a host variable and the string is longer than the length attribute of the variable:

- If the string is not well-formed mixed data, it is truncated as if it were BIT or graphic data.
- If the string is well-formed mixed data, it is truncated on the right such that it is well-formed mixed data with a length that is the same as the length attribute of the variable and the number of characters lost is minimal.

## Assignments involving C NUL-terminated strings

A C NUL-terminated string variable that is referenced in a CONNECT statement does not need to contain a NUL. Otherwise, DB2 enforces the convention that the value of a NUL-terminated string variable, either character or graphic, is NUL-terminated.

An input host variable that does not contain a NUL will cause an error. A value that is assigned to an output variable will always be NUL-terminated even if a character must be truncated to make room for the NUL.

When a string of length  $n$  is assigned to a C NUL-terminated string variable with a length greater than  $n+1$ , the rules depend on whether the source string is a value of a fixed-length string or a varying-length string:

- If the source is a fixed-length string and the value of field PAD NUL-TERMINATED on installation panel DSNTIP4 is YES, the string is padded on the right with  $x-n-1$  blanks, where  $x$  is the length of the variable. The padded string is then assigned to the variable and a NUL is appended at the end of the variable. If the value of field PAD NUL-TERMINATED is NO, the string is assigned to the first  $n$  bytes of the variable and a NUL is appended at the end of the variable.
- If the source is a varying-length string, the string is assigned to the first  $n$  bytes of the variable and a NUL is appended at the end of the variable.

## Conversion rules for string assignment

A character or graphic string that is assigned to a column or host variable is first converted, if necessary, to the coded character set of the target. Conversion is necessary only if certain conditions apply.

Conversion is necessary only if all the following are true:

- The CCSIDs of string and target are different.
- Neither CCSID is X'FFFF' (neither the string nor the target is defined as BIT data).
- The string is neither null nor empty.

An error occurs if:

- The SYSSTRINGS table is used but contains no information about the pair of CCSIDs and DB2 cannot do the conversion through z/OS support for Unicode.
- A character of the string cannot be converted and the operation is assignment to a column or to a host variable that has no indicator variable. For example, a DBCS character cannot be converted to a host variable with an SBCS CCSID.

A warning occurs if:

- A character of the string is converted to a *substitution character*. A *substitution character* is the character that is used when a character of the source character set is not part of the target character set. For example, assuming an EBCDIC target character set, if the source character set includes Katakana characters and the target character set does not, a Katakana character is converted to the EBCDIC SUB X'3F'.
- A character of the string cannot be converted and the operation is assignment to a host variable that has an indicator variable. For example, a DBCS character cannot be converted if the host variable has an SBCS CCSID. In this case, the string is not assigned to the host variable and the indicator variable is set to -2.

## Datetime assignments

A value that is assigned to a date, time, or timestamp column, variable, or parameter must be a valid string representation of a date, a time, or a timestamp.

A value that is assigned to a DATE column, a DATE variable, or a DATE must be a date or a valid string representation of a date. A date can be column, a character-string column, or a character-string variable.

A value that is assigned to a TIME column, a TIME variable, or a TIME parameter must be a time or a valid string representation of a time. A time can be assigned only to a TIME column, a character-string column, or a character-string variable.

A value assigned to a TIMESTAMP column, a TIMESTAMP variable, or a TIMESTAMP parameter must be a timestamp or a valid string representation of a timestamp. A timestamp can be assigned only to a TIMESTAMP column, a character-string column, or a character-string variable.

A valid string representation of a datetime value must not be a BLOB, CLOB, or DBCLOB. A datetime value cannot be assigned to a column that has a field procedure.

When a datetime value is assigned to a character-string variable or column, it is converted to its string representation. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target varies depending on the format of the string representation. If the length of the fixed length character-string target is greater than required, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved, and the type of the target.

- If the target is a string column (except for BLOB, CLOB, or DBCLOB), truncation is not allowed. The length of the column must be at least 10 for a date, 8 for a time, and 19 for a timestamp.
- When the target is a host variable, the following rules apply:
  - **For a DATE:** The length of the variable must not be less than 10.
  - **For a TIME:** If the USA format is used, the length of the variable must not be less than 8. This format does not include seconds.  
If the ISO, EUR, or JIS format is used, the length of the variable must not be less than 5. If the length is 5, 6, or 7, the seconds part of the time is omitted from the result and SQLWARN1 is set to 'W'. In this case, the seconds part of the time is assigned to the indicator variable if one is provided, and, if the length is 6 or 7, the value is padded with blanks so that it is a valid string representation of a time.
  - **For a TIMESTAMP:** The length of the variable must not be less than 19. If the length is between 19 and 25, the timestamp is truncated like a string, causing the omission of one or more digits of the microsecond part. If the length is 20, the trailing decimal point is replaced by a blank so that the value is a valid string representation of a timestamp.

## Row ID assignments

A row ID value can be assigned only to a column, parameter, or host variable with a row ID data type.

For the value of the ROWID column, the column must be defined as GENERATED BY DEFAULT and the column must have a unique, single-column index. The value that is specified for the column must be a valid row ID value that was previously generated by DB2.

## XML assignments

XML data can be assigned to a column, but when the target is not a column, the XML data type can only be assigned to another XML data type.

When the target is a column (for example, data change statements), the source can be the XML data type, or CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, DBCLOB, BINARY, VARBINARY, or BLOB data types. When the source is not XML data, the source is implicitly parsed as if the XMLPARSE function is invoked with the STRIP WHITESPACE option. If the source data is graphic data, the encoding scheme must be Unicode.

All other data types cannot be assigned to a target of the XML data type.

## Distinct type assignments

The rules that apply to the assignments of distinct types to host variables are different than the rules for all other assignments that involve distinct types.

**Assignments to host variables:** The assignment of distinct type to a host variable is based on the source data type of the distinct type. Therefore, the value of a distinct type is assignable to a host variable only if the source data type of the distinct type is assignable to the host variable.

*Example:* Assume that distinct type AGE was created with the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT;
```

When the statement was executed, DB2 also generated these cast functions:

```
AGE (SMALLINT) RETURNS AGE  
AGE (INTEGER) RETURNS AGE  
SMALLINT (AGE) RETURNS SMALLINT
```

Next, assume that column STU\_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable HV\_AGE, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200;
```

The distinct type value is assignable to host variable HV\_AGE because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER). If distinct type AGE had been based on a character data type such as CHAR(5), the above assignment would be invalid because a character type cannot be assigned to an integer type.

**Assignments other than to host variables:** A distinct type can be the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target. (Table 15 on page 97 shows which casts are supported when a distinct type is involved). Therefore, a distinct type value can be assigned to any target other than a host variable when:

- The target of the assignment has the same distinct type, or
- The distinct type is castable to the data type of the target

Any value can be assigned to a distinct type when:

- The value to be assigned has the same distinct type as the target, or
- The data type of the assigned value is castable to the target distinct type

*Example:* Assume that the source data type for distinct type AGE is SMALLINT:

```
CREATE TYPE AGE AS SMALLINT;
```

Next, assume that two tables TABLE1 and TABLE2 were created with four identical column descriptions:

```
AGECOL    AGE  
SMINTCOL  SMALLINT  
INTCOL    INTEGER  
DECCOL    DEC(6,2)
```

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2, the following table shows whether the assignments are valid. DB2 uses assignment rules in this INSERT statement to determine if X can be assigned to Y.

```
INSERT INTO TABLE1 (Y)  
SELECT X FROM TABLE2;
```

*Table 24. Assessment of various assignments for example INSERT statement*

X (column in TABLE2)	Y (column in TABLE1)	Valid	Reason
AGECOL	AGECOL	Yes	Source and target are same distinct type
SMINTCOL	AGECOL	Yes	SMALLINT can be cast to AGE
INTCOL	AGECOL	Yes	INTEGER can be cast to AGE (because AGE's source type is SMALLINT)
DECCOL	AGECOL	No	DECIMAL cannot be cast to AGE
AGECOL	SMINTCOL	Yes	AGE can be cast to its source type of SMALLINT
AGECOL	INTCOL	No	AGE cannot be cast to INTEGER
AGECOL	DECCOL	No	AGE cannot be cast to DECIMAL

## Assignments to LOB locators

When a LOB locator is used, it can refer only to LOB data. If a LOB locator is used for the first fetch of a cursor, LOB locators must be used for all subsequent fetches.

## Numeric comparisons

Numbers are compared algebraically, that is, with regard to sign. For example, -2 is less than +1. When numbers of different data types are compared, certain rules are in effect as to how the comparison is performed.

If one number is an integer and the other is decimal, the comparison is made with a temporary copy of the integer, which has been converted to decimal.

When decimal numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is double precision floating-point and the other is integer, decimal, or single precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to double precision floating-point. However, if a single precision floating-point number is compared with a floating-point constant, the comparison is made with a single precision form of the constant.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is DECFLOAT and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the other number which has been converted to DECFLOAT.

If one number is DECFLOAT(16) and the other number is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison.

Additionally, the DECFLOAT data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the equal (=) predicate will return true for comparisons of positive and negative zero.

The functions, COMPARE\_DECFLOAT and TOTALORDER can be used to perform comparisons at a binary level. For example, for a comparison of  $2.0 < > 2.00$ .

The DECFLOAT data type also supports the specification of negative and positive NaN (quiet and signaling), and negative and positive infinity. From an SQL perspective, infinity = infinity, NaN = NaN, and sNaN = sNaN.

The following rules are the comparison rules for these special values:

- Infinity compares equal only to infinity of the same sign (positive or negative)
- NaN compares equal only to NaN of the same sign (positive or negative)
- sNaN compares equal only to sNaN of the same sign (positive or negative)

The ordering among the different special values is as follows: -NAN < -SNAN < -INFINITY < 0 < INFINITY < SNAN < NAN

## String comparisons

String comparisons can occur with binary string, character strings, and graphic strings.

### Binary string comparisons

Binary string comparisons are always performed according to the binary values.

Two binary strings are equal only if the lengths of the two strings are identical. If the strings are equal up to the length of the shorter string length, the shorter string is considered less than the longer string even when the remaining bytes in the longer string are hexadecimal zeros. This is illustrated in the following table:

*Table 25. Binary string comparison where one operand is longer because of hexadecimal zeros*

Hexadecimal value of the first operand	relationship	Hexadecimal value of the second operand
X'4100'	<	X'410000'

*Table 25. Binary string comparison where one operand is longer because of hexadecimal zeros (continued)*

Hexadecimal value of the first operand	relationship	Hexadecimal value of the second operand
X'4100'	<	X'42'
X'4100'	=	X'4100'
X'4100'	>	X'41'
X'4100'	>	X'400000'

Binary strings cannot be compared to character strings (even FOR BIT DATA) unless the character string is cast to a binary string.

### **Character and graphic string comparisons**

Two strings are compared by comparing the corresponding bytes of each string. If the strings do not have the same length, the comparison is made with a temporary copy of the shorter string that has been padded on the right with blanks so that it has the same length as the other string.

Two strings are equal if they are both empty or if all corresponding bytes are equal. An empty string is equal to a blank string. If two strings are not equal, their relationship (that is, which has the greater value) is determined by the comparison of the first pair of unequal bytes from the left end of the strings. This comparison is made according to the collating sequence associated with the encoding scheme of the data. For ASCII data, characters A through Z (both upper and lowercase) have a greater value than characters 0 through 9. For EBCDIC data, characters A through Z (both upper and lowercase) have a lesser value than characters 0 through 9.

Varying-length strings with different lengths are equal if they differ only in the number of trailing blanks. In operations that select one value from a collection of such values, the value selected is arbitrary. The operations that can involve such an arbitrary selection are DISTINCT, MAX, MIN, and references to a grouping column. See the description of GROUP BY for further information about the arbitrary selection involved in references to a grouping column.

#### **String comparisons with field procedures:**

The rules for string comparisons with field procedures depend on the values being compared.

If a column with a field procedure is compared with the value of a variable or a constant, the variable or constant is encoded by the field procedure before the comparison is made. If the comparison operator is LIKE, the variable or constant is not encoded and the column value is decoded.

If a column with a field procedure is compared with another column, that column must have the same field procedure and both columns must have the same CCSID set. The comparison is performed on the encoded form of the values in the columns. If the encoded values are numeric, their data types must be identical; if they are strings, their data types must be compatible.

If two encoded strings of different lengths are compared, the shorter is temporarily padded with encoded blanks so that it has the same length as the other string.

In a CASE expression, if a column with a field procedure is used as the *result-expression* in a THEN or ELSE clause, all other columns that are used as *result-expressions* must have the same field procedure. Otherwise, no column used in a *result-expression* can name a field procedure.

## Datetime comparisons

A DATE, TIME, or TIMESTAMP value can be compared either with another value of the same data type or with a string representation of that data type.

All comparisons are chronological, which means the further a point in time is from January 1, 0001, the greater the value of that point in time.

Comparisons that involve TIME values and string representations of time values always include seconds. If the string representation omits seconds, zero seconds are implied.

Comparisons that involve timestamp values are chronological without regard to representations that might be considered equivalent. Thus, the following predicate is true:

```
TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'
```

## Row ID comparisons

A value with a row ID type can only be compared to another row ID value.

The comparison of the row ID values is based on their internal representations. The maximum number of bytes that are compared is 17 bytes, which is the number of bytes in the internal representation. Therefore, row ID values that differ in bytes beyond the 17th byte are considered to be equal.

## XML comparisons

The XML data type cannot be directly compared to any data type, including the XML data type. The method for doing comparison is through the use of the XMLEXISTS predicate.

## Distinct type comparisons

A value with a distinct type can only be compared to another value with exactly the same type because distinct types have strong typing, which means that a distinct type is compatible only with its own type.

To compare a distinct type to a value with a different data type, the distinct type value must be cast to the data type of the comparison value or the comparison value must be cast to the distinct type. For example, because constants are built-in data types, a constant can be compared to a distinct type value only if it is first cast to the distinct type or vice versa.

The following table shows examples of valid and invalid comparisons, assuming the following SQL statements were used to define two distinct types AGE\_TYPE and CAMP\_DATE and table CAMP\_ROSTER table.

```
CREATE TYPE AGE_TYPE AS INTEGER;
CREATE TYPE CAMP_DATE AS DATE;
CREATE TABLE CAMP_ROSTER
  ( NAME           VARCHAR(20),
    ATTENDEE_NUMBER  INTEGER NOT NULL,
```

```

        AGE          AGE_TYPE,
FIRST_CAMP_DATE  CAMP_DATE,
LAST_CAMP_DATE   CAMP_DATE,
BIRTHDATE        DATE);

```

Table 26. Examples of valid and invalid comparisons involving distinct types

SQL statement	Valid	Reason
<b>Distinct types with distinct types</b>		
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE < LAST_CAMP_DATE;	Yes	Both values are the same distinct type.
<b>Distinct types with columns of the same source data type</b>		
SELECT * FROM CAMP_ROSTER WHERE AGE > ATTENDEE_NUMBER;	No	A distinct type cannot be compared to integer.
SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) > ATTENDEE_NUMBER;	Yes	The distinct type is cast to an integer, making the comparison of two integers.
SELECT * FROM CAMP_ROSTER WHERE CAST(AGE AS INTEGER) > ATTENDEE_NUMBER;		
SELECT * FROM CAMP_ROSTER WHERE AGE > AGE_TYPE(ATTENDEE_NUMBER);	Yes	Integer ATTENDEE_NUMBER is cast to the distinct type AGE_TYPE, making both values the same distinct type.
SELECT * FROM CAMP_ROSTER WHERE AGE > CAST(ATTENDEE_NUMBER AS AGE_TYPE);		
<b>Distinct types with constants</b>		
SELECT * FROM CAMP_ROSTER WHERE AGE IN (15,16,17);	No	A distinct type cannot be compared to a constant.
SELECT * FROM CAMP_ROSTER WHERE INTEGER(AGE) IN (15,16,17);	Yes	The distinct type is cast to the data type of constants, making all the values in the comparison integers.
SELECT * FROM CAMP_ROSTER WHERE AGE IN (AGE_TYPE(15),AGE_TYPE(16),AGE_TYPE(17));	Yes	Constants are cast to distinct type AGE_TYPE, making all the values in the comparison the same distinct type.
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > '06/12/99';	No	A distinct type cannot be compared to a constant.
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST('06/12/99' AS CAMP_DATE);	No	The string constant '06/12/99', a VARCHAR data type, cannot be cast directly to distinct type CAMP_DATE, which is based on a DATE data type. As illustrated in the next row, the constant must be cast to a DATE data type and then to the distinct type.
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST(DATE('06/12/1999') AS CAMP_DATE);	Yes	The string constant '06/12/99' is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a string constant to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the string constant must first be cast to a DATE, TIME, or TIMESTAMP data type.
<b>Distinct types with host variables</b>		
SELECT * FROM CAMP_ROSTER WHERE AGE BETWEEN :HV_INTEGER AND :HV_INTEGER2;	No	The host variables have integer data types. A distinct type cannot be compared to an integer.
SELECT * FROM CAMP_ROSTER WHERE AGE BETWEEN CAST(:HV_INTEGER AS AGE_TYPE) AND AGE_TYPE(:HV_INTEGER2);	Yes	The host variables are cast to distinct type AGE_TYPE, making all the values the same distinct type.

Table 26. Examples of valid and invalid comparisons involving distinct types (continued)

SQL statement	Valid	Reason
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > :HV_VARCHAR;	No	The host variable has a VARCHAR data type. A distinct type cannot be compared to a VARCHAR.
SELECT * FROM CAMP_ROSTER WHERE FIRST_CAMP_DATE > CAST(DATE(:HV_VARCHAR) AS CAMP_DATE);	Yes	The host variable is cast to the distinct type CAMP_DATE, making both values the same distinct type. To cast a VARCHAR host variable to a distinct type that is based on a DATE, TIME, or TIMESTAMP data type, the host variable must first be cast to a DATE, TIME, or TIMESTAMP data type.

## Rules for result data types

Rules that are applied to the operands of an operation determine the data type of the result. Certain rules apply in certain situations and apply depending on the data type of operands.

The rules apply to:

- Corresponding columns in set operations (UNION, INTERSECT, or EXCEPT)
- Result expressions of a CASE expression
- Arguments of the scalar functions COALESCE and IFNULL
- Expression values of the IN list of an IN predicate

For the result data type of expressions that involve the operators '/', '\*', '+' and '-', see "With arithmetic operators" on page 182.

For the result data type of expressions that involve the CONCAT operator, see "With the concatenation operator" on page 188.

Evaluation of the operands of an operation determines the data type of the result. If an operation has more than one pair of operands, DB2 determines the result type of the first pair, uses this result type with the next operand to determine the next result type, and so on. The last intermediate result type and the last operand determine the result type of the operation.

With the exception of the COALESCE function, the result of an operation can be null unless the operands do not allow nulls.

## Numeric operands

Numeric types are compatible only with other numeric types.

Table 27. Result data types with numeric operands

One operand	Other operand	Data type of the result
SMALLINT	SMALLINT	SMALLINT
INTEGER	INTEGER	INTEGER
INTEGER	SMALLINT	INTEGER
BIGINT	SMALLINT	BIGINT
BIGINT	INTEGER	BIGINT
BIGINT	BIGINT	BIGINT

*Table 27. Result data types with numeric operands (continued)*

One operand	Other operand	Data type of the result
DECIMAL( $w,x$ )	SMALLINT	DECIMAL( $p,x$ ) where $p = x + \max(w-x, 5)$ <sup>1</sup>
DECIMAL( $w,x$ )	INTEGER	DECIMAL( $p,x$ ) where $p = x + \max(w-x, 11)$ <sup>1</sup>
DECIMAL( $w,x$ )	BIGINT	DECIMAL( $p,x$ ) where $p = x + \max(w-x, 19)$ <sup>1</sup>
DECIMAL( $w,x$ )	DECIMAL( $y,z$ )	DECIMAL( $p,s$ ) where $p = \max(x,z) + \max(w-x, y-z)$ <sup>1</sup> $s = \max(x,z)$
REAL	REAL	REAL
REAL	DECIMAL, BIGINT, INTEGER, or SMALLINT	DOUBLE
REAL	BIGINT	DOUBLE
DOUBLE	DOUBLE, REAL, DECIMAL, BIGINT, INTEGER, or SMALLINT	DOUBLE
DECFLOAT( $n$ )	SMALLINT	DECFLOAT( $n$ )
DECFLOAT( $n$ )	INTEGER	DECFLOAT( $n$ )
DECFLOAT( $n$ )	BIGINT	DECFLOAT(34)
DECFLOAT( $n$ )	DECIMAL( $\leq 16,s$ )	DECFLOAT( $n$ )
DECFLOAT( $n$ )	DECIMAL( $> 16,s$ )	DECFLOAT(34)
DECFLOAT( $n$ )	REAL	DECFLOAT( $n$ )
DECFLOAT( $n$ )	DOUBLE	DECFLOAT( $n$ )
DECFLOAT( $n$ )	DECFLOAT( $m$ )	DECFLOAT(max( $n,m$ ))

**Notes:**

- Precision cannot exceed 31.

## Character and graphic string operands

Character and graphic strings are compatible with other character and graphic strings as long as there is a conversion between their corresponding CCSIDs.

*Table 28. Result data types with string operands*

One operand	Other operand	Data type of the result
CHAR( $x$ )	CHAR( $y$ )	CHAR( $z$ ) where $z = \max(x,y)$
GRAPHIC( $x$ )	CHAR( $y$ )	VARGRAPHIC( $y$ ) where $y >$ maximum length of a graphic
GRAPHIC( $x$ )	CHAR( $y$ )	GRAPHIC( $z$ ) where $z = \max(x,y)$
VARCHAR( $x$ )	VARCHAR( $y$ ) or CHAR( $y$ )	VARCHAR( $z$ ) where $z = \max(x,y)$
VARCHAR( $x$ )	GRAPHIC( $y$ )	VARGRAPHIC( $z$ ) where $z = \max(x,y)$

*Table 28. Result data types with string operands (continued)*

One operand	Other operand	Data type of the result
VARGRAPHIC( $x$ )	VARGRAPHIC( $y$ ), GRAPHIC( $y$ ), VARCHAR( $y$ ), or CHAR( $y$ )	VARGRAPHIC( $z$ ) where $z = \max(x, y)$
CLOB( $x$ )	CLOB( $y$ ), VARCHAR( $y$ ), or CHAR( $y$ )	CLOB( $z$ ) where $z = \max(x, y)$
CLOB( $x$ )	GRAPHIC( $y$ ) or VARGRAPHIC( $y$ )	DBCLOB( $z$ ) where $z = \max(x, y)$
DBCLOB( $x$ )	CHAR( $y$ ), VARCHAR( $y$ ), CLOB( $y$ ), GRAPHIC( $y$ ), VARGRAPHIC( $y$ ), or DBCLOB( $y$ )	DBCLOB( $z$ ) where $z = \max(x, y)$

Character string subtypes are determined as indicated in the following table:

*Table 29. Result data types with character string operands*

One operand	Other operand	Data type of the result
Bit data	Mixed, SBCS, or bit data	Bit data
Mixed data	Mixed or SBCS data	Mixed data
SBCS data	SBCS data	SBCS data

## Binary string operands

Binary strings are compatible with other binary strings. Binary strings include BINARY, VARBINARY, and BLOB.

*Table 30. Result data types with binary string operands*

One operand	Other operand	Data type of the result
BINARY( $x$ )	BINARY( $y$ )	BINARY( $z$ ) where $z = \max(x, y)$
VARBINARY( $x$ )	BINARY( $y$ ) or VARBINARY( $y$ )	VARBINARY( $z$ ) where $z = \max(x, y)$
BLOB( $x$ )	BINARY( $y$ ), VARBINARY( $y$ ), or BLOB( $y$ )	BLOB( $z$ ) where $z = \max(x, y)$

## Datetime operands

A date, time, or timestamp value is compatible with another value of the same type or any string expression that contains a valid string representation of the same type.

A DATE type is compatible with another DATE type or any string expression that contains a valid string representation of a date. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is DATE.

A TIME type is compatible with another TIME type or any string expression that contains a valid string representation of a time. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is TIME.

A TIMESTAMP type is compatible with another TIMESTAMP type or any string expression that contains a valid string representation of a timestamp. A string representation is a value that is a built-in character string data type or graphic string data type. A string representation must not be a CLOB or DBCLOB and must have an actual length that is not greater than 255 bytes. The data type of the result is TIMESTAMP.

If both operands are in the same encoding scheme, the result is in that encoding scheme. Otherwise the result is in the application encoding scheme.

## Row ID operands

A row ID data type is compatible only with itself. The result has a row ID data type.

## XML operands

XML data is compatible only with other XML data. The data type of the result is XML.

Other data types can be treated as an XML data type by using the CAST specification or XMLPARSE functions to cast character, graphic, or binary data to XML data.

## Distinct type operands

A distinct type is compatible only with itself. The data type of the result is the distinct type.

## Conversion rules for operations that combine strings

When two strings are compared, one of the strings is first converted, if necessary, to the coded character set of the other string. Conversion is necessary only if certain rules apply.

Conversion is necessary only if all of the following are true:

- The CCSIDs of the two strings are different.
- Neither CCSID is X'FFFF' (neither string is defined as a binary string).
- The string selected for conversion is neither null nor empty.
- The following conversion tables (Table 32 on page 124 or Table 33 on page 125 indicate when conversion is necessary.

These same rules apply to determine the result CCSID in a fullselect.

The string selected for conversion depends on the type of the operands. For the purpose of CCSID determination, string expressions in a statement are divided into 6 types, as described in the following table.

Table 31. Operand types

Type of operand	CCSID of the operand type
Columns	CCSID from the containing table

Table 31. Operand types (continued)

Type of operand	CCSID of the operand type
String constants	CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures..
Special registers	CCSID associated with the application encoding scheme. For dynamic statements, this is the CURRENT APPLICATION ENCODING SCHEME special register. For static statements, this is the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures.
Host variables	CCSID specified in the DECLARE VARIABLE statement, associated with the application encoding scheme, or specified in SQLDAID or SQLDA
Derived value based on a column	<p>CCSID derived from the source of the derived value. A derived value based on a column is an expression whose source is directly or indirectly based on columns. The CCSID of such an expression is the CCSID derived from its source.</p> <p>For example:</p> <ul style="list-style-type: none"> <li>The CCSID of SUBSTR(column_1, 5, length(column_2)) is the CCSID of column_1. Note that the CCSID of column_2 has no influence on the CCSID of SUBSTR.</li> <li>The CCSID of column_1    'ABC' is the CCSID of column_1, derived from the rules described in Table 32 on page 124.</li> <li>The CCSID of column_1    GX'42C1' is the DBCS CCSID from the CCSID set of column_1, derived from the rules described in Table 32 on page 124 and Table 33 on page 125.</li> <li>The CCSID of COALESCE(EBCDIC_column_1, ASCII_column_1) is the UNICODE CCSID, derived from the rules described in Table 32 on page 124.</li> <li>The CCSID of CAST(string_column_1 AS GRAPHIC(10)) is the DBCS CCSID from the CCSID set of string_column_1.</li> <li>The CCSID of CAST(EBCDIC_string_column_1 AS VARCHAR(10) CCSID UNICODE) is the UNICODE CCSID derived from the rules described in Table 32 on page 124.</li> <li>The CCSID of CASE WHEN(1=1) THEN '1' ELSE ASCII_column_1 END is the CCSID of ASCII_column_1, derived from the rules described in Table 32 on page 124.</li> <li>The CCSID of CASE WHEN(1=1) THEN EBCDIC_column_1 ELSE ASCII_column_1 END is the UNICODE CCSID derived from the rules described in Table 32 on page 124.</li> <li>The CCSID of a scalar fullselect (SELECT column_1 FROM table_1) is the CCSID of column_1.</li> </ul>

Table 31. Operand types (continued)

Type of operand	CCSID of the operand type
Derived value not based on a column	<p>CCSID derived from the source of the derived value. A derived value not based on a column is an expression whose source is not directly or indirectly based on any column. The CCSID of such an expression is the CCSID derived from its source.</p> <ul style="list-style-type: none"> <li>For example, the CCSID of SUBSTR('ABDC', 1, length('AB')) is the CCSID of the string constant 'ABCD'. Note that the CCSID of column_1 has no influence on the CCSID of SUBSTR.</li> <li>the CCSID of user_defined_function1(column1) is the output CCSID defined by user_defined_function1.</li> <li>the CCSID of the cast function of distinct type, shape, is the CCSID of distinct type, shape.</li> <li>the CCSID of CURRENT SQLID    UX'0041' is the UNICODE DBCS CCSID, derived from the rules described in Table 32 and Table 33 on page 125.</li> <li>the CCSID of CAST('abc' as CHAR(10) CCSID UNICODE) is the UNICODE CCSID.</li> </ul>

The following table shows which operand supplies the target CCSID set when the comparison is part of an SQL statement involving multiple tables with different CCSID sets.

Table 32. Operand that supplies the CCSID for character conversion

First operand	Second operand					
	Column value	String constant	Special register	Host variable	Derived value based on a column	Derived value not based on a column
Column value	1	first operand	first operand	first operand	1	first operand
String constant	second operand	1	1	1	second operand	1
Special register	second operand	1	1	1	second operand	1
Host variable	second operand	1	1	1	second operand	1
Derived value based on a column	1	first operand	first operand	first operand	1	first operand
Derived value not based on a column	second operand	1	1	1	second operand	1

**Note:** 1. If the CCSID sets are different, both operands are converted, if necessary, to Unicode. SBCS and Mixed are converted to UTF-8. DBCS is converted to UTF-16. See the next table to determine which operand supplies the CCSID for character conversion.

The following table shows which operand is selected for conversion when both operands are based on a column or are not based on a column as represented in the previous table.

*Table 33. Operand that supplies the CCSID for character conversion when both operands are based or not based on a column*

First operand	Second operand		
	SBCS data	Mixed data	DBCS data
SBCS data		second operand <sup>1</sup>	second operand
Mixed data	first operand <sup>1</sup>		second operand
DBCS data	first operand	first operand	

**Note:** 1. For ASCII and EBCDIC data, the conversion depends on the value of the field MIXED DATA on installation panel DSNTIPF at the DB2 that does the comparison. If MIXED DATA = YES, the SBCS operand is converted to MIXED. If MIXED DATA = NO, the MIXED operand is converted to SBCS.

For example, assume a comparison of the form:

```
string-constant-SBCS =derived-value-not-based-on-column-DBCS
```

Assume that the operands have different encoding schemes. First look at Table 32 on page 124. The relevant table entry is in the third row and second column. The value for this entry shows that if the CCSID sets are different, the operands are converted to Unicode. The first operand (string-constant-SBCS) is converted to UTF-8 (Mixed) if it is not already Unicode. In addition, the second operand (derived-value-not-based-on-column-DBCS) is converted to UTF-16 (Unicode DBCS) if necessary. After the operands have been converted to Unicode, Table 33 is used to determine which operand supplies the specific CCSID for the conversion. The relevant table entry is in the second row and third column. It indicates that the second operand (derived-value-not-based-on-column-DBCS) determines the CCSID because DBCS data takes precedence over Mixed data.

An error occurs if a character of the string cannot be converted, the SYSSTRINGS table is used but contains no information about the pair of CCSIDs of the operands being compared, or DB2 cannot do the conversion through z/OS support for Unicode. A warning occurs if a character of the string is converted to a substitution character.

A derived value based on a column is an expression that includes columns that affects the result CCSID of the expression. For example, in the expression COL1 || 'abc', COL1 determines the result CCSID. Therefore, the expression COL1 || 'abc' is considered to be a derived value based on a column that continues to give the column precedence in any further comparisons. The expression CASE WHEN COL1 > 1 THEN 'abc' ELSE 'def' END contains a column that does not affect the result CCSID of the expression and is therefore not considered to be a derived value based on a column.

The following table defines which expressions are considered to be a derived value based on a column.

*Table 34. Derived values based on a column*

Expression	Condition
<i>expression1</i>    <i>expression2</i>	<i>expression1</i> or <i>expression2</i> is a column or a derived value based on a column
CASE <i>when-clause</i> THEN <i>result-expression</i> ELSE <i>result-expression</i> END	any <i>result-expression</i> is a <i>string-expression</i> that is a column or derived value based on a column

Table 34. Derived values based on a column (continued)

Expression	Condition
CAST( <i>expression</i> as <i>data-type</i> )	<i>expression</i> is a <i>string-expression</i> that is a column or a derived value based on a column and <i>data-type</i> is a string data type
Scalar-fullselect: (SELECT <i>expression</i> FROM <i>table</i> )	<i>expression</i> is a <i>string-expression</i> that is a column or a derived value based on a column and <i>data-type</i> is a string data type

When a statement contains multiple CCSID sets, if the length of one of the strings changes after CCSID conversion, the string becomes a varying-length string. That is, the data type becomes VARCHAR, CLOB, VARGRAPHIC, or DBCLOB. The following table shows the worse case resulting lengths of CCSID conversion, where X is length in bytes.

Table 35. Worst case result length of CCSID conversion, where X represents LENGTH(string in bytes)

From CCSID		To CCSID								
		EBCDIC				ASCII		Unicode		
		SBCS	Mixed	DBCS	SBCS	Mixed	DBCS	SBCS	UTF-8	UTF-16
EBCDIC	SBCS	X	X	X*2 <sup>1</sup>	X	X	X*2 <sup>1</sup>	X <sup>1</sup>	X*3	X*2
	Mixed	X	X	X*2 <sup>1</sup>	X	X	X*2 <sup>1</sup>	X <sup>1</sup>	X*3	X*2
	DBCS	X*0.5 <sup>1</sup>	X+2	X	X*0.5 <sup>1</sup>	X	X	X*0.5	X*1.5	X
ASCII	SBCS	X	X	X*2 <sup>1</sup>	X	X	X*2 <sup>1</sup>	X <sup>1</sup>	X*3	X*2
	Mixed	X	X*1.8	X*2 <sup>1</sup>	X	X	X*2 <sup>1</sup>	X <sup>1</sup>	X*3	X*2
	DBCS	X*0.5 <sup>1</sup>	X+2	X	X*0.5 <sup>1</sup>	X	X	X*0.5	X*1.5	X
Unicode	SBCS	X	X	X*2	X	X	X*2	X	X	X*2
	UTF-8	X	X*1.25	X	X	X	X	X	X	X*2
	UTF-16	X*0.5	X+2	X	X*0.5	X	X	X*0.5	X*1.5	X

**Note:**

- Because of the high probability of data loss, IBM does not provide conversion tables for this combination of two CCSIDs and data subtypes.

## Constants

A *constant* (also called a *literal*) specifies a value. Constants are classified as string constants or numeric constants. Numeric constants are further classified as integer, floating-point, decimal, or decimal floating-point. String constants are classified as character, graphic, or binary.

All constants have the attribute NOT NULL. A negative sign in a numeric constant with a value of zero is ignored, except for a decimal floating-point constant.

Constants have a built-in data type. Therefore, an operation that involves a constant and a distinct type requires that the distinct type be cast to the built-in data type of the constant or the constant be cast to the distinct type. For example, see Table 26 on page 118, which contains an example of casting data types to compare a constant to a distinct type.

## Integer constants

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point.

The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of a large integer, but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

*Examples:*

64      -15      +100      32767      720176

In syntax diagrams, the term *integer* is used for a large integer constant that must not include a sign.

## Floating-point constants

A *floating-point constant* specifies a double-precision floating-point number as two numbers separated by an E.

The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point. The value of the constant is the product of the first number and the power of 10 specified by the second number. It must be within the range of floating-point numbers. The number of characters in the constant must not exceed 30. Excluding leading zeros, the number of digits in the first number must not exceed 17 and the number of digits in the second must not exceed 2.

*Examples:* The following floating-point constants represent the numbers '150', '200000', -0.22, and '500':

15E1      2.E5      -2.2E-1      +5.E+2

## Decimal constants

A *decimal constant* is a signed or unsigned number of no more than 31 digits and either includes a decimal point or is not within the range of binary integers.

The precision is the total number of digits, including those, if any, to the right of the decimal point. The total includes all leading and trailing zeros. The scale is the number of digits to the right of the decimal point, including trailing zeros.

*Examples:* The following decimal constants have, respectively, precisions and scales of 5 and 2; 4 and 0; 2 and 0; and 23 and 2:

025.50      1000.      -15.      +37589333333333333333.33

## Decimal floating-point constants

A *decimal floating-point constant* specifies a decimal floating-point number as two numbers separated by an E. The first number can include a sign and a decimal point. The second number can include a sign but not a decimal point.

The value of the constant is the product of the first number and the power of 10 specified by the second number. The value must be within the range of DECFLOAT(34). The number of characters in the constant must not exceed 42.

Excluding leading zeros, the number of digits in the first number must not exceed 34 and the number of digits in the second number must not exceed 4.

A constant that is specified as two numbers separated by an E is a decimal-floating point constant only if the value is outside the range of a floating-point constant. A constant that is specified as a number that does not contain an E, and has more than 31 digits, is also a decimal-floating point constant.

In addition to numeric constants, the following reserved keywords can be used to specify decimal-floating point special values:

- INF or INFINITY - represents infinity
- NAN - represents quiet not-a-number
- SNAN - represents signaling not-a-number

The keywords can be any combination of uppercase or lowercase letters and can be preceded by an operational sign (+ or -).

SNAN results in a warning or exception when it is used in a numerical operation; NAN does not. SNAN can be used in non-numerical operations without causing a warning or exception. For example, SNAN can be used in the VALUES list of an insert operation or as a constant used in a comparison in a predicate.

When the keywords are used in a predicate, the following order of precedence applies:

-NAN < -SNAN < -INFINITY < -0 < 0 < INFINITY < SNAN < NAN

*Examples:* The following decimal floating-point constants represent the numbers 123456789012345678, sNaN, and negative infinity:

123456789012345678E0                    SNAN                    -INFINITY

## Character string constants

A *character string constant* specifies a varying-length character string. There are two forms of character string constant.

- A sequence of characters that starts and ends with a string delimiter, which is either an apostrophe ('') or a quotation mark (""). For the factors that determine which is applicable, see "Apostrophes and quotation marks as string delimiters" on page 253. This form of string constant specifies the character string contained between the string delimiters. The number of bytes between the delimiters must not be greater than 32704. The limit of 32704 refers to the length (in bytes) of the UTF-8 representation of the string. If you produced the string in a CCSID other than UTF-8 (for example, an EBCDIC CCSID), the length of the UTF-8 representation might differ from the length of the string's representation in the source CCSID. Two consecutive string delimiters are used to represent one string delimiter within the character string.
- An X followed by a sequence of characters that starts and ends with a string delimiter. This form of a character string constant is also called a *hexadecimal constant*. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704. A hexadecimal digit is a digit or any of the letters A through F (uppercase or lowercase). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a character. A hexadecimal constant allows you to specify characters that do not have a keyboard representation.

*Examples:*

```
'12/14/1985'      '32'      'DON''T CHANGE'     X'FFFF'      ''
```

The right most string in the example ("") represents an empty character string constant, which is a string of zero length.

A character string constant is classified as mixed data if it includes a DBCS substring. In all other cases, a character string constant is classified as SBCS data. For information about the CCSID that is assigned to the constant, see “Determining the encoding scheme and CCSID of a string” on page 43. A mixed string constant can be continued from one line to the next only if the break occurs between single byte characters. A Unicode string is always considered mixed regardless of the content of the string.

For Unicode, character constants can be assigned to UTF-8 and UTF-16. The form of the constant does not matter. Typically, character string constants are used only with character strings, but they also can be used with graphic UTF-16 data. However, hexadecimal constants are just character data. Thus, hexadecimal constants being used to insert data into UTF-16 data strings should be in UTF-8 format, not UTF-16 format. For example, if you wanted to insert the number 1 into a UTF-16 column, you would use X'31', not X'0031'. Even though X'0031' is a UTF-16 value, DB2 treats it as two separate UTF-8 code points. Thus, X'0031' would become X'00000031'.

## Binary string constants

A binary-string constant specifies a varying-length binary string.

A binary-string constant is formed by specifying a BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32704.

A hexadecimal digit is a digit or any of the letters A through F (upper case or lower case). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents one byte. Note that this representation is similar to the representation of the character-constant that uses the X" form; however binary-string constant and character-string constant are not compatible and the X" form can not be used to specify a binary-string constant, just as the BX" form cannot be used to specify a character-string constant.

Examples of binary-string constants:

```
BX'0000'      BX'C141C242'      BX'FF00FF01FF'
```

## Datetime constants

A *datetime constant* is a character string constant of a particular format.

Character-string constants are described under “Character string constants” on page 128.

For information about the valid string formats, see “String representations of datetime values” on page 89.

## Graphic string constants

A *graphic string constant* specifies a varying-length graphic string.

In EBCDIC environments, the forms of graphic string constants are shown in the following figure. (Shift-in and shift-out characters for EBCDIC data are discussed in “Character strings” on page 73.)<sup>6</sup>

Context	Graphic String Constant	Empty String	Example
PL/I	<code>‰'dbcs-string'G<sup>s<sub>1</sub></sup></code> <code>‰'dbcs-string'<sup>s<sub>1</sub></sup>G</code>	<code>‰'''G<sup>s<sub>1</sub></sup></code> <code>‰''<sup>s<sub>1</sub></sup>G</code>	<code>‰'元€'G<sup>s<sub>1</sub></sup></code>
	<b>G</b> represents a DBCS G (X'42C7')		
	<b>'</b> represents a DBCS apostrophe (X'427D')		
All other contexts	<code>G'‰'dbcs-string<sup>s<sub>1</sub></sup>'</code>  <code>N'‰'dbcs-string<sup>s<sub>1</sub></sup>'</code>	<code>G'‰'<sup>s<sub>1</sub></sup>'</code> <code>G''</code>  <code>N'‰'<sup>s<sub>1</sub></sup>'</code> <code>N''</code>	<code>G'‰'元€'‰'G<sup>s<sub>1</sub></sup>'</code>  <code>N'‰'元€'‰'N<sup>s<sub>1</sub></sup>'</code>

Figure 17. Graphic string constants in EBCDIC

In SQL statements and in host language statements in a source program, graphic string constants cannot be continued from one line to the next. A graphic string constant must be short enough so that its UTF-8 representation requires no more than 32704 bytes.

DB2 supports two types of hexadecimal graphic string constants.

- UX'xxxx' represents a string of graphic Unicode UTF-16 characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4 and must not exceed 32704. Each group of 4 digits represents a single UTF-16 graphic character. For example, the UX constant for 'ABC' is UX'004100420043'.
- GX'xxxx' represents a string of graphic characters, where *x* is a hexadecimal digit. The number of digits must be a multiple of 4. Each group of 4 digits represents a single double-byte graphic character. The hexadecimal shift-in and shift-out ('OE'X and 'OF'X), which apply to EBCDIC only, are not included in the string.

If the MIXED DATA install option is set to NO, a GX constant cannot be used. Instead, a UX constant should be used. A GX constant cannot be used when the encoding scheme is UNICODE.

For information about the CCSID that is assigned to a graphic string constant, including UX'xxxx' and GX'xxxx' string constants, see “Determining the encoding scheme and CCSID of a string” on page 43.

6. The PL/I form of graphic string constants is supported only in static SQL statements.

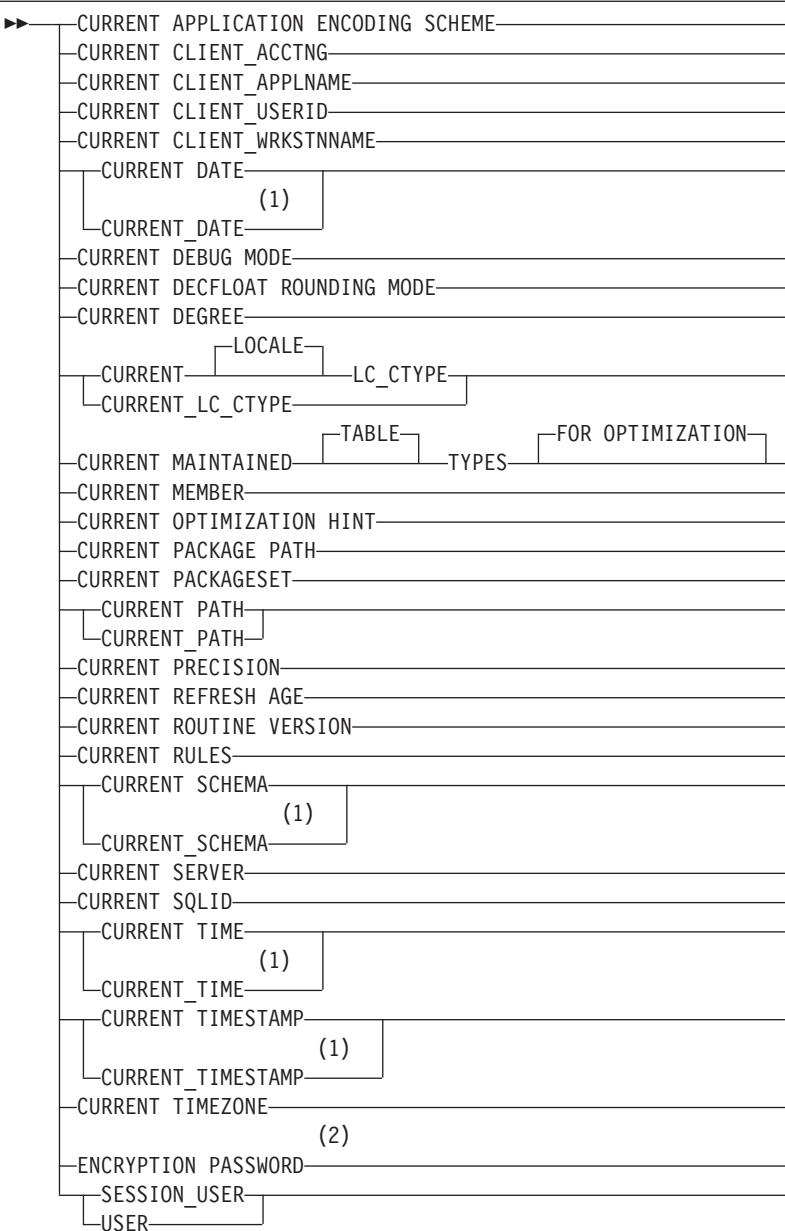

---

## Special registers

A special register is a storage area that is defined for an application process by DB2 and is used to store information that can be referenced in SQL statements. A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:

**special registers**

**Notes:**

- 1 The SQL standard uses the form with the underline.
- 2 The ENCRYPTION PASSWORD special register can only be explicitly referenced in the SET ENCRYPTION PASSWORD statement. It is used implicitly used by the encryption and decryption functions.

## General rules for special registers

A set of general rules applies for special registers. Specific rules for each special register are described with that special register.

Following these general rules for special registers, each special register is described individually.

**Changing register values:** A commit operation might cause special registers to be re-initialized. Whether a special register is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see “CURRENT SQLID” on page 148.

A rollback operation has no effect on the values of special registers. Nor does any SQL statement, with the following exceptions:

- SQL SET statements can change the values of the following special registers:
  - CURRENT APPLICATION ENCODING SCHEME
  - CURRENT DEBUG MODE
  - CURRENT DECFLOAT ROUNDING MODE
  - CURRENT DEGREE
  - CURRENT LOCALE LC\_CTYPE
  - CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
  - CURRENT OPTIMIZATION HINT
  - CURRENT PACKAGE PATH
  - CURRENT PACKAGESET
  - CURRENT PATH
  - CURRENT PRECISION
  - CURRENT REFRESH AGE
  - CURRENT ROUTINE VERSION
  - CURRENT RULES
  - CURRENT SCHEMA
  - CURRENT SQLID<sup>7</sup>
  - ENCRYPTION PASSWORD
- SQL CONNECT statements can change the value of CURRENT SERVER.

You can use various statements to determine the value of a special register. For instance, a SELECT statement, a SET statement, the VALUES statement (if the statement is within a trigger action) will provide the value of a special register. The following examples find the value of the CURRENT PRECISION special register:

```
SELECT CURRENT PRECISION FROM SYSIBM.SYSDUMMY1;
SET :hv = CURRENT PRECISION
VALUES(CURRENT PRECISION)
```

**CCSID for register values:** Special registers that contain character strings have an associated CCSID. The particular CCSID depends on the context in which the special register is referenced. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

**Datetime special registers:** The datetime registers are named CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP. Datetime special registers are

---

7. If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see the discussion of DYNAMICRULES in *DB2 Command Reference*.

stored in an internal format. When two or more of these registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. A datetime special register is implicitly specified when it is used to provide the default value of a datetime column.

If the SQL statement in which a datetime special register is used is in a user-defined function or stored procedure that is within the scope of a trigger, DB2 uses the timestamp for the triggering SQL statement to determine the special register value.

The values of these special registers are based on:

- The time-of-day clock of the processor for the server executing the SQL statement
- The TIMEZONE parameter for this processor. The TIMEZONE parameter is in SYS1.PARMLIB(CLOCKXX).

To evaluate the references when the statement is being executed, a single reading from the time-of-day clock is incremented by the number of hours, minutes, and seconds specified by the TIMEZONE parameter. The values derived from this are assumed to be the local date, time, or timestamp, where local means local to the DB2 that executes the statement. This assumption is correct if the clock is set to local time and the TIMEZONE parameter is zero or the clock is set to GMT and the TIMEZONE parameter gives the difference from GMT. Universal time, coordinated (UTC) is another name for Greenwich Mean Time (GMT).

Since the datetime special registers and the CURRENT TIMEZONE special register depend on the parameter PARMTZ(SYS1.PARMLIB(CLOCKXX)), their values are affected if the local time at the server is changed by the z/OS system command SET CLOCK. The values of the CURRENT DATE and CURRENT TIMESTAMP special registers might be affected if the local date at the server is changed by the system command SET DATE<sup>8</sup>.

*Where special registers are processed:* In distributed applications, CURRENT APPLICATION ENCODING SCHEME, CURRENT SERVER, and CURRENT PACKAGESET are processed locally. All other special registers are processed at the server.

## CURRENT APPLICATION ENCODING SCHEME

CURRENT APPLICATION ENCODING SCHEME specifies which encoding scheme is to be used for dynamic statements. It allows an application to indicate the encoding scheme that is used to process data. This register is not supported in REXX applications or in stored procedures written in REXX.

The initial value of CURRENT APPLICATION ENCODING SCHEME is determined by the value of the ENCODING bind option or the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures if the option is specified. If the option was not specified, the initial value is the value of field DEFAULT APPLICATION ENCODING SCHEME on installation panel DSNTIPF. You can change the value of the register by executing the statement SET CURRENT APPLICATION ENCODING SCHEME. For a description of the statement, see "SET CURRENT APPLICATION ENCODING SCHEME" on page 1477.

---

8. Whether the SET DATE command affects these special registers depends on the system level and the program temporary fix (PTF) level of the system.

The value contained in the special register is a character representation of a CCSID. Although you can use the values ASCII, EBCDIC, or UNICODE to set the special register, what is stored in the special register is a character representation of the numeric CCSID that corresponds to the value used in the SET CURRENT APPLICATION ENCODING SCHEME statement. The value ASCII, EBCDIC, or UNICODE is not stored. The CCSID\_ENCODING scalar function can be used to get a value of ASCII, EBCDIC, or UNICODE from a numeric CCSID value.

The data type is CHAR(8). If necessary, the value is padded on the right with blanks so that its length is 8 bytes.

For stored procedures and user-defined functions, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is determined by the value of the ENCODING bind option for the package that is associated with the procedure or function or by the APPLICATION ENCODING SCHEME option of the CREATE PROCEDURE or ALTER PROCEDURE statement for a native SQL procedure. If the option was not specified, the initial value is the value of the field DEFAULT APPLICATION ENCODING SCHEME field on installation panel DSNTIPF.

For triggers, the initial value of the CURRENT APPLICATION ENCODING SCHEME special register is the value of field DEFAULT APPLICATION ENCODING SCHEME on installation panel DSNTIPF.

*Example:* The CURRENT APPLICATION ENCODING SCHEME special register can be used like any other special register:

```
EXEC SQL VALUES(CURRENT APPLICATION ENCODING SCHEME) INTO :HV1;
EXEC SQL INSERT INTO T1 VALUES (CURRENT APPLICATION ENCODING SCHEME);
EXEC SQL SET :HV1 = CURRENT APPLICATION ENCODING SCHEME;
EXEC SQL SELECT C1 FROM T1 WHERE C1 = CURRENT APPLICATION ENCODING SCHEME;
```

## CURRENT CLIENT\_ACCTNG

CURRENT CLIENT\_ACCTNG contains the value of the accounting string from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- DB2Connection.setDB2ClientAccountingInformation(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET\_CLIENT\_ID function
- The WLM\_SET\_CLIENT\_INFO stored procedure

The value for the accounting string will be obtained first from the accounting string that is set by the SET\_CLIENT\_ID function, AUTH SIGNON function, or the Set Client Information (sqleseti) API, or alternatively from the accounting token set by RRSAF if accounting string has not been set.

In a distributed environment, if the value set by the API exceeds 200 bytes, it is truncated to 200 bytes. If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Get the current value of the accounting string for this connection.

```
SET :ACCT_STRING = CURRENT CLIENT_ACCTNG
```

## CURRENT CLIENT\_APPLNAME

CURRENT CLIENT\_APPLNAME contains the value of the application name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- DB2Connection.setDB2ClientApplicationInformation(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET\_CLIENT\_ID function
- The WLM\_SET\_CLIENT\_INFO stored procedure

In a distributed environment, if the value set by the API exceeds 32 bytes, it is truncated to 32 bytes. If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Select the departments that are allowed to use the application that is being used in this connection.

```
SELECT DEPT  
      FROM DEPT_APPL_MAP  
     WHERE APPL_NAME = CURRENT CLIENT_APPLNAME
```

## CURRENT CLIENT\_USERID

CURRENT CLIENT\_USERID contains the value of the client user ID from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- DB2Connection.setDB2ClientUser(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET\_CLIENT\_ID function
- The WLM\_SET\_CLIENT\_INFO stored procedure

In a distributed environment, if the value set by the API exceeds 16 bytes, it is truncated to 16 bytes. If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Find out in which department the current client user ID works.

```
SELECT DEPT  
      FROM DEPT_USERID_MAP  
     WHERE USER_ID = CURRENT CLIENT_USERID
```

## CURRENT CLIENT\_WRKSTNNNAME

CURRENT CLIENT\_WRKSTNNNAME contains the value of the workstation name from the client information that is specified for the connection.

The data type is VARCHAR(255).

The value of the special register can be changed by using one of the following application programming interfaces (APIs):

- Set Client Information (sqleseti)
- DB2Connection.setDB2ClientWorkstation(String info)
- The RRS DSNRLI SIGNON, AUTH SIGNON, CONTEXT SIGNON, or SET\_CLIENT\_ID function
- The WLM\_SET\_CLIENT\_INFO stored procedure

In a distributed environment, if the value set by the API exceeds 18 bytes, it is truncated to 18 bytes. If one of these APIs is not used to set the value of the special register, an empty string is returned when the special register is referenced.

*Example:* Get the name of the workstation that is being used in this connection.

```
SET :WS_NAME = CURRENT CLIENT_WRKSTNNNAME
```

## CURRENT DATE

The CURRENT DATE special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT TIME or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.<sup>9</sup>

The value of CURRENT DATE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. For other applications, the date is derived by the DB2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

Specifying CURRENT\_DATE is equivalent to specifying CURRENT DATE.

*Example:* Display the average age of employees.

```
SELECT AVG(YEAR(CURRENT DATE - BIRTHDATE))
      FROM DSN8910.EMP;
```

## CURRENT DEBUG MODE

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option when certain routines are created. The DEBUG MODE option specifies whether the routine should be built with the ability to run in debugging mode.

CURRENT DEBUG MODE specifies the default value for the DEBUG MODE option of the following statements:

- ALTER PROCEDURE for a new version of a native SQL procedure
- CREATE PROCEDURE for a Java procedure
- CREATE PROCEDURE for a native SQL procedure

The data type is VARCHAR(8). The following values are valid:

- ALLOW — Specifies that the routine can be run in debugging mode.

9. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

- **DISALLOW** — Specifies that the routine cannot be run in debugging mode. A subsequent ALTER statement can change the DEBUG MODE option to allow the routine to run in debugging mode.
- **DISABLE** — Specifies that the routine can never be run in debugging mode. When DISABLE is in effect, the routine cannot be changed to run in debugging mode. A subsequent ALTER statement cannot change the DEBUG MODE option to allow or disallow the routine to run in debugging mode.

The value of CURRENT DEBUG MODE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. In other contexts the initial value of CURRENT DEBUG MODE is DISALLOW.

You can change the value of the CURRENT DEBUG MODE special register by running the SET CURRENT DEBUG MODE statement. For details about this statement, see “SET CURRENT DEBUG MODE” on page 1478.

*Example:* Set the host variable DEBUG\_MODE\_OPT to the value of the CURRENT DEBUG MODE special register:

```
VALUES CURRENT DEBUG MODE INTO :DEBUG_MODE_OPT;
```

## CURRENT DECFLOAT ROUNDING MODE

CURRENT DECFLOAT ROUNDING MODE specifies the default rounding mode that is used for DECFLOAT values.

The data type is VARCHAR(128). The following rounding modes are supported:

- **ROUND\_CEILING** — rounds the value towards positive infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by 1.
- **ROUND\_DOWN** — rounds the value towards 0 (truncation). The discarded digits are ignored.
- **ROUND\_FLOOR** — rounds the value towards negative infinity. If all of the discarded digits are zero or if the sign is positive the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1.
- **ROUND\_HALF\_DOWN** — rounds the value to the nearest value; if the values are equidistant, rounds the value towards zero. If the discarded digits represent greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.
- **ROUND\_HALF\_EVEN** — rounds the value to the nearest value; if the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represents greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 if its rightmost digit is odd (to make an even digit).
- **ROUND\_HALF\_UP** — rounds the value to the nearest value; if the values are equidistant, rounds the value away from zero. If the discarded digits represent greater than or equal to half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored.

- ROUND\_UP — rounds the value away from 0. If all of the discarded digits are zero the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

The initial value of CURRENT DECFLOAT ROUNDING MODE is the value of the ROUNDING bind option or the native SQL procedure option. If the ROUNDING option is not specified, the initial value is the value of the DEF DECFLOAT ROUND MODE field on installation panel DSNTIPF.

The value of CURRENT DECFLOAT ROUNDING MODE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the CURRENT DECFLOAT ROUNDING MODE by executing the statement SET CURRENT DECFLOAT ROUNDING MODE. For details about this statement, see “SET CURRENT DECFLOAT ROUNDING MODE” on page 1480.

*Example:* Set the DECFLOAT rounding mode to ROUND\_CEILING:

```
SET CURRENT DECFLOAT ROUNDING MODE = 'ROUND_CEILING';
```

## CURRENT DEGREE

CURRENT DEGREE specifies the degree of parallelism for the execution of queries that are dynamically prepared by the application process.

The data type of the register is CHAR(3) and the only valid values are 1 (padded on the right with two blanks) and ANY.

If the value of CURRENT DEGREE is 1 when a query is dynamically prepared, the execution of that query will not use parallelism. If the value of CURRENT DEGREE is ANY when a query is dynamically prepared, the execution of that query can involve parallelism. See *DB2 Performance Monitoring and Tuning Guide* for a description of query parallelism.

The initial value of CURRENT DEGREE is determined by the value of field CURRENT DEGREE on installation panel DSNTIP8. The default for the initial value of that field is 1 unless your installation has changed it to be ANY by modifying the value in that field. The initial value of CURRENT DEGREE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the statement SET CURRENT DEGREE. For details about this statement, see “SET CURRENT DEGREE” on page 1482.

CURRENT DEGREE is a register at the database server. Its value applies to queries that are dynamically prepared at that server and to queries that are dynamically prepared at another DB2 subsystem as a result of the use of a DB2 private connection between that server and that DB2 subsystem.

*Example:* The following statement inhibits parallelism:

```
SET CURRENT DEGREE = '1';
```

## CURRENT LOCALE LC\_CTYPE

CURRENT LOCALE LC\_CTYPE specifies the LC\_CTYPE locale that will be used to execute SQL statements that use a built-in function that references a locale. Functions LCASE, UCASE, and TRANSLATE (with a single argument) refer to the locale when they are executed.

The data type is CHAR(50). If necessary, the value is padded on the right with blanks so that its length is 50 bytes.

The initial value of CURRENT LOCALE LC\_CTYPE is determined by the value of field LOCALE LC\_CTYPE on installation panel DSNTIPF. The default for the initial value of that field is blank unless your installation has changed the value of that field. The initial value of CURRENT LOCALE LC\_CTYPE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the statement SET CURRENT LOCALE LC\_CTYPE. For details about this statement, see “SET CURRENT LOCALE LC\_CTYPE” on page 1483.

*Example:* Save the value of current register CURRENT LOCALE LC\_CTYPE in host variable HV1, which is defined as VARCHAR(50).

```
EXEC SQL VALUES(CURRENT LOCALE LC_CTYPE) INTO :HV1;
```

## CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION specifies a value that identifies the types of objects that can be considered to optimize the processing of dynamic SQL queries. This register contains a keyword representing table types.

The data type is VARCHAR(255).

The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is determined by the value of field CURRENT MAINT TYPES on installation panel DSNTIP8. The default for the initial value of that field is SYSTEM unless your installation has changed the value of that field. The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement. For details about this statement, see “SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION” on page 1485. The object types controlled by this special register are never considered by static embedded SQL queries.

*Example:* Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that all materialized query tables are considered.

```
SET CURRENT MAINTAINED TABLE TYPES ALL;
```

## CURRENT MEMBER

CURRENT MEMBER specifies the member name of a current DB2 data sharing member on which a statement is executing. The value of CURRENT MEMBER is a character string.

The data type is CHAR(8). If necessary, the member name is padded to the right with blanks so that its length is 8 bytes.

The value of a CURRENT MEMBER is a string of blanks when the application process is connected to a DB2 subsystem that is not a member of a data sharing group.

The SQL SET statement cannot change the value of CURRENT MEMBER.

*Example:* Use one of the following statements to set the host variable *MEM* to the name of the current DB2 member.

```
EXEC SQL SET :MEM = CURRENT MEMBER;  
EXEC VALUES (CURRENT MEMBER) into :MEM;
```

## CURRENT OPTIMIZATION HINT

CURRENT OPTIMIZATION HINT specifies the user-defined optimization hint that DB2 should use to generate the access path for dynamic statements.

The data type is VARCHAR(128).

The value of the register identifies the rows in *owner.PLAN\_TABLE* that DB2 uses to generate the access path. DB2 uses information in the rows in *owner.PLAN\_TABLE* for which the value of the OPTHINT column matches the value of the CURRENT OPTIMIZATION special register. If the value of the register is an empty string or all blanks, DB2 uses normal optimization and ignores optimization hints. If the value of the register includes any non-blank characters and DB2 was installed without optimization hints enabled (field OPTIMIZATION HINTS on installation panel DSNTIP8), a warning occurs.

The initial value of CURRENT OPTIMIZATION HINT is the value of the OPTHINT bind option or of the native SQL procedure option. The initial value of CURRENT OPTIMIZATION HINT in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. You can change the value of the special register by executing the statement SET CURRENT OPTIMIZATION HINT. For details about this statement, see “SET CURRENT OPTIMIZATION HINT” on page 1487.

*Example:* Set the CURRENT OPTIMIZATION HINT special register so that DB2 uses the optimization plan hint that is identified by host variable NOHYB when generating the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = :NOHYB
```

For more information about telling DB2 how to generate access paths, see *DB2 Application Programming and SQL Guide*.

## CURRENT PACKAGE PATH

CURRENT PACKAGE PATH specifies a value that identifies the path used to resolve references to packages that are used to execute SQL statements. This special register applies to both static and dynamic statements.

The data type is VARCHAR(4096). The value can be an empty or blank string, or a list of one or more collection IDs, where the collection IDs are enclosed in double quotation marks and separated by commas. Any quotation marks within the string

are repeated as they are in any delimited identifier. The delimiters and commas are included in the length of the special register.

The initial value of CURRENT PACKAGE PATH is an empty string. The value is a list of collections only if the application process has explicitly specified a list of collections by means of the SET CURRENT PACKAGE PATH statement. For details about this statement, see “SET CURRENT PACKAGE PATH” on page 1488. The initial value of CURRENT PACKAGE PATH in a user-defined function or procedure is inherited according to the rules in Table 37 on page 151.

When CURRENT PACKAGE PATH or CURRENT PACKAGESET is set, DB2 uses the values in these registers to resolve the collection for a package. The value of CURRENT PACKAGE PATH takes priority over CURRENT PACKAGESET. In a distributed environment, the value of CURRENT PACKAGE PATH at the remote server takes precedence of the value of CURRENT PACKAGE PATH at the local server (the requester). For more information on package resolution, see *DB2 Application Programming and SQL Guide*.

*Example:* In an application that is using SQLJ packages (in collection SQLJ1 and SQLJ2) and a JDBC package in DB2JAVA, set the CURRENT PACKAGE PATH special register to check SQLJ1 first, followed by SQLJ2, and DB2JAVA:

```
SET CURRENT PACKAGE PATH = SQLJ1, SQLJ2, DB2JAVA;
```

The following statement sets the host variable to the value of the resulting list:

```
SET :HVPKLIST = CURRENT PACKAGE PATH;
```

The value of the host variable would be "SQLJ1", "SQLJ2", "DB2JAVA".

## CURRENT PACKAGESET

CURRENT PACKAGESET specifies an empty string, a string of blanks, or the collection ID of the package that will be used to execute SQL statements.

The data type is VARCHAR(128).

The initial value of CURRENT PACKAGESET is an empty string. The value is a collection ID only if the application process has explicitly specified a collection ID by means of the SET CURRENT PACKAGESET statement. For details about this statement, see “SET CURRENT PACKAGESET” on page 1492. The initial value of CURRENT PACKAGESET in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

*Example:* Before passing control to another program, identify the collection ID for its package as ALPHA.

```
EXEC SQL SET CURRENT PACKAGESET = 'ALPHA';
```

## CURRENT PATH

CURRENT PATH specifies the SQL path used to resolve unqualified data type names and function names in dynamically prepared SQL statements. It is also used to resolve unqualified procedure names that are specified as host variables in SQL CALL statements (CALL *host-variable*).

The data type is VARCHAR(2048).

The CURRENT PATH special register contains a list of one or more schema names, where each schema name is enclosed in delimiters and separated from the following schema by a comma (any delimiters within the string are repeated as they are in any delimited identifier). The delimiters and commas are included in the 2048 character length.

For information on when the SQL path is used to resolve unqualified names in both dynamic and static SQL statements and the effect of its value, see "SQL path" on page 56.

The initial value of the CURRENT PATH special register is either:

- The value of the PATH bind option
- The SQL PATH option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures
- "SYSIBM", "SYSFUN", "SYSPROC", "*value of CURRENT SQLID special register*" if the PATH bind option or SQL PATH option was not specified
- "SYSIBM", "SYSFUN", "SYSPROC", "*value of the role name that is associated with the user in the trusted context*" if the PATH bind option or SQL PATH option was not specified and if the connection is trusted with the role as object owner and qualifier options are in effect.

If the value of the CURRENT SQLID special register changes after the initial value of PATH special register is established, the value of the PATH special register is unaffected when the CURRENT SQLID is updated. However, if a commit later occurs and a SET PATH statement has not been processed, the value of PATH special register is reinitialized taking into consideration the current value of the CURRENT SQLID special register.

The initial value of CURRENT PATH in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the statement SET PATH. For details about this statement, see "SET PATH" on page 1507. For portability across the platforms, it is recommended that a SET PATH statement be issued at the beginning of an application.

*Example:* Set the special register so that schema SMITH is searched before schemas SYSIBM, SYSFUN, and SYSPROC.

```
SET PATH = SMITH, SYSIBM, SYSFUN, SYSPROC;
```

## CURRENT PRECISION

CURRENT PRECISION specifies the rules to be used when both operands in a decimal operation have precisions of 15 or less.

The data type of the register is CHAR(5).

Valid values for the CURRENT PRECISION special register include 'DEC15', 'DEC31', or 'Dpp.s' where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. DEC15 specifies the rules that do not allow a precision greater than 15 digits, and DEC31 specifies the rules that allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used as the rules where DEC15 and DEC31 rules are used, and 's' represents the minimum divide

scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

The initial value of CURRENT PRECISION is determined by the value of field DECIMAL ARITHMETIC on installation panel DSNTIP4. The default for the initial value is DEC15 unless your installation has changed it to be DEC31 by modifying the value in that field. The initial value of CURRENT PRECISION in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the statement SET CURRENT PRECISION. For details about this statement, see "SET CURRENT PRECISION" on page 1494.

CURRENT PRECISION only affects dynamic SQL. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC15 or D15.s, where 's' is a number between 1 and 9, DEC15 rules will apply. When an SQL statement is dynamically prepared and the value of CURRENT PRECISION is DEC31 or D31.s, where 's' is a number between 1 and 9, DEC31 rules will apply. Preparation of a statement with DEC31 instead of DEC15 is more likely to result in an error, especially for division operations. Specification of CURRENT PRECISION in the form 'Dpp.s' where 'pp' is either 15 or 31 and 's' represents the minimum divide scale, will in some cases make division errors less likely when 'pp' is set to 31. For more information, see "Arithmetic with two decimal operands" on page 183.

Example 1: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic:

```
SET CURRENT PRECISION = 'DEC31';
```

Example 2: Set CURRENT PRECISION so that subsequent statements that are prepared use DEC31 rules for decimal arithmetic with a minimum divide scale of 3:

```
SET CURRENT PRECISION = 'D31.3';
```

## CURRENT REFRESH AGE

CURRENT REFRESH AGE specifies a timestamp duration value. This duration is the maximum duration since a REFRESH TABLE statement has been processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This special register affects dynamic statement cache matching.

The data type of the register is DECIMAL(20,6). For a description of durations, see "Datetime operands and durations" on page 192.

If CURRENT REFRESH AGE has a value of 99999999999999 (ANY), REFRESH DEFERRED materialized query tables are considered to optimize the processing of a dynamic SQL query. This value represents 9999 years, 99 months, 99 days, 99 hours, and 99 seconds.

The initial value of CURRENT REFRESH AGE is determined by the value of field CURRENT REFRESH AGE on installation panel DSNTIP8. The default for the initial value of that field is 0 unless your installation has changed it to ANY by

modifying the value of that field. The initial value of CURRENT REFRESH AGE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the SET CURRENT REFRESH AGE statement. For details about this statement, see “SET CURRENT REFRESH AGE” on page 1495.

*Example* : The following example retrieves the current value of the CURRENT REFRESH AGE special register into the host variable, CURMAXAGE:

```
EXEC SQL VALUES (CURRENT REFRESH AGE) INTO :CURMAXAGE;
```

The value would be '9999999999999.000000'.

## CURRENT ROUTINE VERSION

CURRENT ROUTINE VERSION specifies the version identifier that is to be used when invoking a native SQL procedure. CURRENT ROUTINE VERSION is used for CALL statements that use a host variable to specify the procedure name.

The data type of CURRENT ROUTINE VERSION is VARCHAR(64).

The initial value of CURRENT ROUTINE VERSION in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. In other contexts the initial value of CURRENT ROUTINE VERSION is an empty string. An empty string indicates that a version identifier is not in effect for the SQL routine. When an SQL routine that does not have a version identifier in effect is invoked, the currently active version (as indicated in the catalog) of that routine is used.

You can change the value of the CURRENT ROUTINE VERSION by executing the statement SET CURRENT ROUTINE VERSION. For details about this statement, see “SET CURRENT ROUTINE VERSION” on page 1497.

Setting the CURRENT ROUTINE VERSION special register to a version identifier might affect native SQL procedures that are invoked until the value of CURRENT ROUTINE VERSION is changed. If a version of an SQL procedure has a version identifier that matches the version identifier in the special register, that version of the SQL procedure is used when the SQL procedure is invoked. If an SQL procedure does not have a version identifier that matches the version identifier in the special register, the currently active version of the SQL procedure (as defined in the catalog) is used when the SQL procedure is invoked.

*Example*: Set the host variable ROUTINE\_VER to the value of the CURRENT ROUTINE VERSION special register:

```
VALUES CURRENT ROUTINE VERSION INTO :ROUTINE_VER;
```

## CURRENT RULES

CURRENT RULES specifies whether certain SQL statements are executed in accordance with DB2 rules or the rules of the SQL standard.

The data type of the register is CHAR(3), and the only valid values are 'DB2' and 'STD'.

CURRENT RULES is a register at the database server. If the server is not the local DB2, the initial value of the register is 'DB2'. Otherwise, the initial value is the

same as the value of the SQLRULES bind option. The initial value of CURRENT RULES in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

You can change the value of the register by executing the statement SET CURRENT RULES. For details about this statement, see “SET CURRENT RULES” on page 1499.

CURRENT RULES affects the statements listed in the following table. The table summarizes when the statements are affected and shows where to find detailed information. CURRENT RULES also affects whether DB2 issues an existence error (SQLCODE -204) or an authorization error (SQLCODE -551) when an object does not exist. For CURRENT RULES 'STD', DB2 issues an authorization error (SQLCODE -551) when an object does not exist instead of the existence error (SQLCODE -204).

*Table 36. Summary of statements affected by CURRENT RULES*

Statement	What is affected	Details in topic
ALTER TABLE	Enforcement of check constraints added.	“ALTER TABLE” on page 789
	Default value of the delete rule for referential constraints.	
	Whether DB2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for added LOB columns.	
	Whether DB2 creates an index for an added ROWID column that is defined with GENERATED BY DEFAULT.	
CREATE TABLE	Default value of the delete rule for referential constraints.	“CREATE TABLE” on page 1079
	Whether DB2 creates LOB table spaces, auxiliary tables, and indexes on auxiliary tables for LOB columns if the table is explicitly created.	
	Whether DB2 creates an index for a ROWID column that is defined with GENERATED BY DEFAULT if the table is explicitly created.	
DELETE	Authorization requirements for searched DELETE.	“DELETE” on page 1224
GRANT	Granting privileges to yourself.	“GRANT” on page 1333
REVOKE	Revoking privileges from authorization IDs	“REVOKE” on page 1432
UPDATE	Authorization requirements for searched UPDATE.	“UPDATE” on page 1521

*Example:* Set CURRENT RULES so that a later ALTER TABLE statement is executed in accordance with the rules of the SQL standard:

```
SET CURRENT RULES = 'STD';
```

## CURRENT SCHEMA

The CURRENT SCHEMA special register specifies the schema name used to qualify unqualified database object references in dynamically prepared SQL statements.

The data type is VARCHAR(128).

For information on when the CURRENT SCHEMA is used to resolve unqualified names in dynamic SQL statements and the effect of its value, see “Qualification of unqualified object names” on page 57.

The CURRENT SCHEMA special register contains a value that is a single identifier without delimiters.

The initial value of the special register is the value of CURRENT SQLID at the time the connection is established. If the connection is established as a trusted connection with a role as the object owner and qualifier, the initial value of the special register is the value of the role name that is associated with the user in the trusted context. The initial value of the special register in a user-defined function or procedure is inherited according to the rules in Table 37 on page 151.

The value of the special register can be changed by executing the SET SCHEMA statement. The value of CURRENT SCHEMA is the same as the value of CURRENT SQLID unless a SET SCHEMA statement has been issued specifying a different value. After a SET SCHEMA statement has been issued in an application, the values of CURRENT SCHEMA and CURRENT SQLID are separate. Therefore, if the value of CURRENT SCHEMA needs to be changed, a SET SCHEMA statement must be issued.

Specifying CURRENT\_SCHEMA is equivalent to specifying CURRENT SCHEMA.

*Example:* Set the schema for object qualification to 'D123'.

```
SET SCHEMA = 'D123'
```

## CURRENT SERVER

CURRENT SERVER specifies the location name of the current server.

The data type is CHAR(16). If necessary, the location name is padded on the right with blanks so that its length is 16 bytes.

The initial value of CURRENT SERVER depends on the CURRENTSERVER bind option. If CURRENTSERVER X is specified on the bind subcommand, the initial value is X. If the option is not specified, the initial value is the location name of the local DB2. The initial value of CURRENT SERVER in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. The value of CURRENT SERVER is changed by the successful execution of a CONNECT statement.

The value of CURRENT SERVER is a string of blanks when either of the following conditions apply:

- The application process is in the unconnected state

- The application process is connected to a local DB2 subsystem that does not have a location name.

*Example:* Set the host variable CS to the location name of the current server.

```
EXEC SQL SET :CS = CURRENT SERVER;
```

## CURRENT SQLID

CURRENT SQLID specifies the SQL authorization ID of the process.

The data type is VARCHAR(128).

The SQL authorization ID is:

- The authorization ID used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym created by a dynamically issued CREATE statement.

The initial value of CURRENT SQLID can be provided by the connection or sign-on exit routine. If not, the initial value is the primary authorization ID of the process. The value remains in effect until one of the following events occurs:

- The SQL authorization ID is changed by the execution of a SET CURRENT SQLID statement.
- A SIGNON or re-SIGNON request is received from a CICS transaction subtask or an IMS independent region.
- The DB2 connection is ended.

The initial value of CURRENT SQLID in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

CURRENT SQLID can only be referred to in an SQL statement that is executed by the current server.

CURRENT SQLID cannot be a role.

*Example:* Set the SQL authorization ID to 'GROUP34' (one of the authorization IDs of the process).

```
SET CURRENT SQLID = 'GROUP34';
```

## CURRENT TIME

The CURRENT TIME special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

If this special register is used more than one time within a single SQL statement, or used with CURRENT DATE or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.<sup>10</sup>

The value of CURRENT TIME in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151. For other applications, the time is derived by the DB2 that executes the SQL statement that refers to the special register. For a description of how the date is derived, see Datetime special registers.

---

10. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

| Specifying CURRENT\_TIME is equivalent to specifying CURRENT TIME.

*Example:* Display information about all project activities and include the current date and time in each row of the result.

```
SELECT DSN8910.PROJECT.* , CURRENT DATE, CURRENT TIME  
FROM DSN8910.PROJECT;
```

## CURRENT TIMESTAMP

The CURRENT TIMESTAMP special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the current server.

| If this special register is used more than one time within a single SQL statement, or  
| used with CURRENT DATE or CURRENT TIME within a single statement, all  
| values are based on a single clock reading.<sup>11</sup>

| The value of CURRENT TIMESTAMP in a user-defined function or stored  
| procedure is inherited according to the rules in Table 37 on page 151. For other  
| applications, the timestamp is derived by the DB2 that executes the SQL statement  
| that refers to the special register. For a description of how the date is derived, see  
| Datetime special registers.

| Specifying CURRENT\_TIMESTAMP is equivalent to specifying CURRENT  
| TIMESTAMP.

*Example 1:* Display information about the full image copies that were taken in the last week.

```
SELECT * FROM SYSIBM.SYSCOPY  
WHERE TIMESTAMP > CURRENT TIMESTAMP - 7 DAYS;
```

## CURRENT TIMEZONE

CURRENT TIMEZONE specifies the TIMEZONE parameter in the form of a time duration.

The data type is DECIMAL(6,0).

The time duration is derived by the DB2 that executes the SQL statement that refers to the special register. The seconds part of the time duration is always zero. An error occurs if the hours portion of the TIMEZONE parameter is not between -24 and 24. The value of CURRENT TIMEZONE in a user-defined function or stored procedure is inherited according to the rules in Table 37 on page 151.

*Example:* Display information from SYSCOPY, but with the TIMESTAMP converted to GMT. This example is based on the assumption that the installation sets the clock to GMT and the TIMEZONE parameter to the difference from GMT.

```
SELECT DBNAME, TSNAME, DSNUM, ICTYPE, TIMESTAMP - CURRENT TIMEZONE  
FROM SYSIBM.SYSCOPY;
```

## ENCRYPTION PASSWORD

The ENCRYPTION PASSWORD special register specifies the encryption password and the password hint (if one exists) that are used by the encryption and decryption built-in functions.

---

11. Except for the case of a non-atomic multiple row INSERT or MERGE statement.

This special register can only be set, by using the SET ENCRYPTION PASSWORD statement, and cannot be referenced directly. The ENCRYPTION PASSWORD special register contains the value of the password that is used by the ENCRYPTION and DECRYPTION built-in functions to encrypt and decrypt data when a password is not explicitly specified as a function argument. The ENCRYPTION PASSWORD special register can also contain a password hint which is associated with the values that are encrypted using the encryption password. The password hint is a character string that is used to help in remembering the password. The GETHINT function is used to return the password hint for an encrypted value.

The initial value of the ENCRYPTION PASSWORD special register is the empty string ('').

The initial value of the ENCRYPTION PASSWORD special register in a user-defined function or procedure is inherited from the invoking application. In other contexts, the initial value of the special register is the empty string.

The password is not related to DB2 authentication and is used only for data encryption. For more information, see “SET ENCRYPTION PASSWORD” on page 1502.

## **SESSION\_USER**

SESSION\_USER specifies the primary authorization ID of the process.

The data type is VARCHAR(128).

If SESSION\_USER is referred to in an SQL statement that is executed at a remote DB2 and the primary authorization ID has been translated to a different authorization ID, SESSION\_USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *DB2 Administration Guide*. The value of SESSION\_USER in a user-defined function or stored procedure is determined according to the rules in Table 37 on page 151.

USER can be specified as a synonym for SESSION\_USER.

*Example:* Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = SESSION_USER;
```

## **USER**

USER specifies the primary authorization ID of the process. The data type is VARCHAR(128). SESSION\_USER is the preferred spelling.

If USER is referred to in an SQL statement that is executed at a remote DB2 and the primary authorization ID has been translated to a different authorization ID, USER specifies the translated authorization ID. For an explanation of authorization ID translation, see *DB2 Administration Guide*. The value of USER in a user-defined function or stored procedure is determined according to the rules in Table 37 on page 151.

*Example:* Display information about tables, views, and aliases that are owned by the primary authorization ID of the process.

```
SELECT * FROM SYSIBM.SYSTABLES WHERE CREATOR = USER;
```

## Using special registers in a user-defined function or a stored procedure

You can use all special registers in a user-defined function or a stored procedure. However, you can modify only some of those special registers.

After a user-defined function or a stored procedure completes, DB2 restores all special registers to the values they had before invocation.

The following table shows information you need when you use special registers in a user-defined function or stored procedure.

Table 37. Characteristics of special registers in a user-defined function or a stored procedure

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
CURRENT APPLICATION ENCODING SCHEME	The value of bind option ENCODING for the user-defined function or stored procedure package	The value of bind option ENCODING for the user-defined function or stored procedure package	Yes
CURRENT CLIENT_ACCTNG	Inherited from the invoking application	Inherited from the invoking application	Not applicable <sup>5</sup>
CURRENT CLIENT_APPLNAME	Inherited from the invoking application	Inherited from the invoking application	Not applicable <sup>5</sup>
CURRENT CLIENT_USERID	Inherited from the invoking application	Inherited from the invoking application	Not applicable <sup>5</sup>
CURRENT CLIENT_WRKSTNNNAME	Inherited from the invoking application	Inherited from the invoking application	Not applicable <sup>5</sup>
CURRENT DATE	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	Not applicable <sup>5</sup>
CURRENT DEBUG MODE	Inherited from the invoking application	DISALLOW	Yes
CURRENT DECFLOAT ROUNDING MODE	Inherited from the invoking application	The value of bind option ROUNDING for the user-defined function or stored procedure package	Yes
CURRENT DEGREE	CURRENT DEGREE <sup>2</sup>	The value of field CURRENT DEGREE on installation panel DSNTIPF	Yes
CURRENT LOCALE LC_CTYPE	Inherited from the invoking application	The value of field CURRENT LC_CTYPE on installation panel DSNTIPF	Yes
CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION	Inherited from the invoking application	System default value	Yes
CURRENT MEMBER	New value for each SET <i>host-variable</i> =CURRENT MEMBER statement	New value for each SET <i>host-variable</i> =CURRENT MEMBER statement	Not applicable <sup>5</sup>

Table 37. Characteristics of special registers in a user-defined function or a stored procedure (continued)

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
CURRENT OPTIMIZATION HINT	The value of bind option OPTHINT for the user-defined function or stored procedure package or inherited from the invoking application <sup>6</sup>	The value of bind option OPTHINT for the user-defined function or stored procedure package	Yes
CURRENT PACKAGE PATH	An empty string if the routine was defined with a COLLID value; otherwise, inherited from the invoking application <sup>4</sup>	An empty string, regardless of whether a COLLID value was specified for the routine <sup>4</sup>	Yes
CURRENT PACKAGESET	Inherited from the invoking application <sup>3</sup>	Inherited from the invoking application <sup>3</sup>	Yes
CURRENT PATH	The value of bind option PATH for the user-defined function or stored procedure package or inherited from the invoking application <sup>6</sup>	The value of bind option PATH for the user-defined function or stored procedure package	Yes
CURRENT PRECISION	Inherited from the invoking application	The value of field DECIMAL ARITHMETIC on installation panel DSNTIP4	Yes
CURRENT REFRESH AGE	Inherited from the invoking application	System default value	Yes
CURRENT ROUTINE VERSION	Inherited from the invoking application	The empty string	Yes
CURRENT RULES	Inherited from the invoking application	The value of bind option SQLRULES for the plan that invokes a user-defined function or stored procedure	Yes
CURRENT SCHEMA	Inherited from the invoking application	The value of CURRENT SCHEMA when the routine is entered	Yes
CURRENT SERVER	Inherited from the invoking application	Inherited from the invoking application	Yes
CURRENT SQLID	The primary authorization ID of the application process or inherited from the invoking application <sup>7</sup>	The primary authorization ID of the application process	Yes <sup>8</sup>
CURRENT TIME	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	Not applicable <sup>5</sup>
CURRENT TIMESTAMP	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	New value for each SQL statement in the user-defined function or stored procedure package <sup>1</sup>	Not applicable <sup>5</sup>
CURRENT TIMEZONE	Inherited from the invoking application	Inherited from the invoking application	Not applicable <sup>5</sup>
ENCRYPTION PASSWORD	Inherited from the invoking application	Inherited from the invoking application	Yes

Table 37. Characteristics of special registers in a user-defined function or a stored procedure (continued)

Special register	Initial value when INHERIT SPECIAL REGISTERS option is specified	Initial value when DEFAULT SPECIAL REGISTERS option is specified	Routine can use SET statement to modify?
SESSION_USER or USER	Primary authorization ID of the application process	Primary authorization ID of the application process	Not applicable <sup>5</sup>

**Notes:**

1. If the user-defined function or stored procedure is invoked within the scope of a trigger, DB2 uses the timestamp for the triggering SQL statement as the timestamp for all SQL statements in the package.
2. DB2 allows parallelism at only one level of a nested SQL statement. If you set the value of the CURRENT DEGREE special register to ANY, and parallelism is disabled, DB2 ignores the CURRENT DEGREE value.
3. If the routine definition includes a specification for COLLID, DB2 sets CURRENT PACKAGESET to the value of COLLID. If both CURRENT PACKAGE PATH and COLLID are specified, the CURRENT PACKAGE PATH value takes precedence and COLLID is ignored.
4. If the function definition includes a specification for PACKAGE PATH, DB2 sets CURRENT PACKAGE PATH to the value of PACKAGE PATH.
5. Not applicable because no SET statement exists for the special register.
6. If a program within the scope of the invoking program issues a SET statement for the special register before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, the special register contains the value that is set by the bind option for the user-defined function or stored procedure package.
7. If a program within the scope of the invoking program issues a SET CURRENT SQLID statement before the user-defined function or stored procedure is invoked, the special register inherits the value from the SET statement. Otherwise, CURRENT SQLID contains the authorization ID of the application process.
8. If the user-defined function or stored procedure package uses a value other than RUN for the DYNAMICRULES bind option, the SET CURRENT SQLID statement can be executed but does not affect the authorization ID that is used for the dynamic SQL statements in the package. The DYNAMICRULES value determines the authorization ID that is used for dynamic SQL statements. For more information, see the discussion of DYNAMICRULES in *DB2 Command Reference*.

## Column names

The meaning of a column name depends on its context.

A column name can be used to:

- Declare the name of a column, as in a CREATE TABLE statement.
- Specify the name of a column, as in a CREATE FUNCTION statement to name a column of the result table of a table function.
- Identify a column, as in a CREATE INDEX statement.
- Specify values of the column, as in the following contexts:
  - In an *aggregate function*, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. (Groups and intermediate result tables are explained in Chapter 4, “Queries,” on page 629.) For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
  - In a GROUP BY or ORDER BY clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
  - In an *expression*, a *search condition*, or a *scalar function*, a column name specifies a value for each row or group to which the construct is applied. For example,

when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.

- Provide a column name for an expression to temporarily rename a column, as in the *correlation-clause* of a *table-reference* in a FROM clause or as in the AS clause in the *select-clause*.

## Qualified column names

A qualifier for a column name can be a table name, a view name, an alias name, a synonym, or a correlation name. Whether a column name can be qualified depends, like its meaning, on its context.

- In some forms of the COMMENT and LABEL statements, a column name must be qualified. This is shown in the syntax diagrams.
- Where the column name specifies values of the column, a column name can be qualified at the user's option.
- In the column list of an INSERT statement, a column name can be qualified.
- In the *assignment-clause* of an UPDATE or a MERGE statement, a column name can be qualified.
- In all other contexts, a column name must not be qualified. This rule will be mentioned in the discussion of each statement to which it applies.

Where a qualifier is optional, it can serve two purposes. See “Column name qualifiers to avoid ambiguity” on page 155 and “Column name qualifiers in correlated references” on page 157 for details.

## Correlation names

A *correlation name* can be defined in the FROM clause of a query and after the name of the target table or view in an UPDATE, MERGE, or DELETE statement.

For example, the following clause establishes Z as a correlation name for X.MYTABLE:

```
FROM X.MYTABLE Z
```

With Z defined as a correlation name for table X.MYTABLE, only Z should be used to qualify a reference to a column of X.MYTABLE in that SELECT statement.

A correlation name is associated with a table, view, nested table expression or table function only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements. In a nested table expression or table function, a correlation name is required.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. It can also be used merely as a shorter name for a table or view. In the example, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

Names that are specified in a FROM clause are either *exposed* or *non-exposed*. A correlation name is always an exposed name. A table name or view name is said to be exposed in that FROM clause if a correlation name is not specified. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE, but not for DEPARTMENT; therefore, DEPARTMENT is an exposed name, and EMPLOYEE is not an exposed name:

```
FROM EMPLOYEE E, DEPARTMENT
```

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, the listed column names should be the names that are used to reference the columns in that SELECT statement. For example, assume that the name of the first column in the DEPT table is DEPTNO. Given this FROM clause in a SELECT statement:

```
FROM DEPT D (NUM,NAME,MGR,ANUM,LOC)
```

You should use D.NUM instead of D.DEPTNO to reference the first column of the table.

If a list of columns is specified, it must consist of as many names as there are columns in the *table-reference*. Each column must be unique and unqualified.

## Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, an ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some table or view in a DELETE or UPDATE statement or *table-reference* in a FROM clause.

The tables, views, and *table-references*<sup>12</sup> that might contain the column are called the *object tables* of the context. Two or more object tables might contain columns with the same name. One reason for qualifying a column name is to designate the object from which the column comes. For information on avoiding ambiguity between SQL parameters and variables and column names, see “References to SQL parameters and SQL variables” on page 1611.

A nested table expression which is preceded by a TABLE keyword will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow it are not considered as object tables.

**Table designators:** A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them. For example, the object tables of an expression in a SELECT statement are named in the FROM clause that follows it, as in the following statement:

```
SELECT DISTINCT Z.EMPNO, EMPTIME, PHONENO  
  FROM DSN8910.EMP Z, DSN8910.EMPPROJECT  
 WHERE WORKDEPT = 'D11'  
   AND EMPTIME > 0.5  
   AND Z.EMPNO = DSN8910.EMPPROJECT.EMPNO;
```

Table designators in the FROM clause are established as follows:

- A name that follows a table or view name is both a correlation name and a table designator. Thus, Z is a table designator and qualifies the first column name in the select list.
- An exposed table or view name is a table designator. Thus, the qualified table name, DSN8910.EMPPROJECT is a table designator and qualifies the second column name in the select list.

Two or more object tables can be instances of the same table. In this case, distinct correlation names must be used to unambiguously designate the particular

12. In the case of a *joined-table*, each *table-reference* within the *joined-table* is an object table.

instance of the table. In the following example, the X and Y in the FROM clause are defined to refer, respectively, to the first and second instances of the DSN8910.EMP table:

```
SELECT *  
  FROM DSN8910.EMP X, DSN8910.EMP Y;
```

**Avoiding undefined or ambiguous references in DB2 SQL:** When a column name refers to values of a column, the following situations result in errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table named does not include a column with the specified name. Again, the reference is undefined.
- The name is unqualified and more than one object table includes a column with that name. The reference is ambiguous.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

Two or more object tables can be instances of the same table. A FROM clause that includes  $n$  references to the same table should include at least  $n - 1$  unique correlation names.

For example, in the following FROM clause X and Y are defined to refer, respectively, to the first and second instances of the table EMP.

```
SELECT X.LASTNAME, Y.LASTNAME  
  FROM DSN8910.EMP X, DSN8910.EMP Y  
 WHERE Y.JOB = 'MANAGER'  
   AND X.WORKDEPT = Y.WORKDEPT  
   AND X.JOB <> 'MANAGER';
```

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name can be used. However, the qualifier used and the table used must be the same after fully qualifying the table name or view name and the table designator.

*Example 1:* If the authorization ID of the statement is CORPDATA, the following statement is valid:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT  
  FROM EMPLOYEE;
```

*Example 2:* If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT          -- Incorrect  
  FROM EMPLOYEE;
```

*Example 3:* If the authorization ID of the statement is REGION, the following statement is invalid because EMPLOYEE in the select list represents the table REGION.EMPLOYEE, but the explicitly qualified table name in the FROM clause represents a different table, CORPDATA.EMPLOYEE.

```
SELECT EMPLOYEE.WORKDEPT          -- Incorrect  
      FROM CORPDATA.EMPLOYEE;
```

## Column name qualifiers in correlated references

A reference to a column of a table identified at a higher level is called a *correlated reference*. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. It is good practice to use these unique correlation names to qualify column names.

A *subselect* is a form of a query that can be used as a component of various SQL statements. Refer to Chapter 4, “Queries,” on page 629 for more information on subselects. A *subquery* is a form of a fullselect that is enclosed within parenthesis. For example, a subquery can be used in a search condition. A fullselect that is used to retrieve a single value as an expression within a statement is called a *scalar fullselect* or a *scalar subquery*. A fullselect that is used in the FROM clause of a query is called a *nested table expression*.

A subquery can include search conditions of its own, and these search conditions can, in turn, include subqueries. Thus, an SQL statement can contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy has a clause that establishes one or more table designators. This is the FROM clause, except in the highest level of an UPDATE, where it is the table or view being updated. A search condition of a subquery can reference not only columns of the tables identified by the FROM clause of its own element of the hierarchy, but also columns of tables identified at any level along the path from its own element to the highest level of the hierarchy. A reference to a column of a table identified at a higher level is called a *correlated reference*.

A correlated reference to column C of table T can be of the form C, T.C, or Q.C, if Q is a correlation name defined for T. However, a **correlated reference in the form of an unqualified column name is not good practice**. The following explanation is based on the assumption that a correlated reference is always in the form of a qualified column name and that the qualifier is a correlation name.

A qualified column name, Q.C, is a correlated reference only if these three conditions are met:

- Q.C is used in a search condition or in a select list of a subquery.
- Q does not name a table used in the FROM clause of that subquery.
- Q does name a table used at some higher level.

Q.C refers to column C of the table or view at the level where Q is used as the table designator of that table or view. Because the same table or view can be identified at many levels, unique correlation names are recommended as table designators. If Q is used to name a table at more than one level, Q.C refers to the lowest level that contains the subquery that includes Q.C.

For example, in the following statement, the correlated reference X.WORKDEPT (in the last line) refers to the value of WORKDEPT in table DSN8910.EMP at the level of the first FROM clause (which establishes X as a correlation name for DSN8910.EMP). The statement lists employees who make less than the average salary for their department.

```

SELECT EMPNO, LASTNAME, WORKDEPT
  FROM DSN8910.EMP X
 WHERE SALARY < (SELECT AVG(SALARY)
                   FROM DSN8910.EMP
                  WHERE WORKDEPT = X.WORKDEPT);

```

The following example shows a correlated reference in the select list of the subquery.

```

SELECT T1.KEY1
  FROM BP1TBL T1
 GROUP BY T1.KEY1
 HAVING MAX(T1.KEY1) = (SELECT MIN(T1.KEY1) + MIN(T2.KEY1)
                        FROM BP2TBL T2);

```

## Resolution of column name qualifiers and column names

The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved.

Names in a FROM clause are either *exposed* or *non-exposed*. A correlation name for a table name, view name, nested table expression, or reference to a table function is always exposed. A table name or a view name that is not followed by a correlation name is also exposed.

Although DB2 for z/OS does not enforce this rule strictly, in IBM SQL and ANSI/ISO SQL, the exposed names in a FROM clause must be unique, and the qualifier of a column name must be an exposed name. Therefore, for good programming practices, ensure that all exposed names are unique and that all qualified column names are qualified with the appropriate exposed name.

The rules for finding the referent of a column name qualifier are as follows:

1. Let Q be a one-, two-, or three-part name, and let Q.C denote a column name in subselect S. Q must designate a table or view identified in the statement that includes S and that table or view must have a column named C. An additional requirement differs for two cases:
  - If Q.C is *not* in a *search-condition* or S is *not* a subquery, Q must designate a table or view identified in the FROM clause of S. For example, if Q.C is in a SELECT clause, Q refers to a table or view in the following FROM clause.
  - If Q.C is in a *search-condition* and S is a subquery, Q must designate a table or view identified either in the FROM clause of S or in a FROM clause of a subselect that directly or indirectly includes S. For example, if Q.C is in a WHERE clause and S is the only subquery in the statement, the table or view that Q refers to is either in the FROM clause of S or the FROM clause of the subselect that includes S.
2. The same table or view can be identified more than once in the same statement. The particular occurrence of the table or view that Q refers to is determined by a procedure equivalent to the following steps:
  - a. The one- and two-part names in every FROM clause and the one- and two-part qualifiers of column names are expanded into a fully-qualified form.

For example, if a dynamic SQL statement uses FROM Q and DYNAMICRULES run behavior (RUN) is in effect, Q is expanded to S.A.Q, where S is the value of CURRENT SERVER and A is the value of CURRENT SCHEMA. (If DYNAMICRULES bind behavior is in effect instead, A is the plan or package qualifier as determined during the bind process or the qualifier for the native SQL procedure as determined when

- the procedure was defined.) This step is later referred to as “name completion”. An error occurs if the first part of every name (the location) is not the same.
- b. Q, now a three-part name, is compared with every name in the FROM clause of S. If Q.C is in a *search-condition* and S is a subquery, Q is next compared with every name in the FROM clause of the subselect that contains S. If that subselect is a subquery, Q is then compared with every name in the FROM clause of the subselect containing that subquery, and so on. If a FROM clause includes multiple names, the comparisons in that clause are made in order from left to right.
  - c. The referent of Q is selected by these rules:
    - If Q matches exactly one name, that name is selected.
    - If Q matches more than one name, but only one exposed name, that exposed name is selected.
    - If Q matches more than one exposed name, the first of those names is selected.
    - If Q matches more than one name, none of which are exposed names, the first of those names is selected.If Q does not match any name, or if the table or view designated by Q does not include a column named C, an error occurs.
  - d. Otherwise, Q.C is resolved to column C of the occurrence of the table or view identified by the selected name.
3. A warning occurs for any of these cases:
    - The selected name is not an exposed name.
    - The selected name is an exposed name that has an unexposed duplicate that appears before the selected name in the ordered list of names to which Q is compared.
    - The selected name is an exposed name that has an exposed duplicate in the same FROM clause.
    - Another name would have been selected had the matching been performed before name completion.The rules for resolving column name qualifiers apply to every SQL statement that includes a subselect and are applied before synonyms and aliases are resolved. In the case of a searched UPDATE or DELETE statement, the first clause of the statement identifies the table or view to be updated or deleted. That clause can include a correlation name and, with regard to name resolution, is equivalent to the first FROM clause of a SELECT statement. For example, a subquery in the search condition of an UPDATE statement can include a correlated reference to a column of the updated rows.
- The rules for column names in the ORDER BY clause are the same as other clauses.

---

## References to variables

A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements.

### host variable

Host variables are defined by statements of a host language. For more information about how to refer to host variables, see “References to host variables” on page 160.

#### **transition variable**

Transition variables are defined in a trigger and refer to either the old or new values of columns of the subject table of a trigger. For more information about how to refer to transition variables, see “CREATE TRIGGER” on page 1151.

#### **SQL variable**

SQL variables are defined by an SQL compound statement in an SQL procedure. For more information about SQL variables, see “References to SQL parameters and SQL variables” on page 1542.

#### **SQL parameter**

SQL parameters are defined in an CREATE FUNCTION (SQL Scalar) or CREATE PROCEDURE (SQL) statement. For more information about SQL parameters, see “References to SQL parameters and SQL variables” on page 1542.

#### **parameter marker**

Parameter markers are specified in an SQL statement that is dynamically prepared instead of host variables. For more information about parameter markers, see Parameter markers. in the PREPARE statement.

Unless otherwise noted, the term *host variable* in syntax diagrams is used to describe where a host variable, transition variable, SQL variable, SQL parameter, or parameter marker can be used.

## **References to host variables**

Host variables are defined directly by statements of the host language or indirectly by SQL extensions. A *host-variable* in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead.

A *host variable* is either of these items that is referred to in an SQL statement:

- A variable in a host language such as a PL/I variable, C variable, Fortran variable, REXX variable, Java variable, COBOL data item, or Assembler language storage area
- A host language construct that was generated by an SQL precompiler from a variable declared using SQL extensions

Host variables are defined directly by statements of the host language or indirectly by SQL extensions as described in *DB2 Application Programming and SQL Guide*. Host variables cannot be referenced in dynamic SQL statements; parameter markers must be used instead. For more information about parameter markers, see “Host variables in dynamic SQL” on page 162.

A host-variable in an SQL statement must identify a host variable that is described in the program according to the rules for declaring host variables.

In PL/I, C, and COBOL, host variables can be referred to in ways that do not apply to Fortran and Assembler language. This is explained in “Host structures in PL/I, C, and COBOL” on page 171. The following applies to all host languages.

The term *host-variable*, as used in the syntax diagrams, shows a reference to a host variable. In a SET *host variable* statement and the INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, a host variable is an output variable

to which a value is assigned by DB2. In a CALL statement, a host variable can be an output argument that is assigned a value after execution of the procedure, an input argument that provides an input value for the procedure, or both an input and output argument. In all other contexts, a host variable is an input variable which provides a value to DB2.

### Non-Java variable references

The general form of a host variable reference in all languages other than Java is:

Each host identifier must be declared in the source program, except in a program written in REXX. The first host identifier designates the main variable; the second host identifier designates its indicator variable. The variable designated by the second host identifier must be a small integer. The purposes of the indicator variable are to:

- Specify the null value. A negative value of the indicator variable specifies the null value. A -1 value indicates that the value that was selected was the null value. A -2 value indicates that a numeric conversion or arithmetic expression error occurred in the SELECT list of an outer SELECT statement. A -3 value indicates that values were not returned for the row because a hole was detected on a multiple row FETCH. The value of -3 is used only for multiple-row FETCH statements; otherwise, the only indication of a hole is a warning.
- Record the original length of a truncated string.
- Indicate that a character could not be converted.
- Record the seconds portion of a time if the time is truncated on assignment to a host variable.

For example, if :V1:V2 is used to specify an insert or update value, and if V2 is negative, the value specified is the null value. If V2 is not negative, the value specified is the value of V1.

Similarly, if :V1:V2 is specified in certain statements (like a FETCH or SELECT INTO statement), and if the value returned is null, V1 is not changed and V2 is set to -1 or -2. It is set to -1 if the value selected was actually null. It is set to -2 if the null value was returned because of numeric conversion errors or arithmetic expression errors in the SELECT list of an outer SELECT statement. It is also set to -2 as the result of a character conversion error.

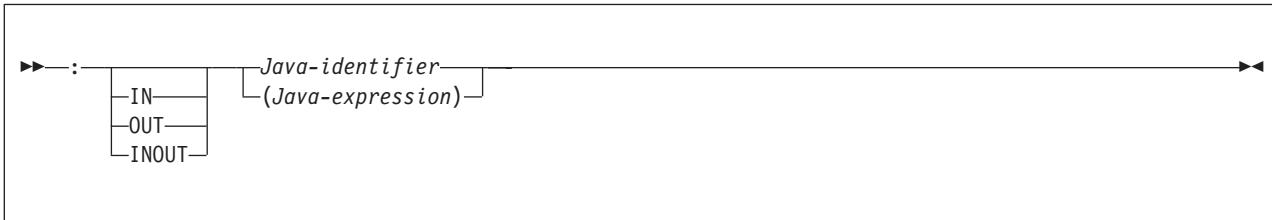

If the value returned is not null, that value is assigned to V1, and V2 is set to zero (unless the assignment to V1 requires string truncation, in which case V2 is set to the original length of the string). If an assignment requires truncation of the seconds part of a time, V2 is set to the number of seconds.

If the second host identifier is omitted, the host variable does not have an indicator variable: the value specified by the host variable :V1 is always the value of V1 and null values cannot be assigned to the variable. Thus, this form should not be used in an INTO clause unless the corresponding

result column cannot contain null values. If this form is used for an output host variable and the value returned is null, DB2 will generate an error at run time.

### Java variable references

The general form of a host variable reference in Java is:

In Java, indicator variables are not used. Instead, instances of a Java class can be set to a null value. Variables defined as Java primitive types can not be set to a null value.

If IN, OUT, or INOUT is not specified, the default depends on the context in which the variable is used. If the Java variable is used in an INTO clause, OUT is the default. Otherwise, IN is the default.

An SQL statement that refers to host variables must be within the scope of the declaration of those host variables. For host variables referred to in the SELECT statement of a cursor, the OPEN statement, and the DECLARE CURSOR statement have to be in the same scope.

All references to host variables must be preceded by a colon. If an SQL statement references a host variable without a preceding colon, the precompiler issues an error for the missing colon or interprets the host variable as an unqualified column name, which might lead to unintended results. The interpretation of a host variable without a colon as a column name occurs when the host variable is referenced in a context in which a column name can also be referenced.

## Host variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of host variables.

A *parameter marker* is a question mark (?) that represents a position in a dynamic SQL statement where the application will provide a value; that is, where a host variable would be found if the statement string were a static SQL statement. The following examples show a static SQL statement that uses host variables and a dynamic statement that uses parameter markers:

```
INSERT INTO DEPT VALUES (:HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO, :HV_ADMRDEPT)  
INSERT INTO DEPT VALUES (?, ?, ?, ?)
```

For more information on parameter markers, see Parameter markers under the PREPARE statement.

## References to LOB host variables

Regular LOB variables (CLOB, DBCLOB, and BLOB), LOB locator variables and LOB file reference variables can be defined in all host languages with a few exceptions.

Where LOBs are allowed, the term *host-variable* in a syntax diagram can refer to a regular host variable, a locator variable, or a file reference variable. Since these variables are not native data types in host programming languages, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable.

- REXX supports LOB locators and LOB file reference variables.
- Java supports LOBs and LOB file references, but not LOB locators.

When it is possible to define a host variable that is large enough to hold an entire LOB value and the performance benefit of delaying the transfer of data from the server is not required, a LOB locator or LOB file reference is not needed. However, it is often not acceptable to store an entire LOB value in temporary storage due to host language restrictions, storage restrictions, or performance requirements. When storing an entire LOB value at one time is not acceptable, a LOB value can be referenced using a LOB locator and portions of the LOB value can be accessed or the entire LOB value can be stored in a file and a LOB file reference can be used to access the LOB data.

## References to LOB locator variables

A LOB locator variable is a host variable that contains the locator representing a LOB value on the database server.

A locator variable in an SQL statement must identify a LOB locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement. For example, in C:

```
static volatile SQL TYPE IS CLOB_LOCATOR *loc1;
```

The term *locator-variable*, as used in the syntax diagrams, shows a reference to a LOB locator variable. The meta-variable *locator-variable* can be expanded to include a *host-identifier* the same as that for *host-variable*.

Like all other host variables, a LOB locator variable can have an associated indicator variable. Indicator variables for LOB locator variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the locator host variable is unchanged. This means a locator can never represent a null value. However, when the indicator variable associated with a LOB locator is null, the value of the referenced LOB value is null.

If a locator variable does not currently represent any value, an error occurs when the locator variable is referenced.

When a transaction commits, LOB locators that were acquired by the transaction are released unless a HOLD LOCATOR statement was issued for the LOB locator. When the transaction ends, all LOB locators are released.

It is the application programmer's responsibility to guarantee that any LOB locator is used only in SQL statements that are executed at the same server that originally generated the LOB locator. For example, assume that a LOB locator is returned from one server and assigned to a LOB locator variable. If that LOB locator variable is subsequently used in an SQL statement that is executed at a different server unpredictable results will occur.

## References to XML host variables

XML host variables can be declared as another host variable type. This allows XML data to be declared in host languages that do not support XML data as a native data type.

XML host variables can be declared as the following host variable types:

- XML AS CLOB(*n*)

Declares a CLOB host variable that contains XML data that is encoded in the CCSID for the host variable.

- XML AS DBCLOB(*n*)

Declares a DBCLOB host variable that contains XML data that is encoded in the graphic CCSID for the host variable.

- XML AS BLOB(*n*)

Declares a BLOB host variable that contains XML data that is encoded as specified within the data according to the XML 1.0 specification for determining encoding.

- XML AS CLOB\_FILE

Declares a CLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

- XML AS DBCLOB\_FILE

Declares a DBCLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

- XML AS BLOB\_FILE

Declares a BLOB file reference variable that contains XML data that is encoded in the CCSID for the file reference variable.

See “References to file reference variables” on page 165 for additional information about file reference variables.

Although the application XML host variable declaration includes a LOB type specification, the host variable declarations all map to the XML data type, not the LOB type that is used in the application declaration. The application might also use non-XML host variables in place of XML host variables. For example, when a prepared statement is executed, the application might use a character host variable to replace an XML parameter marker in the statement.

Although the XML data type is incompatible with all other data types, both XML and non-XML data types can be used for input to and output from XML data. Applications can use either XML host variables, character host variables, or binary string host variables to input to and output from XML data by using SQL statements.

The following table summarizes the conversions built-in data types (including XML) to and from the supported host variable data types within embedded applications. The built-in data types are specified in the rows. A Y indicates that the built-in data type can be assigned to or assigned from the host variable type.

*Table 38. Application host variable compatibility with the built-in data types for applications that contain embedded SQL*

		application host variable data type					
built-in data type		CHAR, VARCHAR, CLOB, CLOB_FILE	GRAPHIC, VARGRAPHIC, DBCLOB, DBCLOB_FILE	BINARY, VARBINARY, BLOB, BLOB_FILE	XML AS CLOB, XML AS CLOB_FILE	XML AS DBCLOB, XML AS DBCLOB_FILE	XML AS BLOB, XML AS BLOB_FILE
CHAR	Y	Y					
VARCHAR	Y	Y					
CLOB	Y	Y					
GRAPHIC	Y	Y					
VARGRAPHIC	Y	Y					
DBCLOB	Y	Y					
BINARY			Y				
VARBINARY				Y			
BLOB				Y			
XML	Y	Y	Y	Y	Y	Y	Y

## References to file reference variables

File reference variables and arrays are used for direct file input and output for LOB and XML values (when the XML value is declared using XML AS *variable-type*), and can be defined in all host languages.

Since these are not native data types, SQL extensions are used and the DB2 precompiler or coprocessor generates the host language constructs necessary to represent each variable or array. In the case of REXX, LOB values are mapped to strings. See “References to XML host variables” on page 164 for more information about XML host variables.

A file reference variable represents (rather than contains) the file, just as a LOB locator represents, rather than contains, the LOB data. Database queries, updates, and inserts can use file reference variables to store or to retrieve single column values. As with all other host variables, file reference variables can have an associated indicator variable.

A file reference variable has the following properties:

### Data type

BLOB, CLOB, or DBCLOB. This property is specified when the variable is declared using BLOB\_FILE, CLOB\_FILE, or DBCLOB\_FILE.

### Direction

This must be specified by the application program at run time (it is implicitly specified as part of the File options value). The direction can be either of the following:

- Input

Input is used as a source of data on an EXECUTE statement, an OPEN statement, an update operation, an insert operation, or a delete operation.

- Output

Output is used as the target of data. For example, on a FETCH statement or a SELECT INTO statement.

**File name**

This must be specified by the application program at run time. It must be the complete path name of the file. Within an application, a file should only be referenced one time in a file reference variable.

**File name length**

This must be specified by the application program at run time. It is the length of the file name in bytes.

**Data length**

Sets the data length to the length of the new data that is written to the file. The length is in bytes. Data length is unused on input.

**File options**

Options are set by an INTEGER value in a field in the file reference variable structure. One of the following values must be specified in an application for each file reference variable before that file reference variable can be used in the application:

**SQL\_FILE\_READ**

This is a regular file that can be opened, read and closed. (The option is SQL-FILE-READ in COBOL, sql\_file\_read in FORTRAN, and READ in REXX.) SQL\_FILE\_READ is an input (from client to server) file option.

**SQL\_FILE\_CREATE**

Create a new file. If the file already exists, an error is returned. (The option is SQL-FILE-CREATE in COBOL, sql\_file\_create in FORTRAN, and CREATE in REXX.) SQL\_FILE\_CREATE is an output (from server to client) file option.

**SQL\_FILE\_OVERWRITE**

If an existing file with the specified name exists, it is overwritten; otherwise a new file is created. (The option is SQL-FILE-OVERWRITE in COBOL, sql\_file\_overwrite in FORTRAN, and OVERWRITE in REXX.). SQL\_FILE\_OVERWRITE is an output (from server to client) file option.

**SQL\_FILE\_APPEND**

If an existing file with the specified name exists, the output is appended to it; otherwise a new file is created. (The option is SQL-FILE-APPEND in COBOL, sql\_file\_append in FORTRAN, and APPEND in REXX.) SQL\_FILE\_APPEND is an output (from server to client) file option.

The encoding scheme CCSID of the file name is based on the encoding scheme of the application. The CCSID of the LOB or XML data (the contents of the file) can be set by the application by using a `DECLARE host-variable CCSID` statement if the CCSID of the LOB or XML data is different from the CCSID of the application. DB2 will perform any character conversion that is required prior to the LOB or XML data being inserted into a table or written to a file.

## References to stored procedure result sets

An application, written in a programming language other than Java, can access a result set that is returned from a stored procedure. A result set locator is used by the invoking application to access the result set.

A result set locator value for a result set can be obtained from an ASSOCIATE LOCATOR statement or with the DESCRIBE PROCEDURE statement. For more information, see “ASSOCIATE LOCATORS” on page 868 and “DESCRIBE PROCEDURE” on page 1250.

The result set locator value is specified on an ALLOCATE CURSOR statement to define a cursor in the invoking application and to associate it with a stored procedure result set. For more information, see “ALLOCATE CURSOR” on page 696.

A DESCRIBE CURSOR statement can be used in the invoking application to obtain information on the characteristics of the columns of a stored procedure result set. For more information, see “DESCRIBE CURSOR” on page 1238.

The application can then access the rows of the result set using FETCH statements with the allocated cursor.

## References to result set locator variables

A *result set locator variable* is a variable that contains the locator that identifies a stored procedure result set. A result set locator variable in an SQL statement must identify a result set locator variable described in the program according to the rules for declaring result set locator variables. This is always indirectly through an SQL statement.

For example, in C:

```
static volatile SQL TYPE IS RESULT_SET_LOCATOR *loc1;
```

A result set locator variable in an SQL procedure is defined with the RESULT\_SET\_LOCATOR VARYING in a compound statement. See “compound-statement” on page 1554 for additional information.

The term *rs-locator-variable*, as used in the syntax diagrams, shows a reference to a result set locator variable. The meta-variable *rs-locator-variable* can be expanded to include a *host-identifier* the same as that for *host-variable*.

When the indicator variable associated with a result set locator is null, the referenced result set is not defined.

If a result set locator variable does not currently represent any stored procedure result set, an error occurs when the locator variable is referenced.

A commit operation destroys all open cursors that were declared in the stored procedure without the WITH HOLD option and the result set locators that are associated with those cursors. Otherwise, a cursor and its associated result set locator persist past the commit.

## References to built-in session variables

DB2 provides several built-in session variables that contain information about the server and application process. The value of a built-in session variable can be obtained by invoking the GETVARIABLE function with the name of the built-in session variable.

DB2 provides the following built-in session variables:

### **SYSIBM.APPLICATION\_ENCODING\_SCHEME**

Contains a string that corresponds to the value that is specified for the APPLICATION ENCODING field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, UNICODE, or 1-65533, and this session variable can never be null.

### **SYSIBM.COBOL\_STRING\_DELIMITER**

Contains a string that corresponds to the value that is specified for the STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

### **SYSIBM.DATA\_SHARING\_GROUP\_NAME**

Contains a string that corresponds to the name of the data sharing group for this DB2 subsystem. If the subsystem is not part of data sharing group, the null value is returned.

### **SYSIBM.DATE\_FORMAT**

Contains a string that corresponds to the value that is specified for the DATE FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

### **SYSIBM.DATE\_LENGTH**

Contains a string that corresponds to the value that is specified for the LOCAL DATE LENGTH field on the DSNTIP4 installation panel. The value will be 10-254, or 0 for no exit, and this session variable can never be null.

### **SYSIBM.DECIMAL\_ARITHMETIC**

Contains a string that corresponds to the value that is specified for the DECIMAL ARITHMETIC field on the DSNTIP4 installation panel. The value will be DEC15, DEC31, 15, or 31, and this session variable can never be null.

### **SYSIBM.DECIMAL\_POINT**

Contains a string that corresponds to the value that is specified for the DECIMAL POINT IS field on the DSNTIPF installation panel. The value will be '.' or ',' and this session variable can never be null.

### **SYSIBM.DEFAULT\_DECFLOAT\_ROUND\_MODE**

Contains a string that corresponds to the value that is specified for the DECFLOAT ROUNDING MODE field on the DSNTIPF installation panel. This session variable can never be null.

### **SYSIBM.DEFAULT\_DEFAULT\_SSID**

Contains a string that corresponds to the value that is specified for the GROUP ATTACH field on the DSNTIPK installation panel or the SUBSYSTEM NAME field on the DSNTIPM installation panel. This session variable can never be null.

### **SYSIBM.DEFAULT\_LANGUAGE**

Contains a string that corresponds to the value that is specified for the

LANGUAGE DEFAULT field on the DSNTIPF installation panel. The value will be ASM, C, CPP, IBMCOB, FORTRAN, or PL/I, and this session variable can never be null.

#### **SYSIBM.DEFAULT\_LOCALE\_LC\_CTYPE**

Contains a string that corresponds to the value that is specified for the LOCALE LC\_CTYPE field on the DSNTIPF installation panel. This session variable can never be null.

#### **SYSIBM.DISTRIBUTED\_SQL\_STRING\_DELIMITER**

Contains a string that corresponds to the value that is specified for the DIST SQL STR DELIMTR field on the DSNTIPF installation panel. The value will be ", or ', and this session variable can never be null.

#### **SYSIBM.DSNHDECP\_NAME**

Contains a string that corresponds to the fully qualified data set name of the data set from which the application defaults module DSNHDECP was loaded. For instance, 'DSN910.SDSNEXIT(DSNHDECP)'. This session variable can never be null.

#### **SYSIBM.DYNAMIC\_RULES**

Contains a string that corresponds to the value that is specified for the USE FOR DYNAMICRULES field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

#### **SYSIBM.ENCODING\_SCHEME**

Contains a string that corresponds to the value that is specified for the DEF ENCODING SCHEME field on the DSNTIPF installation panel. The value will be EBCDIC, ASCII, or UNICODE, and this session variable can never be null.

#### **SYSIBM.MIXED\_DATA**

Contains a string that corresponds to the value that is specified for the MIXED DATA field on the DSNTIPF installation panel. The value will be YES or NO, and this session variable can never be null.

#### **SYSIBM.NEWFUN**

Contains a string that corresponds to the value that is specified for the INSTALL TYPE field on the DSNTIPA1 installation panel. The value will be INSTALL, UPDATE, MIGRATE, or ENFM, and this session variable can never be null. The value reflects the setting of the DSNHDECP variable NEWFUN.

#### **SYSIBM.PACKAGE\_NAME**

Contains a string that corresponds to the name of the package that is currently being executed. If a package is not currently being executed, the null value is returned. (This situation can occur when the plan that is being executed bound one or more DBRMs directly).

#### **SYSIBM.PACKAGE\_SCHEMA**

Contains a string that corresponds to the collection id of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

#### **SYSIBM.PACKAGE\_VERSION**

Contains a string that corresponds to the version of the package that is currently being executed. If a package is not currently being executed, the null value is returned.

#### **SYSIBM.PAD\_NUL\_TERMINATED**

Contains a string that corresponds to the value that is specified for the

PAD NUL-TERMINATED field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

#### **SYSIBM.PLAN\_NAME**

Contains a string that corresponds to the name to the plan that is currently being executed. This session variable can never be null.

#### **SYSIBM.SECLABEL**

Contains a string that corresponds to the RACF SECLABEL value, if any, that has been defined for the current userid. If a value has not been defined, the null value is returned.

#### **SYSIBM.SQL\_STRING\_DELIMITER**

Contains a string that corresponds to the value that is specified for the SQL STRING DELIMITER field on the DSNTIPF installation panel. The value will be DEFAULT, ", or ', and this session variable can never be null.

#### **SYSIBM.SSID**

Contains a string that corresponds to the actual DB2 subsystem identifier for this DB2 subsystem. This session variable can never be null.

#### **SYSIBM.STANDARD\_SQL**

Contains a string that corresponds to the value that is specified for the STD SQL LANGUAGE field on the DSNTIP4 installation panel. The value will be YES or NO, and this session variable can never be null.

#### **SYSIBM.SYSTEM\_NAME**

Contains a string that corresponds to the name of the DB2 for z/OS subsystem, as defined in field SUBSYSTEM NAME on installation panel DSNTIPM. This session variable can never be null.

#### **SYSIBM.SYSTEM\_ASCII\_CCSID**

Contains a value that represents the ASCII CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the ASCII CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for ASCII data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

#### **SYSIBM.SYSTEM\_EBCDIC\_CCSID**

Contains a value that represents the EBCDIC CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the EBCDIC CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for EBCDIC data on this system. A value of 65534 for the MIXED or graphic CCSID indicates that this system does not support storing data in that CCSID. This session variable can never be null.

#### **SYSIBM.SYSTEM\_UNICODE\_CCSID**

Contains a value that represents the Unicode CCSIDs that are in use on this system. The information is returned as a comma-delimited string that corresponds to the UNICODE CCSID that was specified on installation panel DSNTIPF. The three values that are returned correspond to the SBCS, MIXED, and graphic CCSID that are in use for Unicode data on this system. This session variable can never be null.

#### **SYSIBM.TIME\_FORMAT**

Contains a string that corresponds to the value that is specified for the

TIME FORMAT field on the DSNTIP4 installation panel. The value will be ISO, JIS, USA, EUR, or LOCAL, and this session variable can never be null.

#### SYSIBM.TIME\_LENGTH

Contains a string that corresponds to the value that is specified for the LOCAL TIME LENGTH field on the DSNTIP4 installation panel. The value will be 8-254 or 0 for no exit, and this session variable can never be null.

#### SYSIBM.VERSION

Contains a string that represents the version of DB2. This string has the form *pppvrrrm* where:

- *ppp* is a product string that is set to the value 'DSN'
- *vv* is a two-digit version identifier such as '09'
- *rr* is a two-digit release identifier such as '01'
- *m* is a one-digit maintenance level identifier such as '5' (Values 0, 1, 2, 3, and 4 are reserved for conversion mode and enabling-new-function mode, and values 5, 6, 7, 8, and 9 are reserved for new function mode.)

This session variable can never be null.

For example, the following statement sets the value of host variable *hv1* to the name of the plan that is currently being executed:

```
SET :hv1 = GETVARIABLE(SYSIBM.PLAN_NAME);
```

For more information about the GETVARIABLE function, see "GETVARIABLE" on page 374.

---

## Host structures in PL/I, C, and COBOL

A *host structure* is a PL/I structure, C structure, or COBOL group that is referred to in an SQL statement.

In Java and REXX, there is no equivalent to a host structure. Host structures are defined by statements of the host language, as explained in *DB2 Application Programming and SQL Guide*. As used here, the term *host structure* does not include an SQLCA or SQLDA.

The form of a host structure reference is identical to the form of a host variable reference. The reference *:S1:S2* is a host structure reference if *S1* names a host structure. If *S1* designates a host structure, *S2* must be a small integer variable or an array of small integer variables. *S1* is the host structure and *S2* is its indicator array.

A host structure can be referred to in any context where a list of host variables can be referenced. A host structure reference is equivalent to a reference to each of the host variables contained within the structure in the order which they are defined in the host language structure declaration. The *n*th variable of the indicator array is the indicator variable for the *n*th variable of the host structure.

In PL/I, for example, if *V1*, *V2*, and *V3* are declared as the variables within the structure *S1*, the following two statements are equivalent:

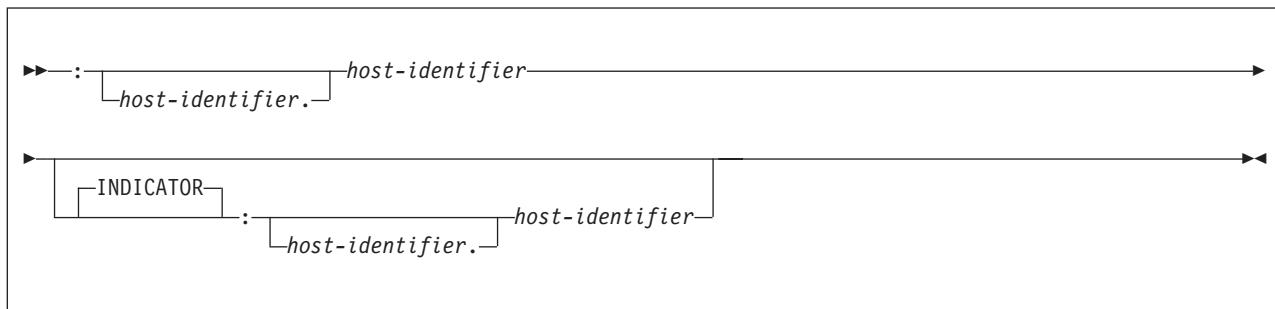

```
EXEC SQL FETCH CURSOR1 INTO :S1;  
EXEC SQL FETCH CURSOR1 INTO :V1, :V2, :V3;
```

If the host structure has *m* more variables than the indicator array, the last *m* variables of the host structure do not have indicator variables. If the host structure has *m* fewer variables than the indicator array, the last *m* variables of the indicator

array are ignored. These rules also apply if a reference to a host structure includes an indicator variable or a reference to a host variable includes an indicator array. If an indicator array or variable is not specified, no variable of the host structure has an indicator variable.

In addition to structure references, individual host variables or indicator variables in PL/I, C, and COBOL can be referred to by qualified names. The qualified form is a host identifier followed by a period and another host identifier. The first host identifier must name a structure, and the second host identifier must name a host variable at the next level within that structure.

In PL/I, C, and COBOL, the syntax of *host-variable* is:

In general, a *host-variable* in an expression must identify a host variable (not a structure) described in the program according to the rules for declaring host variables. However, there are a few SQL statements that allow a host variable in an expression to identify a structure, as specifically noted in the descriptions of the statements.

The following examples show references to host variables and host structures:

:V1 :S1.V1 :S1.V1:V2 :S1.V2:S2.V4

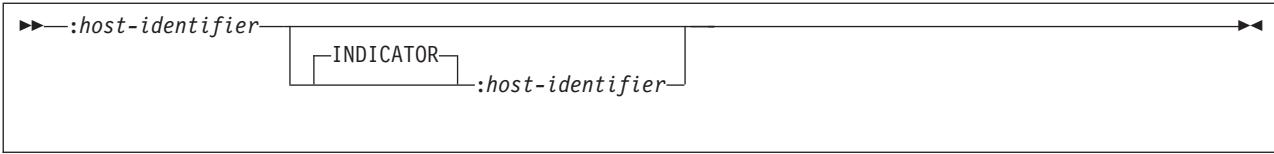

## Host-variable-arrays in PL/I, C, C++, and COBOL

A *host-variable-array* is an array in which each element of the array contains a value for the same column. The first element in the array corresponds to the first value, the second element in the array corresponds to the second value, and so on. A host-variable-array can only be referenced in a FETCH statement for a multiple row fetch, in an INSERT statement with a multiple row insert, or in a multiple row MERGE statement.

Host-variable-arrays are defined by statements of the host language as explained in *DB2 Application Programming and SQL Guide*.

The form of a host structure reference is similar to the form of a host variable reference. The reference :COL1:COL1IND is a host-variable-array reference if COL1 designates an array. If COL1 designates an array, COL1IND must be a one dimensional array of small integer host variables. The dimension of the host-variable-array must be less than or equal to the dimension of the indicator array. If an indicator array is not specified, no variable of the main host-variable-array has an indicator variable.

In PL/I, C, C++, and COBOL, the syntax of *host-variable-array* is:

In the following example, *COL1* is the main host-variable-array and *COL1IND* is its indicator array. If *COL1* has 10 elements for fetching a single column of data for multiple rows of data, *COL1IND* must also have 10 entries.

```
EXEC SQL FETCH CURSOR FOR 5 ROWS INTO :COL1 :COL1IND;
```

## Functions

A *function* is an operation denoted by a function name followed by zero or more operands that are enclosed in parentheses.

It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*. For example, a function can be passed with two input arguments that have date and time data types and return a value with a timestamp data type as the result.

### Types of functions

There are several ways to classify functions. One way to classify functions is as built-in functions, user-defined functions, or cast functions that are generated for distinct types.

#### Built-in functions

*Built-in functions* are functions that come with DB2 for z/OS. These functions provide a single-value result.

Built-in functions include operator functions such as "+", aggregate functions such as AVG, and scalar functions such as SUBSTR. For a list of the built-in aggregate and scalar functions and information on these functions, see Chapter 3, "Functions," on page 259.

The built-in functions are in schema SYSIBM.

The RANK, DENSE\_RANK, and ROW\_NUMBER specifications are sometimes referred to as built-in functions. Refer to "OLAP specification" on page 212 for more information on these specifications.

#### User-defined functions

*User-defined functions* are functions that are created using the CREATE FUNCTION statement and registered to the DB2 in the catalog. These functions allow users to extend the function of DB2 by adding their own or third party vendor function definitions.

A user-defined function is an SQL, external, or sourced function. An SQL function is defined to the database using only an SQL RETURN statement. An external function is defined to the database with a reference to an external program that is executed when the function is invoked. A sourced function is defined to the database with a reference to a built-in function or another user-defined function. Sourced functions can be used to extend built-in aggregate and scalar functions for use on distinct types.

A user-defined function resides in the schema in which it was registered. The schema cannot be SYSIBM.

To help you define and implement user-defined functions, sample user-defined functions are supplied with DB2. You can also use these sample user-defined functions in your application program just as you would any other user-defined function if the appropriate installation job has been run. For a list of the sample user-defined functions, see “Sample user-defined functions” on page 2007. For more information on creating and using user-defined functions, see *DB2 Application Programming and SQL Guide*.

## Cast functions

*Cast functions* are functions that DB2 automatically generates when a distinct type is created using the CREATE TYPE statement.

Cast functions support casting from the distinct type to the source type and from the source type to the distinct type. The ability to cast between the data types is important because a distinct type is compatible only with itself.

The generated cast functions reside in the same schema as the distinct type for which they were created. The schema cannot be SYSIBM. For more information on the functions that are generated for a distinct type, see “CREATE TYPE” on page 1177.

## Additional way to classify functions

Another way to classify functions is as aggregate, scalar, or table functions, depending on the input data values and result values.

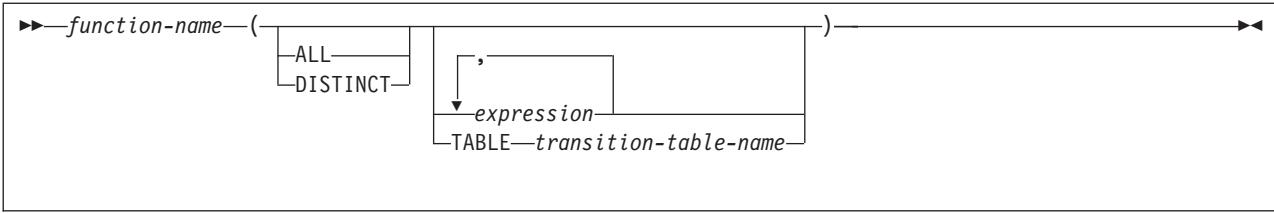

- An *aggregate function* receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Aggregate functions are sometimes called *column functions*. Built-in functions and user-defined sourced functions can be aggregate functions. Aggregate functions cannot be external user-defined function or SQL functions.
- A *scalar function* receives a single value for each argument and returns a single-value result. Built-in functions and user-defined functions, external, sourced, and SQL, can be scalar functions. The functions that are created for distinct types are also scalar functions.
- A *table function* returns a table for the set of arguments it receives. Each argument is a single value. A table function can only be referenced in the FROM clause of a subselect. A table function can be defined as an external function, but a table function cannot be a sourced function, or an SQL function.

Table functions can be used to apply SQL language processing power to data that is not DB2 data or to convert such data into a DB2 table. For example, a table function can take a file and convert it to a table or can get data from the Internet and tabularize it.

For a list of the aggregate, scalar, and table functions and information on these functions, see Chapter 3, “Functions,” on page 259.

## Function invocation

Each reference to a scalar or aggregate function (either built-in or user-defined) conforms to the following syntax:

In the above syntax, *expression* cannot include an aggregate function. See “Expressions” on page 180 for other rules for *expression*.

The **ALL** or **DISTINCT** keyword can only be specified for an aggregate function or a user-defined function that is sourced on an aggregate function.

When a function is invoked within a trigger body, the **TABLE** keyword can be specified to indicate that an argument is a trigger transition table. In this case, the corresponding parameter of the function must have been defined with the **TABLE LIKE** clause.

Table functions can be referenced only in the **FROM** clause of a subselect. For more information on referencing a table function, see the description of the “from-clause” on page 638.

When the function is invoked, the value of each of its parameters is assigned using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined aggregate or scalar function is complete, the result of the function is assigned, using storage assignment, to the result data type. For information about assignment rules, see “Assignment and comparison” on page 102.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter defined as character FOR BIT DATA.

## Function resolution

After a function is invoked, DB2 must determine which function to execute. This process is called *function resolution* and it applies to both built-in and user-defined function.

A function is invoked by its function name, which is implicitly or explicitly qualified with a schema name, followed by parentheses that enclose the arguments to the function. Within the database, each function is uniquely identified by its *function signature*, which is its schema name, function name, the number of parameters, and the data types of the parameters. Thus, a schema can contain several functions that have the same name but each of which have a different number of parameters or parameters with different data types. Also, a function with the same name, number of parameters, and types of parameters can exist in multiple schemas.

Function resolution is similar for functions that are invoked with a qualified or unqualified function name with the exception that for an unqualified name, DB2 needs to search more than one schema.

**Qualified function resolution:** When a function is invoked with a schema name and a function name, DB2 only searches the specified schema to resolve which function to execute.

DB2 finds the appropriate function instance when all of the following conditions are true:

- The name of the function instance matches the name in the function invocation.
- The number of input parameters in the function instance matches the number of function arguments in the function invocation.
- The authorization ID of the statement has the EXECUTE privilege to the function instance.
- The data type of each input argument of the function invocation matches or is *promotable* to the data type of the corresponding parameter of the function instance.

For a function invocation that passes a transition table, the data type, length, precision, and scale of each column in the transition table must match exactly the data type, length, precision, and scale of each column of the table that is named in the function instance definition.

If the function invocation contains no untyped parameter markers, the comparison of data types results in one best fit, which is the choice for execution (see “Determining the best fit” on page 177). For information on the promotion of data types, see “Promotion of data types” on page 95.

For a function invocation that contains untyped parameter markers, the data types of those parameter markers are considered to match or be promotable to the data types of the parameters in the function instance.

- The create timestamp for the function must be older than the bind timestamp for the package or plan in which the function is invoked.

If a function invoked from a trigger body receives a transition table, and the invocation occurs during an automatic rebind, the form of the invoked function used for function selection includes only the columns of the table that existed at the time of the original BIND or REBIND package or plan for the invoking program.

If the function invocation contains untyped parameter markers, the comparison can result in more than one best fit. In that case, DB2 returns an error.

If DB2 authorization checking is in effect, and DB2 performs an automatic rebind on a plan or package that contains a user-defined function invocation, any user-defined functions that were created after the original BIND or REBIND of the invoking plan or package are not candidates for execution.

If you use an access control authorization exit routine, some user-defined functions that were not candidates for execution before the original BIND or REBIND of the invoking plan or package might become candidates for execution during the automatic rebind of the invoking plan or package. See *DB2 Administration Guide* for information about function resolution with access control authorization exit routines.

If no function in the schema meets these criteria, an error occurs. If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns an integer data type where a character data type is required or returns a table where a table function is not allowed, an error occurs.

**Unqualified function resolution:** When a function is invoked with only a function name and no schema name, DB2 needs to search more than one schema to resolve the function instance to execute. DB2 uses these steps to choose the function:

1. The *SQL path* contains the list of schemas to search. For each schema in the path, DB2 selects a candidate function based on the same criteria described immediately above for qualified function resolution. However, if no function in the schema meets the criteria, an error does not occur, and a candidate function is not selected for that schema.
2. After identifying the candidate functions for the schemas in the path, DB2 selects the candidate with the best fit as the function to execute. If more than one schema contains the function instance with the best fit (the function signatures are identical except for the schema name), DB2 selects the function whose schema is first in the SQL path. If no function in any schema in the SQL path meets the criteria, an error occurs.

The create timestamp of a user-defined function must be older than the timestamp resulting from an explicit bind for the plan or package containing the function invocation. During autobind, built-in functions introduced in a later DB2 release than the DB2 release that was used to explicitly bind the package or plan are not considered for function resolution.

In a CREATE VIEW statement, function resolution occurs at the time the view is created. If another function with the same name is subsequently created, the view is not affected, even if the new function is a better fit than the one chosen at the time the view was created.

For more information on user-defined functions, such as how you can simplify function resolution or use the DSN\_FUNCTION\_TABLE to see how DB2 resolves a function, see *DB2 Application Programming and SQL Guide*.

## Determining the best fit

More than one function with the same name might exist that is a candidate for execution. In that case, DB2 determines which function is the best fit for the invocation by comparing the data types of the parameters of each function in the set of candidate functions to determine which function satisfies the best fit requirements.

DB2 determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the argument and parameter data types. The data type of the result of the function or the type of function (aggregate, scalar, or table) under consideration does not enter into the determination of best fit.

When determining whether the data types of the parameters are the same as the arguments:

- Synonyms of data types match. For example, DOUBLE and FLOAT are considered to be the same.
- Attributes of a data type (such as length, precision, scale, CCSID) are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2) and DECIMAL(4,3).
- The character and graphic types are considered to be the same. For example, the following data types are considered to be the same type: CHAR and GRAPHIC, VARCHAR and VARGRAPHIC, and CLOB and DBCLOB. CHAR(13) and GRAPHIC(8) are considered to be the same type.

- For this argument, if one function has a data type that fits the function invocation better than the data types in the other functions, that function is the best fit. The precedence list for the promotion of data types in shows the data types that fit each data type, in best-to-worst order.
- If the data types of the first parameter for all the candidate functions fit the function invocation equally well, DB2 repeats this process for the next argument of the function invocation. DB2 continues this process for each argument until a best fit is found.

A subset of the candidate functions is obtained by considering only those functions for which the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance. The precedence list for the promotion of data types in Table 14 on page 95 shows the data types that fit (considering promotion) for each data type in best-to-worst order. If this subset is not empty, the best fit is determined using the promotable process on this subset of candidate functions. If this subset is empty, and the original set of candidate functions consisted of a single function, the best fit is determined using the castable process on the original candidate function. Otherwise, an error is returned.

#### **Best-fit consideration:**

After determining the function that is the best fit, use of the function still might not be permitted. Each function is defined to return a result with a specific data type. If this result data type is not compatible with the context in which the function is invoked, an error occurs.

For example, assume functions named STEP are defined with different data types:

```
STEP(SMALLINT) returns CHAR(5)
STEP(DOUBLE) returns INTEGER
```

Assume also that the function is invoked with the following function reference (where S is a SMALLINT column):

```
SELECT ... 3+STEP(S) ...
```

Because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement because the result type is CHAR(5) instead of a numeric type as required for an argument of the addition operator.

In cases where the arguments of the function invocation are not an exact match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns. See “Assignment and comparison” on page 102. Problems with conversions can also occur when precision, scale, length, or the encoding scheme differs between the argument and the parameter. Conversion might occur for a character string argument when the corresponding parameter of the function has a different encoding scheme or CCSID. For example, an error occurs on function invocation when mixed data that actually contains DBCS characters is specified as an argument and the corresponding parameter of the function is declared with an SBCS subtype.

Additionally, a character FOR BIT DATA argument cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

An error also occurs in the following examples:

- The function is referenced in a FROM clause, but the function selected by the function resolution step is a scalar or aggregate function.
- The function calls for a scalar or aggregate function, but the function selected by the resolution step is a table function.

## SQL path considerations for built-in functions

Function resolution applies to all functions, including built-in functions and other functions provided by DB2. If a function is invoked without its schema name, the SQL path is searched.

With the exception of the DB2 MQSeries® functions, which are in schemas DB2MQ1C and DB2MQ2C, the other built-in functions are in schema SYSIBM. If SYSIBM is not first in the path, it is possible that DB2 will select another function instead of the intended built-in function. Likewise, if DB2MQ1C and DB2MQ2C are not in the path, it is possible that DB2 will select a function other than one of the provided DB2 MQSeries functions. If schema SYSIBM, SYSFUN, or SYSPROC is not explicitly specified in the SQL path, the schema is implicitly assumed at the front of the path. DB2 adds implicitly assumed schemas in the order of SYSIBM, SYSFUN, and SYSPROC. See “SQL path” on page 56 for information on how to specify the path so that the intended function is selected when it is invoked with an unqualified name.

## Examples of function resolution

The following examples illustrate function resolution.

*Example 1:* Assume that MYSHEMA contains two functions, both named FUNA, that were registered with these partial CREATE FUNCTION statements.

1. CREATE FUNCTION MYSHEMA.FUNA (VARCHAR(10), INT, DOUBLE) ...
2. CREATE FUNCTION MYSHEMA.FUNA (VARCHAR(10), REAL, DOUBLE) ...

Also assume that a function with three arguments of data types VARCHAR(10), SMALLINT, and DECIMAL is invoked with a qualified name:

```
MYSHEMA.FUNA(VARCHARCOL, SMALLINTCOL, DECIMALCOL)
```

Both MYSHEMA.FUNA functions are candidates for this function invocation because they meet the criteria specified in “Function resolution” on page 175. The data types of the first parameter for the two function instances in the schema, which are both VARCHAR, fit the data type of the first argument of the function invocation, which is VARCHAR, equally well. However, for the second parameter, the data type of the first function (INT) fits the data type of the second argument (SMALLINT) better than the data type of second function (REAL). Therefore, DB2 selects the first MYSHEMA.FUNA function as the function instance to execute.

*Example 2:* Assume that these functions were registered with these partial CREATE FUNCTION statements:

1. CREATE FUNCTION SMITH.ADDIT (CHAR(5), INT, DOUBLE) ...
2. CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE) ...
3. CREATE FUNCTION SMITH.ADDIT (INT, INT, DOUBLE, INT) ...
4. CREATE FUNCTION JOHNSON.ADDIT (INT, DOUBLE, DOUBLE) ...
5. CREATE FUNCTION JOHNSON.ADDIT (INT, INT, DOUBLE) ...
6. CREATE FUNCTION TODD.ADDIT (REAL) ...
7. CREATE FUNCTION TAYLOR.SUBIT (INT, INT, DECIMAL) ...

Also assume that the SQL path at the time an application invokes a function is "TAYLOR" "JOHNSON", "SMITH". The function is invoked with three data types (INT, INT, DECIMAL) as follows:

```
SELECT ... ADDIT(INTCOL1, INTCOL2, DECIMALCOL) ...
```

Function 5 is chosen as the function instance to execute based on the following evaluation:

- Function 6 is eliminated as a candidate because schema TODD is not in the SQL path.
- Function 7 in schema TAYLOR is eliminated as a candidate because it does not have the correct function name.
- Function 1 in schema SMITH is eliminated as a candidate because the INT data type is not promotable to the CHAR data type of the first parameter of Function 1.
- Function 3 in schema SMITH is eliminated as a candidate because it has the wrong number of parameters.
- Function 2 is a candidate because the data types of its parameters match or are promotable to the data types of the arguments.
- Both Function 4 and 5 in schema JOHNSON are candidates because the data types of their parameters match or are promotable to the data types of the arguments. However, Function 5 is chosen as the better candidate because although the data types of the first parameter of both functions (INT) match the first argument (INT), the data type of the second parameter of Function 5 (INT) is a better match of the second argument (INT) than Function 4 (DOUBLE).
- Of the remaining candidates, Function 2 and 5, DB2 selects Function 5 because schema JOHNSON comes before schema SMITH in the SQL path.

---

## Expressions

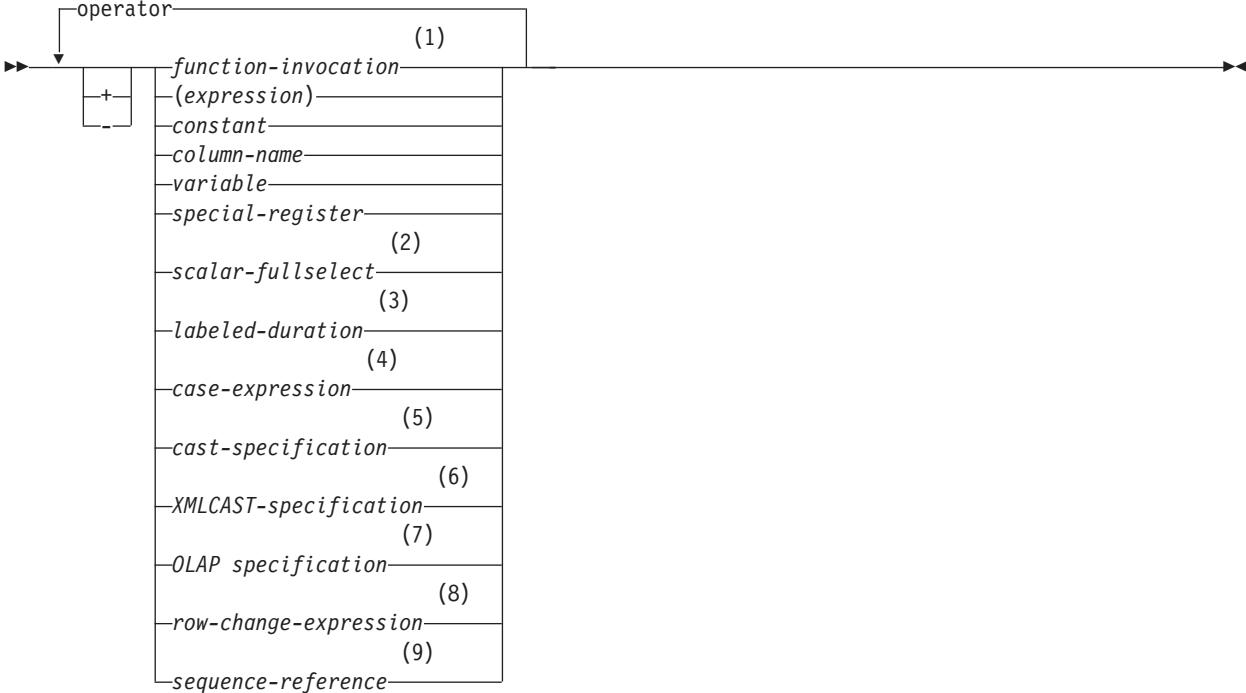

An *expression* specifies a value and can take a number of different forms.

**Authorization:** The use of some of the expressions, such as a *scalar-fullselect*, *sequence-reference*, or user-defined *function*, requires having the appropriate authorization. For these objects, the privilege set that is defined below must include the following authorization:

- *scalar-fullselect*. For information about authorization considerations, see “Authorization” on page 630.
- *sequence-reference*. The USAGE privilege on the specified sequence, ownership of the sequence, or SYSADM authority. For example, with a sequence reference, USAGE authorization on the sequence is required.
- *function-invocation*. Authorization to execute the function. For information about how the particular function is chosen and authorization considerations, see “Function resolution” on page 175.
- *cast-specification*. The authorization to reference a user-defined type in a cast specification. For information about authorization considerations, see “CAST specification” on page 202.

*Privilege set:* If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

The form of an expression is as follows:

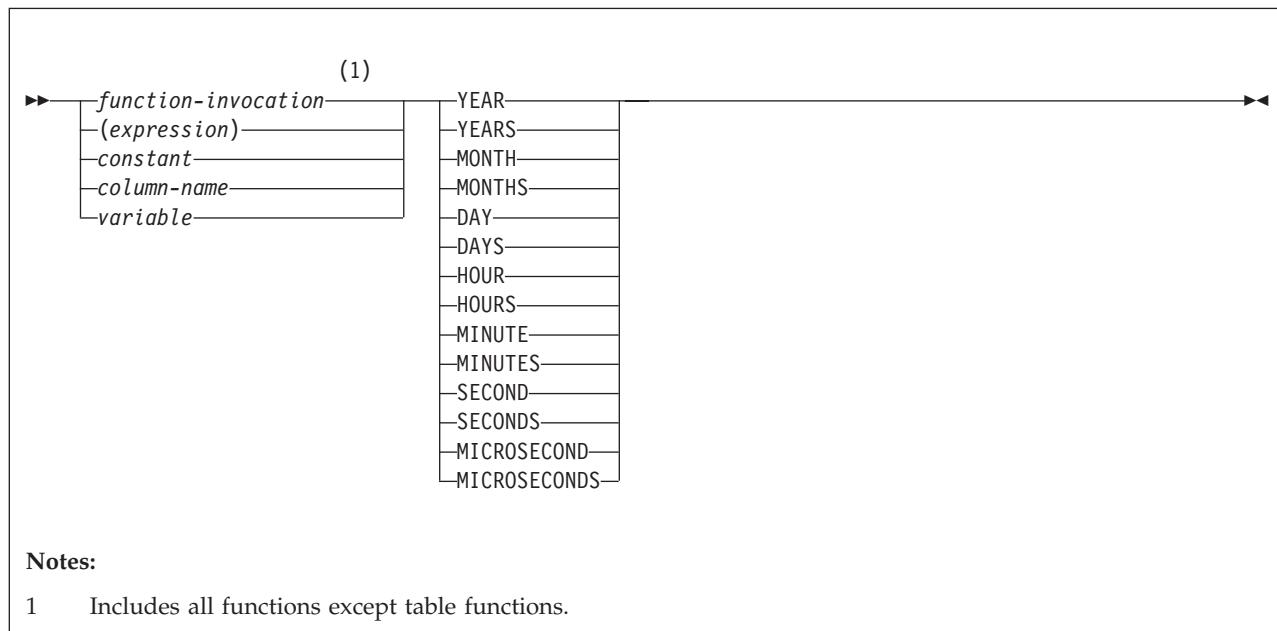

**Notes:**

- 1 Includes all functions except table functions. See “Functions” on page 173 for more information.
- 2 See “Scalar-fullselect” on page 191 for more information.
- 3 See Labeled durations for more information.
- 4 See “CASE expressions” on page 199 for more information.
- 5 See “CAST specification” on page 202 for more information.
- 6 See “XMLCAST specification” on page 210 for more information.
- 7 See “OLAP specification” on page 212
- 8 See “ROW CHANGE expression” on page 216
- 9 See “Sequence reference” on page 217

**operator:**

**labeled-duration:**

## Without operators

If no operators are used, the result of the expression is the specified value.

*Examples:*

SALARY      :SALARY      'SALARY'      MAX(SALARY)

## With arithmetic operators

If arithmetic operators are used, the result of the expression is a number derived from the application of the operators to the values of the operands.

The result of the expression can be null. If any operand has the null value, the result of the expression is the null value. Arithmetic operators (except unary plus, which is meaningless) must not be applied to strings. For example, USER+2 is invalid. Multiplication and division operators must not be applied to datetime values, which can only be added and subtracted.

The prefix operator **+** (*unary plus*) does not change its operand. The prefix operator **-** (*unary minus*) reverses the sign of a nonzero operand. If the data type of *A* is *small integer*, the data type of **-A** is *large integer*. The first character of the token following a prefix operator must not be a plus or minus sign.

The *infix operators* **+**, **-**, **\***, and **/** specify addition, subtraction, multiplication, and division, respectively. The value of the second operand of division must not be zero.

### Arithmetic with two integer operands

If both operands of an arithmetic operator are integers, the operation is performed in binary. The result is a large integer unless either (or both) operand is a big integer, in which case the result is a big integer.

The result of an integer arithmetic operation (including unary minus) must be within the range of the result type.

### **Arithmetic with an integer and a decimal operand**

If one operand is an integer and the other operand is decimal, the operation is performed in decimal. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal number.

The temporary copy of the integer that has been converted to a decimal number has a precision  $p$  and scale 0.  $p$  is 19 for a big integer, 11 for a large integer, and 5 for a small integer. In the case of an integer constant,  $p$  depends on the number of digits in the integer constant.  $p$  is 5 for an integer constant consisting of 5 digits or fewer. Otherwise,  $p$  is the same as the number of digits in the integer constant.

### **Arithmetic with an integer and a decimal floating-point operand**

If one operand is a small integer, large integer, or big integer and the other is a decimal floating-point number, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the integer that has been converted to a decimal floating-point number.

For small integer or large integer, the temporary copy of the integer is converted to DECFLOAT(16). For big integer, the temporary copy of the big integer is converted to DECFLOAT(34). The rules for two decimal floating point operands are then applied.

### **Arithmetic with two decimal operands**

If both operands are decimal, the operation is performed in decimal.

The result of any decimal arithmetic operation is a decimal number with a precision and scale that depend on two factors:

#### **The precision and scale of the operands**

In the discussion of operations with two decimal operands, the precision and scale of the first operand are denoted by  $p$  and  $s$ , that of the second operand by  $p'$  and  $s'$ . Thus, for a division, the dividend has precision  $p$  and scale  $s$ , and the divisor has precision  $p'$  and scale  $s'$ .

#### **Whether DEC31 or DEC15 is in effect for the operation**

DEC31 and DEC15 specify the rules to be used when both operands in a decimal operation have precisions of 15 or less. DEC15 specifies the rules which do not allow a precision greater than 15 digits, and DEC31 specifies the rules which allow a precision of up to 31 digits. The rules for DEC31 are always used if either operand has a precision greater than 15.

For static SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4 or the precompiler option DEC determines whether DEC15 or DEC31 is used.

For dynamic SQL statements, the value of the field DECIMAL ARITHMETIC on installation panel DSNTIP4, the precompiler option DEC, or the special register CURRENT PRECISION determines whether DEC15 or DEC31 is used according to these rules:

- Field DECIMAL ARITHMETIC applies if either of these conditions is true:
  - DYNAMICRULES run behavior applies and the application has not set CURRENT PRECISION.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.

- DYNAMICRULES bind, define, or invoke behavior applies; the value of installation panel field USE FOR DYNAMICRULES is YES; and the application has not set CURRENT PRECISION.
- Precompiler option DEC applies if DYNAMICRULES bind, define, or invoke behavior is in effect, the value of installation panel field USE FOR DYNAMICRULES is NO, and the application has not set CURRENT PRECISION.
- Special register CURRENT PRECISION applies if the application sets the register.

The value of DECIMAL ARITHMETIC is the default value for the precompiler option and the special register. SQL statements executed using SPUFI use the value in DECIMAL ARITHMETIC.

#### **Decimal addition and subtraction:**

For decimal operations, the precision and scale of the result depends on the precision and scale of the operands.

If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands that has been extended with trailing zeros so that its fractional part has the same number of digits as the other operand.

The precision of the result is the minimum of  $n$  and the quantity  $\text{MAX}(p-s, p'-s') + \text{MAX}(s, s') + 1$ . The scale is  $\text{MAX}(s, s')$ .  $n$  is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise,  $n$  is 15.

In COBOL, blanks must precede and follow a minus sign to avoid any ambiguity with COBOL host variable names (which allow the use of a dash).

#### **Decimal multiplication:**

For decimal multiplication, the precision and scale of the result depends on the precision and scale of the operands.

For multiplication, the precision of the result is  $\text{MIN}(n, p+p')$ , and the scale is  $\text{MIN}(n, s+s')$ .  $n$  is 31 if DEC31 is in effect or if the precision of at least one operand is greater than 15. Otherwise,  $n$  is 15.

If both operands have a precision greater than 15, the operation is performed using a temporary copy of the operand with the smaller precision. If the operands have the same precision, the second operand is selected. If more than 15 significant digits are needed for the integral part of the copy, the statement's execution is ended and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of  $\text{MAX}(0, S - (P - 15))$ , where  $P$  and  $S$  are the original precision and scale. If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

When both operands have a precision greater than 15, the foregoing formulas for the precision and scale of the result still apply, with one change: for the operand selected as the copy, use the precision and scale of the truncated copy; that is, use 15 as the precision and  $\text{MAX}(0, S - (P - 15))$  for the scale.

Let  $n$  denote the value of the operand with the greater precision or the first operand in the case of operands with the same precision. The number of leading zeros in a 31-digit representation of  $n$  must be greater than the precision of the other operand. This is always the case if the precision of the operand is 15 or less. With greater precisions, overflow can occur even if the precision of the result is less than 31. For example, the expression:

will cause overflow because the number of leading zeros in the 31-digit representation of the large number and the precision of the small number are both 5 (see “Arithmetic with an integer and a decimal operand” on page 183).

## Decimal division:

The rules for a specific decimal division depend on whether the DEC31 option is in effect for the operation, whether p is greater than 15, and whether p' is greater than 15.

The following table shows how the precision and scale of the result depend on these factors. In that table, the occurrence of "N/A" in a row implies that the indicated factor is not relevant to the case represented by the row.

Table 39. Precision ( $p$ ) and scale ( $s$ ) of the result of a decimal division

<b>DEC31</b>	$p$	$p'$	$P$	$S$
Not in effect	$\leq 15$	$\leq 15$	15	$15 - (p - s + s')$
In effect	$\leq 15$	$\leq 15$	31	$N - (p - s + s')$ , where $N$ is $30 - p'$ if $p'$ is odd. $N$ is $29 - p'$ if $p'$ is even.
N/A	$> 15$	$\leq 15$	31	$N - (p - s + s')$ , where $N$ is $30 - p'$ if $p'$ is odd. $N$ is $29 - p'$ if $p'$ is even.
N/A	N/A	$> 15$	31	$15 - (p - s + x)$ , where $x$ is $\text{MAX}(0, s' - (p' - 15))$ (See Note 2 below)

## Notes on decimal division:

1. If the calculated value of 's' is negative, an error occurs. If a minimum divide result scale is specified, this error does not occur. A minimum divide result scale of 3 can be specified using the MINIMUM DIVIDE SCALE field on the installation panel DSNTIP4. A minimum divide scale result between 1 and 9 can be specified using the DECIMAL ARITHMETIC OPTION of the form 'D<sub>p</sub>.s' where '<sub>p</sub>' is 15 or 31 and represents the precision and 's' represents the minimum divide scale, as a number between 1 and 9. Such a specification overrides the MINIMUM DIVIDE SCALE. When a minimum divide result scale is specified, the formula MAX(s, s'), where s represents the scale derived from the above table and s' represents the value specified by the minimum divide result scale, is applied and a new scale is derived. The newly derived scale is the scale of the result and overrides any scale derived using the table above.
  2. If p' is greater than 15, the division is performed using a temporary copy of the divisor. If more than 15 significant digits are needed for the integral part of the divisor, the statement's execution is ended, and an error occurs. Otherwise, the copy is converted to a number with precision 15, by truncating the copy on the right. The truncated copy has a scale of MAX(0, s' - (p' - 15)), which is the

formula for  $x$ . If, in the process of truncation, one or more nonzero digits are removed, SQLWARN7 in SQLCA is set to W, indicating loss of precision.

### **Arithmetic with a decimal and a decimal floating-point operand**

If one operand is a decimal and the other is a decimal floating point, the operation is performed in decimal floating point. The arithmetic operation uses a temporary copy of the decimal that has been converted to a decimal floating point based on the precision of the decimal number.

If the decimal number has a precision of less than 17, the decimal number is converted to DECFLOAT(16). Otherwise, the decimal number is converted to DECFLOAT(34). The rules for two decimal floating-point operands are then applied.

### **Arithmetic with floating-point operands**

If either operand of an arithmetic operator is floating-point, the operation is performed in floating-point. If necessary, the operands are first converted to double-precision floating-point numbers. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer that has been converted to double-precision floating-point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number that has been converted to double-precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can affect the results slightly because floating-point operands are approximate representations of real numbers. Because the order in which operands are processed might be implicitly modified by DB2 (for example, DB2 might decide what degree of parallelism to use and what access plan to use), an application that uses floating-point operands should not depend on the results being precisely the same each time an SQL statement is executed.

### **Arithmetic with a floating-point and a decimal floating-point operand**

If one operand is a floating-point number (real or double) and the other is a decimal floating-point number, the operation is performed in decimal floating-point. The arithmetic operation uses a temporary copy of the floating-point number that has been converted to a decimal floating-point number.

### **Arithmetic with two decimal floating-point operands**

If both operands are decimal floating point, the operation is performed in decimal floating point. If one operand is DECFLOAT( $n$ ) and the other is DECFLOAT( $m$ ), the operation is performed in DECFLOAT(max( $n,m$ )).

#### **General Arithmetic Operation Rules for DECFLOAT:**

Certain general rules apply to all arithmetic operations on the DECFLOAT data type.

The following general rules apply to all arithmetic operations on the DECFLOAT data type:

- Every operation on finite numbers is carried out as though an exact mathematical result is computed, using integer arithmetic on the coefficient where possible.

If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), it is used for the result without change (unless there is an underflow or overflow condition). If the coefficient has more than the number of digits that reflect its precision, it is rounded to exactly the number of digits that reflect its precision (16 or 34), and the exponent is increased by the number of digits that are removed.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

If the value of the adjusted exponent of the result is less than  $E_{\min}$ , an exception condition is returned. In this case, the calculated coefficient and exponent form the result, unless the value of the exponent is less than  $E_{\text{tiny}}$ , in which case the exponent is set to  $E_{\text{tiny}}$ , the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign is unchanged. If this rounding gives an inexact result, an underflow exception condition is returned.

If the value of the adjusted exponent of the result is larger than  $E_{\max}$ , an overflow exception condition is returned. In this case, the result is as defined as an overflow exception condition and might be infinite. It will have the same sign as the theoretical result.

- Arithmetic that uses the special value infinity follows the usual rules, where negative infinity is less than every finite number and positive infinity is greater than every finite number.

Under these rules, an infinite result is always exact. Certain uses of infinity return an invalid operation condition. The following list is a list of operations that can cause an invalid operation condition and the result of the operation is NaN when one of the operands is infinity but the other operand is not NaN nor sNaN.

- Add +infinity to -infinity during an addition or subtraction operation
- Multiply 0 by +infinity or -infinity
- Divide either +infinity or -infinity by either +infinity or -infinity
- The dividend for a MOD function is either +infinity or -infinity
- Either argument of the QUANTIZE function is +infinity or -infinity
- The second argument of the POWER® function is +infinity or -infinity
- Signaling NaNs when used as an operand to an arithmetic operation

The following arithmetic rules apply to arithmetic operations and the NaN value:

- The result of any arithmetic operation which has an operand which is a NaN (a quiet NaN or signaling NaNs) is NaN. The sign of the result is copied from the first operand which is a signaling NaN, or if neither operand is signaling then the sign is copied from the first operand which is a NaN. Whenever a result is a NaN, the sign of the result depends only on the copied operand.
- The sign of the result of a multiplication or division will be negative only if the operands have different signs and neither is a NaN.
- The sign of the result of an addition or subtraction will be negative only if the result is less than zero and neither operand is a NaN, except for the following cases where the result is a negative 0:

- A result is rounded to zero, and the value, before rounding, had a negative sign
- Subtract 0 from -0
- Addition of operands with opposite signs (or subtraction of operands with the same sign), the result has a coefficient of 0, and the rounding mode is ROUND\_FLOOR
- Multiplication or division and the result has a coefficient of 0 and the signs of the operands are different
- The first argument of the POWER function is -0, and the second argument is a positive odd number
- The argument of the CEIL, FLOOR, or SQRT function is -0
- The first argument of the ROUND or TRUNCATE function is -0

*Examples involving special DECFLOAT values:*

INFINITY + 1	= INFINITY
INFINITY + INFINITY	= INFINITY
INFINITY + -INFINITY	= NAN -- exception
NAN + 1	= NaN
NAN + INFINITY	= NaN
1 - INFINITY	= -INFINITY
INFINITY - INFINITY	= NAN -- exception
-INFINITY - -INFINITY	= NAN -- exception
-0.0 - 0.0E1	= -0
-1.0 * 0.0E1	= -0
1.0E1 / 0	= INFINITY
-1.0E5 / 0.0	= -INFINITY
1.0E5 / -0	= -INFINITY
INFINITY / -INFINITY	= NAN -- exception
INFINITY / 0	= INFINITY
-INFINITY / 0	= -INFINITY
-INFINITY / -0	= INFINITY

## Arithmetic with distinct type operands

A distinct type cannot be used with arithmetic operators even if its source data type is numeric.

To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, the following user-defined function, REVENUE, could be used to subtract one from the other.

```
CREATE FUNCTION REVENUE ( INCOME, EXPENSES )
    RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL )
```

Alternately, the - (minus) operator could be overloaded using a function to subtract the new data types.

```
CREATE FUNCTION "-" ( INCOME, EXPENSES )
    RETURNS DECIMAL(8,2) SOURCE "-" ( DECIMAL, DECIMAL )
```

Alternatively, the distinct type can be cast to a built-in data type and the result used as an operand of an arithmetic operator.

## With the concatenation operator

When two strings operands are concatenated, the result of the expression is a string.

The operands of concatenation must be compatible strings. A binary string cannot be concatenated with a character string, including character strings that are defined as FOR BIT DATA (for more information on the compatibility of data types, see the compatibility matrix in Table 20 on page 102). A distinct type that is based on a string type can be concatenated only if an appropriate user-defined function is created.

Both CONCAT and the vertical bars (||) represent the concatenation operator. Vertical bars (or the characters that must be used in place of vertical bars in some countries<sup>13)</sup> can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs<sup>13</sup>. Thus, CONCAT is the preferable concatenation operator.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second.

The following table shows how the string operands determine the data type and the length attribute of the result (the order in which the operands are concatenated has no effect on the result).

*Table 40. Data type and length of concatenated operands*

If one operand column is	And the other operand is	The data type of the result column is <sup>1</sup>
CHAR(x)	CHAR(y) with a combined length attribute that is less than 256	CHAR(x+y) <sup>2</sup>
	CHAR(y) with a combined length attribute that is greater than 255	VARCHAR(MIN(x'+y',32704)) <sup>3</sup>
VARCHAR(y)		
VARCHAR(x)	VARCHAR(y)	VARCHAR(MIN(x'+y',32704)) <sup>3</sup>
CLOB(x)	CHAR(y)	CLOB(MIN(x'+y',2G))
	VARCHAR(y)	
	CLOB(y)	
	GRAPHIC(y)	DBCLOB(MIN(x+y,1G))
GRAPHIC(x)	VARGRAPHIC(y)	
	DBCLOB(y)	
	CHAR(y)	VARGRAPHIC(MIN(x+y,16352)) <sup>4</sup>
	VARCHAR(y)	
VARGRAPHIC(x)	VARGRAPHIC(y)	
	CHAR(y)	VARGRAPHIC(MIN(x+y,16352)) <sup>4</sup>
	VARCHAR(y)	
	GRAPHIC(y)	
GRAPHIC(y)	GRAPHIC(y)	
	DBCLOB(y)	
	VARCHAR(y)	
	CHAR(y)	

13. In various EBCDIC code pages, DB2 supports code point combinations X'4F4F', X'BBBB', and X'5A5A' to mean concatenation. X'BBBB' and X'5A5A' are interpreted to mean concatenation only on single byte character set DB2 subsystems.

Table 40. Data type and length of concatenated operands (continued)

If one operand column is	And the other operand is	The data type of the result column is <sup>1</sup>
DBCLOB( <i>x</i> )	CHAR( <i>y</i> )	DBCLOB(MIN( <i>x+y</i> ,1G))
	VARCHAR( <i>y</i> )	
	CLOB( <i>y</i> )	
	GRAPHIC( <i>y</i> )	
	VARGRAPHIC( <i>y</i> )	
	DBCLOB( <i>y</i> )	
BINARY( <i>x</i> )	BINARY( <i>y</i> ) with a combined length attribute that is less than 256	BINARY( <i>x+y</i> )
	BINARY( <i>y</i> ) with a combined length attribute that is greater than 255	VARBINARY( MIN( <i>x+y</i> ,32704))
VARBINARY( <i>x</i> )	VARBINARY( <i>y</i> )	VARBINARY( MIN( <i>x+y</i> ,32704))
	BINARY( <i>y</i> )	
BLOB( <i>x</i> )	BLOB( <i>y</i> )	BLOB(MIN( <i>x+y</i> , 2G))

**Notes:**

1.
  - 2G represents 2,147,483,647 bytes
  - 1G represents 1,073,741,823 double-byte characters
2. Neither CHAR(*x*) nor CHAR(*y*) can contain mixed data. If either operand contains mixed data, the result is VARCHAR(MIN(*x'+y'*,32704)).
3. If conversion of the first operand is required, *x' = 3x*; otherwise, it remains *x*. If conversion of the second operand is required, *y' = 3y*; otherwise, it remains *y*.
4. Both operands are converted to UTF-16, if necessary (that is, the operand is not already UTF-16), and the results are concatenated.

As the previous table shows, the length of the result is the sum of the lengths of the operands. However, the length of the result is two bytes less if redundant shift code characters are eliminated from the result. Redundant shift code characters exist when both character strings are EBCDIC mixed data, and the first string ends with a “shift-in” character (X'0F') and the second operand begins with a “shift-out” character (X'0E'). These two shift code characters are removed from the result.

The CCSID of the result is determined by the rules set forth in “Character conversion in set operations and concatenations” on page 666. Some consequences of those rules are the following:

- If either operand is BIT data, the result is BIT data.
- The conversion that occurs when SBCS data is compared with mixed data depends on the encoding scheme. If the encoding scheme is Unicode, the SBCS operand is converted to MIXED. Otherwise, the conversion depends on the field MIXED DATA on installation panel DSNTIPF for the DB2 that does the comparison:
  - Mixed data if the MIXED DATA option at the server is YES. The result is not necessarily well-formed mixed data.
  - SBCS data if the MIXED DATA option at the server is NO. If the mixed data cannot be converted to pure SBCS data, an error occurs.

If an operand is a string from a column with a field procedure, the operation applies to the decoded form of the value. The result does not inherit the field procedure.

One operand of concatenation can be a parameter marker. When one operand is a parameter marker, its data type and length attributes are considered to be the same as those for the operand that is not a parameter marker except for a string data type. Refer to Table 40 on page 189 for the formula used to calculate data type length for untyped parameter markers in the CONCAT operator when another operand is a string data type. The order of concatenation operations must be considered to determine these attributes in the case of nested concatenation.

No operand of concatenation can be a distinct type even if the distinct type is based on a character data type. To concatenate a distinct type, create a user-defined function that is sourced on the CONCAT operator. For example, if distinct types TITLE and TITLE\_DESCRIPTION were both sourced on data type VARCHAR(25), the following user-defined function, named ATTACH, could be used to concatenate the two distinct types:

```
CREATE FUNCTION ATTACH (TITLE, TITLE_DESCRIPTION)
    RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Alternatively, the concatenation operator could be overloaded by using a user-defined function to add the distinct types:

```
CREATE FUNCTION "||" (TITLE, TITLE_DESCRIPTION)
    RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

## Scalar-fullselect

A *scalar-fullselect* as supported in an expression is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If more than one row is to be returned for a scalar fullselect, an error occurs.

►—(*fullselect*)—►

If a set operator is not specified in the outermost fullselect and the select list element is an expression that is simply a column name, the result column name is based on the name of the column. Otherwise, the result column is unnamed.

A scalar fullselect cannot be used in the following instances:

- A CHECK constraint in CREATE TABLE and ALTER TABLE statements
- A CREATE VIEW statement where the view definition includes the WITH CHECK option
- A CREATE FUNCTION (SQL) statement (subselect already restricted from the expression in the RETURN clause)
- An argument in a CALL statement for an input parameter
- An argument to an aggregate function
- An ORDER BY clause
- A GROUP BY clause
- A join-condition of the ON clause for INNER and OUTER JOINS

If the scalar fullselect is a subselect, it is also referred to as a scalar subselect. See “subselect” on page 632 for more information.

The following examples illustrate the use of *scalar-fullselect*. Assume that four tables (PARTS, PRODUCTS, PARTPRICE, and PARTINVENTORY) contain product data.

**Example 1 - *scalar-fullselect* in a WHERE clause:**

Find which products have the prices in the range of at least twice the lowest price of all the products and at most half the price of all the products.

```
SELECT PRODUCT, PRICE FROM PRODUCTS A  
WHERE  
    PRICE BETWEEN 2 * (SELECT MIN(PRICE) FROM PRODUCTS)  
        AND .5 * (SELECT MAX(PRICE) FROM PRODUCTS);
```

**Example 2 - *scalar-fullselect* in a SELECT list:**

For each part, find its price and its inventory.

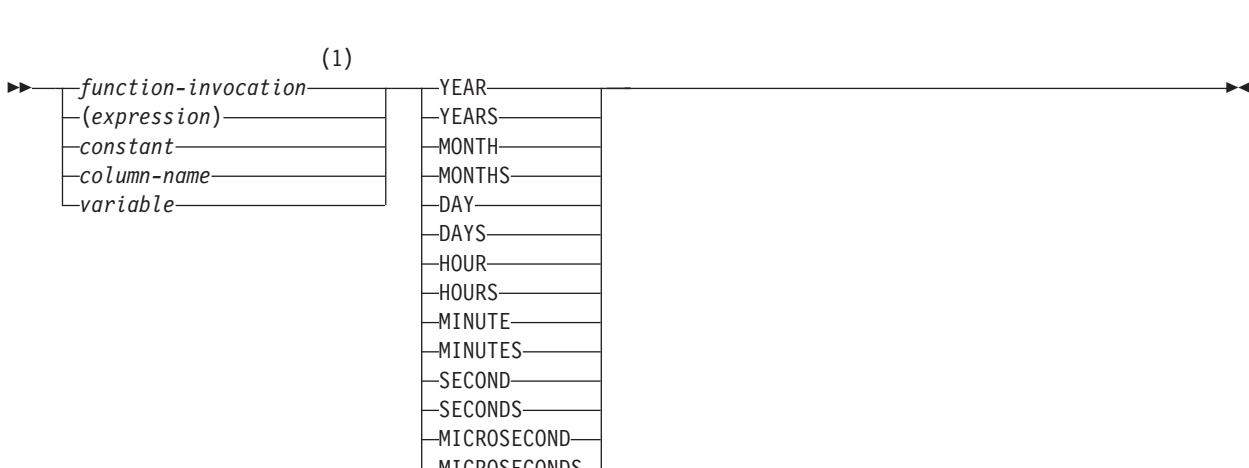

```
SELECT PART,  
    (SELECT PRICE FROM PARTPRICE WHERE PART=A.PART),  
    (SELECT ONHAND# FROM INVENTORY WHERE PART=A.PART)  
FROM PARTS A;
```

## Datetime operands and durations

Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations. A *duration* is a positive or negative number representing an interval of time.

### Labeled durations

The form a labeled duration is as follows:

**Notes:**

- 1 Includes all functions except table functions.

A *labeled duration* represents a specific unit of time as expressed by a number (which can be the result of an expression) followed by one of the

seven duration keywords.<sup>14</sup> The number specified is converted as if it were assigned to a DECIMAL(15,0) number.

A labeled duration can only be used as an operand of an arithmetic operator in which the other operand is a value of the data type of date, time, or timestamp. Thus, the expression HIREDATE + 2 MONTHS + 14 DAYS is valid, whereas the expression HIREDATE + (2 MONTHS + 14 DAYS) is not. In both of these expressions, the labeled durations are 2 MONTHS and 14 DAYS.

#### Date duration

A *date duration* represents a number of years, months, and days expressed as a DECIMAL(8,0) number. To be properly interpreted, the number must have the format *yyyymmdd*, where *yyyy* represents the number of years, *mm* the number of months, and *dd* the number of days. The result of subtracting one DATE value from another, as in the expression HIREDATE - BIRTHDATE, is a date duration.

#### Time duration

A *time duration* represents a number of hours, minutes, and seconds expressed as a DECIMAL(6,0) number. To be properly interpreted, the number must have the format *hhmmss*, where *hh* represents the number of hours, *mm* the number of minutes, and *ss* the number of seconds. The result of subtracting one TIME value from another is a time duration.

#### Timestamp duration

A *timestamp duration* represents a number of years, months, days, hours, minutes, seconds, and microseconds expressed as a DECIMAL(20,6) number. To be properly interpreted, the number must have the format *yyyymmddhhmmssnnnnnn*, where *yyyy*, *xx*, *dd*, *hh*, *mm*, *ss*, and *nnnnnn* represent, respectively, the number of years, months, days, hours, minutes, seconds, and microseconds. The result of subtracting one TIMESTAMP value from another is a timestamp duration.

## Datetime arithmetic in SQL

The only arithmetic operations that can be performed on datetime values are addition and subtraction.

If a datetime value is the operand of addition, the other operand must be a duration. The specific rules governing the use of the addition operator with datetime values follow.

- If one operand is a date, the other operand must be a date duration or labeled duration of years, months, or days.
- If one operand is a time, the other operand must be a time duration or a labeled duration of hours, minutes, or seconds.
- If one operand is a timestamp, the other operand must be a duration. Any type of duration is valid.
- Neither operand of the addition operator can be a parameter marker. For a discussion of parameter markers, see Parameter markers in “PREPARE” on page 1405.

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a

---

14. The singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.

duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow.

- If the first operand is a date, the second operand must be a date, a date duration, a string representation of a date, or a labeled duration of years, months, or days.
- If the second operand is a date, the first operand must be a date, or a string representation of a date.
- If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of hours, minutes, or seconds.
- If the second operand is a time, the first operand must be a time, or string representation of a time.
- If the first operand is a timestamp, the second operand must be a timestamp, a string representation of a timestamp, or a duration.
- If the second operand is a timestamp, the first operand must be a timestamp or a string representation of a timestamp.
- Neither operand of the subtraction operator can be a parameter marker.

When an operand in a datetime expression is a string, it might undergo character conversion before it is interpreted and converted to a datetime value. When its CCSID is not that of the default for mixed strings, a mixed string is converted to the default mixed data representation. When its CCSID is not that of the default for SBCS strings, an SBCS string is converted to the default SBCS representation.

## Date arithmetic

Date values can be subtracted, incremented, or decremented.

**Subtracting dates:** The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation  $\text{RESULT} = \text{DATE1} - \text{DATE2}$ .

### Date subtraction: $\text{result} = \text{date1} - \text{date2}$

- If  $\text{DAY}(\text{DATE2}) \leq \text{DAY}(\text{DATE1})$  then  $\text{DAY}(\text{RESULT}) = \text{DAY}(\text{DATE1}) - \text{DAY}(\text{DATE2})$
- If  $\text{DAY}(\text{DATE2}) > \text{DAY}(\text{DATE1})$  then  $\text{DAY}(\text{RESULT}) = N + \text{DAY}(\text{DATE1}) - \text{DAY}(\text{DATE2})$  where  $N$  = the last day of  $\text{MONTH}(\text{DATE2})$ .  $\text{MONTH}(\text{DATE2})$  is then incremented by 1.
- If  $\text{MONTH}(\text{DATE2}) \leq \text{MONTH}(\text{DATE1})$  then  $\text{MONTH}(\text{RESULT}) = \text{MONTH}(\text{DATE1}) - \text{MONTH}(\text{DATE2})$
- If  $\text{MONTH}(\text{DATE2}) > \text{MONTH}(\text{DATE1})$  then  $\text{MONTH}(\text{RESULT}) = 12 + \text{MONTH}(\text{DATE1}) - \text{MONTH}(\text{DATE2})$  and  $\text{YEAR}(\text{DATE2})$  is incremented by 1.
- $\text{YEAR}(\text{RESULT}) = \text{YEAR}(\text{DATE1}) - \text{YEAR}(\text{DATE2})$

For example, the result of  $\text{DATE}'3/15/2005' - '12/31/2004'$  is 215 (or, a duration of 0 years, 2 months, and 15 days). In this example, notice that the second operand did not need to be converted to a date. According to one of the rules for subtraction, described under "Datetime arithmetic in SQL" on page 193, the second operand can be a string representation of a date if the first operand is a date.

**Incrementing and decrementing dates:** The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this

operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive. If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. Here the day portion of the result is set to 28, and the SQLWARN6 field of the SQLCA is set to W, indicating that an end-of-month adjustment was made to correct an invalid date. *DB2 Application Programming and SQL Guide* also describes how SQLWARN6 is set.

Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case the day is set to the last day of the month, and the SQLWARN6 field of the SQLCA is set to W to indicate the adjustment.

Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year. Adding or subtracting a duration of days will not cause an end-of-the-month adjustment.

Date durations, whether positive or negative, can also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and SQLWARN6 is set to W to indicate any necessary end-of-month adjustment.

When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus, DATE1+X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

DATE1 + YEAR(X) YEARS + MONTH(X) MONTHS + DAY(X) DAYS

When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1-X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

DATE1 - DAY(X) DAYS - MONTH(X) MONTHS - YEAR(X) YEARS

Adding a month to a date gives the same day one month later unless that day does not exist in the later month. In that case, the day in the result is set to the last day of the later month. For example, January 28 plus one month gives February 28; one month added to January 29, 30, or 31 results in either February 28 or, for a leap year, February 29. If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

If one or more months are added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date. In addition, logically equivalent expressions might not produce the same result. For example, the following two expressions do not produce the same result:

(DATE('2005 01 31') + 1 MONTH) + 1 MONTH	-- results in 2005-03-28
DATE('2005 01 31') + 2 MONTHS	-- results in 2005-03-31

The order in which labeled date durations are added to and subtracted from dates can affect the results. When you add labeled date durations to a date, specify them in the order of YEARS + MONTHS + DAYS. When you subtract labeled date

durations from a date, specify them in the order of DAYS - MONTHS - YEARS. For example, to add one year and one day to a date, specify:

DATE1 + 1 YEAR + 1 DAY

To subtract one year, one month, and one day from a date, specify:

DATE1 - 1 DAY - 1 MONTH - 1 YEAR

## Time arithmetic

Times can be subtracted, incremented, or decremented.

**Subtracting times:** The result of subtracting one time (*TIME2*) from another (*TIME1*) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0). If *TIME1* is greater than or equal to *TIME2*, *TIME2* is subtracted from *TIME1*. If *TIME1* is less than *TIME2*, however, *TIME1* is subtracted from *TIME2*, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation *RESULT* = *TIME1* - *TIME2*.

### Time subtraction: *result* = *time1* - *time2*

- If SECOND(*TIME2*) <= SECOND(*TIME1*) then SECOND(*RESULT*) = SECOND(*TIME1*) - SECOND(*TIME2*).
- If SECOND(*TIME2*) > SECOND(*TIME1*) then SECOND(*RESULT*) = 60 + SECOND(*TIME1*) - SECOND(*TIME2*) and MINUTE(*TIME2*) is incremented by 1.
- If MINUTE(*TIME2*) <= MINUTE(*TIME1*) then MINUTE(*RESULT*) = MINUTE(*TIME1*) - MINUTE(*TIME2*).
- If MINUTE(*TIME2*) > MINUTE(*TIME1*) then MINUTE(*RESULT*) = 60 + MINUTE(*TIME1*) - MINUTE(*TIME2*) and HOUR(*TIME2*) is incremented by 1.
- HOUR(*RESULT*) = HOUR(*TIME1*) - HOUR(*TIME2*).

For example, the result of TIME('11:02:26') - '00:32:56' is '102930' (a duration of 10 hours, 29 minutes, and 30 seconds). In this example, notice that the second operand did not need to be converted to a time. According to one of the rules for subtraction, described under "Datetime arithmetic in SQL" on page 193, the second operand can be a string representation of a time if the first operand is a time.

**Incrementing and decrementing times:** The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. Adding 24 hours to the time '00:00:00' results in the time '24:00:00'. However, adding 24 hours to any other time results in the same time; for example, adding 24 hours to the time '00:00:59' results in the time '00:00:59'. The minutes and seconds are unchanged.

Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

Adding or subtracting a duration of seconds affects the seconds portion of the time and might affect the minutes and hours.

Time durations, whether positive or negative, can also be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. Thus, *TIME1* + *X*, where *X* is a positive DECIMAL(6,0) number, is equivalent to the expression

$TIME1 + HOUR(X) \text{ HOURS} + MINUTE(X) \text{ MINUTES} + SECOND(X) \text{ SECONDS}$

## Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

**Subtracting timestamps:** The result of subtracting one timestamp ( $TS2$ ) from another ( $TS1$ ) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and microseconds between the two timestamps. The data type of the result is DECIMAL(20,6). If  $TS1$  is greater than or equal to  $TS2$ ,  $TS2$  is subtracted from  $TS1$ . If  $TS1$  is less than  $TS2$ , however,  $TS1$  is subtracted from  $TS2$  and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation  $RESULT = TS1 - TS2$ .

### Timestamp subtraction: $result = ts1 - ts2$

- If  $\text{MICROSECOND}(TS2) \leq \text{MICROSECOND}(TS1)$  then  $\text{MICROSECOND}(RESULT) = \text{MICROSECOND}(TS1) - \text{MICROSECOND}(TS2)$ .
- If  $\text{MICROSECOND}(TS2) > \text{MICROSECOND}(TS1)$  then  $\text{MICROSECOND}(RESULT) = 1000000 + \text{MICROSECOND}(TS1) - \text{MICROSECOND}(TS2)$  and  $\text{SECOND}(TS2)$  is incremented by 1.
- If  $\text{HOUR}(TS2) \leq \text{HOUR}(TS1)$  then  $\text{HOUR}(RESULT) = \text{HOUR}(TS1) - \text{HOUR}(TS2)$ .
- If  $\text{HOUR}(TS2) > \text{HOUR}(TS1)$  then  $\text{HOUR}(RESULT) = 24 + \text{HOUR}(TS1) - \text{HOUR}(TS2)$  and  $\text{DAY}(TS2)$  is incremented by 1.

The seconds and minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

**Incrementing and decrementing timestamps:** The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp, is itself a timestamp. Date and time arithmetic is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. When the result of an operation is midnight, the time portion of the result can be '24.00.00' or '00.00.00'; a comparison of those two values does not result in 'equal'. Microseconds overflow into seconds.

## Precedence of operations

Expressions within parentheses are evaluated first. When the order of evaluation is not specified by parentheses, prefix operators are applied before multiplication and division, and multiplication, division, and concatenation are applied before addition and subtraction. Operators at the same precedence level are applied from left to right.

*Example 1:* In this example, the first operation is the addition in  $(SALARY + BONUS)$  because it is within parenthesis. The second operation is multiplication because it is a higher precedence level than the second addition operator and it is to the left of the division operator. The third operation is division because it is at a higher precedence level than the second addition operator. Finally, the remaining addition is performed.

1.10 \* (SALARY + BONUS) + SALARY / :VAR3  
(2) (1) (4) (3)

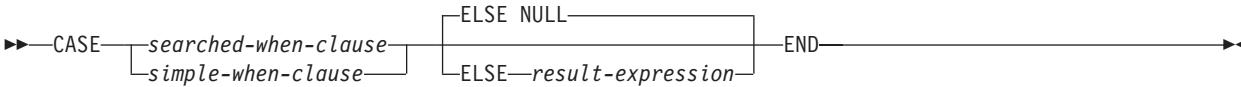

*Example 2:* In this example, the first operation (CONCAT) combines the character strings in the variables  $YYYYMM$  and  $DD$  into a string representing a date. The

second operation (-) then subtracts that date from the date being processed in DATECOL. The result is a date duration that indicates the time elapsed between the two dates.

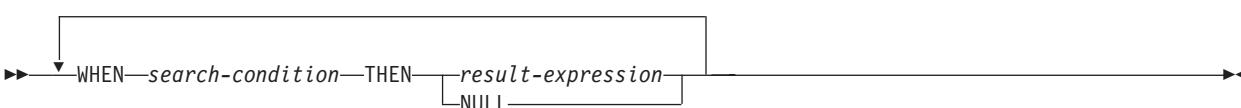

```
DATECOL - :YYYYMM CONCAT :DD  
      (2)           (1)
```

## CASE expressions

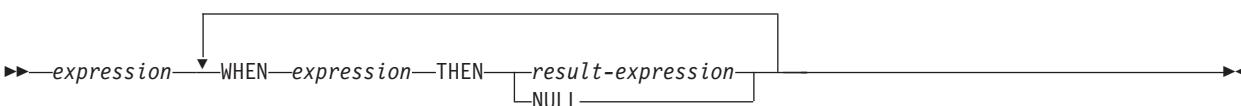

A CASE expression allows an expression to be selected based on the evaluation of one or more conditions.

### searched-when-clause:

### simple-when-clause:

In general, the value of the *case-expression* is the value of the *result-expression* following the first (leftmost) *when-clause* that evaluates to true. If no case evaluates to true and the ELSE keyword is present, the result is the value of the *result-expression* or NULL. If no case evaluates to true and the ELSE keyword is not present, the result is NULL. When a case evaluates to unknown (because of NULL values), the case is NOT true and hence is treated the same way as a case that evaluates to false.

#### searched-when-clause

Specifies a *search-condition* that is applied to each row or group of table data presented for evaluation, and the result when that condition is true.

#### simple-when-clause

Specifies that the value of the *expression* prior to the first WHEN keyword is tested for equality with the value of each *expression* that follows the WHEN keyword. It also specifies the result for when that condition is true.

The data type of the *expression* prior to the first WHEN keyword must be compatible with the data types of the *expression* that follows each WHEN keyword. The data type of any of the expressions cannot be a CLOB, DBCLOB or BLOB. In addition, the *expression* prior to the first WHEN keyword cannot include a function that is not deterministic or has an external action.

*result-expression or NULL*

Specifies the value that follows the THEN and ELSE keywords. It specifies the result of a *searched-when-clause* or a *simple-when-clause* that is true, or the result if no case is true. There must be at least one *result-expression* in the CASE expression with a defined data type. NULL cannot be specified for every case.

All *result-expressions* must have compatible data types. The attributes of the result are determined according to the rules that are described in “Rules for result data types” on page 119. When the result is a string, its attributes include a CCSID. For the rules on how the CCSID is determined, see “Determining the encoding scheme and CCSID of a string” on page 43.

*search-condition*

Specifies a condition that is true, false, or unknown about a row or group of table data. The *search-condition* can be a predicate, including predicates that contain fullselects (scalar or non-scalar) or row-value expressions.

If the CASE expression is in a select list, a SET clause, a VALUES clause of an INSERT or MERGE statement, or an IN predicate, the *search-condition* cannot be a quantified predicate, an IN predicate, or an EXISTS predicate. However, an IN predicate is allowed within a select list or a VALUES clause if that IN predicate explicitly includes a list of expressions.

**END**

Ends a *case-expression*.

Two scalar functions, NULLIF and COALESCE, are specialized to handle a subset of the functionality provided by CASE. The following table shows the equivalent expressions using CASE or these functions.

*Table 41. Equivalent case expressions*

CASE expression	Equivalent expression
CASE WHEN e1=e2 THEN NULL ELSE e1 END	NULLIF(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END	COALESCE(e1,e2)
CASE WHEN e1 IS NOT NULL THEN e1 ELSE COALESCE(e2,...,eN) END	COALESCE(e1,e2,...,eN)

*Example 1 (simple-when-clause):* Assume that in the EMPLOYEE table the first character of a department number represents the division in the organization. Use a CASE expression to list the full name of the division to which each employee belongs.

```
SELECT EMPNO, LASTNAME,  
      CASE SUBSTR(WORKDEPT,1,1)  
        WHEN 'A' THEN 'Administration'  
        WHEN 'B' THEN 'Human Resources'  
        WHEN 'C' THEN 'Design'  
        WHEN 'D' THEN 'Operations'  
      END  
FROM EMPLOYEE;
```

*Example 2 (searched-when-clause):* You can also use a CASE expression to avoid “division by zero” errors. From the EMPLOYEE table, find all employees who earn more than 25 percent of their income from commission, but who are not fully paid on commission:

```
SELECT EMPNO, WORKDEPT, SALARY+COMM FROM EMPLOYEE
WHERE (CASE WHEN SALARY=0 THEN 0
            ELSE COMM/(SALARY+COMM)
        END) > 0.25;
```

*Example 3 (searched-when-clause):* You can use a CASE expression to avoid “division by zero” errors in another way. The following queries show an accumulation or summing operation. In the first query, DB2 performs the division before performing the CASE statement and an error occurs along with the results.

```
SELECT REF_ID,PAYMT_PAST_DUE_CT,
CASE
    WHEN PAYMT_PAST_DUE_CT=0 THEN 0
    WHEN PAYMT_PAST_DUE_CT>0 THEN
        SUM(BAL_AMT/PAYMT_PAST_DUE_CT)
    END
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

However, if the CASE expression is included in the SUM aggregate function, the CASE expression would prevent the errors. In the following query, the CASE expression screens out the unwanted division because the CASE operation is performed before the division.

```
SELECT REF_ID,PAYMT_PAST_DUE_CT,
SUM(CASE
    WHEN PAYMT_PAST_DUE_CT=0 THEN 0
    WHEN PAYMT_PAST_DUE_CT>0 THEN
        BAL_AMT/PAYMT_PAST_DUE_CT
    END)
FROM PAY_TABLE
GROUP BY REF_ID,PAYMT_PAST_DUE_CT;
```

*Example 4:* This example shows how to group the results of a query by a CASE expression without having to re-type the expression. Using the sample employee table, find the maximum, minimum, and average salary. Instead of finding these values for each department, assume that you want to combine some departments into the same group.

```
SELECT CASE_DEPT,MAX(SALARY),MIN(SALARY),AVG(SALARY)
FROM (SELECT SALARY,CASE WHEN WORKDEPT = 'A00' OR WORKDEPT = 'E21'
                        THEN 'A00_E21'
                        WHEN WORKDEPT = 'D11' OR WORKDEPT = 'E11'
                        THEN 'D11_E11'
                        ELSE WORKDEPT
                    END AS CASE_DEPT
      FROM DSN8910.EMP) X
GROUP BY CASE_DEPT;
```

## CAST specification

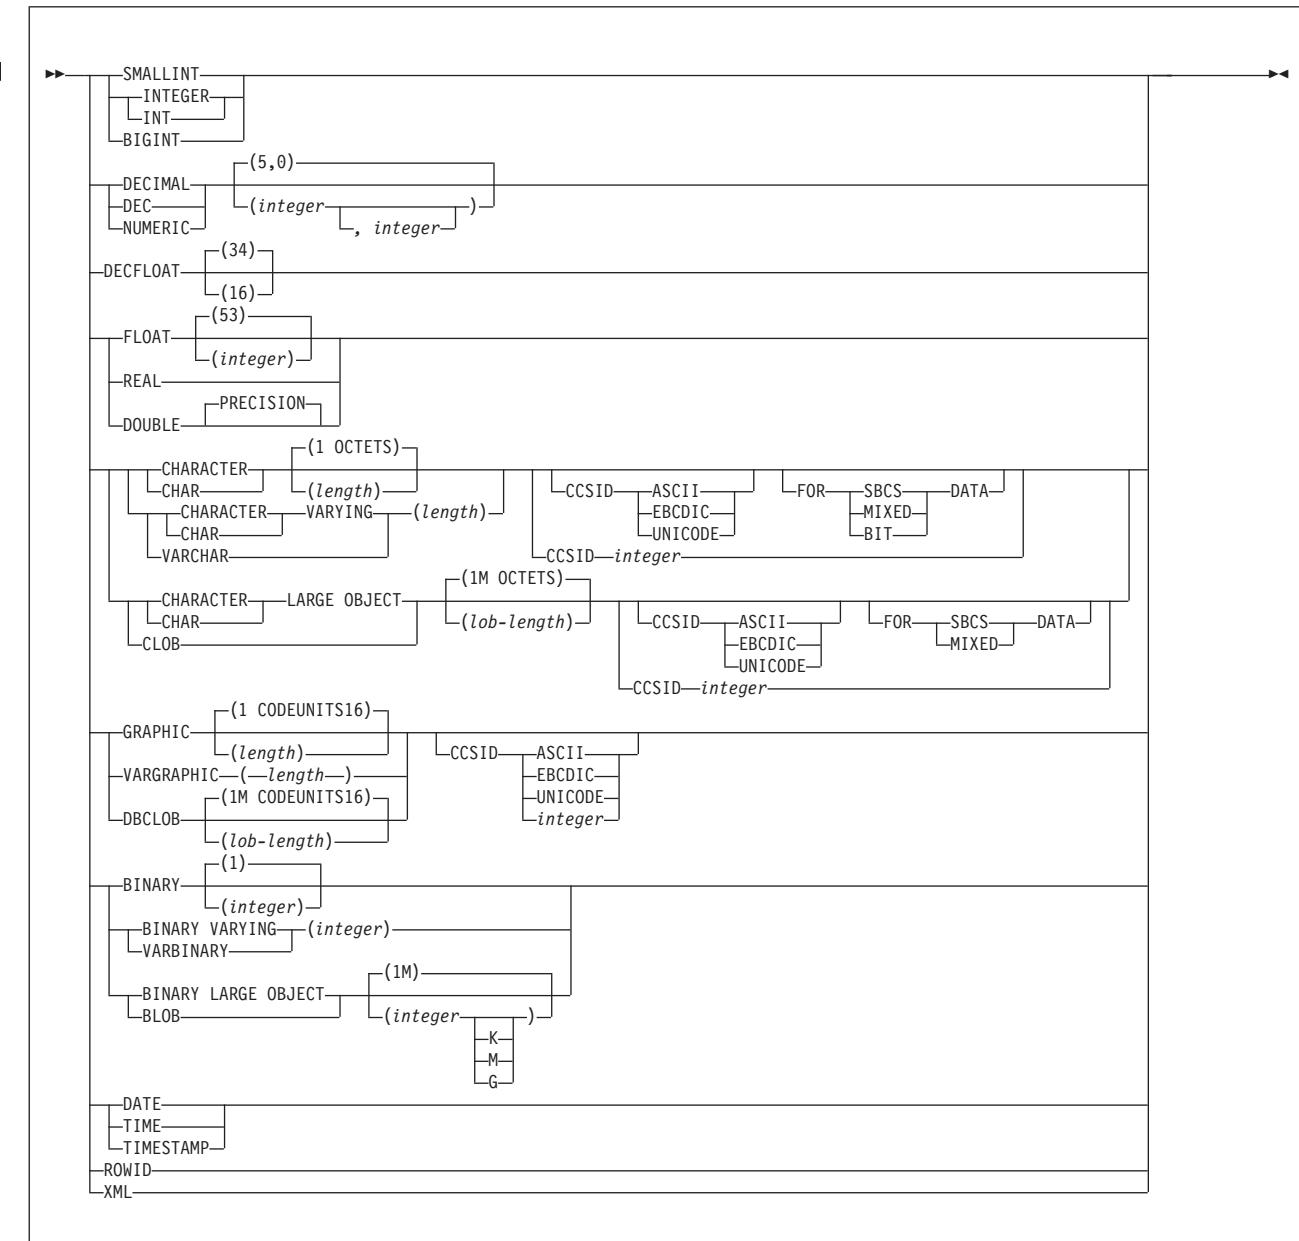

The CAST specification returns the first operand (the cast operand) converted to the data type that is specified by *data-type*.

```
►►CAST—(—expression— AS—data-type—)►►  
    ┌─────────┐  
    | NULL ──|  
    └─────────┘  
    parameter-marker
```

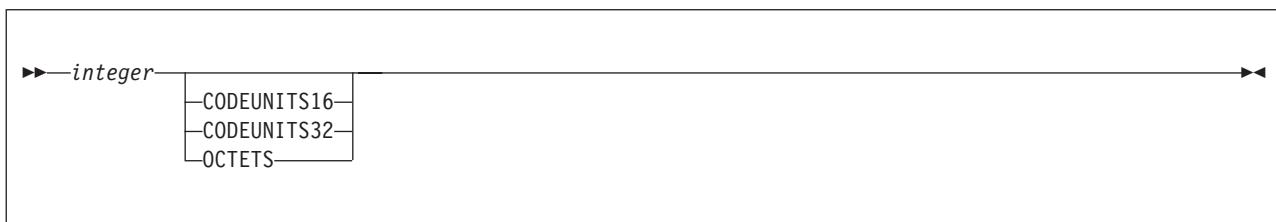

### **data-type:**

```
►►—built-in-type—  
    ┌─────────┐  
    | distinct-type-name ──|  
    └─────────┘
```

## built-in-type:

## length:

## **lob-length:**

►►—	<i>integer</i>	—►►
	K	CODEUNITS16
	M	CODEUNITS32
	G	OCTETS

If the data type of either operand is a distinct type, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type. The CAST specification allows the second operand to be cast to a particular encoding scheme or CCSID if the second operand represents character data. The CCSID clause can be specified following CHAR, VARCHAR, CLOB, GRAPHIC, VARGRAPHIC, and DBCLOB data types.

### *expression*

Specifies that the cast operand is an expression other than NULL or a parameter marker. The result is the value of the operand value converted to the specified target *data type*.

The supported casts are shown in “Casting between data types” on page 96. If the cast is not supported, an error is returned.

When a character string is cast to a character string with a different length or a graphic string is cast to a graphic string with a different length, a warning occurs if any characters except trailing blanks are truncated. A warning also occurs if any bytes are truncated when a binary string is cast.

### **NULL**

Specifies that the cast operand is null. The result is a null value with the specified target *data type*.

### *parameter-marker*

A parameter marker, which is normally considered an expression, has a special meaning as a cast operand. When the cast operand is a *parameter-marker*, the *data type* that is specified represents the “promise” that the replacement value for the parameter marker will be assignable to the specified data type (using “store assignment” rules). Such a parameter marker is considered a *typed parameter marker*. Typed parameter markers are treated like any other typed value for the purpose of function resolution, a DESCRIBE of a select list, or column assignment.

### *data-type*

Specifies the data type of the result. If the data type is not qualified, the SQL path is used to find the appropriate data type. For more information, see “SQL path” on page 56. For a description of *data-type*, see “CREATE TABLE” on page 1079. (For portability across operating systems, when specifying a floating-point data type, use REAL or DOUBLE instead of FLOAT.)

- If the cast operand is *expression*, see “Casting between data types” on page 96 and use any of the target data types that are supported for the data type of the cast operand.
- If the cast operand is NULL, you can use any data type.
- If the cast operand is a *parameter-marker*, you can use any data type. If the data type is a distinct type, the application that uses the parameter marker will use the source data type of the distinct type.

*length*

Specifies the length of the result.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If *expression* is a graphic string, OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

*lob-length*

Specifies the length of the result.

You can specify that the length of the result be evaluated in a specific number of string units: CODEUNITS16, CODEUNITS32, or OCTETS. If *expression* is a graphic string, OCTETS cannot be specified.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

**CCSID** *encoding-scheme*

Specifies the encoding scheme for the target data type. The specific CCSIDs for SBCS, BIT, and MIXED data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

**CCSID** *integer*

Specifies that the target data type be encoded using the CCSID *integer*. If the second operand is CHAR, VARCHAR, or CLOB, the CCSID specified must be either a SBCS, or MIXED CCSID, or 65535 for bit data. If the second operand is GRAPHIC, VARGRAPHIC, or DBCLOB, the CCSID specified must be a DBCS CCSID. See Determining the CCSID of the result if neither CCSID *integer* nor CCSID *encoding-scheme* is specified. See Determining the CCSID of the result for special considerations regarding CCSID 367.

**Interaction between length and CCSID clauses:** If both the *length* and CCSID clauses are specified, the data is first cast to the specified CCSID, and then the *length* is applied. If either CODEUNITS16 or CODEUNITS32 is specified, the specification of length applies to the units specified. That is, the data is converted to an intermediate form (in Unicode), the length is applied, and the data is converted to the specified CCSID.

**Resolution of cast functions:** DB2 uses the implicit or explicit schema name and the data type name of *data-type*, and function resolution to determine the specific function to use to convert *expression* to *data-type*. See Qualified function resolution for more information.

**Result of the CAST:** When numeric data is cast to character data, the data type of the result is a fixed-length character string, which is similar to the result that the CHAR function would give. (For more information, see “CHAR” on page 302.) When character data is cast to numeric data, the data type of the result depends on the data type of the specified number. For example, character data that is cast to an integer becomes a large integer, which is similar to the result that the INTEGER function would give. (For more information see “INTEGER or INT” on page 392.)

If the data type of the result is character, the subtype of the result is determined as follows:

- If *expression* is graphic, the subtype of the result is mixed.
- If *expression* is a datetime data type, the subtype of the result is mixed.<sup>15</sup>
- If *expression* is a row ID and *data-type* is not CLOB, the result is bit data.
- If *expression* is character, the subtype of the result is the same as *expression*.
- Otherwise, the subtype depends on the encoding scheme of the result. If the encoding scheme of the result is not Unicode and the field MIXED DATA on installation panel DSNTIPF is NO, the subtype of the result is SBCS. Otherwise, the subtype of the result is mixed.

**Casting constant values to DECFLOAT:** To cast a constant value, where the value is negative zero, or a floating point constant to DECFLOAT, specify the value as a character string constant rather than a numeric constant. For example:

```
DECFLOAT('-0')          -- causes DB2 to retain the negative sign for a
                         -- value of negative zero
DECFLOAT('1.00E20')    -- causes DB2 to preserve the precision of the
                         -- floating point constant
```

**Determining the CCSID and encoding scheme of the result:** The CCSID of the result depends on whether the CCSID clause was specified and the context in which the CAST specification was specified.

If the CCSID clause was specified, the CCSID clause is used to determine the CCSID of the result as follows:

- If the CCSID clause was specified with EBCDIC, ASCII, or UNICODE, the clause determines the encoding scheme of the result. The CCSID of the result is the appropriate CCSID (from DECP) for that encoding scheme for the data type of the result.
- If the CCSID clause was specified with a numeric value representing bit data (65535), the CCSID of the result depends on the data type of the source. If the source data is not string data, the CCSID of the result is the appropriate CCSID for the application encoding scheme. See Note 1 in Table 4 on page 44. If the source is string data, the encoding scheme of the result is the same as the encoding scheme of expression, but the result is considered bit data.
- If the CCSID clause was specified with a numeric value, the value must be one of the CCSID values in DECP, and that number is the CCSID of the result. The encoding scheme of the result is determined from the numeric CCSID. In a CAST specification, CCSID 367 refers to ASCII data. For example, assume that MYDATA is string data to be cast to CHAR(10). The following CAST specification returns ASCII SBCS data:

```
CAST(MYDATA AS CHAR(10) CCSID 367)
```

To explicitly cast the data to Unicode SBCS, use the following syntax:

```
CAST(MYDATA AS CHAR(10) CCSID UNICODE
     FOR SBCS DATA)
```

If the CCSID clause was not specified, the CCSID of the result is 65535 if the result is bit data. Otherwise, if the data type of the result is a character or graphic string data type, the encoding scheme and CCSID of the result are determined as follows:

---

15. The exception is when the default encoding scheme is EBCDIC and there is no mixed or graphic data on the system for EBCDIC.

- If the *expression* and *data-type* are both character, the encoding scheme of the result is the same as *expression*. For example, assume CHAR\_COL is a character column in the following:

```
CAST(CHAR_COL AS VARCHAR(25))
```

The result of the CAST is a varying length string with the same encoding scheme as the input. The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.

- If the *expression* and *data-type* are both graphic, the encoding scheme and CCSID of the result is the same as *expression*.
- If the result is string and the *expression* is datetime, the result CCSID is the appropriate CCSID of the *expression* encoding scheme and the result subtype is the appropriate subtype of the CCSID.
- If the result is character, the encoding scheme and CCSID of the result depends on the context in which the CAST specification is specified:
  - If the statement follows the rules that are described for type 1 statements in “Determining the encoding scheme and CCSID of a string” on page 43, the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.
  - The CCSID of the result is the appropriate CCSID for the encoding scheme and subtype of the result.
- Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme and subtype of the result.
- If the result is graphic, the encoding scheme and the CCSID of the result depends on the context in which the CAST specification is specified:
  - If the statement follows the rules that are described for type 1 statements in “Determining the encoding scheme and CCSID of a string” on page 43, the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.
  - The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.
- Otherwise, the CCSID of the result is the appropriate CCSID for the application encoding scheme of the result.
- Otherwise, the CCSID of the result depends on the context in which the CAST specification was specified.
  - If the statement follows the rules that are described for type 1 in statements in “Determining the encoding scheme and CCSID of a string” on page 43, the CCSID is determined as follows:
    - If the statement references a table or view, the encoding scheme of that table or view determines the encoding scheme for the result.
    - Otherwise, the default EBCDIC encoding scheme is used for the result.
  - The CCSID of the result is the appropriate CCSID for the encoding scheme and data type of the result.

**Alternative syntax for casting distinct types:** There is alternative syntax for casting a distinct type to its source data type and vice versa. Assume that a distinct type D\_MONEY was defined with the following statement and column MONEY was defined with that data type.

```
CREATE TYPE D_MONEY AS DECIMAL(9,2);
```

DECIMAL(MONEY) is equivalent syntax to CAST(MONEY AS DECIMAL(9,2)). Both forms of the syntax use the cast function that DB2 generated when the distinct type D\_MONEY was created to convert the distinct type to its source type of DECIMAL(9,2).

However, it is possible that different cast functions might be chosen for the equivalent syntax forms because of the difference in function resolution, particularly the treatment on unqualified names. Although the process of function resolution is similar for both, in the CAST specification as described above, DB2 uses the schema name of the target data type to locate the function. Therefore, if an unqualified data type name is specified as the target data type, DB2 uses the SQL path to resolve the schema name of the distinct type and then searches for the function in that schema. In function notation, when an unqualified function name is specified, DB2 searches the schemas in the SQL path to find an appropriate function match, as described under “Function resolution” on page 175. For example, assume that you defined the following distinct types, which implicitly gives you both USAGE authority on the distinct types and EXECUTE authority on the cast functions that are generated for them:

```
CREATE TYPE SCHEMA1.AGE AS DECIMAL(2,0);
  one of the generated cast functions is:
  FUNCTION SCHEMA1.AGE(SYSIBM.DECIMAL(2,0)) RETURNS SCHEMA1.AGE
CREATE TYPE SCHEMA2.AGE AS INTEGER;
  one of the generated cast functions is:
  FUNCTION SCHEMA2.AGE(SYSIBM.INTEGER) RETURNS SCHEMA2.AGE
```

If *STU\_AGE*, an INTEGER host variable, is cast to the distinct type with either of the following statements and the SQL path is SYSIBM, SCHEMA1, SCHEMA2:

Syntax 1: `CAST(:STU_AGE AS AGE);`  
Syntax 2: `AGE(:STU_AGE);`

different cast functions are chosen. For syntax 1, DB2 first resolves the schema name of distinct type AGE as SCHEMA1 (the first schema in the path that contains a distinct type named AGE for which you have EXECUTE authority for the appropriate generated cast function). Then it looks for a suitable function in that schema and chooses SCHEMA1.AGE because the data type of *STU\_AGE*, which is INTEGER, is promotable to the data type of the function argument, which is DECIMAL(2,0). For syntax 2, DB2 searches all the schemas in the path for an appropriate function and chooses SCHEMA2.AGE. DB2 selects SCHEMA2.AGE over SCHEMA1.AGE because the data type of its argument (INTEGER) is an exact match for *STU\_AGE* (INTEGER) and, therefore, a better match than the argument for SCHEMA1.AGE, which is DECIMAL(2,0).

*Example 1:* Assume that an application needs only the integer portion of the SALARY column, which is defined as DECIMAL(9,2) from the EMPLOYEE table. The following query for the employee number and the integer value of SALARY could be prepared.

```
SELECT EMPNO, CAST(SALARY AS INTEGER) FROM EMPLOYEE;
```

*Example 2:* Assume that two distinct types exist in schema SCHEMAX. Distinct type D\_AGE was based on SMALLINT and is the data type for the AGE column in

the PERSONNEL table. Distinct type D\_YEAR was based on INTEGER and is the data type for the RETIRE\_YEAR column in the same table. The following UPDATE statement could be prepared.

```
UPDATE PERSONNEL SET RETIRE_YEAR =?
    WHERE AGE = CAST( ? AS SCHEMAX.D_AGE);
```

The first parameter is an untyped parameter marker that has a data type of RETIRE\_YEAR. However, the application will use an integer for the parameter marker. The parameter marker does not need to be cast because the SET is an assignment.

The second parameter marker is a typed parameter marker that is cast to the distinct type D\_AGE. Casting the parameter marker satisfies the requirement that comparisons must be performed with compatible data types. The application will use the source data type, SMALLINT, to process the parameter marker.

*Example 3:* A CAST specification can be used to explicitly specify the data type of a parameter in a context where a parameter marker must be typed. In the following example, the CAST specification is used to tell DB2 to assume that the value that will be provided as input to the TIME function will be CHAR(20). See “PREPARE” on page 1405 for a list of contexts when invoking functions where parameter markers can be untyped. For all other contexts when invoking a function, the CAST specification can be used to explicitly specify the type of a parameter marker.

```
INSERT INTO ADMF001.CASTSQLJ VALUES( TIME(CAST(? AS CHAR(20)) ) )
```

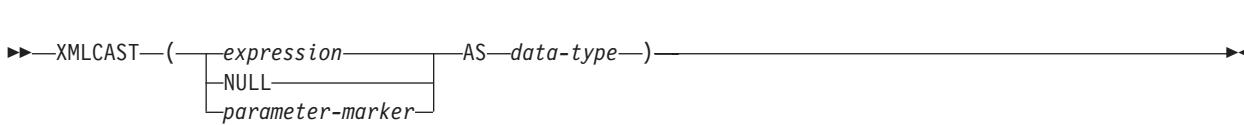

*Example 4:* Assume that an application wants to cast an EBCDIC string to Unicode UTF-8. The string contains the value 'Jürgen', which is 6 bytes in ASCII or EBCDIC and is 7 bytes in Unicode UTF-8. In the following query, the CAST specification is invoked with the *length* clause with CODEUNITS32 specified to ensure that the data is not truncated. (In this case, CODEUNITS16 could also be specified as the string unit.)

```
SELECT CAST('Jürgen' AS VARCHAR(6 CODEUNITS32) CCSID UNICODE)
    FROM SYSIBM.SYSDUMMY1;
```

For this query, the data is converted from EBCDIC to Unicode UTF-16, the length clause is applied, and then the UTF-16 result is converted to UTF-8.

## XMLCAST specification

The XMLCAST specification returns the first operand (the cast operand) converted to the type specified by *data-type*.

XMLCAST supports casts involving XML values, including conversions between non-XML data types and the XML data type. Either the type of the cast operand or the specified data type must be XML. If both the type of the cast operand and the target data type are XML, XMLCAST acts as a no-op.

### *expression*

If the cast operand is an expression (other than a parameter marker or NULL), the result is the argument value converted to the specified target data type.

The expression or the target data type must be the XML data type.

### *NULL*

If the cast operand is the NULL keyword, the target data type must be the XML data type. The result is a null XML value.

### *parameter-marker*

If the cast operand is a parameter marker, the target data type must be the XML data type. A parameter marker (specified as a question mark character) is normally considered to be an expression, but is documented separately in this case because it has special meaning. When the cast operand is a parameter-marker, the data type that is specified represents the "promise" that the replacement value for the parameter marker will be assignable to the specified data type (using "store assignment" rules). Such a parameter marker is considered to be a typed parameter marker, which is treated like any other typed value for the purpose of function resolution, a describe operation on a select list, or column assignment.

### *data-type*

The name of an SQL data type. If the name is not qualified, the SQL path is used to perform data type resolution. *data-type* must not specify a distinct type. If a data type has associated attributes, such as length or precision and scale, these attributes should be included when specifying a value for *data-type*. CHAR defaults to a length of 1, and DECIMAL defaults to a precision of 5 and a scale of 0 if not specified. CLOB and DBCLOB default to a length of 1M. Restrictions on the supported data types are based on the specified cast operand. The default encoding scheme for string data types is Unicode. The encoding scheme can be changed by specifying the CCSID clause.

## Examples

*Example 1:* Create a null XML value.

```
XMLCAST(NULL AS XML)
```

*Example 2:* Convert a value extracted from an XMLQUERY expression into an INTEGER:

```
| XMLCAST(XMLQUERY('/PRODUCT/QUANTITY'  
| PASSING xm1col) AS INTEGER)
```

| *Example 3:* Convert a value extracted from an XMLQUERY expression into a  
| varying-length character string:

```
| XMLCAST(XMLQUERY('/PRODUCT/NAME'  
| PASSING xm1col) AS VARCHAR(20))
```

| Note that in the above two examples, if the XMLQUERY returns a sequence of  
| more than one node, the XMLCAST specification will return an error.

| *Example 4:* Convert a value extracted from an SQL scalar subquery into an XML  
| value:

```
| XMLCAST((SELECT quantity FROM product AS p  
| WHERE p.id = 1077) AS XML)
```

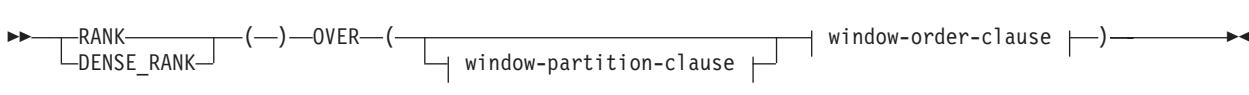

## OLAP specification

Online analytical processing (OLAP) specifications provide the ability to return ranking and row numbering information as a scalar value in the result of a query. An OLAP specification can be included in an expression, in a *select-list*, or in the ORDER BY clause of a *select-statement*. The query result to which the OLAP specifications is applied is the result table of the innermost subselect that includes the OLAP specification.

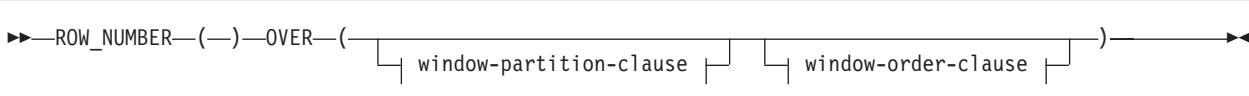

### OLAP-specification

#### ordered-OLAP-specification

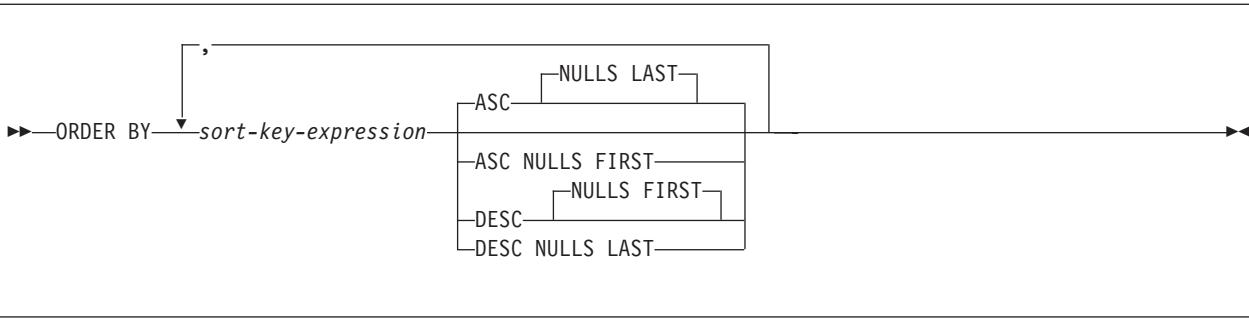

#### numbering-specification

#### window-partition-clause

#### window-order-clause

RANK, DENSE\_RANK, and ROW\_NUMBER are sometimes called window functions.

An OLAP specification is not valid in a **WHERE**, **VALUES**, **GROUP BY**, **HAVING**, or **SET** clause. An OLAP specification cannot be used as an argument of an aggregate function.

When invoking an OLAP specification, a window is specified that defines the rows over which the function is applied and in which order.

The result of a **RANK**, **DENSE\_RANK**, or **ROW\_NUMBER** specification is **BIGINT**. The result cannot be null.

#### **RANK** or **DENSE\_RANK**

Specifies that the ordinal rank of a row within the specified window is computed. Rows that are not distinct with respect to the ordering within the specified window are assigned the same rank. The results of the ranking can be defined with or without gaps in the numbers that result from duplicate values.

##### **RANK**

Specifies that the rank of a row is defined as 1 plus the number of rows that strictly precede the row. Thus, if two or more rows are not distinct with respect to the ordering, there will be one or more gaps in the sequential rank numbering.

##### **DENSE\_RANK**

Specifies that the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering. Therefore, there will be no gaps in the sequential rank numbering.

#### **ROW\_NUMBER**

Specifies that a sequential row number is computed for the row that is defined by the ordering, starting with 1 for the first row. If the **ORDER BY** clause is not specified in the window, the row numbers are assigned to the rows in an arbitrary order, as the rows are returned (not according to any **ORDER BY** clause in the *select-statement*).

#### **PARTITION BY** (*partitioning-expression*,...)

Defines the partition within which the OLAP operation is applied. A *partitioning-expression* is an expression that is used in defining the partitioning of the result table. Each column name that is referenced in a *partitioning-expression* must unambiguously reference a column of the result table of the subselect that contains the OLAP specification. A *partitioning-expression* cannot include a *scalar-fullselect* or any function that is not deterministic or has an external action.

#### **ORDER BY** (*sort-key-expression*,...)

Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification. It does not define the ordering of the result table.

##### *sort-key-expression*

Specifies an expression to use in defining the ordering of the rows within a window partition. Each column name that is referenced in a *sort-key-expression* must unambiguously reference a column of the result table of the subselect, including the OLAP specification. A *sort-key-expression* cannot include a scalar fullselect or any function that is not deterministic or that has an external action.

##### **ASC**

Specifies that the values of *sort-key-expression* are used in ascending order.

**DESC**

Specifies that the values of *sort-key-expression* are used in descending order.

**NULLS FIRST**

Specifies that the window ordering considers null values before all non-null values in the sort order.

**NULLS LAST**

Specifies that the window ordering considers null values after all non-null values in the sort order.

## Notes

**Syntax alternatives and synonyms:** For compatibility, the keywords **DENSERANK** and **ROWNUMBER** can be used as synonyms for **DENSE\_RANK** and **ROW\_NUMBER** respectively.

**Example 1:** Display the ranking of employees that have a total salary of more than \$30,000, in order by last name:

```
SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,  
      RANK() OVER(ORDER BY SALARY+BONUS DESC) AS RANK_SALARY  
   FROM EMP WHERE SALARY+BONUS > 30000  
 ORDER BY LASTNAME;
```

If the result is to be ordered by rank, ORDER BY LASTNAME would be replaced with ORDER BY RANK\_SALARY.

**Example 2:** Rank the departments according to their average total salary:

```
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,  
      RANK() OVER(ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL  
   FROM EMP  
 GROUP BY WORKDEPT  
 ORDER BY RANK_AVG_SAL;
```

**Example 3:** Rank the departments according to their education level. Having multiple employees with the same rank in the department should not increase the next ranking value:

```
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNAME, EDLEVEL,  
      DENSE_RANK() OVER  
        (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC) AS RANK_EDLEVEL  
   FROM EMP  
 ORDER BY WORKDEPT, LASTNAME;
```

**Example 4:** Provide row numbers in the results of a query:

```
SELECT ROW_NUMBER() OVER(ORDER BY WORKDEPT, LASTNAME) AS NUMBER,  
      LASTNAME, SALARY  
   FROM EMP  
 ORDER BY WORKDEPT, LASTNAME;
```

**Example 5:** List the top five wage earners:

```
SELECT EMPNO, LASTNAME, FIRSTNAME, TOTAL_SALARY, RANK_SALARY  
   FROM (SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,  
          RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY  
       FROM EMP) AS RANKED_EMPLOYEE  
 WHERE RANK_SALARY < 6  
 ORDER BY RANK_SALARY;
```

A nested table expression is used to first compute the result, including the ranking, before the rank can be used in the **WHERE** clause. A common table expression

| could also have been used.

## ROW CHANGE expression

A ROW CHANGE expression returns a token or a timestamp that represents the last change to a row.

### ROW CHANGE expression

#### TIMESTAMP

Specifies that a timestamp is returned that represents the last time when a row was changed. If the row has not been changed, the result is the time that the initial value was inserted.

#### TOKEN

Specifies that a token that is a BIGINT value is returned that represents a relative point in the modification sequence of a row. If the row has not been changed, the result is a token that represents when the initial value was inserted.

#### FOR *table-designator*

Identifies the table in which the expression is referenced. *table-designator* must uniquely identify a base table, a view, or a nested table expression of a subselect. If *table-designator* identifies a view or a nested table expression, the ROW CHANGE expression returns the TIMESTAMP or TOKEN of the base table of the view or the nested table expression. The view or nested table expression must contain only one base table in its outer subselect.

*table-designator* must not identify a materialized view or a nested table expression that is materialized.

The result can be null. The **ROW CHANGE TIMESTAMP** and **ROW CHANGE TOKEN** expressions are not deterministic.

#### Example 1:

The following example returns all the rows that have been changed in the last day:

```
SELECT * FROM ORDERS  
WHERE ROW CHANGE TIMESTAMP FOR ORDERS >  
CURRENT TIMESTAMP - 24 HOURS;
```

#### Example 2:

The following example returns a timestamp value that corresponds to the most recent change to each row from the EMP table for those employees in department 20:

```
SELECT ROW CHANGE TIMESTAMP FOR EMP  
FROM EMP WHERE DEPTNO = 20;
```

#### Example 3:

The following example returns a BIGINT value that corresponds to a relative point in the modification sequence of EMP with employee number '3500':

```
SELECT ROW CHANGE TOKEN FOR EMP  
FROM EMP WHERE EMPNO = '3500';
```

## Sequence reference

A sequence is referenced by using the NEXT VALUE and PREVIOUS VALUE expressions specifying the name of the sequence.

*sequence-reference*

►►—*nextval-expression*—  
  └─*prevval-expression*┘

*nextval-expression*

►►—NEXT VALUE FOR—*sequence-name*—

*prevval-expression*

►►—PREVIOUS VALUE FOR—*sequence-name*—

*nextval-expression*

A NEXT VALUE expression generates and returns the next value for a specified sequence. A new value is generated for a sequence when a NEXT VALUE expression specifies the name of the sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the sequence value is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result. The NEXT VALUE expression is not deterministic with external actions since it causes the sequence value to be incremented.

When the next value for the sequence is generated, if the maximum value for an ascending sequence or the minimum value for a descending sequence of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, then an error occurs. To avoid this error, either alter the sequence attributes to extend the range of value or to enable cycles for the sequence or drop and recreate the sequence with a different data type that allows a larger range of values.

The data type and length attributes of the result of a NEXT VALUE expression are the same as for the specified sequence. The result cannot be null.

*prevval-expression*

A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be repeatedly referenced by using PREVIOUS VALUE expressions to specify the name of the sequence. There can be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement and they all return the same value.

A PREVIOUS VALUE expression can be used only if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process.

The data type and length attributes of the result of a PREVIOUS VALUE expression are the same as for the specified sequence. The result cannot be null.

*sequence-name*

Identifies the sequence that is to be referenced. The combination of name and the implicit or explicit schema name must identify an existing sequence at the current server. *sequence-name* must not be the name of an internal sequence object that is generated by DB2 for an identity column. The contents of the SQL PATH are not used to determine the implicit qualifier of a sequence name.

**Authorization:** If a sequence is referenced in a statement, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For the sequence identified in the statement:
  - The USAGE privilege on the sequence
  - Ownership of the sequence
- SYSADM or SYSCTRL authority

**Generating values with NEXT VALUE:** When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

**Scope of NEXT VALUE and PREVIOUS VALUE:** The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence. The value of PREVIOUS VALUE persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends.

The value for the sequence cannot persist across a COMMIT or ROLLBACK for a local or remote application if, after the COMMIT or ROLLBACK, the DB2 application thread or server thread is assigned to another user or DB2 connection because of some form of thread reuse, re-signon, or connection pooling is in effect. For example, this can occur for CICS-DB2 applications and for client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing because they are not able to restore the NEXT or PREVIOUS VALUES for a sequence. In these situations, the availability of the value for a sequence should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following:

- issue an EXEC CICS SYNCPOINT command
- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value that is associated with NEXT VALUE or PREVIOUS VALUE expressions across transaction boundaries for local or

distributed applications that are subject to thread reuse, re-signon, or connection pooling, take one of the following actions to prevent the local or server thread from re-signon, being reused by a different user, or from being pooled:

- Define at least one cursor as WITH HOLD and leave it as OPEN.
- Specify the bind option KEEPDYNAMIC(YES).
- For CICS users of local DB2 threads, set the DB2 system parameter PREVALKEEP = YES (the default value is NO). Note that the system parameter PREVALKEEP is deprecated and might be removed from a version of DB2 after DB2 Version 9, and only the previous two choices will be available.

**Use as a unique key value:** The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown in the following example:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
    VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEM (ORDERNO, PARTNO, QUANTITY)
    VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 1);
```

**Allowed use of NEXT VALUE and PREVIOUS VALUE:** The NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

- Within the *select-clause* of a SELECT statement or SELECT statement that does not contain a DISTINCT keyword, a GROUP BY clause, an ORDER BY clause, or a set operator.
- Within a **VALUES** clause of an INSERT statement, including a multiple row INSERT statement with multiple **VALUES** clauses and the insert operation of a MERGE statement, which can include a NEXT VALUE expression for a particular sequence name for each **VALUES** clause.
- Within the *select-clause* of the fullselect of an INSERT statement.
- Within the **SET** clause of a searched or positioned UPDATE statement, including the update operation of the MERGE statement, though NEXT VALUE cannot be specified in the *select-clause* of the fullselect of an expression in the **SET** clause.

A PREVIOUS VALUE expression can be specified anywhere with a **SET** clause of an update operation (the UPDATE or MERGE statement), but a NEXT VALUE expression can be specified only in a **SET** clause if it is not within the *select-clause* of the fullselect of an expression. For instance, the following uses of sequence references are supported:

```
UPDATE T SET C1 = (SELECT PREVIOUS VALUE FOR S1 FROM T);
UPDATE T SET C1 = PREVIOUS VALUE FOR S1;
UPDATE T SET C1 = NEXT VALUE FOR S1;
```

The following uses of sequence references are not supported:

```
UPDATE T SET C1 = (SELECT NEXT VALUE FOR S1 FROM T);
SET :C2 = (SELECT NEXT VALUE FOR S1 FROM T);
```

- In a **SET host-variable** or *assignment-statement*, except within the *select-clause* of the fullselect of an expression.

The following uses of sequence references are supported:

```
SET ORDERNUM = NEXT VALUE FOR INVOICE;
SET ORDERNUM = PREVIOUS VALUE FOR INVOICE;
```

The following uses of sequence references are not supported:

```
SET X = (SELECT NEXT VALUE FOR S1 FROM T);
SET X = (SELECT PREVIOUS VALUE FOR S1 FROM T);
```

- In a **VALUES** or **VALUES INTO** statement though not within the *select-clause* of the fullselect of an expression.
- Within the *SQL-routine-body* of a CREATE or ALTER PROCEDURE statement for a SQL procedure.
- Within the *RETURN-statement* of a CREATE FUNCTION statement for an SQL function.
- Within the *SQL-trigger-body* of a CREATE TRIGGER statement (PREVIOUS VALUE is not allowed).

PREVIOUS VALUE is defined to have a linear scope within an application session. Therefore, in a nested application on entry to a nested function, procedure, or trigger, the nested application inherits the most recently generated value for a sequence. That is, an invocation of PREVIOUS VALUE in a nested application reflects sequence activity done in the invoking environment prior to entering the nested application. In addition, on return from a function, procedure, or trigger, the invoking application is affected by any sequence activity in the lower level applications. That is, an invocation of PREVIOUS VALUE in the invoking application after returning from the nested application reflects any sequence activity that occurred in the lower level applications.

**Restrictions on the use of NEXT VALUE and PREVIOUS VALUE:** Some of the places where the NEXT VALUE and PREVIOUS VALUE expressions cannot be specified include the following:

- Join condition of a full outer join
- DEFAULT value for a column in a CREATE TABLE or ALTER TABLE statement
- Materialized query table definition in a CREATE TABLE or ALTER TABLE statement
- Condition of a CHECK constraint
- Input value specification for LOAD
- CREATE VIEW statement
- The SELECT list of a subselect that contains a NOT ATOMIC data change statement
- ORDER BY clause when used in an OLAP specification

In addition, the NEXT VALUE expression cannot be specified in the following places:

- CASE expression
- Parameter list of an aggregate function
- Subquery in a context other than those explicitly allowed
- SELECT statement for which the outer SELECT contains a DISTINCT operator or a GROUP BY clause
- SELECT statement for which the outer SELECT is combined with another SELECT statement using a set operator
- Join condition of a join
- Nested table expression
- Parameter list of a table function
- *select-clause* of the fullselect of an expression in the SET clause of an UPDATE, a DELETE, or a MERGE statement.

- WHERE clause of the outer-most SELECT statement or a DELETE, , an UPDATE, or a MERGE statement
- ORDER BY clause of the outer-most SELECT statement
- IF, WHILE, DO UNTIL, or CASE statements in an SQL routine

**Using sequence expressions with a cursor:** Normally, a SELECT NEXT VALUE FOR ORDER\_SEQ FROM T1 would produce a result table containing as many generated values from the sequence ORDER\_SEQ as the number of rows retrieved from T1. A reference to a NEXT VALUE expression in the SELECT statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression each time a row is retrieved.

If blocking is done at a client in a DRDA environment, sequence values might get generated at the DB2 server before the processing of an application's FETCH statement. If the client application does not explicitly fetch all the rows that have been retrieved from the database, the application will never see all those values of the sequence that are generated but not fetched (as many values as the rows that are not fetched). These generated but not fetched values might constitute a gap in the sequence. If it is important to prevent such a gap, do the following:

- Use NEXT VALUE only in places where it would function without being controlled by a cursor and where block-fetching by the client will have no effect on it.
- If you must use NEXT VALUE in the SELECT statement of a cursor-definition, weigh the importance of preventing the gap against performance and other implications of taking the following actions:
  - Use FETCH FOR 1 ROW ONLY clause with the SELECT statement.
  - Try preventing block-fetch by other means documented in *DB2 Application Programming and SQL Guide*,

**Using the PREVIOUS VALUE expression with a cursor:** A reference to the PREVIOUS VALUE expression in a SELECT statement of a cursor is evaluated at OPEN time. In other words, a reference to the PREVIOUS VALUE expression in the SELECT statement of a cursor refers to the last value generated by this application process for the specified sequence prior to the opening of the cursor and, once evaluated at OPEN time, the value returned by PREVIOUS VALUE within the select statement of the cursor will not change from FETCH to FETCH, even if NEXT VALUE is invoked with the select statement of the cursor. After the cursor is closed, the value of PREVIOUS VALUE will be the last NEXT VALUE that is generated by the application process.

IF PREVIOUS VALUE is used in the SELECT statement of a cursor while the cursor is open, the PREVIOUS VALUE value would be the last NEXT VALUE for the sequence generated before the cursor was opened. After the cursor is closed, the PREVIOUS VALUE value would be the last NEXT VALUE generated by the application process.

**Syntax alternatives and synonyms:** For compatibility, the keywords NEXTVAL and PREVVAL can be used as synonyms for NEXT VALUE and PREVIOUS VALUE respectively.

**Example:** Assume that there is a table called ORDER, and that a sequence called ORDER\_SEQ is created as follows:

```
CREATE SEQUENCE ORDER_SEQ START WITH 1
    INCREMENT BY 1
    NO MAXVALUE
    NO CYCLE
    CACHE 24
```

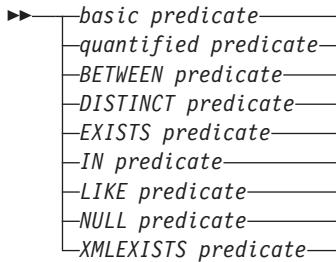

The following examples illustrate how to generate an ORDER\_SEQ sequence number with a NEXT VALUE expression:

```
INSERT INTO ORDER (ORDERNO, CUSTNO)
    VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
UPDATE ORDER SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
    WHERE CUSTNO = 123456;
VALUES NEXT VALUE FOR ORDER_SEQ INTO :HV_SEQ;
```

## Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given row or group.

The types of predicates are:

The following rules apply to predicates of any type:

- Predicates are evaluated after the expressions that are operands of the predicate.
- All values that are specified in the same predicate must be compatible.
- Except for the EXISTS predicate, a subquery in a predicate must specify a single column unless the operand on the other side of the comparison operator is a fullselect.
- The value of a host variable can be null (that is, the variable can have a negative indicator variable).
- The CCSID conversion of operands of predicates that involve two or more operands is done according to “Conversion rules for operations that combine strings” on page 122.
- Use of an XML value is limited to the NULL or XMLEXISTS predicates.

**Row-value-expression:** The operand of several predicates (basic, quantified, DISTINCT, and IN) can be a *row-value-expression*:

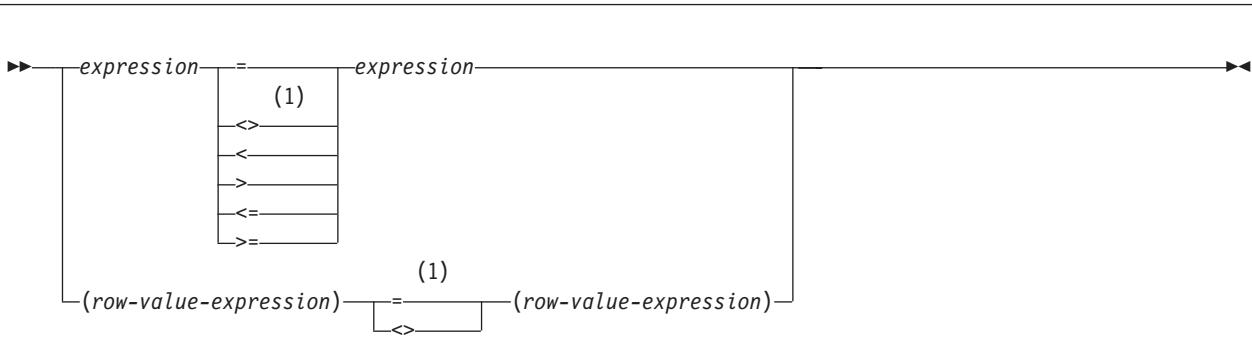

A *row-value-expression* returns a single row that consists of one or more column values. The values can be specified as a list of expressions. The number of columns that are returned by the *row-value-expression* is equal to the number of expressions that are specified in the list.

**Other predicate examples:** In addition to the examples of predicates in the following topics, see information on distinct type comparisons in “Assignment and comparison” on page 102, which contains several examples of predicates that use distinct types.“Distinct type comparisons” on page 117, which contains several examples of predicates that use distinct types.

## Basic predicate

A *basic predicate* compares two values or compares a set of values with another set of values.

### Notes:

- 1 Other comparison operators are also supported.<sup>16</sup>

When *expression* is a fullselect, the fullselect must return a single result column with a single value, whether null or not null. If the value of either operand is null or the result of the fullselect is empty, the result of the predicate is unknown. Otherwise, the result is either true or false.

When a *row-value-expression* is specified on the left side of the operator (= or <>), another *row-value-expression*, with an identical number of value expressions, must be specified on the right side. The data types of the corresponding expressions or columns of the *row-value-expressions* must be compatible. The value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the operator, as in the following two cases:

- If the operator is =, the result of the predicate is:
  - True if all pairs of corresponding value expressions evaluate to true.
  - False if any one pair of corresponding value expressions evaluates to false.
  - Otherwise, unknown (that is, if at least one comparison of corresponding value expressions is unknown because of a null value and no pair of corresponding value expressions evaluates to false).
- If the operator is <>, the result of the predicate  $(x_1, x_2, \dots, x_n) <> (y_1, y_2, \dots, y_n)$  is:
  - True, if and only if  $x_i = y_i$  evaluates to false for some value of i. (that is, there is at least one pair of non-null values,  $x_i$  and  $y_i$ , that are not equal to each other)

16. The following forms of the comparison operators are also supported in basic and quantified predicates in coded pages where the exclamation point is X'5A': !=, !<, and !>. In addition, in code pages 437, 819, and 850, the forms ~=, ~<, and ~> are supported. All these product-specific forms of the comparison operators are intended only to support existing SQL statements that use these operators and are not recommended for use when writing new SQL statements.

A not sign (~) or the character that must be used in its place in certain countries, can cause parsing errors in statements passed from one DBMS to another. The problem occurs if the statement undergoes character conversion with certain combinations of source and target CCSIDs. To avoid this problem, substitute an equivalent operator for any operator that includes a not sign. For example, substitute '<>' for '!=', '<=' for '~=', and '>=' for '~='.

- False, if and only if  $x_i=y_i$  evaluates to true for every value of  $i$ . (that is,  $(x_1,x_2,\dots,x_n)=(y_1,y_2,\dots,y_n)$  is true)
- Otherwise, unknown (that is,  $x_i$  or  $y_i$  is a null value for some value of  $i$ , and there is no value of  $j$  such that  $x_j=y_j$  evaluates to false).

*Table 42. For values  $x$  and  $y$*

Predicate	Is true if and only if ...
$x = y$	$x$ is equal to $y$
$x <> y$	$x$ is not equal to $y$
$x < y$	$x$ is less than $y$
$x > y$	$x$ is greater than $y$
$x \leq y$	$x$ is less than or equal to $y$
$x \geq y$	$x$ is greater than or equal to $y$

*Examples for values  $x$  and  $y$ :*

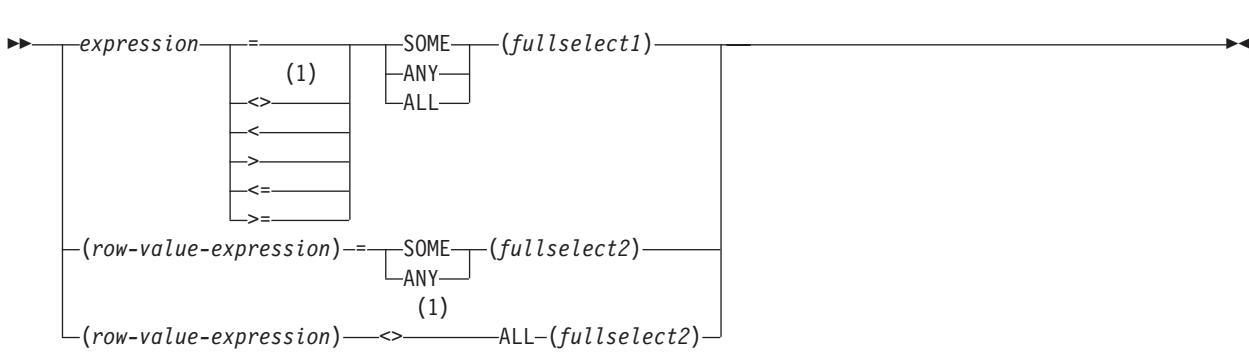

```
EMPNO = '528671'
SALARY < 20000
PRSTAFF <> :VAR1
SALARY >= (SELECT AVG(SALARY) FROM DSN8910.EMP)
```

*Example:* List the name, first name, and salary of the employee who is responsible for the 'SECRET' project. This employee might appear in either the PROJA1 or PROJA2 tables. A UNION is used in case the employee appears in both tables to eliminate duplicate RESPEMP values.

```
SELECT LASTNAME, FIRSTNAME, SALARY
  FROM DSN8910.EMP X
 WHERE EMPNO = (
  SELECT RESPEMP
    FROM PROJA1 Y
   WHERE MAJPROJ = 'SECRET'
UNION
  SELECT RESPEMP
    FROM PROJA2 Z
   WHERE MAJPROJ = 'SECRET');
```

## Quantified predicate

A *quantified predicate* compares a value or values with a collection of values.

### Notes:

- 1 Other comparison operators are also supported.<sup>16</sup>

When *expression* is specified, *fullselect1* must return a single result column, and can return any number of values, whether null or not null. The result depends on the operator that is specified:

- When the operator is ALL, the result of the predicate is:
  - True – if the result of the fullselect is empty or if the specified relationship is true for every value returned by the fullselect.
  - False – if the specified relationship is false for at least one value returned by the fullselect.
  - Unknown – if the specified relationship is not false for any values returned by the fullselect and at least one comparison is unknown because of a null value.
- When the operator is SOME or ANY, the result of the predicate is:
  - True – if the specified relationship is true for at least one value returned by the fullselect.
  - False – if the result of the fullselect is empty or if the specified relationship is false for every value returned by the fullselect.
  - Unknown – if the specified relationship is not true for any of the values returned by the fullselect and at least one comparison is unknown because of a null value.

When *row-value-expression* is specified, the number of result columns returned by *fullselect2* must be the same as the number of value expressions specified by *row-value-expression*, and *fullselect2* can return any number of rows of values. The data types of the corresponding expressions of the row value expressions must be compatible. The value of each expression from *row-value-expression* is compared with the value of the corresponding result column from *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is ALL, the result of the predicate is:
  - True – if the result of *fullselect2* is empty or if the specified relationship is true for every row returned by *fullselect2*.
  - False – if the specified relationship is false for at least one row returned by *fullselect2*.

- Unknown – if the specified relationship is not false for any row returned by *fullselect2* and at least one comparison is unknown because of a null value.
- When the operator is SOME or ANY, the result of the predicate is:
  - True – if the specified relationship is true for at least one row returned by *fullselect2*
  - False – if the result of the *fullselect* is empty or if the specified relationship is false for every row returned by *fullselect2*.
  - Unknown – if the specified relationship is not true for any of the rows returned by *fullselect2* and at least one comparison is unknown because of a null value.

Quantified predicates are equivalent to IN predicates. See Table 47 on page 235 for some examples of equivalent quantified and IN predicates.

*Examples:* Use the following tables when referring to the following examples. In all examples, “row *n* of TBLA” refers to the row in TBLA for which COLA has the value *n*.

Table 43. TBLA

COLA
1
2
3
4

Table 44. TBLB

COLB	COLC
2	2
3	--

Table 45. TBLC

COLB	COLC
2	2

*Example 1:* In the following predicate, the *fullselect* returns the values 2 and 3. The predicate is false for rows 1, 2, and 3 of TBLA, and is true for row 4.

```
COLA > ALL(SELECT COLB FROM TBLB
              UNION
              SELECT COLB FROM TBLC)
```

*Example 2:* In the following predicate, the *fullselect* returns the values 2 and 3. The predicate is false for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > ANY(SELECT COLB FROM TBLB
              UNION
              SELECT COLB FROM TBLC)
```

*Example 3:* In the following predicate, the *fullselect* returns the values 2 and null. The predicate is false for rows 1 and 2 of TBLA, and is unknown for rows 3 and 4. The result is an empty table.

```
COLA > ALL(SELECT COLC FROM TBLB  
UNION  
SELECT COLC FROM TBLC)
```

*Example 4:* In the following predicate, the fullselect returns the values 2 and null. The predicate is unknown for rows 1 and 2 of TBLA, and is true for rows 3 and 4.

```
COLA > SOME(SELECT COLC FROM TBLB  
UNION  
SELECT COLC FROM TBLC)
```

*Example 5:* In the following predicate, the fullselect returns an empty result column. Hence, the predicate is true for all rows of TBLA.

```
COLA < ALL(SELECT COLB FROM TBLB WHERE COLB>3  
UNION  
SELECT COLB FROM TBLC WHERE COLB>3)
```

*Example 6:* In the following predicate, the fullselect returns an empty result column. Hence, the predicate is false for all rows of TBLA.

```
COLA < ANY(SELECT COLB FROM TBLB WHERE COLB>3  
UNION  
SELECT COLB FROM TBLC WHERE COLB>3)
```

If COLA were null in one or more rows of TBLA, the predicate would still be false for all rows of TBLA.

## BETWEEN predicate

The BETWEEN predicate determines whether a given value lies between two other given values that are specified in ascending order.

Each of the predicate's two forms has an equivalent search condition, as shown in the following table:

Table 46. BETWEEN predicate and equivalent search conditions

BETWEEN predicate	Equivalent search condition
<i>value1</i> BETWEEN <i>value2</i> AND <i>value3</i>	<i>value1</i> $\geq$ <i>value2</i> AND <i>value1</i> $\leq$ <i>value3</i> <sup>1</sup>
<i>value1</i> NOT BETWEEN <i>value2</i> AND <i>value3</i>	<i>value1</i> $<$ <i>value2</i> OR <i>value1</i> $>$ <i>value3</i> <sup>1</sup>
or, equivalently: NOT( <i>value1</i> BETWEEN <i>value2</i> AND <i>value3</i> )	

**Note:** 1. Might not be equivalent if *value1*, *value2*, or *value3* are columns or derived values based on columns that are not the same CCSID set because the clause is evaluated in Unicode.

Search conditions are discussed in “Search conditions” on page 247.

If the operands include a mixture of datetime values and valid string representations of datetime values, all values are converted to the data type of the datetime operand.

*Example:* Consider the following predicate:

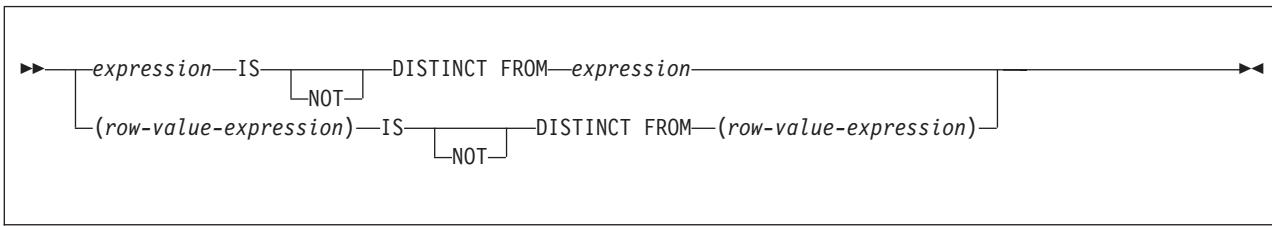

A BETWEEN B AND C

The following table shows the value of the predicate for various values of A, B, and C.

Value of A	Value of B	Value of C	Value of predicate
1,2, or 3	1	3	true
0 or 4	1	3	false
0	1	null	false
4	null	3	false
null	any value	any value	unknown
2	1	null	unknown
3	null	4	unknown

## DISTINCT predicate

A distinct predicate compares a value with another value or a set of values with another set of values.

The number of elements that are returned by the *row-value-expression* that specified after the distinct operator must match the number of elements that are returned by the *row-value-expression* that is specified prior to the distinct operator. The data types of the corresponding columns or expressions of the *row-value-expressions* must be compatible. When the predicate is evaluated, the value of each expression on the left side is compared with the value of its corresponding expression on the right side. The result of the predicate depends on the form of the predicate.

When the predicate is **IS DISTINCT**, the result of the predicate is true if at least one comparison of a pair of corresponding value expressions evaluates to false. Otherwise, the result of the predicate is false. The result cannot be unknown.

When the predicate **IS NOT DISTINCT FROM**, the result of the predicate is true if all pairs of corresponding value expressions evaluate to true (null values are considered equal to null values). Otherwise, the predicate is false. The result cannot be unknown.

The DISTINCT predicate cannot be used in the following contexts:

- The **ON join-condition** of a full outer join
- A check constraint
- A quantified predicate

The following DISTINCT predicate is logically equivalent to the following search conditions:

```
value1 IS NOT DISTINCT FROM value2
  -- is logically equivalent to
  (value1 IS NOT NULL AND value2 IS NOT NULL AND value1 = value2)
    -- or is logically equivalent to
  (value1 IS NULL AND value2 IS NULL)
```

The following DISTINCT predicate is logically equivalent to the following search condition:

```
value1 IS DISTINCT FROM value2
  -- is logically equivalent to
  NOT (value1 IS NOT DISTINCT FROM value2)
```

*Example 1:* Assume that T1 is a single-column table with three rows. Column C1 has the following values: 1, 2, and null. Consider the following query:

```
SELECT * FROM T1
WHERE C1 IS DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

<b>Value of C1</b>	<b>Value of HV</b>	<b>Result of predicate</b>
1	2	True
2	2	False
null	2	True
1	null	True
2	null	True
null	null	False

*Example 2:* Assume the same table as in the first example, but now consider the negative form of the predicate in the query:

```
SELECT * FROM T1
WHERE C1 IS NOT DISTINCT FROM :HV;
```

The following table shows the value of the predicate for various values of C1 and the host variable.

<b>Value of C1</b>	<b>Value of HV</b>	<b>Result of predicate</b>
1	2	False
2	2	True
null	2	False
1	null	False
2	null	False
null	null	True

## EXISTS predicate

The EXISTS predicate tests for the existence of certain rows. The fullselect can specify any number of columns, and can result in true or false.

►►EXISTS-(fullselect)—————►►

The result of the EXISTS predicate:

- Is true only if the number of rows that is specified by the fullselect is not zero.
- Is false only if the number of rows specified by the fullselect is zero.
- Cannot be unknown.

The SELECT clause in the fullselect can specify any number of columns because the values returned by the fullselect are ignored. For convenience, use:

```
SELECT *
```

Unlike the NULL, LIKE, and IN predicates, the EXISTS predicate has no form that contains the word NOT. To negate an EXISTS predicate, precede it with the logical operator NOT, as follows:

```
NOT EXISTS (fullselect)
```

The result is then false if the EXISTS predicate is true, and true if the predicate is false. Here, NOT is a logical operator and not a part of the predicate. Logical operators are discussed in “Search conditions” on page 247.

*Example 1:* The following query lists the employee number of everyone represented in DSN8910.EMP who works in a department where at least one employee has a salary less than 20000. Like many EXISTS predicates, the one in this query involves a correlated variable.

```
SELECT EMPNO
  FROM DSN8910.EMP X
 WHERE EXISTS (SELECT * FROM DSN8910.EMP
                WHERE X.WORKDEPT=WORKDEPT AND SALARY<20000);
```

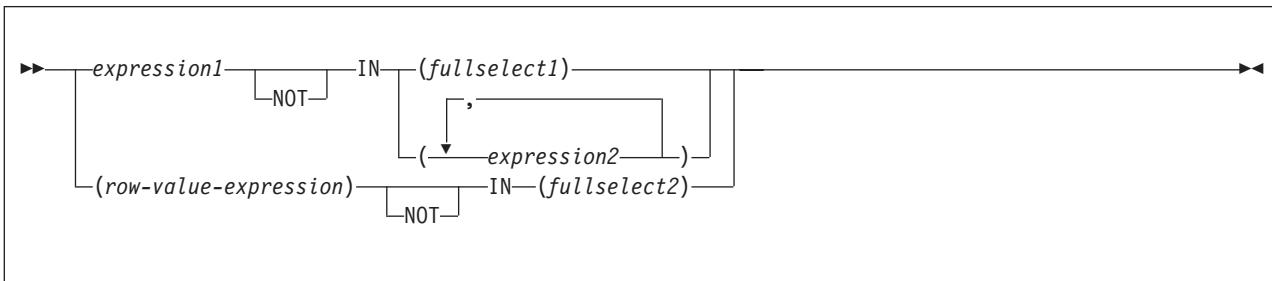

*Example 2:* List the subscribers (SNO) in the state of California who made at least one call during the first quarter of 2009. Order the results according to SNO. Each MONTHnn table has columns for SNO, CHARGES, and DATE. The CUST table has columns for SNO and STATE.

```
SELECT C.SNO
  FROM CUST C
 WHERE C.STATE = 'CA'
 AND EXISTS (
  SELECT *
    FROM MONTH1
   WHERE DATE BETWEEN '01/01/2009' AND '01/31/2009'
   AND C.SNO = SNO
 UNION ALL
  SELECT *
    FROM MONTH2
   WHERE DATE BETWEEN '02/01/2009' AND '02/28/2009'
   AND C.SNO = SNO
 UNION ALL
  SELECT *
```

```
FROM MONTH3
WHERE DATE BETWEEN '03/01/2009 AND '03/31/2009'
AND C.SNO = SNO
)
ORDER BY C.SNO;
```

## IN predicate

The IN predicate compares a value or values with a set of values.

When *expression1* is specified, the IN predicate compares a value with a set of values. When *fullselect1* is specified, the fullselect must return a single result column, and can return any number of values, whether null or not null. The data type of *expression1* and the data type of the result column of *fullselect1* or *expression2* must be compatible. If *expression* is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

When a *row-value-expression* is specified, the IN predicate compares values with a collection of values. The result table of the *fullselect2* must have the same number of columns as the *row-value-expression*. The data type of each expression in *row-value-expression* and the data type of its corresponding result column of *fullselect2* must be compatible. The value of each expression in *row-value-expression* is compared with the value of its corresponding result column of *fullselect2*. The value of the predicate depends on the operator that is specified:

- When the operator is IN, the result of the predicate is:
  - True if at least one row returned from *fullselect2* is equal to the *row-value-expression*.
  - False if the result of *fullselect2* is empty or if no row returned from *fullselect2* is equal to the *row-value-expression*.
  - Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and no row returned from *fullselect2* is equal to the *row-value-expression*).
- When the operator is NOT IN, the result of the predicate is:  
True if the result of *fullselect2* is empty or if the *row-value-expression* is not equal to any of the rows returned by *fullselect2*.  
False if the *row-value-expression* is equal to at least one row returned by *fullselect2*.  
Otherwise, unknown (that is, if the comparison of *row-value-expression* to the row returned from *fullselect2* evaluates to unknown because of a null value for at least one row returned from *fullselect2* and the comparison of *row-value-expression* to the row returned from *fullselect2* is not true for any row returned by the *fullselect2*).

The IN predicate is equivalent to the quantified predicate as follows:

Table 47. IN predicate and equivalent quantified predicates

IN predicate	Equivalent quantified predicate
<i>expression1</i> IN ( <i>expression2</i> )	<i>expression1</i> = <i>expression2</i>
<i>expression</i> IN ( <i>fullselect1</i> )	<i>expression</i> = ANY ( <i>fullselect1</i> )
<i>expression</i> NOT IN ( <i>fullselect1</i> )	<i>expression</i> <> ALL ( <i>fullselect1</i> )
<i>expression1</i> IN ( <i>expressiona</i> , <i>expressionb</i> , ...)	<i>expression1</i> IN ( SELECT * FROM R )
	When T is a table with a single row and R is a result table formed by the following fullselect: SELECT value1 FROM T UNION SELECT value2 FROM T UNION . . . UNION SELECT valueN FROM T
<i>row-value-expression</i> IN ( <i>fullselect2</i> )	<i>row-value-expression</i> = SOME ( <i>fullselect2</i> )
<i>row-value-expression</i> IN ( <i>fullselect2</i> )	<i>row-value-expression</i> = ANY ( <i>fullselect2</i> )
<i>row-value-expression</i> NOT IN ( <i>fullselect2</i> )	<i>row-value-expression</i> <> ALL ( <i>fullselect2</i> )

If the operands of the IN predicate are strings with different CCSIDs, the rules used to determine which operands are converted are those for operations that combine strings. See “Character and graphic string comparisons” on page 116.

*Example 1:* The following predicate is true for any row whose employee is in department D11, B01, or C01.

```
WORKDEPT IN ('D11', 'B01', 'C01')
```

*Example 2:* The following predicate is true for any row whose employee works in department E11.

```
EMPNO IN (SELECT EMPNO FROM DSN8910.EMP  
WHERE WORKDEPT = 'E11')
```

*Example 3:* The following predicate is true if the date that a project is estimated to start (PRENDATE) is within the next two years.

```
YEAR(PRENDATE) IN (YEAR(CURRENT DATE),  
YEAR(CURRENT DATE + 1 YEAR),  
YEAR(CURRENT DATE + 2 YEARS))
```

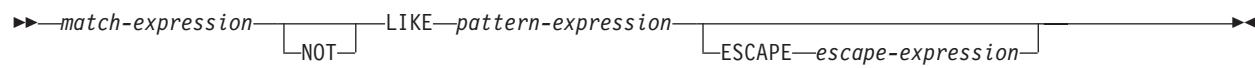

*Example 4:* The following example obtains the phone number of an employee in DSN8910.EMP where the employee number (EMPNO) is a value specified within the COBOL structure defined below.

```
77 PHNUM PIC X(6).  
01 EMPNO-STRUCTURE.  
    05 CHAR-ELEMENT-1 PIC X(6) VALUE '000140'.  
    05 CHAR-ELEMENT-2 PIC X(6) VALUE '000340'.  
    05 CHAR-ELEMENT-3 PIC X(6) VALUE '000220'.  
    .  
    .  
    .  
EXEC SQL DECLARE PHCURS CURSOR FOR  
    SELECT PHONENO FROM DSN8910.EMP
```

```
WHERE EMPNO IN
  (:EMPNO-STRUCTURE.CHAR-ELEMENT-1,
   :EMPNO-STRUCTURE.CHAR-ELEMENT-2,
   :EMPNO-STRUCTURE.CHAR-ELEMENT-3)
END-EXEC.
EXEC SQL OPEN PHCURS
END-EXEC.
EXEC SQL FETCH PHCURS INTO :PHNUM
END-EXEC.
```

## LIKE predicate

The LIKE predicate searches for strings that have a certain pattern.

The *match-expression* is the string to be tested for conformity to the pattern specified in *pattern-expression*. Underscore and percent sign characters in the pattern have a special meaning instead of their literal meanings unless *escape-expression* is specified, as discussed under the description of *pattern-expression*.

The following rules summarize how a predicate in the form of *m* LIKE *p* is evaluated:

- If *m* or *p* is null, the result of the predicate is unknown.
- If *m* and *p* are both empty, the result of the predicate is true.
- If *m* is empty and *p* is not, the result of the predicate is unknown unless *p* consists of one or more percent signs.
- If *m* is not empty and *p* is empty, the result of the predicate is false.
- Otherwise, if *m* matches the pattern in *p*, the result of the predicate is true. The description of *pattern-expression* provides a detailed explanation on how the pattern is matched to evaluate the predicate to true or false. See the “rigorous description of the pattern” for this information.

The values for *match-expression*, *pattern-expression*, and *escape-expression* must all be character or graphic strings or a mixture of both or they must all be binary strings (BLOBs). None of the expressions can yield a distinct type; however, an expression can be a function that casts a distinct type to its source type.

There are slight differences in what expressions are supported for each argument. The description of each argument lists the supported expressions:

### *match-expression*

An expression that specifies the string to be tested for conformity to a certain pattern of characters.

### **LIKE** *pattern-expression*

An expression that specifies the pattern of characters to be matched.

The expression can be specified by any one of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

The expression must also meet these restrictions:

- The maximum length of *pattern-expression* must not be larger than 4000 bytes.

- If a host variable is used in *pattern-expression*, the host variable must be defined in accordance with the rules for declaring string host variables and must not be a structure.
- If *escape-expression* is specified, *pattern-expression* must not contain the escape character identified by *escape-expression* except when immediately followed by the escape character, '%', or '\_'. For example, if '+' is the escape character, any occurrences of '+' other than '++', '+\_', or '+' in the pattern is an error.

When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character host variable is used to replace the parameter marker, specify a value for the host variable that is the correct length. If you do not specify the correct length, the select does not return the intended results. For example, if the host variable is defined as CHAR(10) and the value WYSE% is assigned to that host variable, the host variable is padded with blanks on assignment. The pattern used is 'WYSE ', which requests DB2 to search for all values that start with WYSE and end with five blank spaces. If you intended to search for only the values that start with 'WYSE ', you should assign the value 'WYSE%%%%%%%%%' to the host variable.

If the pattern is specified in a fixed-length string variable, any trailing blanks are interpreted as part of the pattern. Therefore, it is better to use a varying-length string variable with an actual length that is the same as the length of the pattern. If the host language does not allow varying-length string variables, place the pattern in a fixed-length string variable whose length is the length of the pattern.

For more on the use of host variables with specific programming languages, see *DB2 Application Programming and SQL Guide*.

The pattern is used to specify the conformance criteria for values in the *match-expression* where:

- The underscore character (\_) represents any single character.
- The percent sign (%) represents a string of zero or more characters.
- Any other character represents a single occurrence of itself.

If the *pattern-expression* needs to include either the underscore or the percent character, the *escape-expression* is used to specify a character to precede either the underscore or percent character in the pattern. For character strings, the terms *character*, *percent sign*, and *underscore* refer to SBCS characters. For graphic strings, the terms refer to double-byte or UTF-16 characters.

**A rigorous description of the pattern:** This more rigorous description of the pattern ignores the use of the *escape-expression*.

Let  $m$  denote the value of *match-expression* and let  $p$  denote the value of *pattern-expression*. The string  $p$  is interpreted as a sequence of the minimum number of substring specifiers so each character of  $p$  is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any non-empty sequence of characters other than an underscore or a percent sign.

The result of the predicate is unknown if  $m$  or  $p$  is the null value. Otherwise, the result is either true or false. The result is true if  $m$  and  $p$  are both empty strings or there exists a partitioning of  $m$  into substrings such that:

- A substring of  $m$  is a sequence of zero or more contiguous characters and each character of  $m$  is part of exactly one substring.
- If the  $n$ th substring specifier is an underscore, the  $n$ th substring of  $m$  is any single character.
- If the  $n$ th substring specifier is a percent sign, the  $n$ th substring of  $m$  is any sequence of zero or more characters.
- If the  $n$ th substring specifier is neither an underscore nor a percent sign, the  $n$ th substring of  $m$  is equal to that substring specifier and has the same length as that substring specifier.
- The number of substrings of  $m$  is the same as the number of substring specifiers.

It follows that if  $p$  is an empty string and  $m$  is not an empty string, the result is false. Similarly, if  $m$  is an empty string and  $p$  is not an empty string consisting of a value other than percentage signs, the result is false.

The predicate  $m \text{ NOT LIKE } p$  is equivalent to the search condition  $\text{NOT } (m \text{ LIKE } p)$ .

**Mixed data patterns:** If *match-expression* represents mixed data, the pattern is assumed to be mixed data. For ASCII and EBCDIC, the special characters in the pattern are interpreted as follows:

- An SBCS underscore refers to one SBCS character.
- A DBCS underscore refers to one MBCS character.
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

For EBCDIC, redundant shift bytes in *match-expression* or *pattern-expression* are ignored.

For Unicode, the special characters in the pattern are interpreted as follows:

- An SBCS or DBCS underscore refers to one character (either SBCS or MBCS).
- A percent sign (either SBCS or DBCS) refers to a string of zero or more SBCS or MBCS characters.

When the LIKE predicate is used with Unicode data, the Unicode percent sign and underscore use the code points indicated in the following table:

Character	UTF-8	UTF-16
Half-width %	X'25'	X'0025'
Full-width %	X'EFBC85'	X'FF05'
Half-width_	X'5F'	X'005F'
Full-width_	X'EFBCBF'	X'FF3F'

The full-width or half-width % matches zero or more characters. The full-width or half width\_ character matches exactly one character. (For ASCII or EBCDIC

data, a full-width \_ character matches one DBCS character.)

#### **ESCAPE** *escape-expression*

An expression that specifies the escape character to be used to modify the special meaning of the underscore (\_) and percent (%) characters in *pattern-expression*. Specifying an expression, which is optional, allows the LIKE predicate to explicitly test that the value contains a "%" or '\_' in the desired character positions. The escape character consists of a single SBCS (1 byte) or DBCS (2 bytes) character. An escape clause is allowed for Unicode mixed (UTF-8) data, but is restricted for ASCII and EBCDIC mixed data.

The expression can be specified by any one of:

- A constant
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above

The following rules also apply to the use of the **ESCAPE** clause and *escape-expression*:

- The result of *escape-expression* must be one SBCS or DBCS character or a binary string that contains exactly 1 byte.
- The **ESCAPE** clause cannot be used if *match-expression* is mixed data.
- If *escape-expression* is specified by a host variable, the host variable must be defined in accordance with the rules for declaring fixed-length string host variables.<sup>17</sup> If the host variable has a negative indicator variable, the result of the predicate is unknown.
- The pattern must not contain the escape character except when followed by the escape character, '%' or '\_'. For example, if '+' is the escape character, any occurrences of '+' other than '+%', '+\_', or '+%' in the pattern is an error.

The following table shows the effect of successive occurrences of the escape character, which in this case is the plus sign (+).

*Table 48. Effect of successive occurrences of the escape character*

When the pattern string is...	The actual pattern is...
+%	A percent sign
++%	A plus sign followed by zero or more arbitrary characters
+++%	A plus sign followed by a percent sign

## Examples

*Example 1:* The following predicate is true when the string to be tested in NAME has the value SMITH, NESMITH, SMITHSON, or NESMITHY. It is not true when the string has the value SMYTHe:

```
NAME LIKE '%SMITH%'
```

*Example 2:* In the predicate below, a host variable named PATTERN holds the string for the pattern:

```
NAME LIKE :PATTERN ESCAPE '+'
```

17. If it is NUL-terminated, a C character string variable of length 2 can be specified.

Assume that the string in PATTERN has the value:

`AB+_C_%`

Observe that in this string, the plus sign preceding the first underscore is an escape character. The predicate is true when the string being tested in NAME has the value AB\_CD or AB\_CDE. It is false when this string has the value AB, AB\_, or AB\_C.

*Example 3:* The following two predicates are equivalent; three of the four percent signs in the first predicate are redundant.

```
NAME LIKE 'AB%%%CD'
NAME LIKE 'AB%CD'
```

*Example 4:* Assume that a distinct type named ZIP\_TYPE with a source data type of CHAR(5) exists and an ADDRZIP column with data type ZIP\_TYPE exists in some table TABLEY. The following statement selects the row if the zip code (ADDRZIP) begins with '9555'.

```
SELECT * FROM TABLEY
  WHERE CHAR(ADDRZIP) LIKE '9555'
```

*Example 5:* The RESUME column in sample table DSN8910.EMP\_PHOTO\_RESUME is defined as a CLOB. The following statement selects the RESUME column when the string JONES appears anywhere in the column.

```
SELECT RESUME FROM DSN8910.EMP_PHOTO_RESUME
  WHERE RESUME LIKE '%JONES%'
```

*Example 6:* In the following table, assume COL1 is a column that contains mixed EBCDIC data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

Predicates	COL1 Values	Result
WHERE COL1 LIKE 'aaa <sup>s</sup> <sub>o</sub> AB% <sup>s</sup> <sub>i</sub> C <sup>s</sup> <sub>i</sub> '	'aaa <sup>s</sup> <sub>o</sub> ABDZC <sup>s</sup> <sub>i</sub> '	True
WHERE COL1 LIKE 'aaa <sup>s</sup> <sub>o</sub> AB <sup>s</sup> <sub>i</sub> % <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	'aaa <sup>s</sup> <sub>o</sub> AB <sup>s</sup> <sub>i</sub> dzx <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	True
WHERE COL1 LIKE 'a% <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	'a <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> ' 'ax <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> ' 'ab <sup>s</sup> <sub>o</sub> DE <sup>s</sup> <sub>i</sub> fg <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	True True True
WHERE COL1 LIKE 'a_ <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	'a% <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> ' 'a <sup>s</sup> <sub>o</sub> XC <sup>s</sup> <sub>i</sub> '	True False
WHERE COL1 LIKE 'a <sup>s</sup> <sub>o</sub> _C <sup>s</sup> <sub>i</sub> '	'a <sup>s</sup> <sub>o</sub> XC <sup>s</sup> <sub>i</sub> ' 'ax <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> '	True False
WHERE COL1 LIKE '_ <sup>s</sup> <sub>o</sub> <sup>s</sup> <sub>i</sub> '	Empty string	True
WHERE COL1 LIKE 'ab <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> d'	'ab <sup>s</sup> <sub>o</sub> C <sup>s</sup> <sub>i</sub> d' 'ab <sup>s</sup> <sub>o</sub> <sup>s</sup> <sub>i</sub> oC <sup>s</sup> <sub>i</sub> d'	True True

*Example 7:* In the following table, assume COL1 is a column that contains mixed ASCII data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

Predicates	COL1 Values	Result
WHERE COL1 LIKE 'aaa <b>A</b> B% <b>C</b> '	'aaa <b>A</b> BDZC'	True
WHERE COL1 LIKE 'aaa <b>A</b> B % <b>C</b> '	'aaa <b>A</b> B dzx <b>C</b> '	True

*Example 8:* In the following table, assume COL1 is a column that contains Unicode data. The table shows the results when the predicate in the first column is evaluated using the COL1 value in the second column:

Table 49. COL1 contain Unicode data

Predicates	COL1 values	Result
WHERE COL1 LIKE 'aaaAB%C'	'aaaABDZC'	True
	'aaaABdzcC'	True
	empty string	False
WHERE COL1 LIKE 'aaaAB%C'	'aaaABDZC'	True
	'aaaABdzcC'	True
	empty string	False
WHERE COL1 LIKE ''	'aaaABDZC'	False
	'aaaABdzcC'	False
	empty string	True
WHERE COL1 LIKE '%'	'aaaABDZC'	True
	'aaaABdzcC'	True
	empty string	True
WHERE COL1 LIKE '%'	'aaaABDZC'	True
	'aaaABdzcC'	True
	empty string	False
' WHERE COL1 LIKE '''	'aaaABDZC'	False
	'aaaABdzcC'	False
	empty string	False

## **NULL predicate**

The NULL predicate tests for null values.

The result of a NULL predicate cannot be unknown. If the value of the expression is null, the result is true. If the value is not null, the result is false. If NOT is specified, the result is reversed.

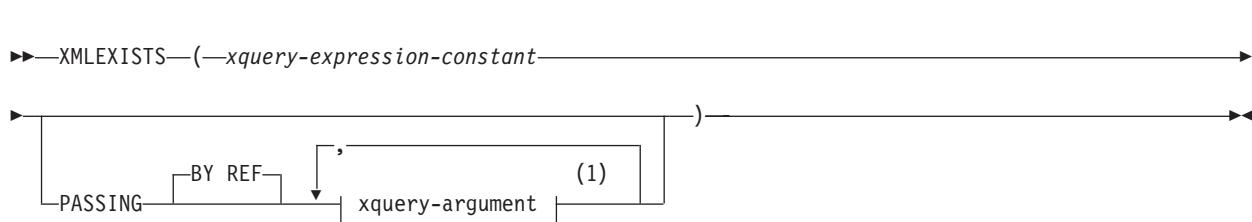

A parameter marker must not be specified for or within the expression.

*Example:* The following predicate is true whenever PHONENO has the null value, and is false otherwise.

PHONENO IS NULL

## XMLEXISTS predicate

The XMLEXISTS predicate tests whether an XPath expression returns a sequence of one or more items.

### Notes:

- 1 *xquery-context-item-expression* must not be specified more than one time.

## xquery-argument

### xquery-expression-constant

Specifies a character string constant that is interpreted as an XPath expression using supported XPath language syntax. See *DB2 XML Guide* for information about the XPath language syntax. The XPath expression is evaluated with the arguments specified in *xquery-argument*. *xquery-expression-constant* must not be an empty string or a string of all blanks.

### PASSING

Specifies input values and the manner in which these values are passed to the XPath expression specified by *xquery-expression-constant*.

### BY REF

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XPath evaluation uses the input node trees, preserving all properties including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons that involve some nodes that are contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

### xquery-argument

Specifies an argument to use in the evaluation of the XPath expression specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression or a *OLAP-specification*.

An argument specifies a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XPath expression depends on whether the argument is specified as the *xquery-context-item-expression* or an *xquery-variable-expression*. The argument includes an SQL expression that is evaluated before passing the result to the XPath expression.

- If the resulting value is an XML value, it becomes an *input-xml-value*. It is passed by reference which means that the original values, not copies, are used in the evaluation of the XPath expression.
- If the resulting value is not an XML value, the result of the expression must be able to be cast to an XML value. The cast value becomes an *input-xml-value*. An empty string is converted to an XML empty string.
- If the resulting value is a null value, it is converted to an XML empty sequence if the argument is *xquery-variable-expression*. If the argument is *xquery-context-expression*, the XMLEXISTS predicates returns unknown.

#### *xquery-context-item-expression*

*xquery-context-item-expression* specifies the *initial context item* in the XPath expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

*xquery-context-item-expression* must not be a sequence of more than one item. If the result of *xquery-context-item-expression* is an empty string, the XPath expression is evaluated with the initial context item set to an XML empty string.

If the *xquery-context-item-expression* is not specified or is an empty string, the initial context item in the XPath expression is undefined, and the XPath expression must not reference the initial context item. An XPath variable is not created for the context item expression.

If the *xquery-context-expression* is not specified or the *input-xml-value* that results from the *xquery-context-expression* is an XML empty sequence, the initial context item is undefined. If the XPath expression refers to the initial context item, it must be specified with a value that is not an XML empty sequence.

#### *xquery-variable-expression*

*xquery-variable-expression* specifies an argument to the XPath expression. An XPath variable is created for each *xquery-variable-expression*, and the XPath variable is set to the result of *xquery-argument-expression* cast to XML. If the result of *xquery-variable-expression* is an empty string, the XPath variable is set to an XML empty string. If *xquery-variable-expression* is null, the XPath variable is set to an XML empty sequence. For example, PASSING T.A + T.B as "sum" creates an XPath variable named sum. The scope of the XPath variables created from the PASSING clause is the XPath expression that is specified by *xquery-expression-constant*.

#### **AS** *identifier*

Specifies that the value that is generated by *xquery-variable-expression* will be passed to *xquery-expression-constant* as an XPath variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign (\$) that precedes variable names in the XPath language is not included in *identifier*. The name must be an XML NCName that is not the same as *identifier* for another *xquery-variable-expression* in the same PASSING clause.

The result of the predicate is determined as follows:

- The result is unknown if *xquery-context-item-expression* specified in the PASSING clause is a NULL value
- the result is false if the result of the XPath expression is an empty sequence
- the result is true in all other cases

If the evaluation of the XPath expression results in an error, XMLEXISTS returns an error. The XMLEXISTS predicate is not supported in ON clause of outer joins.

*Example:* Find all the purchase orders that buy a baby monitor. This example finds the product number for baby monitors from the product table and joins the result to the PurchaseOrders table. It then evaluates the XPath expression //item[@partnum = \$n] for each row and returns those rows that contain an item element node with a partNum attribute that is equal to the product number of 'Baby Monitor'. The context item for the XPath expression is PO.POrder. An XPath variable, \$n, is created and initialized to the value of S.prodno:

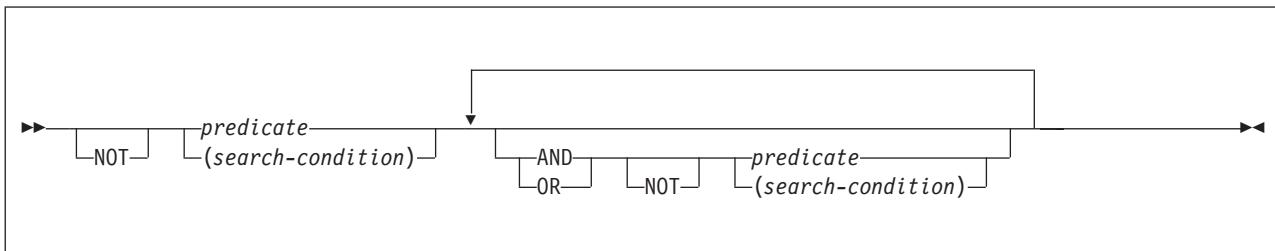

```
SELECT S.prodno, count(*) as result
      FROM PurchaseOrders PO, Products S
     WHERE XMLEXISTS ('//item[@partNum = $n]' 
                      PASSING PO.POrder,
                      S.prodno AS "n")
       AND S.prod_name = 'Baby Monitor';
```

The results might be similar to the following:

Prodno	result
926-AA	1

## Search conditions

A *search condition* specifies a condition that is true, false, or unknown about a given row or group. When the condition is true, the row or group qualifies for the results. When the condition is false or unknown, the row or group does not qualify.

The result of a search condition is derived by application of the specified *logical operators* (AND, OR, NOT) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and OR are defined in the following table, in which *P* and *Q* are any predicates:

Table 50. Truth table for AND and OR

<i>P</i>	<i>Q</i>	<i>P and Q</i>	<i>P or Q</i>
True	True	True	True
True	False	False	True
True	Unknown	Unknown	True
False	True	False	True
False	False	False	False
False	Unknown	False	Unknown
Unknown	True	Unknown	True
Unknown	False	False	Unknown
Unknown	Unknown	Unknown	Unknown

NOT(true) is false and NOT(false) is true, but NOT(unknown) is still unknown. The NOT logical operator has no affect on an unknown condition. The result of NOT(unknown) is still unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

*Example 1:* In the first of the search conditions below, AND is applied before OR. In the second, OR is applied before AND.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB  
SALARY>:SS AND (COMM>:CC OR BONUS>:BB)
```

*Example 2:* In the first of the search conditions below, NOT is applied before AND. In the second, AND is applied before NOT.

```
NOT SALARY>:SS AND COMM>:CC  
NOT (SALARY>:SS AND COMM>:CC)
```

*Example 3:* For the following search condition, AND is applied first. After the application of AND, the OR operators could be applied in either order without changing the result. DB2 can therefore select the order of applying the OR operators.

```
SALARY>:SS AND COMM>:CC OR BONUS>:BB OR SEX=:GG
```

## Options affecting SQL

Certain DB2 precompiler options, DB2 subsystem parameters (set through the installation panels), bind options, options for CREATE PROCEDURE and ALTER PROCEDURE statements for native SQL procedures, and special registers affect how SQL statements can be composed or determine how SQL statements are processed.

The following table summarizes the effect of these options and shows where to find more information. (Some of the items are described in detail following the table, while other items are described elsewhere.)

*Table 51. Summary of items affecting composition and processing of SQL statements*

Precompiler option	Other <sup>1</sup>	Affects
	DYNAMICRULES bind option or the native SQL procedures option	The rules that DB2 applies to dynamic SQL statements. For details about authorization, see “Authorization IDs and dynamic SQL” on page 64. The option can also affect decimal point representation, string delimiters, and decimal arithmetic.
	USE FOR DYNAMICRULES	For details about how DB2 applies the options to dynamic SQL statements when DYNAMICRULES bind, define, or invoke behavior is in effect, see “Precompiler options for dynamic statements” on page 250.
COMMA PERIOD	DECIMAL POINT IS	Use of options for dynamic statements when DYNAMICRULES bind, define, or, invoke behavior is in effect. For details, see “Precompiler options for dynamic statements” on page 250.
APOSTSQL QUOTESQL	SQL STRING DELIMITER	Representation of decimal points in SQL statements.
		For details, see page “Decimal point representation” on page 251.
	ASCII CODED CHAR SET	Representation of string delimiters in SQL statements.
		For details, see page “Apostrophes and quotation marks as string delimiters” on page 253.
		A numeric value that determines the CCSID of ASCII string data.
		For details, see page “Mixed data in character strings” on page 254.

*Table 51. Summary of items affecting composition and processing of SQL statements (continued)*

Precompiler option	Other <sup>1</sup>	Affects
	EBCDIC CODED CHAR SET	A numeric value that determines the CCSID of EBCDIC string data and whether Katakana characters can be used in ordinary identifiers.  For details, see page “Katakana characters for EBCDIC” on page 254.
	UNICODE CCSID	A numeric value that determines the CCSID of Unicode string data.  For details, see page “Mixed data in character strings” on page 254.
CCSID	MIXED DATA	Use of ASCII or EBCDIC character strings with a mixture of SBCS and DBCS characters.  For details, see page “Mixed data in character strings” on page 254.
DATE TIME	DATE FORMAT TIME FORMAT LOCAL DATE LENGTH LOCAL TIME LENGTH	Formatting of datetime strings.  For details, see page “Formatting of datetime strings” on page 255.
STDSQL		Conformance with the SQL standard.  For details, see page “SQL standard language” on page 255.
NOFOR or STDSQL		Whether the FOR UPDATE clause must be specified (in the SELECT statement of the DECLARE CURSOR statement).  For details, see page “Positioned updates of columns” on page 256.
CONNECT		Whether the rules for the CONNECT(1) or CONNECT(2) precompiler option apply.  For details about the precompiler option, see <i>DB2 Application Programming and SQL Guide</i> .
	SQLRULES bind option	Whether a CONNECT statement is processed with DB2 rules or SQL standard rules.

*Table 51. Summary of items affecting composition and processing of SQL statements (continued)*

Precompiler option	Other <sup>1</sup>	Affects
	CURRENT RULES special register	Whether the statements ALTER TABLE, CREATE TABLE, GRANT, and REVOKE are processed with DB2 rules or SQL standard rules. For details, see "CURRENT RULES" on page 145.
		Whether DB2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for a LOB column in a base table. For details, see Creating a table with LOB columns.
		Whether DB2 automatically creates an index on a ROWID column that is defined with GENERATED BY DEFAULT. For details, see the description of the clause for "CREATE TABLE" on page 1079.
		Whether an external stored procedure runs as a main or subprogram. For details, see "CREATE PROCEDURE (external)" on page 1016.
	SQLRULES bind option or CURRENT RULES special register	Whether SQLCODE +236 is issued when the SQLDA provided on DESCRIBE or PREPARE INTO is too small and the result columns do not involve LOBs or distinct types. For details, see "DESCRIBE" on page 1237 and "SQL descriptor area (SQLDA)" on page 1656.
		Whether the SELECT privilege is required in a searched DELETE or UPDATE. For details, see "DELETE" on page 1224 or "UPDATE" on page 1521.
DEC	DECIMAL ARITHMETIC or CURRENT PRECISION special register	Whether DEC15 or DEC31 rules are used when both operands in a decimal operation have 15 digits or less. For details, see "Arithmetic with two decimal operands" on page 183.

**Note:** <sup>1</sup> The entries in this column are fields on installation panels unless otherwise noted.

For further details on precompiler options, see *DB2 Application Programming and SQL Guide*. For more details on bind options, see *DB2 Command Reference*.

## Precompiler options for dynamic statements

Generally, dynamic statements use the application programming defaults specified on installation panel DSNTIPF. However, if the value of installation panel field USE FOR DYNAMICRULES is NO and DYNAMICRULES bind, define, or invoke behavior is in effect, certain precompiler options are used instead of the application programming defaults.

The following precompiler options are used instead of the application programming defaults:

- COMMA or PERIOD
- APOST or QUOTE
- APOSTSQL or QUOTESQL
- DEC(15) or DEC(31)

For some languages, the precompiler option defaults to a value and no alternative is allowed. If the value of installation panel field USE FOR DYNAMICRULES is YES, dynamic statements use the application programming defaults regardless of the value of DYNAMICRULES option.

For additional information on the effect of precompiler options and application programming defaults on:

- Decimal point representation, see “Decimal point representation.”
- String delimiters, see “Apostrophes and quotation marks as string delimiters” on page 253.
- Decimal arithmetic, see “Arithmetic with two decimal operands” on page 183.

For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.

## DECFLOAT rounding mode

All views and SQL functions referenced in an SQL statement must either not have rounding mode information stored in the SYSENVIRONMENT catalog, or they must all have the same rounding mode information in the SYSENVIRONMENT catalog.

## Decimal point representation

Decimal points in SQL statements are represented with either periods or commas.

Two values control the representation:

- The value of field DECIMAL POINT IS on installation panel DSNTIPF, which can be a comma (,) or period (.)
- COMMA or PERIOD, which are mutually exclusive DB2 precompiler options for COBOL

These values apply to SQL statements as follows:

- For a distributed operation, the decimal point is the first of the following values that applies:
  - The decimal point value specified by the requester
  - The value of field DECIMAL POINT IS on panel DSNTIPF at the DB2 where the package is bound
- Otherwise:
  - For static SQL statements:
    - In a COBOL program, the DB2 precompiler option COMMA or PERIOD determines the decimal point representation for every static SQL statement. If neither precompiler option is specified, the value of DECIMAL POINT IS at precompilation time determines the representation.
    - In non-COBOL programs, the decimal representation for static SQL statements is always the period.
  - For dynamic SQL statements:
    - If DYNAMICRULES run behavior applies, the decimal point is the value of field DECIMAL POINT IS on installation panel DSNTIPF at the local DB2 when the statement is prepared.
    - For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.
    - If DYNAMICRULES bind, define, or invoke behavior applies, and the value of install panel field USE FOR DYNAMICRULES is YES, the decimal point is the value of field DECIMAL POINT IS.

If bind, define, or invoke behavior applies, and field USE FOR DYNAMIC RULES is NO, the precompiler option determines the decimal point representation. For COBOL programs, which supports precompiler option COMMA or PERIOD, the decimal point representation is determined as described above for static SQL statements in COBOL programs. For programs written in other host languages, the default precompiler option, which can only be PERIOD, is used.

If the comma is the decimal point, these rules apply:

- In any context, a comma intended as a separator must be followed by a space. Such commas could appear, for example, in a VALUES clause, an IN predicate, or an ORDER BY clause in which numbers are used to identify columns.
- In any context, a comma intended as a decimal point must not be followed by a space.
- If the DECIMAL POINT IS field (and not the precompiler option) determines the comma as the decimal point, DB2 will recognize either a comma or a period as the decimal point in numbers in dynamic SQL.

## Apostrophes and quotation marks as string delimiters

Precompiler options and DB2 installation panel fields control the representation of string delimiters in COBOL and SQL statements.

The following precompiler options control the representation of string delimiters:

- APOST and QUOTE are mutually exclusive DB2 precompiler options for COBOL. Their meanings are exactly what they are for the COBOL compilers:
  - APOST names the apostrophe (') as the string delimiter in COBOL statements.
  - QUOTE names the quotation mark ("") as the string delimiter.
- Neither option applies to SQL syntax. Do not confuse them with the APOSTSQL and QUOTESQL options.
- APOSTSQL and QUOTESQL are mutually exclusive DB2 precompiler options for COBOL. Their meanings are:
  - APOSTSQL names the apostrophe (') as the string delimiter and the quotation mark ("") as the escape character in SQL statements.
  - QUOTESQL names the quotation mark ("") as the string delimiter and the apostrophe (') as the escape character in SQL statements.

These values apply to SQL statements as follows:

- For a distributed operation, the string delimiter is the first of the following values that applies:
  - The SQL string delimiter value specified by the requester
  - The value of the field SQL STRING DELIMITER on installation panel DSNTIPF at the DB2 where the package is bound
- Otherwise:
  - For static SQL statements:

In a COBOL program, the DB2 precompiler option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither precompiler option is specified, the value of field SQL STRING DELIMITER on installation panel DSNTIPF determines the string delimiter and escape character.  
In a non-COBOL program, the string delimiter is the apostrophe, and the escape character is the quotation mark.
  - For dynamic SQL statements:
    - If DYNAMICRULES run behavior applies, the string delimiter and escape character is the value of field SQL STRING DELIMITER on installation panel DSNTIPF at the local DB2 when the statement is prepared.  
For a list of the DYNAMICRULES option values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.
    - If DYNAMICRULES bind, define, or invoke behavior applies and the value of install panel field USE FOR DYNAMICRULES is YES, the string delimiter and escape character is the value of field SQL STRING DELIMITER.

If bind, define, or invoke behavior applies and USE FOR DYNAMICRULES is NO, the precompiler option determines the string delimiter and escape character. For COBOL programs, precompiler option APOSTSQL or QUOTESQL determines the string delimiter and escape character. If neither precompiler option is specified, the value of field SQL STRING DELIMITER determines them. For programs written in other host languages, the default precompiler option, which can only be APOSTSQL, determines the string delimiter and escape character.

## Katakana characters for EBCDIC

Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the DB2 installation is set to allow it.

The field EBCDIC CODED CHAR SET on installation panel DSNTIPF determines the system CCSIDs for EBCDIC-encoded data. Ordinary identifiers with an EBCDIC encoding scheme can contain Katakana characters if the field contains the value 5026 or 930. There are no corresponding precompiler options. EBCDIC CODED CHAR SET applies equally to static and dynamic statements. For dynamically prepared statements, the applicable value is always the one at the local DB2.

## Mixed data in character strings

Mixed character data and graphic data are always allowed for Unicode, but for EBCDIC and ASCII, the specific installation of DB2 determines whether mixed data can be used.

The field MIXED DATA on installation panel DSNTIPF can have the value YES or NO for ASCII or EBCDIC character strings. The value YES indicates that character strings can contain a mixture of SBCS and DBCS characters. The value NO indicates that they cannot. Mixed character data and graphic data are always allowed for Unicode; that is the MIXED DATA field does not have an effect on Unicode data.

For static SQL statements, the value of the CCSID precompiler option or the derived CCSID for the DB2 coprocessor determines whether ASCII or EBCDIC character strings can contain mixed data. If a mixed CCSID is used, mixed strings are allowed. If a single-byte CCSID is used, mixed strings are not allowed.

For dynamic SQL statements, the CCSID that is selected to convert the dynamic statement text to UTF-8 determines whether ASCII or EBCDIC character strings can contain mixed data. The CCSID for a dynamic statement is determined from the SQLDA override (if any) for the host variable on the PREPARE statement, the value of the CURRENT ENCODING SCHEME special register, and the ENCODING bind option.

The value of MIXED DATA affects the parsing of SQL character string constants, the execution of the LIKE predicate, and the assignment of character strings to host variables when truncation is needed. It can also affect concatenation, as explained in “With the concatenation operator” on page 188. A value that applies to a statement executed at the local DB2 also applies to any statement executed at another server. An exception is the LIKE predicate, for which the applicable value of MIXED DATA is always the one at the statement’s server.

The value of MIXED DATA also affects the choice of system CCSIDs for the local DB2 and the choice of data subtypes for character columns. When this value is YES, multiple CCSIDs are available for ASCII and EBCDIC data (SBCS, DBCS, and MIXED). The CCSID specified in the ASCII CODED CHAR SET or EBCDIC CODED CHAR SET field is the MIXED CCSID. In this case, DB2 derives the SBCS and MIXED CCSIDs from the DBCS CCSID specified installation panel DSNTIPF. Moreover, a character column can have any one of the allowable data subtypes—BIT, SBCS, or MIXED.

On the other hand, when MIXED DATA is NO, the only ASCII or EBCDIC system CCSIDs are those for SBCS data. Therefore, only BIT and SBCS can be data subtypes for character columns.

## Formatting of datetime strings

The format for a datetime string that is in effect for a statement that is executed at the local DB2 is not necessarily in effect for a statement that is executed at a different server.

Fields on installation panel DSNTIP4 (DATE FORMAT, TIME FORMAT, LOCAL DATE LENGTH, and LOCAL TIME LENGTH) and DB2 precompiler options affect the formatting of datetime strings.

The formatting of datetime strings is described in “String representations of datetime values” on page 89. Unlike the subsystem parameters and options previously described, a value in effect for a statement executed at the local DB2 is not necessarily in effect for a statement executed at a different server. See “Restrictions on the use of local datetime formats” on page 92 for more information.

## SQL standard language

DB2 SQL and the SQL standard are not identical. The STDSQL precompiler option addresses some of the differences.

- STDSQL(NO) indicates that conformance with the SQL standard is not intended. The default is the value of field STD SQL LANGUAGE on installation panel DSNTIP4 (which has a default of NO).
- STDSQL(YES)<sup>18</sup> indicates that conformance with the SQL standard is intended.

When a program is precompiled with the STDSQL(YES) option, the following rules apply:

*Declaring host variables:* All host variable declarations except in Java and REXX must lie between pairs of BEGIN DECLARE SECTION and END DECLARE SECTION statements:

```
BEGIN DECLARE SECTION
  -- one or more host variable declarations
END DECLARE SECTION
```

Separate pairs of these statements can bracket separate sets of host variable declarations.

*Declarations for SQLCODE and SQLSTATE:* The programmer must declare host variables for either SQLCODE or SQLSTATE, or both. SQLCODE should be defined as a fullword integer and SQLSTATE should be defined as a 5-byte character string. SQLCODE and SQLSTATE cannot be part of any structure. The variables must be declared in the DECLARE SECTION of a program; however, SQLCODE can be declared outside of the DECLARE SECTION when no host variable is defined for SQLSTATE. For PL/I, an acceptable declaration can look like this:

```
DECLARE SQLCODE BIN FIXED(31);
DECLARE SQLSTATE CHAR(5);
```

---

18. STDSQL(86) is a synonym, but STDSQL(YES) should be used.

In Fortran programs, the variable SQLCOD should be used for SQLCODE, and either SQLSTATE or SQLSTA can be used for SQLSTATE.

**Definitions for the SQLCA:** An SQLCA must not be defined in your program, either by coding its definition manually or by using the INCLUDE SQLCA statement. When STDSQL(YES) is specified, the DB2 precompiler automatically generates an SQLCA that includes the variable name SQLCADE instead of SQLCODE and SQLSTAT instead of SQLSTATE. After each SQL statement executes, DB2 assigns status information to SQLCODE and SQLSTATE, whose declarations are described above, as follows:

- SQLCODE: DB2 assigns the value in SQLCADE to SQLCODE. In Fortran, SQLCAD and SQLCOD are used for SQLCADE and SQLCODE, respectively.
- SQLSTATE: DB2 assigns the value in SQLSTAT to SQLSTATE. (In Fortran, SQLSTT and SQLSTA are used for SQLSTAT and SQLSTATE, respectively.)
- No declaration for either SQLSTATE or SQLCODE: DB2 assigns the value in SQLCADE to SQLCODE.

If the precompiler encounters an INCLUDE SQLCA statement, it ignores the statement and issues a warning message. The precompiler also does not recognize hand-coded definitions, and a hand-coded definition creates a compile-time conflict with the precompiler-generated definition. A similar conflict arises if definitions of SQLCADE or SQLSTAT, other than the ones generated by the DB2 precompiler, appear in the program.

## Positioned updates of columns

Certain precompiler options affect the use of the FOR UPDATE clause to achieve positioned column updates.

The NOFOR precompiler option affects the use of the FOR UPDATE clause. The NOFOR option is in effect when either of the following are true:

- The NOFOR option is specified.
- The STDSQL(YES) option is in effect.

Otherwise, the NOFOR option is not in effect. The following table summarizes the differences when the option is in effect and when the option is not in effect:

*Table 52. The NOFOR precompiler option*

When NOFOR is in effect	When NOFOR is not in effect
The use of the FOR UPDATE clause in the SELECT statement of the DECLARE CURSOR statement is optional. This clause restricts updates to the specified columns and causes the acquisition of update locks when the cursor is used to fetch a row. If no columns are specified, positioned updates can be made to any updatable columns in the table or view that is identified in the first FROM clause in the SELECT statement. If the FOR UPDATE clause is not specified, positioned updates can be made to any columns that the program has DB2 authority to update.	The FOR UPDATE clause must be specified.

*Table 52. The NOFOR precompiler option (continued)*

When NOFOR is in effect	When NOFOR is not in effect
DBRMs must be built entirely in virtual storage, which might possibly increase the virtual storage requirements of the DB2 precompiler. However, creating DBRMs entirely in virtual storage might cause concurrency problems with DBRM libraries.	DBRMs can be built incrementally using the DB2 precompiler.

Precompiler options do not affect ODBC behavior.

## Mappings from SQL to XML

DB2 maps SQL to XML data according to industry standards and performs several different mappings.

To construct XML data from SQL data, the following mappings are performed:

- SQL character sets to XML character sets
- SQL identifiers to XML names
- SQL data values to XML data values

DB2 maps SQL to XML data according to industry standards. For complete information, see *Information technology - Database languages - SQL- Part 14: XML-Related Specifications (SQL/XML) ISO/IEC 9075-14:2003*.

### Mapping SQL character sets to XML character sets

The character set used for XML data is Unicode UTF-8. SQL character data is converted into Unicode when it is used in XML built-in functions.

### Mapping SQL identifiers to XML names

Many SQL identifiers that contain certain characters must be escaped when the SQL identifier is converted into an XML name.

Strings that start with 'XML', in any case combination, are reserved for standardization, and characters such as '#', '{', and '}' are not allowed in XML names. Many SQL identifiers containing these characters have to be escaped when converting into XML names.

Full escaping is applied to SQL identifiers that are column names to derive an XML name. The mapping converts a colon (:) to \_x003A\_, \_x to \_X005F\_x, and other restricted characters to a string of the form \_xUUUU\_ where xUUUU is the Unicode value for the character. An identifier with an initial 'xml' (in any case combination) is escaped by mapping the initial 'x' or 'X' to \_x0058\_ or \_0078\_, respectively, while the partially escaped variant does not.

### Mapping SQL data values to XML data values

SQL data values are mapped to XML values based on SQL data types.

The following data types are not supported and cannot be used as arguments to XML value constructors:

- ROWID
- Character strings that are defined with the FOR BIT DATA attribute
- Binary strings

- A string or a binary string distinct type that is based on a ROWID, FOR BIT DATA character string, or BLOB

For supported data types, the encoding scheme for XML values is Unicode.

---

## Chapter 3. Functions

A *function* is an operation denoted by a function name followed by zero or more input values that are enclosed in parentheses. It represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*.

The types of functions are aggregate, scalar, and table. A built-in function is classified as a aggregate function or a scalar function. A user-defined function can be a column, scalar, or table function.

### OLAP specification and functions

The RANK, DENSE\_RANK, and ROW\_NUMBER specifications are sometimes referred to as built-in 'functions'. Refer to "OLAP specification" on page 212 for more information on these specifications.

### DB2 MQSeries functions

DB2 MQSeries functions integrate MQSeries messaging operations within SQL statements. The functions help you integrate MQSeries messaging with database applications. You can use the functions to access MQSeries messaging from within SQL statements and to combine MQSeries messaging with DB2 database access.

To use the MQSeries functions that provide support for XML messages, you must have IBM DB2 XML Extender installed. DB2 XML Extender introduces the user-defined data types DB2XML.XMLVARCHAR and DB2XML.XMCLLOB that are used to support XML data in message processing. XMLVARCHAR is defined as VARCHAR(3000) and XMCLLOB is defined as CLOB(2G). Refer to *DB2 XML Extender for z/OS Administration and Programming* for more information about DB2 XML Extender.

The functions can be scalar or table functions. For more information on using MQSeries functions, see the information on enabling MQSeries functions in *DB2 Installation Guide* and on programming techniques in *DB2 Application Programming and SQL Guide*.

### Administrative scheduler functions

The administrative scheduler table functions provide information and status about the tasks that are scheduled to run using the administrative scheduler. The administrative scheduler provides the ability to run stored procedures, JCL jobs, and other administrative tasks according to a time or an event-based schedule. Refer to *DB2 Administration Guide* for additional information about the administrative scheduler.

The following table lists the functions that DB2 supports.

Table 53. Supported functions

Function name	Description
ABS	Returns the absolute value of its argument
ACOS	Returns the arc cosine of an argument as an angle, expressed in radians
ADD_MONTHS	Returns a date that represents the date argument plus the number of months argument

Table 53. Supported functions (continued)

Function name	Description
ADMIN_TASK_LIST	Returns a table with one row for each of the tasks that are defined in the administrative scheduler task list
ADMIN_TASK_STATUS	Returns a table with one row for each task in the administrative scheduler task list that contains the status for the last time the task was run
ASCII	Returns the ASCII code value of the leftmost character of the argument as an integer
ASCII CHR	Returns the character that corresponds to the ASCII code value that is specified by the argument
ASCII STR	Returns an ASCII version of the character or graphic string argument.
ASIN	Returns the arc sine of an argument as an angle, expressed in radians
ATAN	Returns the arc tangent of an argument as an angle, expressed in radians
ATANH	Returns the hyperbolic arc tangent of an argument as an angle, expressed in radians
ATAN2	Returns the arc tangent of $x$ and $y$ coordinates as an angle, expressed in radians
AVG	Returns the average of a set of numbers
BLOB	Returns a BLOB representation of its argument
BIGINT	Returns a big integer representation of its argument
BINARY	Returns a fixed-length binary string representation of its argument
CCSID_ENCODING	Returns the encoding scheme of a CCSID with a value of ASCII, EBCDIC, UNICODE, or UNKNOWN
CEILING	Returns the smallest integer greater than or equal to the argument
CHAR	Returns a fixed-length character string representation of its argument
CHARACTER_LENGTH	Returns the length of its argument in the number of string units that are specified
CLOB	Returns a CLOB representation of its argument
COALESCE	Returns the first argument in a set of arguments that is not null
COLLATION_KEY	Returns a string that represents the collation key of the argument in the specified collation
COMPARE_DECFLOAT	Returns a SMALLINT value that indicates whether two arguments are equal, or unordered, or whether one argument is greater than the other.
CONCAT	Returns the concatenation of two strings
CONTAINS	Returns a result about whether or not a match was found during a search of a text search index
CORRELATION	Returns the coefficient of the correlation of a set of number pairs
COS	Returns the cosine of an argument that is expressed as an angle in radians
COSH	Returns the hyperbolic cosine of an argument that is expressed as an angle in radians
COUNT	Returns the number of rows or values in a set of rows or values
COUNT_BIG	Same as COUNT, except the result can be greater than the maximum value of an integer

*Table 53. Supported functions (continued)*

Function name	Description
COVARIANCE or COVARIANCE_SAMP	Returns the (population) covariance of a set of number pairs
DATE	Returns a date derived from its argument
DAY	Returns the day part of its argument
DAYOFMONTH	Similar to DAY
DAYOFWEEK	Returns an integer in the range of 1 to 7, where 1 represents Sunday
DAYOFWEEK_ISO	Returns an integer in the range of 1 to 7, where 1 represents Monday
DAYOFYEAR	Returns an integer in the range of 1 to 366, where 1 represents January 1
DAYS	Returns an integer representation of a date
DBCLOB	Returns a DBCLOB representation of its argument
DECIMAL or DEC	Returns a decimal representation of its argument
DECFLOAT	Returns a DECFLOAT representation of its argument
DECFLOAT_SORTKEY	Returns a binary value that can be used when sorting DECFLOAT values
DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, or DECRYPT_DB	Returns the decrypted value of an encrypted argument
DEGREES	Returns the number of degrees for an argument that is expressed in radians
DIFFERENCE	Returns a value that represents the difference between the sounds of two strings based on applying the SOUNDEX function to the strings.
DIGITS	Returns a character string representation of a number
DOUBLE or DOUBLE_PRECISION	Returns a double precision floating-point representation of its argument
DSN_XMLVALIDATE	Returns an XML value that is the result of applying XML schema validation to the first argument.
DSN_XMLVALIDATE	Returns a varying length binary value that can only be used with the XMLPARSE function
EBCDIC_CHR	Returns the character that corresponds to the EBCDIC code value that is specified by the argument
EBCDIC_STR	Returns an EBCDIC version of the string argument
ENCRYPT_TDES	Returns the argument as an encrypted value
EXP	Returns the exponential function of an argument
EXTRACT	Returns a portion of a date or timestamp based on its arguments
FLOAT	Same as DOUBLE
FLOOR	Returns the largest integer that is less than or equal to the argument
GENERATE_UNIQUE	Returns a character string of bit data that is unique compared to any other execution of the function
GETHINT	Returns the embedded password hint from encrypted data, if one exists
GETVARIABLE	Returns a varying-length character string representation of the value of a session variable
GRAPHIC	Returns a fixed-length graphic string representation of its argument
HEX	Returns a hexadecimal representation of its argument

Table 53. Supported functions (continued)

Function name	Description
HOUR	Returns the hour part of its argument
IDENTITY_VAL_LOCAL	Returns the most recently assigned value for an identity column
IFNULL	Returns the first argument in a set of two arguments that is not null
INSERT	Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted
INTEGER or INT	Returns an integer representation of its argument
JULIAN_DAY	Returns an integer that represents the number of days from January 1, 4712 B.C.
LAST_DAY	Returns a date that represents the last day of the month of the date argument
LCASE	Returns a string with the characters converted to lowercase
LEFT	Returns a string that consists of the specified number of leftmost bytes or the specified string units
LENGTH	Returns the length of its argument
LN	Returns the natural logarithm of an argument
LOCATE	Returns the starting position of one string within another string
LOCATE_IN_STRING	Returns the starting position of the first occurrence of one string within another string
LOG10	Returns the base 10 logarithm of an argument
LOWER	Returns a string with the characters converted to lowercase
LPAD	Returns a string that is padded on the left with blanks or a specified string
LTRIM	Returns the characters of a string with the leading blanks or hexadecimal zeros removed
MAX (aggregate)	Returns the maximum value in a set of column values
MAX (scalar)	Returns the maximum value in a set of values
MICROSECOND	Returns the microsecond part of its argument
MIDNIGHT_SECONDS	Returns an integer in the range of 0 to 86400 that represents the number of seconds between midnight and the argument
MIN (aggregate)	Returns the minimum value in a set of column values
MIN (scalar)	Returns the minimum value in a set of values
MINUTE	Returns the minute part of its argument
MOD	Returns the remainder of one argument divided by a second argument
MONTH	Returns the month part of its argument
MONTHS_BETWEEN	Returns an estimate of the number of months between two arguments
MQPUBLISH	Publishes a message to the specified MQSeries publisher, and returns a varying-length character string that indicates whether the function was successful or unsuccessful
MQPUBLISHXML	Publishes the XML data in a message to the specified MQSeries publisher

*Table 53. Supported functions (continued)*

Function name	Description
MQREAD	Returns a message from a specified MQSeries location (return value of VARCHAR) without removing the message from the queue
MQREADALL	Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and without removing the messages from the queue
MQREADALLCLOB	Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and without removing the messages from the queue
MQREADALLXML	Returns a table containing the messages and message metadata from a specified MQSeries location with a column that contains XML data without removing the messages from the queue
MQREADCLOB	Returns a message from a specified MQSeries location (return value of CLOB) without removing the message from the queue
MQREADXML	Returns an XML message from a specified MQSeries location without removing the message from the queue
MQRECEIVE	Returns a message from a specified MQSeries location (return value of VARCHAR) with removal of message from the queue
MQRECEIVEALL	Returns a table containing the messages and message metadata from a specified MQSeries location with a VARCHAR column and with removal of messages from the queue
MQRECEIVEALLCLOB	Returns a table containing the messages and message metadata from a specified MQSeries location with a CLOB column and with removal of messages from the queue
MQRECEIVEALLXML	Returns a table containing the messages and message metadata from a specified MQSeries location with column that contains XML data and with removal of messages from the queue
MQRECEIVECLOB	Returns a message from a specified MQSeries location (return value of CLOB) with removal of message from the queue
MQRECEIVEXML	Returns a message from a specified MQSeries location (return value of XML data in a user-defined data type that is based on VARCHAR) with removal of message from the queue
MQSEND	Sends data to a specified MQSeries location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful
MQSENDXML	Sends XML data to a specified MQSeries location
MQSENDXMLFILE	Sends data contained in an XML file that is up to 3K in size to a specified MQSeries location
MQSENDXMLFILECLOB	Sends data contained in an XML file that is up to 1M in size to a specified MQSeries location
MQSUBSCRIBE	Registers a subscription to MQSeries messages that are published on a specified topic, and returns a varying-length character string that indicates whether the function was successful or unsuccessful
MQUNSUBSCRIBE	Unregisters an existing subscription to MQSeries messages that are published on a specified topic, and returns a varying-length character string that indicates whether the function was successful or unsuccessful
MULTIPLY_ALT	Returns the product of the two arguments as a decimal value, used when the sum of the argument precisions exceeds 31

Table 53. Supported functions (continued)

Function name	Description
NEXT_DAY	Returns a timestamp that represents the first weekday, specified by the second argument, after the date argument
NORMALIZE_DECFLOAT	Returns a DECFLOAT value that is the result of normalizing the input argument
NORMALIZE_STRING	Returns a string value that is the result of normalizing the input Unicode value
NULLIF	Returns NULL if the arguments are equal; else the first argument
OVERLAY	Returns a string that is composed of an argument inserted into another argument at the same position where some number of bytes have been deleted
POSITION	Returns the position of the first occurrence of an argument within another argument where the position is expressed in terms of the string units that are specified
POSSTR	Returns the position of the first occurrence of an argument within another argument
POWER	Returns the value of one argument raised to the power of a second argument
QUANTIZE	Returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and which has an exponent set to be equal to the exponent of the second argument
QUARTER	Returns an integer in the range of 1 to 4 that represents the quarter of the year for the date specified in the argument
RADIANS	Returns the number of radians for an argument that is expressed in degrees
RAISE_ERROR	Raises an error in the SQLCA with the specified SQLSTATE and error description
RAND	Returns a double precision floating-point random number
REAL	Returns a single precision floating-point representation of its argument
REPEAT	Returns a character string composed of an argument repeated a specified number of times
REPLACE	Returns a string in which all occurrences of an argument within a second argument are replaced with a third argument
RID	Returns the RID of a row
RIGHT	Returns a string that consists of the specified number of rightmost bytes or specified string unit
ROUND	Returns a number rounded to the specified number of places to the right or left of the decimal place
ROUND_TIMESTAMP	Returns a timestamp rounded to the unit specified by the timestamp format string
ROWID	Returns a row ID representation of its argument
RPAD	Returns a string that is padded on the right with blanks or a specified string
RTRIM	Returns the characters of an argument with the trailing blanks or hexadecimal zeros removed
SCORE	Returns a relevance score that measures how well a document matches the query used to search a text search index

*Table 53. Supported functions (continued)*

Function name	Description
SECOND	Returns the second part of its argument
SIGN	Returns the sign of an argument
SIN	Returns the sine of an argument that is expressed as an angle in radians
SINH	Returns the hyperbolic sine of an argument that is expressed as an angle in radians
SMALLINT	Returns a small integer representation of its argument
SOAPHTTPC or SOAPHTTPV	Returns a CLOB or VARCHAR representation of XML data from a request to a web service
SOAPHTTPNC or SOAPHTTPNV	Returns a complete CLOB or VARCHAR representation of XML data from a complete request to a web service
SOUNDEX	Returns a value that represents the sound of the words in the argument.
SPACE	Returns a string that consists of the number of blanks the argument specifies
SQRT	Returns the square root of its argument
STDDEV or STDDEV_SAMP	Returns the standard deviation (/n), or the sample standard deviation (/n-1), of a set of numbers
STRIP	Returns the characters of a string with the blanks (or specified character) at the beginning, end, or both beginning and end of the string removed
SUBSTR	Returns a substring of a string
SUBSTRING	Returns a substring of a string using the specified string units
SUM	Returns the sum of a set of numbers
TAN	Returns the tangent of an argument that is expressed as an angle in radians
TANH	Returns the hyperbolic tangent of an argument that is expressed as an angle in radians
TIME	Returns a time derived from its argument
TIMESTAMP	Returns a timestamp derived from its arguments
TIMESTAMPADD	Returns a timestamp derived from adding the specified interval to a timestamp
TIMESTAMP_FORMAT	Returns a timestamp for a character string expression, using a specified format to interpret the string
TIMESTAMP_ISO	Returns a timestamp derived from its arguments
TIMESTAMPDIFF	Returns an estimated number of the specified intervals based on the difference between two timestamps
TOTALORDER	Returns a SMALLINT value that indicates the comparison order of two arguments
TRANSLATE	Returns a string with one or more characters translated
TRUNCATE	Returns a number truncated to the specified number of places to the right or left of the decimal point
TRUNC_TIMESTAMP	Returns a timestamp truncated to the unit specified by the timestamp format string
UCASE	Returns a string with the characters converted to uppercase

Table 53. Supported functions (continued)

Function name	Description
UNICODE	Returns the Unicode (UTF-16) code value of the leftmost character of the argument as an integer
UNICODE_STR	Returns a string in Unicode (UTF-8 or UTF-16) that represents a Unicode encoding of the argument
UPPER	Returns a string with the characters converted to uppercase
VALUE	Same as COALESCE
VARBINARY	Returns a varying-length binary string representation of its argument
VARCHAR	Returns the varying-length character string representation of its argument
VARCHAR_FORMAT	Returns a varying-length character string representation of a timestamp, with the string in a specified format
VARGRAPHIC	Returns a varying-length graphic string representation of its argument
VARIANCE or VARIANCE_SAMP	Returns the variance, or sample variance, of a set of numbers
WEEK	Returns an integer that represents the week of the year with Sunday as the first day of the week
WEEK_ISO	Returns an integer that represents the week of the year with Monday as first day of a week
XMLAGG	Returns an XML type that represents a concatenation of XML elements from a collection of XML elements
XMLATTRIBUTES	Returns an XML sequence that contains an XQuery attribute node for each non-null argument
XMLCOMMENT	Returns an XML value with a single comment node from a string expression
XMLCONCAT	Returns an XML value that represents a forest of XML elements generated by concatenating a variable number of arguments
XMLDOCUMENT	Returns an XML value with a single document node and zero or more nodes as its children
XMLEMENT	Returns an XML value that represents an XML element
XMLFOREST	Returns an XML value that represents a forest of XML elements that all share a specific pattern
XMLNAMESPACES	Returns the declaration of one or more XML namespaces
XMLPARSE	Returns an XML value from parsing the argument as an XML document
XMLPI	Returns an XML value with a single processing instruction node
XMLQUERY	Returns an XML value from the evaluation of an XPath expression against a set of arguments
XMLSERIALIZE	Returns an SQL character string or a BLOB value from an XML value
XMLTABLE	Returns a result table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables
XMLTEXT	Returns an XML value with a single text node that contains the value of the argument
YEAR	Returns the year part of its argument

## Aggregate functions

An aggregate function receives a set of values for each argument (such as the values of a column) and returns a single-value result for the set of input values. Certain rules apply to all aggregate functions.

The following information applies to all aggregate functions, except for the COUNT(\*) and COUNT\_BIG(\*) variations of the COUNT and COUNT\_BIG functions and the XMLAGG function.

The argument of an aggregate function is a set of values derived from an expression. The expression must not include another aggregate function. The scope of the set is a group or an intermediate result table.

If a GROUP BY clause is specified in a query and the intermediate result from the FROM, WHERE, GROUP BY, and HAVING clauses is the empty set, then the aggregate functions are not applied and the result of the query is the empty set.

If the GROUP BY clause is not specified in a query and the intermediate result table of the FROM, WHERE, and HAVING clauses is the empty set, then the aggregate functions are applied to the empty set.

For example, the result of the following SELECT statement is the number of distinct values of JOB for employees in department D11:

```
SELECT COUNT(DISTINCT JOB)
      FROM DSN8910.EMP
        WHERE WORKDEPT = 'D11';
```

The keyword DISTINCT is not an argument of the function but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, redundant duplicate values are eliminated. If ALL is implicitly or explicitly specified, redundant duplicate values are not eliminated. DISTINCT must not be specified preceding an XML value.

When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

An aggregate function can be used in a WHERE clause only if that clause is part of a subquery of a HAVING clause and the column name specified in the expression is a correlated reference to a group. If the expression includes more than one column name, each column name must be a correlated reference to the same group.

The result of the COUNT and COUNT\_BIG functions cannot be the null value. As specified in the description of AVG, MAX, MIN, STDDEV, SUM, and VARIANCE, the result is the null value when the function is applied to an empty set. However, the result is also the null value when the function is specified in an outer select list, the argument is given by an arithmetic expression, and any evaluation of the expression causes an arithmetic exception (such as division by zero).

If the argument values of an aggregate function are strings from a column with a field procedure, the function is applied to the encoded form of the values and the

result of the function inherits the field procedure.

## AVG

The AVG function returns the average of a set of numbers.

The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT( $n$ ).
- Large integer is the argument is small integer.
- Double precision floating-point is the argument is single precision floating-point.
- Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal with precision  $p$  and scale  $s$ , the precision (P) and scale (S) of the result depend on  $p$  and the decimal precision option:

- If  $p$  is greater than 15 or the DEC31 option is in effect, P is 31 and S is  $\max(0, 28-p+s)$ .
- Otherwise, P is 15 and S is  $15-p+s$ .

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the average value of the set. The order in which the summation part of the operation is performed is undefined but every intermediate result must be within the range of the result data type.

If the type of the result is integer, the fractional part of the average is lost.

*Example:* Assuming DEC15, set the DECIMAL(15,2) variable AVERAGE to the average salary in department D11 of the employees in the sample table DSN8910.EMP.

```
EXEC SQL SELECT AVG(SALARY)
  INTO :AVERAGE
  FROM DSN8910.EMP
  WHERE WORKDEPT = 'D11';
```

## CORRELATION

The CORRELATION function returns the coefficient of the correlation of a set of number pairs.

```
►►CORRELATION(expression-1,expression-2)—————►►
```

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result is between -1 and 1. The result can be null.

The function is applied to the set of (*expression-1, expression-2*) pairs derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, or if either STDDEV(*expression-1*) or STDDEV(*expression-2*) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following expression:

```
COVARIANCE(expression-1,expression-2)/  
(STDDEV(expression-1)* STDDEV(expression-2))
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

CORR can be specified as a synonym for CORRELATION.

*Example:* Using sample table DSN8910.EMP, set the host variable :corrln (double-precision floating point) to the correlation between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT CORRELATION(SALARY, BONUS) INTO :corrln  
FROM DSN8910.EMP WHERE WORKDEPT = 'A00';
```

:corrln is set to approximately 9.99853953399538E-001.

## COUNT

The COUNT function returns the number of rows or values in a set of rows or values.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result is a large integer. The result cannot be null.

The argument of COUNT(\*) is a set of rows. The result is the number of rows in the set. Any row that includes only null values is included in the count.

The argument of COUNT(expression) or COUNT(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values and redundant duplicate values. The result is the number of different nonnull values in the set.

*Example 1:* Set the integer host variable FEMALE to the number of females represented in the sample table DSN8910.EMP.

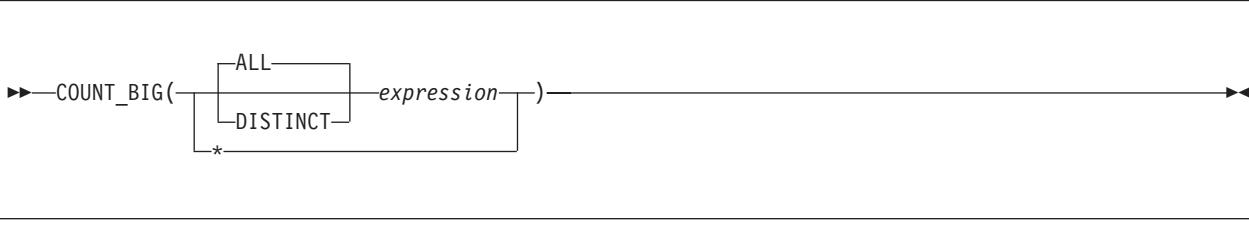

```
EXEC SQL SELECT COUNT(*)
  INTO :FEMALE
  FROM DSN8910.EMP
  WHERE SEX = 'F';
```

*Example 2:* Set the integer host variable FEMALE\_IN\_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT(DISTINCT WORKDEPT)
  INTO :FEMALE_IN_DEPT
  FROM DSN8910.EMP
  WHERE SEX = 'F';
```

## COUNT\_BIG

The COUNT\_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of an integer.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The result of the function is a decimal number with precision 31 and scale 0. The result cannot be null.

The argument of COUNT\_BIG(\*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT\_BIG(expression) or COUNT\_BIG(ALL expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of nonnull values in the set, including duplicates.

The argument of COUNT\_BIG(DISTINCT expression) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and redundant duplicate values. The result is the number of different nonnull values in the set.

*Example 1:* Set the integer host variable FEMALE to the number of females represented in the sample table DSN8910.EMP.

```
EXEC SQL SELECT COUNT_BIG(*)
  INTO :FEMALE
  FROM DSN8910.EMP
 WHERE SEX = 'F';
```

*Example 2:* Set the integer host variable FEMALE\_IN\_DEPT to the number of departments that have at least one female as a member.

```
EXEC SQL SELECT COUNT_BIG(DISTINCT WORKDEPT)
  INTO :FEMALE_IN_DEPT
  FROM DSN8910.EMP
 WHERE SEX = 'F';
```

*Example 3:* To create a sourced function that is similar to the built-in COUNT\_BIG function, the definition of the sourced function must include the type of the column that can be specified when the new function is invoked. In this example, the CREATE FUNCTION statement creates a sourced function that takes a CHAR column as input and uses COUNT\_BIG to perform the counting. The result is

returned as a double precision floating-point number. The query shown counts the number of unique departments in the sample employee table.

```
CREATE FUNCTION RICK.COUNT(CHAR()) RETURNS DOUBLE  
    SOURCE SYSIBM.COUNT_BIG(CHAR());  
SET CURRENT PATH RICK, SYSTEM PATH;  
SELECT COUNT(DISTINCT WORKDEPT) FROM DSN8910.EMP;
```

The empty parenthesis in the parameter list for the new function (RICK.COUNT) means that the input parameter for the new function is the same type as the input parameter for the function named in the SOURCE clause. The empty parenthesis in the parameter list in the SOURCE clause (SYSIBM.COUNT\_BIG) means that the length attribute of the CHAR parameter of the COUNT\_BIG function is ignored when DB2 locates the COUNT\_BIG function.

## COVARIANCE or COVARIANCE\_SAMP

The COVARIANCE and COVARIANCE\_SAMP functions return the covariance (population) of a set of number pairs.

```
►-- COVARIANCE---(expression-1,expression-2)---►
   |----- COVARIANCE_SAMP -----|
```

The schema is SYSIBM.

The argument values must each be the value of any built-in numeric data type.

If an argument is DECFLOAT(*n*), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

The function is applied to the set of (*expression-1*, *expression-2*) pairs that are derived from the argument values by the elimination of all pairs for which either *expression-1* or *expression-2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the covariance of the value pairs in the set. The result is equivalent to the following:

For COVARIANCE:

1. Let *avgexp1* be the result of AVG(*expression-1*) and let *avgexp2* be the result of AVG(*expression-2*).
2. The result of COVARIANCE(*expression-1*,*expression-2*) is AVG( (*expression-1* - *avgexp1*) \* (*expression-2* - *avgexp2*) )

For COVARIANCE\_SAMP:

1. Let *samp\_avgexp1* be the result of SUM(*expression-1*)/*n*-1 and let *samp\_avgexp2* be the result of SUM(*expression-2*)/*n*-1.
2. The result of COVARIANCE\_SAMP(*expression-1*, *expression-2*) is AVG((*expression-1* - *samp\_avgexp1*) \* (*expression-2* - *samp\_avgexp2*))

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

COVAR can be specified as a synonym for COVARIANCE.

COVAR\_SAMP can be specified as a synonym for COVARIANCE\_SAMP.

*Example:* Using sample table DSN8910.EMP, set the host variable *covarnc* (double-precision floating point) to the covariance between the salary and the bonus for those employees in department (WORKDEPT) 'A00'.

```
SELECT COVARIANCE(SALARY, BONUS) INTO :covarnc
   FROM EMPLOYEE WHERE WORKDEPT = 'A00';
```

*covarnc* is set to approximately 1.6888888888889E+006.

## MAX

The MAX function returns the maximum value in a set of values.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, row ID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 255, and graphic string arguments cannot have a length attribute greater than 127.

The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

*Example 1:* Set the DECIMAL(8,2) variable MAX\_SALARY to the maximum monthly salary of the employees represented in the sample table DSN8910.EMP.

```
EXEC SQL SELECT MAX(SALARY) / 12
  INTO :MAX_SALARY
  FROM DSN8910.EMP;
```

*Example 2:* Find the surname that comes last in the collating sequence for the employees represented in the sample table DSN8910.EMP. Set the VARCHAR(15) variable LAST\_NAME to that surname.

```
EXEC SQL SELECT MAX(LASTNAME)
  INTO :LAST_NAME
  FROM DSN8910.EMP;
```

## MIN

The MIN function returns the minimum value in a set of values.

The schema is SYSIBM.

The argument values can be of any built-in data type other than a BLOB, CLOB, DBCLOB, row ID, or XML. Character string arguments and binary string arguments cannot have a length attribute greater than 255, and graphic string arguments cannot have a length attribute greater than 127.

The data type of the result and its other attributes (for example, the length and CCSID of a string or a datetime value) are the same as the data type and attributes of the argument values. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and is not advised.

*Example 1:* Set the DECIMAL(15,2) variable MIN\_SALARY to the minimum monthly salary of the employees represented in the sample table DSN8910.EMP.

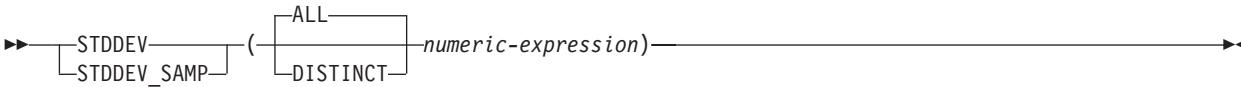

```
EXEC SQL SELECT MIN(SALARY) / 12
  INTO :MIN_SALARY
  FROM DSN8910.EMP;
```

*Example 2:* Find the surname that comes first in the collating sequence for the employees represented in the sample table DSN8910.EMP. Set the VARCHAR(15) variable FIRST\_NAME to that surname.

```
EXEC SQL SELECT MIN(LASTNAME)
  INTO :FIRST_NAME
  FROM DSN8910.EMP;
```

## STDDEV or STDDEV\_SAMP

The STDDEV or STDDEV\_SAMP function returns the standard deviation ( $/n$ ), or the sample standard deviation ( $/n-1$ ), of a set of numbers.

The schema is SYSIBM.

The function returns the biased standard deviation ( $/n$ ) or the sample standard deviation ( $/n-1$ ) of a set of numbers, depending on which keyword is specified:

### STDDEV

The formula that is used to calculate the biased standard deviation is logically equivalent to:

$$\text{STDDEV} = \text{SQRT}(\text{VAR})$$

### STDDEV\_SAMP

The formula that is used to calculate the sample standard deviation is logically equivalent to:

$$\text{STDDEV} = \text{SQRT}(\text{VARIANCE\_SAMP})$$

The argument values must each be the value of any built-in numeric data type, and their sum must be within the range of the data type of the result.

If the argument is DECFLOAT( $n$ ), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point. The result can be null.

Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the standard deviation of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

STDDEV\_POP can be specified as a synonym for STDDEV.

*Example:* Using sample table DSN8910.EMP, set the host variable *DEV*, which is defined as double precision floating-point, to the standard deviation of the salaries for the employees in department 'A00' (WORKDEPT='A00').

```
SELECT STDDEV(SALARY)
  INTO :DEV
  FROM DSN8910.EMP
 WHERE WORKDEPT = 'A00';
```

For this example, host variable *DEV* is set to a double precision float-pointing number with an approximate value of '9742.43'.

## SUM

The SUM function returns the sum of a set of numbers.

►► SUM( [ ALL | DISTINCT ] numeric-expression ) ►►

The schema is SYSIBM.

The argument values can be of any built-in numeric data type, and their sum must be within the range of the data type of the result.

The data type of the result is determined as follows:

- DECFLOAT(34) if the argument is DECFLOAT( $n$ ).
  - Large integer if the argument is small integer.
  - Double precision floating-point if the argument is single precision floating-point.
  - Otherwise, the result is the same as the data type of the argument.

The result can be null.

If the data type of the argument values is decimal, the scale of the result is the same as the scale of the argument values, and the precision of the result depends on the precision of the argument values and the decimal precision option:

- If the precision of the argument values is greater than 15 or the DEC31 option is in effect, the precision of the result is  $\min(31, P+10)$ , where  $P$  is the precision of the argument values.
  - Otherwise, the precision of the result is 15.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated.

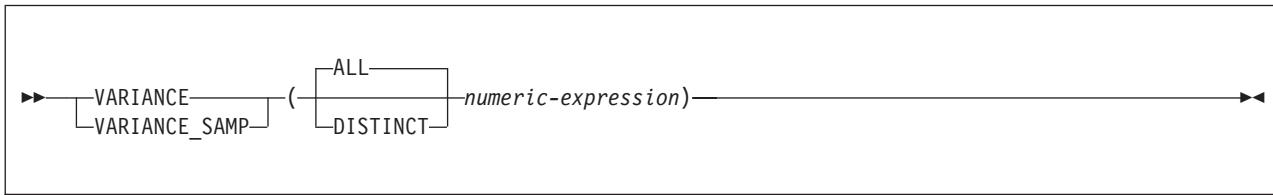

If the function is applied to an empty set, the result is the null value. Otherwise, the result is the sum of the values in the set. The order in which the summation is performed is undefined but every intermediate result must be within the range of the result data type.

*Example:* Set the large integer host variable *INCOME* to the total income from all sources (salaries, commissions, and bonuses) of the employees represented in the sample table DSN8910.EMP. If DEC31 is not in effect, the resultant sum is DECIMAL(15,2) because all three columns are DECIMAL(9,2).

```
EXEC SQL SELECT SUM(SALARY+COMM+BONUS)
  INTO :INCOME
  FROM DSN8910.EMP;
```

## VARIANCE or VARIANCE\_SAMP

The VARIANCE function returns the biased variance (/n) of a set of numbers. The VARIANCE\_SAMP function returns the sample variance (/n-1) of a set of numbers.

The schema is SYSIBM.

The function returns the biased variance (/n) or the sample variance (/n-1) of a set of numbers, depending on which keyword is specified.

### VARIANCE

The formula that is used to calculate the biased variance is logically equivalent to:

$$\text{VARIANCE} = \text{SUM}(X^{**2})/\text{COUNT}(X) - (\text{SUM}(X)/\text{COUNT}(X))^{**2}$$

### VARIANCE\_SAMP

The formula that is used to calculate the sample variance is logically equivalent to:

$$\text{VARIANCE\_SAMP} = (\text{SUM}(X^{**2}) - ((\text{SUM}(X)^{**2}) / (\text{COUNT}(*)))) / (\text{COUNT}(*) - 1)$$

The argument values can be of any built-in numeric type, and their sum must be within the range of the data type of the result. Before the function is applied to the set of values derived from the argument values, null values are eliminated. If DISTINCT is specified, redundant duplicate values are also eliminated.

If the argument is DECFLOAT(n), the result of the function is DECFLOAT(34). Otherwise, the result of the function is double precision floating-point.

The result can be null. If the set of values is empty, the result is the null value. Otherwise, the result is the variance of the values in the set.

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

#### *Alternative syntax and synonyms:*

- VAR or VAR\_POP can be specified as synonym for VARIANCE
- VAR\_SAMP can be specified as a synonym for VARIANCE\_SAMP

*Example 1:* Using sample table DSN8910.EMP, set host variable VARNCE, which is defined as double precision floating-point, to the variance of the salaries (SALARY) for those employees in department (WORKDEPT) 'A00'.

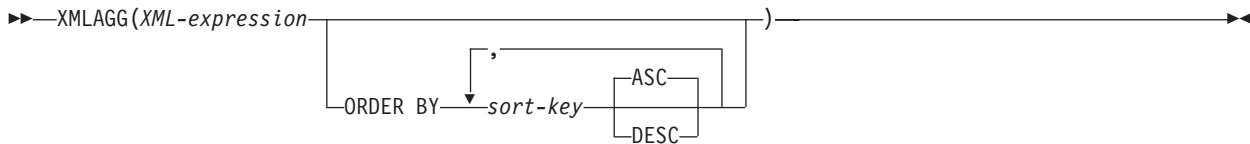

```
SELECT VARIANCE(SALARY)
  INTO :VARNCE
  FROM DSN8910.EMP
 WHERE WORKDEPT = 'A00';
```

The result in *VARNCE* is set to a double precision-floating point number with an approximate value of '94915000.00'.

If *VARIANCE\_SAMP* had been specified to find the sample variance of the salaries, the result in *VARNCE* would be set to a double precision-floating point number with an approximate value of '94915000.00'.

## XMLAGG

The XMLAGG function returns an XML sequence that contains an item for each non-null value in a set of XML values.

### sort-key

The schema is SYSIBM.

#### *XML-expression*

An expression that returns an XML value.

Unlike the arguments for other aggregate functions, a scalar fullselect is allowed in *XML-expression*.

#### ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value, the rows in the same grouping set are arbitrarily ordered.

#### *sort-key*

Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a LOB or an XML value. A character string expression cannot have a length greater than 4000 bytes. If the sort key value is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but is simply a constant, which implies no sort key.

The ordering is based on the values of the sort keys, which might or might not be used in *XML-expression*.

If the sort key value is a character string that uses an encoding scheme other than Unicode, the ordering might be different. For example, a column PRODCODE uses EBCDIC. For two values, ('P001' and 'PA01'), relationship 'P001' > 'PA01' is true in EBCDIC, whereas 'P001' < 'PA01' is true in UTF-8. If the same sort key values are used in *XML-expression*, use the CAST specification to convert the sort key to Unicode to keep the ordering of XML values consistent with that of the sort key.

The function is applied to the set of values derived from the argument values by the elimination of null values.

The result can be null; if all *XML-expression* arguments are null. If the function is applied to an empty set, the result is the null value. Otherwise, the result is an XML sequence that contains an item for each value in the set.

*Example:* Group employees by their department, generate a 'Department' element for each department with its name as the attribute, nest all the 'emp' elements for employees in each department, and order the 'emp' elements by 'lname.'

```
SELECT XMLSERIALIZE(XMLDOCUMENT
  ( XMLELEMENT
    ( NAME "Department",
      XMLATTRIBUTES ( e.dept AS "name" ),
      XMLAGG ( XMLELEMENT ( NAME "emp", e.lname)
        ORDER BY e.lname)
      ) ) AS "dept_list"
      AS CLOB(1M))
FROM employees e
GROUP BY dept;
```

The result of the query would look similar to the following result:

```
dept_list
-----
<Department name="Accounting">
  <emp>SMITH</emp>
  <emp>Yates</emp>
</Department>
<Department name="Shipping">
  <emp>Martin</emp>
  <emp>Oppenheimer</emp>
</Department>
-----
```

---

## Scalar functions

A scalar function can be used wherever an expression can be used. The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to single set of parameter values rather than to sets of values. The argument of a scalar function can be a function. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be a aggregate function only if a aggregate function is allowed in the context in which the scalar function is used.

If the argument of a scalar function is a string from a column with a field procedure, the function applies to the decoded form of the value and the result of the function does not inherit the field procedure.

*Example:* The following SELECT statement calls for the employee number, last name, and age of each employee in department D11 in the sample table DSN8910.EMP. To obtain the ages, the scalar function YEAR is applied to the expression:

```
CURRENT DATE - BIRTHDATE
```

in each row of DSN8910.EMP for which the employee represented is in department D11:

```
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BIRTHDATE)
  FROM DSN8910.EMP
 WHERE WORKDEPT = 'D11';
```

## ABS

The ABS function returns the absolute value of a number.

```
►►—ABS(numeric-expression)————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The result of the function has the same data type and length attribute as the argument. The result can be null. If the argument is null, the result is the null value.

ABSVAL can be specified as a synonym for ABS. DB2 supports this keyword to provide compatibility with previous releases.

*Example:* Assume that host variable PROFIT is a large integer with a value of -50000. The following statement returns a large integer with a value of 50000.

```
SELECT ABS(:PROFIT)
      FROM SYSIBM.SYSDUMMY1;
```

## ACOS

The ACOS function returns the arc cosine of the argument as an angle, expressed in radians. The ACOS and COS functions are inverse operations.

►►—ACOS(*numeric-expression*)—►►

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable ACOSINE is DECIMAL(10,9) with a value of 0.070737202. The following statement:

```
SELECT ACOS(:ACOSINE)
      FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.49.

## ADD\_MONTHS

The ADD\_MONTHS function returns a date that represents *expression* plus a specified number of months.

```
►►—ADD_MONTHS(expression,numeric-expression)—►►
```

The schema is SYSIBM.

### *expression*

An expression that specifies the starting date. *expression* must return a value that is a date, timestamp, or a valid string representation of a date or timestamp. A string representation is a value that is a built-in character string data type or graphic string data type, that is not a LOB, and that has an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

### *numeric-expression*

An expression that returns a value of any built-in numeric data type. The integer portion of *numeric-expression* specifies the number of months to add to the starting date specified by *expression*.

The result of the function is a DATE.

The result can be null; if any argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

*Example 1:* Assume today is January 31, 2007. Set the host variable ADD\_MONTH with the last day of January plus 1 month.

```
SET :ADD_MONTH = ADD_MONTHS(LAST_DAY(CURRENT_DATE), 1);
```

The host variable ADD\_MONTH is set with the value representing the end of February, 2007-02-28.

*Example 2:* Assume DATE is a host variable with the value July 27, 1965. Set the host variable ADD\_MONTH with the value of that day plus 3 months.

```
SET :ADD_MONTH = ADD_MONTHS(:DATE,3);
```

The host variable ADD\_MONTH is set with the value representing the day plus 3 months, 1965-10-27.

*Example 3:* It is possible to achieve similar results with the ADD\_MONTHS function and date arithmetic. The following examples demonstrate the similarities and contrasts.

```
SET :DATEHV = DATE('2008-2-28') + 4 MONTHS;
```

```
SET :DATEHV = ADD_MONTHS('2008-2-28', 4);
```

In both cases, the host variable DATEHV is set with the value '2008-06-29'.

Now consider the same examples but with the date '2008-2-29' as the argument.

```
SET :DATEHV = DATE('2008-2-29') + 4 MONTHS;
```

The host variable DATEHV is set with the value '2008-06-29'.

```
SET :DATEHV = ADD_MONTHS('2008-2-29', 4);
```

The host variable DATEHV is set with the value '2008-06-30'.

In this case, the ADD\_MONTHS function returns the last day of the month, which is June 30, 2008, instead of June 29, 2008. The reason is that February 29 is the last day of the month. So, the ADD\_MONTHS function returns the last day of June.

## ASCII

The ASCII function returns the leftmost character of the argument as an integer.

```
►►—ASCII(string-expression)————►►
```

The schema is SYSIBM.

The argument can be any built-in character or graphic string data type, except for CLOB or DBCLOB. If the argument is an EBCDIC, Unicode, or graphic string, it is first converted to an SBCS ASCII character string (CCSID 367)<sup>19</sup> before the function is executed.

The result of the function is an integer. The result can be null; if the argument is null, the result is the null value.

*Example:* The following statement returns the ASCII value for the character 'A':

```
SET :hv = ASCII('A');
```

The host variable, :hv, is set to an integer with the value 65.

19. If the conversion does not exist, the ASCII function will return an error, or a substitution character might be returned.

## ASCII\_CHR

The ASCII\_CHR function returns the character that has the ASCII code value that is specified by the argument.

```
►►—ASCII_CHR(expression)—►►
```

The schema is SYSIBM.

*expression*

An expression that returns a built-in data type of BIGINT, INTEGER, or SMALLINT.

The result of the function is a fixed length character string encoded in the SBCS ASCII CCSID (regardless of the setting of the MIXED option in DSNHDECP). The length of the result is 1. If the value of *expression* is not in the range of 0 to 255, (0 to 127 if the SBCS ASCII CCSID for this system is CCSID 367) the null value is returned.

The result can be null; if the argument is null, the result is the null value.

CHR can be specified as a synonym for ASCII\_CHR.

*Example:* Set :hv with the Euro symbol "€" in CCSID 923:

```
SET :hv = ASCII_CHR(164); -- x'A4'
```

Set :hv with the Euro symbol "€" in CCSID 1252:

```
SET :hv = ASCII_CHR(128); -- x'80'
```

In both cases, the "€" is assigned to :hv, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

## ASCII\_STR

The ASCII\_STR function returns an ASCII version of the string in the system ASCII CCSID. The system ASCII CCSID is the SBCS ASCII CCSID on a MIXED=NO system or the MIXED ASCII CCSID on a MIXED=YES system.

```
►►ASCII_STR(string-expression)-----►►
```

The schema is SYSIBM.

*string-expression*

An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string. ASCII\_STR returns an ASCII version of the string. Non-ASCII characters are converted to the form \xxxx, where xxxx represents a UTF-16 code unit.

The length attribute of the result will be MIN( ( 5\*n ),32704). Where n is the result of applying the formulas in Table 35 on page 126 based on input and output data types.

The result of the function is a varying-length character string in the system ASCII CCSID. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

ASCIISTR can be specified as a synonym for ASCII\_STR.

*Example:* The following example returns the ASCII string equivalent of the text string "Hi my name is А н д р е й (Andrei)"

```
SET :HV1 = ASCII_STR('Hi, my name is А н д р е й (Andrei)');
```

:HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

## ASIN

The ASIN function returns the arc sine of the argument as an angle, expressed in radians. The ASIN and SIN functions are inverse operations.

```
►►—ASIN(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type except for DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to  $-\pi/2$  and less than or equal to  $\pi/2$ .

*Example:* Assume that host variable ASINE is DECIMAL(10,9) with a value of 0.997494987. The following statement:

```
SELECT ASIN(:ASINE)
      FROM SYSIBM.SYSDUMMY1;
```

returns a double precision floating-point number with an approximate value of 1.50.

## ATAN

The ATAN function returns the arc tangent of the argument as an angle, expressed in radians. The ATAN and TAN functions are inverse operations.

```
►►—ATAN(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than or equal to -1 and less than or equal to 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

The result is greater than or equal to  $-\pi/2$  and less than or equal to  $\pi/2$ .

*Example:* Assume that host variable ATANGENT is DECIMAL(10,9) with a value of 14.10141995. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATAN(:ATANGENT)
   FROM SYSIBM.SYSDUMMY1;
```

## ATANH

The ATANH function returns the hyperbolic arc tangent of a number, expressed in radians. The ATANH and TANH functions are inverse operations.

```
►►—ATANH(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. The value must be greater than -1 and less than 1. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HATAN is DECIMAL(10,9) with a value of 0.905148254. The following statement returns a double precision floating-point number with an approximate value of 1.50:

```
SELECT ATANH(:HATAN)
      FROM SYSIBM.SYSDUMMY1;
```

## ATAN2

The ATAN2 function returns the arc tangent of  $x$  and  $y$  coordinates as an angle, expressed in radians.

```
►►—ATAN2(numeric-expression-1,numeric-expression-2)—————►►
```

The schema is SYSIBM.

The first and second arguments specify the  $x$  and  $y$  coordinates, respectively.

Each argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. Both arguments must not be 0. Any argument that is not a double precision floating-point number is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if any argument is null, the result is the null value.

*Example:* Assume that host variables HATAN2A and HATAN2B are DOUBLE host variables with values of 1 and 2, respectively. The following statement returns a double precision floating-point number with an approximate value of 1.1071487:

```
SELECT ATAN2(:HATAN2A,:HATAN2B)
   FROM SYSIBM.SYSDUMMY1;
```

## **BIGINT**

The BIGINT function returns a big integer representation of either a number or a character or graphic string representation of a number.

### **Numeric to Big Integer:**

```
►►—BIGINT(numeric-expression)—————►►
```

### **String to Big Integer:**

```
►►—BIGINT(string-expression)—————►►
```

The schema is SYSIBM.

#### **Numeric to Big Integer**

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. If the whole part of the argument is not within the range of big integers, an error is returned. The fractional part of the argument is truncated.

#### **String to Big Integer**

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB and DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS BIGINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of big integers, an error is returned. Any fractional part of the argument is truncated.

The result of the function is a big integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

To increase the portability of applications, use the CAST specification.

*Example 1:* The following function returns the number 12345 (a BIGINT) for the number 12345.6:

```
SELECT BIGINT(12345.6)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a BIGINT value of 123456789012 for the number 00123456789012.

```
|           SELECT BIGINT('00123456789012')
|           FROM SYSIBM.SYSDUMMY1;
```

**Related reference**

“CAST specification” on page 202

## BINARY

The BINARY function returns a BINARY (fixed-length binary string) representation of a string of any type or of a row ID type.

```
►►—BINARY(string-expression [, —integer])—►►
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

### *integer*

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 255 inclusive.

If *integer* is not specified:

- If the *string-expression* is the empty string constant, an error occurs
- Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *string-expression*.

The result of the function is a fixed-length binary string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length is the same as the length attribute of the result. If the length of the *string-expression* is less than the length of the result, the result is padded with hexadecimal zeroes up to the length of the result. If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks, or the first input argument is a binary string and all the truncated bytes are hexadecimal zeroes.

Following examples assume EBCDIC encoding of the input string constants.

*Example 1:* The following function returns a fixed-length binary string with a length attribute 1 and a value BX'00'.

```
SELECT BINARY(' ',1)  
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a fixed-length binary string with a length attribute 5 and a value BX'D2C2C80000'

```
SELECT BINARY('KBH',5)  
      FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following function returns a fixed-length binary string with a length attribute 3 and a value BX'D2C2C8'

```
|           SELECT BINARY('KBH')
|           FROM SYSIBM.SYSDUMMY1;
```

| *Example 4:* The following function returns a fixed-length binary string with a length  
| attribute 3 and a value BX'D2C2C8'

```
|           SELECT BINARY('KBH ',3)
|           FROM SYSIBM.SYSDUMMY1;
```

| *Example 5:* The following function returns a fixed-length binary string with a length  
| attribute 3 and a value BX'D2C2C8', a warning is also returned.

```
|           SELECT BINARY('KBH 93',3)
|           FROM SYSIBM.SYSDUMMY1;
```

| *Example 6:* The following function returns a fixed-length binary string with a length  
| attribute 3 and a value BX'C1C2C3', a warning is also returned.

```
|           SELECT BINARY(BINARY('ABC',5),3)
|           FROM SYSIBM.SYSDUMMY1;
```

## BLOB

The BLOB function returns a BLOB representation of a string of any type or of a row ID type.

```
►►—BLOB(string-expression [ ,—integer ])—►►
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

### *integer*

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and the maximum length of a BLOB.

Do not specify *integer* if *string-expression* is a row ID type.

If you do not specify *integer* and *string-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string.

Otherwise, the length attribute of the result is the same as the length attribute of *string-expression*, except when the input is graphic data. In this case, the length attribute of the result is twice the length of *expression*.

The result of the function is a BLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *string-expression* (or twice the length of *string-expression* when the input is graphic data). If the length of *string-expression* is greater than the length attribute of the result, truncation is performed. A warning is returned unless the first input argument is a character string and all the truncated characters are blanks, or the first input argument is a graphic string and all the truncated characters are double-byte blanks.

*Example 1:* The following function returns a BLOB for the string 'This is a BLOB'.

```
SELECT BLOB('This is a BLOB')
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a BLOB for the large object that is identified by locator myblob\_locator.

```
SELECT BLOB(:myblob_locator)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* Assume that a table has a BLOB column named TOPOGRAPHIC\_MAP and a VARCHAR column named MAP\_NAME. Locate any maps that contain the string 'Engles Island' and return a single binary string with the map name concatenated in front of the actual map.

```
SELECT BLOB(MAP_NAME || ': ' ) || TOPOGRAPHIC_MAP
      FROM ONTARIO_SERIES_4
     WHERE TOPOGRAPHIC_MAP LIKE BLOB('%Engles Island%')
```

## CCSID\_ENCODING

The CCSID\_ENCODING function returns a string value that indicates the encoding scheme of a CCSID that is specified by the argument.

```
►►CCSID_ENCODING(expression)————►►
```

The schema is SYSIBM.

*expression*

*expression* must be an expression that returns a value of a built-in numeric, character, or graphic string data type that is not a LOB. A character string must not have a length attribute greater than 255, and a graphic string must not have a length attribute greater than 127. If *expression* is a character or graphic string, the string must contain a valid string representation of a number. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a numeric constant.

The function returns a value of ASCII, EBCDIC, UNICODE, or UNKNOWN depending on the CCSID specified by *expression*.

The result of the function is a fixed-length character string of length 8, which is padded on the right if necessary.

If the argument can be null, the result can be null. If the argument is null, the result is the null value. The CCSID of the result is determined from the context in which the function was invoked. For more information, refer to “Determining the encoding scheme and CCSID of a string” on page 43.

*Example 1:* The following function returns a CCSID with a value for EBCDIC data.

```
SELECT CCSID_ENCODING(37) AS CCSID  
  FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a CCSID with a value for ASCII data.

```
SELECT CCSID_ENCODING(850) AS CCSID  
  FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following function returns a CCSID with a value for Unicode data.

```
SELECT CCSID_ENCODING(1208) AS CCSID  
  FROM SYSIBM.SYSDUMMY1;
```

*Example 4:* The following function returns a CCSID with a value of UNKNOWN.

```
SELECT CCSID_ENCODING(1) AS CCSID  
  FROM SYSIBM.SYSDUMMY1;
```

*Example 5:* The following function returns a CCSID with a value for EBCDIC data. The input data is a character string.

```
SELECT CCSID_ENCODING('37') AS CCSID  
  FROM SYSIBM.SYSDUMMY1;
```

## CEILING

The CEILING function returns the smallest integer value that is greater than or equal to the argument.

```
►►—CEILING—(numeric-expression)——————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) results in DECIMAL(5,0). The result can be null. If the argument is null, the result is the null value.

CEIL can be specified as a synonym for CEILING.

*Example 1:* The following statement shows the use of CEILING on positive and negative values:

```
SELECT CEILING(3.5), CEILING(3.1), CEILING(-3.1), CEILING(-3.5)
      FROM SYSIBM.SYSDUMMY1;
```

This example returns: 04., 04., -03., -03.

*Example 2:* Using sample table DSN8910.EMP, find the highest monthly salary for all the employees. Round the result up to the next integer. The SALARY column has a decimal data type.

```
SELECT CEILING(MAX(SALARY)/12)
      FROM DSN8910.EMP;
```

This example returns 04396. because the highest paid employee is Christine Haas who earns \$52750.00 per year. Her average monthly salary before applying the CEILING function is 4395.83.

## CHAR

The CHAR function returns a fixed-length character string representation of the argument.

### Integer to Character:

```
►►CHAR(integer-expression)—————►►
```

### Decimal to Character:

```
►►CHAR(decimal-expression [ ,decimal-character ])—————►►
```

### Floating-Point to Character:

```
►►CHAR(floating-point-expression)—————►►
```

### Decimal floating-point to Character:

```
►►CHAR(decimal-floating-point-expression)—————►►
```

### Character to Character:

```
►►CHAR(character-expression [ ,integer [ ,CODEUNITS16 [ ,CODEUNITS32 [ ,OCTETS ] ] ] ])—————►►
```

## Graphic to Character:

```
►►—CHAR(graphic-expression)—  
     |  
     |,—integer—  
     |  
     |,—CODEUNITS16—  
     |  
     |,—CODEUNITS32—
```

## Datetime to Character:

```
►►—CHAR(datetime-expression)—  
     |  
     |,—ISO—  
     |  
     |,—USA—  
     |  
     |,—EUR—  
     |  
     |,—JIS—  
     |  
     |,—LOCAL—
```

## Row ID to Character:

```
►►—CHAR(row-ID-expression)—
```

The schema is SYSIBM.

The CHAR function returns a fixed-length character string representation of one of the following values:

- | • An integer number if the first argument is a small, large, or big integer
- | • A decimal number if the first argument is a decimal number
- | • A floating-point number if the first argument is a single or double precision floating-point number
- | • A decimal floating-point number if the first argument is a decimal floating-point number
- | • A character string value if the first argument is any type of string
- | • A datetime value if the first argument is a date, time, or timestamp
- | • A row ID value if the first argument is a row ID

The result of the function is a fixed-length character string (CHAR).

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

### Integer to Character

*integer-expression*

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, or BIGINT).

The result is the fixed-length character string representation of the argument in the form of an SQL integer constant. The result consists of  $n$  characters that are the significant digits that represent the value of the argument. If the argument is negative, the result has a preceding minus sign. The result is left justified, and its length depends on whether the argument is a small or large integer:

- For a small integer, the length of the result is 6. If the number of characters in the result is less than 6, the result is padded on the right with blanks to a length of 6.
- For a large integer, the length of the result is 11; if the number of characters in the result is less than 11, the result is padded on the right with blanks to a length of 11.

A positive value always includes one trailing blank.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

### Decimal to Character

#### *decimal-expression*

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the value of the expression, apply the DECIMAL function before applying the CHAR function.

#### *decimal-character*

Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see “Decimal point representation” on page 251.

The result is the fixed-length character string representation of the argument. The result includes a decimal character and up to  $p$  digits, where  $p$  is the precision of the *decimal-expression* with the preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with blanks.

The leading blank is not returned for `CAST(decimal-expression AS CHAR( $n$ ))`.

The length of the result is  $2 + p$ , where  $p$  is the precision of the *decimal-expression*.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

### Floating-Point to Character

#### *floating-point-expression*

An expression that returns a value that is a built-in floating-point data type (DOUBLE or REAL).

The result is the fixed-length character string representation of the argument in the form of an SQL floating-point constant. The length of the result is 24 bytes.

If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit. If the value of the argument is zero, the result is 0E0. Otherwise, the result includes the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit, other than zero, followed by a period and a sequence of digits.

If the number of characters in the result is less than 24, the result is padded on the right with blanks to length of 24.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

### Decimal floating-point to Character

*decimal-floating-point-expression*

An expression that returns a value that is a built-in decimal floating-point data type (DECFLOAT).

The result is the fixed-length character string representation of the argument in the form of an SQL decimal floating-point constant. The length of the result is 42 bytes. If the number of characters in the result is less than 42, the result is padded on the right with blanks to length of 42.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

### Character to Character

*character-expression*

An expression that returns a value of a built-in character string.

*integer*

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *character-expression*. If *character-expression* is an empty string constant, an error occurs.

If **CODEUNITS16** or **CODEUNITS32** is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

#### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, **CODEUNITS16** and **CODEUNITS32** cannot be specified.

#### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that *integer* is expressed in terms of bytes.

For more information about **CODEUNITS16**, **CODEUNITS32**, and **OCTETS**, see “String unit specifications” on page 76.

The actual length is the same as the length attribute of the result. If the length of *character-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

**Graphic to Character**

*graphic-expression*

An expression that returns a value of a built-in graphic string.

*integer*

The length attribute for the resulting fixed-length character string. The value must be an integer constant between 1 and 255.

If the length is not specified, the length attribute of the result is the minimum of 255 and the length attribute of *graphic-expression*. The length attribute of *graphic-expression* is  $(3 * \text{length}(\text{graphic-expression}))$ . If *graphic-expression* is an empty string constant, an error occurs.

If **CODEUNITS16** or **CODEUNITS32** is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about **CODEUNITS16** and **CODEUNITS32**, see “String unit specifications” on page 76.

The actual length is the same as the length attribute of the result. If the length of *graphic-expression* is less than the length attribute of the result, the result is padded with blanks to the length of the result. If the length of *graphic-expression* is greater than the length attribute of the result, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

**Datetime to Character**

*datetime-expression*

An expression that is one of the following built-in data types:

**date** The result is the character string representation of the date in the format that is specified by the second argument. If the second argument is omitted, the DATE precompiler option, if one is provided, otherwise field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is LOCAL, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 10.

LOCAL denotes the local format at the DB2 subsystem that executes the SQL statement. If LOCAL is used for the format, a date exit routine must be installed at that DB2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

**time** The result is the character string representation of the time in the format that is specified by the second argument. If the second argument is omitted, the TIME precompiler option, if one is provided, otherwise field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length of the result is 8.

LOCAL denotes the local format at the DB2 subsystem that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that DB2 subsystem.

An error occurs if the second argument is specified and is not a valid value.

#### **timestamp**

The result is the character string representation of the timestamp. The length of the result is 26. The second argument must not be specified.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

#### **ISO, EUR, USA, JIS, or LOCAL**

Specifies the date or time format of the resulting character string. For more information, see “String representations of datetime values” on page 89.

### **Row ID to Character**

#### *row-ID-expression*

An expression that returns a value that is a built-in row ID data type.

The result is the fixed-length character string representation of the argument. The result is bit data.

The length of the result is 40. If the length of *row-ID-expression* is less than 40, the result is padded on the right with hexadecimal zeros to a length of 40.

**Recommendation:** To increase the portability of applications, use the CAST specification when the first argument is numeric, or the first argument is a string and the length argument is specified. For more information, see “CAST specification” on page 202.

*Example 1:* HIREDATE is a DATE column in sample table DSN8910.EMP. When it represents the date 15 December 1976 (as it does for employee 140), the following example returns the string value '12/15/1976' in character string variable DATESTRING:

```
EXEC SQL SELECT CHAR(HIREDATE, USA)
  INTO :DATESTRING
  FROM DSN8910.EMP
 WHERE EMPNO = '000140';
```

*Example 2:* Host variable HOUR has a data type of DECIMAL(6,0) and contains a value of 50000. Interpreted as a time duration, this value is 5 hours. Assume that STARTING is a TIME column in some table. Then, when STARTING represents 17 hours, 30 minutes, and 12 seconds after midnight, the following example returns the value '10:30 PM':

```
CHAR(STARTING+:HOURS, USA)
```

*Example 3:* Assume that RECEIVED is defined as a TIMESTAMP column in table TABLEY. When the value of the date portion of RECEIVED represents the date 10 March 1997 and the time portion represents 6 hours and 15 seconds after midnight, the following example returns the string value '1997-03-10-06.00.15.000000':

```
SELECT CHAR(RECEIVED)
  FROM TABLEY
 WHERE INTCOL = 1234;
```

*Example 4:* For sample table DSN8910.EMP, the following SQL statement sets the host variable AVERAGE, which is defined as CHAR(33), to the character string representation of the average employee salary.

```
EXEC SQL SELECT CHAR(AVG(SALARY))
  INTO :AVERAGE
  FROM DSN8910.EMP;
```

With DEC31, the result of AVG applied to a decimal number is a decimal number with a precision of 31 digits. The only host languages in which such a large decimal variable can be defined are Assembler and C. For host languages that do not support such large decimal numbers, use the method shown in this example.

*Example 5:* For the rows in sample table DSN8910.EMP, return the values in column LASTNAME, which is defined as VARCHAR(15), as a fixed-length character string and limit the length of the results to 10 characters.

```
SELECT CHAR(LASTNAME,10)
  FROM DSN8910.EMP;
```

For rows that have a LASTNAME with a length greater than 10 characters (excluding trailing blanks), a warning that the value is truncated is returned.

*Example 6:* FIRSTNAME is a VARCHAR(12) column in a Unicode table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the values shown under 'Function', the results are shown under 'Returns':

Function ...	Returns ...
CHAR(FIRSTNAME,3,CODEUNITS32)	'Jür'        ' -- x'4AC3BC7220202020202020'
CHAR(FIRSTNAME,3,CODEUNITS16)	'Jür'        ' -- x'4AC3BC722020202020'
CHAR(FIRSTNAME,3,OCTETS)	'Jü'        -- x'4AC3BC'

*Example 7:* For the rows in sample table DSN8910.EMP, return the values in column EDLEVEL, which is defined as SMALLINT, as a fixed-length character string.

```
SELECT CHAR(EDLEVEL)
  FROM DSN8910.EMP;
```

An EDLEVEL of 18 is returned as CHAR(6) value '18      ' (18 followed by four blanks).

*Example 8:* In sample table DSN8910.EMP, the SALARY column is defined as DECIMAL(9,2). For those employees who have a salary of 52750.00, return the hire date and the salary, using a comma as the decimal character in the salary (52750,00).

```
SELECT HIREDATE, CHAR(SALARY, ',')
  FROM DSN8910.EMP
 WHERE SALARY = 52750.00;
```

The salary is returned as the string value '52750,00'.

*Example 9:* Repeat the scenario in Example 8 except subtract the SALARY column from 60000.00 and return the salary with the default decimal character.

```
SELECT HIREDATE, CHAR (60000.00 - SALARY)
  FROM DSN8910.EMP
 WHERE SALARY = 52750.00;
```

The salary is returned as the string value '7250.00'.

*Example 10:* Assume that host variable SEASONS\_TICKETS is defined as INTEGER and has a value of 10000. Use the DECIMAL and CHAR functions to change the value into the character string ' 10000.00'.

```
SELECT CHAR(DECIMAL(:SEASONS_TICKETS,7,2))
  FROM SYSIBM.SYSDUMMY1;
```

*Example 11:* Assume that columns COL1 and COL2 in table T1 are both defined as REAL and that T1 contains a single row with the values 7.1E+1 and 7.2E+2 for the two columns. Add the two columns and represent the result as a character string.

```
SELECT CHAR(COL1 + COL2)
  FROM T1;
```

The result is the character value '1.43E2'.

## **CHARACTER\_LENGTH**

The CHARACTER\_LENGTH function returns the length of the first argument in the specified string unit.

### **Character string:**

```
►►CHARACTER_LENGTH(—character-expression—, [CODEUNITS16  
          | CODEUNITS32  
          | OCTETS])►►
```

### **Graphic string:**

```
►►CHARACTER_LENGTH(—graphic-expression—, [CODEUNITS16  
          | CODEUNITS32])►►
```

The schema is SYSIBM.

#### **Character string:**

##### *character-expression*

An expression that returns a value of a built-in character string.  
*character-expression* cannot be bit data.

##### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express the length of the result.

##### **CODEUNITS16**

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

##### **CODEUNITS32**

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

##### **OCTETS**

Specifies the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the length of *character-expression* expressed in the number of string units that were specified. The length of fixed-length strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

#### **Graphic string:**

##### *graphic-expression*

An expression that returns a value of a built-in graphic string.

| **CODEUNITS16 or CODEUNITS32**

| Specifies the unit that is used to express the length of the result.

| **CODEUNITS16**

| Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

| **CODEUNITS32**

| Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

| For more information about CODEUNITS16 and CODEUNITS32 see “String  
| unit specifications” on page 76.

| The result of the function is a large integer. If the argument can be null, the result  
| can be null; if the argument is null, the result is the null value.

| The result is the length of *graphic-expression* expressed in the number of string units  
| that were specified. The length of fixed-length strings includes trailing blanks. The  
| length of varying-length strings is the actual length and not the maximum length.

| *Example:* Assume that NAME is a VARCHAR(128) column, encoded in Unicode  
| UTF-8, that contains the value 'Jürgen'. The following two queries return the value  
| 6:

```
|     SELECT CHARACTER_LENGTH(NAME,CODEUNITS32)
|           FROM T1 WHERE NAME = 'Jürgen';
|     SELECT CHARACTER_LENGTH(NAME,CODEUNITS16)
|           FROM T1 WHERE NAME = 'Jürgen';
```

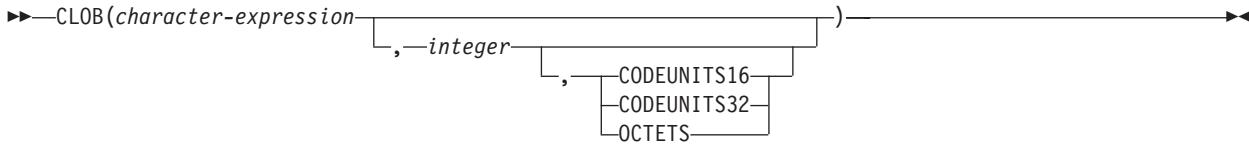

| The following two queries return the value 7:

```
|     SELECT CHARACTER_LENGTH(NAME,OCTETS)
|           FROM T1 WHERE NAME = 'Jürgen';
|     SELECT LENGTH(NAME)
|           FROM T1 WHERE NAME = 'Jürgen';
```

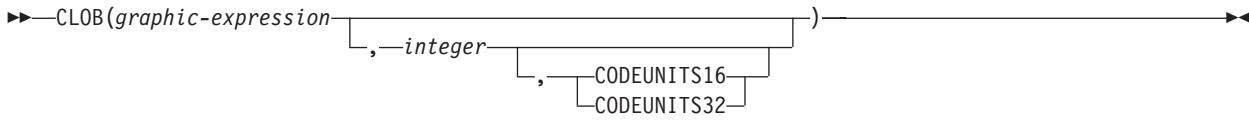

## CLOB

The CLOB function returns a CLOB representation of a string.

### Character to CLOB:

### Graphic to CLOB:

The schema is SYSIBM.

#### Character to CLOB

##### *character-expression*

An expression that returns a value of a character string. If *character-expression* is bit data, an error occurs.

##### *integer*

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information on how to calculate the length attribute of the result string.

##### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express *integer*.

##### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

##### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

##### **OCTETS**

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The result of the function is a CLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *character-expression*.

### Graphic to CLOB

*graphic-expression*

An expression that returns a value of a graphic string.

*integer*

An integer constant that specifies the length attribute of the resulting CLOB data type. The value must be between 1 and the maximum length of a CLOB, expressed in the units that are either implicitly or explicitly specified.

If you do not specify *integer* and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is  $(3 * \text{length}(\text{graphic-expression}))$ .

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information on how to calculate the length attribute of the result string.

### CODEUNITS16 or CODEUNITS32

Specifies the unit that is used to express *integer*.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The result of the function is a CLOB. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are blanks, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

*Example 1:* The following function returns a CLOB for the string 'This is a CLOB'.

```
SELECT CLOB('This is a CLOB')
  FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

Function ...	Returns ...
CLOB(FIRSTNAME,3,CODEUNITS32)	'Jür' -- x'4AC3BC72'
CLOB(FIRSTNAME,3,CODEUNITS16)	'Jür' -- x'4AC3BC72'
CLOB(FIRSTNAME,3,OCTETS)	'Jü' -- x'4AC3BC'

## COALESCE

The COALESCE function returns the value of the first nonnull expression.

```
►► COALESCE-(expression , expression )
```

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 20 on page 102. The arguments can be of either a built-in or user-defined data type.<sup>20</sup>

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. The result can be null only if all arguments can be null. The result is null only if all arguments are null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the “Rules for result data types” on page 119. If the COALESCE function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type is determined.

The COALESCE function can also handle a subset of the functions provided by CASE expressions. The result of using COALESCE(e1,e2) is the same as using the expression:

```
CASE WHEN e1 IS NOT NULL THEN e1 ELSE e2 END
```

VALUE can be specified as a synonym for COALESCE.

*Example 1:* Assume that SCORE1 and SCORE2 are SMALLINT columns in table GRADES, and that nulls are allowed in SCORE1 but not in SCORE2. Select all the rows in GRADES for which SCORE1 + SCORE2 > 100, assuming a value of 0 for SCORE1 when SCORE1 is null.

```
SELECT * FROM GRADES  
WHERE COALESCE(SCORE1,0) + SCORE2 > 100;
```

*Example 2:* Assume that a table named DSN8910.EMP contains a DATE column named HIREDATE, and that nulls are allowed for this column. The following query selects all rows in DSN8910.EMP for which the date in HIREDATE is either unknown (null) or earlier than 1 January 1960.

```
SELECT * FROM DSN8910.EMP  
WHERE COALESCE(HIREDATE,DATE('1959-12-31')) < '1960-01-01';
```

20. This function cannot be used as a source function when creating a user-defined function.

The predicate could also be coded as COALESCE(HIREDATE, '1959-12-31') because, for comparison purposes, a string representation of a date can be compared to a date.

*Example 3:* Assume that for the years 1993 and 1994 there is a table that records the sales results of each department. Each table, S1993 and S1994, consists of a DEPTNO column and a SALES column, neither of which can be null. The following query provides the sales information for both years.

```
SELECT COALESCE(S1993.DEPTNO,S1994.DEPTNO) AS DEPT, S1993.SALES, S1994.SALES  
  FROM S1993 FULL JOIN S1994 ON S1993.DEPTNO = S1994.DEPTNO  
 ORDER BY DEPT;
```

The full outer join ensures that the results include all departments, regardless of whether they had sales or existed in both years. The COALESCE function allows the two join columns to be combined into a single column, which enables the results to be ordered.

## COLLATION\_KEY

The COLLATION\_KEY function returns a varying-length binary string that represents the collation key of the argument in the specified collation.

```
►►—COLLATION_KEY(string-expression, collation-name [, —integer ])—►►
```

The schema is SYSIBM.

The result of COLLATION\_KEY on one string can be compared in binary form with the result of COLLATION\_KEY on another string to determine their order within the specified *collation-name*. For the comparison to be meaningful, the results of the COLLATION\_KEY must be from the same *collation-name*.

### *string-expression*

An expression that returns a character or graphic string that is not a LOB for which the collation key is to be determined. If *string-expression* is a character string, it must not be FOR BIT DATA. If *string-expression* is not in Unicode UTF-16 (CCSID 1200), it is converted to Unicode UTF-16 before the corresponding collation key is obtained. The length of *string-expression* must not exceed 32704 bytes of the UTF-16 representation.

### *collation-name*

A string constant or a string host variable that is not a binary string, CLOB, or DBCLOB. *collation-name* specifies the collation to use when determining the collation key. If *collation-name* is not an EBCDIC value, it is converted to EBCDIC. The length of *collation-name* must be between 1 and 255 bytes of the EBCDIC representation. The value of *collation-name* is not case sensitive and must be a left justified, valid "short path" collation setting for the parameter CUNBOPRM\_Collation\_Keyword in area CUN4BOPR. For detailed information about the "short path" setting in the parameter CUNBOPRM\_Collation\_Keyword, see *z/OS Support for Unicode: Using Conversion Services*.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. *collation-name* must be left justified within the host variable. It must also be padded on the right with blanks if the length is less than that of the host variable and the host variable is a fixed length CHAR or GRAPHIC data type.

*collation-name* is in the form of CUN4BOPR\_Collation\_Keyword specification.

The following table lists some supported values:

Table 54. Collation Keywords Reference

Attribute name	Key	Possible values
Locale	L.R.V	<locale>
Strength	S	1, 2, 3, 4, I, D
Case_Level	K	X, O, D
Case_First	C	X, L, U, D

| *Table 54. Collation Keywords Reference (continued)*

Attribute name	Key	Possible values
Alternate	A	N, S, D
Variable_Top	T	<hex digits>
Normalization	N	X, O, D
French	F	X, O, D
Hinayana	H	X, O, D

| The following table describes the abbreviations for the collation keywords:

Abbreviation	Definition
D	default
O	on
X	off
1	primary
2	secondary
3	tertiary
4	quaternary
I	identical
S	shifted
N	non-ignorable
L	lower-first
U	upper-first

| The following examples show keywords using the above specifications:

| 'UCA400R1\_AS\_LSV\_S3 CU'

| UCA version 4.0.1; ignore spaces, punctuation and symbols; use Swedish  
| linguistic conventions; use case-first upper; compare case-sensitive.

| 'UCA400R1\_AN\_LSV\_S3\_CL\_NO'

| UCA version 4.0.1; do not ignore spaces, punctuation and symbols; use  
| Swedish linguistic conventions; use case-first lower (or does not set it to mean  
| the same, since lower is used in most locales as the default); normalization  
| ON; compare case-sensitive.

| *integer*

| An integer value that specifies the length attribute of the result. If specified,  
| the value must be an integer constant between 1 and 32704.

| If the length is not specified, the length attribute of the result is determined as  
| follows:

<i>string-expression</i>	Result length attribute
CHAR( <i>n</i> ) or VARCHAR( <i>n</i> )	MIN (VARBINARY(12 <i>n</i> ), 32704)
GRAPHIC( <i>n</i> ) or VARGRAPHIC( <i>n</i> )	MIN (VARBINARY(12 <i>n</i> ), 32704)

| Regardless of whether the length is specified, the length of the collation key  
| must be less than or equal to the length attribute of the result. The actual result  
| length of the collation key is approximately six times of the length of  
| *string-expression* where the length of *string-expression* is in Unicode byte  
| representation. For certain *collation-name* such as UCA410\_LKO\_RKR (for  
| Korean collation) the default length attribute of the result, 12*n*, might not be

large enough and an error will be returned. To avoid such an error, the length attribute of the result must be explicitly specified to a larger constant. For the proper length attribute of the result, see *z/OS Support for Unicode: Using Conversion Services* for information about target buffer length considerations for Collation Services.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The COLLATION\_KEY function uses Unicode Collation Services in z/OS to return the collation key. Unicode Collation Services support two collation versions:

- UCA400R1. This Collation version support Unicode standard character suite 4.0.0 and use Normalization Service under 4.0.1 Unicode character suite.
- UCA410. This Collation version support Unicode standard character suite 4.1.0 and use Normalization Service under 4.1.0 Unicode character suite.

If Unicode Collation Services are not available when the COLLATION\_KEY function is run, an error is returned.

*Example 1:* The following query orders the employees by their surnames using the default Unicode Collation Algorithm V4.0.1(UCA), ignoring spaces, punctuation, and symbols, using Swedish linguistic conventions, and not comparing case:

```
SELECT FIRSTNAME, LASTNAME
      FROM DSN8910.EMP
     ORDER BY COLLATION_KEY(LASTNAME, 'UCA400R1_AS_LSV_S2');
```

*Example 2:* The following query uses the COLLATION\_KEY function on the LASTNAME column and the SALES\_PERSON column to obtain the sort keys from the same collation name in order to do a culturally correct comparison. It finds the departments of employees in Quebec:

```
SELECT E.WORKDEPT
      FROM EMPLOYEE AS E INNER JOIN SALES AS S
     ON COLLATION_KEY(E.LASTNAME, 'UCA400R1_LFR') =
        COLLATION_KEY(S.SALES_PERSON, 'UCA400R1_LFR')
    WHERE S.REGION = 'Quebec';
```

*Example 3:* Create an index EMPLOYEE\_NAME\_SORT\_KEY for table EMPLOYEE based on built-in function COLLATION\_KEY with collation name 'UCA410\_LDE' tailored for German.

```
CREATE INDEX EMPLOYEE_NAME_SORT_KEY
  ON EMPLOYEE (COLLATION_KEY(LASTNAME, 'UCA410_LDE', 600),
                COLLATION_KEY(FIRSTNAME, 'UCA410_LDE', 600),
                ID);
```

## COMPARE\_DECFLOAT

The COMPARE\_DECFLOAT function returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.

```
►►COMPARE_DECFLOAT(decfloat-expression1,decfloat-expression2)►►
```

The schema is SYSIBM.

*decfloat-expression1*

An expression that returns a DECFLOAT value.

*decfloat-expression2*

An expression that returns a DECFLOAT value.

*decfloat-expression1* is compared with *decfloat-expression2* and the result is returned according to the following rules:

- If both arguments are finite, the comparison is algebraic and follows the procedure for DECFLOAT subtraction. If the difference is exactly zero with either sign, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.
- Positive zero and negative zero compare as equal.
- Positive infinity compares equal to positive infinity.
- Positive infinity compares greater than any finite number.
- Negative infinity compares equal to negative infinity.
- Negative infinity compares less than any finite number.
- Numeric comparison is exact and the result is determined for finite operands as if range and precision were unlimited. Overflow or underflow cannot occur.
- If either argument is NaN or sNaN (positive or negative), the result is unordered.

Numeric comparison is exact, and the result is determined for finite operands as if the range and precision were unlimited. An overflow or underflow condition cannot occur.

If one argument is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

One of the following values will be the result:

- 0 The arguments are exactly equal
- 1 *decfloat-expression1* is less than *decfloat-expression2*
- 2 *decfloat-expression1* is greater than *decfloat-expression2*
- 3 The arguments are unordered

The result of the function is a SMALLINT value. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

*Examples:* The following examples demonstrate the values that will be returned when the function is used:

COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.17))	= 0
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.170))	= 2
COMPARE_DECFLOAT(DECFLOAT(2.170), DECFLOAT(2.17))	= 1
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(0.0))	= 2
COMPARE_DECFLOAT(INFINITY,INFINITY)	= 0
COMPARE_DECFLOAT(INFINITY,-INFINITY)	= 2
COMPARE_DECFLOAT(DECFLOAT(-2),INFINITY)	= 1
COMPARE_DECFLOAT(NAN,NAN)	= 3
COMPARE_DECFLOAT(DECFLOAT(-0.1),SNAN)	= 3

## CONCAT

The CONCAT function combines two compatible string arguments.

```
►►—CONCAT(string-expression-1,string-expression-2)—————►►
```

The schema is SYSIBM.

The arguments must be compatible strings. For more information on compatibility, refer to the compatibility matrix in Table 20 on page 102.

The result of the function is a string that consists of the first string followed by the second string. If either argument can be null, and if either is null, the result is the null value.

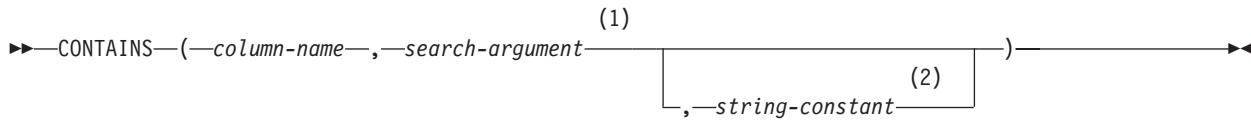

The CONCAT function is identical to the CONCAT operator. For more information, see “With the concatenation operator” on page 188.

*Example:* Using sample table DSN8910.EMP, concatenate column FIRSTNME with column LASTNAME. Both columns are defined as varying-length character strings.

```
SELECT CONCAT(FIRSTNME, LASTNAME)
      FROM DSN8910.EMP;
```

## CONTAINS

The CONTAINS function searches a text search index using criteria that are specified in a search argument and returns a result about whether or not a match was found.

### Notes:

- 1 The SQL statement that invokes the CONTAINS function can be dynamically prepared by using a typed parameter marker for the *search-argument*, as in the following example: CONTAINS(C1,CAST(?) AS CHAR(10))).
- 2 *string-constant* must conform to the rules for the *search-argument-options*.

### search-argument-options:

### Notes:

- 1 The same clause must not be specified more than once.

The schema is SYSIBM.

#### *column-name*

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, directly or through another nested view.

#### *search-argument*

Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

*string-constant*

Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

**QUERYLANGUAGE = *value***

Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en\_US.

**RESULTLIMIT = *value***

Specifies the maximum number of results to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

**SYNONYM = OFF or SYNONYM = ON**

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

**OFF** Do not use a synonym dictionary.

**ON** Use the synonym dictionary that is associated with the text search index.

The result of the function is a large integer. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is 1 if the document contains a match for the search criteria that are specified in the search argument. Otherwise, the result is 0.

CONTAINS is a non-deterministic function.

## Example 1

The following statement finds all of the employees who have "COBOL" in their resume. The text search argument is not case-sensitive.

```
SELECT EMPNO
  FROM EMP_RESUME
 WHERE RESUME_FORMAT = 'ascii'
   AND CONTAINS(RESUME, 'cobol') = 1
```

## Example 2

The search argument does not need to be a string constant. The search argument can be any SQL string expression, including a string contained in a host variable.

The following statement searches for the exact term "ate" in the COMMENT column.

```
char search_arg[100]; /* input host variable */  
...  
EXEC SQL DECLARE C3 CURSOR FOR  
    SELECT CUSTKEY  
    FROM K55ADMIN.CUSTOMERS  
    WHERE CONTAINS(COMMENT, :search_arg)= 1  
    ORDER BY CUSTKEY;  
strcpy(search_arg, "ate");  
EXEC SQL OPEN C3;  
...
```

## Example 3

The following statement finds 10 students at random who wrote online essays that contain the phrase "fossil fuel" in Spanish, which is "combustible fósil." These students will be invited for a radio interview. Use the synonym dictionary that was created for the associated text search index. Because only 10 students are needed, you can optimize the query by using the RESULTLIMIT option to limit the number of results from the underlying text search server.

```
SELECT FIRSTNME, LASTNAME  
    FROM STUDENT_ESAYS  
    WHERE CONTAINS(TERM_PAPER, 'combustible fósil',  
        'QUERYLANGUAGE= es_ES RESULTLIMIT = 10 SYNONYM=ON') = 1
```

**COS**

The COS function returns the cosine of the argument, where the argument is an angle, expressed in radians. The COS and ACOS functions are inverse operations.

►►—COS(*numeric-expression*)—

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable COSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.07:

```
SELECT COS(:COSINE)
      FROM SYSIBM.SYSDUMMY1;
```

## COSH

The COSH function returns the hyperbolic cosine of the argument, where the argument is an angle, expressed in radians.

```
►►—COSH(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HCOS is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.35:

```
SELECT COSH(:HCOS)
      FROM SYSIBM.SYSDUMMY1;
```

## DATE

The DATE function returns a date that is derived from a value.

```
►►—DATE(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be one of the following:
  - A valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.
  - A character or graphic string with an actual length of 7 that represents a valid date in the form *yyyynnn*, where *yyyy* are digits denoting a year and *nnn* are digits between 001 and 366 denoting a day of that year.
- If *expression* is a number, it must be greater than or equal to one and less than or equal to 3652059.

If the argument is a string, the result is the date represented by the string. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result of the function is a date. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a timestamp**, the result is the date part of the timestamp.

**If the argument is a date**, the result is that date.

**If the argument is a number**, the result is the date that is *n*-1 days after January 1, 0001, where *n* is the integral part of the number.

**If the argument is a string**, the result is the date represented by the string. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

*Example 1:* Assume that RECEIVED is a TIMESTAMP column in some table, and that one of its values is equivalent to the timestamp '1988-12-25-17.12.30.000000'. For this value, the following statement returns the internal representation of 25 December 1988.

```
DATE(RECEIVED)
```

*Example 2:* Assume that DATCOL is a CHAR(7) column in some table, and that one of its values is the character string '1989061'. For this value, the following statement returns the internal representation of 2 March 1989.

```
DATE(DATCOL)
```

*Example 3:* DB2 recognizes '1989-03-02' as the ISO representation of 2 March 1989. So, the following statement returns the internal representation of 2 March 1989.

```
DATE('1989-03-02')
```

## DAY

The DAY function returns the day part of a value.

```
►►—DAY(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or any numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a date duration or a timestamp duration. For the valid formats of datetime durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules for the function depend on the data type of the argument:

**If the argument is a date, timestamp, or string representation of either,** the result is the day part of the value, which is an integer between 1 and 31.

**If the argument is a date duration or timestamp duration,** the result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

*Example 1:* Set the INTEGER host variable DAYVAR to the day of the month on which employee 140 in the sample table DSN8910.EMP was hired.

```
EXEC SQL SELECT DAY(HIREDATE)
  INTO :DAYVAR
  FROM DSN8910.EMP
 WHERE EMPNO = '000140';
```

*Example 2:* Assume that DATE1 and DATE2 are DATE columns in the same table. Assume also that for a given row in this table, DATE1 and DATE2 represent the dates 15 January 2000 and 31 December 1999, respectively. Then, for the given row:

```
DAY(DATE1 - DATE2)
```

returns the value 15.

## DAYOFMONTH

The DAYOFMONTH function returns the day part of a value. The function is similar to the DAY function, except DAYOFMONTH does not support a date or timestamp duration as an argument.

```
►►—DAYOFMONTH(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of a date, a timestamp, a character string, or a graphic string built-in data type.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer between 1 and 31, which represents the day part of the value. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Set the INTEGER variable DAYVAR to the day of the month on which employee 140 in sample table DSN8910.EMP was hired.

```
SELECT DAYOFMONTH(HIREDATE)
      INTO :DAYVAR
     FROM DSN8910.EMP
    WHERE EMPNO = '000140';
```

## DAYOFWEEK

The DAYOFWEEK function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Sunday and 7 is Saturday. The DAYOFWEEK function is similar to the DAYOFWEEK\_ISO function.

```
►►DAYOFWEEK(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.EMP, set the integer host variable DAY\_OF\_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```
SELECT DAYOFWEEK(HIREDATE)
      INTO :DAY_OF_WEEK
     FROM DSN8910.EMP
    WHERE EMPNO = '000010';
```

The result is that DAY\_OF\_WEEK is set to 6, which represents Friday.

*Example 2:* The following query returns four values: 1, 2, 1, and 2.

```
SELECT DAYOFWEEK(CAST('10/11/1998' AS DATE)),
       DAYOFWEEK(TIMESTAMP('10/12/1998', '01.02')),
       DAYOFWEEK(CHAR(20) CAST(CAST('10/11/1998' AS DATE) AS CHAR(20))),
       DAYOFWEEK(CHAR(20) CAST(TIMESTAMP('10/12/1998', '01.02') AS CHAR(20)))
  FROM SYSIBM.SYSDUMMY1;
```

## DAYOFWEEK\_ISO

The DAYOFWEEK\_ISO function returns an integer, in the range of 1 to 7, that represents the day of the week, where 1 is Monday and 7 is Sunday. The DAYOFWEEK\_ISO function is similar to the DAYOFWEEK function.

```
►►—DAYOFWEEK_ISO(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.EMP, set the integer host variable DAY\_OF\_WEEK to the day of the week that Christine Haas (EMPNO = '000010') was hired (HIREDATE).

```
SELECT DAYOFWEEK_ISO(HIREDATE)
      INTO :DAY_OF_WEEK
     FROM DSN8910.EMP
    WHERE EMPNO = '000010';
```

The result is that DAY\_OF\_WEEK is set to 5, which represents Friday.

*Example 2:* The following query returns four values: 7, 1, 7, and 1.

```
SELECT DAYOFWEEK_ISO(CAST('10/11/1998' AS DATE)),
       DAYOFWEEK_ISO(TIMESTAMP('10/12/1998', '01.02')),
       DAYOFWEEK_ISO(CHAR(20)),
       DAYOFWEEK_ISO(CHAR(20))
     FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following list shows what is returned by the DAYOFWEEK\_ISO function for various dates.

DATE:	DAYOFWEEK_ISO returns:
2003-12-28	'7'
2003-12-31	'3'
2004-01-01	'4'
2004-01-10	'6'
2005-01-04	'2'
2005-12-31	'7'
2006-01-01	'7'
2006-01-03	'2'

## DAYOFYEAR

The DAYOFYEAR function returns an integer, in the range of 1 to 366, that represents the day of the year, where 1 is January 1.

```
►►DAYOFYEAR(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.EMP, set the integer host variable AVG\_DAY\_OF\_YEAR to the average of the day of the year on which employees were hired (HIREDATE):

```
SELECT AVG(DAYOFYEAR(HIREDATE))
  INTO :AVG_DAY_OF_YEAR
  FROM DSN8910.EMP;
```

The result is that AVG\_DAY\_OF\_YEAR is set to 202.

## DAYS

The DAYS function returns an integer representation of a date.

```
►►—DAYS(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string.

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to *D*, where *D* is the date that would occur if the DATE function were applied to the argument.

*Example1:* Set the INTEGER host variable DAYSVAR to the number of days that employee 140 had been with the company on the last day of 1997.

```
EXEC SQL SELECT DAYS('1997-12-31') - DAYS(HIREDATE) + 1  
      INTO :DAYSVAR  
     FROM DSN8910.EMP  
    WHERE EMPNO = '000140';
```

## DBCLOB

The DBCLOB function returns a DBCLOB representation of a character string value (with the single-byte characters converted to double-byte characters) or a graphic string value.

### Character to DBCLOB:

```
►►DBCLOB(character-expression  
          |,—integer  
          |, —CODEUNITS16  
          |, —CODEUNITS32
```

### Graphic to DBCLOB:

```
►►DBCLOB(graphic-expression  
          |,—integer  
          |, —CODEUNITS16  
          |, —CODEUNITS32
```

The schema is SYSIBM.

#### Character to DBCLOB

##### *character-expression*

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See “Character strings” on page 73 for these rules.)

##### *integer*

The length attribute of the resulting DBCLOB. The value of *integer* must be between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string. If CODEUNITS32 is specified, the value of *integer* must be between 1 and the maximum length of a DBCLOB divided by two (to allow for an intermediate result string that is long enough to evaluate the function).

If *integer* is not specified and *character-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *character-expression*.

##### **CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*.

For EBCDIC input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is *M*.
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string  $S$  derived by converting the characters to the coded character set identified by  $M$ .

The result is derived from  $S$  using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

### Graphic to DBCLOB

#### *graphic-expression*

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded graphic string.

#### *integer*

The length attribute for the resulting varying-length graphic string. The value must be an integer between 1 and the maximum length of a DBCLOB, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and *graphic-expression* is an empty string constant, the length attribute of the result is 1, and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of *graphic-expression*.

#### **CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

#### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of *graphic-expression* is greater than the length attribute of the result, truncation is performed. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

The result of the function is a DBCLOB.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

*Example 1:* Assume that the application encoding scheme is Unicode. The following statement returns a graphic (UTF-16) host variable.

```
VALUES DBCLOB('123')
      INTO :GHV1;
```

*Example 2:* FIRSTNAME is a VARCHAR(12) column (Unicode UTF-8 data) in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

Function ...	Returns ...
DBCLOB(FIRSTNAME,3,CODEUNITS32)	'Jür' -- x'004A00FC0072'
DBCLOB(FIRSTNAME,3,CODEUNITS16)	'Jür' -- x'004A00FC0072'

## DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of either a number or a character string representation of a number, a decimal number, an integer, a floating-point number, or a decimal floating-point number.

### Numeric to DECFLOAT:

```
►►DECFLOAT(numeric-expression [ ,34 ] [ ,16 ])►►
```

### String to DECFLOAT:

```
►►DECFLOAT(string-expression [ ,34 ] [ ,16 ])►►
```

The schema is SYSIBM.

#### Numeric to DECFLOAT

##### *numeric-expression*

An expression that returns a value of any built-in numeric data type.

##### **34 or 16**

Specifies the number of digits of precision for the result. The default is 34.

#### String to DECFLOAT

##### *string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes.

The string must contain a valid string representation of a number.

Use the *string-expression* syntax variation to specify a negative zero as a constant, or to preserve the precision of a floating point constant.

##### **34 or 16**

Specifies the number of digits of precision for the result. The default is 34.

The result is the same number that would result from `CAST(string-expression AS DECFLOAT(n))` or `CAST(numeric-expression AS DECFLOAT(n))`. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a string representation of an SQL decimal-floating point constant.

If necessary, the source is rounded to the precision of the target.

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

| For dynamic SQL statements (and static CREATE VIEW statements), the special  
| register CURRENT DECFLOAT ROUNDING MODE determines the rounding  
| mode.

| The result of the function is a DECFLOAT with the implicitly or explicitly specified  
| number of digits of precision. If the first argument can be null, the result can be  
| null; if the first argument is null, the result is the null value.

| **Note:** To increase the portability of applications, use the CAST specification. For  
| more information, see “CAST specification” on page 202.

## DECFLOAT\_SORTKEY

The DECFLOAT\_SORTKEY function returns a binary value that can be used when sorting DECFLOAT values. The sorting occurs in a manner that is consistent with the IEEE 754R specification on total ordering.

```
►►DECFLOAT_SORTKEY(decfloat-expression)—►►
```

The schema is SYSIBM.

*decfloat-expression*

An expression that returns a DECFLOAT value.

The result is a fixed length binary string with a length attribute of 9 if *decfloat-expression* is a DECFLOAT(16) value or 17 if *decfloat-expression* is a DECFLOAT(34) value.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example:* Assume that the following CREATE TABLE statement is used to create a table with a column that contains DECFLOAT values and the INSERT statements are used to populate the table:

```
CREATE TABLE T1(D1 DECFLOAT(16));
INSERT INTO T1 VALUES (2.100);
INSERT INTO T1 VALUES (2.10);
INSERT INTO T1 VALUES (2.1000);
INSERT INTO T1 VALUES (2.1);
```

Then the following SELECT statement is used to return the values from D1:

```
SELECT D1 FROM T1 ORDER BY D1;
```

The SELECT statement returns the following values, but because all numbers in the column have the same value, the ORDER BY clause has no effect and the values are returned in an arbitrary order:

```
D1
-----
2.1
2.1000
2.10
2.100
```

The following SELECT statement, which includes the DECFLOAT\_SORTKEY function in the ORDER BY clause, returns the properly ordered values:

```
SELECT D1
      FROM T1
     ORDER BY (DECFLOAT_SORTKEY(D1));
D1
-----
```

```
| 2.1000  
| 2.100  
| 2.10  
| 2.1
```

```
|
```

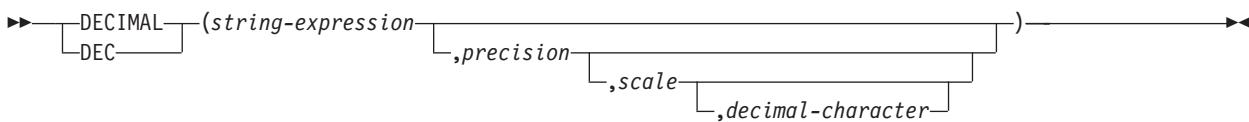

## DECIMAL or DEC

The DECIMAL function returns a decimal representation of either a number or a character-string or graphic-string representation of a number, an integer, or a decimal number.

### Numeric to Decimal:

### String to Decimal:

The schema is SYSIBM.

#### Numeric to decimal

##### *numeric-expression*

An expression that returns a value of any built-in numeric data type.

##### *precision*

An integer constant with a value in the range of 1 to 31. The value of this second argument specifies the precision of the result.

The default value depends on the data type of the first argument as follows:

- 5 if the first argument is a small integer
- 11 if the first argument is a large integer
- 19 if the first argument is a big integer
- 31 if the first argument is a DECFLOAT value
- 15 in all other cases

##### *scale*

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

The result of the function is the same number that would occur if the argument were assigned to a decimal column or variable with precision *p* and scale *s*, where *p* and *s* are specified by the second and third arguments. An error occurs if the number of significant digits required to represent the whole part of the number is greater than *p-s*.

#### String to decimal

##### *string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes.

The string must contain a valid string representation of a number. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL integer or decimal constant.

*precision*

An integer constant with a value in the range of 1 to 31. The value of this second argument specifies the precision of the result.

The default value depends on the data type of the first argument as follows:

- 5 if the first argument is a small integer
- 11 if the first argument is a large integer
- 15 in all other cases

*scale*

An integer constant that is greater than or equal to zero and less than or equal to *precision*. The value specifies the scale of the result. The default value is 0.

*decimal-character*

A single-byte character constant used to delimit the decimal digits in *string-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank. The default value is period (.) or comma (,), the default value cannot be used in *string-expression* if a different value for *decimal-character* is specified.

The result is the same number that would result from `CAST(string-expression AS DECIMAL(p,s))`. Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *s*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *p-s*.

The result of the function is a decimal number with precision of *p* and scale of *s*, where *p* and *s* are the second and third arguments. If the first argument can be null, the result can be null; if the first argument is null, the result is null.

**Note:** To increase the portability of applications when the precision is specified, use the `CAST` specification. For more information, see “`CAST` specification” on page 202.

*Example 1:* Represent the average salary of the employees in DSN8910.EMP as an 8-digit decimal number with two of these digits to the right of the decimal point.

```
SELECT DECIMAL( AVG(SALARY) ,8,2 )
      FROM DSN8910.EMP;
```

*Example 2:* Assume that updates to the SALARY column are input as a character string that uses comma as the decimal character. For example, the user inputs 21400,50. The input value is assigned to the host variable NEWSALARY that is defined as CHAR(10), and the host variable is used in the following UPDATE statement:

```
UPDATE DSN8910.EMP
   SET SALARY = DECIMAL (:NEWSALARY,9,2,',')
 WHERE EMPNO = :EMPID;
```

## **DECRYPT\_BINARY, DECRYPT\_BIT, DECRYPT\_CHAR, and DECRYPT\_DB**

The decryption functions return a value that is the result of decrypting encrypted data. The decryption functions can decrypt only values that are encrypted by using the ENCRYPT\_TDES function.

The schema is SYSIBM.

The password used for decryption is either the *password-string* value or the ENCRYPTION PASSWORD value, which is assigned by the SET ENCRYPTION PASSWORD statement.

### *encrypted-data*

An expression that returns a complete, encrypted data value of a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY data type. The data string must have been encrypted using the ENCRYPT\_TDES function. The length attribute must be greater than or equal to 0 (zero) and less than or equal to 32672.

### *password-string*

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes. This expression must be the same password that was used to encrypt the data or decryption will result in a different value than was originally encrypted. For enhanced security, *password-string* should be specified using a host variable rather than a string constant. If the value of the password argument is null or not provided, the data will be decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

For a static SQL statement, it is recommended that the password be specified with a host variable rather than with a string constant.

### **DEFAULT**

The data is decrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

### *ccsid-constant*

A integer constant that specifies the CCSID in which the data should be returned by the decryption function. If DECRYPT\_BIT or DECRYPT\_BINARY is specified, *ccsid-constant* must not be specified. The default is

- The ENCODING bind option of the plan or package or the APPLICATION ENCODING SCHEMA option of the CREATE PROCEDURE or ALTER PROCEDURE statement for native SQL procedures that contain the static SQL statements
- The value of the APPLICATION ENCODING special register for dynamic SQL statements

The data type of the result of the function is determined by the function that is specified and the data type of the first argument, as shown in the following table. If the cast from the actual type of the encrypted data to the result of the function is not supported, a warning or error is returned.

*Table 55. Result of the decryption function*

Function	Type of first argument	Actual type of encrypted data	Result
DECRYPT_BINARY	FOR BIT DATA <sup>1</sup> , BINARY, VARBINARY	Any string (except for LOBs)	VARBINARY
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR	VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (UTF16)	Warning or error  If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (not UTF16)	Warning or error  If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_BIT	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error  If a warning is returned, the result is VARCHAR FOR BIT DATA
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR	VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (UTF16)	VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	GRAPHIC, VARGRAPHIC (not UTF16)	Warning or error  If a warning is returned, the result is VARCHAR(3)
DECRYPT_CHAR	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error  If a warning is returned, the result is VARCHAR(3)
DECRYPT_DB	FOR BIT DATA, BINARY, VARBINARY	CHAR, VARCHAR, GRAPHIC, VARGRAPHIC	VARGRAPHIC
DECRYPT_DB	FOR BIT DATA, BINARY, VARBINARY	BINARY, VARBINARY	Warning or error  If a warning is returned, the result is VARGRAPHIC

Table 55. Result of the decryption function (continued)

Function	Type of first argument	Actual type of encrypted data	Result
<b>Note:</b> <sup>1</sup> FOR BIT DATA means CHAR or VARCHAR FOR BIT DATA			

If *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length attribute of *encrypted-data* minus 8 bytes. The actual length of the value that is returned by the function will match the length of the original string that was encrypted. If *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

**Administration of encrypted data:** The decryption functions can only decrypt data that was encrypted using the Triple DES encryption algorithm. Therefore, columns with encrypted data can only be used after replication if they were encrypted using the Triple DES encryption algorithm.

If the data is decrypted using a different CCSID than the originally encrypted value, it is possible that expansion might occur when converting the decrypted value to this CCSID. In such situations, the *encrypted-data* value must first be cast to a VARCHAR string with a larger number of bytes before performing the decryption functions.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

For additional information about using the decryption functions, see “ENCRYPT\_TDES” on page 363 and “GETHINT” on page 373.

**Password protection:** To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source statement. Instead, use the ENCRYPTION PASSWORD special register or specify the password using a host variable.

*Example 1:* Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password to insert a decrypted social security number into the table. Decrypt the value of the added social security number, using the ENCRYPTION PASSWORD value.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

This example returns the value '289-46-8832'.

*Example 2:* Decrypt the social security number that is inserted into the table. Instead of using the ENCRYPTION PASSWORD value, explicitly specify 'Ben123' as the encryption password.

```
SELECT DECRYPT_CHAR(SSN,'Ben123') FROM EMP;
```

This example returns the value '289-46-8832'.

*Example 3:* Insert a decrypted social security number into the table, explicitly specifying 'Ben123' as the password. Decrypt the data and have it converted to CCSID 1208.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES('289-46-8832');
SELECT DECRYPT_CHAR(SSN) FROM EMP;
```

When a CCSID is specified, it might be necessary to explicitly cast the data to a longer value to ensure that there is room for expansion when the data is decrypted. The following example illustrates the technique:

```
SELECT DECRYPT_CHAR(CAST(SSN AS VARCHAR(57)),
                     'Ben123',1208)
      FROM EMP;
```

In the first case, where the data is not cast to a longer value, the result is a VARCHAR(11) value. In the second case, to allow for expansion, SSN is cast as VARCHAR(57) ( $11 * 3 + 24$ ). Casting the data to a longer value allows for three times expansion in the normal VARCHAR(11) result. Three times expansion is often associated with a worst case of ASCII or EBCDIC to Unicode UTF-8 conversion. In both cases in this example, the result is the VARCHAR(11) value '289-46-8832'.

## DEGREES

The DEGREES function returns the number of degrees of the argument, which is an angle, expressed in radians.

```
►►DEGREES(numeric-expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HRAD is a DOUBLE with a value of 3.1415926536. The following statement returns a double precision floating-point number with an approximate value of 180.0.

```
SELECT DEGREES(:HRAD)
   FROM SYSIBM.SYSDUMMY1;
```

## DIFFERENCE

The DIFFERENCE function returns a value, from 0 to 4, that represents the difference between the sounds of two strings, based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

```
►►—DIFFERENCE(expression-1,expression-2)—►►
```

The schema is SYSIBM.

*expression-1 or expression-2*

Each expression must return a value that is a built-in numeric, character string, or graphic string data type that is not a LOB. A numeric argument is cast to a character string before the function is evaluated. For more information on converting a numeric string to a character string, see "VARCHAR" on page 558.

The data type of the result is INTEGER. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONSTANT':

```
SELECT DIFFERENCE('CONSTRAINT','CONSTANT'),  
       SOUNDEX('CONSTRAINT'),  
       SOUNDEX('CONSTANT')  
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 4, C523, and C523. Since the two strings return the same SOUNDEX value, the difference is 4 (the highest value possible).

*Example 2:* Find the DIFFERENCE and SOUNDEX values for 'CONSTRAINT' and 'CONTRITE':

```
SELECT DIFFERENCE('CONSTRAINT','CONTRITE'),  
       SOUNDEX('CONSTRAINT'),  
       SOUNDEX('CONTRITE')  
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the values 2, C523, and C536. In this case, the two strings return different SOUNDEX values, and hence, a lower difference value.

# DIGITS

The DIGITS function returns a character string representation of the absolute value of a number.

►—DIGITS(*numeric-expression*)—

The schema is SYSIBM.

The argument must be an expression that returns a value that is a SMALLINT, INTEGER, BIGINT, or DECIMAL built-in numeric data type.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal point. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer
  - 10 if the argument is a large integer
  - 19 if the argument is a big integer
  - $p$  if the argument is a decimal number with a precision of  $p$

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

*Example 1:* Assume that an INTEGER column called INTCOL containing a 10-digit number is in a table called TABLEX. INTCOL has the data type INTEGER instead of CHAR(10) to save space. the following query lists all combinations of the first four digits in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
  FROM TABLEX;
```

*Example 2:* Assume that COLUMNX has the data type DECIMAL(6,2), and that one of its values is -6.28. For this value, the following statement returns the value '000628'.

DIGITS(COLUMNX)

The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

## **DOUBLE\_PRECISION or DOUBLE**

The DOUBLE\_PRECISION and DOUBLE functions returns a floating-point representation of either a number or a character-string or graphic-string representation of a number, an integer, a decimal number, or a floating-point number.

### **Numeric to Double:**

### **String to Double:**

The schema is SYSIBM.

#### **Numeric to Double**

##### *numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the expression were assigned to a double precision floating-point column or variable.

#### **String to Double**

##### *string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS DOUBLE PRECISION)`. Leading and trailing blanks are removed from the string, and the resulting substring must conform to the rules for forming a valid string representation of an SQL floating-point, integer, or decimal constant.

The result of the function is a double precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

**Note:** To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 202.

FLOAT can be specified as a synonym for DOUBLE or DOUBLE\_PRECISION.

*Example:* Using sample table DSN8910.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved in the

calculation, SALARY and COMM, have decimal data types. To eliminate the possibility of out-of-range results, apply the DOUBLE function to SALARY so that the division is carried out in floating-point.

```
SELECT EMPNO, DOUBLE(SALARY)/COMM  
      FROM DSN8910.EMP  
     WHERE COMM > 0;
```

## DSN\_XMLVALIDATE

The DSN\_XMLVALIDATE function returns an XML value that is the result of applying XML schema validation to the first argument of the function.

DSN\_XMLVALIDATE can validate XML data that has a maximum length of 2 GB - 1 byte.

```
►►—DSN_XMLVALIDATE(string-expression, [schema-name-string  
                          target-namespace-uri-string,schema-location-string])—►►
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a built-in character, graphic, or binary string. The value must be a well-formed XML document that conforms to the XML Version 1.0 standard.

### *schema-name-string*

An expression that returns a built-in varying length character string that is not a CLOB. The value specifies the name of the XML schema object that is used for validation. The value must not be an empty string or the null value, and the actual length must be less than or equal to 257. If the XML schema name is qualified, the qualifier must be SYSXSR (SYSXSR is the default qualifier). The value must identify a registered XML schema in the DB2 XML schema repository.

### *target-namespace-uri-string*

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the target namespace name or universal resource identifier (URI) of the XML schema that is to be used for validation. If the value is an empty string or the null value, no namespace is used to locate the XML schema.

### *schema-location-string*

An expression that returns a built-in varying length character string that is not a CLOB, with a length attribute that is not greater than 1000. The value specifies the XML schema location hint URI of the XML schema that is to be used for validation. If the value is an empty string or the null value, no schema location is used to locate the XML schema.

If *target-namespace-uri-string* and *schema-location-string* are specified, the combination must identify a registered XML schema in the DB2 XML schema repository, and there must be only one such registered XML schema.

A schema must be registered successfully in the DB2 XML schema repository before it can be used for DSN\_XMLVALIDATE. If the validation fails, DB2 returns an error.

To use the version of DSN\_XMLVALIDATE described here, you need to explicitly qualify DSN\_XMLVALIDATE with SYSIBM. When DSN\_XMLVALIDATE is unqualified or is qualified with SYSFUN, the version of the DSN\_XMLVALIDATE function that is used as input to the DSN\_XMLPARSE function is invoked.

The result of the function is an XML value. The result can be null; if the first argument is null, the result is the null value.

*Example 1:* The following example shows how the DSN\_XMLVALIDATE function validates the XML data that is contained in the *value\_host\_var* host variable. The XML schema, SYSXSR.ORDERSCHEMA, was registered prior to this statement:

```
INSERT INTO T1(C1) VALUES(
    DSN_XMLVALIDATE(:value_host_var, 'SYSXSR.MYXMLSCHEMA'));
```

*Example 2:* The following example is similar to the previous example but references the namespace and schema location:

```
INSERT INTO T1(C1) VALUES(
    DSN_XMLVALIDATE(:value_host_var,
        'http://www.n1.com',
        'http://www.n1.com/report.xsd'));
```

## **DSN\_XMLVALIDATE**

The result of DSN\_XMLVALIDATE is a varying-length binary value of up to 50 MB. The result of this function is relevant only as input to the XMLPARSE function.

This version of DSN\_XMLVALIDATE can be used, but has been deprecated in favor of a new version of DSN\_XMLVALIDATE.

### **CLOB input with an XML schema name:**

```
►►—DSN_XMLVALIDATE(clob-expression,varchar-expression)————►►
```

### **CLOB input with namespace and location hint URIs:**

```
►►—DSN_XMLVALIDATE(clob-expression,varchar-expression1,varchar-expression2)————►►
```

### **BLOB input with an XML schema name:**

```
►►—DSN_XMLVALIDATE(blob-expression,varchar-expression)————►►
```

### **BLOB input with namespace and location hint URIs:**

```
►►—DSN_XMLVALIDATE(blob-expression,varchar-expression1,varchar-expression2)————►►
```

### **VARCHAR input with an XML schema name:**

```
►►—DSN_XMLVALIDATE(varchar-expression1,varchar-expression2)————►►
```

### **VARCHAR input with namespace and location hint URIs:**

```
►►—DSN_XMLVALIDATE(varchar-expression1,varchar-expression2,varchar-expression3)————►►
```

The schema is SYSFUN.

#### **CLOB input with an XML schema name:**

##### *clob-expression*

An expression that returns a value that is CLOB(250M). *clob-expression* contains the XML value that is to be validated. DB2 will convert this value from the application encoding scheme to UTF-8. *clob-expression* cannot be null.

##### *varchar-expression*

An expression that returns a value that is VARCHAR(257). *varchar-expression* contains the name of the XML schema object to use for validation. *varchar-expression* cannot be null.

If the name contains a '.', the characters before the '.' are the schema name, which is the qualifier for the name of the XML schema to use for validation of the VALUE parameter. It must be the value 'SYSXSR'. If the name does not contain '.', DB2 will use the value 'SYSXSR' for the relational schema qualifier. The number of characters after the '.' must not exceed 128.

Rules for valid characters and delimiters that apply to any SQL identifier also apply to *varchar-expression*. If an invalid character is used as an ordinary SQL identifier, an error will be returned.

#### **CLOB input with namespace and location hint URIs:**

##### *clob-expression*

An expression that returns a value that is CLOB(250M). *clob-expression* contains the XML value that is to be validated. *clob-expression* cannot be null.

##### *varchar-expression1*

An expression that returns a value that is VARCHAR(1000). *varchar-expression1* contains the target namespace URI.

##### *varchar-expression2*

An expression that returns a value that is VARCHAR(1000). *varchar-expression2* contains the XML schema location hint URI.

Both *varchar-expression1* and *varchar-expression2* can be null. If both values are null, DB2 will look for a single XML schema with null values for both the target namespace and the XML schema location hint. An XML schema with the combination of namespace URI and location hint URI must exist at the current server. The combination of namespace URI and location hint URI must be unique.

#### **BLOB input with an XML schema name:**

##### *blob-expression*

An expression that returns a value that is BLOB(250M). *blob-expression* contains the XML value that is to be validated. *blob-expression* cannot be null.

##### *varchar-expression*

An expression that returns a value that is VARCHAR(257). *varchar-expression* contains the name of the XML schema object to use for validation. *varchar-expression* cannot be null.

If the name contains a '.', the characters before the '.' are the schema name, which is the qualifier for the name of the XML schema to use for validation of the VALUE parameter. It must be the value 'SYSXSR'. If the name does not contain '.', DB2 will use the value 'SYSXSR' for the relational schema qualifier. The number of characters after the '.' must not exceed 128.

Rules for valid characters and delimiters that apply to any SQL identifier also apply to *varchar-expression*. If an invalid character is used as an ordinary SQL identifier, an error will be returned.

#### BLOB input with namespace and location hint URIs:

##### *blob-expression*

An expression that returns a value that is BLOB(250M). *blob-expression* contains the XML value that is to be validated. *blob-expression* cannot be null.

##### *varchar-expression1*

An expression that returns a value that is VARCHAR(1000). *varchar-expression1* contains the target namespace URI.

##### *varchar-expression2*

An expression that returns a value that is VARCHAR(1000). *varchar-expression2* contains the XML schema location hint URI.

Both *varchar-expression1* and *varchar-expression2* can be null. If both values are null, DB2 will look for a single XML schema with null values for both the target namespace and the XML schema location hint. An XML schema with the combination of namespace URI and location hint URI must exist at the current server. The combination of namespace URI and location hint URI must be unique.

#### VARCHAR input with an XML schema name:

##### *varchar-expression1*

An expression that returns a value that is VARCHAR(32K). *varchar-expression1* contains the XML value that is to be validated. DB2 will convert this value from the application encoding scheme to UTF-8. *varchar-expression1* cannot be null.

##### *varchar-expression2*

An expression that returns a value that is VARCHAR(257). *varchar-expression2* contains the name of the XML schema object to use for validation. *varchar-expression2* cannot be null.

If the name contains a '.', the characters before the '.' are the schema name, which is the qualifier for the name of the XML schema to use for validation of the VALUE parameter. It must be the value 'SYSXSR'. If the name does not contain '.', DB2 will use the value 'SYSXSR' for the relational schema qualifier. The number of characters after the '.' must not exceed 128.

Rules for valid characters and delimiters that apply to any SQL identifier also apply to *varchar-expression2*. If an invalid character is used as an ordinary SQL identifier, an error will be returned.

#### VARCHAR input with namespace and location hint URIs:

##### *varchar-expression1*

An expression that returns a value that is VARCHAR(32K). *varchar-expression1* contains the XML value that is to be validated. DB2 will convert this value from the application encoding scheme to UTF-8. *varchar-expression1* cannot be null.

##### *varchar-expression2*

An expression that returns a value that is VARCHAR(1000). *varchar-expression2* contains the target namespace URI.

*varchar-expression3*

An expression that returns a value that is VARCHAR(1000). *varchar-expression3* contains the XML schema location hint URI.

Both *varchar-expression1* and *varchar-expression2* can be null. If both values are null, DB2 will look for a single XML schema with null values for both the target namespace and the XML schema location hint. An XML schema with the combination of namespace URI and location hint URI must exist at the current server. The combination of namespace URI and location hint URI must be unique.

*Example 1:* The following example shows how the DSN\_XMLVALIDATE function provides input to the XMLPARSE function. The XML schema, SYSXSR.ORDERSCHEMA, was registered prior to this statement:

```
INSERT INTO T1(C1) VALUES
  (XMLPARSE (DOCUMENT SYSFUN.DSN_XMLVALIDATE(:value_host_variable,
    'SYSXSR.ORDERSCHEMA')));
```

*Example 2:* The following example is similar to the previous example but references the namespace and schema location:

```
INSERT INTO T1(C1) VALUES
  (XMLPARSE (DOCUMENT DSN_XMLVALIDATE(:value_host_variable,
    'REPORT',
    'http://www.n1.com/report.xsd')));
```

## EBCDIC\_CHR

The EBCDIC\_CHR function returns the character that has the EBCDIC code value that is specified by the argument.

```
►►—EBCDIC_CHR(expression)—►►
```

The schema is SYSIBM.

*expression*

An expression that returns a BIGINT, INTEGER, or SMALLINT built-in data type value.

The result of the function is a CHAR(1) string encoded in the SBCS EBCDIC CCSID (regardless of the setting of the MIXED option in DSNHDECP). If the value of *expression* is not in the range of 0 to 255, the null value is returned.

The result can be null; if the argument is null, the result is the null value.

*Example:* Set *hv* with the Euro symbol "€" in CCSID 1140:

```
SET :hv = EBCDIC_CHR(159); -- x'9F'
```

Set *hv* with the Euro symbol "€" in CCSID 1142:

```
SET :hv = EBCDIC_CHR(90); -- x'5A'
```

In both cases, the "€" is assigned to *hv*, but because the Euro symbol is located at different code points for the two CCSIDs, the input value is different.

## EBCDIC\_STR

The EBCDIC\_STR function returns a string, in the system EBCDIC CCSID, that is an EBCDIC version of the string.

```
►►EBCDIC_STR(string-expression)-----►►
```

The schema is SYSIBM.

The system EBCDIC CCSID is defined as the SBCS EBCDIC CCSID on a MIXED=NO system or the MIXED EBCDIC CCSID on a MIXED=YES system.

*string-expression*

An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. *string-expression* must be an ASCII, EBCDIC, or Unicode string. EBCDIC\_STR returns an EBCDIC version of the string. Non-EBCDIC characters are converted to the form \xxxx, where xxxx represents a UTF-16 code unit.

The length attribute of the result is calculated using the formulas in Table 35 on page 126. The length attribute of the result will be MAX( ( 5\*n ), 32704). Where n is the result of applying the formulas in Table 35 on page 126 based on input and output data types.

The result of the function is an EBCDIC character string (in the system EBCDIC CCSID). If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

*Example:* The following example returns the EBCDIC string equivalent of the text string "Hi my name is А н д р е й (Andrei)"

```
SET :HV1 = EBCDIC_STR('Hi, my name is А н д р е й (Andrei)');
```

*HV1* is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

## ENCRYPT\_TDES

The ENCRYPT\_TDES function returns a value that is the result of encrypting the first argument by using the Triple DES encryption algorithm. The function can also set the password that is used for encryption.

The encryption password can also be set by using the ENCRYPTION PASSWORD value, which is assigned by using the SET ENCRYPTION PASSWORD statement.

```
►►—ENCRYPT_TDES(data-string [,—password-string] [,—hint-string])—►►
```

The schema is SYSIBM.

### *data-string*

An expression that returns the string value to be encrypted. The string expression must return a built-in string data type that is not a LOB. The length attribute must be greater than or equal to 0 (zero). The length attribute is limited to 32640 if *hint-string* is specified and 32672 if *hint-string* is not specified.

### *password-string*

An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes.

The value represents the password that is used to encrypt *data-string*. If the value of the password argument is null or not specified, the data is encrypted using the ENCRYPTION PASSWORD value, which must have been assigned by the SET ENCRYPTION PASSWORD statement.

### *hint-string*

An expression that returns a CHAR or VARCHAR value up to 32 bytes that is to help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific').

If a hint value is specified, the hint is embedded into the result and can be retrieved using the GETHINT function. If this argument is null or not specified and no hint was specified when the ENCRYPTION PASSWORD was set, no hint is embedded in the result. If *password-string* is not specified, the hint can be specified using the SET ENCRYPTION PASSWORD statement.

The data type of the result is determined by the first argument as shown in the following table:

Table 56. Data type of the results of the ENCRYPT\_TDES function

Data type of the first argument	Data type of the result
BINARY, VARBINARY	VARBINARY
CHAR, VARCHAR, GRAPHIC, VARGRAPHIC	VARCHAR FOR BIT DATA

The encoding scheme of the result is the same as the encoding scheme of *data-string*. If the result is character data, the result is bit data.

The length attribute of the result is different depending of whether *hint-string* is specified:

- If *hint-string* is specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
- If *hint-string* is not specified, the length attribute of the result is the length attribute of the non-encrypted data + 24 bytes + the number of bytes to the next 8 byte boundary.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The encrypted result is longer than the *data-string* value. Therefore, when assigning encrypted values, ensure that the target is declared with a length that can contain the entire encrypted value.

When encrypting data, be aware of the following points:

- **Password protection:** To prevent inadvertent access to the encryption password, do not specify *password-string* as a string constant in the source for a program, procedure, or function. Instead, use the SET ENCRYPTION PASSWORD statement or a variable.
- **Encryption algorithm:** The internal encryption algorithm used is Triple DES cipher block chaining (CBC) with padding. The 128-bit secret key is derived from the password using an MD5 hash.
- **Encryption passwords and data:** It is your responsibility to perform password management. After data is encrypted, only the password that is used to encrypt it can be used to decrypt it. If a different password is used to decrypt the data than was used to encrypt the data, the results of decryption will not match the original string. No error or warning is returned. CHAR variables might be padded with blanks if they are used to set password values. The encrypted result might contain null terminator and other non-printable characters.
- **Table column definitions:** When defining columns and types to contain encrypted data, always calculate the length attribute as follows:
  - For encrypted data with an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary + 32 bytes for the hint.
  - For encrypted data without an embedded hint, the column length should be the length attribute of the non-encrypted data + 24 bytes + number of bytes to the next 8 byte boundary.

Here are some sample column length calculations, which assume that a hint is not embedded:

Maximum length of non-encrypted data	6 bytes
24 bytes for encryption key	24 bytes
Number of bytes to the next 8 byte boundary	2 bytes

---

Encrypted data column length	32 bytes
Maximum length of non-encrypted data	32 bytes
24 bytes for encryption key	24 bytes
Number of bytes to the next 8 byte boundary	0 bytes

---

Encrypted data column length	56 bytes
------------------------------	----------

- **Administration of encrypted data:** Encrypted data can be decrypted only on servers that support the decryption of data that was encrypted using the Triple

| DES encryption algorithm. Hence, replication of columns with encrypted data  
| should only be done to servers that support the decryption functions and the  
| same encryption algorithms.

ENCRYPT can be specified as a synonym for ENCRYPT\_TDES. DB2 supports this keyword to provide compatibility with other products in the DB2 family.

*Example 1:* Encrypt the social security number that is inserted into the table. Set the ENCRYPTION PASSWORD value to 'Ben123' and use it as the password.

```
SET ENCRYPTION PASSWORD ='Ben123';
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832');
```

*Example 2:* Encrypt the social security number that is inserted into the table. Explicitly specify 'Ben123' as the encryption password.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Ben123');
```

*Example 3:* Encrypt the social security number that is inserted into the table. Specify 'Pacific' as the encryption password, and provide 'Ocean' as a hint to help the user remember the password of 'Pacific'.

```
INSERT INTO EMP(SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');
```

The preceding statement returns a double precision floating-point number with an approximate value of 31.62.

## EXP

The EXP function returns a value that is the base of the natural logarithm (e), raised to a power that is specified by the argument. The EXP and LN functions are inverse operations.

►—EXP(*numeric-expression*)—►

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable E is DECIMAL(10,9) with a value of 3.453789832. The following statement returns a double precision floating-point number with an approximate value of 31.62.

```
SELECT EXP(:E)
      FROM SYSIBM.SYSDUMMY1;
```

## EXTRACT

The EXTRACT function returns a portion of a date or timestamp, based on its arguments.

### Extract date values:

```
►►—EXTRACT( [YEAR|MONTH|DAY] FROM date-expression )—►►
```

### Extract time values:

```
►►—EXTRACT( [HOUR|MINUTE|SECOND] FROM time-expression )—►►
```

The schema is SYSIBM.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

#### Extract date values

##### YEAR

Specifies that the year portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the YEAR scalar function. For more information, see "YEAR" on page 600.

##### MONTH

Specifies that the month portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the MONTH scalar function. For more information, see "MONTH" on page 423.

##### DAY

Specifies that the day portion of *date-expression* or *timestamp-expression* is returned. The result is identical to the DAY scalar function. For more information, see "DAY" on page 330.

##### *date-expression*

An expression that returns the value of either a built-in date or built-in character string data type.

If *date-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a date. For the valid formats of string representations of dates, see "String representations of datetime values" on page 89.

##### *timestamp-expression*

An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid character-string or graphic-string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 89.

#### Extract time values

##### HOUR

Specifies that the hour portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the HOUR scalar function. For more information, see “HOUR” on page 381.

##### MINUTE

Specifies that the minute portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the MINUTE scalar function. For more information, see “MINUTE” on page 420.

##### SECOND

Specifies that the second portion of *time-expression* or *timestamp-expression* is returned. The result is identical to the SECOND scalar function. For more information, see “SECOND” on page 501.

##### *time-expression*

An expression that returns the value of either a built-in time or built-in character string data type.

If *time-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a time. For the valid formats of string representations of times, see “String representations of datetime values” on page 89.

##### *timestamp-expression*

An expression that returns the value of either a built-in timestamp or built-in character string data type.

If *timestamp-expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a timestamp. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 89.

The data type of the result of the function depends on the part of the datetime value that is specified:

- The result is INTEGER, if one of the following is specified:
  - YEAR
  - MONTH
  - DAY
  - HOUR
  - MINUTE
- The result is DECIMAL(8,6), if SECOND is specified. The fractional digits contains microseconds.

##### *Example 1:*

Assume that the column PRSTDAT has an internal value that is equivalent to 2010-12-25. The following statement returns the value 12:

```
SELECT EXTRACT(MONTH FROM PRSTDAT)
      FROM PROJECT;
```

## FLOAT

The FLOAT function returns a floating-point representation of either a number or a string representation of a number. FLOAT is a synonym for the DOUBLE function.

```
►►—FLOAT(numeric-expression)—►►
```

The schema is SYSIBM.

FLOAT is a synonym for the DOUBLE function. See “DOUBLE\_PRECISION or DOUBLE” on page 353 for details.

## FLOOR

The FLOOR function returns the largest integer value that is less than or equal to the argument.

```
►►FLOOR(numeric-expression)-----►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in numeric data type.

The result of the function has the same data type and length attribute as the argument. When the argument is DECIMAL, the scale of the result is 0 and not the scale of the input argument. For example, an argument with a date type of DECIMAL(5,5) results in DECIMAL(5,0).

The result can be null. If the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.EMP, find the highest monthly salary, rounding the result down to the next integer. The SALARY column has a decimal data type.

```
SELECT FLOOR(MAX(SALARY)/12)
      FROM DSN8910.EMP;
```

This example returns 04395 because the highest paid employee is Christine Haas who earns \$52750.00 per year. Her average monthly salary before applying the FLOOR function is 4395.83.

*Example 2:* This example demonstrates using FLOOR with both positive and negative numbers.

```
SELECT FLOOR( 3.5),
       FLOOR( 3.1),
       FLOOR(-3.1),
       FLOOR(-3.5)
     FROM SYSIBM.SYSDUMMY1;
```

This example returns (leading zeros are shown to demonstrate the precision and scale of the result):

03. 03. -04. -04.

## GENERATE\_UNIQUE

The GENERATE\_UNIQUE function returns a bit data character string that is unique, compared to any other execution of the same function.

►►GENERATE\_UNIQUE()—►►

The schema is SYSIBM.

The GENERATE\_UNIQUE function returns a bit data character string 13 bytes long (CHAR(13) FOR BIT DATA) that is unique compared to any other execution of the same function. The function is defined as not deterministic. Although the function has no arguments, the empty parentheses must be specified when the function is invoked.

The result of the function is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and, if in a sysplex environment, the sysplex member where the function was processed. The result cannot be null.

The result of this function can be used to provide unique values in a table. Each successive value will be greater than the previous value, providing a sequence that can be used within a table. The sequence is based on the time when the function was executed.

| This function differs from using the special register CURRENT TIMESTAMP in  
| that a unique value is generated for each row of a multiple row insert statement,  
| an insert statement with a fullselect, or an insert operation in a MERGE statement.  
|

The timestamp value that is part of the result of this function can be determined using the TIMESTAMP function with the result of GENERATE\_UNIQUE as an argument.

*Example:* Create a table that includes a column that is unique for each row. Populate this column using the GENERATE\_UNIQUE function. Notice that the UNIQUE\_ID column is defined as FOR BIT DATA to identify the column as a bit data character string.

```
CREATE TABLE EMP_UPDATE
  (UNIQUE_ID VARCHAR(13)FOR BIT DATA,
   EMPNO CHAR(6),
   TEXT VARCHAR(1000));
  INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'0000020','Update entry 1...');
  INSERT INTO EMP_UPDATE VALUES (GENERATE_UNIQUE(),'0000050','Update entry 2...');
```

This table will have a unique identifier for each row if GENERATE\_UNIQUE is always used to set the value the UNIQUE\_ID column. You can create an insert trigger on the table to ensure that GENERATE\_UNIQUE is used to set the value:

```
CREATE TRIGGER EMP_UPDATE_UNIQUE
  NO CASCADE BEFORE INSERT ON EMP_UPDATE
  REFERENCING NEW AS NEW_UPD
  FOR EACH ROW MODE DB2SQL
  SET NEW_UPD.UNIQUE_ID = GENERATE_UNIQUE();
```

With this trigger, the previous INSERT statements that were used to populate the table could be issued without specifying a value for the UNIQUE\_ID column:

```
INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000020','Update entry 1...');  
INSERT INTO EMP_UPDATE (EMPNO,TEXT) VALUES ('000050','Update entry 2...');
```

The timestamp (in UTC) for when a row was added to EMP\_UPDATE can be returned using:

```
SELECT TIMESTAMP(UNIQUE_ID), EMPNO, TEXT FROM EMP_UPDATE;
```

Therefore, the table does not need a timestamp column to record when a row is inserted.

## GETHINT

The GETHINT function returns a hint for the password if a hint was embedded in the encrypted data. A password hint is a phrase that helps you remember the password with which the data was encrypted. For example, 'Ocean' might be used as a hint to help remember the password 'Pacific'.

```
►►—GETHINT(encrypted-data)—►►
```

The schema is SYSIBM.

*encrypted-data*

An expression that returns a string that contains a complete, encrypted data string. *encrypted-data* must return a value that is a CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, BINARY, or VARBINARY built-in data type. The string must have been encrypted using ENCRYPT\_TDES function.

The result of the function is VARCHAR(32). The actual length of the result is the actual length of the hint that was provided when the data was encrypted.

The result can be null; if the argument is null or no hint was specified when the ENCRYPT\_TDES function was used to encrypt the data, the result is the null value.

The encoding scheme of the result is the same as the encoding scheme of *encrypted-data*. If *encrypted-data* is bit data, the CCSID of the result is the default character CCSID for that encoding scheme. Otherwise, the CCSID of the result is the same as the CCSID of *encrypted-data*.

For additional information about this function, see “DECRYPT\_BINARY, DECRYPT\_BIT, DECRYPT\_CHAR, and DECRYPT\_DB” on page 346 and “ENCRYPT\_TDES” on page 363.

*Example:* This example shows how to embed a hint for the password when encrypting data and how to later use the GETHINT function to retrieve the embedded hint. In this example, the hint 'Ocean' is used to help remember the encryption password 'Pacific'.

```
INSERT INTO EMP (SSN) VALUES ENCRYPT_TDES ('289-46-8832','Pacific','Ocean');  
SELECT GETHINT (SSN) FROM EMP;
```

The value that is returned is 'Ocean'.

## GETVARIABLE

The GETVARIABLE function returns a varying-length character-string representation of the current value of the session variable that is identified by the argument.

```
►--GETVARIABLE(string-constant)  
      [ ,default-value  
      ,CAST(NULL AS VARCHAR(1)) ]
```

The schema is SYSIBM.

### *string-constant*

Specifies a string constant that contains the name of the session variable whose value is to be returned. The string constant:

- Must have a length that does not exceed 142 bytes.
- Must contain the fully qualified name of the variable, with no embedded blanks. Delimited identifiers must not be specified.
- Must not contain lowercase letters or characters that cannot be specified in an ordinary identifier.

The schema qualifier for the variable must be:

- SESSION for user-defined session variables. User-defined session variables are established via the connection or signon exit routines.
- SYSIBM for built-in session variables. For a list of the built-in session variables, see “References to built-in session variables” on page 168.

### *default-value*

Specifies a string constant that contains the value to be returned if the specified variable does not exist or is not supported by DB2. *default-value* must be a string constant that does not exceed 255 bytes.

If *default-value* is not specified and the specified user-defined session variable does not exist or the built-in session variable is not supported by DB2, an error is returned.

### **CAST(NULL AS VARCHAR(1))**

Specifies that a null value is to be returned if the specified variable does not exist or is not supported by DB2.

The data type of the result is VARCHAR(255). The result can be null.

The CCSID of the result is the CCSID for Unicode mixed data.

*Example 1:* Use the GETVARIABLE function to set the value of host variable :hv1 to the name of the plan that is currently being executed. The name of the built-in session variable that contains the name of the plan is SYSIBM.PLAN\_NAME.

```
SET :hv1 = GETVARIABLE('SYSIBM.PLAN_NAME');
```

If DB2 does not support the name of the session variable, an error is returned. For example, the following statement returns an error because DB2 does not support a built-in session variable that is named SYSIBM.XYZ.

```
SET :hv1 = GETVARIABLE('SYSIBM.XYZ');
```

*Example 2:* Use the GETVARIABLE function to set the value of host variable :hv2 to the value for the user that is defined in user-defined session variable TEST. If the session variable has not been set or cannot be found, have the function return the value 'TEST FAILED'.

```
SET :hv2 = GETVARIABLE('SESSION.TEST','TEST FAILED');
```

*Example 3:* Use the GETVARIABLE function to set the value of host variable :hv3 to a string representation of the SYSTEM EBCDIC CCSIDs. The name of the built-in session variable that contains the system EBCDIC CCSIDs is SYSIBM.SYSTEM\_EBCDIC\_CCSID.

```
SET :hv3 = GETVARIABLE('SYSIBM.SYSTEM_EBCDIC_CCSID');
```

Regardless of the setting of the field MIXED DATA on the installation panel (YES or NO), the function returns three comma-delimited values that correspond to the SBCS, MIXED, and GRAPHIC CCSIDs for the encoding scheme.

For example, if the statement were issued on a system with the field MIXED DATA on the installation panel equal to NO and the default system CCSID of 37, this string would be returned:

'37,65534,65534'

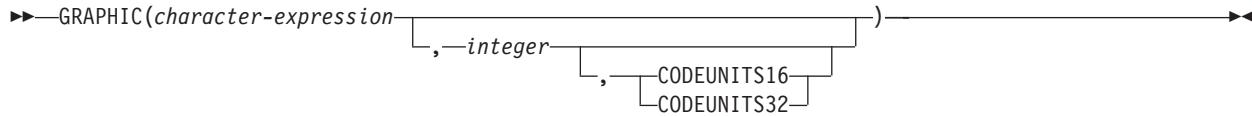

If the statement were issued on a system with the field MIXED DATA on the installation panel equal to YES and a default system CCSID of 930 (the mixed CCSID for the system), this string would be returned:

'290,930,300'

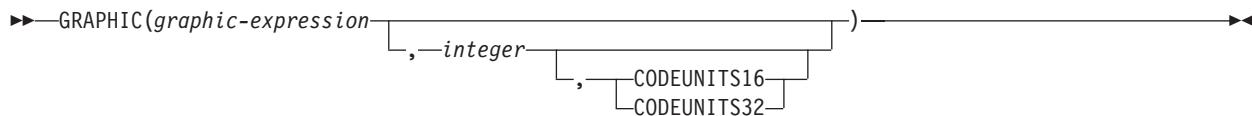

## GRAPHIC

The GRAPHIC function returns a fixed-length graphic-string representation of a character string or a graphic string value, depending on the type of the first argument.

### Character to Graphic:

### Graphic to Graphic:

The schema is SYSIBM.

The result of the function is a fixed-length graphic string (GRAPHIC).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The length attribute of the result is measured in double-byte characters because it is a graphic string.

#### Character to Graphic

##### *character-expression*

An expression that returns a value that is an EBCDIC-encoded or Unicode-encoded character string. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 73 for these rules.)

The value of the expression must not be an empty string if *integer* is not specified or have the value X'0EOF' if the string is an EBCDIC string.

##### *integer*

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *character-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result for an EBCDIC string is the minimum of 127 and the length attribute of *character-expression*, excluding shift characters. For a Unicode (UTF-8) string, the length is data dependent, but does not exceed 127.

#### **CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

#### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC data, each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for EBCDIC mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for an SBCS character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xxxx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the

result is derived. Let  $M$  be the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is  $M$ .
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is  $M$ .

Otherwise, the argument is a new string  $S$  derived by converting the characters to the coded character set identified by  $M$ .

The result is derived from  $S$  by using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FEFE'.

## Graphic to Graphic

### *graphic-expression*

An expression that returns a value that is a graphic string. The graphic string must not be an empty string if *integer* is not specified.

### *integer*

The length of the resulting fixed-length graphic string in the units that are either implicitly or explicitly specified. The value must be an integer constant between 1 and 127. If the length of *graphic-expression* is less than the length specified, the result is padded with double-byte blanks to the length of the result.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If *integer* is not specified, the length of the result is the minimum of 127 and the length attribute of *graphic-expression*.

### **CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no system CCSID for EBCDIC GRAPHIC data, an error occurs.

### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

If the length of the *graphic-expression* is greater than the specified length of the result, the result is truncated. Unless all the truncated characters are blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

*Example:* Assume that MYCOL is a VARCHAR column in TABLEY. The following function returns the string in MYCOL as a fixed-length graphic string.

```
SELECT GRAPHIC(MYCOL)
      FROM TABLEY;
```

## HEX

The HEX function returns a hexadecimal representation of a value.

```
►►—HEX(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML. A character or binary string must not have a maximum length greater than 16352. A graphic string must not have a maximum length greater than 8176.

The result of the function is a character string. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is a string of hexadecimal digits. The first two represent the first byte of the argument, the next two represent the second byte of the argument, and so forth. If the argument is a datetime value, the result is the hexadecimal representation of the internal form of the argument.

If the argument is a fixed-length string and the length of the result is less than 255, the result is a fixed-length string. Otherwise, the result is a varying-length string with a length attribute that depends on the following considerations:

**If the argument is not a varying-length string**, the length attribute of the result string is the same as the length of the result.

**If the argument is a varying-length character or binary string**, the length attribute of the result string is twice the length attribute of the argument.

**If the argument is a varying-length graphic string**, the length attribute of the result string is four times the length attribute of the argument.

If *expression* returns string data, the CCSID of the result is the SBCS CCSID that corresponds to the CCSID of *expression*. Otherwise, the CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

If the argument is a graphic string, the length of the result is four times the maximum length of the argument. Otherwise, the length of the result is twice the (maximum) length of the argument.

*Example:* Return the hexadecimal representation of START\_RBA in the SYSIBM.SYSCOPY catalog table.

```
SELECT HEX(START_RBA) FROM SYSIBM.SYSCOPY;
```

## HOUR

The HOUR function returns the hour part of a value.

```
►►—HOUR(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a time, timestamp, or string representation of either**, the result is the hour part of the value, which is an integer between 1 and 24.

**If the argument is a time duration or timestamp duration**, the result is the hour part of the value, which is an integer between -99 and +99. A nonzero result has the same sign as the argument.

*Example 1:* Assume that a table named CLASSES contains a row for each scheduled class. Also assume that the class starting times are in a TIME column named STARTTM. Select those rows in CLASSES that represent classes that start after the noon hour.

```
SELECT *
  FROM CLASSES
 WHERE HOUR(STARTTM) > 12;
```

## **IDENTITY\_VAL\_LOCAL**

The IDENTITY\_VAL\_LOCAL function returns the most recently assigned value for an identity column.

```
►►IDENTITY_VAL_LOCAL()————►►
```

The schema is SYSIBM.

The IDENTITY\_VAL\_LOCAL function is not deterministic.<sup>21</sup> Although the function has no input parameters, the empty parentheses must be specified when the function is invoked.

The result is DECIMAL(31,0), regardless of the actual data type of the identity column to which the result value corresponds.

A *qualifying data change statement* refers to an insert operation (specified in either an INSERT statement or a MERGE statement).

The value that is returned is the value that was assigned to the identity column of the table identified in the most recent qualifying data change statement or LOAD utility operation for a table with an identity column. The insert operation has to be issued at the same level; that is, the value has to be available locally within the level at which it was assigned until replaced by the next assigned value. A new level is initiated when a trigger, function, or stored procedure is invoked. A trigger condition is at the same level as the associated triggered action.

The assigned value can be a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT) or an identity value that was generated by DB2.

**Note:** Use a SELECT FROM data change statement to obtain the assigned value for an identity column. See *data-change-table-reference* for more information.

The result can be null. The result is null in the following situations:

- When a qualifying data change statement has not been issued for a table containing an identity column at the current processing level
- When a COMMIT or ROLLBACK of a unit of work occurred since the most recent qualifying data change statement that assigned a value

The result of the function is not affected by a ROLLBACK TO SAVEPOINT statement.

***Invoking the function within a qualifying data change statement:*** Expressions in a qualifying data change statement are evaluated before values are assigned to the target columns of the qualifying data change statement. Thus, when you invoke IDENTITY\_VAL\_LOCAL in a qualifying data change statement, the value that is

21. Being not deterministic affects what optimization (such as view processing and parallel processing) can be done when this function is used and in what contexts the function can be invoked. For example, the RAND function is another built-in scalar function that is not deterministic. Using functions that are not deterministic within a predicate can cause unpredictable results.

used is the most recently assigned value for an identity column from a previous qualifying data change statement. The function returns the null value if no such qualifying data change statement had been executed within the same level as the invocation of the IDENTITY\_VAL\_LOCAL function. Each qualifying data change statement that involves an IDENTITY column causes the identity value to be copied into connection-specific storage in DB2. Thus, the most recent identity value is used for a connection, regardless of what is happening with other concurrent user connections.

***Invoking the function following a failed insert operation:*** The function returns an unpredictable result when it is invoked after the unsuccessful execution of a qualifying data change statement for a table with an identity column. The value might be the value that would have been returned from the function had it been invoked before the failed qualifying data change statement or the value that would have been assigned had the qualifying data change statement succeeded. The actual value returned depends on the point of failure and is therefore unpredictable.

***Invoking the function within the SELECT statement of a cursor:*** Because the results of the IDENTITY\_VAL\_LOCAL function are not deterministic, the result of an invocation of the IDENTITY\_VAL\_LOCAL function from within the SELECT statement of a cursor can vary for each FETCH statement.

***Invoking the function within the trigger condition of an insert trigger:*** The result of invoking the IDENTITY\_VAL\_LOCAL function from within the condition of an insert trigger is the null value.

***Invoking the function within a triggered action of an insert trigger:*** Multiple before or after insert triggers can exist for a table. In such cases, each trigger is processed separately, and identity values generated by SQL statements issued within a triggered action are not available to other triggered actions using the IDENTITY\_VAL\_LOCAL function. This is the case even though the multiple triggered actions are conceptually defined at the same level.

Do not use the IDENTITY\_VAL\_LOCAL function in the triggered action of a before insert trigger. The result of invoking the IDENTITY\_VAL\_LOCAL function from within the triggered action of a before insert trigger is the null value.

The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the IDENTITY\_VAL\_LOCAL function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.

The result of invoking the IDENTITY\_VAL\_LOCAL function in the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent qualifying data change statement. That statement is the one invoked in the same triggered action that had a qualifying data change statement for a table containing an identity column. If a qualifying data change statement for a table containing an identity column was not executed within the same triggered action before invoking the IDENTITY\_VAL\_LOCAL function, then the function returns a null value.

***Invoking the function following an insert operation with triggered actions:*** The result of invoking the function after an insert that activates triggers is the value actually assigned to the identity column (that is, the value that would be returned

on a subsequent SELECT statement). This value is not necessarily the value provided in the qualifying data change statement or a value generated by DB2. The assigned value could be a value that was specified in a SET transition variable statement within the triggered action of a before insert trigger for a trigger transition variable associated with the identity column.

**Scope of IDENTITY\_VAL\_LOCAL:** The IDENTITY\_VAL\_LOCAL value persists until the next insert in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements for local applications. The IDENTITY\_VAL\_LOCAL value cannot be directly set and is a result of inserting a row into a table. Client applications or middleware products that save the state of a session and then restore the state of a session for subsequent processing are not able to restore the IDENTITY\_VAL\_LOCAL value. In these situations, the availability of the IDENTITY\_VAL\_LOCAL value should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that do the following:

- use XA protocols
- use connection pooling
- use the connection concentrator
- use Sysplex workload balancing
- connect to a z/OS server that uses DDF inactive threads

When there is a need to preserve the value associated with IDENTITY\_VAL\_LOCAL across transaction boundaries for distributed applications, define the cursors as WITH HOLD, or specify the bind option KEEPDYNAMIC(YES) to prevent the server thread from being pooled.

*Example 1:* Set the variable IVAR to the value assigned to the identity column in the EMPLOYEE table. The value returned from the function in the VALUES statement should be 1.

```
CREATE TABLE EMPLOYEE  
(EMPNO      INTEGER GENERATED ALWAYS AS IDENTITY,  
 NAME        CHAR(30),  
 SALARY      DECIMAL(5,2),  
 DEPTNO     SMALLINT);  
INSERT INTO EMPLOYEE  
(NAME, SALARY, DEPTNO)  
VALUES ('Rupert', 989.99, 50);  
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

*Example 2:* Assume two tables, T1 and T2, have an identity column named C1. DB2 generates values 1, 2, 3, . . . for the C1 column in table T1, and values 10, 11, 12, . . . for the C1 column in table T2.

```
CREATE TABLE T1 (C1 SMALLINT GENERATED ALWAYS AS IDENTITY,  
                 C2 SMALLINT );  
CREATE TABLE T2 (C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY  
                 (START WITH 10),  
                 C2 SMALLINT );  
INSERT INTO T1 (C2) VALUES (5);  
INSERT INTO T1 (C2) VALUES (5);  
SELECT * FROM T1;  
C1          C2  
-----  -----  
1           5  
2           5  
VALUES IDENTITY_VAL_LOCAL() INTO :IVAR;
```

At this point, the IDENTITY\_VAL\_LOCAL function would return a value of 2 in IVAR. The following INSERT statement inserts a single row into T2 where column C2 gets a value of 2 from the IDENTITY\_VAL\_LOCAL function

```
INSERT INTO T2 (C2) VALUES (IDENTITY_VAL_LOCAL());
SELECT * FROM T2
WHERE C1 = DECIMAL(IDENTITY_VAL_LOCAL(),15,0);
      C1          C2
-----
10           2
```

Invoking the IDENTITY\_VAL\_LOCAL function after this insert would result in a value of 10, which is the value generated by DB2 for column C1 of T2. Assume another single row is inserted into T2. For the following INSERT statement, DB2 assigns a value of 13 to identity column C1 and gives C2 a value of 10 from IDENTITY\_VAL\_LOCAL. Thus, C2 is given the last identity value that was inserted into T2.

```
INSERT INTO T2 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 13);
```

*Example 3:* The IDENTITY\_VAL\_LOCAL function can also be invoked in an INSERT statement that both invokes the IDENTITY\_VAL\_LOCAL function and causes a new value for an identity column to be assigned. The next value to be returned is thus established when the IDENTITY\_VAL\_LOCAL function is invoked after the INSERT statement completes. For example, consider the following table definition:

```
CREATE TABLE T1 (C1 SMALLINT GENERATED BY DEFAULT AS IDENTITY,
                 C2 SMALLINT);
```

For the following INSERT statement, specify a value of 25 for the C2 column, and DB2 generates a value of 1 for C1, the identity column. This establishes 1 as the value that will be returned on the next invocation of the IDENTITY\_VAL\_LOCAL function.

```
INSERT INTO T1 (C2) VALUES (25);
```

In the following INSERT statement, the IDENTITY\_VAL\_LOCAL function is invoked to provide a value for the C2 column. A value of 1 (the identity value assigned to the C1 column of the first row) is assigned to the C2 column, and DB2 generates a value of 2 for C1, the identity column. This establishes 2 as the value that will be returned on the next invocation of the IDENTITY\_VAL\_LOCAL function.

```
INSERT INTO T1 (C2) VALUES (IDENTITY_VAL_LOCAL());
```

In the following INSERT statement, the IDENTITY\_VAL\_LOCAL function is again invoked to provide a value for the C2 column, and the user provides a value of 11 for C1, the identity column. A value of 2 (the identity value assigned to the C1 column of the second row) is assigned to the C2 column. The assignment of 11 to C1 establishes 11 as the value that will be returned on the next invocation of the IDENTITY\_VAL\_LOCAL function.

```
INSERT INTO T1 (C2, C1) VALUES (IDENTITY_VAL_LOCAL(), 11);
```

After the 3 INSERT statements have been processed, table T1 contains the following:

```
SELECT * FROM T1;
      C1          C2
-----
-----
```

1	25
2	1
11	2

The contents of T1 illustrate that the expressions in the VALUES clause are evaluated before the assignments for the columns of the INSERT statement. Thus, an invocation of an IDENTITY\_VAL\_LOCAL function invoked from a VALUES clause of an INSERT statement uses the most recently assigned value for an identity column in a previous INSERT statement.

## **IFNULL**

The IFNULL function returns the first nonnull expression.

```
►►—IFNULL(expression,expression)—►►
```

The schema is SYSIBM.

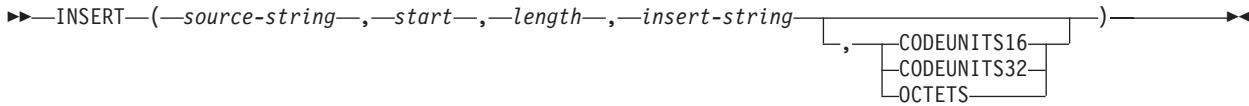

IFNULL is identical to the COALESCE scalar function except that IFNULL is limited to two arguments instead of multiple arguments. For a description, see “COALESCE” on page 315.

*Example:* For all the rows in sample table DSN8910.EMP, select the employee number and salary. If the salary is missing (is null), have the value 0 returned.

```
SELECT EMPNO, IFNULL(SALARY,0)  
      FROM DSN8910.EMP;
```

## INSERT

The INSERT function returns a string where, beginning at *start* in *source-string*, *length* characters have been deleted and *insert-string* has been inserted.

The schema is SYSIBM.

The INSERT function returns a string where *length* characters have been deleted from *source-string*, beginning at *start*, and where *insert-string* has been inserted into *source-string*, beginning at *start*.

### *source-string*

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater than or equal to 1 and less than or equal to 32704 bytes.

### *start*

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

### *length*

An expression that specifies the length of the string to replace in *source-string* starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

### *insert-string*

An expression that specifies the string to be inserted into the source string, starting at the position identified by *start*. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB.

*source-string* and *insert-string* must have compatible data types.

### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the units that are used to express *start* and *length*. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used:

- If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point.
- Otherwise, a string unit is a byte.

#### **CODEUNITS16**

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

#### **OCTETS**

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:
  - If either *source-string* or *insert-string* is character bit data, the result is bit data.
  - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

$$L1 - \text{MIN}((L1 - V2 + 1), V3) + L4$$

where:

*L1* is the length attribute of *source-string*  
*V2* is the value of *start*

*V3* is the value of *length*

*L4* is the length attribute of *insert-string*

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See “Determining the length attribute of the final result” on page 79 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

$$A1 - \text{MIN}(A1 - V2 + 1), V3) + A4$$

where:

*A1* is the actual length of *source-string*

*V2* is the value of *start*

*V3* is the value of *length*

*A4* is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
SELECT CHAR(INSERT('INSERTING',4,2,'IS'),10),
       CHAR(INSERT('INSERTING',4,0,'IS'),10),
       CHAR(INSERT('INSERTING',4,2,''),10)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING '

*Example 2:* The previous example demonstrated how to insert text into the middle of some text. This example shows how to insert text before some text by using 1 as the starting point (*start*).

```
SELECT CHAR(INSERT('INSERTING',1,0,'XX'),10),
       CHAR(INSERT('INSERTING',1,1,'XX'),10),
       CHAR(INSERT('INSERTING',1,2,'XX'),10),
       CHAR(INSERT('INSERTING',1,3,'XX'),10)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns 'XXINSERTIN', 'XXNINSERTING', 'XXSERTING ', and 'XXERTING '

*Example 3:* The following example shows how to insert text after some text. Add 'XX' at the end of string 'ABCABC'. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT CHAR(INSERT('ABCABC',7,0,'XX'),10)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns 'ABCABCXX '.

*Example 4:* The following example shows how the string 'Hegelstraße' can be changed to 'Hegelstrasse'.

```
SELECT VARCHAR(INSERT('Hegelstraße',10,1,'ss'),15)
   FROM SYSIBM.SYSDUMMY1;
```

This example returns 'Hegelstrasse'.

## INTEGER or INT

The INTEGER function returns an integer representation of either a number or a character string or graphic string representation of an integer.

### Numeric to Integer:

### String to Integer:

The schema is SYSIBM.

#### Numeric to Integer

*numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a large integer column or variable. If the whole part of the argument is not within the range of large integers, an error occurs. The fractional part of the argument is truncated.

#### String to Integer

*string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS INTEGER)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer constant. If the whole part of the argument is not within the range of large integers, an error is returned.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 202.

*Example 1:* Using sample table DSN8910.EMP, find the average salary of the employees in department A00, rounding the result to the nearest dollar.

```
SELECT INTEGER(AVG(SALARY)+.5)
   FROM DSN8910.EMP
 WHERE WORKDEPT = 'A00';
```

*Example 2:* Using sample table DSN8910.EMP, select the EMPNO column, which is defined as CHAR(6), in integer form.

```
SELECT INTEGER(EMPNO)
      FROM DSN8910.EMP;
```

## JULIAN\_DAY

The JULIAN\_DAY function returns an integer value that represents a number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date that is specified in the argument.

```
►►JULIAN_DAY(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following data types: a date, a timestamp, or a valid string representation of a date or timestamp. An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.EMP, set the integer host variable JDAY to the Julian day of the day that Christine Haas (EMPNO = '000010') was employed (HIREDATE = '1965-01-01').

```
SELECT JULIAN_DAY(HIREDATE)
      INTO :JDAY
     FROM DSN8910.EMP
    WHERE EMPNO = '000010';
```

The result is that JDAY is set to 2438762.

*Example 2:* Set integer host variable JDAY to the Julian day for January 1, 1998.

```
SELECT JULIAN_DAY('1998-01-01')
      INTO :JDAY
     FROM SYSIBM.SYSDUMMY1;
```

The result is that JDAY is set to 2450815.

## LAST\_DAY

The LAST\_DAY scalar function returns a date that represents the last day of the month of the date argument.

```
►►—LAST_DAY(expression)—————►►
```

The schema is SYSIBM.

*expression*

An expression that specifies the starting date. The expression must return a value of one of the following data types:

- a date
- a timestamp
- a valid string representation of a date or timestamp

An argument with a character string data type must not be a CLOB. An argument with a graphic string data type must not be a DBCLOB. A string argument must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a DATE.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

The result can be null; if any argument is null, the result is the null value.

*Example 1:* Set the host variable END\_OF\_MONTH with the last day of the current month.

```
SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE);
```

The host variable END\_OF\_MONTH is set with the value representing the end of the current month. If the current day is 2000-02-10, END\_OF\_MONTH is set to 2000-02-29.

*Example 2:* Set the host variable END\_OF\_MONTH with the last day of the month in EUR format for the given date.

```
SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR);
```

The host variable END\_OF\_MONTH is set with the value '31.07.1965'.

## LCASE

The LCASE function returns a string in which all the characters are converted to lowercase characters.

```
| ►--LCASE(string-expression [ ,locale-name] [ ,integer ])-->
```

The schema is SYSIBM.

The LCASE function is identical to the LOWER function. For more information, see “LOWER” on page 410.

## LEFT

The LEFT function returns a string that consists of the specified number of leftmost bytes of the specified string units.

### Character string:

### Graphic string:

### Binary string:

The schema is SYSIBM.

The LEFT function returns the leftmost string of *character-expression*, *graphic-expression*, or *binary-expression* consisting of length of the string units that are specified implicitly or explicitly.

### Character string:

#### *character-expression*

An expression that specifies the string from which the result is derived. The string must be a character string. A substring of *character-expression* is zero or more contiguous code points of *character-expression*.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

#### *length*

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *character-expression*, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express *length*. If *character-expression* is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

**CODEUNITS16**

Specifies that *length* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *length* is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that *length* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

**Graphic string:***graphic-expression*

An expression that specifies the string from which the result is derived. The string must be a graphic string. A substring of *graphic-expression* is zero or more contiguous code points of *graphic-expression*.

*length*

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *graphic-expression*, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *length*.

**CODEUNITS16**

Specifies that *length* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *length* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

**Binary string:***binary-expression*

An expression that specifies the string from which the result is derived. The string must be a binary string. A substring of *binary-expression* is zero or more contiguous code points of *binary-expression*.

*length*

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *binary-expression*, expressed in the units that are either implicitly or explicitly specified.

The *character-expression*, *graphic-expression*, or *binary-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of the expression always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.

- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 (Unicode mixed data), the padding character is X'20'.
- For UTF-16 (Unicode DBCS) data, the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of the first expression and a data type that depends on the data type of the expression:

- VARCHAR if *character-expression* is CHAR or VARCHAR
- CLOB if *character-expression* is CLOB
- VARGRAPHIC if *graphic-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *graphic-expression* is DBCLOB
- VARBINARY if *binary-expression* is BINARY or VARBINARY
- BLOB if *binary-expression* is BLOB

The actual length of the result is determined from *length*.

If any argument of the function can be null, the result can be null; if any argument is null, the result is the null value.

The CCSID of the result is the same as that of the first expression.

*Example 1:* Assume that host variable ALPHA has a value of 'ABCDEF'. The following statement returns 'ABC', which are the three leftmost characters in ALPHA:

```
SELECT LEFT(:ALPHA,3)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* Assume that host variable NAME, which is defined as VARCHAR(50), has a value of 'KATIE AUSTIN' and the integer host variable FIRSTNAME\_LEN has a value of 5. The following statement returns the value 'KATIE':

```
SELECT LEFT(:NAME, :FIRSTNAME_LEN)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following statement returns a zero length string.

```
SELECT LEFT('ABCABC',0)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 4:* The FIRSTNAME column in sample EMP table is defined as VARCHAR(12). Find the first name for an employee whose last name is 'BROWN' and return the first name in a 10-byte string.

```
SELECT LEFT(FIRSTNAME,10)
      FROM DSN8910.EMP
     WHERE LASTNAME='BROWN' ;
```

This function returns a VARCHAR(10) string that has the value of 'DAVID' followed by 5 blank characters.

*Example 5:* FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

Function ...	Returns ...
LEFT(FIRSTNAME,2,CODEUNITS32)	'Jü' -- x'4AC3BC'
LEFT(FIRSTNAME,2,CODEUNITS16)	'Jü' -- x'4AC3BC'
LEFT(FIRSTNAME,2,OCTETS)	'J ' -- x'4A20' a truncated string

## LENGTH

The LENGTH function returns the length of a value.

```
►►—LENGTH(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of any built-in data type that is not XML.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is the length of the argument. The length does not include the null indicator byte of column arguments that allow null values. The length of strings includes blanks. The length of a varying-length string is the actual length, not the maximum length.

The length of a graphic string is the number of double-byte characters. Unicode UTF-16 data is treated as graphic data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The length of all other values is the number of bytes used to represent the value:

- 2 for small integer
- 4 for large integer
- 8 for big integer
- The integer part of  $(p/2)+1$  for decimal numbers with precision  $p$
- 16 for DECFLOAT(34)
- 8 for DECFLOAT(16)
- 4 for single precision floating-point
- 8 for double precision floating-point
- The length of the string for strings
- 4 for DATE
- 3 for TIME
- 10 for TIMESTAMP
- The length of the row ID

*Example 1:* Assume that FIRSTNAME is a VARCHAR(12) column that contains 'ETHEL' for employee 280. The following query returns the value 5:

```
SELECT LENGTH(FIRSTNAME)
      FROM DSN8910.EMP
     WHERE EMPNO = '000280';
```

*Example 2:* Assume that HIREDATE is a column of data type DATE. Then, regardless of value the following statement returns the value 4:

```
LENGTH(HIREDATE)
```

And the following function returns the value 10:

```
LENGTH(CHAR(HIREDATE, EUR))
```

## LN

The LN function returns the natural logarithm of the argument. The LN and EXP functions are inverse operations.

```
►►LN(numeric-expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

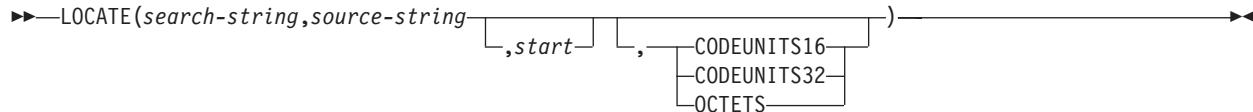

LOG is a synonym for LN.

*Example:* Assume that host variable NATLOG is DECIMAL(4,2) with a value of 31.62. The following statement returns a double precision floating-point number with an approximate value of 3.45:

```
SELECT LN(:NATLOG)
      FROM SYSIBM.SYSDUMMY1;
```

## LOCATE

The LOCATE function returns the position at which the first occurrence of an argument starts within another argument.

The schema is SYSIBM.

The LOCATE function returns the starting position of *search-string* within *source-string*. If *search-string* is not found and neither argument is null, the result is zero. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*. If the optional *start* is specified, it indicates the character position in *source-string* at which the search is to begin. An optional string unit can be specified to indicate in what units the start and result of the function are expressed.

### *search-string*

An expression that specifies the string that is to be searched for. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes. The expression can be specified by any of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

### *source-string*

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type. The expression can be specified by any of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

*start*

An expression that specifies the position within *search-string* where the search is to start. *start* is expressed in the specified string unit and must return an integer value that is greater than zero.

If *start* is specified, the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string,  
        SUBSTRING(source-string, start, string-units)) + start - 1
```

If *start* is not specified, the search begins at the first position of *source-string* and the LOCATE function is similar to the following POSITION function, where *string-units* is CODEUNITS16, CODEUNITS32, or OCTETS:

```
POSITION(search-string, source-string, string-units)
```

**CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

**CODEUNITS16**

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings” on page 122.

The result of the function is a large integer. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

For more information about LOCATE, see the description of “POSITION” on page 466.

*Example 1:* Find the location of the first occurrence of the character 'N' in the string 'DINING'.

```
SELECT LOCATE('N', 'DINING')  
      FROM SYSIBM.SYSDUMMY1;
```

The result is the value 3.

*Example 2:* For all the rows in the table named IN\_TRAY, select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD' within the NOTE\_TEXT column.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
  FROM IN_TRAY
 WHERE LOCATE('GOOD', NOTE_TEXT) <> 0;
```

*Example 3:* Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS32);
```

The value of host variable LOCATION is set to 26.

*Example 4:* Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS16 units, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,CODEUNITS16);
```

The value of host variable LOCATION is set to 26.

*Example 5:* Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = LOCATE('ß','Jürgen lives on Hegelstraße',1,OCTETS);
```

The value of host variable LOCATION is set to 27.

"POSSTR" on page 469

## LOCATE\_IN\_STRING

The LOCATE\_IN\_STRING function returns the position at which an argument starts within a specified string.

```
►►—LOCATE_IN_STRING(source-string,search-string [, start] [, instance] [, CODEUNITS16] [, CODEUNITS32] [, OCTETS])—►►
```

The schema is SYSIBM.

The LOCATE\_IN\_STRING function returns the starting position of a string (called the *search-string*) within another string (called the *source-string*). If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*.

If the optional *start* is specified, it indicates the character position in the *source-string* at which the search is to begin. If *start* is specified, an instance number can also be specified. The instance argument determines the position of a specific occurrence of *search-string* within *source-string*. An optional string unit can be specified to indicate in what units the start and result of the function are expressed. Each unique instance can include any of the characters in a previous instance, but not all characters in a previous instance.

If *search-string* has a length of zero, the result returned by the function is 1. If *source-string* has a length of zero, the result returned by the function is 0. If neither condition exists, and if the value of *search-string* is equal to an identical length of a substring of contiguous positions within the value of *source-string*, the result returned by the function is the starting position of that substring within the *source-string* value. Otherwise, the result returned by the function is 0.

### *source-string*

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type. The expression can be specified by any of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

### *search-string*

An expression that specifies the string that is the object of the search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes. The expression can be specified by any of the following:

- A constant

- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- A column name
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

#### *start*

An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value that is a built-in INTEGER or SMALLINT data type.

If the value of the integer is greater than zero, the search begins at *start* and continues for each position to the end of the string. If the value of the integer is less than zero, the search begins at the LENGTH(*source-string*) + *start* + 1 and continues for each position to the beginning of the string.

If *start* is not specified, the default is 1. If the value of the integer is zero, an error is returned.

#### *instance*

An expression that specifies which instance of *search-string* to search for within *source-string*. The expression must return a value that is a built-in INTEGER or SMALLINT data type. If *instance* is not specified, the default is 1. The value of the integer must be greater than or equal to one.

#### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit that is used to express *start* and the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

#### **CODEUNITS16**

Specifies that *start* and the result are expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *start* and the result are expressed in terms of 32-bit UTF-32 code units.

#### **OCTETS**

Specifies that *start* and the result are expressed in terms of bytes.

If a string unit is not explicitly specified, the data type of the result determines the string unit that is used. If the result is graphic data, *start* and the returned position are expressed in two-byte units; otherwise, they are expressed in bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings” on page 122.

The result of the function is a large integer. The result is the starting position of the instance of *search-string* within *source-string*. The value is relative to the beginning of the string (regardless of the specification of *start*). If any argument can be null, the result can be null; if any argument is null, the result is the null value.

INSTR can be used as a synonym for LOCATE\_IN\_STRING.

*Example 1:* Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable POSITION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :POSITION = LOCATE_IN_STRING('Jürgen lives on Hegelstraße',
                                  'ß',1,CODEUNITS32);
```

The value of host variable POSITION is set to 26.

*Example 2:* Locate the character 'ß' in the string 'Jürgen lives on Hegelstraße' by searching from the end of the string, and set the host variable POSITION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :POSITION = LOCATE_IN_STRING('Jürgen lives on Hegelstraße',
                                  'ß',-1,CODEUNITS32);
```

The value of host variable POSITION is set to 26.

*Example 3:* Find the position of an occurrence of the character 'N' in the string 'WINNING' by searching from the start of the string as measured in bytes, within the string.

```
SELECT LOCATE_IN_STRING('WINNING','N',1,3,OCTETS),
       LOCATE_IN_STRING('WINNING','N',3,2,OCTETS),
       LOCATE_IN_STRING('WINNING','N',3,3,OCTETS),
       LOCATE_IN_STRING('WINNING','N',-1,3,OCTETS),
       LOCATE_IN_STRING('WINNING','N',-3,2,OCTETS),
       LOCATE_IN_STRING('WINNING','N',-3,3,OCTETS)
  FROM SYSIBM.SYSDUMMY1;
```

Returns the values:

6 4 6 3 3 0

"POSITION" on page 466

"POSSTR" on page 469

## LOG10

The LOG10 function returns the common logarithm (base 10) of a number.

```
►►—LOG10(numeric-expression)—►►
```

The schema is SYSIBM.

The argument is an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HLOG is an INTEGER with a value of 100. The following statement returns a double precision floating-point number with an approximate value of 2:

```
SELECT LOG10(:HLOG)
      FROM SYSIBM.SYSDUMMY1;
```

## LOWER

The LOWER function returns a string in which all the characters are converted to lowercase characters.

```
| ►--LOWER(string-expression [ ,locale-name] [ ,integer ])-->
```

The schema is SYSIBM.

### *string-expression*

An expression that specifies the string to be converted. The string must be a character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB.

### *locale-name*

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

Fr\_BE  
Fr\_FR@EURO  
En\_US  
Ja\_JP

For EBCDIC and ASCII data, there are two options for *local-name*:

- blank — *string-expression* must not specify a graphic string. For a character string, characters A-Z are converted to a-z and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin uppercase letters A-Z are converted to full-width lowercase letters a-z. This is the default value specified in the LOCALE LC\_CTYPE on the installation panel DSNTIPF.
- a local — local specific casing will be done using the "LOCAL" casing capabilities, as specified during installation

For optimal performance, use blank for *locale-name* unless your data must be interpreted using the rules provided for specific locales.

For Unicode data, there are three options for *locale-name*:

- blank — simple casting on A-Z, a-z, and full-width Latin lowercase letters a-z and full-width Latin uppercase letters A-Z. Characters with diacritics are not affected.
- "UNI" — If the value "UNI" is specified, casting will use both the "NORMAL" and "SPECIAL" casing capabilities as described in *z/OS Support for Unicode: Using Conversion Services*.
- a locale — In this case, locale specific casing will be performed using the "LOCALE" casing capabilities as described in *z/OS Support for Unicode: Using Conversion Services*.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable
- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length character or graphic data type

If *locale-name* is not specified, the locale is determined by special register CURRENT LOCALE LC\_CTYPE. For information about the special register, see "CURRENT LOCALE LC\_CTYPE" on page 140. However, if an index references the LOWER function, the local is determined as follows (in order) to determine if the index can be used:

- At prepare time — using the value in the CURRENT LOCALE LC\_CTYPE special register
- At bind time — using the value in the LOCALE LC\_CTYPE field on installation panel DSNTIPF

If the index is chosen in the access path, the locale in the CURRENT LOCALE LC\_CTYPE special register must remain the same at run time, and prepare or bind time. To avoid this dependence, don't omit *locale-name*.

If the LOWER function is referenced in an index that is based on an expression, *locale-name* must be specified. See the examples section for an example of how the index can be utilized in a query.

#### *integer*

An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the LOWER function can result in expansion if certain characters are processed. For example, LOWER ('I') —UX'00CC'— will result in UX'006903070300' (if the LT\_LT locale is in effect at the time). You should ensure that the result length is large enough to contain the result of the expression.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

LCASE is a synonym for LOWER.

*Example 1:* Return the characters in the value of host variable NAME in lowercase. NAME has a data type of VARCHAR(30) and a value of 'Christine Smith'. Assume that the locale in effect is blank.

```
SELECT LCASE(:NAME)
      FROM SYSIBM.SYSDUMMY1;
```

The result is the value 'christine smith'.

*Example 2:* Return the lowercase of 'I'. Assume that the locale in effect is LT\_LT.

```
SELECT LOWER('I')
      FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT LOWER(VARCHAR('í', 3))
  FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value UX'006903070300'.

*Example 3:* Create an index EMPLOYEE\_NAME\_LOWER for table EMPLOYEE based on built-in function LOWER with locale name 'LT\_LT'.

```
CREATE INDEX EMPLOYEE_NAME_LOWER
  ON EMPLOYEE (LOWER(LASTNAME, 'LT_LT', 60),
                LOWER(FIRSTNAME, 'LT_LT', 60),
                ID);
```

*Example 4:* Create an index LNAME for table T1 based on the LOWER function with the default local value, ' '. Then specify the same expression in a query.

```
CREATE INDEX LNAME
  ON TI (LOWER(LASTNAME, ' '));
SELECT LOWER(LASTNAME, ' ')
  FROM TI
 WHERE LOWER(LASTNAME, ' ') = 'smith';
```

*Example 5:* Create an index LNAME that is based on the LOWER function with a locale name 'FR\_CA' for the table T1. Then specify the same expression in a query except *locale-name* is omitted.

```
CREATE INDEX LNAME
  ON TI (LOWER(LASTNAME, 'FR_CA'));
```

If the query is a dynamic statement and the CURRENT LOCALE LC\_CTYPE special register contains 'FR\_CA':

```
SELECT LASTNAME
  FROM TI
 WHERE LOWER(LASTNAME)='smith';
```

At prepare time, locale 'FR\_CA' in CURRENT LOCALE LC\_CTYPE is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME can be used for index access. If index LNAME is used in access path selection, at run time, the locale in CURRENT LOCALE LC\_CTYPE must remain the same.

If the query is a static statement and locale 'FR\_CA' has been set on the LOCALE LC\_CTYPE field of installation panel DSNTIPF:

```
SELECT LASTNAME
  FROM TI
 WHERE LOWER(LASTNAME)='smith';
```

At bind time, local 'FR\_CA' in the LOCALE LC\_CTYPE file of installation panel DSNTIPF is used for LOWER(LASTNAME) in the predicate to determine whether index LNAME is used for index access. If index LNAME is chosen in access path selection, the locale in the CURRENT LOCALE LC\_CTYPE special register must contain 'FR\_CA'.

## LPAD

The LPAD function returns a string that is composed of *string-expression* that is padded on the left, with *pad* or blanks. The LPAD function treats leading or trailing blanks in *string-expression* as significant.

```
►►—LPAD(string-expression,integer——,—pad—)—►►
```

Padding occurs only if the actual length of *string-expression* is less than *integer*, and if *pad* is not an empty string.

The schema is SYSIBM.

*string-expression*

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

*integer*

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

*pad*

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero ('X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty result string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will pad a value on the left with periods.

```
|           SELECT LPAD(NAME,15,'.') AS NAME  
|           FROM T1;
```

| The results are similar to the following:

```
|           NAME  
|           -----  
|           .....Chris  
|           .....Meg  
|           .....Jeff
```

| *Example 2:* Similar to Example 1, the following query will only pad each value to a length of 5:

```
|           SELECT LPAD(NAME,5,'.') AS NAME  
|           FROM T1;
```

| The results are similar to the following:

```
|           NAME  
|           -----  
|           Chris  
|           ..Meg  
|           .Jeff
```

| *Example 3:* Assume that NAME is a CHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff'. Note that the LPAD function does not pad because NAME is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```
|           SELECT LPAD(NAME,5,'.') AS NAME  
|           FROM T1;
```

| The results are similar to the following:

```
|           NAME  
|           -----  
|           Chris  
|           Meg  
|           Jeff
```

| *Example 4:* Assume that NAME is a VARCHAR(15) column containing the values 'Chris', 'Meg', and 'Jeff'. Note that in some cases, a partial instance of the pad specification is returned.

```
|           SELECT LPAD(NAME,15,'123') AS NAME  
|           FROM T1
```

| The results are similar to the following:

```
|           NAME  
|           -----  
|           1231231231Chris  
|           123123123123Meg  
|           12312312312Jeff
```

## LTRIM

The LTRIM function removes blanks or hexadecimal zeros from the beginning of a string expression.

```
►►—LTRIM(string-expression)—►►
```

The schema is SYSIBM.

The LTRIM function returns the same results as the STRIP function with LEADING specified:

```
STRIP(string-expression,LEADING)
```

The argument must be an expression that returns a value that is a character string, graphic string, or binary string built-in data type. The argument must not be a LOB.

- If the argument is a binary string, the leading hexadecimal zeros (X'00') are removed.
- If the argument is a DBCS graphic string, the leading DBCS blanks are removed.
- If the argument is a Unicode graphic string, the leading UTF-16 or UCS-2 blanks are removed.
- If the argument is a UTF-8 character string, the leading UTF-8 blanks are removed.
- Otherwise, leading SBCS blanks are removed.

The result of the function depends on the data type of its argument:

- VARBINARY if the argument is a binary string
- VARCHAR if the argument is a character string
- VARGRAPHIC if the argument is a graphic string

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result is the length of the expression minus the number of characters removed. If all of the bytes are removed, the result is an empty string.

If the argument can be null, the result can be null; if the argument is null, the result is the null value. The CCSID of the result is the same as that of *string-expression*.

*Example 1:* Assume that host variable HELLO is defined as CHAR(9) and has a value of 'Hello'.

```
SELECT LTRIM(:HELLO)
      FROM SYSIBM.SYSDUMMY1;
```

The result is 'Hello'.

*Example 2:* The following function returns a VARBINARY string with a length attribute 5, actual length 1 and a value BX'C1':

```
SELECT LTRIM(BINARY(X'00000000C1'))
      FROM SYSIBM.SYSDUMMY1;
```

## MAX

The MAX scalar function returns the maximum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 20 on page 102. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML. Character and binary string arguments cannot have an actual length greater than 255, and graphic string arguments cannot have an actual length greater than 127.

The arguments are evaluated in the order in which they are specified. The result of the function is the maximum argument value. The result can be null if at least one argument is null; the result is the null value if one of the arguments is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the “Rules for result data types” on page 119. If the MAX function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

GREATEST can be specified as a synonym for MAX.

*Example 1:* Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 6.25.

```
MAX(:M1,:M2,:M3)
```

*Example 2:* Assume the host variable M1 is a CHAR(2) host variable with a value of 'AA', host variable M2 is a CHAR(3) host variable with a value of 'AA ', and host variable M3 is a CHAR(4) host variable with a value of 'AA A'. The following function returns the value 'AA A'.

```
MAX(:M1,:M2,:M3)
```

## MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

```
►►MICROSECOND(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a timestamp duration. For the valid formats of timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a timestamp or string representation of a timestamp**, the result is the microsecond part of the value, which is an integer between 0 and 999999.

**If the argument is a duration**, the result is the microsecond part of the value, which is an integer between -999999 and 999999. A nonzero result has the same sign as the argument.

*Example 1:* Assume that table TABLEX contains a TIMESTAMP column named TSTMPCOL and a SMALLINT column named INTCOL. Select the microseconds part of the TSTMPCOL column of the rows where the INTCOL value is 1234:

```
SELECT MICROSECOND(TSTMPCOL) FROM TABLEX  
WHERE INTCOL = 1234;
```

## MIDNIGHT\_SECONDS

The MIDNIGHT\_SECONDS function returns an integer, in the range of 0 to 86400, that represents the number of seconds between midnight and the time that is specified in the argument.

```
►►MIDNIGHT_SECONDS(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Find the number of seconds between midnight and 00:01:00, and midnight and 13:10:10. Assume that host variable XTIME1 has a value of '00:01:00', and that XTIME2 has a value of '13:10:10'.

```
SELECT MIDNIGHT_SECONDS(:XTIME1), MIDNIGHT_SECONDS(:XTIME2)
   FROM SYSIBM.SYSDUMMY1;
```

This example returns 60 and 47410. Because there are 60 seconds in a minute and 3600 seconds in an hour, 00:01:00 is 60 seconds after midnight  $((60 * 1) + 0)$ , and 13:10:10 is 47410 seconds  $((3600 * 13) + (60 * 10) + 10)$ .

*Example 2:* Find the number of seconds between midnight and 24:00:00, and midnight and 00:00:00.

```
SELECT MIDNIGHT_SECONDS('24:00:00'), MIDNIGHT_SECONDS('00:00:00')
   FROM SYSIBM.SYSDUMMY1;
```

This example returns 86400 and 0. Although these two values represent the same point in time, different values are returned.

## MIN

The MIN scalar function returns the minimum value in a set of values.

The schema is SYSIBM.

The arguments must be compatible. For more information on compatibility, refer to the compatibility matrix in Table 20 on page 102. All but the first argument can be parameter markers. There must be two or more arguments.

Each argument must be an expression that returns a value of any built-in data type other than a CLOB, DBCLOB, BLOB, ROWID, or XML. Character string and binary string arguments cannot have an actual length greater than 255, and graphic string arguments cannot have an actual length greater than 127.

The arguments are evaluated in the order in which they are specified. The result of the function is the minimum argument value. The result can be null if at least one argument is null; the result is the null value if one of the arguments is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined using the "Rules for result data types" on page 119. If the MIN function has more than two arguments, the rules are applied to the first two arguments to determine a candidate result type. The rules are then applied to that candidate result type and the third argument to determine another candidate result type. This process continues until all arguments are analyzed and the final result type and CCSID is determined.

LEAST can be specified as a synonym for MIN.

*Example 1:* Assume the host variable M1 is a DECIMAL(2,1) host variable with a value of 5.5, host variable M2 is a DECIMAL(3,1) host variable with a value of 4.5, and host variable M3 is a DECIMAL(3,2) host variable with a value of 6.25. The following function returns the value 4.5.

```
MIN(:M1,:M2,:M3)
```

*Example 2:* Assume the host variable M1 is a CHAR(2) host variable with a value of 'AA', host variable M2 is a CHAR(3) host variable with a value of 'AAA', and host variable M3 is a CHAR(4) host variable with a value of 'AAAA'. The following function returns the value 'AA'.

```
MIN(:M1,:M2,:M3)
```

## MINUTE

The MINUTE function returns the minute part of a value.

```
►►—MINUTE(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a time, timestamp, or string representation of either,** the result is the minute part of the value, which is an integer between 0 and 59.

**If the argument is a time duration or timestamp duration,** the result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

*Example 1:* Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start on the hour.

```
SELECT * FROM CLASSES  
WHERE MINUTE(STARTTM) = 0;
```

## MOD

The MOD function divides the first argument by the second argument and returns the remainder.

```
►►MOD(numeric-expression-1,numeric-expression-2)►►
```

The schema is SYSIBM.

The formula used to calculate the remainder is:

$$\text{MOD}(x,y) = x - (x/y) * y$$

Where  $x/y$  is the truncated integer result of the division. The result is negative only if the first argument is negative.

Each argument must be an expression that returns a value of any built-in numeric data type. The second argument cannot be zero.

If an argument can be null, the result can be null; if an argument is null, the result is the null value.

The attributes of the result are based on the arguments as follows:

- If both arguments are large or small integers, the data type of the result is large integer.
- If both arguments are integers and at least one argument is a big integer, the data type of the result is big integer.
- If one argument is an integer and the other is a decimal, the data type of the result is decimal with the same precision and scale as the decimal argument.
- If both arguments are decimal, the data type of the result is decimal. The precision of the result is  $\min(p-s,p'-s') + \max(s,s')$ , and the scale of the result is  $\max(s,s')$ , where the symbols  $p$  and  $s$  denote the precision and scale of the first argument, and the symbols  $p'$  and  $s'$  denote the precision and scale of the second argument.
- If one argument is a floating-point number, and the other is not a DECFLOAT, or both argument is a floating-point number, the data type of the result is double precision floating-point.

The operation is performed in floating-point. If necessary, the operands are first converted to double precision floating-point numbers. For example, an operation that involves a floating-point number and either an integer or a decimal number is performed with a temporary copy of the integer or decimal number that has been converted to double precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34). If either argument is a special decimal floating point value, the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 186 for more information.

If one argument is a DECFLOAT and the second argument is zero, the result is NaN and an invalid operation condition is returned.

*Example:* Assume that *M1* and *M2* are two host variables. Find the remainder of dividing *M1* by *M2*.

```
SELECT MOD(:M1,:M2)
   FROM SYSIBM.SYSDUMMY1;
```

The following table shows the result for this function for various values of *M1* and *M2*.

<i>M1</i> data type	<i>M1</i> value	<i>M2</i> data type	<i>M2</i> value	Result of MOD(:M1,:M2)
INTEGER	5	INTEGER	2	1
INTEGER	5	DECIMAL(3,1)	2.2	0.6
INTEGER	5	DECIMAL(3,2)	2.20	0.60
DECIMAL(4,2)	5.50	DECIMAL(4,1)	2.0	1.50
DECFLOAT	1	DECFLOAT	-INFINITY	1
DECFLOAT	-0	DECFLOAT	INFINITY	-0
DECFLOAT	-0	DECFLOAT	-INFINITY	-0

## MONTH

The MONTH function returns the month part of a value.

```
►►MONTH(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a date, timestamp, or string representation of either,** the result is the month part of the value, which is an integer between 1 and 12.

**If the argument is a date duration or timestamp duration,** the result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

*Example 1:* Select all rows in the sample table DSN8910.EMP for employees who were born in May:

```
SELECT * FROM DSN8910.EMP  
WHERE MONTH(BIRTHDATE) = 5;
```

## MONTHS\_BETWEEN

The MONTHS\_BETWEEN function returns an estimate of the number of months between two arguments.

```
►►MONTHS_BETWEEN(expression1,expression2)-----►►
```

The schema is SYSIBM.

*expression1 or expression2*

Expressions that return a value of any of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If either expression is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 89.

If *expression1* represents a date that is later than *expression2*, the result is positive. If *expression1* represents a date that is earlier than *expression2*, the result is negative.

- If *expression1* and *expression2* represent dates or timestamps with the same day of the month, or both arguments represent the last day of their respective months, the result is a the whole number difference based on the year and month values, ignoring any time portions of timestamp arguments.
- Otherwise, the whole number part of the result is the difference based on the year and month values. The fractional part of the result is calculated from the remainder based on an assumption that every month has 31 days. If either argument represents a timestamp, the arguments are effectively processed as timestamps with maximum precision, and the time portions of these values are also considered when determining the result.

The result of the function is a DECIMAL(31,15). If either argument can be null, the result can be null. If either argument is null, the result is the null value.

*Examples 1:* The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN ('2008-01-17','2008-02-17')
   AS MONTHS_BETWEEN
  FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
-----
-1.000000000000000
```

*Examples 2:* The following example calculates the months between two dates:

```
SELECT MONTHS_BETWEEN ('2008-02-20','2008-01-17')
   AS MONTHS_BETWEEN
  FROM SYSIBM.SYSDUMMY1;
```

The results of this statement are similar to the following results:

```
MONTHS_BETWEEN
```

---

```
1.096774193548387
```

|  
| *Example 3:* Calculate the number of months that project AD3100 will take. Assume  
| that the start date is 1982-01-01 and the end date is 1983-02-01:

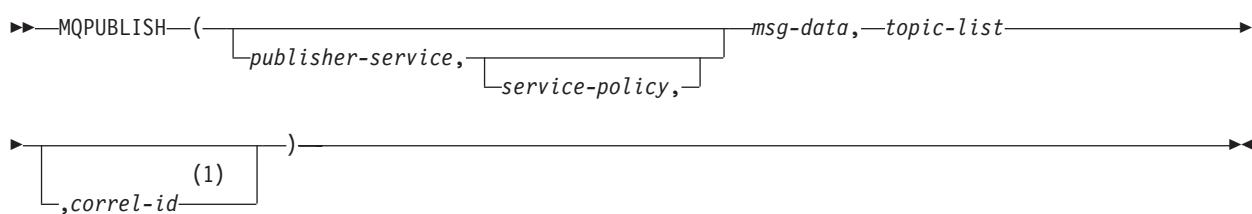

```
| SELECT MONTHS_BETWEEN (PRENDATE, PRSDATE)  
|   FROM PROJECT  
| WHERE PROJNO='AD3100';
```

| The result is 13.000000000000000.

| *Example 4:* The following table illustrates the use of the MONTHS\_BETWEEN  
| function in certain situations:

## MQPUBLISH

The MQPUBLISH function publishes a message to the specified MQSeries publisher, and returns a varying-length character string that indicates whether the function was successful or unsuccessful.

### Notes:

- 1 *correl-id* can be specified only if a publisher service and a service policy have been defined.

The schema is DB2MQ1N or DB2MQ2N.

The MQPUBLISH function publishes the data that is contained in *msg-data* to the MQSeries publisher that is specified in *publisher-service*, using the quality-of-service policy that is defined by *service-policy*. A list of topics for the message must be specified, and an optional user-defined message correlation identifier can also be specified. The MQPUBLISH function requires the installation and configuration of an MQSeries-based publish and subscribe system, such as Websphere MQSeries Integrator. See [www.ibm.com/software/MQSeries](http://www.ibm.com/software/MQSeries) for more details. The function returns a value of '1' if successful or '0' if unsuccessful.

#### *publisher-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAMT repository file, and it specifies a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *WebSphere MQ application messaging interface* for more details.

If *publisher-service* is not specified, DB2.DEFAULT.PUBLISHER is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to the MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *WebSphere MQ application messaging interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

*msg-data*

An expression that returns a value that is a built-in character string or graphic string data type. If the expression is a CLOB, the value must not be longer than 1 MB. Otherwise, the value must not be longer than 4000 bytes. The value of the expression specifies the data to be sent via MQSeries. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

*topic-list*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 40 bytes. The value of the expression specifies the topics for the message publication. One or more topics can be specified, where the topics are separated with a colon. For example, 't1:t2:the third topic' indicates that the message is associated with all three topics: t1, t2, and 'the third topic'.

*correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression specifies the correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQPUBLISH, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE will not match a *correl-id* value of 'test' (with trailing blanks) specified earlier on an MQPUBLISH request.

If *correl-id* is not specified, a correlation identifier is not used, and a correlation identifier is not added to the message.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Publish the string 'Testing 123' to the default publisher service (DB2.DEFAULT.PUBLISHER), using the default service policy (DB2.DEFAULT.POLICY). Do not specify a topic or correlation identifier for the message.

```
SELECT DB2MQ2C.MQPUBLISH('Testing 123')
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* Publish the string 'Testing 345' to the publisher service 'MYPUBLISHER' under the topic 'TESTS', using the default service policy (DB2.DEFAULT.POLICY). Do not specify a correlation identifier for the message.

```
SELECT DB2MQ2C.MQPUBLISH('MYPUBLISHER','Testing 345', 'TESTS')
      FROM SYSIBM.SYSDUMMY1;
```

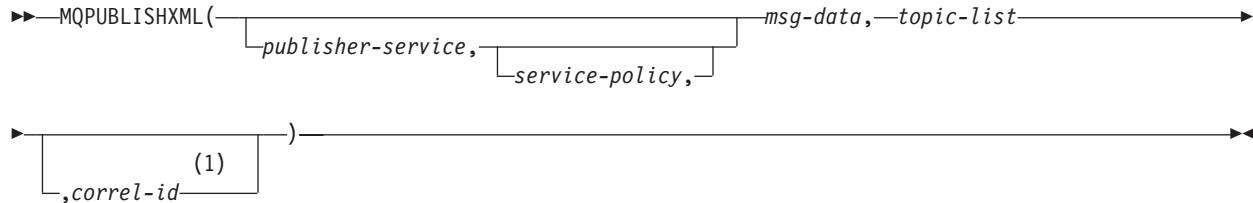

*Example 3:* Publishes the string 'Testing 678' to the publisher service 'MYPUBLISHER' under the topic 'TESTS', using the service policy 'MYPOLICY'. Specify a correlation identifier of 'TEST1' for the message.

```
SELECT DB2MQ2C.MQPUBLISH('MYPUBLISHER', 'MYPOLICY', 'Testing 678', 'TESTS', 'TEST1')
      FROM SYSIBM.SYSDUMMY1;
```

All of the examples return a value of '1' if they are successful.

## MQPUBLISHXML

The MQPUBLISHXML function publishes the XML data in a message to the specified MQSeries publisher.

### Notes:

- 1    *correl-id* cannot be specified unless a publisher service and a service policy are also specified.

The schema is DMQXML1C or DMQXML2C.

The MQPUBLISHXML function publishes the XML data that is contained in *msg-data* to the MQSeries publisher that is specified in *publisher-service*, using the quality-of-service policy that is defined by *service-policy*. A list of topics for the message must be specified, and an optional user-defined message correlation identifier can also be specified. The MQPUBLISHXML function requires the installation and configuration of an MQSeries-based publish and subscribe system, such as Websphere MQSeries Integrator. See [www.ibm.com/software/MQSeries](http://www.ibm.com/software/MQSeries) for more details. The function returns a value of '1' if it is successful or '0' if it is unsuccessful.

#### *publisher-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAMT repository file, and it specifies a logical end point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See for more details.

If *publisher-service* is not specified, DB2.DEFAULT.PUBLISHER is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to the MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

*msg-data*

An expression that returns a value with a user-defined data type of DB2XML.XMLVARCHAR (for messages up to 3K in size) or DB2XML.XMLCLOB (for messages up to 1M in size). The value of the expression specifies the message data to be sent via MQSeries.

*topic-list*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 40 bytes. The value of the expression specifies the topics for the message publication. One or more topics can be specified, where the topics are separated with a colon. For example, 't1:t2:the third topic' indicates that the message is associated with all three topics: t1, t2, and 'the third topic'.

*correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed-length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request, such as MQPUBLISHXML, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEXML will not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQPUBLISHXML request.

If *correl-id* is not specified, a correlation identifier is not used, and a correlation identifier is not added to the message.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed.

*Example 1:* The ORDER column in table ORDER\_TABLE contains XML documents. Publish these XML documents to the default publisher service (DB2.DEFAULT.PUBLISHER), using the default service policy (DB2.DEFAULT.POLICY). Do not specify a topic or correlation identifier for the message.

```
SELECT MQPUBLISHXML(ORDER, 't1')
   FROM ORDER_TABLE;
```

*Example 2:* The CUSTOMER column in table CUSTOMER\_TABLE contains XML documents. Publish the XML documents for the Midwestern customers to the publisher service 'MYPUBLISHER' under the topic '/MIDWEST/CUSTOMERS', using the default service policy (DB2.DEFAULT.POLICY). Do not specify a correlation identifier for the message.

```
SELECT MQPUBLISHXML('MYPUBLISHER', CUSTOMER, '/MIDWEST/CUSTOMERS')
   FROM CUSTOMER_TABLE
 WHERE TERRITORY = 'MIDWEST';
```

All of the examples return a value of '1' if they are successful.

## MQREAD

The MQREAD function returns a message from a specified MQSeries location without removing the message from the queue.

```
►►—MQREAD( [receive-service], [service-policy] )—►►
```

The schema is DB2MQ1N or DB2MQ2N.

The MQREAD function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is received. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

The result of the function is a varying-length string with a length attribute of 4000. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve the message at the beginning of the queue that is specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREAD()  
      FROM TABLE;
```

The message at the beginning of the queue specified by the default server and using the default policy is returned as VARCHAR(4000).

*Example 2:* Read the message from the beginning of the queue specified by the service MYSERVICE, using the default policy MYPOLICY.

```
SELECT MQREAD('MYSERVICE','MYPOLICY')  
      FROM TABLE;
```

The message at the beginning of the queue specified by MYSERVICE and using MYPOLICY is returned as VARCHAR(4000).

## MQREADCLOB

The MQREADCLOB function returns a message from a specified MQSeries location without removing the message from the queue.

```
►►—MQREADCLOB( [receive-service] [,—service-policy] )—►►
```

The schema is DB2MQ1N or DB2MQ2N.

The MQREADCLOB function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is received. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Read the message from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB(0)  
      FROM TABLE;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a CLOB.

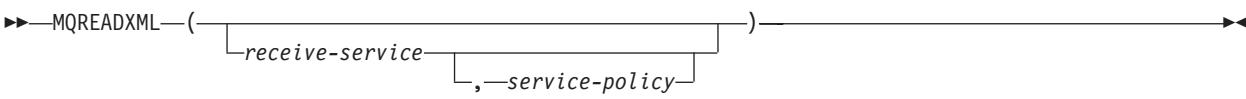

*Example 2:* Read the message from the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADCLOB('MYSERVICE')
  FROM TABLE;
```

The message at the beginning of the queue specified by MYSERVICE and using the default policy is returned as a CLOB.

## MQREADXML

The MQREADXML function returns an XML message from a specified MQSeries location without removing the message from the queue.

The schema is DMQXML1C or DMQXML2C

The MQREADXML function returns an XML message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the message from the queue that is associated with *receive-service*, but instead returns the message at the beginning of the queue.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

The result of the function is a value with the user-defined data type DB2XML.XMLVARCHAR that contains the XML messages. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

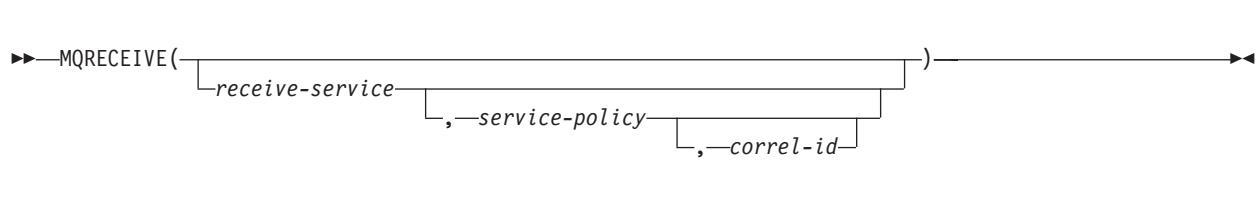

*Example:* Read the message from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQREADXML()
      FROM SYSIBM.SYSDUMMY;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a XMLVARCHAR.

## MQRECEIVE

The MQRECEIVE function returns a message from a specified MQSeries location and removes the message from the queue.

The schema is DB2MQ1N or DB2MQ2N.

The MQRECEIVE function returns a message from the MQSeries location specified by *receive-service*, using the quality-of-service policy defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is received. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another

request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVE does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a varying-length string of length attribute of 4000. The result can be null. The result is null if no messages are available to return.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve the message from beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVE()
      FROM TABLE;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as VARCHAR(4000) and is deleted from the queue.

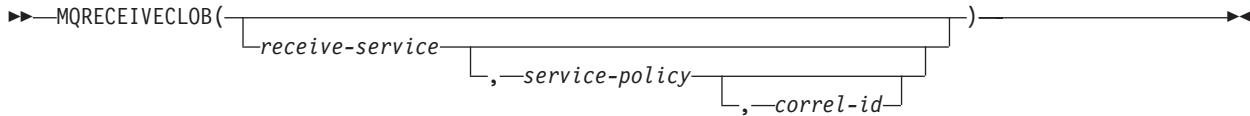

*Example 2:* Retrieve the first message with a correlation identifier that matches '1234' from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT MQRECEIVE('MYSERVICE','MYPOLICY','1234')
      FROM TABLE;
```

The message with CORRELID of '1234' from the beginning of the queue specified by MYSERVICE and using MYPOLICY is returned as VARCHAR(4000) and is deleted from the queue.

## MQRECEIVECLOB

The MQRECEIVECLOB function returns a message from a specified MQSeries location and removes the message from the queue.

The schema is DB2MQ1N or DB2MQ2N.

The MQRECEIVECLOB function returns a message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is received. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another

request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVECLOB does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a CLOB with a length attribute of 1 MB. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve the message from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MORERECEIVECLOB()
      FROM TABLE;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned as a CLOB and is deleted from the queue.

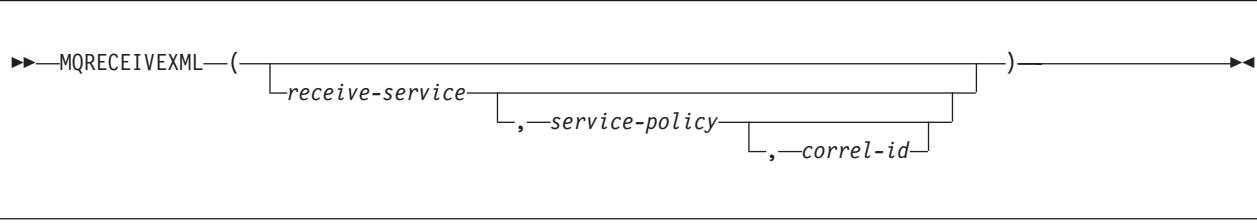

*Example 2:* Retrieve the message from the beginning of the queue specified by the service MYSERVICE, using the policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVECLOB('MYSERVICE')
      FROM TABLE;
```

The message at the beginning of the queue specified by MYSERVICE and using the default policy is returned as a CLOB and is deleted from the queue.

## MQRECEIVEXML

The MQRECEIVEXML function returns a message from a specified MQSeries location and removes the message from the queue.

The schema is DMQXML1C or DMQXML2C.

The MQRECEIVEXML function returns an XML message from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the message from the queue that is associated with *receive-service*.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies. The first message with a matching correlation identifier is returned.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSENDXML, the *correl-id* must be specified the same to be

recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEXML does not match a *correl-id* value of 'test   ' (with trailing blanks) specified earlier on an MQSENDXML request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

The result of the function is a value with user-defined data type DB2XML.XMLVARCHAR that contains the XML messages. The result can be null. If no messages are available to be returned, the result is the null value.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example:* Retrieve the message from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT MQRECEIVEXML()
      FROM SYSIBM.SYSDUMMY;
```

The message at the beginning of the queue specified by the default service and using the default policy is returned. The message is deleted from the queue.

## MQSEND

The MQSEND function sends data to a specified MQSeries location, and returns a varying-length character string that indicates whether the function was successful or unsuccessful.

```
►►—MQSEND(—  
    |  
    | send-service,—  
    | service-policy,—  
    | msg-data  
    | (1)  
    | ,—correl-id—  
    )—►►
```

### Notes:

- 1    *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DB2MQ1N or DB2MQ2N.

The MQSEND function sends the data that is contained in *msg-data* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The returned value is '1' if the function was successful or '0' if unsuccessful.

#### *send-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *send-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *msg-data*

An expression that returns a value that is a built-in character string data type. If the expression is a CLOB, the value must not be longer than 1 MB. Otherwise, the value must not be longer than 4000 bytes. The value of the expression is the message data that is to be sent via MQSeries. A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values.

*correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. *correl-id* must not be specified unless *send-service* and *service-policy* are also specified.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQRECEIVE, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQSEND does not match a *correl-id* value of 'test' (with trailing blanks) specified subsequently on an MQRECEIVE request.

If *correl-id* is not specified, a correlation identifier is not sent.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Send the string "Testing msg" to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY) and no correlation identifier.

```
SELECT MQSEND('Testing msg')
    FROM TABLE;
```

The message is sent to the default service, using the default policy.

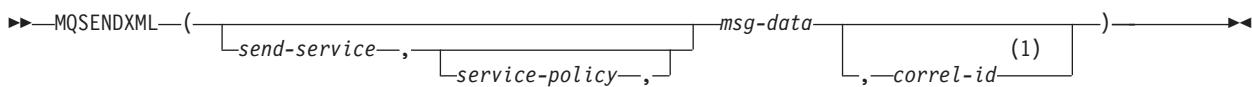

*Example 2:* Send the string "Testing 123" to the service MYSERVICE, using the policy MYPOLICY and the correlation identifier "TEST3".

```
SELECT MQSEND('MYSERVICE','MYPOLICY','Testing 123','TEST3')
    FROM TABLE;
```

The string "TESTING 123" is sent to MYSERVICE, using MYPOLICY and the correlation identifier "TEST3".

## MQSENDXML

The MQSENDXML function sends XML data to a specified MQSeries location.

### Notes:

- 1    *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DMQXML1C or DMQXML2C.

The MQSENDXML function sends the XML data that is contained in *msg-data* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The function returns a value of '1' if it is successful or a '0' if it is unsuccessful.

#### *send-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *send-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *msg-data*

An expression that returns a value with a user-defined data type of DB2XML.XMLVARCHAR (for data up to 3 KB in size) or DB2XML.XMCLCLOB (for data up to 1 MB in size). The value of the expression specifies the message data to be sent via MQSeries.

#### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the

correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSENDXML, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEXML does not match a *correl-id* value of 'test ' (with trailing blanks) specified subsequently on an MQSENDXML request.

If *correl-id* is not specified, a correlation identifier is not sent.

The result of the function is a varying-length string with a length attribute of 1. The data type of the result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* The ORDER column in table ORDER\_TABLE contains XML documents. Send the XML documents in this column to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Do not specify a correlation identifier.

```
SELECT MQSENDXML(ORDER)
      FROM ORDER_TABLE;
```

The message is sent to the default service, using the default policy.

*Example 2:* The CUSTOMER column in table CUSTOMER\_TABLE contains XML documents. Send the XML documents for the Midwestern customers to the service 'MYSERVICE', using the default service policy (DB2.DEFAULT.POLICY) and a correlation identifier of 'MIDWESTERN'.

```
SELECT MQSENDXML('MYSERVICE', 'MYPOLICY', CUSTOMER, 'MIDWESTERN')
      FROM CUSTOMER_TABLE
     WHERE TERRITORY = 'MIDWESTERN';
```

All of the examples return a value of '1' if they are successful.

## MQSENDXMLFILE

The MQSENDXMLFILE function sends up to 3 KB of data that is contained in the specified XML file to a specified MQSeries location.

```
►►MQSENDXMLFILE(—  
|   send-service,—  
|   service-policy,—  
|   xml-file  
|   ,—correl-id—  
|   (1))—►►
```

### Notes:

- 1    *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DMQXML1C or DMQXML2C.

The MQSENDXMLFILE function sends the XML data that is contained in *xml-file* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The function returns a value of '1' if it is successful or a '0' if it is unsuccessful.

#### *send-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *send-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *xml-file*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies the name of the file that contains the XML data that is to be sent via MQSeries.

#### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length

that is no greater than 24 bytes. The value of the expression specifies the correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSENDXML, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEXML does not match a *correl-id* value of 'test ' (with trailing blanks) specified subsequently on an MQSENDXML request.

If *correl-id* is not specified, a correlation identifier is not sent.

The result of the function is a varying-length string with a length attribute of 1. The data type of the result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Send the XML documents that are in file '/tmp/test1.xml' to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Do not specify a correlation identifier.

```
SELECT MQSENDXMLFILE('/tmp/test1.xml')
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* Send the XML documents that are in file '/tmp/test2.xml' to the service 'MYSERVICE', using the service policy 'MYPOLICY' and the correlation identifier 'Test 2').

```
SELECT MQSENDXMLFILE('MYSERVICE', 'MYPOLICY', CUSTOMER, '/tmp/test2.xml','Test2')
      FROM SYSIBM.SYSDUMMY1;
```

All of the examples return a value of '1' if they are successful.

## MQSENDXMLFILECLOB

The MQSENDXMLFILECLOB function sends up to 1 MB of data that is contained in an XML file to a specified MQSeries location.

```
►►—MQSENDXMLFILECLOB—(—send-service,—service-policy,—xml-file,—correl-id(1))—►►
```

### Notes:

- 1   *correl-id* cannot be specified unless a send service and a service policy are also specified.

The schema is DMQXML1C or DMQXML2C.

The MQSENDXMLFILECLOB function sends the XML data that is contained in *xml-file* to the MQSeries location that is specified by *send-service*, using the quality-of-service policy that is defined in *service-policy*. The function returns a value of '1' if it is successful or a '0' if it is unsuccessful.

#### *send-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination to which the message is sent. A service point is defined in the DSNAME repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *send-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAME repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *xml-file*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 48 bytes. The value of the expression specifies the name of the file that contains the XML data that is to be sent via MQSeries.

#### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length

that is no greater than 24 bytes. The value of the expression specifies the correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSENDXML, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEXML does not match a *correl-id* value of 'test ' (with trailing blanks) specified subsequently on an MQSENDXML request.

If *correl-id* is not specified, a correlation identifier is not sent.

The result of the function is a varying-length string with a length attribute of 1. The data type of the result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example:* Send the XML documents that are in file '/tmp/test1.xml' to the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY). Do not specify a correlation identifier.

```
SELECT MQSENDXMLFILECLOB('/tmp/test1.xml')
      FROM SYSIBM.SYSDUMMY1;
```

The example returns a value of '1' if it is successful.

## MQSUBSCRIBE

The MQSUBSCRIBE function registers a subscription to MQSeries messages that are published on a specified topic, and returns a varying-length character string that indicates if the function was successful.

```
►►—MQSUBSCRIBE( [ subscriber-service ], [ service-policy ], [ topic-list ] )—►►
```

The schema is DB2MQ1N or DB2MQ2N.

The MQSUBSCRIBE function is used to register interest in MQSeries messages published on specified topics. The *subscriber-service* specifies a logical destination for messages that match the specified topics. Messages that match the specified topics are placed on the queue defined by *subscriber-service*. The messages can then be read or received through a subsequent invocation of the MQREAD, MQRECEIVE, MQREADALL, or MQRECEIVEALL functions. The MQSUBSCRIBE function requires the installation and configuration of an MQSeries-based publish and subscribe system, such as Websphere MQSeries Integrator. See [www.ibm.com/software/MQSeries](http://www.ibm.com/software/MQSeries) for more details.

The function returns a value of '1' if successful or '0' if unsuccessful. A successful execution of this function causes the publish and subscribe server to forward messages that match the specified topics to the service point defined by *subscriber-service*.

### *subscriber-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries subscription point to which messages that match the specified topics are sent. A subscriber's service point is defined in the DSNAMT repository file, and it specifies a logical subscription point to which a message is sent. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *subscriber-service* is not specified, DB2.DEFAULT.SUBSCRIBER is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to the MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

*topic-list*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 40 bytes. The value of the expression specifies the types of messages to receive. Only messages published with the specified topics are received by this subscription. Multiple subscriptions can coexist. One or more topics can be specified, where the topics are separated with a colon. For example, 't1:t2:the third topic' indicates that the message is associated with all three topics: t1, t2, and 'the third topic'.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Register an interest in messages that contain the topic 'Weather'. Allow the message to be sent to the default subscriber service point (DB2.DEFAULT.SUBSCRIBER), using the default service policy.

```
SELECT DB2MQ2C.MQSUBSCRIBE('Weather')
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* Registering an interest in messages that contain the topic 'Stocks'. Specify 'PORTFOLIO-UPDATES' as the subscriber service point to which the message is to be sent, using service policy 'BASIC-POLICY'.

```
SELECT DB2MQ2C.MQSUBSCRIBE ('PORTFOLIO-UPDATES','BASIC-POLICY','Stocks')
      FROM SYSIBM.SYSDUMMY1;
```

All of the examples return a value of '1' if they are successful.

## MQUNSUBSCRIBE

The MQUNSUBSCRIBE function unsubscribes to MQSeries messages that are published on a specified topic, and returns a varying-length character string that indicates if the function was successful.

```
►►—MQUNSUBSCRIBE( [subscriber-service], [topic-list] )—►►
```

[*subscriber-service*], [*topic-list*]

The schema is DB2MQ1N or DB2MQ2N.

The MQUNSUBSCRIBE function is used to unregister an existing message subscription. The *subscriber-service*, *service-policy*, and *topic-list* identify which subscription is canceled. The MQUNSUBSCRIBE function requires the installation and configuration of an MQSeries-based publish and subscribe system, such as Websphere MQSeries Integrator. See [www.ibm.com/software/MQSeries](http://www.ibm.com/software/MQSeries) for more details.

The function returns a value of '1' if successful or '0' if unsuccessful. A successful execution of this function causes the publish and subscribe server to remove the subscription that is identified by the given parameters. Messages that match the specified topics are no longer sent to the service point defined by *subscriber-service*.

### *subscriber-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries subscription point to which messages that match the specified topics are sent. A subscriber's service point is defined in the DSNAMT repository file, and it specifies a logical subscription point to which a message is sent. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *subscriber-service* is not specified, DB2.DEFAULT.SUBSCRIBER is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to the MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *topic-list*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the

null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 40 bytes. The value of the expression specifies the types of messages to receive. Only messages published with the specified topics are received by this subscription. Multiple subscriptions can coexist. One or more topics can be specified, where the topics are separated with a colon. For example, 't1:f2:the third topic' indicates that the message is associated with all three topics: t1, t2, and 'the third topic'.

The result of the function is a varying-length string with a length attribute of 1. The result is nullable, even though a null value is never returned.

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Cancel the subscription for messages that contain the topic 'Weather'. The subscriber is registered with the default subscriber service point (DB2.DEFAULT.SERVICE) with the default service policy (DB2.DEFAULT.SERVICE).

```
SELECT DB2MQ2C.UNMQSUBSCRIBE('Weather')
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* Cancel the subscription for messages that contain the topic 'Stocks'. The subscriber is registered with the subscriber service point 'PORTFOLIO-UPDATES' with the service policy 'BASIC-POLICY'.

```
SELECT DB2MQ2C.MQUNSUBSCRIBE ('PORTFOLIO-UPDATES','BASIC-POLICY','Stocks')
      FROM SYSIBM.SYSDUMMY1;
```

All of the examples return a value of '1' if they are successful.

## MULTIPLY\_ALT

The MULTIPLY\_ALT scalar function returns the product of the two arguments. This function is an alternative to the multiplication operator and is especially useful when the sum of the precisions of the arguments exceeds 31.

```
►►MULTIPLY_ALT(exact-numeric-expression-1,exact-numeric-expression-2)►►
```

The schema is SYSIBM.

Each argument must be an expression that returns the value of one of the following built-in numeric data types: DECIMAL, BIGINT, INTEGER, or SMALLINT.

The result of the function is a DECIMAL. The precision and scale of the result are determined as follows, using the symbols  $p$  and  $s$  to denote the precision and scale of the first argument, and the symbols  $p'$  and  $s'$  to denote the precision and scale of the second argument.

- The precision is  $\text{MIN}(31, p+p')$
- The scale is:
  - 0 if the scale of both arguments is 0
  - $\text{MIN}(31, s+s')$  if  $p+p'$  is less than or equal to 31
  - $\text{MAX}(\text{MIN}(3, s+s'), 31-(p-s+p'-s'))$  if  $p+p'$  is greater than 31.

The result can be null if at least one argument can be null; the result is the null value if one of the arguments is null.

The MULTIPLY\_ALT function is a better choice than the multiplication operator when performing decimal arithmetic where a scale of at least 3 is desired and the sum of the precisions exceeds 31. In these cases, the internal computation is performed so that overflows are avoided and then assigned to the result type value using truncation for any loss of scale in the final result. Note that the possibility of overflow of the final result is still possible when the scale is 3.

The following table compares the result data types from the MULTIPLY\_ALT function with the result data type of the multiplication operator when decimal data is used:

Type of Argument1	Type of Argument2	Result using MULTIPLY_ALT	Result using multiplication operator
DECIMAL(31,3)	DECIMAL(15,8)	DECIMAL(31,3)	DECIMAL(31,11)
DECIMAL(26,23)	DECIMAL(10,1)	DECIMAL(31,19)	DECIMAL(31,24)
DECIMAL(18,17)	DECIMAL(20,19)	DECIMAL(31,29)	DECIMAL(31,31)
DECIMAL(16,3)	DECIMAL(17,8)	DECIMAL(31,9)	DECIMAL(31,11)
DECIMAL(26,5)	DECIMAL(11,0)	DECIMAL(31,3)	DECIMAL(31,5)
DECIMAL(21,1)	DECIMAL(15,1)	DECIMAL(31,2)	DECIMAL(31,2)

## NEXT\_DAY

The NEXT\_DAY function returns a timestamp that represents the first occurrence of the specified weekday that is after the date argument.

```
►►NEXT_DAY(expression,string-expression)—————►►
```

The schema is SYSIBM.

If *expression* is a timestamp or valid string representation of a timestamp, the timestamp value has the same hours, minutes, seconds, and partial seconds as *expression*. If *expression* is a date, or a valid string representation of a date, then the hours, minutes, seconds, and partial seconds value of the result is 0.

### *expression*

An expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

### *string-expression*

An expression that returns a built-in character or graphic string data type that is not a LOB. For portability across the platforms, the value should compare equal to the full name of a day of the week or should compare equal to the abbreviation of a day of the week. For example:

Day of week	Abbreviation
MONDAY	MON
TUESDAY	TUE
WEDNESDAY	WED
THURSDAY	THU
FRIDAY	FRI
SATURDAY	SAT
SUNDAY	SUN

The minimum length of the input value is the length of the abbreviation. Leading blanks must not be specified in *string-expression*. Trailing blanks are trimmed from *string-expression*. The resulting value is folded to uppercase. Any characters other than blank that immediately follow a valid abbreviation are ignored.

The result of the function is a timestamp. The result can be null; if any argument is null, the result is the null value.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

*Example 1:* Set the host variable NEXTDAY with a timestamp for the date of the Tuesday that follows April 24, 2007.

```
|      SET :NEXTDAY = NEXT_DAY(TIMESTAMP '2007-04-24-00.00.00.000000', 'TUESDAY');  
|  
| The host variable NEXTDAY is set with the value of '2007-05-01-00.00.00.000000',  
| since April, 24, 2007 is itself a Tuesday'.  
|  
| Example 2: Set the host variable vNEXTDAY with the date of the first Monday in  
| May, 2007. Assume the host variable vDAYOFWEEK = 'MON':  
|      SET :vNEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_DATE),:vDAYOFWEEK);  
|  
| The host variable vNEXTDAY is set with the value of '2007-05-07', assuming that  
| the value of the CURRENT_DATE special register is '2007-04-24'.
```

## NORMALIZE\_DECFLOAT

The NORMALIZE\_DECFLOAT function returns a DECFLOAT value that is the result of the argument, set to its simplest form. That is, a non-zero number that has any trailing zeros in the coefficient has those zeros removed by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero has its exponent set to 0.

```
►►NORMALIZE_DECFLOAT(decfloat-expression)--►►
```

The schema is SYSIBM.

*decfloat-expression*

The argument must be an expression that returns a DECFLOAT value.

If the argument is a special decimal floating point value then the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 186 for more information.

The result of the function is a DECFLOAT(16) value if the data type of *decfloat-expression* is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

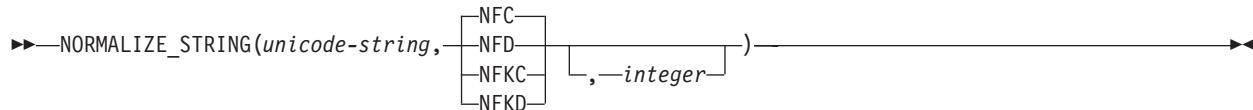

*Examples:* The following examples show the result of using the NORMALIZE\_DECFLOAT function on various DECFLOAT values:

NORMALIZE_DECFLOAT(DECFLOAT(2.1))	= 2.1
NORMALIZE_DECFLOAT(DECFLOAT(-2.0))	= -2
NORMALIZE_DECFLOAT(DECFLOAT(1.200))	= 1.2
NORMALIZE_DECFLOAT(DECFLOAT(-120))	= -1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(120.00))	= 1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(0.00))	= 0
NORMALIZE_DECFLOAT(-NAN)	= -NAN
NORMALIZE_DECFLOAT(-INFINITY)	= -INFINITY

## NORMALIZE\_STRING

The NORMALIZE\_STRING function takes a Unicode string argument and returns a normalized string that can be used for comparison.

The NORMALIZE\_STRING function can convert two strings that look the same (such as Å, which can be encoded in UTF-16 as X'00C5' and as X'00410307') but might not be encoded using the same Unicode code point, to a normalized form that can be compared.

The schema is SYSIBM.

### *unicode\_string*

An expression that returns a value of a built-in character string or graphic string data type that is either Unicode UTF-8 or Unicode UTF-16, and is not a LOB. The CAST specification can be used to convert ASCII or EBCDIC data to Unicode for use with this function.

### **NFC, NFD, NFKC, or NFKD**

Specifies the normalized form:

**NFC** Canonical Decomposition followed by Canonical Composition

**NFD** Canonical Decomposition

**NFKC** Compatibility Decomposition followed by Canonical Composition

**NFKD** Compatibility Decomposition

### *integer*

The length attribute, in bytes if the string is a character string, or in double byte code points if the string is a graphic string, for the resulting variable length string. The value must be an integer between 1 and 32704 if the source string is character, or 16352 if the source string is graphic.

The result of the function is a varying length string with a data type that depends on the data type of *unicode-string*:

- VARCHAR if *unicode-string* is CHAR or VARCHAR
- VARGRAPHIC if *unicode-string* is GRAPHIC or VARGRAPHIC

The CCSID of the result is the same as the CCSID of *unicode-string*.

The length attribute of the result depends on whether *integer* is specified. If *integer* is specified, the length attribute of the result is *integer* bytes or double byte code points. If *integer* is not specified, the length attribute of the result is MIN(3\*n, 32704) for character strings, or MIN(3\*n, 16352) for graphic strings, where *n* is the length attribute of the source.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

|     *Example 1:* In the following example, "ábc" is normalized to normalization form  
|     NFC:

```
|       SET :hv1 = NORMALIZE_STRING('ábc',NFC) -- x'0061030100620063'
```

|     *hv1* is set to 'ábc' -- X'00E100620063'. Using normalization form NFC, the two  
|     code-point sequence X'00610301', which represents the character 'á', is normalized  
|     to X'00E1' which is also the pre-composed equivalent of X'00610301'.

|     *Example 2:* In the following example, "ábc" is normalized to normalization form  
|     NFD.

```
|       SET :hv1 = NORMALIZE_STRING('ábc',NFD) -- x'00E100620063'
```

|     *hv1* is set to 'ábc' -- X'0061030100620063'. Using normalization form NFD, the code  
|     point X'00E1' is decomposed into the two code-point sequence X'00610301', which  
|     consists of the Latin lower case letter A and the combining acute accent character.

## NULLIF

The NULLIF function returns the null value if the two arguments are equal; otherwise, it returns the value of the first argument.

```
►►—NULLIF(expression,expression)—►►
```

The schema is SYSIBM.

The two arguments must be compatible and comparable. (See the compatibility matrix in Table 20 on page 102.) Neither argument can be a BLOB, CLOB, DBCLOB, XML, or distinct type. Character-string and graphic-string arguments are compatible and comparable with datetime values.

The attributes of the result are the attributes of the first argument.

The result of using `NULLIF(e1,e2)` is the same as using the CASE expression:

```
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

When `e1=e2` evaluates to unknown because one or both arguments is null, CASE expressions consider the evaluation not true. In this case, NULLIF returns the value of the first argument.

*Example:* Assume that host variables `PROFIT`, `CASH`, and `LOSSES` have decimal data types with the values of 4500.00, 500.00, and 5000.00 respectively. The following function returns a null value:

```
NULLIF (:PROFIT + :CASH , :LOSSES)
```

## OVERLAY

The OVERLAY function returns a string that is composed of one argument that is inserted into another argument at the same position where some number of bytes have been deleted.

```
►►OVERLAY—(—source-string—,—insert-string—,—start—  
                  [—length—], —CODEUNITS16—)  
                  [—CODEUNITS32—]  
                  [—OCTETS—]—►►
```

The schema is SYSIBM.

The OVERLAY function returns a string where a substring of *length*, beginning at *start* has been deleted from *source-string*, and where *insert-string* has been inserted into *source-string* beginning at *start*. If the value of *start* plus *length* is greater than the length of *source-string*, the substring that is deleted is from *start* to the end of *source-string*.

If the length of the result string exceeds the maximum for the return type, an error is returned.

The OVERLAY function is identical to the INSERT function, except that the length argument is optional.

### *source-string*

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater than or equal to 1 byte and less than or equal to 32704 bytes.

### *insert-string*

An expression that specifies the string that is inserted into *source-string*, starting at the position that is identified by *start*. *insert-string* must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. *source-string* and *insert-string* must have compatible data types.

### *start*

An expression that returns an integer. The integer specifies the starting point within the source string where the deletion of bytes and the insertion of another string is to begin. The value of the integer must be in the range of 1 to the length of *source-string* plus one. If OCTETS is specified and the result is graphic data, the value must be an odd value between 1 and twice the length of *source-string* plus one.

### *length*

An expression that specifies the length of the string to replace in *source-string* starting at *start*. *length* must be an expression that returns a value of the built-in INTEGER data type. *length* is expressed in the string unit specified, and the value must be in the range of 0 to the length of *source-string*. If OCTETS is specified and the result is graphic data, *length* must be even and be between 0 and twice the length of *source-string*. Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the units that are used to express *start* and *length* in the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified. If *source-string* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

If a string unit is not explicitly specified, the data type of the result determines the unit that is used. If the result is a graphic string, a string unit is two bytes. For ASCII and EBCDIC data, this corresponds to a double byte character. For Unicode, this corresponds to a UTF-16 code point. Otherwise, a string unit is a byte.

#### **CODEUNITS16**

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

#### **OCTETS**

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76. *length* must be an even number if *source-string* is graphic data and OCTETS is specified

If *source-string* and *insert-string* have different CCSID sets, *insert-string* (the string to be inserted) is converted to the CCSID of *source-string* (the source string).

The encoding scheme of the result is the same as *source-string*. The data type of the result of the function depends on the data type of *source-string* and *insert-string*:

- VARCHAR if *source-string* is a character string. The CCSID of the result depends on the arguments:
  - If either *source-string* or *insert-string* is character bit data, the result is bit data.
  - If both *source-string* and *insert-string* are SBCS:
    - If both *source-string* and *insert-string* are SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If *source-string* is SBCS Unicode data and *insert-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of *source-string*.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.
- VARGRAPHIC if *source-string* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string* and *insert-string* are both binary strings.

The length attribute of the result depends on the arguments:

- If *start* and *length* are constants, the length attribute of the result is:

$$L1 - \text{MIN}((L1 - V2 + 1), V3) + L4$$

where:

*L1* is the length attribute of *source-string*  
*V2* is the value of *start*  
*V3* is the value of *length*  
*L4* is the length attribute of *insert-string*

- Otherwise, the length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string*. In this case, the length attribute of *source-string* plus the length attribute of *insert-string* must not exceed 32704 for a VARCHAR result or 16352 for a VARGRAPHIC result.

If CODEUNITS16 or CODEUNITS32 is specified, the insert operation is performed on a Unicode version of the data. If needed, the data is converted to an intermediate form in order to evaluate the function. If an intermediate form is used, the actual length of the result depends on the original data (*source-string* and *insert-string*), and the representation of that data in Unicode. See “Determining the length attribute of the final result” on page 79 for more information on how to calculate the length attribute of the result string.

If CODEUNITS16 or CODEUNITS32 are not specified, the actual length of the result is:

$A1 - \text{MIN}(A1 - V2 + 1, V3) + A4$

where:

*A1* is the actual length of *source-string*  
*V2* is the value of *start*  
*V3* is the value of *length*  
*A4* is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* The following example shows how the string 'INSERTING' can be changed into other strings. The use of the CHAR function limits the length of the resulting string to 10 bytes.

```
SELECT CHAR(OVERLAY('INSERTING','IS',4,2,OCTETS),10),
       CHAR(OVERLAY('INSERTING','IS',4,0,OCTETS),10),
       CHAR(OVERLAY('INSERTING','','4,2,OCTETS),10)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns 'INSISTING ', 'INSISERTIN', and 'INSTING '

*Example 2:* Use the OVERLAY function to insert the character 'C' into the Unicode string '&N~AB', where '&' is the character for the musical symbol, G CLEF, and '~' is the character for combining tilde. The following table shows the Unicode string in different Unicode encoding forms:

Unicode format	&	N	~	A	B
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

Assume the host variable *UTF8\_VAR* contains the UTF-8 representation of

'&N~AB', and *UTF16\_VAR* contains the UTF-16 representation of '&N~AB'. Then the following SELECT statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 1, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 1, OCTETS)
  FROM SYSIBM.SYSDUMMY1
```

This statement returns the following values:

```
C N~AB
CN~AB
C?N~AB -- ? is the invalid UTF-8 sequence X'9D849E'
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```
SELECT OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF8_VAR, 'C', 5, CODEUNITS32),
       OVERLAY (:UTF8_VAR, 'C', 5, OCTETS)
  FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
&C~AB
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

```
SELECT OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS16),
       OVERLAY (:UTF16_VAR, 'C', 1, CODEUNITS32)
  FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
C?N~AB
CN~AB
```

Assume that the previous SELECT statement was not run, but the following SELECT statement is run:

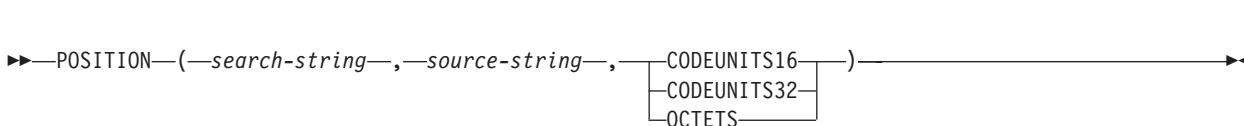

```
SELECT OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS16),
       OVERLAY (:UTF16_VAR, 'C', 5, CODEUNITS32),
  FROM SYSIBM.SYSDUMMY1;
```

This statement returns the values:

```
&N~CB
&N~AC
```

## POSITION

The POSITION function returns the position of the first occurrence of an argument within another argument, where the position is expressed in terms of the string units that are specified.

The schema is SYSIBM

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*, expressed in the units that are explicitly specified.

### *search-string*

An expression that specifies the string for which to search. *search-string* must return a value that is any built-in string data type with an actual length that is no greater than 4000 bytes. The expression can be specified by any of the following:

- A constant
  - A special register
  - A host variable (including a LOB locator variable or a file reference variable)
  - A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
  - An expression that concatenates (using CONCAT or ||) any of the above
  - CAST specification
  - A column name

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

*source-string*

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is any built-in string data type. The expression can be specified by any of the following:

- A constant
  - A special register
  - A host variable (including a LOB locator variable or a file reference variable)
  - A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
  - A column name
  - A CAST specification whose arguments are any of the above
  - An expression that concatenates (using CONCAT or ||) any of the above

`CODEUNITS16`, `CODEUNITS32`, or `OCTETS`

Specifies the string unit that is used to express the result. If *source-string* is a character string that is defined as bit data, CODEUNITS16, or CODEUNITS32 cannot be specified. If *source-string* is a graphic string, OCTETS cannot be specified.

CODEUNITS16

Specifies that the result is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that the result is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that the result is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings”.

If the search string and source string have different CCSID sets, then the *search-string* is converted to the CCSID set of the source string. If either CODEUNITS16 or CODEUNITS32 is specified, the function might be evaluated on a temporary copy of the data in Unicode.

The strings can contain mixed data. If OCTETS is specified:

- For ASCII data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and double-byte characters are found in the source string in exactly the same positions.
- For EBCDIC data, if the search string or source string contains mixed data, the search string is found only if any shift-in or shift-out characters are found in the source string in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if the search string or source string contains mixed data, the search string is found only if the same combination of single-byte and multi-byte characters are found in the source string in exactly the same position.

The result of the function is a large integer. If either of the arguments can be null, the result can be null. If either of the arguments is null, the result is the null value. The POSITION function accepts mixed data strings.

When the POSITION function is invoked with OCTETS, the function operates on a strict byte-count basis without regard to single-byte or double-byte characters.

If the CCSID of the search string is different than the CCSID of the source string, it is converted to the CCSID of the source string.

The value of the result is determined by applying these rules in the order in which they appear:

- If *search-string* has a length of zero, the result is 1.
- If *source-string* has a length of zero, the result is 0.
- If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, the result is the starting position of the first such substring within the source string value.
- Otherwise, the result is 0. This includes the case where *search-string* is longer than *source-string*.

*Example1:* Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE\_TEXT column for all rows in the IN\_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSITION('GOOD BEER', NOTE_TEXT, OCTETS)
  FROM IN_TRAY
 WHERE POSITION('GOOD BEER', NOTE_TEXT, OCTETS) <> 0;
```

*Example 2:* Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',CODEUNITS32);
```

The value of host variable *LOCATION* is set to 27.

*Example 3:* Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable *LOCATION* with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = POSITION('ß','Jürgen lives on Hegelstraße',OCTETS);
```

The value of host variable *LOCATION* is set to 28.

"LOCATE" on page 403

"LOCATE\_IN\_STRING" on page 406

"POSSTR" on page 469

## POSSTR

The POSSTR function returns the position of the first occurrence of an argument within another argument.

```
►►—POSSTR(source-string,search-string)—————►►
```

The schema is SYSIBM.

If *search-string* is not found and neither argument is null, the result is 0. If *search-string* is found, the result is a number from 1 to the actual length of *source-string*.

### *source-string*

An expression that specifies the source string in which the search is to take place. *source-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type. The expression can be specified by any of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A column name
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

### *search-string*

An expression that specifies the string for which to search. *search-string* must return a value that is a built-in character string data type, graphic string data type, or binary string data type with an actual length that is no greater than 4000 bytes. The expression can be specified by any of the following:

- A constant
- A special register
- A host variable (including a LOB locator variable or a file reference variable)
- A scalar function whose arguments are any of the above (though nested function invocations cannot be used)
- A CAST specification whose arguments are any of the above
- An expression that concatenates (using CONCAT or ||) any of the above

These rules are similar to those that are described for *pattern-expression* for the LIKE predicate.

The first and second arguments must have compatible string types. For more information on compatibility, see “Conversion rules for operations that combine strings” on page 122.

If the *search-string* and *source-string* have different CCSID sets, then the *search-string* is converted to the CCSID set of the *source-string*.

Both *search-string* and *source-string* have zero or more contiguous positions. For character strings and binary strings, a position is a byte. For graphic strings, a

position is a DBCS character. Graphic Unicode data is treated as UTF-16 data; a UTF-16 supplementary character takes two DBCS characters to represent and as such is counted as two DBCS characters.

The strings can contain mixed data.

- For ASCII data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and double-byte characters are found in *source-string* in exactly the same positions.
- For EBCDIC data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if any shift-in or shift-out characters are found in *source-string* in exactly the same positions, ignoring any redundant shift characters.
- For UTF-8 data, if *search-string* or *source-string* contains mixed data, *search-string* is found only if the same combination of single-byte and multi-byte characters are found in *source-string* in exactly the same position.

POSSTR operates on a strict byte-count basis without regard to single-byte or double-byte characters. It is recommended that if either the *search-string* or *source-string* contains mixed data, POSITION should be used instead of POSSTR. The POSITION function operates on a character basis. In an EBCDIC encoding scheme, any shift-in and shift-out characters are not required to be in exactly the same position and their only significance is to indicate which characters are SBCS and which characters are DBCS.

The result of the function is a large integer. If either of the arguments can be null, the result can be null; if either of the arguments are null, the result is the null value. The value of the result is determined by applying these rules in the order in which they appear:

- If the length of *search-string* is zero, the result is 1.
- If the length of *source-string* is zero, the result is 0.
- If the value of *search-string* is equal to an identical length substring of contiguous positions from the value of *source-string*, the result is the starting position of the first such substring within the value of *source-string*.
- If none of the above conditions are met, the result is 0.

*Example:* Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE\_TEXT column for all rows in the IN\_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD BEER')
  FROM IN_TRAY
 WHERE POSSTR(NOTE_TEXT, 'GOOD BEER') <> 0;
```

"LOCATE" on page 403

"LOCATE\_IN\_STRING" on page 406

"POSITION" on page 466

## POWER

The POWER function returns the value of the first argument to the power of the second argument.

```
►►—POWER(numeric-expression-1,numeric-expression-2)—————►►
```

The schema is SYSIBM.

Each argument must be an expression that returns the value of any built-in numeric data type. If either argument includes a DECIMAL or REAL data type, but not a DECFLOAT data type, the arguments are converted to a double precision floating-point number for processing by the function. If either argument includes a DECFLOAT data type, the arguments are converted to DECFLOAT for processing by the function.

The result of the function depends on the data type of the arguments:

- If both arguments are SMALLINT or INTEGER, the result is INTEGER.
- If either argument is a DECFLOAT, the data type of the result is DECFLOAT(34). If either argument is a DECFLOAT and one of the following statements is true, the result is NaN and an invalid operation condition:
  - both arguments are zero
  - the second argument has a non-zero fractional part
  - the second argument has more than 9 digits
  - the second argument is Infinite
- Otherwise, the result is DOUBLE.

The result can be null; if any argument is null, the result is the null value.

*Example 1:* Assume that host variable HPOWER is INTEGER with a value of 3. The following statement returns the value 8.

```
SELECT POWER(2,:HPOWER)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following statement returns the value 1.

```
SELECT POWER(0,0)
      FROM SYSIBM.SYSDUMMY1;
```

## QUANTIZE

The QUANTIZE function returns a DECFLOAT value that is equal in value (except for any rounding) and sign to the first argument and that has an exponent that is set to equal the exponent of the second argument.

```
►►QUANTIZE(expression-1,expression-2)►►
```

The schema is SYSIBM.

The number of digits that is returned (16 or 34) is the same as the number of digits in *expression-1*.

*expression-1*

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing.

*expression-2*

The argument must be an expression that returns a value of any built-in numeric data type. If the argument is not a DECFLOAT value, it is converted to DECFLOAT(34) for processing. *expression-2* is an expression that is used as an example pattern that will be used to rescale *expression-1*. The sign and coefficient of the second argument are ignored.

If one argument (after conversion) is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) argument is converted to DECFLOAT(34) before the function is processed.

The coefficient of the result is derived from that of *expression-1*. It is rounded, if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *expression-2*).

For static SQL statements other than CREATE VIEW, the ROUNDING bind option or the native SQL procedure option determines the rounding mode.

For dynamic SQL statements (and static CREATE VIEW statements), the special register CURRENT DECFLOAT ROUNDING MODE determines the rounding mode.

Unlike other arithmetic operations on the DECFLOAT data type, if the length of the coefficient after the quantize operation is greater than the precision specified by *expression-2*, a warning occurs. This ensures that, unless there is an error condition, the exponent of the result of QUANTIZE is always equal to that of *expression-2*. Furthermore:

- If either argument is NaN, NaN is returned
- If either argument is sNaN, NaN is returned and an exception occurs
- If both arguments are infinity (positive or negative), infinity (positive or negative) is returned.
- If one argument is infinity (positive or negative) and the other argument is not infinity (positive or negative), NaN is returned and an exception occurs

The result of the function is a DECFLOAT(16) value if both arguments are DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. The result can be null; if any argument is null, the result is the null value.

*Examples:* The following examples illustrate the value that is returned for the QUANTIZE function given the input DECFLOAT values:

```
QUANTIZE(2.17, DECFLOAT(0.001)) = 2.170
QUANTIZE(2.17, DECFLOAT(0.01)) = 2.17
QUANTIZE(2.17, DECFLOAT(0.1)) = 2.2
QUANTIZE(2.17, DECFLOAT('1E+0')) = 2
QUANTIZE(2.17, DECFLOAT('1E+1')) = 0E+1
QUANTIZE(2, DECFLOAT(INFINITY)) = NAN -- exception
QUANTIZE(-0.1, DECFLOAT(1) ) = 0
QUANTIZE(0, DECFLOAT('1E+5')) = 0E+5
QUANTIZE(217, DECFLOAT('1E-1')) = 217.0
QUANTIZE(217, DECFLOAT('1E+0')) = 217
QUANTIZE(217, DECFLOAT('1E+1')) = 2.2E+2
QUANTIZE(217, DECFLOAT('1E+2')) = 2E+2
```

## QUARTER

The QUARTER function returns an integer between 1 and 4 that represents the quarter of the year in which the date resides. For example, any dates in January, February, or March return the integer 1.

```
►►QUARTER(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string data type, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* The following function returns 3 because August is in the third quarter of the year.

```
SELECT QUARTER('2008-08-25')
  FROM SYSIBM.SYSDUMMY1
```

*Example 2:* Using sample table DSN8910.PROJ, set the integer host variable QUART to the quarter of the year in which activity number 70 for project 'AD3111' occurred. Activity completion dates are recorded in column ACENDATE.

```
SELECT QUARTER(ACENDATE)
  INTO :QUART
  FROM DSN8910.PROJ
 WHERE PROJNO = 'AD3111' AND ACTNO = 70;
```

QUART is set to 4.

## RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

```
►►—RADIANS(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HDEG is an INTEGER with a value of 180. The following statement returns a double precision floating-point number with an approximate value of 3.1415926536.

```
SELECT RADIANS(:HDEG)
      FROM SYSIBM.SYSDUMMY1;
```

## RAISE\_ERROR

The RAISE\_ERROR function causes the statement that invokes the function to return an error with the specified SQLSTATE (along with SQLCODE -438) and error condition. The RAISE\_ERROR function always returns the null value with an undefined data type.

```
►►—RAISE_ERROR(sqlstate,diagnostic-string)—►►
```

The schema is SYSIBM.

### *sqlstate*

An expression that returns a character string (CHAR or VARCHAR) of exactly 5 characters. The *sqlstate* value must follow these rules for application-defined SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letters ('A' through 'Z').
- The SQLSTATE class (first two characters) cannot be '00', '01', or '02' because these are not error classes.
- If the SQLSTATE class (first two characters) starts with the character '0' through '6' or 'A' through 'H', the subclass (last three characters) must start with a letter in the range 'I' through 'Z'.
- If the SQLSTATE class (first two characters) starts with the character '7', '8', '9', or 'T' though 'Z', the subclass (last three characters) can be any of '0' through '9' or 'A through 'Z'.

### *diagnostic-string*

An expression that returns a character string with a data type of CHAR or VARCHAR and a length of up to 70 bytes. The string contains EBCDIC data that describes the error condition. If the string is longer than 70 bytes, it is truncated.

Since the data type of the result of RAISE\_ERROR is undefined, it can only be used in a SET *host-variable* or SQL procedure language assignment statement. To use this function in another context, such as alone in a select list, you must use a cast specification to give a data type to the null value that is returned. The RAISE\_ERROR function is most useful with CASE expressions.

*Example:* For each employee in sample table DSN8910.EMP, list the employee number and education level. List the education level as 'Post Graduate', 'Graduate' and 'Diploma' instead of the integer that it is stored as in the table. If an education level is greater than '20', raise an error ('70001') with a description.

```
SELECT EMPNO,  
      CASE WHEN EDLEVEL < 16 THEN 'Diploma'  
            WHEN EDLEVEL < 18 THEN 'Graduate'  
            WHEN EDLEVEL < 21 THEN 'Post Graduate'  
            ELSE RAISE_ERROR('70001',  
                           'EDUCLVL has a value greater than 20')  
      END  
     FROM DSN8910.EMP;
```

## RAND

The RAND function returns a random floating-point value between 0 and 1. An argument can be specified as an optional seed value.

```
|    ►► RAND( [ numeric-expression ] ) ──────────►
```

The schema is SYSIBM.

*numeric-expression*

If *numeric-expression* is specified, it is used as the seed value. The argument must be an expression that returns a value of a built-in integer data type (SMALLINT or INTEGER). The value must be between 0 and 2,147,483,646.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

A specific seed value, other than zero, will produce the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RAND function within a statement. RAND(0) is processed the same as RAND().

The RAND function is not deterministic.

*Example:* Assume that host variable HRAND is an INTEGER with a value of 100. The following statement returns a random floating-point number between 0 and 1, such as the approximate value .0121398:

```
SELECT RAND(:HRAND)
      FROM SYSIBM.SYSDUMMY1;
```

To generate values in a numeric interval other than 0 to 1, multiply the RAND function by the size of the desired interval. For example, to get a random number between 0 and 10, such as the approximate value 5.8731398, multiply the function by 10:

```
SELECT (RAND(:HRAND) * 10)
      FROM SYSIBM.SYSDUMMY1;
```

## REAL

The REAL function returns a single-precision floating-point representation of either a number or a string representation of a number.

### Numeric to Real:

```
►►REAL(numeric-expression)►►
```

### String to Real:

```
►►REAL(string-expression)►►
```

The schema is SYSIBM.

#### Numeric to Real

##### *numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single precision floating-point column or variable. If the numeric value of the argument is not within the range of single precision floating-point, an error occurs.

#### String to Real

##### *string-expression*

An expression that returns a value of a character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS REAL)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL floating-point, integer, or decimal constant.

The result of the function is a single precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the `CAST` specification. For more information, see “`CAST` specification” on page 202.

*Example:* Using sample table DSN8910.EMP, find the ratio of salary to commission for employees whose commission is not zero. The columns involved, SALARY and COMM, have decimal data types. To express the result in single precision floating-point, apply `REAL` to SALARY so that the division is carried out in floating-point (actually double precision) and then apply `REAL` to the complete expression so that the results are returned in single precision floating-point.

```
SELECT EMPNO, REAL(REAL(SALARY)/COMM)
  FROM DSN8910.EMP
 WHERE COMM > 0;
```

## REPEAT

The REPEAT function returns a character string that is composed of an argument that is repeated a specified number of times.

```
►►REPEAT(expression,integer)—►►
```

The schema is SYSIBM.

### *expression*

An expression that specifies the string to be repeated. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. The actual length of the string must be greater or equal to 1 and less than or equal to 32704 bytes.

### *integer*

*integer* must be a positive large integer value that specifies the number of times to repeat the string.

If any argument can be null, the result can be null; if any argument is null, the result is the null value. The encoding scheme of the result is the same as *expression*. The data type of the result of the function depends on the data type of *expression*:

- VARBINARY if *expression* is a binary string
- VARCHAR if *expression* is a character string
- VARGRAPHIC if *expression* is graphic string

The CCSID of the result is the same as the CCSID of *expression*.

If *integer* is a constant, the length attribute of the result is the length attribute of *expression* times *integer*. Otherwise, the length attribute depends on the data type of the result:

- 4000 for VARBINARY and VARCHAR
- 2000 for VARGRAPHIC

The actual length of the result is the actual length of *expression* times *integer*. If the actual length of the result string exceeds the maximum for the return type, an error occurs.

*Example 1:* Repeat 'abc' two times to create 'abcabc'.

```
SELECT REPEAT('abc',2)  
  FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```
SELECT CHAR(REPEAT('REPEAT THIS',5), 60)  
  FROM SYSIBM.SYSDUMMY1;
```

This example results in 'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS' .

*Example 3:* For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('REPEAT THIS',0))
   FROM SYSIBM.SYSDUMMY1;
```

*Example 4:* For the following query, the LENGTH function returns a value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('', 5))
   FROM SYSIBM.SYSDUMMY1;
```

## REPLACE

The REPLACE function replaces all occurrences of *search-string* in *source-string* with *replace-string*. If *search-string* is not found in *source-string*, *source-string* is returned unchanged.

```
►►REPLACE(source-string,search-string,replace-string)—————►►
```

The schema is SYSIBM.

*source-string*

An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB and it cannot be an empty string. The length of *source-string* must be greater than or equal to the length of *search-string*.

*search-string*

An expression that specifies the string to be removed from the source string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB; the value cannot be an empty string.

*replace-string*

An expression that specifies the replacement string. The expression must return a value that is a built-in character string, graphic string, or binary string data type that is not a LOB. If the expression is an empty string, nothing replaces the string that is removed from the source string.

The actual length of each string must be 32704 bytes or less for character and binary strings or 16352 or less for graphic strings.

All three arguments must have compatible data types. If the expressions have different CCSID sets, then the expressions are converted to the CCSID set of *source-string*.

The data type of the result of the function depends on the data type of *source-string*, *search-string*, and *replace-string*:

- VARCHAR if *source-string* is a character string. The encoding scheme of the result is the same as *source-string*. The CCSID of the result depends on the arguments:
  - If *source-string*, *search-string*, or *replace-string* is bit data, the result is bit data.
  - If *source-string*, *search-string*, and *replace-string* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
  - If *source-string* is SBCS Unicode data, and *search-string* or *replace-string* is not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
  - Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *source-string*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *source-string*.

- VARGRAPHIC if *source-string* is a graphic. The encoding scheme of the result is the same as *source-string*. The CCSID of the result is the same as the CCSID of *source-string*.
- VARBINARY if *source-string*, *search-string*, and *replace-string* are binary strings.

The length attribute of the result depends on the arguments:

- If the length attribute of *replace-string* is less than or equal to the length attribute of *search-string*, the length attribute of the result is the length attribute of *source-string*.
- If the length attribute of *replace-string* is greater than the length attribute of *search-string*, the length attribute of the result is determined as follows depending on the data type of the result:
  - For VARCHAR or VARBINARY:
    - If  $L1 \leq 4000$ , the length attribute of the result is  $\text{MIN}(4000, (L3*(L1/L2)) + \text{MOD}(L1, L2))$
    - Otherwise, the length attribute of the result is  $\text{MIN}(32704, (L3*(L1/L2)) + \text{MOD}(L1, L2))$
  - For VARGRAPHIC:
    - If  $L1 \leq 2000$ , the length attribute of the result is  $\text{MIN}(2000, (L3*(L1/L2)) + \text{MOD}(L1, L2))$
    - Otherwise, the length attribute of the result is  $\text{MIN}(16352, (L3*(L1/L2)) + \text{MOD}(L1, L2))$

where:

*L1* is the length attribute of *source-string*

*L2* is the length attribute of *search-string* if the search string is a string constant. Otherwise, *L2* is 1.

*L3* is the length attribute of *replace-string*

If the result is a character string or binary string, the length attribute of the result must not exceed 32704. If the result is a graphic string, the length attribute of the result must not exceed 16352.

The actual length of the result is the actual length of *source-string* plus the number of occurrences of *search-string* that exist in *source-string* multiplied by the actual length of *replace-string* minus the actual length of *search-string*. If the actual length of the result string exceeds the maximum for the return data type, an error occurs.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* Replace all occurrences of the character 'N' in the string 'DINING' with 'VID'. Use the CHAR function to limit the output to 10 bytes.

```
SELECT CHAR(REPLACE('DINING','N','VID'),10)
  FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'DIVIDIVIDG'.

*Example 2:* Replace string 'ABC' in the string 'ABCXYZ' with nothing, which is the same as removing 'ABC' from the string.

```
SELECT REPLACE('ABCXYZ','ABC','')
  FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'XYZ'.

*Example 3:* Replace string 'ABC' in the string 'ABCCABCC' with 'AB'. This example illustrates that the result can still contain the string that is to be replaced (in this case, 'ABC') because all occurrences of the string to be replaced are identified prior to any replacement.

```
SELECT REPLACE('ABCCABCC','ABC','AB')
   FROM SYSIBM.SYSDUMMY1;
```

The result is the string 'ABCABC'.

## RID

The RID function returns the record ID (RID) of a row. The RID is used to uniquely identify a row.

```
►►RID(table-designator)►►
```

The schema is SYSIBM.

The function might return a different value when it is invoked multiple times for a row. For example, after the REORG utility is run, the RID function might return a different value for a row than would have been returned prior to the REORG utility being run. The RID function is not deterministic.

*table-designator*

*table-designator* must uniquely identify a base table, a view, or a nested table expression of a subselect in which the function is referenced.

If *table-designator* specifies a view or a nested table expression, the RID function returns the RID of the base table of the view or nested table expression. The specified view or nested table expression must contain only one base table in its outer subselect. *table-designator* must not specify a view or a nested table expression that is materialized.

The result of the function is BIGINT. The result can be null.

**Considerations for RID values:** DB2 might reuse RID numbers when a REORG operation is performed. If the RID function is used to obtain a value for a row and an application depends on that value remaining the same as long as the row exists, consider the following alternatives:

- Add a ROWID column to the table to provide a value that can be associated with each row, rather than invoking the RID function to generate a value for a row.
- Define a primary key for the table, using the columns of the primary key to ensure uniqueness, rather than invoking the RID function to generate a value for a row.

*Example 1:* Return the RID and last name of employees who are in department '20':

```
SELECT RID(EMP), LASTNAME  
  FROM EMP  
 WHERE DEPTNO = '20';
```

*Example 2:* Set the host variable HV\_EMP\_RID as the value of the RID for the employee with the employee number of '3500':

```
SELECT RID(EMP) INTO :HV_EMP_RID  
  FROM EMP  
 WHERE EMPNO = '3500';
```

## RIGHT

The RIGHT function returns a string that consists of the specified number of rightmost bytes or specified string unit from a string.

The schema is SYSIBM.

### *string-expression*

An expression that specifies the string from which the result is derived. The string must be any built-in string data type. A substring of *string-expression* is zero or more contiguous code points of *string-expression*.

The string can contain mixed data. Depending on the units that are specified to evaluate the function, the result is not necessarily a properly formed mixed data character string.

### *integer*

An expression that specifies the length of the result. The value must be an integer between 0 and *n*, where *n* is the length attribute of *string-expression*, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the unit that is used to express *integer*. If *string-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified. If *string-expression* is a graphic string, OCTETS cannot be specified. If *string-expression* is a binary string, CODEUNITS16, CODEUNITS32, and OCTETS cannot be specified.

#### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

#### **OCTETS**

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The *string-expression* is effectively padded on the right with the necessary number of padding characters so that the specified substring of *string-expression* always exists. The encoding scheme of the data determines the padding character:

- For ASCII SBCS data or ASCII mixed data, the padding character is X'20'.

- For ASCII DBCS data, the padding character depends on the CCSID; for example, for Japanese (CCSID 301) the padding character is X'8140', while for simplified Chinese it is X'A1A1'.
- For EBCDIC SBCS data or EBCDIC mixed data, the padding character is X'40'.
- For EBCDIC DBCS data, the padding character is X'4040'.
- For Unicode SBCS data or UTF-8 data (Unicode mixed data), the padding character is X'20'.
- For UTF-16 data (Unicode DBCS data), the padding character is X'0020'.
- For binary data, the padding character is X'00'.

The result of the function is a varying-length string with a length attribute that is the same as the length attribute of *string-expression* and a data type that depends on the data type of *string-expression*:

- VARBINARY if *string-expression* is BINARY or VARBINARY
- VARCHAR if *string-expression* is CHAR or VARCHAR
- CLOB if *string-expression* is CLOB
- VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *string-expression* is DBCLOB
- BLOB if *string-expression* is BLOB

The actual length of the result is determined from *integer*.

If any argument of the function can be null, the result can be null; if any argument is null, the result is the null value. The CCSID of the result is the same as that of *string-expression*.

*Example 1:* Assume that host variable ALPHA has a value of 'ABCDEF'. The following statement returns the value 'DEF', which are the three rightmost characters in ALPHA.

```
SELECT RIGHT(ALPHA,3)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following statement returns a zero length string.

```
SELECT RIGHT('ABCABC',0)
      FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* FIRSTNME is a VARCHAR(12) column in table T1. When FIRSTNME has the 6-character string 'Jürgen' as a value:

Function ...	Returns ...
RIGHT(FIRSTNME,5,CODEUNITS32)	'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,CODEUNITS16)	'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNME,5,OCTETS)	' rgen' -- x'207267656E' a truncated string

## ROUND

The ROUND function returns a number that is rounded to the specified number of places to the right or left of the decimal place.

```
►►ROUND(numeric-expression-1,numeric-expression-2)►►
```

The schema is SYSIBM.

### *numeric-expression-1*

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of ROUND corresponds to a value of ROUND\_HALF\_UP. If a different rounding behavior is desired, use the QUANTIZE function.

### *numeric-expression-2*

An expression that returns a value of a built-in small integer data type or large integer data type.

The absolute value of integer specifies the number of places to the right of the decimal point for the result if *numeric-expression-2* is not negative. If *numeric-expression-2* is negative, *numeric-expression-1* is rounded to the sum of the absolute value of *numeric-expression-2+1* number of places to the left of the decimal point.

If the absolute value of *numeric-expression-2* is larger than the number of digits to the left of the decimal point, the result is 0. (For example, ROUND(748.58,-4) returns 0.)

If *numeric-expression-1* is positive, a digit value of 5 is rounded to the next higher positive number. If *numeric-expression-1* is negative, a digit value of 5 is rounded to the next lower negative number.

The result of the function has the same data type and length attribute as the first argument except that the precision is increased by one if the argument is DECIMAL and the precision is less than 31. For example, an argument with a data type of DECIMAL(5,2) results in DECIMAL(6,2). An argument with a data type of DECIMAL(31,2) results in DECIMAL(31,2).

The result can be null. If any argument is null, the result is the null value.

*Example 1:* Calculate the number '873.726' rounded to '2', '1', '0', '-1', and '-2' decimal places respectively.

```
SELECT ROUND(873.726,2),  
       ROUND(873.726,1),  
       ROUND(873.726,0),  
       ROUND(873.726,-1),  
       ROUND(873.726,-2)  
       ROUND(873.726,-3),  
       ROUND(873.726,-4),  
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '0873.730', '0873.700', '0874.000', '0870.000', '0900.000', '1000.000', and '0000.000'.

*Example 2:* To demonstrate how numbers are rounded in positive and negative values, calculate the numbers '3.5', '3.1', '-3.1', '-3.5' rounded to '0' decimal places.

```
SELECT ROUND(3.5,0),
       ROUND(3.1,0),
       ROUND(-3.1,0),
       ROUND(-3.5,0)
  FROM SYSIBM.SYSDUMMY1;
```

This example returns the values '04.0', '03.0', '-03.0', and '-04.0'. (Notice that in the positive value '3.5' is rounded up to the next higher number while in the negative value '-3.5' is rounded down to the next lower negative number.)

## ROUND\_TIMESTAMP

The ROUND\_TIMESTAMP scalar function returns a timestamp that is rounded to the unit that is specified by the timestamp format string.

```
►►ROUND_TIMESTAMP(—expression—format-string)—►►
```

The schema is SYSIBM.

### *expression*

An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

### *format-string*

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by *expression* should be rounded. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is rounded to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks.

Allowable values for *format-string* are listed in the following table.

Table 57. ROUND\_TIMESTAMP and TRUNC\_TIMESTAMP format models

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
CC	Century	Input Value: 1897-12-04-12.22.22.000000	Input Value: 1897-12-04-12.22.22.000000
SCC	Rounds up to the start of the next century after the 50th year of the century (for example on 1951-01-01-00.00.00).	Result: 1900-01-01-00.00.00.000000	Result: 1800-01-01-00.00.00.000000
	Not valid for a TIME argument.		
YYYY	Year (Rounds up on July 1st)	Input Value: 1897-12-04-12.22.22.000000	Input Value: 1897-12-04-12.22.22.000000
YEAR		Result: 1898-01-01-00.00.00.000000	Result: 1897-01-01-00.00.00.000000

Table 57. ROUND\_TIMESTAMP and TRUNC\_TIMESTAMP format models (continued)

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
Q	Quarter (Rounds up on the sixteenth day of the second month of the quarter)	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000
MONTH	Month (Rounds up on the sixteenth day of the month)	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-18-12.15.00.000000 Result: 1999-06-01-00.00.00.000000
MON			
MM			
RM			
WW	Same day of the week as the first day of the year (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the year)	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000	Input Value: 2000-05-05-12.15.00.000000 Result: 2000-04-29-00.00.00.000000
IW	Same day of the week as the first day of the ISO year (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the ISO year)	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-08-00.00.00.000000	Input Value: 2000-05-05-12.15.00.000000 Result: 2000-05-01-00.00.00.000000
W	Same day of the week as the first day of the month (Rounds up on the 12th hour of the 3rd day of the week, with respect to the first day of the month)	Input Value: 2000-05-17-12.12.30.000000 Result: 2000-05-15-00.00.00.000000	Input Value: 2000-05-17-12.15.00.000000 Result: 2000-05-15-00.00.00.000000
DDD	Day (Rounds up on the 12th hour of the day)	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-17-00.00.00.000000
DD			
J			
DAY	Starting day of the week (Rounds up with respect to the 12th hour of the third day of the week. The first day of the week is always Sunday).	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000
DY			
D			
HH	Hour (Rounds up at 30 minutes)	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000
HH12			
HH24			
MI	Minute (Rounds up at 30 seconds)	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000
SS	Second (Rounds up at 500000 microseconds)	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000

The result of the function is a TIMESTAMP.

The result can be null; if any argument is null, the result is the null value.

| The result CCSID is the appropriate CCSID of the argument encoding scheme and  
| the result subtype is the appropriate subtype of the CCSID.

*Example 1:* Set the host variable *RND\_TMSTMP* with the input timestamp rounded to the nearest year value.

```
SET :RND_TMSTMP = ROUND_TIMESTAMP(TIMESTAMP_FORMAT('2000-08-14 17:30:00',
    'YYYY-MM-DD HH24:MI:SS'), 'YEAR');
```

The value set is '2001-01-01-00.00.000000'.

## ROWID

The ROWID function returns a row ID representation of its argument.

```
►►ROWID(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of a built-in character string data type, other than a CLOB, with a maximum length that is no greater than 255 bytes. Although the character string can contain any value, it is recommended that the character string contain a ROWID value that was previously generated by DB2 to ensure a valid ROWID value is returned. For example, the function can be used to convert a ROWID value that was cast to a CHAR value back to a ROWID value.

If the actual length of *expression* is less than 40, the result is not padded. If the actual length of *expression* is greater than 40, the result is truncated. If non-blank characters are truncated, a warning is returned.

The result of the function is a ROWID value.

The length attribute of the result is 40. The actual length of the result is the length of *expression*.

If the argument can be null, the result can be null; if the argument is null, the result is the null value. However, a null ROWID value cannot be used as the value for a row ID column in the database.

*Example:* Assume that table EMPLOYEE contains a row ID column, 'EMP\_ROWID'. Also assume that the table contains a row that is identified by a ROWID value that is equivalent to X'F0DFD230E3C0D80D81C201AA0A280100000000000203'. Using direct row access, select the employee number for that row.

```
SELECT EMPNO  
  FROM EMPLOYEE  
 WHERE EMP_ROWID=ROWID(X'F0DFD230E3C0D80D81C201AA0A280100000000000203');
```

## RPAD

The RPAD function returns a string that is padded on the right with blanks or a specified string.

```
►►RPAD(string-expression, integer [,-pad-])-->
```

The schema is SYSIBM.

The RPAD function returns a string composed of *string-expression* padded on the right, with *pad* or blanks. The RPAD function treats leading or trailing blanks in *string-expression* as significant. Padding will only occur if the actual length of *string-expression* is less than *integer*, and *pad* is not an empty string.

*string-expression*

An expression that specifies the source string. The expression must return a value that is a built-in string data type that is not a LOB.

*integer*

An integer constant that specifies the length of the result. The value must be zero or a positive integer that is less than or equal to *n*, where *n* is 32704 if *string-expression* is a character or binary string, or where *n* is 16352 if *string-expression* is a graphic string.

*pad*

An expression that specifies the string with which to pad. The expression must return a value that is a built-in string data type that is not a LOB. If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- DBCS blank character if *string-expression* is a graphic string.
- Hexadecimal zero ('X'00'), if *string-expression* is a binary string.

The result of the function is a varying length string that has the same CCSID of *string-expression*. *string-expression* and *pad* must have compatible data types. If the string expressions have different CCSID sets, then *pad* is converted to the CCSID set of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA, no character conversion occurs. The actual length of the result is determined from *integer*.

The length attribute of the result depends on *integer*. If *integer* is greater than 0, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1.

The actual length of the result is determined from *integer*. If *integer* is 0, the actual length is 0, and the result is the empty string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* Assume that NAME is a VARCHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. The following query will completely pad out a value on the right with periods.

```
SELECT RPAD(NAME,15,'.') AS NAME  
FROM T1;
```

The results are similar to the following:

NAME
Chris.....
Meg.....
Jeff.....

*Example 2:* Similar to Example 1, the following query will completely pad out a value on the right with *pad* (note that in some cases there is a partial instance of the padding specification):

```
SELECT RPAD(NAME,15,'123') AS NAME  
FROM T1;
```

The results are similar to the following:

NAME
Chris1231231231
Meg123123123123
Jeff12312312312

*Example 3:* Similarly, the following query will only pad each value to a length of 5:

```
SELECT RPAD(NAME,5,'.') AS NAME  
FROM T1;
```

The results are similar to the following:

NAME
Chris
Meg..
Jeff..

*Example 4:* Assume that NAME is a CHAR(15) column that contains the values 'Chris', 'Meg', and 'Jeff'. Note that the result of RTRIM in the following example is a varying length string with the blanks removed:

```
SELECT RPAD(RTRIM(NAME),15,'.') AS NAME  
FROM T1;
```

The results are similar to the following:

NAME
Chris.....
Meg.....
Jeff.....

## RTRIM

The RTRIM function removes blanks or hexadecimal zeros from the end of a string expression.

```
►►RTRIM(string-expression)-----►►
```

The schema is SYSIBM.

The RTRIM function returns the same results as the STRIP function with TRAILING specified:

```
STRIP(string-expression,TRAILING)
```

The argument must be an expression that returns a value that is a built-in character string data type, graphic data type, or binary string data type. The argument must not be a LOB.

The trailing blanks or hexadecimal zeros depend on the encoding scheme of the data and the data type:

- If the argument is a graphic string, then the trailing DBCS blanks are removed.
  - For ASCII, the ASCII CCSID determines the hex value that represents a double-byte blank. For example, for Japanese (CCSID 301), X'8140' represents a double-byte blank, while it is X'A1A1' for Simplified Chinese.
  - For EBCDIC-encoded data, X'4040' represents a double-byte blank.
  - For Unicode-encoded data, X'0020' represents a double-byte blank.
- If the argument is a binary string, the trailing hexadecimal zeros (BX'00') are removed.
- Otherwise, the trailing SBCS blanks are removed.
  - For data that is encoded in ASCII, X'20' represents a blank.
  - For EBCDIC-encoded data, X'40' represents a blank.
  - For Unicode-encoded data, X'20' represents an SBCS or UTF-8 blank.

The result of the function depends on the data type of its argument:

- VARBINARY if *string-expression* is a binary string
- VARCHAR if *string-expression* is a character string
- VARGRAPHIC if *string-expression* is a graphic string

The length attribute of the result is the same as the length attribute of *string-expression*. The actual length of the result is the length of the expression minus the number of characters removed. If all of the characters are removed, the result is an empty string.

If the argument can be null, the result can be null; if the argument is null, the result is the null value. The CCSID of the result is the same as that of *string-expression*.

*Example 1:* Assume that host variable HELLO is defined as CHAR(9) and has a value of 'Hello '.

```
SELECT RTRIM(:HELLO)
   FROM SYSIBM.SYSDUMMY1;
```

This example removes the trailing blanks and results in 'Hello'.

*Example 2:* The following function returns a VARBINARY string with a length attribute 10, actual length 6 and a value BX'C1D5C4D9C5C9'.

```
SELECT RTRIM(BINARY(X'C1D5C4D9C5C900000000'))
   FROM SYSIBM.SYSDUMMY1;
```

## SCORE

The SCORE function searches a text search index using criteria that are specified in a search argument and returns a relevance score that measures how well a document matches the query.

## Notes:

- 1     *string-constant* must conform to the rules for the *search-argument-options*.

## search-argument-options:

(1)												
	<table border="1"><tr><td>QUERYLANGUAGE</td><td>=====</td><td>value</td></tr><tr><td>RESULTLIMIT</td><td>=====</td><td>value</td></tr><tr><td>SYNONYM</td><td>=</td><td><table border="1"><tr><td>OFF</td></tr><tr><td>ON</td></tr></table></td></tr></table>	QUERYLANGUAGE	=====	value	RESULTLIMIT	=====	value	SYNONYM	=	<table border="1"><tr><td>OFF</td></tr><tr><td>ON</td></tr></table>	OFF	ON

SYNONYM	=	<table border="1"><tr><td>OFF</td></tr><tr><td>ON</td></tr></table>	OFF	ON								
OFF												
ON												

## Notes:

- 1 The same clause must not be specified more than once.

The schema is SYSIBM.

*column-name*

Specifies a qualified or unqualified name of a column that has a text search index that is to be searched. The column must exist in the table or view that is identified in the FROM clause in the statement and the column of the table, or the column of the underlying base table of the view must have an associated text search index. The underlying expression of the column of a view must be a simple column reference to the column of an underlying table, either directly or through another nested view.

*search-argument*

Specifies an expression that returns a value that is a string value (except a LOB) that contains the terms to be searched for and must not be all blanks or the empty string. The actual length of the string must not exceed 4096 Unicode characters. The value is converted to Unicode before it is used to search the text search index. The maximum number of terms per query must not exceed 1024.

### *string-constant*

Identifies a string constant that specifies the search argument options that are in effect for the function.

The options that can be specified as part of the *search-argument-options* are as follows:

**QUERYLANGUAGE = *value***

Specifies the query language. The value can be any of the supported language codes. If the QUERYLANGUAGE option is not specified, the default is the language value of the text search index that is used when this function is invoked. If the language value of the text search index is AUTO, the default value for QUERYLANGUAGE is en\_US.

**RESULTLIMIT = *value***

Specifies the maximum number of results that are to be returned from the underlying search engine. The *value* can be an integer value between 1 and 2 147 483 647. If the RESULTLIMIT option is not specified, no result limit is in effect for the query.

This scalar function cannot be called for each row of the result table, depending on the plan that the optimizer chooses. This function can be called once for the query to the underlying search engine, and a result set of all of the primary keys that match are returned from the search engine. This result set is then joined to the table containing the column to identify the result rows. In this case, the RESULTLIMIT value acts like a FETCH FIRST ?? ROWS from the underlying text search engine and can be used as an optimization. If the search engine is called for each row of the result because the optimizer determines that is the best plan, then the RESULTLIMIT option has no effect.

**SYNONYM = OFF or SYNONYM = ON**

Specifies whether to use a synonym dictionary that is associated with the text search index. Use the Synonym Tool to add a synonym dictionary to the collection. The default is OFF.

**OFF** Do not use a synonym dictionary.

**ON** Use the synonym dictionary that is associated with the text search index.

The result of the function is a double-precision floating-point number. If the second argument can be null, the result can be null. If the second argument is null, the result is the null value. If the third argument is null, the result is as if the third argument was not specified.

The result is greater than 0 but less than 1 if the column contains a match for the search criteria that the search argument specifies. The better a document matches the query, the more relevant the score and the larger the result value. If the column does not contain a match, the result is 0.

SCORE is a non-deterministic function.

## Example

The following statement generates a list of employees in the order of how well their resumes matches the query "programmer AND (java OR cobol)", along with a relevance value that is normalized between 0 (zero) and 100.

```
SELECT EMPNO, INTEGER(SCORE(RESUME, 'programmer AND  
          (java OR cobol)') * 100) AS RELEVANCE  
FROM EMP_RESUME  
WHERE RESUME_FORMAT = 'ascii'  
AND CONTAINS(RESUME, 'programmer AND (java OR cobol)') = 1  
ORDER BY RELEVANCE DESC
```

| DB2 first evaluates the CONTAINS predicate in the WHERE clause, and therefore,  
| does not evaluate the SCORE function in the SELECT list for every row of the  
| table. In this case, the arguments for SCORE and CONTAINS must be identical.

## SECOND

The SECOND function returns the seconds part of a value.

```
►►SECOND(expression)—————►►
```

The schema is SYSIBM.

*expression*

*expression* must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a time or timestamp duration. For the valid formats of time and timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a time, timestamp, or string representation of a time or a timestamp:**

The result is the seconds part of the value, which is an integer between 0 and 59.

**If the argument is a time duration or timestamp duration:**

The result is the seconds part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

*Example 1:* Assume that the variable *TIME\_DUR* is declared in a PL/I program as DECIMAL(6,0) and can therefore be interpreted as a time duration. When *TIME\_DUR* has the value 153045, the following function returns the value 45.

```
SECOND(:TIME_DUR)
```

*Example 2:* Assume that RECEIVED is a TIMESTAMP column and that one of its values is the internal equivalent of '1988-12-25-17.12.30.000000'. The following function returns the value 30.

```
SECOND(RECEIVED)
```

## SIGN

The SIGN function returns an indicator of the sign of the argument.

```
►►—SIGN(numeric-expression)—►►
```

The schema is SYSIBM.

The returned value is one of the following values:

- 1 if the argument is less than zero
- 0 if the argument is DECFLOAT negative zero
- 0 if the argument is zero
- 1 if the argument is greater than zero

The argument must be an expression that returns a value of any built-in numeric data type, except DECIMAL(31,31).

The result has the same data type and length attribute as the argument, except that precision is increased by one if the argument is DECIMAL and the scale of the argument is equal to its precision. For example, an argument with a data type of DECIMAL(5,5) will result in DECIMAL(6,5).

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable PROFIT is a large integer with a value of 50000.

```
SELECT SIGN(:PROFIT)
   FROM SYSIBM.SYSDUMMY1;
```

This example returns the value 1.

## SIN

The SIN function returns the sine of the argument, where the argument is an angle, expressed in radians.

```
►►—SIN(numeric-expression)—————►►
```

The schema is SYSIBM.

The SIN and ASIN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable SINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.99.

```
SELECT SIN(:SINE)
   FROM SYSIBM.SYSDUMMY1;
```

SINH

The SINH function returns the hyperbolic sine of the argument, where the argument is an angle, expressed in radians.

►—SINH(*numeric-expression*)—

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HSINE is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 2.12.

```
SELECT SINH(:HSINE)
      FROM SYSIBM.SYSDUMMY1;
```

## SMALLINT

The SMALLINT function returns a small integer representation either of a number or of a string representation of a number.

### Numeric to Smallint:

►►—SMALLINT(*numeric-expression*)—►►

### String to Smallint:

►►—SMALLINT(*string-expression*)—►►

The schema is SYSIBM.

#### Numeric to Smallint

##### *numeric-expression*

An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. If the whole part of the argument is not within the range of small integers, an error occurs. If present, the decimal part of the argument is truncated.

#### String to Smallint

##### *string-expression*

An expression that returns a value of character or graphic string (except a CLOB or DBCLOB) with a length attribute that is not greater than 255 bytes for a character string or 127 for a graphic string. The string must contain a valid string representation of a number.

The result is the same number that would result from `CAST(string-expression AS SMALLINT)`. Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an SQL integer constant. If the whole part of the argument is not within the range of small integers, an error is returned.

The result of the function is a small integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

**Recommendation:** To increase the portability of applications, use the CAST specification. For more information, see “CAST specification” on page 202.

*Example:* Using sample table DSN8910.EMP, find the average education level (EDLEVEL) of the employees in department 'A00'. Round the result to the nearest full education level.

```
SELECT SMALLINT(AVG(EDLEVEL)+.5)
  FROM DSN8910.EMP
 WHERE DEPT = 'A00';
```

Assuming that the five employees in the department have education levels of '19', '18', '14', '18', and '14', the result is '17'.

## SOUNDEX

The SOUNDEX function returns a 4-character code that represents the sound of the words in the argument. The result can be compared to the results of the SOUNDEX function of other strings.

```
►►—SOUNDEX(expression)—►►
```

The schema is SYSIBM.

### *expression*

An *expression* that must return a value of any built-in numeric, character, or graphic string data type that is not a LOB. A numeric, mixed character, or graphic string value is cast to a Unicode SBCS character string before the function is evaluated. For more information about converting numeric data to a character string, see “VARCHAR” on page 558. For more information about converting mixed or graphic strings to Unicode SBCS, see “CAST specification” on page 202.

The data type of the result is CHAR(4). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is the Unicode SBCS CCSID.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search for words with similar sounds. The comparison of words can be done directly or by passing the strings as arguments to the DIFFERENCE function. For more information, see “DIFFERENCE” on page 351.

*Example 1:* Use the SOUNDEX function to find a row where the sound of the LASTNAME value closely matches the phonetic spelling of 'Loucesy':

```
SELECT EMPNO, LASTNAME  
      FROM DSN910.EMPLOYEE  
     WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy');
```

This example returns the following row:

```
000110 LUCCHESSI;
```

## SOAPHTTPC and SOAPHTTPV

The SOAPHTTPC function returns a CLOB representation of XML data that results from a SOAP request to the web service that is specified by the first argument. The SOAPHTTPV function returns a VARCHAR representation of XML data that results from a SOAP request to the web service that is specified by the first argument.

The schema is DB2XML.

### *endpoint\_url*

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies the URL of the web service endpoint for which DB2 is acting as a client.

### *soap\_action*

An expression that returns a value of a built-in character string or graphic string data type that is not a LOB. The value specifies a SOAP action URI reference. If it is required for the web service that is specified in *endpoint\_url*, the required value is defined in the WSDL of that web service.

### *soap\_body*

An expression that returns a value of a built-in character string data type that is defined as VARCHAR(3072) or CLOB(1M). The value specifies the name of an operation with the requested namespace URI, an encoding style, and input arguments. *soap\_body* can include well-formed XML content for the SOAP body. The specific operations and arguments for a web service are defined in the WSDL of the specified web service.

If the arguments can be null, the result can be null; if all of the arguments are null, the result is the null value.

*Example 1:* The following SQL statement retrieves information (as VARCHAR data) about a web service:

```
SELECT DB2XML.SOAPHTTPV(  
    'http://www.myserver.com/services/db2sample/ivt.dadx/SOAP',  
    'http://tempuri.org/db2sample/ivt.dadx',  
    '<testInstallation xmlns="http://tempuri.org/db2sample/ivt.dadx" />')  
FROM SYSIBM.SYSDUMMY1
```

*Example 2:* The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```
INSERT INTO EMPLOYEE(XMLCOL)  
VALUES (DB2XML.SOAPHTTPC(  
    'http://www.myserver.com/services/db2sample/list.dadx/SOAP',  
    'http://tempuri.org/db2sample/list.dadx',  
    '<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">  
        <deptNo>A00</deptNo>  
    </listDepartments>'))
```

## SOAPHTTPNC and SOAPHTTPNV

The SOAPHTTPNC and SOAPHTTPNV functions allow you to specify a complete SOAP message as input and to return complete SOAP messages from the specified web service. The returned SOAP messages are CLOB or VARCHAR representations of the returned XML data.

The schema is DB2XML.

### *endpoint\_url*

Specifies the URL of the web service for which DB2 is acting as a client. *endpoint\_url* is defined as a VARCHAR(256) value. The URL is in the following format:

*proto://[user[:password]@]hostname[:port]/[path]*

Where *proto* can be http or https.

### *soap\_action*

Specifies a SOAP action URI reference. Depending on the web server, *soap\_action* might be required. If it is required for the web service that is specified in *endpoint\_url*, the required value is defined in the WSDL of that web service.

### *soap\_input*

Specifies an XML document that contains the complete SOAP message. *soap\_input* can contain optional SOAP headers and must contain a SOAP body that specifies the operation name and parameters to the web service. *soap\_input* should be well-formed XML that is defined as VARCHAR(32672) or CLOB(1M).

*Example 1:* The following SQL statement retrieves information (as VARCHAR data) about a web service:

```
SELECT DB2XML.SOAPHTTPNV(
  'http://rpc.geocoder.us/service/soap/',
  '"http://rpc.geocoder.us/Geo/Coder/US#geocode_address"',
  '<?xml version="1.0" encoding="UTF-8" ?>' ||
  '<SOAP-ENV:Envelope ' ||
  'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" ' ||
  'xmlns:xsd="http://www.w3.org/2001/XMLSchema" ' ||
  'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
  '<SOAP-ENV:Body>' ||
  '<ns0:geocode_address ' ||
  'xmlns:ns0="http://rpc.geocoder.us/Geo/Coder/US/" ' ||
  'SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">' ||
  '<address xsi:type="xsd:string">555 Bailey Avenue, San Jose,' ||
  'CA,95141</address>' ||
  '</ns0:geocode_address>' ||
  '</SOAP-ENV:Body>' ||
  '</SOAP-ENV:Envelope>')
FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following SQL statement inserts the results (as CLOB data) from a request to a web service into a table:

```
INSERT INTO EMPLOYEE(XMLCOL)
VALUES (DB2XML.SOAPHTTPNC(
'http://www.myserver.com/services/db2sample/list.dadx/SOAP',
'http://tempuri.org/db2sample/list.dadx',
'<?xml version="1.0" encoding="UTF-8" ?>' ||
'<SOAP-ENV:Envelope' ||
'xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"' ||
'xmlns:xsd="http://www.w3.org/2001/XMLSchema"' ||
'xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">' ||
'<SOAP-ENV:Body>' ||
'<listDepartments xmlns="http://tempuri.org/db2sample/list.dadx">
<deptNo>A00</deptNo>
</listDepartments>' ||
'</SOAP-ENV:Body>' ||
'</SOAP-ENV:Envelope>'))
```

## SPACE

The SPACE function returns a character string that consists of the number of SBCS blanks that the argument specifies.

```
►►—SPACE(numeric-expression)—►►
```

The schema is SYSIBM.

*numeric-expression*

An expression that returns the value of any built-in integer data type. The expression specifies the number of SBCS blanks for the result, and it must be between 0 and 32767.

The result of the function is a varying-length character string (VARCHAR) that contains SBCS data.

If *numeric-expression* is a constant, the length attribute of the result is the constant. Otherwise, the length attribute of the result is 4000. The actual length of the result is the value of *numeric-expression*. The actual length of the result must not be greater than the length attribute of the result.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example:* The following statement returns a character string that consists of 5 blanks followed by a zero-length string.

```
SELECT SPACE(5), SPACE(0)
      FROM SYSIBM.SYSDUMMY1;
```

## SQRT

The SQRT function returns the square root of the argument.

```
►►—SQRT(numeric-expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns the value of any built-in numeric data type. If the argument is DECFLOAT, the operation is performed in DECFLOAT. Otherwise, the argument is converted to a double precision floating-point number for processing by the functions.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*). Otherwise, the result of the function is a double precision floating-point number. If the argument is a special decimal floating point value, the general rules for arithmetic operations apply. See “General Arithmetic Operation Rules for DECFLOAT” on page 186 for more information.

The result can be null; if the argument is null, the result is the null value.

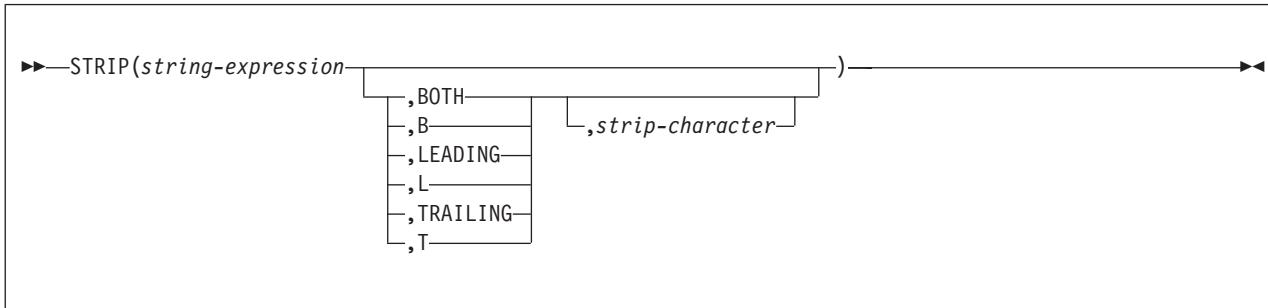

*Example:* Assume that host variable *SQUARE* is defined as DECIMAL(2,1) and has a value of 9.0. Find the square root of *SQUARE*.

```
SELECT SQRT(:SQUARE)
   FROM SYSIBM.SYSDUMMY1;
```

This example returns a double precision floating-point number with an approximate value of 3.

## STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.

The schema is SYSIBM.

*string-expression* must be an expression that returns a value that is a built-in character string data type, graphic data type, or binary string data type.  
*string-expression* must not be a LOB.

The second argument indicates whether characters are removed from the beginning (LEADING or L), the end (TRAILING or T), or both the beginning and end (BOTH or B) of the string. If you do not specify a second argument, blanks are removed from both the beginning and end of the string.

*strip-character* must be an SBCS, or DBCS single-character (2 bytes) constant or a single-byte binary constant that is to be removed. If the data type is not appropriate or the value contains more than one character, an error is returned.

If *strip-character* is not specified, the default strip character is:

- SBCS space character if *string-expression* is a character string
- DBCS space character if *string-expression* is a graphic string
- Hexadecimal zero (BX'00') if *string-expression* is a binary string

The data type of the result depends on the data type of *string-expression*:

- If *string-expression* is a character string data type, the result is VARCHAR.
- If *string-expression* is a graphic string data type, the result is VARGRAPHIC.
- If *string-expression* is a binary string data type, the result is VARBINARY.

The result of the function has the same maximum length as the length attribute of *string-expression*. The actual length of the result is the length of the expression minus the number of characters removed. If all of the characters are removed, the result is an empty, varying-length string.

If *string-expression* and *strip-character* have different CCSID sets, *strip-character* is converted to the CCSID of *string-expression*. The CCSID of the result is the same as that of the string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

*Example 1:* Assume that host variable HELLO is defined as CHAR(9) and has a value of 'Hello':

```
STRIP(:HELLO)
```

This example results in 'Hello'. If there had been any ending blanks, they would have been removed as well because the second argument was not specified.

No beginning blanks are removed from the following example:

```
STRIP(:HELLO,TRAILING)
```

This results in ' Hello'.

*Example 2:* Assume that host variable *BALANCE* is defined as CHAR(9) and has a value of '000345.50':

```
STRIP(:BALANCE,L,'0')
```

This example results in '345.50'.

*Example 3:* The following function returns a VARBINARY string with a length attribute 6, actual length 3 and a value BX'C1C1C1'

```
SELECT STRIP(BINARY(X'C1C1C1D2D2D2'), B, BX'D2')  
      FROM SYSIBM.SYSDUMMY1;
```

## SUBSTR

The SUBSTR function returns a substring of a string.

```
►►—SUBSTR(string-expression,start  
          └,length)─►►
```

The schema is SYSIBM.

### *string-expression*

An expression that specifies the string from which the result is derived. The string must be a character, graphic, or binary string. If *string-expression* is a character string, the result of the function is a character string. If it is a graphic string, the result of the function is a graphic string. If it is a binary string, the result of the function is a binary string.

A substring of *string-expression* is zero or more contiguous characters of *string-expression*. If *string-expression* is a graphic string, a character is a DBCS character. If *string-expression* is a character string or a binary string, a character is a byte. The SUBSTR function accepts mixed data strings. However, because SUBSTR operates on a strict byte-count basis, the result will not necessarily be a properly formed mixed data string.

### *start*

An expression that specifies the position within *string-expression* to be the first character of the result. The value of the large integer must be between 1 and the length attribute of *string-expression*. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first character of the substring is the first character of *string-expression*.

### *length*

An expression that specifies the length of the resulting substring. If specified, *length* must be an expression that returns a value that is a built-in large integer data type. The value must be greater than or equal to 0 and less than or equal to *n*, where *n* is the length attribute of *string-expression* - *start* + 1. The specified length must not, however, be the large integer constant 0.

If *length* is explicitly specified, *string-expression* is effectively padded on the right with the necessary number of characters so that the specified substring of *string-expression* always exists. Hexadecimal zeros are used as the padding character when *string-expression* is binary data. Otherwise, a blank is used as the padding character.

If *string-expression* is a fixed-length string, omission of *length* is an implicit specification of LENGTH(*string-expression*) - *start* + 1, which is the number of characters (or bytes) from the character (or byte) specified by *start* to the last character (or byte) of *string-expression*. If *string-expression* is a varying-length string, omission of *length* is an implicit specification of the greater of zero or LENGTH(*string-expression*) - *start* + 1. If the resulting length is zero, the result is an empty string.

If *length* is explicitly specified by a large integer constant that is 255 or less, and *string-expression* is not a LOB, the result is a fixed-length string with a length attribute of *length*. If *length* is not explicitly specified, but *string-expression* is a fixed-length string and *start* is an integer constant, the

result is a fixed-length string with a length attribute equal to  $\text{LENGTH}(\text{string-expression}) - \text{start} + 1$ . In all other cases, the result is a varying-length string. If *length* is explicitly specified by a large integer constant, the length attribute of the result is *length*; otherwise, the length attribute of the result is the same as the length attribute of *string-expression*.

If any argument of SUBSTR can be null, the result can be null. If any argument is null, the result is the null value. The CCSID of the result is the CCSID of *string-expression*.

*Example 1:* FIRSTNME is a VARCHAR(12) column in sample table DSN8910.EMP. When FIRSTNME has the value 'MAUDE':

Function:	Returns:
SUBSTR(FIRSTNME,2,3)	-- 'AUD'
SUBSTR(FIRSTNME,2)	-- 'AUDE'
SUBSTR(FIRSTNME,2,6)	-- 'AUDE' followed by two blanks
SUBSTR(FIRSTNME,6)	-- a zero-length string
SUBSTR(FIRSTNME,6,4)	-- four blanks

*Example 2:* Sample table DSN8910.PROJ contains column PROJNAME, which is defined as VARCHAR(24). Select all rows from that table for which the string in PROJNAME begins with 'W L PROGRAM'.

```
SELECT * FROM DSN8910.PROJ
      WHERE SUBSTR(PROJNAME,1,12) = 'W L PROGRAM ';
```

Assume that the table has only the rows that were supplied by DB2. Then the predicate is true for just one row, for which PROJNAME has the value 'W L PROGRAM DESIGN'. The predicate is not true for the row in which PROJNAME has the value 'W L PROGRAMMING' because, in the predicate's string constant, 'PROGRAM' is followed by a blank.

*Example 3:* Assume that a LOB locator named *my\_loc* represents a LOB value that has a length of 1 gigabyte. Assign the first 50 bytes of the LOB value to host variable *PORTION*.

```
SET :PORTION = SUBSTR(:my_loc,1,50);
```

*Example 4:* Assume that host variable *RESUME* has a CLOB data type and holds an employee's resume. This example shows some of the statements that find the section of department information in the resume and assign it to host variable *DeptBuf*. First, the POSSTR function is used to find the beginning and ending location of the department information. Within the resume, the department information starts with the string 'Department Information Section' and ends immediately before the string 'Education Section'. Then, using these beginning and ending positions, the SUBSTR function assigns the information to the host variable.

```
SET :DInfoBegPos = POSSTR(:RESUME, 'Department Information Section');
SET :DInfoEnPos = POSSTR(:RESUME, 'Education Section');
SET :DeptBuf = SUBSTR(:RESUME, :DInfoBegPos, :DInfoEnPos - :DInfoBegPos);
```

## SUBSTRING

The SUBSTRING function returns a substring of a string.

### Character:

```
►►SUBSTRING(—character-expression,—start  
              [,—length], [CODEUNITS16  
                  | CODEUNITS32  
                  | OCTETS])►►
```

### Graphic:

```
►►SUBSTRING(—graphic-expression,—start  
              [,—length], [CODEUNITS16  
                  | CODEUNITS32])►►
```

### Binary:

```
►►SUBSTRING(—binary-expression,—start  
              [,—length])►►
```

The schema is SYSIBM.

#### Character

##### *character-expression*

An expression that specifies the string from which the result is derived. The string must be a built-in character string. The result of the function is a character string.

A substring of *character-expression* is zero or more contiguous units of *character-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character. If OCTETS is specified, a unit is a byte.

##### *start*

An expression that specifies the position within the *character-expression* that is to be the first string unit of the result. *start* is expressed in the specified string unit, and must return a large integer value. The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *character-expression*.

##### *length*

An expression that specifies the maximum length of the resulting substring.

If *character-expression* is a fixed-length string, omission of *length* is an implicit specification of CHARACTER\_LENGTH(*character-expression*) - *start* + 1, which is the number of string units (CODEUNITS16, CODEUNITS32, or OCTETS) from *start* to the last position of *character-expression*.

If *character-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(character-expression) - start + 1`, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value that is a built-in large integer data type.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *character-expression* - *start* + 1, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

**A rigorous description of the actual length and result:** In this description, the term "character" means the "unit specified by string units".

Let *C* be the value of the first argument, let *LC* be the length in characters of *C*, and let *S* be the value of the *start*.

- If *length* is specified, let *L* be the value of *length* and let *E* be *S+L*. Otherwise, let *E* be the larger of *LC* + 1 and *S*.
- If either *C*, *S*, or *L* is the null value, the result of the function is the null value.
- If *E* is less than *S*, an exception condition is raised: data exception — substring error.
- Otherwise:
  - If *S* is greater than *LC* or if *E* is less than 1 (one), the result of the function is a zero-length string.
  - Otherwise:
    - Let *S1* be the larger of *S* and 1 (one). Let *E1* be the smaller of *E* and *LC*+1. Let *L1* be *E1-S1*.
    - The result of the function is a character string that contains the *L1* characters of *C* starting at character number *S1* in the same order that the characters appear in *C*.

#### **CODEUNITS16, CODEUNITS32, or OCTETS**

Specifies the string unit that is used to express *start* and *length*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

#### **CODEUNITS16**

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

#### **OCTETS**

Specifies that *start* and *length* are expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String unit specifications" on page 76.

#### **Graphic**

##### *graphic-expression*

An expression that specifies the string from which the result is derived. The string must be a built-in graphic string. The result of the function is a graphic string.

A substring of *graphic-expression* is zero or more contiguous units of *graphic-expression*. If CODEUNITS32 is specified, a unit is a Unicode UTF-32 character. If CODEUNITS16 is specified, a unit is a Unicode UTF-16 character.

*start*

An expression that specifies the position within the *graphic-expression* that is to be the first string unit of the result. *start* is expressed in the specified string unit, and must return a large integer value. The value of *start* can be positive, negative, or zero. A value of 1 indicates that the first string unit of the result is the first string unit of *graphic-expression*.

*length*

An expression that specifies the maximum length of the resulting substring.

If *graphic-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(graphic-expression) - start + 1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, from the start position to the last position of *graphic-expression*. If *graphic-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(graphic-expression) - start + 1`, which is the number of units (CODEUNITS16, CODEUNITS32) either explicitly or implicitly specified, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be an expression that returns a value that is a built-in large integer data type.

The value must be greater than or equal to 0. If a value greater than *n* is specified, where *n* is the length attribute of *graphic-expression - start + 1*, then *n* is used as the length of the resulting substring. The value is expressed in the units that are explicitly specified.

**A rigorous description of the actual length and result:** In this description, the term "character" means the "unit specified by string units".

Let *C* be the value of the first argument, let *LC* be the length in characters of *C*, and let *S* be the value of the *start*.

- If *length* is specified, let *L* be the value of *length* and let *E* be *S+L*. Otherwise, let *E* be the larger of *LC + 1* and *S*.
- If either *C*, *S*, or *L* is the null value, the result of the function is the null value.
- If *E* is less than *S*, an exception condition is raised: data exception — substring error.
- Otherwise:
  - If *S* is greater than *LC* or if *E* is less than 1 (one), the result of the function is a zero-length string.
  - Otherwise:
    - Let *S1* be the larger of *S* and 1 (one). Let *E1* be the smaller of *E* and *LC+1*. Let *L1* be *E1-S1*.
    - The result of the function is a character string that contains the *L1* characters of *C* starting at character number *S1* in the same order that the characters appear in *C*.

**CODEUNITS16 or CODEUNITS32**

Specifies the string unit that is used to express *start* and *length*.

**CODEUNITS16**

Specifies that *start* and *length* are expressed in terms of 16-bit UTF-16 code units.

## CODEUNITS32

Specifies that *start* and *length* are expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

### Binary

#### *binary-expression*

An expression that specifies the string from which the result is derived. The string must be a built-in binary string. The result of the function is a binary string.

A substring of *binary-expression* is zero or more contiguous units of *binary-expression*.

#### *start*

An expression that specifies the position within *binary-expression* to be the first character of the result. It must be a binary large integer. *start* can be negative or zero. (The length attribute of a varying-length string is its maximum length.) A value of 1 indicates that the first string unit of the substring is the first string unit of *binary-expression*.

#### *length*

An expression that specifies the length of the resulting substring.

If *binary-expression* is a fixed-length string, omission of *length* is an implicit specification of `CHARACTER_LENGTH(binary-expression) - start + 1`, which is the number of units either explicitly or implicitly specified, from the start position to the last position of *binary-expression*. If *binary-expression* is a varying length string, omission of *length* is an implicit specification of zero or `CHARACTER_LENGTH(binary-expression) - start + 1`, which is the number of units either explicitly or implicitly specified, whichever is greater. If the resulting length is zero, the result is an empty string.

If specified, *length* must be a value that is a built-in large integer data type. The value must be greater than or equal to 0 and less than or equal to *n*, where *n* is the length attribute of *binary-expression* - *start* + 1. The specified length must not, however, be the large integer constant 0.

**A rigorous description of the actual length and result:** In this description, the term “character” means the “unit specified by string units”.

Let *C* be the value of the first argument, let *LC* be the length in characters of *C*, and let *S* be the value of the *start*.

- If *length* is specified, let *L* be the value of *length* and let *E* be *S+L*. Otherwise, let *E* be the larger of *LC* + 1 and *S*.
- If either *C*, *S*, or *L* is the null value, the result of the function is the null value.
- If *E* is less than *S*, an exception condition is raised: data exception — substring error.
- Otherwise:
  - If *S* is greater than *LC* or if *E* is less than 1 (one), the result of the function is a zero-length string.
  - Otherwise:
    - Let *S1* be the larger of *S* and 1 (one). Let *E1* be the smaller of *E* and *LC*+1. Let *L1* be *E1-S1*.
    - The result of the function is a character string that contains the *L1* characters of *C* starting at character number *S1* in the same order that the characters appear in *C*.

The data type of the result depends on the data type of the first argument, as shown in the following table.

*Table 58. Data type of the result of SUBSTRING*

Data type of the first argument	Data type of the result
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
	If <i>character-expression</i> is mixed data, the result is mixed data. Otherwise, the result is SBCS data.
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is equal to the length attribute of the first argument. If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If any argument of SUBSTRING can be null, the result can be null. If any argument is null, the result is the null value.

If the first argument is character or graphic data, the CCSID of the result is the same as that of the first argument.

*Example 1:* FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has the value 'Jürgen':

Function:	Returns:
SUBSTRING(FIRSTNAME,1,2,CODEUNITS32)	'Jü' -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,CODEUNITS16)	'Jü' -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,OCTETS)	'J' -- x'4A20' (a truncated string)
SUBSTRING(FIRSTNAME,8,CODEUNITS16)	-- a zero-length string
SUBSTRING(FIRSTNAME,8,4,OCTETS)	-- a zero-length string

*Example 2:* C1 is a VARCHAR(12) column in table T1. One of its values is the string 'ABCDEFG'. When C1 has the value 'ABCDEFG':

Function:	Returns:
SUBSTRING(C1,-2,2,OCTETS)	-- a zero-length string
SUBSTRING(C1,-2,4,OCTETS)	'A'
SUBSTRING(C1,-2,OCTETS)	'ABCDEFG'
SUBSTRING(C1,0,1,OCTETS)	-- a zero-length string

TAN

The TAN function returns the tangent of the argument, where the argument is an angle, expressed in radians.

►—TAN(*numeric-expression*)—

The schema is SYSIBM.

The TAN and ATAN functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable *TANGENT* is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 14.10 .

```
SELECT TAN(:TANGENT)  
  FROM SYSIBM.SYSDUMMY1;
```

## TANH

The TANH function returns the hyperbolic tangent of the argument, where the argument is an angle, expressed in radians.

```
►►—TANH(numeric-expression)—►►
```

The schema is SYSIBM.

The TANH and ATANH functions are inverse operations.

The argument must be an expression that returns the value of any built-in numeric data type that is not DECFLOAT. If the argument is not a double precision floating-point number, it is converted to one for processing by the function.

The result of the function is a double precision floating-point number. The result can be null; if the argument is null, the result is the null value.

*Example:* Assume that host variable HTANGENT is DECIMAL(2,1) with a value of 1.5. The following statement returns a double precision floating-point number with an approximate value of 0.90.

```
SELECT TANH(:HTANGENT)
   FROM SYSIBM.SYSDUMMY1;
```

## TIME

The TIME function returns a time that is derived from a value.

```
►►—TIME(expression)—————►►
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a time, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of times and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a time. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

**If the argument is a time**

the result is that time.

**If the argument is a timestamp**

the result is the time part of the timestamp.

**If the argument is a string**

the result is the time or time part of the timestamp represented by the string. If the CCSID of the string is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID.

*Example:* Assume that a table named CLASSES contains one row for each scheduled class. Assume also that the class starting times are in the TIME column named STARTTM. Using these assumptions, select those rows in CLASSES that represent classes that start at 1:30 P.M.

```
SELECT *
  FROM CLASSES
 WHERE TIME(STARTTM) = '13:30:00';
```

## TIMESTAMP

The `TIMESTAMP` function returns a timestamp that is derived from its argument or arguments.

```
►►—TIMESTAMP(expression-1 [ ,expression-2 ])—►►
```

The schema is `SYSIBM`.

The rules for the arguments depend on whether the second argument is specified.

- **If only one argument is specified:**

The argument must be an expression that returns a value of one of the following built-in data types: a timestamp, a character string, or a graphic string. If *expression-1* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be one of the following:

- A valid string representation of a timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of timestamps, see “String representations of datetime values” on page 89.
- A character string or graphic string with an actual length of 8 that is assumed to be a System z® Store Clock value.
- A character string with an actual length of 13 that is assumed to be a result from the `GENERATE_UNIQUE` function.
- A character string or graphic string with an actual length of 14 that represents a valid date and time in the form *yyyyxxddhhmmss*, where *yyyy* is the year, *xx* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *ss* is the seconds.

- **If both arguments are specified:**

The first argument must be an expression that returns a value of one of the following built-in data types: a date, a character string, or a graphic string. The second argument must be an expression that returns a value of one of the following built-in data types: a time, a character string, or a graphic string. A character or graphic string must be a valid string representation of a time.

If *expression-1* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date with an actual length that is not greater than 255 bytes. If *expression-2* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a time with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and times, see “String representations of datetime values” on page 89.

The result of the function is a timestamp. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The other rules depend on whether the second argument is specified:

**If both arguments are specified**, the result is a timestamp with the date specified by the first argument and the time specified by the second argument. The microsecond part of the timestamp is zero.

**If only one argument is specified and it is a timestamp**, the result is that timestamp.

**If only one argument is specified and it is a string**, the result is the timestamp represented by that string. The timestamp represented by a string of length 14 has a microsecond part of zero. The interpretation of a string as a Store Clock value will yield a timestamp with a year between 1900 to 2042.

If an argument is a string with a CCSID that is not the same as the corresponding default CCSID at the server, the string is first converted to that CCSID.

The result CCSID is the appropriate CCSID of the argument encoding scheme and the result subtype is the appropriate subtype of the CCSID. If both arguments are specified and their encoding schemes are different, the result CCSID is the appropriate CCSID of the application encoding scheme.

*Example 1:* Assume that table TABLEX contains a DATE column named DATECOL and a TIME column named TIMECOL. For some row in the table, assume that DATECOL represents 25 December 2008 and TIMECOL represents 17 hours, 12 minutes, and 30 seconds after midnight. The following function returns the value '2008-12-25-17.12.30.000000'.

```
TIMESTAMP(DATECOL, TIMECOL)
```

## TIMESTAMPADD

The TIMESTAMPADD function returns the result of adding the specified number of the designated interval to the timestamp value.

```
►►—TIMESTAMPADD(interval,number,expression)—————►►
```

The schema is SYSIBM.

### *interval*

An expression that returns a value of a built-in SMALLINT or INTEGER data type. The following values are valid values for *interval*:

*Table 59. Valid values for intervals*

Valid values for <i>interval</i>	equivalent intervals
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks
64	Months
128	Quarters
256	Years

### *number*

An expression that returns a value of a built-in SMALLINT or INTEGER data type.

### *timestamp*

An expression that returns a value of a built-in timestamp data type.

The result of the function is a timestamp.

The result is determined using the normal rules for datetime arithmetic. See “Datetime arithmetic in SQL” on page 193. When the interval to add is expressed as weeks, the result is calculated as if *number* x 7 days had been specified. When the interval to add is expressed as quarters, the result is calculated as if *number* x 3 months had been specified.

The result must be a valid timestamp value. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

*Example 1:* The following example will add 40 years to the specified timestamp. An interval of 256 designates years, while 40 specifies the number of intervals to add. The following statement returns the value '2005-07-27-15.30.00.000000'.

```
SELECT TIMESTAMPADD(256,40,TIMESTAMP('1965-07-27-15.30.00'))  
      FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following example will add 18 months to the specified timestamp. An interval of 64 designates months, while 18 specifies the number of intervals to add. The following statement returns the value '2008-07-20-08.08.00.000000'.

```
SELECT TIMESTAMPADD(64,18,TIMESTAMP('2007-01-20-08.08.00'))  
      FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following example will subtract 16 quarters (4 years) from the specified timestamp. An interval of 128 designates quarters, while -16 specifies the number of intervals to add (the '-' adds a negative amount). The following statement returns the value '2003-09-28-05.30.00.000000'.

```
SELECT TIMESTAMPADD(128,-16,TIMESTAMP('2007-09-28-05.30.00'))  
      FROM SYSIBM.SYSDUMMY1;
```

*Example 4:* The following example will add 18 weeks to the specified timestamp. An interval of 32 designates weeks, while 18 specifies the number of intervals to add. The following statement returns the value '2007-05-27-08.08.00.000000'.

```
SELECT TIMESTAMPADD(32,18,TIMESTAMP('2007-01-20-08.08.00'))  
      FROM SYSIBM.SYSDUMMY1;
```

## TIMESTAMP\_FORMAT

The TIMESTAMP\_FORMAT function returns a timestamp that is based on interpreting the input string by using the specified format.

```
►►—TIMESTAMP_FORMAT—(—string-expression—,—format-string—)—————►►
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a value of any built-in character or graphic string data type, other than a CLOB or DBCLOB, with a length attribute that is not greater than 255 bytes. The *string-expression* must contain the components of a timestamp that correspond to the format that is specified in *format-string*, except for hour, minute, second, or fractional seconds.

### *format-string*

A character string constant with a length that is not greater than 255 bytes. The value is a template for how *string-expression* is interpreted and then converted to a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a timestamp, and can contain any combination of the format elements, unless otherwise noted in the following table. For example, *format-string* cannot contain both YY and YYYY, because both are used to interpret the year component of a *string-expression*. Two format elements can be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start and end of *format-string*. These separator characters can be used in any combination in the format string, for example 'YYYY/MM-DD HH:MM:SS'. Separator character that is specified in a *string-expression* are used to separate components and are not required to match the separator character that is specified in the *format-string*.

Table 60. Format elements for the TIMESTAMP\_FORMAT function

Format element	Related component of a timestamp	Description
AM or PM <sup>1</sup>	hour	Meridian indicator (morning or evening) without periods. This format element uses the exact strings "AM" or "PM".
DD	day	Day of the month (0-31).

Table 60. Format elements for the `TIMESTAMP_FORMAT` function (continued)

Format element	Related component of a timestamp	Description
FF or FF $n$	fractional seconds	Fractional seconds (0-999999). The number $n$ is used to specify the number of digits that is expected in the <i>string-expression</i> . Valid values for $n$ are 1-6 with no leading zeros.
		Specifying FF is equivalent to specifying FF6. When the number of digits for the fractional seconds is less than what is specified by the format element, zero digits are padded onto the right of the number of specified digits.
HH	hour	HH behaves the same as HH12.
HH12	hour	Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator.
HH24	hour	Hour of the day (00-24) in 24-hour format.
MI	minute	Minute (00-59).
MM	month	Month (01-12).
MONTH, Month, or month <sup>1, 2</sup>	month	Name of the month in English.
MON, Mon, or mon <sup>1, 2</sup>	month	Abbreviated name of the month in English.
NNNNNN	microseconds	Microseconds (000000-999999).
RR	year	Last two digits of the adjusted year (00-99).
RRRR	year	Four digit adjusted year (0000-9999).
SS	seconds	Seconds (00-59).
Y	year	Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year.
YY	year	Last two digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year.

*Table 60. Format elements for the TIMESTAMP\_FORMAT function (continued)*

Format element	Related component of a timestamp	Description
YYY	year	Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year.
YYYY	year	4-digit year (0000-9999).

**Notes:**

1. This format element is case sensitive.
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.

The RR and RRRR format elements can be used to change how a specification for a year is to be interpreted by adjusting the value to produce a 2-digit or a 4-digit value depending on the leftmost two digits of the current year according to the following table:

*Table 61. Correspondence of adjusted year value and timestamp component*

Digits of the current year	Two-digit year in string-expression	First two digits of the year component of timestamp
00-50	00-49	First two digits of the current year
51-99	00-49	First two digits of the current year + 1
00-50	50-99	First two digits of the current year -1
51-99	50-99	First two digits of the current year

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults are used when a format-string does not include a format element for one of the following components of a timestamp:

Timestamp component	Default
year	current year, as 4 digits
month	current month, as 2 digits
day	01 (first day of the month)
hour	00
minute	00
second	00
fractional seconds	a number of zeros to match the timestamp precision of the result

If *string-expression* does not include a value that corresponds to an hour, minute, second, or fractional seconds format element that is specified in the *format-string*, the same defaults are used.

Leading zeros can be specified for any component of the timestamp value (that is, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* that represents a component of a timestamp (such as year, month, day, hour, minutes, seconds) can include fewer than the maximum number of digits for that component of the timestamp that is indicated by the corresponding format element. Any missing digits default to zero. For example, with a format-string of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' produces the same result as '0999-03-09 05:07:02'.

The result of the function is a timestamp.

If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

The result CCSID is the appropriate CCSID of the encoding scheme of the first argument and the result subtype is the appropriate subtype of the CCSID.

## Notes

### Determinism:

`TIMESTAMP_FORMAT` is a deterministic function. However, the following invocations of the function depend on the value of the special register `CURRENT TIMESTAMP`.

- *format-string* is a constant and includes format elements that are locale sensitive
- *format-string* is a constant and does not include a format element that fully defines the year (that is, `YYYY`). In this case the current year is used.
- *format-string* is a constant and does not include a format element that fully defines the month (for example, `MM`, `MONTH`, or `MON`). In this case the current month is used.

These invocations, which depend on the value of a special register, cannot be used wherever special registers cannot be used.

### Using the 'D', 'Y', and 'y' format elements:

DB2 for z/OS does not support the '`DY`', '`dy`', and '`Dy`' format elements that are supported by other platforms. If '`DY`' or '`Dy`' is specified in the format string, it is interpreted as the '`D`' format element followed by the '`Y`' or '`y`' format element. This behavior might change in a future release. To ensure that a '`D`' followed by '`Y`' or '`y`' is interpreted as two separate format elements, include a separator character after the '`D`' format element.

### Syntax alternatives:

`TO_DATE` can be specified as a synonym for `TIMESTAMP_FORMAT`.

### Example 1:

Insert a row into the `IN_TRAY` table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT('1999-12-31 23:59:59', 'YYYY-MM-DD HH24:MI:SS'))
```

### Example 2:

An application receives strings of date information into a variable called `INDATEVAR`. This value is not strictly formatted and might include two or

four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or forward-slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include '15/12/98 13:48' and '9-3-2004 8:02'. Insert such values into the IN\_TRAY table.

```
INSERT INTO IN_TRAY (RECEIVED)
VALUES (TIMESTAMP_FORMAT(:INDATEVAR, 'DD/MM/YYYY HH24:MI'))
```

The use of 'RRRR' in the format allows for 2-digit and 4-digit year values and assigns the missing first two digits based on the current year. If 'YYYY' is used, input values with a 2-digit year will have leading zeros. The forward-slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamp values from the sample values are as follows:

```
'15/12/98 13:48' --> 1998-12-15-13.48.00.000000
'9-3-2004 8:02' --> 2004-03-09-08.02.00.000000
```

## TIMESTAMP\_ISO

The TIMESTAMP\_ISO function returns a timestamp value that is based on a date, a time, or a timestamp argument.

```
►►TIMESTAMP_ISO(expression)—————►►
```

The schema is SYSIBM.

If the argument is a date, TIMESTAMP\_ISO inserts a value of zero for the time and the partial seconds parts of the timestamp. If the argument is a time, TIMESTAMP\_ISO inserts the value of CURRENT DATE for the date part of the timestamp and a value of zero for the partial seconds part of the timestamp.

*expression*

An expression that returns a value of one of the following built-in data types:

- a timestamp
- a date
- a time
- a character string
- or a graphic string

If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB and its value must be a valid string representation of a date, a time, or a timestamp. For the valid formats of string representations of dates, times, and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a timestamp. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

**Recommendation:** Use the CAST specification for maximum portability. For more information, see “CAST specification” on page 202.

*Example:* Assume the following date value '1965-07-27'. The following statement returns the value '1965-07-27-00.00.000000'.

```
SELECT TIMESTAMP_ISO( DATE( '1965-07-27' ) )
   FROM SYSIBM.SYSDUMMY1
```

## TIMESTAMPDIFF

The TIMESTAMPDIFF function returns an estimated number of intervals of the type that is defined by the first argument, based on the difference between two timestamps.

►►—TIMESTAMPDIFF(*numeric-expression*,*string-expression*)—————►►

The schema is SYSIBM.

### *numeric-expression*

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The value specifies the interval that is used to determine the difference between two timestamps. The following table lists the valid values for *numeric-expression*:

*Table 62. Valid values for numeric-expression and equivalent intervals that are used to determine the difference between two timestamps*

Valid values for <i>numeric-expression</i>	equivalent intervals
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks
64	Months
128	Quarters
256	Years

### *string-expression*

*string-expression* must be the equivalent of subtracting two timestamps and converting the result to a string of length 22. The argument must be an expression that returns a value of a built-in character string or a graphic string data type that is not a LOB. If the supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The following table lists the valid input value ranges for *string-expression*:

*Table 63. TIMESTAMPDIFF String Elements*

String elements	Valid values	Character position from the decimal point (negative is left)
Years	1-9998 or blank	-14 to -11
Months	0-11 or blank	-10 to -9
Days	0-30 or blank	-8 to -7
Hours	0-24 or blank	-6 to -5
Minutes	0-59 or blank	-4 to -3

*Table 63. TIMESTAMPDIFF String Elements (continued)*

String elements	Valid values	Character position from the decimal point (negative is left)
Seconds	0-59	-2 to -1
Decimal separator	period	0
Microsecond	000000-999999	1 to 6

The result of the function is an integer. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

*Table 64. TIMESTAMPDIFF Computations*

Result interval	Computation using duration elements
Years	years
Quarters	integer value of (months+(years*12))/3
Months	months + (years*12)
Weeks	integer value of ((days+months*30))/7)+(years*52)
Days	days + (months*30)+(years*365)*24
Minutes (the absolute value of the duration must not exceed 40850913020759.999999)	minutes + (hours+((days+(months*30)+(years*365)*24))*60
Seconds (the absolute value of the duration must be less than 680105031408.000000)	seconds + (minutes+(hours+((days+(months*30)+(years*365)*24))*60 )*60
Microseconds (the absolute value of the duration must be less than 3547.483648)	microseconds + (seconds+(minutes*60))*1000000

The following assumptions are used when converting the information in the second argument, which is a timestamp duration, to the interval type that is specified in the first argument, and can be used in estimating the difference between the timestamps:

- One year has 365 days
- One year has 52 weeks
- One year has 12 months
- One month has 30 days
- One week has 7 days
- One day has 24 hours
- One hour has 60 minutes
- One minute has 60 seconds

The use of these assumptions imply that some result values are an estimate of the interval. Consider the following examples:

- Difference of 1 month where the month has less than 30 days.

```
TIMESTAMPDIFF(16, CHAR(TIMESTAMP('1997-03-01-00.00.00'))  
- TIMESTAMP('1997-02-01-00.00.00'))
```

The result of the timestamp arithmetic is a duration of 0000010000000.000000, or 1 month. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the assumption of 30 days in a month is applied and the result is 30.

- Difference of 1 day less than 1 month where the month has less than 30 days.  

$$\text{TIMESTAMPDIFF}(16, \text{CHAR}(\text{TIMESTAMP}('1997-03-01-00.00.00')) - \text{TIMESTAMP}('1997-02-02-00.00.00'))$$

The result of the timestamp arithmetic is a duration of 0000002700000.000000, or 27 days. When the TIMESTAMPDIFF function is invoked with 16 for the interval argument (days), the result is 27.
- Difference of 1 day less than 1 month where the month has 31 days.  

$$\text{TIMESTAMPDIFF}(64, \text{CHAR}(\text{TIMESTAMP}('1997-09-01-00.00.00')) - \text{TIMESTAMP}('1997-08-02-00.00.00'))$$

The result of the timestamp arithmetic is a duration of 0000003000000.000000, or 30 days. When the TIMESTAMPDIFF function is invoked with 64 for the interval argument (months), the result is 0. The days portion of the duration is 30, but it is ignored because the interval specified months.

*Example:* The following statement estimates the age of employees in months and returns that value as AGE\_IN\_MONTHS:

```
SELECT
    TIMESTAMPDIFF(64, CAST(CURRENT_TIMESTAMP-CAST(BIRTHDATE AS TIMESTAMP)
        AS CHAR(22)))
    AS AGE_IN_MONTHS
FROM EMPLOYEE;
```

## TO\_CHAR

The TO\_CHAR function returns a character string representation of a timestamp value that has been formatted using a specified character template.

```
►►TO_CHAR(—string-expression—,—format-string—)►►
```

The schema is SYSIBM.

The TO\_CHAR scalar function is a synonym for the VARCHAR\_FORMAT scalar function.

## **TO\_DATE**

The TO\_DATE function returns a timestamp value that is based on the interpretation of the input string using the specified format.

```
►►TO_DATE(—string-expression—,—format-string—)►►
```

The schema is SYSIBM.

The TO\_DATE scalar function is a synonym for the TIMESTAMP\_FORMAT scalar function.

## TOTALORDER

The TOTALORDER function returns an ordering for DECFLOAT values. The TOTALORDER function returns a small integer value that indicates how *expression1* compares with *expression2*.

```
►►TOTALORDER(expression1,expression2)————►►
```

The schema is SYSIBM.

*expression1*

An expression that returns a built-in DECFLOAT value.

*expression2*

An expression that returns a built-in DECFLOAT value.

Numeric comparison is exact, and the result is determined for finite operands as if range and precision are unlimited. An overflow or underflow conditions cannot occur.

If one value is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

TOTALORDER determines ordering based on the total order predicate rules of IEEE 754R, with the following result:

- -1 if the first argument is lower in order compared to the second.
- 0 if both arguments have the same order.
- 1 if the first argument is higher in order compared to the second.

The ordering of the special values and finite numbers is as follows:

-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0<0.100<0.10<INFINITY<SNAN<NAN

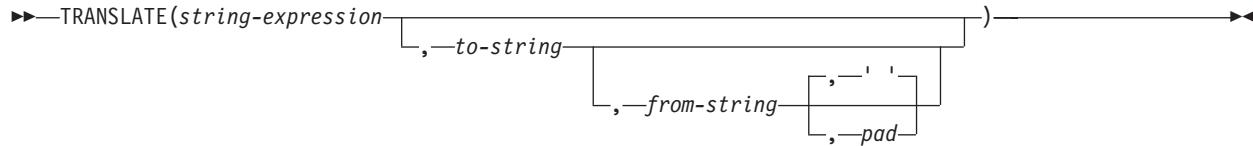

The result of the function is a SMALLINT value. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

*Examples:* The following examples show the use of the TOTALORDER function to compare decimal floating point values:

TOTALORDER(-INFINITY, -INFINITY)	= 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0))	= 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00))	= -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5))	= -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5))	= -1
TOTALORDER(DECFLOAT(-1.0), INFINITY)	= -1
TOTALORDER(DECFLOAT(-1.0), SNAN)	= -1
TOTALORDER(DECFLOAT(-1.0), NAN)	= -1
TOTALORDER(NAN, DECFLOAT(-1.0))	= 1
TOTALORDER(-NAN, -NAN)	= 0
TOTALORDER(-SNAN, -SNAN)	= 0
TOTALORDER(NAN, NAN)	= 0
TOTALORDER(SNAN, SNAN)	= 0

## TRANSLATE

The TRANSLATE function returns a value in which one or more characters of the first argument might have been converted to other characters.

The schema is SYSIBM.

### *string-expression*

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string data type that is not a LOB.

### *to-string*

An expression that specifies the characters to which certain characters in *string-expression* are to be converted. This string is sometimes called the *output translation table*. *to-string* must return a value that is a built-in character or graphic string data type that is not a LOB.

If the length of *to-string* is less than the length of *from-string*, *to-string* is padded to the length of *from-string* with the *pad* or a blank. If the length of *to-string* is greater than *from-string*, the extra characters in *to-string* are ignored without warning.

### *from-string*

An expression that specifies the characters that if found in *string-expression* are to be converted. This string is sometimes called the *input translation table*. When a character in *from-string* is found, the character in *string-expression* is converted to the character in *to-string* that is in the corresponding position of the character in *from-string*.

*from-string* must return a value that is a built-in character or graphic string data type that is not a LOB.

If *from-string* contains duplicate characters, the first occurrence of the character is used, and no warning is issued. The default value for *from-string* is a string that starts with the character X'00' and ends with the character X'FF' (decimal 255).

### *pad*

An expression that specifies the character with which to pad *to-string* if its length is less than *from-string*. *pad* is an expression that must return a value that is a built-in character or graphic string data type that is not a LOB and has a length of 1. A length of 1 is one single byte for character strings and one double byte string for graphic strings. The default is a blank that is appropriate for *string-expression*.

If *string-expression* is the only argument that is specified, the SBCS characters of its value are converted to uppercase based on the LC\_CTYPE locale in effect for the statement, which is determined by special register CURRENT LOCALE

`LC_CTYPE`. For example, `a-z` are converted to `A-Z`, and characters with diacritical marks are converted to their uppercase equivalent, if any. (For a description of the uppercase tables that are used for this conversion, see *IBM National Language Support Reference Manual Volume 2*.) For Unicode data, usage of the `TRANSLATE` function (the `TRANSLATE` function with one argument is equivalent to the `UPPER` function) can result in expansion if certain characters are processed. See the “`UPPER`” on page 552 function for more information. You should ensure that the result string is large enough to contain the result of the expression.

If the `LC_CTYPE` locale is blank when the function is executed, the result of the function depends on the data type of *string-expression*.

- For ASCII and EBCDIC, *string-expression* must not specify a graphic string expression. For a character string expression, characters `a-z` are converted to `A-Z` and characters with diacritical marks are not translated. If the string contains MIXED or DBCS characters, full-width Latin uppercase letters `A-Z` are converted to full-width lowercase letters `a-z`.
- For Unicode, *string-expression* can be either a character string expression or a graphic string expression, and `LOCALE LC_CTYPE` must be blank (no locale specified). The characters `a-z` are converted to `A-Z` and all other characters, including characters with diacritic marks, are left unchanged. Full-width Latin uppercase letters `A-Z` are converted to full-width Latin lowercase letters `a-z`.

If more than one argument is specified, the result string is built character-by-character from *string-expression* with each character in *from-string* being converted to the corresponding character in *to-string*. For each character in *string-expression*, the *from-string* is searched for the same character. If the character is found to be the *n*th character in *from-string*, the resulting string will contain the *n*th character from *to-string*. If *to-string* is less than *n* characters long, the resulting string will contain the *pad*. If the character is not found in *from-string*, it is moved to the result string without being converted.

The string can contain mixed data. If only one argument is specified, the `UPPER` function is performed on the argument, and the rules for operating on mixed data in the `UPPER` function are observed. Full-width Latin lowercase `a-z` are converted to full-width Latin uppercase letters `A-Z`. Otherwise, the function operates on a strict byte-count basis, and the result is not necessarily a properly formed mixed data character string.

The encoding scheme of the result is the same as *string-expression*. The data type of the result of the function depends on the data type of *string-expression*, *to-string*, *from-string*, and *pad*:

- `VARCHAR` if *string-expression* is a character string. The CCSID of the result depends on the arguments:
  - If *string-expression*, *to-string*, *from-string*, or *pad* is bit data, the result is bit data.
  - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS:
    - If *string-expression*, *to-string*, *from-string*, and *pad* are all SBCS Unicode data, the CCSID of the result is the CCSID for SBCS Unicode data.
    - If *string-expression* is SBCS Unicode data, and *to-string*, *from-string*, or *pad* are not SBCS Unicode data, the CCSID of the result is the mixed CCSID for Unicode data.
    - Otherwise, the CCSID of the result is the same as the CCSID of *string-expression*.

- Otherwise, the CCSID of the result is the mixed CCSID that corresponds to the CCSID of *string-expression*. However, if the input is EBCDIC or ASCII and there is no corresponding system CCSID for mixed, the CCSID of the result is the CCSID of *string-expression*.
- VARGRAPHIC if *string-expression* is a graphic. The CCSID of the result is the same as the CCSID of *source-string*.

If the first argument can be null, the result can be null. If the argument is null, the result is the null value.

*Example 1:* Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
SELECT TRANSLATE ('abcdef')
  FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

*Example 2:* Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Hanauma Bay'.

```
SELECT TRANSLATE (:SITE)
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HANAUMA BAY'. The result is all uppercase characters because only one argument is specified.

```
SELECT TRANSLATE (:SITE, 'j', 'B')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hanauma jay'.

```
SELECT TRANSLATE (:SITE, 'ei', 'aa')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Heneume Bey'.

```
SELECT TRANSLATE (:SITE, 'bA', 'Bay', '%')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'HAnAumA bA%'.

```
SELECT TRANSLATE (:SITE, 'r', 'Bu')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Hana ma ray'.

*Example 3:* Assume that host variable *SITE* has a data type of VARCHAR(30) and contains 'Pivabiska Lake Place'.

```
SELECT TRANSLATE (:SITE, '$$', 'L1')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'Pivabiska \$ake P\$ace'.

```
SELECT TRANSLATE (:SITE, 'pLA', 'Place', '.')
  FROM SYSIBM.SYSDUMMY1
```

Returns the value 'pivAbiskA LAk. pLA..'.

## TRUNCATE or TRUNC

The TRUNCATE function returns the first argument, truncated as specified. Truncation is to the number of places to the right or left of the decimal point this is specified by the second argument.

```
►--> TRUNCATE (numeric-expression-1, numeric-expression-2)-----►  
| TRUNC
```

The schema is SYSIBM.

*numeric-expression-1*

An expression that returns a value of any built-in numeric data type.

If *expression-1* is a decimal floating-point data type, the DECFLOAT ROUNDING MODE will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND\_DOWN. If a different rounding behavior is desired, use the QUANTIZE function.

*numeric-expression-2*

An expression that returns a value that is a built-in SMALLINT or INTEGER data type. The absolute value of the integer specifies the number of places to truncate. The value of *numeric-expression-2* determines whether truncation is to the right or left of the decimal point.

If *numeric-expression-2* is not negative, *numeric-expression-1* is truncated to the absolute value of *numeric-expression-2* places to the right of the decimal point.

If *numeric-expression-2* is negative, *numeric-expression-1* is truncated to  $1 + (\text{the absolute value of } \textit{numeric-expression-2})$  places to the left of the decimal point. If  $1 + (\text{the absolute value of } \textit{numeric-expression-2})$  is greater than or equal to the number of digits to the left of the decimal point, the result is 0. For example, TRUNCATE(748.58,-4) returns 0.

The result of the function has the same data type and length attribute as the first argument. The result can be null. If any argument is null, the result is the null value.

*Example 1:* Using sample employee table DSN8910.EMP, calculate the average monthly salary for the highest paid employee. Truncate the result to two places to the right of the decimal point.

```
SELECT TRUNCATE(MAX(SALARY/12),2)  
      FROM DSN8910.EMP;
```

Because the highest paid employee in the sample employee table earns \$52750.00 per year, the example returns the value 4395.83.

*Example 2:* Return the number 873.726 truncated to 2, 1, 0, -1, -2, -3, and -4 decimal places respectively.

```
SELECT TRUNC(873.726,2),  
       TRUNC(873.726,1),  
       TRUNC(873.726,0),  
       TRUNC(873.726,-1),  
       TRUNC(873.726,-2)
```

```
TRUNC(873.726,-3),  
TRUNC(873.726,-4)  
FROM TABLEX  
WHERE INTCOL = 1234;
```

This example returns the values 873.720, 873.700, 873.000, 870.000, 800.000, 0000.000, and 0000.000.

| *Example 3: Calculate both positive and negative numbers.*

```
| SELECT TRUNCATE( 3.5, 0),  
|   TRUNCATE( 3.1, 0),  
|   TRUNCATE(-3.1, 0),  
|   TRUNCATE(-3.5, 0)  
| FROM TABLEX;
```

| This example returns: the values 3.0, 3.0, -3.0, -3.0.

## TRUNC\_TIMESTAMP

The TRUNC\_TIMESTAMP function returns a timestamp that is the *expression*, truncated to the unit that is specified by the *format-string*.

```
►►TRUNC_TIMESTAMP(—expression—'DD'—,—format-string—)►►
```

The schema is SYSIBM.

### *expression*

An expression that returns a value of any of the following built-in data types: a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

### *format-string*

An expression that returns a built-in character string or graphic string data type, with a length that is not greater than 255 bytes. *format-string* contains a template of how the timestamp represented by *expression* should be truncated. For example, if *format-string* is 'DD', the timestamp that is represented by *expression* is truncated to the nearest day. *format-string* must be a valid template for a timestamp, and not include leading or trailing blanks. Allowable values for *format-string* are listed in the following table.

Table 65. ROUND\_TIMESTAMP and TRUNC\_TIMESTAMP format models

Format model	Rounding or truncating unit	ROUND_TIMESTAMP example	TRUNC_TIMESTAMP example
CC	Century	Input Value: 1897-12-04-12.22.22.000000	Input Value: 1897-12-04-12.22.22.000000
SCC	Rounds up to the start of the next century after the 50th year of the century (for example on 1951-01-01-00.00.00).	Result: 1900-01-01-00.00.00.000000	Result: 1800-01-01-00.00.00.000000
	Not valid for a TIME argument.		
YYYY	Year (Rounds up on July 1st)	Input Value: 1897-12-04-12.22.22.000000	Input Value: 1897-12-04-12.22.22.000000
YYYY		Result: 1898-01-01-00.00.00.000000	Result: 1897-01-01-00.00.00.000000

DD			
J			
DAY	Starting day of the week (Rounds up with respect to the 12th hour of the third day of the week. The first day of the week is always Sunday).	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000
DY			
D			
HH	Hour (Rounds up at 30 minutes)	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000
HH12			
HH24			
MI	Minute (Rounds up at 30 seconds)	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000
SS	Second (Rounds up at 500000 microseconds)	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000

The result of the function is a TIMESTAMP. The result can be null; if any argument is null, the result is the null value.

| The result CCSID is the appropriate CCSID of the argument encoding scheme and  
| the result subtype is the appropriate subtype of the CCSID.

*Example:* Set the host variable *TRNK\_TMSTMP* with the specified date rounded to the nearest year value.

```
SET :TRNK_TMSTMP = TRUNC_TIMESTAMP('2008-03-14-17.30.00', 'YEAR');
```

The host variable *TRNK\_TMSTMP* is set with the value '2008-01-01-00.00.00.000000'.

## UCASE

The UCASE function returns a string in which all the characters have been converted to uppercase characters, based on the CCSID of the argument. The UCASE function is identical to the UPPER function.

```
| ►►—UCASE(string-expression [ ,locale-name] [ ,integer])—►►
```

The schema is SYSIBM.

For more information, see “UPPER” on page 552.

## UNICODE

The UNICODE function returns the Unicode UTF-16 code value of the leftmost character of the argument as an integer.

```
►►UNICODE(string-expression)►►
```

The schema is SYSIBM.

*string-expression* can be of any built-in string data type that is not a LOB.

If the argument is ASCII, EBCDIC, or Unicode UTF-8, it is first converted to a Unicode UTF-16 string (CCSID 1200) before the function is executed.

The result of the function is an INTEGER. The result can be null; if the argument is the null value, the result is the null value.

*Example:* The following example returns the Unicode value of 峰 as an integer and assigns the value to the host variable *hv*:

```
Set :hv = UNICODE('');hv is set to an integer with a value '23792'.
```

## UNICODE\_STR

The UNICODE\_STR function returns a string in Unicode UTF-8 or UTF-16, depending on the specified option. The string represents a Unicode encoding of the input string.

```
►►—UNICODE_STR(string-expression [ , —UTF8 — ] ) ——————►►
```

The schema is SYSIBM.

*string-expression*

An expression that returns a value of a built-in character or graphic string. If the string is a character string, it cannot be bit data. Values that are preceded by a backslash ('\') are treated as Unicode UTF-16 characters (for example '\0041' is the Unicode UTF-16 representation for 'A'). A double backslash '\\\' indicates a backslash in the string.

**UTF8 or UTF16**

Specifies the Unicode encoding of the result. If UTF8 is specified, the result is returned as a Unicode UTF-8 character string. If UTF16 is specified, the result is returned as a Unicode UTF-16 graphic string. UTF8 is the default.

The result of the function depends on the second argument:

- VARCHAR if **UTF8** is specified
- VARGRAPHIC if **UTF16** is specified

The length attribute of the result depends on the second argument (**UTF8** or **UTF16**). The length attribute of the result is calculated using the formulas in Table 35 on page 126. If the result is a character string, the length attribute of the result is MAX( $n$ , 32704). If the result is a graphic string, the length attribute of the result is MAX( $n$ , 16352). Where  $n$  is the result of applying the formulas in Table 35 on page 126 based on input and output data types.

If the actual length of the result string exceeds the maximum for the return type, an error occurs.

The result can be null; if the argument is null, the result is the null value.

UNISTR can be specified as a synonym for UNICODE\_STR.

*Example:* The following example sets the host variable HV1 to a VARCHAR value that represents the Unicode UTF-8 string that corresponds to the argument:

```
SET :HV1 = UNICODE_STR('Hi, my name is \5CF0');
```

HV1 is assigned a Unicode UTF-8 string with the following value 'Hi, my name is

峰

## UPPER

The UPPER function returns a string in which all the characters have been converted to uppercase characters.

```
| ►--UPPER(string-expression [ ,locale-name] [ ,integer ])-->
```

The schema is SYSIBM.

### *string-expression*

An expression that specifies the string to be converted. *string-expression* must return a value that is a built-in character or graphic string. A character string argument must not be a CLOB, and a graphic string argument must not be a DBCLOB.

### *locale-name*

A string constant or a string host variable other than a CLOB or DBCLOB that specifies a valid locale name. If *locale-name* is not in EBCDIC, it is converted to EBCDIC. The length of *locale-name* must be between 1 and 255 bytes of the EBCDIC representation. The value of *locale-name* is not case sensitive and must be a valid locale. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

Fr\_BE  
Fr\_FR@EURO  
En\_US  
Ja\_JP

For EBCDIC and ASCII data, there are two options for *locale-name*:

- blank — *string-expression* must not specify a graphic string. For a character string, characters a-z are converted to A-Z and characters with diacritical marks are not converted. If the string contains MIXED or DBCS characters, full-width Latin lowercase letters a-z are converted to full-width uppercase letters A-Z. This is the default value specified in the LOCALE LC\_CTYPE on the installation panel DSNTIPF.
- a locale — locale specific casing will be done using the "LOCAL" casing capabilities, as specified during installation

For optimal performance, use blank for *locale-name* unless your data must be interpreted using the rules provided for specific locales.

For Unicode data, there are three options for *locale-name*:

- blank — simple casting on A-Z, a-z, full-width Latin lowercase letters a-z, and full-width Latin uppercase letters A-Z. Characters with diacritics are not affected.
- "UNI" — If the value "UNI" is specified, casting will use both the "NORMAL" and "SPECIAL" casing capabilities as described in *z/OS Support for Unicode: Using Conversion Services*.
- a locale — In this case, locale specific casing will be performed using the "LOCALE" casing capabilities as described in *z/OS Support for Unicode: Using Conversion Services*.

The value of the host variable must not be null. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value. The locale name must be:

- left justified within the host variable
- padded on the right with blanks if its length is less than that of the host variable and the host variable is in fixed length CHAR or GRAPHIC data type

If *locale-name* is not specified, the locale is determined by special register CURRENT LOCALE LC\_CTYPE. For information about the special register, see "CURRENT LOCALE LC\_CTYPE" on page 140.

If the UPPER function is referenced in an index that is based on an expression, *locale-name* must be specified

#### *integer*

An integer value that specifies the length attribute of the result. If specified, *integer* must be an integer constant between 1 and 32704 bytes in the representation of the encoding scheme of *string-expression*.

If *integer* is not specified, the length attribute of the result is the same as the length of *string-expression*.

For Unicode data, usage of the UPPER function can result in expansion if certain characters are processed. For example, UPPER(UX'FB03') will result in UX'004600460049'. You should ensure that the result string is large enough to contain the result of the expression.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Return the string 'abcdef' in uppercase characters. Assume that the locale in effect is blank.

```
SELECT UPPER('abcdef')
      FROM SYSIBM.SYSDUMMY1
```

The result is the value 'ABCDEF'.

*Example 2:* Return the string 'ffi' in the uppercase characters ('FFI'). Assume that the locale in effect is "UNI".

```
SELECT UPPER(UX'FB03')
      FROM SYSIBM.SYSDUMMYU;
```

This would result in an error because of the expansion that occurs when certain Unicode characters are processed. To avoid the error, you would need to use the following statement instead:

```
SELECT UPPER(CAST(UX'FB03' AS VARCHAR(3))
      FROM SYSIBM.SYSDUMMYU;
```

The result of the preceding statement is the value 'FFI'.

*Example 3:* Create an index EMPLOYEE\_NAME\_UPPER for table EMPLOYEE based on built-in function UPPER with locale name 'Fr\_FR@EURO'.

```
CREATE INDEX EMPLOYEE_NAME_UPPER
  ON EMPLOYEE (UPPER(LASTNAME, 'Fr_FR@EURO', 60),
                UPPER(FIRSTNAME, 'Fr_FR@EURO', 60),
                ID);
```

| The result is the value 'ABCDEF'.

## VALUE

The VALUE function returns the value of the first non-null expression.

```
►►—VALUE—(expression↓,expression——)————►►
```

The schema is SYSIBM.

**Syntax alternatives:** The VALUE function can be specified in place of the COALESCE function. COALESCE should be used for conformance to SQL 2003 Core. For more information, see “COALESCE” on page 315.

## VARBINARY

The VARBINARY function returns a VARBINARY (varying-length binary string) representation of a string of any type.

```
►►VARBINARY(string-expression [,—integer])
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a value that is a built-in character string, graphic string, binary string, or a row ID type.

### *integer*

An integer value that specifies the length attribute of the resulting binary string. The value must be an integer between 1 and 32704 inclusive. If integer is not specified:

- If the *string-expression* is the empty string constant, the length attribute of the result is 1.
- Otherwise, the length attribute of the result is the same as the length attribute of the *string-expression*, unless the *string-expression* is a graphic string. In this case, the length attribute of the result is twice the length attribute of the *string-expression*.

The result of the function is a varying-length binary string. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length of the *string-expression* (or twice the length of the *string-expression* if *string-expression* returns a graphic string). If the length of the *string-expression* is less than the length of the result, the result is padded with hexadecimal zeros up to the length of the result. If the length of the *string-expression* is greater than the length attribute of the result, truncation is performed, and a warning is returned unless the *string-expression* is a character string and all the truncated characters are blanks, or the *string-expression* is a graphic string and all the truncated characters are double-byte blanks.

*Example 1:* The following function returns a varying-length binary string with a length attribute 1, actual length 0, and a value of empty string:

```
SELECT VARBINARY('')
   FROM SYSIBM.SYSDUMMY1;
```

*Example 2:* The following function returns a varying-length binary string with a length attribute 5, actual length 3, and a value BX'D2C2C8':

```
SELECT VARBINARY('KBH',5)
   FROM SYSIBM.SYSDUMMY1;
```

*Example 3:* The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8'

```
| SELECT VARBINARY('KBH ',3)
|   FROM SYSIBM.SYSDUMMY1;
```

*Example 4:* The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'D2C2C8', a warning is also returned.

```
| SELECT VARBINARY('KBH-93',3)
|   FROM SYSIBM.SYSDUMMY1;
```

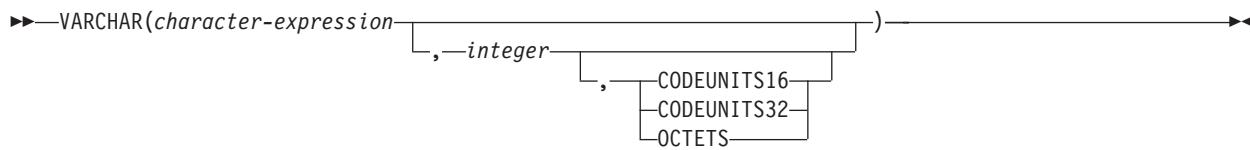

*Example 5:* The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'C1C2C3', a warning is also returned.

```
| SELECT VARBINARY(BINARY('ABC',5),3)
|   FROM SYSIBM.SYSDUMMY1;
```

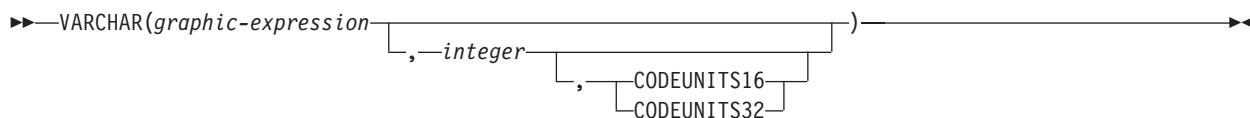

## VARCHAR

The VARCHAR function returns a varying-length character string representation of the value specified by the first argument. The first argument can be a character string, a graphic string, a datetime value, an integer number, a decimal number, a floating-point number, or a row ID value.

### Character to Varchar:

### Graphic to Varchar:

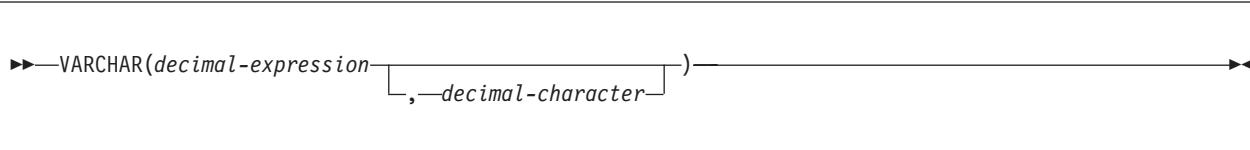

### Datetime to Varchar:

### Integer to Varchar:

### Decimal to Varchar:

## Decimal floating point to Varchar:

```
►►—VARCHAR(decimal-floating-point-expression)—►►
```

## Floating-point to Varchar:

```
►►—VARCHAR(floating-point-expression)—►►
```

## Row ID to Varchar:

```
►►—VARCHAR(row-ID-expression)—►►
```

The schema is SYSIBM.

The result of the function is a varying-length character string (VARCHAR). If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

### Character to Varchar

*character-expression*

An expression that returns a value that is a built-in character data type.

*integer*

Specifies the length attribute for the resulting varying-length character string. The value must be between 1 and 32767, expressed in the units that are either implicitly or explicitly specified. If the length is not specified, the length of the result is the same as the length of *character-expression*.

If CODEUNITS16, CODEUNITS32, or OCTETS is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified and if the *character-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

### CODEUNITS16, CODEUNITS32, or OCTETS

Specifies the unit that is used to express *integer*. If *character-expression* is a character string that is defined as bit data, CODEUNITS16 and CODEUNITS32 cannot be specified.

### CODEUNITS16

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

### CODEUNITS32

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

**OCTETS**

Specifies that *integer* is expressed in terms of bytes.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see “String unit specifications” on page 76.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression* is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

If *character-expression* is bit data, the result is bit data. Otherwise, the CCSID of the result is the same as the CCSID of *character-expression*.

**Graphic to Varchar**

*graphic-expression*

An expression that returns a value that is a built-in graphic data type.

*integer*

The length attribute for the resulting varying-length graphic string. The value must be between 1 and 32740, expressed in the units that are either implicitly or explicitly specified.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If a length attribute is not specified, the length attribute of the result is determined as follows (where *n* is the length attribute of the first argument):

- If the *graphic-expression* is the empty graphic string constant, the length attribute of the result is 1.
- If the result is SBCS data, the result length is *n*.
- If the result is mixed data, the result length is  $3 * (\text{length}(\text{graphic-expression}))$ .

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 or CODEUNITS32, see “String unit specifications” on page 76.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *graphic-expression*. If the length of the graphic expression is greater than the length attribute of the result, the result is truncated. Unless all the truncated characters were blanks appropriate for *graphic-expression*, a warning is returned.

The CCSID of the result is the character mixed CCSID that corresponds to the graphic CCSID of *graphic-expression*.

**Datetime to Varchar**

*datetime-expression*

An expression whose value has one of the following three built-in data types:

**date** The result is a varying-length character string representation of the date in the format that is specified by the DATE precompiler option, if one is provided, or else field DATE FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, field LOCAL DATE LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 10.

LOCAL denotes the local format at the DB2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that DB2.

An error occurs if the second argument is specified and is not a valid value.

**time** The result is a varying-length character string representation of the time in the format specified by the TIME precompiler option, if one is provided, or else field TIME FORMAT on installation panel DSNTIP4 specifies the format. If the format is to be LOCAL, the field LOCAL TIME LENGTH on installation panel DSNTIP4 specifies the length of the result. Otherwise, the length attribute and actual length of the result is 8.

LOCAL denotes the local format at the DB2 that executes the SQL statement. If LOCAL is used for the format, a time exit routine must be installed at that DB2.

An error occurs if the second argument is specified and is not a valid value.

**timestamp**

The result is the varying-length character string representation of the timestamp. The length attribute and actual length of the result is 26.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

**Integer to Varchar**

*integer-expression*

An expression that returns a value that is a built-in integer data type (SMALLINT, INTEGER, BIGINT).

The result is a varying-length character string representation (VARCHAR) of the argument in the form of an SQL integer constant.

The length attribute of the result depends on whether the argument is a small or large integer as follows:

- If the argument is a small integer, the length attribute of the result is 6 bytes.
- If the argument is a large integer, the length attribute of the result is 11 bytes.
- If the argument is a big integer, the length attribute of the result is 20 bytes.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit.

The CCSID of the result is the SBCS CCSID of the appropriate encoding scheme.

### Decimal to Varchar

#### *decimal-expression*

An expression that returns a value that is a built-in decimal data type. To specify a different precision and scale for the expression's value, apply the DECIMAL function to the expression before applying the VARCHAR function.

#### *decimal-character*

Specifies the single-byte character constant (CHAR or VARCHAR) that is used to delimit the decimal digits in the result character string. The character must not be a digit, a plus sign (+), a minus sign (-), or a blank. The default is the period (.) or comma (,). For information on what factors govern the choice, see "Decimal point representation" on page 251.

The result is a varying-length character string representation of the argument. The result includes a decimal character and up to  $p$  digits where  $p$  is the precision of *decimal-expression* with a preceding minus sign if the argument is negative. Leading zeros are not returned. Trailing zeros are returned.

The length attribute of the result is  $2+p$  where  $p$  is the precision of *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. If the argument is negative, the result begins with a minus sign. Otherwise, the result begins with a digit. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see "Determining the encoding scheme and CCSID of a string" on page 43.

### Decimal floating-Point to Varchar

#### *decimal-floating-point-expression*

An expression that returns a value that is the built-in DECFLOAT data type.

The result is the varying-length character string representation of the argument in the form of an SQL decimal floating-point constant.

The length attribute of the result is 42 bytes.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see "Determining the encoding scheme and CCSID of a string" on page 43.

### Floating-Point to Varchar

#### *floating-point-expression*

An expression that returns a value that is a built-in floating-point data type.

The result is a varying-length character string representation (VARCHAR) of the argument in the form of an SQL floating-point constant.

The length attribute of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of the argument such that the mantissa consists of a single digit other than zero followed by a period

and a sequence of digits. If the argument is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If the argument is zero, the result is '0E0'.

The CCSID of the result is determined from the context in which the function was invoked. For more information, see "Determining the encoding scheme and CCSID of a string" on page 43.

### Row ID to Varchar

*row-ID-expression*

An expression that returns a value that is a built-in row ID data type.

The result is a varying-length character string representation (VARCHAR) of the argument. It is bit data.

The length attribute of the result is 40. The actual length of the result is the length of *row-ID-expression*.

*Example 1:* Assume that host variable *JOB\_DESC* is defined as VARCHAR(8). Using sample table DSN8910.EMP, set *JOB\_DESC* to the varying-length string equivalent of the job description (column *JOB* defined as CHAR(8)) for the employee with the last name of 'QUINTANA'.

```
SELECT VARCHAR(JOB)
      INTO :JOB_DESC
      FROM DSN8910.EMP
      WHERE LASTNAME = 'QUINTANA';
```

*Example 2:* FIRSTNME is a VARGRAPHIC(6) column in a Unicode table T1. One of its values is the string 'Jürgen' (X'004A00FC007200670055006E'). When FIRSTNME has this value:

Function ...	Returns ...
<hr/>	
VARCHAR(FIRSTNME,3,CODEUNITS32)	'Jür' -- x'4AC3BC72'
VARCHAR(FIRSTNME,3,CODEUNITS16)	'Jür' -- x'4AC3BC72'
VARCHAR(FIRSTNME,3,OCTETS)	'Jü' -- x'4AC3BC'

## VARCHAR\_FORMAT

The VARCHAR\_FORMAT function returns a character string representation of a timestamp that is based on applying the specified format string argument to the first argument. The expression must be formatted according to a specified character template.

```
►►VARCHAR_FORMAT(timestamp-expression,format-string)►►
```

The schema is SYSIBM.

### Timestamp to varchar

*timestamp-expression*

An expression that returns a value that must be a DATE or TIMESTAMP.

*format-string*

An expression that returns a built-in character string data type that is not a LOB and has a length attribute that is not greater than 255 bytes.

The value is a template for how timestamp-expression is to be formatted.

A valid *format-string* can contain a combination of the format elements listed below. Two format elements can be separated by one or more of the following separator characters.

- minus sign (-)
- period (.)
- forward slash (/)
- comma (,)
- apostrophe (')
- semicolon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-string*. *format-string* can also be an empty string, a string of blanks, or a string of separator characters.

The following table lists the valid format elements that *format-string* can contain.

Table 66. Valid format elements of *format-string*

Format element	Description (assuming the default is to return leading zeros)
CC	Century (00-99).  If the last two digits of the four digit year are zero, the result is the first two digits of the year. Otherwise, the result is the first two digits of the year plus one.
D <sup>1</sup>	Day of the week (1-7).  1 is Sunday and 7 is Saturday.

| *Table 66. Valid format elements of format-string (continued)*

Format element	Description (assuming the default is to return leading zeros)
DD	Day of the month (01-31).
DDD	Day of the year (001-366).
FF or FF $n$	Fractional seconds (0-999999999999).
	The number $n$ is used to specify the number of digits to include in the returned value. Valid values for $n$ are 1-12 with no leading zeros. Specifying FF is equivalent to specifying FF6. If the timestamp precision of <i>timestamp-expression</i> is less than what is specified by the format, zero digits are padded onto the right of the specified digits.
HH	Hour of the day (01-12).
HH12	Hour of the day (01-12).
HH24	Hour of the day (00-24).
I	ISO year (0-9). The last digit of the year based on the ISO week that is returned.
ID	ISO day of the week (1-7).
	1 is Monday and 7 is Sunday.
IW	ISO week of the year (01-53).
	The week starts on Monday and includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4.
IY	ISO year (00-99).
	The last two digits of the year based on the ISO week that is returned.
IYY	ISO year (000-999).
	The last three digits of the year based on the ISO week that is returned.
IYYY	ISO year (0000-9999).
	The last four digits of the year based on the ISO week that is returned.
J	Julian date (0000000-9999999).
MI	Minute (00-59).
MM	Month (01-12).
	January is 01.
MONTH, Month, or month <sup>1, 2</sup>	Name of the month in uppercase, sentence case, or lowercase format in English.
MON, Mon, or mon <sup>1, 2</sup>	Three-character abbreviated name of the month in uppercase, sentence case, or lowercase format in English.
NNNNNN	Microseconds (000000-999999).
	This format is equivalent to specifying FF6.

| *Table 66. Valid format elements of format-string (continued)*

Format element	Description (assuming the default is to return leading zeros)
Q	Quarter (1-4).
	January through March is 1.
RRRR	Year (0000-9999).
	RRRR behaves the same as YYYY.
RR	Last two digits of the year (00-99).
SS	Seconds (00-59).
SSSS	Seconds since the previous midnight (00000-86400).
W	Week of the month (1-5).
	Week 1 starts on the first day of the month and ends on the seventh day.
WW	Week of the year (01-53).
	Week 1 begins on January 1 and ends on January 7.
Y	Last digit of the year (0-9).
YY	Last two digits of the year (00-99).
YYY	Last three digits of the year (000-999).
YYYY	Year (0000-9999).
<b>Notes:</b>	
1. This format element is case sensitive. In cases where the format elements are ambiguous, the case insensitive format elements will be considered first.	
2. Only these exact spellings and case combinations can be used. If this format element is specified in an invalid case combination an error is returned.	

The result is a representation of *timestamp-expression* in the format specified by *format-string*. *format-string* is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in *format-string* is interpreted as the longest matching format element in the previous table. If two format elements that contain the same characters are not delimited by a separator character, the specification is interpreted, starting from the left, as the longest matching element in the table, and continues until matches are found for the remainder of the format string. For example, 'YYYYYYDD' is interpreted as the format elements, 'YYYY', 'YY', and 'DD'.

The result is the varying-length character string. The length attribute of the result is the maximum of 255 and the length attribute of *format-string*. The *format-string* determines the actual length of the result. The actual length must not be greater than the length attribute of the result. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The CCSID of the result is determined from the context in which the function is invoked. For more information, see “Determining the encoding scheme and CCSID of a string” on page 43.

## Notes

### Determinism:

`VARCHAR_FORMAT` is a deterministic function.

### Using the 'D', 'Y', and 'y' format elements:

DB2 for z/OS does not support the 'DY', 'dy', and 'Dy' format elements that are supported by other platforms. If 'DY' or 'Dy' is specified in the format string, it is interpreted as the 'D' format element followed by the 'Y' or 'y' format element. This behavior might change in a future release. To ensure that a 'D' followed by 'Y' or 'y' is interpreted as two separate format elements, include a separator character after the 'D' format element.

### Syntax alternatives:

`TO_CHAR` can be specified as a synonym for `VARCHAR_FORMAT`.

### Example 1:

Set the character variable `TVAR` to a string representation of the timestamp value of `RECEIVED` from `CORPDATA.IN_TRAY`, formatted as 'YYYY-MM-DD HH24:MI:SS'.

```
SELECT VARCHAR_FORMAT(RECEIVED, 'YYYY-MM-DD HH24:MI:SS')
      INTO :TVAR
     FROM CORPDATA.IN_TRAY;
```

Assuming that the value in the `RECEIVED` column is 'January 1, 2000 at 10am', the following string is returned:

'2000-01-01 10:00:00'

Assuming that the value in the `RECEIVED` column is now one second before the beginning of the year 2000 ('December 31, 1999 at 23:59:59pm', the following string is returned:

'1999-12-31 23:59:59'

The result would be different if `HH12` had been specified instead of `HH24` in the format string:

'1999-12-31 11:59:59'

### Example 2:

Assume that the variable `TMSTAMP` is defined as a `TIMESTAMP` and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result data type in each case is `VARCHAR(255)`.

Function invocation	Result
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMISSFF3')</code>	20070309020738123
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHH24MISS')</code>	20070309140738
<code>VARCHAR_FORMAT(TMSTAMP, 'YYYYMMDDHHMI')</code>	200703090207
<code>VARCHAR_FORMAT(TMSTAMP, 'DD/MM/YY')</code>	09/03/07
<code>VARCHAR_FORMAT(TMSTAMP, 'MM-DD-YYYY')</code>	03-09-2007
<code>VARCHAR_FORMAT(TMSTAMP, 'J')</code>	2454169
<code>VARCHAR_FORMAT(TMSTAMP, 'Q')</code>	1
<code>VARCHAR_FORMAT(TMSTAMP, 'W')</code>	2
<code>VARCHAR_FORMAT(TMSTAMP, 'IW')</code>	10
<code>VARCHAR_FORMAT(TMSTAMP, 'WW')</code>	10
<code>VARCHAR_FORMAT(TMSTAMP, 'Month')</code>	March
<code>VARCHAR_FORMAT(TMSTAMP, 'MONTH')</code>	MARCH
<code>VARCHAR_FORMAT(TMSTAMP, 'MON')</code>	MAR

### Example 4:

Format the hour of the specified string representation of a timestamp using a 12 hour clock and a 24 hour clock:

```

SELECT
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-14.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH12'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-00.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-12.00.00.000000'), 'HH24'),
  VARCHAR_FORMAT(TIMESTAMP('2000-01-01-24.00.00.000000'), 'HH24')
FROM SYSIBM.SYSDUMMY1;

```

The previous SELECT statement returns the following values:

```
'02'  '02'  '14'  '12'  '12'  '12'  '12'  '12'  '00'  '12'  '24'
```

Note that the values '00' and '24' on a 24 hour scale both map to a value of '12' on a 12 hour scale.

**Example 5:**

Format the month, day, and hour of the specified string representation of a timestamp using a 24 hour clock, and indicate that the result should not contain leading zeros for the components:

```

SELECT
  VARCHAR_FORMAT(TIMESTAMP('1979-04-07-09.14.00.000000'),
                 'FM MM DD HH24'),
FROM SYSIBM.SYSDUMMY1;

```

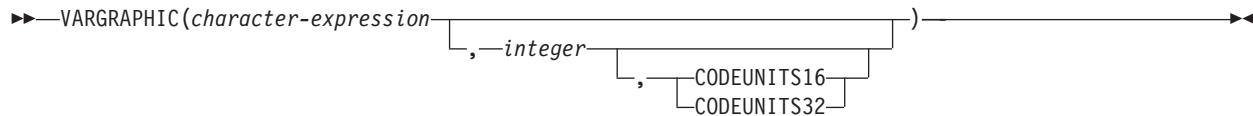

The previous SELECT statement returns the following values:

```
4  7  9
```

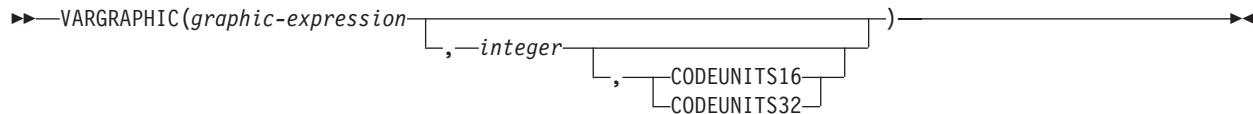

## VARGRAPHIC

The VARGRAPHIC function returns a varying-length graphic string representation of the first argument. The first argument can be a character string value or a graphic string value.

### Character to Vargraphic:

### Graphic to Vargraphic:

The schema is SYSIBM.

The result of the function is a varying-length graphic string (VARGRAPHIC).

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The length attribute and actual length of the result are measured in double-byte characters because the result is a graphic string.

#### Character to Vargraphic

##### *character-expression*

An expression that returns a value of a built-in character string data type that contains an EBCDIC-encoded or Unicode-encoded character string value. It cannot be BIT data. The argument does not need to be mixed data, but any occurrences of X'0E' and X'0F' in the string must conform to the rules for EBCDIC mixed data. (See "Character strings" on page 73 for these rules.)

##### *integer*

The length attribute of the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see "Determining the length attribute of the final result" on page 79 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *character-expression* is an empty string constant or has a value X'0EOF', the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

**CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

**CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

**CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The actual length of the result is the minimum of the length attribute of the result and the actual length of *character-expression*. If the length of *character-expression*, as measured in single-byte characters, is greater than the specified length of the result, as measured in double-byte characters, the result is truncated. Unless all the truncated characters are blanks appropriate for *character-expression*, a warning is returned.

The CCSID of the result is the graphic CCSID that corresponds to the character CCSID of *character-expression*. If the input is EBCDIC and there is no system CCSID for EBCDIC GRAPHIC data, the CCSID of the result is X'FFFE'.

For EBCDIC input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the result is derived. Let *M* denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data and its CCSID is *M*.
- The argument is SBCS data and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is *M*.

Otherwise, the argument is a new string *S* derived by converting the characters to the coded character set identified by *M*. If there is no system CCSID for mixed data, conversion is to the coded character set that the system CCSID for SBCS data identifies.

The result is derived from *S* using the following steps:

- Each shift character (X'0E' or X'0F') is removed.
- Each double-byte character remains as is.
- Each single-byte character is replaced by a double-byte character.

The replacement for a single-byte character is the equivalent DBCS character if an equivalent exists. Otherwise, the replacement is X'FEFE'. The existence of an equivalent character depends on *M*. If there is no system CCSID for mixed data, the DBCS equivalent of X'xx' for EBCDIC is X'42xx', except for X'40', whose DBCS equivalent is X'4040'.

For Unicode input data:

Each character of *character-expression* determines a character of the result. The argument might need to be converted to the native form of mixed data before the

result is derived. Let  $M$  denote the system CCSID for mixed data. The argument is not converted if any of the following conditions is true:

- The argument is mixed data, and its CCSID is  $M$ .
- The argument is SBCS data, and its CCSID is the same as the system CCSID for SBCS data. In this case, the operation proceeds as if the CCSID of the argument is  $M$ .

Otherwise, the argument is a new string  $S$  derived by converting the characters to the coded character set identified by  $M$ .

The result is derived from  $S$  using the following steps:

- Each non-supplementary character is replaced by a Unicode double-byte character (a UTF-16 code point). A non-supplementary character in UTF-8 is between 1 and 3 bytes.
- Each supplementary character is replaced by a pair of Unicode double-byte characters (a pair of UTF-16 code points).

The replacement for a single-byte character is the Unicode equivalent character if an equivalent exists. Otherwise, the replacement is X'FFFD'.

### Graphic to Vargraphic

#### *graphic-expression*

An expression that returns a value of a built-in graphic string data type that contains an EBCDIC-encoded or Unicode-encoded graphic string value.

#### *integer*

The length attribute for the resulting varying-length graphic string. The value must be an integer constant between 1 and 16352.

If CODEUNITS16 or CODEUNITS32 is specified, see “Determining the length attribute of the final result” on page 79 for information about how to calculate the length attribute of the result string.

If *integer* is not specified and if the *graphic-expression* is an empty string constant, the length attribute of the result is 1 and the result is an empty string. Otherwise, the length attribute of the result is the same as the length attribute of the first argument.

#### **CODEUNITS16 or CODEUNITS32**

Specifies the unit that is used to express *integer*. If CODEUNITS16 or CODEUNITS32 is specified, the input is EBCDIC, and there is no corresponding CCSID for EBCDIC GRAPHIC data, an error occurs.

#### **CODEUNITS16**

Specifies that *integer* is expressed in terms of 16-bit UTF-16 code units.

#### **CODEUNITS32**

Specifies that *integer* is expressed in terms of 32-bit UTF-32 code units.

For more information about CODEUNITS16 and CODEUNITS32, see “String unit specifications” on page 76.

The actual length of the result depends on the number of characters in *graphic-expression*. If the length of *graphic-expression* is greater than the length specified, the result is truncated. Unless all of the truncated characters are double-byte blanks, a warning is returned.

The CCSID of the result is the same as the CCSID of *graphic-expression*.

*Example 1:* Assume that GRPHCOL is a VARGRAPHIC column in table TABLEX and MIXEDSTRING is a character string host variable that contains mixed data. For various rows in TABLEX, an application uses a positioned UPDATE statement to replace the value of GRPHCOL with the value of MIXEDSTRING. Before GRPHCOL can be updated, the current value of MIXEDSTRING must be converted to a varying-length graphic string. The following statement shows how to code the VARGRAPHIC function within the UPDATE statement to ensure this conversion.

```
EXEC SQL UPDATE TABLEX  
  SET GRPHCOL = VARGRAPHIC(:MIXEDSTRING)  
 WHERE CURRENT OF CRSNAME;
```

*Example 2:* FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the string 'Jürgen'. When FIRSTNAME has this value:

Function ...	Returns ...
VARGRAPHIC(FIRSTNAME,3,CODEUNITS32)	'Jür' -- x'004A00FC0072'
VARGRAPHIC(FIRSTNAME,3,CODEUNITS16)	'Jür' -- x'004A00FC0072'
VARGRAPHIC(FIRSTNAME,3,OCTETS)	An error because OCTETS not allowed

## WEEK

The WEEK function returns an integer in the range of 1 to 54 that represents the week of the year. The week starts with Sunday, and January 1 is always in the first week.

```
►►WEEK(expression)
```

The schema is SYSIBM.

The argument must be an expression that returns a value of one of the following built-in data types: a date, a timestamp, a character string, or a graphic string. If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see "String representations of datetime values" on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.PROJ, set the integer host variable WEEK to the week of the year that project 'AD2100' ended.

```
SELECT WEEK(PRENDATE)
  INTO :WEEK
  FROM DSN8910.PROJ
 WHERE PROJNO = 'AD2100';
```

The result is that WEEK is set 6.

## **WEEK\_ISO**

The WEEK\_ISO function returns an integer in the range of 1 to 53 that represents the week of the year. The week starts with Monday and includes seven days. Week 1 is the first week of the year that contains a Thursday, which is equivalent to the first week that contains January 4.

```
►►—WEEK_ISO(expression)—————►►
```

With the WEEK\_ISO function, the first one, two, or three days in January might be included in the last week of the previous year. Likewise, the last one, two, or three days in December might be included in the first week of the next year.

The schema is SYSIBM.

The argument must be a date, a timestamp, or a valid string representation of a date or timestamp. A string representation must not be a CLOB or DBCLOB value and must have an actual length that is not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

*Example 1:* Using sample table DSN8910.PROJ, set the integer host variable WEEKISO to the week of the year that project 'AD2100' ended.

```
SELECT WEEK_ISO(PRENDATE)
  INTO :WEEKISO
  FROM DSN8910.PROJ
 WHERE PROJNO = 'AD2100';
```

*Example 2:* The following list shows what is returned by the WEEK\_ISO function for various dates.

DATE:	WEEK_ISO returns:
2003-12-28	52
2003-12-31	1
2004-01-01	1
2005-01-01	53
2005-01-04	1
2005-12-31	52
2006-01-01	52
2006-01-03	1

## XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments. This function can be used as an argument only for the XMLELEMENT function.

```
►►—XMLATTRIBUTES(—attribute-value-expression—
                    [AS—attribute-name—]—)————►►
```

The schema is SYSIBM.

The result is an XML sequence that contains an XQuery attribute node for each non-null *attribute-value-expression* argument.

### *attribute-value-expression*

An expression that returns a value for the attribute. The data type of *attribute-value-expression* must not be ROWID, a LOB, a distinct type that is based on a ROWID or a LOB, or XML.

The result of *attribute-value-expression* is mapped to an XML value according to the rules for mapping an SQL value to an XML value. If the expression is not a simple column reference, an attribute name must be specified.

### **AS** *attribute-name*

Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName. If *attribute-name* is a qualified name, the namespace prefix must be declared within the scope of the qualified name.

*attribute-name* cannot be 'xmlns' or prefixed with 'xmlns:'. A namespace is declared using the function XMLNAMESPACES. The attribute names for an element must be unique for the XML element to be well-formed.

If *attribute-name* is not specified, the expression for *attribute-value* must be a column name. The attribute name will be created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The result of the function is an XML value. The result can be null; if all *attribute-value-expression* arguments are null, the result is the null value.

## XMLCOMMENT

The XMLCOMMENT function returns an XML value with a single comment node from a string expression. The content of the comment node is the value of the input string expression, mapped to Unicode (UTF-8).

```
►►XMLCOMMENT(string-expression)—————►►
```

The schema is SYSIBM.

### *string-expression*

An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The result of *string-expression* is converted to UTF-8 and then parsed to check for conformance to the content of XML comment as specified by the following rules:

- '--' (double-hyphen) must not occur in the string expression
- The string expression must not end with a hyphen ('-')
- Each character of the string can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'

If *string-expression* does not conform to the previous rules, an error is returned.

The result of the function is an XML value that is an XML sequence that contains one XML comment node. The result can be null; if the argument is null, the result is the null value.

*Example:* Generate an XML comment:

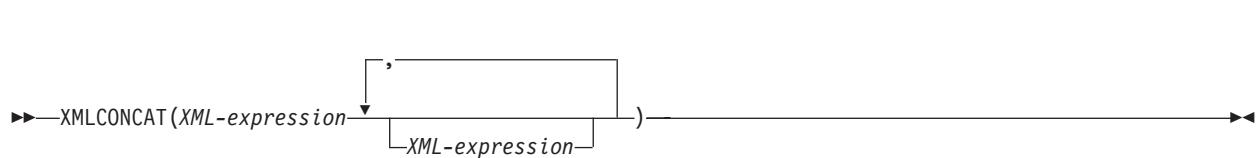

```
SELECT XMLCOMMENT('This is an XML comment')
   FROM SYSIBM.SYSDUMMY1;
```

The result of the query would look similar to the following result:

```
<!--This is an XML comment-->
```

## XMLCONCAT

The XMLCONCAT function returns an XML sequence that contains the concatenation of a variable number of XML input arguments.

The schema is SYSIBM.

*XML-expression*

An expression that returns an XML value.

The data type of the result is XML. The result of the function is an XML sequence that contains the concatenation of the non-null input XML values. Null values in the input are ignored. The result can be null; if the result of every input value is null, the result is the null value.

*Example:* Concatenate first name and last name elements by using 'first' and 'last' element names for each employee.

```
SELECT XMLSERIALIZE( XMLCONCAT
    ( XMLELEMENT ( NAME "first", e.fname),
      XMLELEMENT ( NAME "last", e.lname)
    ) ) AS "result"
FROM employees e;
```

The result of the query would look similar to the following result:

result

```
<first>John</first><last>Smith</last>
<first>Mary</first><last>Smith</last>
```

## XMLDOCUMENT

The XMLDOCUMENT function returns an XML value with a single document node and zero or more nodes as its children. The content of the generated XML document node is specified by a list of expressions.

The schema is SYSIBM.

### XML-expression

An expression that returns an XML value. A sequence item in the XML value must not be an attribute node. If *XML-expression* returns a null value, it is ignored for further processing. However, if all *XML-expression* values are null, the result of the function is the null value.

The result of the function is an XML value. The result can be null; if all the arguments are null, the result is the null value.

The resulting XML value is built from the list of *XML-expression* arguments. The children of the resulting document node are constructed as follows:

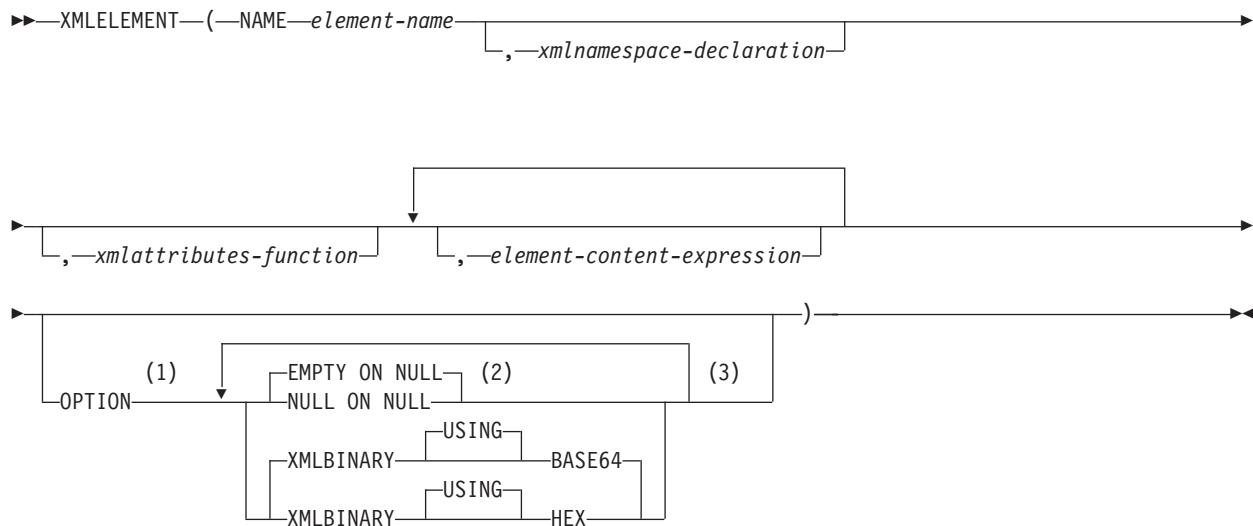

1. All of the non-null XML values that are returned by *XML-expression* are concatenated together. The result is a sequence of nodes or atomic values, which is referred to in the following steps as the *input sequence*. Any document node in the input sequence is replaced by copies of its children.
2. For each node in the input sequence, a new deep copy of the node is constructed. A *deep copy* of a node is a copy of the whole subtree that is rooted at that node, including the node itself and its descendants and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation 'xdt:untyped', and copied attribute nodes are given the type annotation 'xdt:untypedAtomic'. For each adjacent sequence of one or more atomic values that is returned in the input sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. The resulting sequence of nodes is called the *content sequence*. Adjacent text nodes in the content sequence are merged into a single text node by concatenating the contents of the text nodes with no intervening blanks. After concatenation, any text node that contains a zero-length string is deleted from the content sequence.
3. The nodes in the content sequence become the children of the new document node.

*Example 1:* Insert a constructed document into an XML column:

```
INSERT INTO T1 VALUES(123,
  (SELECT XMLDOCUMENT(XMLELEMENT(NAME "Emp",
    e.fname || ' ' || e.lname),
    XMLCOMMENT('This is just a simple example'))
  FROM EMPLOYEE e
  WHERE e.empid = 123));
```

## XMLELEMENT

The XMLELEMENT function returns an XML value that is an XML element node.

### Notes:

- 1 The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified
- 2 If *element-content-expression* is not specified, EMPTY ON NULL and NULL ON NULL must not be specified.
- 3 The same clause must not be specified more than one time.

The schema is SYSIBM.

#### **NAME** *element-name*

Specifies the name of an XML element. *element-name* is an SQL identifier that must be in the form of an XML qualified name, or QName. If the name is qualified, the namespace prefix must be declared within the scope.

#### *xmlnamespace-declaration*

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect. See "XMLNAMESPACES" on page 587 for more information on declaring XML namespaces.

If *xmlnamespace-declaration* is not specified, namespace declarations are not associated with the constructed XML element node.

#### *xmlattributes-function*

Specifies the attributes for the XML element. The attributes are the result of the XMLATTRIBUTES function. See "XMLATTRIBUTES" on page 575 for more information on constructing attributes.

If *xmlattributes-function* is not specified, attributes are not explicitly part of the constructed XML element node.

#### *element-content-expression*

The content of the generated XML element node is specified by an expression or a list of expressions. Each *element-content-expression* must return a value of any built-in data type or distinct type. The expression is used to construct the namespace declarations, attributes, and content of the constructed element node.

If *element-content-expression* is not specified, an empty string is used as the content for the element and NULL ON NULL or EMPTY ON NULL must not be specified.

#### **OPTION**

Specifies additional options for constructing the XML element. This clause has no impact on nested invocations of the XMLELEMENT function invocations that are specified in *element-content-expression*.

#### **EMPTY ON NULL or NULL ON NULL**

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. This option only affects null handling of element contents, not attribute values. The option is not inherited by a nested invocation of XMLELEMENT function within an *element-content-expression*.

#### **EMPTY ON NULL**

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

#### **NULL ON NULL**

If the value of each *element-content-expression* is null, a null value is returned.

#### **XMLBINARY USING BASE64 or XMLBINARY USING HEX**

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

#### **XMLBINARY USING BASE64**

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

#### **XMLBINARY USING HEX**

Specifies that the assumed encoding is hexadecimal characters as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more optional arguments that make up the content of the XML element. The result is an XML sequence that contains an XML element node or the null value. If the results of all *element-content-expression* arguments are empty strings, the result is an XML sequence that contains an empty element.

The result of the function is an XML value. The result can be null; if all *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

**Constructing an element node:** The resulting element node is constructed as follows:

1. *xmlnamespace-declaration* adds a set of in-scope namespaces for the constructed element. Each in-scope namespace associates a namespace prefix (or the default namespace) with a namespace URI. The in-scope namespaces define the set of namespace prefixes that are available for interpreting QNames within the scope of the element.
2. If the *xmlattributes-function* is specified, it is evaluated and the result is a sequence of attribute nodes.
3. Each *element-content-expression* is evaluated and the result is converted into a sequence of nodes as follows:
  - If the result type is not XML, it is converted to an XML text node that contains the result of the *element-content-expression* this is mapped to XML.
  - If the result type is XML, the result is a sequence of items. Some of the items in that sequence might be document nodes. Each document node in the sequence is replaced by the sequence of its top-level children. Then for each node in the resulting sequence, a new deep copy of the node is constructed, including its children and attributes. Each copied node has a new node identity. Copied element nodes are given the type annotation `xdt:untyped`, and copied attribute nodes are given the type annotation `xdt:untypedAtomic`. For each adjacent sequence of one or more atomic values that are returned in the sequence, a new text node is constructed that contains the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. If any of these atomic values cannot be cast into a string, an error is returned.
4. The result sequence of *xmlattributes-function* and the resulting sequences of all *element-content-expression* clauses are concatenated into one sequence which is called the *content sequence*. Any sequence of adjacent text nodes in the content sequence is merged into a single text node by concatenating their contents, with no intervening blanks. After concatenation, any text node that is a zero-length string is deleted from the content sequence.
5. If the content sequence contains an attribute node that follows a node that is not an attribute node, an error is returned. Attribute nodes that occur in the content sequence become attributes of the new element node. If two or more of these attribute nodes have the same name, an error is returned. A namespace declaration is created that corresponds to any namespace that is used in the names of the attribute nodes if the namespace URI is not in the in-scope namespaces of the constructed element.
6. Element, text, comment, and processing instruction nodes in the content sequence become the children of the constructed element node.

- The constructed element node is given a type annotation of `xdt:untyped`, and each of its attributes is given a type annotation of `xdt:untypedAtomic`. The node name of the constructed element node is the XML element name that is specified after the `NAME` keyword.

**Rules for using namespaces within XMLEMENT:** The following rules describe scoping of namespaces:

- The namespaces that are declared in the `XMLNAMESPACES` function are the in-scope namespaces of the element node that are constructed by the `XMLEMENT` function. If the element node is serialized, each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of the parent of the element node and the parent element is also serialized.
- The scope of these namespaces is the lexical scope of the `XMLEMENT` function, including the element name, the attribute names that are specified in the `XMLATTRIBUTES` function, and all *element-content-expressions*. These are used to resolve the QNames in the scope.
- If an `XMLQUERY` or `XMLEXISTS` function is in an *element-content-expression*, the namespaces become the *statically known namespaces* of the XPath expression of the `XMLQUERY` or `XMLEXISTS` function. Statically known namespaces are used to resolve the QNames that are in the XPath expression. If the XPath prolog declares a namespace that has the same prefix within the scope of the XPath expression, the namespace that is declared in the prolog will override the namespaces that are declared in the `XMLNAMESPACES` function.
- If an attribute of the constructed element comes from *element-content-expression*, its namespace might not already be declared as an in-scope namespace of the constructed element. In this case, a new namespace is created for it. If the prefix of the attribute name is already bound to a different URI by a in-scope namespace, DB2 generates a different prefix to be used in the attribute name. A namespace is created for this generated prefix. The name of the generated prefix follows the following pattern: `db2ns-xx`, where `xx` is a pair of characters chosen from the set `[A-Z,a-z,0-9]`.

*Example 1:* The following statement uses the `XMLEMENT` function to create an XML element that contains an employees name. The statement also stores the employee number as an attribute named `serial`. If there is a null value in the referenced column, the function returns the null value:

```
SELECT e.empno, e.firstname, e.lastname,
       XMLEMENT ( NAME "foo:Emp",
                  XMLNAMESPACES('http://www.foo.com' AS "foo"),
                  XMLATTRIBUTES(e.empno as "serial"),
                  e.firstname,
                  e.lastname
                  OPTION NULL ON NULL ) AS "Result"
  FROM EMP e
 WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

EMPNO	FIRSTNAME	LASTNAME	Result
A0001	John	Parker	<foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp>
B0001	(null)	Smith	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp>
B0002	(null)	(null)	(null)
	(null)	(null)	(null)

*Example 2:* The following example is similar to Example 1, however, when a null value is in one of the referenced columns, an empty element is returned:

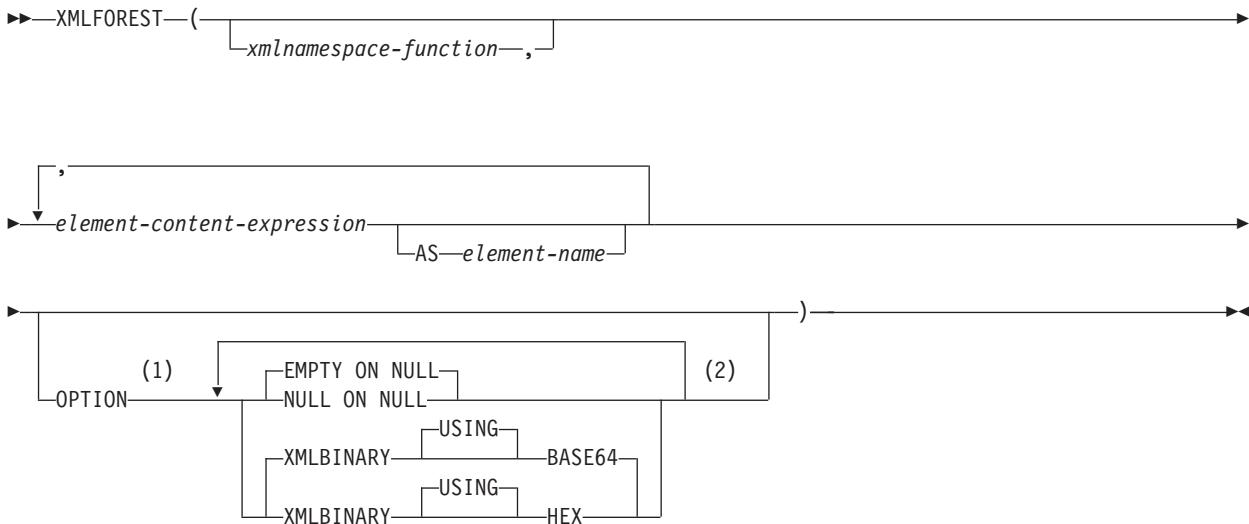

```
SELECT e.empno, e.firstname, e.lastname,
       XMLELEMENT (NAME "foo:Emp",
                   XMLNAMESPACES('http://www.foo.com' AS "foo"),
                   XMLATTRIBUTES(e.empno as "serial"),
                   e.firstname,
                   e.lastname
                   OPTION EMPTY ON NULL) AS "Result"
  FROM EMP e
 WHERE e.edlevel = 12;
```

The result of the query would look similar to the following result:

EMPNO	FIRSTNME	LASTNAME	Result
A0001	John	Parker	<foo:Emp xmlns:foo="http://www.foo.com" serial="A0001">JohnParker</foo:Emp>
B0001	(null)	Smith	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0001">Smith</foo:Emp>
B0002	(null)	(null)	<foo:Emp xmlns:foo="http://www.foo.com" serial="B0002"></foo:Emp>
(null)	(null)	(null)	<foo:Emp></foo:Emp>

## XMLFOREST

The XMLFOREST function returns an XML value that is a sequence of XML element nodes.

### Notes:

- 1 The *OPTION* clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified.
- 2 The same clause must not be specified more than one time.

The schema is SYSIBM.

### *xmlnamespace-function*

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES function. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not those functions appear inside another subselect. See "XMLNAMESPACES" on page 587 for more information on declaring XML namespaces.

If *xmlnamespace-function* is not specified, namespace declarations are not associated with the constructed sequence of XML element nodes.

### *element-content-expression*

Specifies an expression that returns a value that is used for the content of a generated XML element. The result of the expression is mapped to an XML value according to the mapping rules from an SQL value to an XML value. If the expression is not a simple column reference, *element-name* must be specified.

### **AS** *element-name*

Specifies an identifier that is used for the XML element name.

An XML element name must be an XML QName. If the name is qualified, the namespace prefix must be declared within the scope.

If *element-name* is not specified, *element-content-expression* must be a column name. The element name is created from the column name using the fully escaped mapping from a column name to a QName.

#### **OPTION**

Specifies options for the result for NULL values, binary data, and bit data. The options will not be inherited by the XMLEMENT or XMLFOREST functions that appear in *element-content-expression*.

##### **EMPTY ON NULL or NULL ON NULL**

Specifies if a null value or an empty element is returned when the values of each *element-content-expression* is a null value. EMPTY ON NULL and NULL on NULL only affect null handling of the *element-content-expression* arguments, not the handling of values from an *xmlelements-function* argument.

##### **EMPTY ON NULL**

If the value of each *element-content-expression* is null, an empty element is returned.

EMPTY ON NULL is the default.

##### **NULL ON NULL**

If the value of each *element-content-expression* is null, a null value is returned.

#### **XMLBINARY USING BASE64 or XMLBINARY USING HEX**

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, ROWID, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values.

##### **XMLBINARY USING BASE64**

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+' and '/') to represent every 6 bits of the binary or bit data by one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING BASE64 is the default.

##### **XMLBINARY USING HEX**

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hex encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

The XMLFOREST function can be expressed using the XMLCONCAT and XMLEMENT functions.

This function takes an optional set of namespace declarations and one or more arguments that make up the name and element content for one or more element nodes. The result is an XML sequence containing a sequence of element nodes or the null value.

The result of the function is an XML value. The result can be null; if all the *element-content-expression* arguments are null and the NULL ON NULL option is in effect, the result is the null value.

*Example:* Generate an "Emp" element for each employee. Use employee name as its attribute and two subelements generated from columns HIRE and DEPT by using XMLFOREST as its content. The element names for the two subelements are "HIRE" and "department".

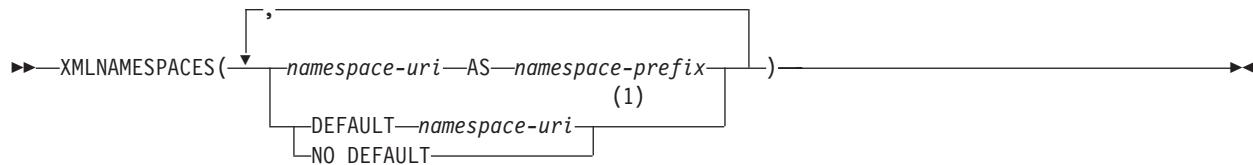

```
SELECT e.id, XMLSERIALIZE ( XMLELEMENT
    ( NAME "Emp",
        XMLATTRIBUTES ( e.fname || ' ' || e.lname
                        AS "name" ),
        XMLFOREST ( e.hire,
                     e.dept AS "department" )
    ) ) AS "result"
FROM employees e;
```

The result of the query would be similar to the following result:

ID	result
1001	<Emp name="John Smith"> <HIRE>2000-05-24</HIRE> <department>Accounting</department> </Emp>
1001	<Emp name="Mary Martin"> <HIRE>1996-02-01</HIRE> <department>Shipping</department> </Emp>

## XMLNAMESPACES

The XMLNAMESPACES function constructs namespace declarations from the arguments. This function can be used as an argument only for specific functions, such as the XMLELEMENT function and the XMLFOREST function.

### Notes:

- 1 The DEFAULT or NO DEFAULT clause can only be specified one time.

The schema is SYSIBM.

The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

#### *namespace-uri*

Specifies an SQL character string constant that contains the namespace name or a universal resource identifier (URI). The character string constant must not be an empty string if it is used with *namespace-prefix*. *namespace-uri* cannot be <http://www.w3.org/XML/1998/namespace> or <http://www.w3.org/2000/xmlns/>.

#### **AS** *namespace-prefix*

Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName. The prefix must not be "xml" or "xmlns". The prefix must be unique within the list of namespace declarations.

The following namespace prefixes are pre-defined in SQL/XML: "xml", "xs", "xsd", "xsi", and "sqlxml". Their bindings are:

- xmlns:xml = "http://www.w3.org/XML/1998/namespace"
- xmlns:xs = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsd = "http://www.w3.org/2001/XMLSchema"
- xmlns:xsi = "http://www.w3.org/2001/XMLSchema-instance"
- xmlns:sqlxml= "http://standards.iso.org/iso/9075/2003/sqlxml"

#### **DEFAULT** *namespace-uri* **or** **NO DEFAULT**

Specifies whether a default namespace is to be used within the scope of this namespace declaration.

The scope of this namespace declaration is the specified XML element and all XML expressions that are contained in the specified XML element.

#### **DEFAULT** *namespace-uri*

Specifies the default namespace to use within the scope of this namespace declaration. The *namespace-uri* applies for unqualified names in the scope unless it is overridden in a nested scope by another DEFAULT declaration or by a NO DEFAULT declaration.

*namespace-uri* specifies an SQL character string constant that contains a namespace name or universal resource identifier (URI). The character string constant can be an empty string in the context of the DEFAULT clause.

#### NO DEFAULT

Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless the NO DEFAULT clause is overridden in a nested scope by a DEFAULT declaration.

The result of the function is an XML value that is an XML sequence that contains an XML namespace declaration for each specified namespace. The result cannot be null.

*Example 1:* Generate an "employee" element for each employee. The employee element is associated with XML namespace "urn:bo", which is bound to prefix "bo". The element contains attributes for names and a hiredate subelement.

```
SELECT e.empno, XMLSERIALIZE(XMLELEMENT(NAME "bo:employee",
    XMLNAMESPACES('urn:bo' AS "bo"),
    XMLATTRIBUTES(e.lastname, e.firstname),
    XMLELEMENT(NAME "bo:hiredate", e.hiredate)) AS CLOB(50))
FROM employee e where e.edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <bo:employee xmlns:bo="urn:bo" LASTNAME="PARKER" FIRSTNAME="JOHN">
    <bo:hiredate>198-5-3</bo:hiredate>
</bo:employee>
00031 <bo:employee xmlns:bo="urn:bo" LASTNAME="SETRIGHT"
    FIRSTNAME="MAUDE">
    <bo:hiredate>1964-9-12</bo:hiredate>
</bo:employee>
```

*Example 2:* Generate two elements for each employee using XMLFOREST. The first "lastname" element is associated with the default namespace "http://hr.org", and the second "job" element is associated with XML namespace "http://fed.gov", which is bound to prefix "d".

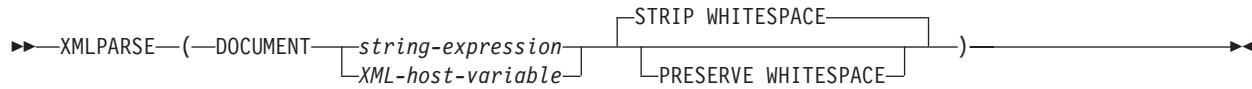

```
SELECT empno, XMLSERIALIZE(XMLFOREST(
    XMLNAMESPACES(DEFAULT 'http://hr.org', 'http://fed.gov' AS "d"),
    lastname, job AS "d:job") AS CLOB(50))
FROM employee where edlevel = 12;
```

The result of the query would be similar to the following result:

```
00029 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER
</LASTNAME>
<d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
OPERATOR</d:job>
00031 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">
SETRIGHT</LASTNAME>
<d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">
OPERATOR</d:job>
```

## XMLPARSE

The XMLPARSE function parses the argument as an XML document and returns an XML value.

The schema is SYSIBM.

### DOCUMENT

Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0.

### *string-expression*

An expression that returns a character, graphic, or binary string.

*string-expression* must evaluate to a character string that conforms to the definition of a well-formed XML document as defined in XML 1.0.

### *XML-host-variable*

An XML host variable that contains a well-formed XML document as defined in XML 1.0.

### STRIP WHITESPACE or PRESERVE WHITESPACE

Specifies whether whitespace is to be removed or preserved. Any DTD attributes for xml:space have no impact on whitespace handling.

### STRIP WHITESPACE

Specifies that whitespace (space that is between element nodes without any non-whitespace text nodes) will be stripped unless the nearest containing element has a value of 'preserve' for the xml:space attribute.

STRIP WHITESPACE is the default.

### PRESERVE WHITESPACE

Specifies that all whitespace is preserved, even when the nearest containing element has a value of 'default' for the xml:space attribute.

The result of the function is XML. If *string-expression* can be null, the result can be null; if *string-expression* is null, the result is the null value.

**Direct use of XMLPARSE with character string input:** Applications should avoid direct use of the XMLPARSE function with character string input and should send strings that contain XML documents directly by using host variables to maintain the match between the external encoding and the encoding in the XML declaration. If XMLPARSE must be used in this situation, a BLOB type should be specified as the argument to avoid code page conversion.

*Example 1:* The following example inserts an XML document into the EMP table and preserves the whitespace in the original XML document. Assume that *hv* contains the value, '<a xml:space='preserve'> <b> <c>c</c>b </b> </a>':

```
INSERT INTO EMP (id, xvalue) VALUES(1001,  
          XMLPARSE(DOCUMENT :hv  
          PRESERVE WHITESPACE));
```

| XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the  
| following value:

```
<a xml:space='preserve'> <b> <c>c</c>b </b>  
</a>
```

| Example 2: The following example inserts an XML document into the EMP table  
| and strips the whitespace in the original XML document. Assume that *hv* contains  
| the value, '<a xml:space='preserve'> <b xml:space='default'> <c>c</c>b </b>  
</a>':

```
INSERT INTO EMP (id, xvalue) VALUES(1001,  
          XMLPARSE(DOCUMENT :hv  
                      STRIP WHITESPACE));
```

| XMLPARSE will treat the value in *hv* for the insert statement as equivalent to the  
| following value:

```
<a xml:space='preserve'>  
<b xml:space='default'><c>c</c>b </b>  
</a>
```

## XMLPI

The XMLPI function returns an XML value with a single processing instruction node.

```
►-> XMLPI(—NAME—pi-name [—, —string-expression] )—>
```

The schema is SYSIBM.

### NAME *pi-name*

Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName. The name must not contain "xml" in any case combination.

### *string-expression*

An expression that returns a value of a built-in character or graphic string that is not a LOB and is not bit data. The resulting string will be converted to UTF-8 and parsed to check for conformance to the content of XML processing instruction as specified by the following rules:

- The string must not contain the substring '?>' as this terminates a processing instruction.
- Each character can be any Unicode character, excluding the surrogate blocks, X'FFFE', and X'FFFF'.

If the resulting string does not conform to the preceding rules, an error is returned. The resulting string becomes the contents of the constructed processing instruction node. If *string-expression* is not specified or is an empty string, the contents of the processing instruction node are empty.

The result of the function is an XML value. The result can be null; if the *string-expression* argument is null, the result is the null value.

*Example:* Generate an XML processing instruction node:

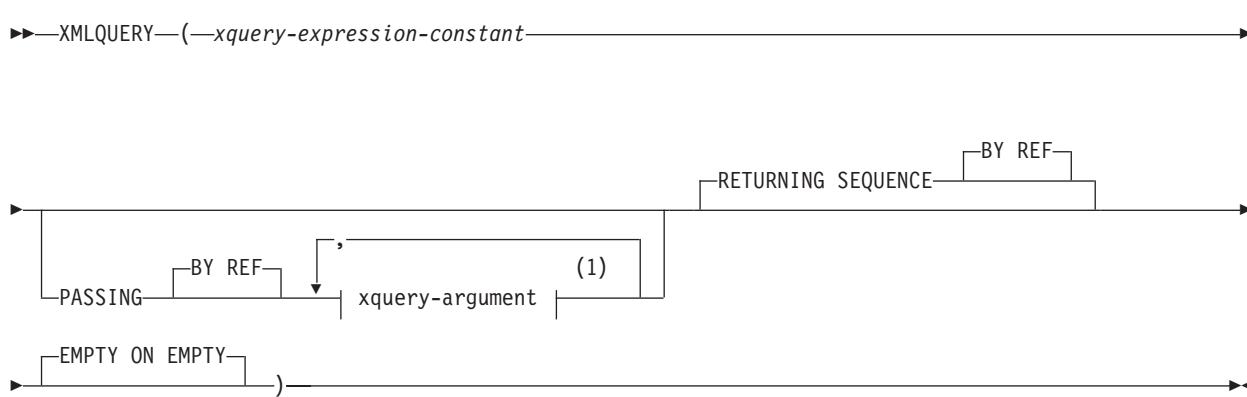

```
SELECT XMLPI(NAME "Instruction", 'Push the red button')
  FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

```
<?Instruction Push the red button?>
```

## XMLQUERY

The XMLQUERY function returns an XML value from the evaluation of an XPath expression, by using specified input arguments, a context item, and XPath variables.

### Notes:

- 1 *xquery-context-item-expression* must not be specified more than one time.

## xquery-argument:

The schema is SYSIBM.

### xquery-expression-constant

Specifies an SQL character string constant that is interpreted as an XPath expression using supported XPath language syntax. See *DB2 XML Guide* for information about the supported XPath expressions. The XPath expression is evaluated with the arguments specified in *xquery-argument*, and returns an output sequence that is also returned as the result of the XMLQUERY function. *xquery-expression-constant* must not be an empty string or a string of all blanks.

### PASSING

Specifies input values and the manner in which these values are passed to the XPath expression that is specified by *xquery-expression-constant*.

### BY REF

Specifies that the XML input value arguments are to be passed by reference. When XML values are passed by reference, the XPath evaluation uses the input node trees which preserves all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some

nodes that are contained between the two input arguments might refer to nodes that are within the same XML node tree.

BY REF has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

#### *xquery-argument*

Specifies an argument that is passed to the XPath expression that is specified by *xquery-expression-constant*. A query argument is an expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-argument* must not return ROWID, TIMESTAMP, binary string, REAL, DECFLOAT data types, or a character string data type that is bit data, and must not reference a sequence expression.

*xquery-argument* specifies both a value and the manner in which that value is to be passed. How an argument in the PASSING clause is used in the XPath expression depends on whether the argument is specified as *xquery-context-item-expression* or *xquery-variable-expression*. *xquery-argument* includes an SQL expression that is evaluated before passing the result to the XPath expression.

- If the resulting value is of type XML, it becomes an *input-xml-value*. It is passed by reference, which means that the original values, not copies, are used in the evaluation of the XPath expression. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, the result of the expression must be able to be cast to an XML value. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When *xquery-expression-constant* is evaluated, an XPath variable receives a value that is equal to *input-xml-value* and a name as specified by the AS clause.

#### *xquery-context-item-expression*

*xquery-context-item-expression* specifies the initial context item in the XPath expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

*xquery-context-item-expression* must not be a sequence of more than one item. If *input-xml-value* is an empty XML string, the XPath expression is evaluated with the initial context item set to an empty XML string. If the value of *input-xml-value* is null, the function returns a null value.

If the *xquery-context-item-expression* is not specified or is an empty sequence, the initial context item in the XPath expression is undefined and the XPath expression must not reference the initial context item.

An XPath variable is not created for the context item expression.

#### *xquery-variable-expression*

*xquery-variable-expression* specifies an SQL expression whose value is available to the XPath expression that is specified by *xquery-expression-constant* during execution. The sequence cannot contain a sequence reference.

An XPath variable is created for each *xquery-variable-expression*, and the XPath variable is set to a value equal to *input-xml-value*. For example, PASSING T.A + T.B AS "sum" creates an XPath variable named sum. The scope of the XPath variables that are created from the PASSING clause is the XPath expression that is specified by *xquery-expression-constant*.

**AS *identifier***

Specifies that the value that is generated by *xquery-variable-expression* is passed to *xquery-expression-constant* as an XPath variable named *identifier*. The length of the name must not be longer than 128 bytes. The leading dollar sign (\$) that precedes variable names in the XPath language is not included in *identifier*. The name must be an XML 1.0 NCName that is not the same as the identifier for another *xquery-variable-expression* in the same PASSING clause.

**RETURNING SEQUENCE**

Specifies that the XPath expression returns a sequence.

**BY REF**

Specifies that the result of the XPath expression is returned by reference. If this value contains nodes, any expression that is using the return value of the XPath expression will receive node references directly, preserving all node properties including the original node identities and document order.

**EMPTY ON EMPTY**

Specifies that an empty sequence that results from processing the XPath expression is returned as an empty sequence.

The result of the function is an XML value. The result cannot be null.

If the evaluation of the XPath expression results in an error, the XMLQUERY function returns the XQuery error.

*Implicit casting of a non XML value to an XML value:* If the result of *xquery-argument* is not an XML type, the value is cast to XML as follows. The SQL data type of the expression is mapped to a corresponding XML Schema data type according to the following table:

*Table 67. SQL data types and corresponding XML schema data types*

SQL data type	XML schema data type
CHAR, VARCHAR	xs:string
GRAPHIC, VARGRAPHIC	xs:string
SMALLINT	xs:integer
INTEGER	xs:integer
BIGINT	xs:integer
DECIMAL	xs:decimal
DOUBLE	xs:double
FLOAT	xs:double

Let *V* be the value of the expression. An atomic value of the corresponding XML schema data type is constructed such that the result of cast (*V* as varchar) is a lexical representation of the constructed atomic value. For example, an SQL VARCHAR value '123' is converted to an atomic value '123' of xs:string type. An SQL integer '12' is converted to an atomic value '12' of xs:integer. An SQL decimal value '1.20' is converted to an atomic value '1.2' of xs:decimal.

*Example 1:* The following example returns an XML value from evaluation of the specified XPath expression:

```
|           SELECT XMLQUERY('//*[productName=$n]'  
|                           PASSING PO.POrder,  
|                               :hv AS "n") AS "Result"  
|           FROM PurchaseOrders PO;
```

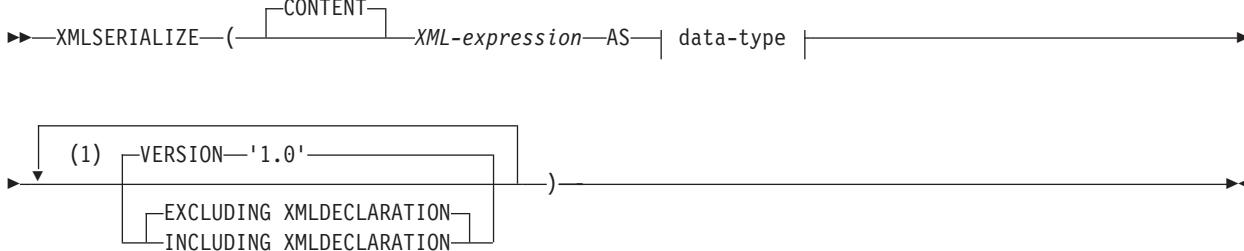

| Assume that the value of the host variable *hv* is 'Baby Monitor', the result is similar  
| to the following results:

| Result

```
| -----  
| <item partNum="926-AA"><productName>Baby Monitor</productName><quantity>1  
| </quantity><USPrice>39.98</USPrice><shipDate>1999-05-21</shipDate></item>
```

## XMLSERIALIZE

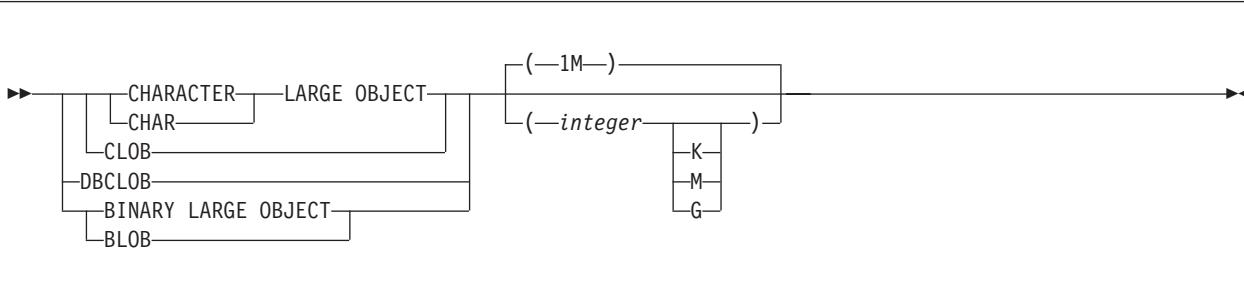

The XMLSERIALIZE function returns a serialized XML value of the specified data type that is generated from the first argument.

### Notes:

- 1 The same clause must not be specified more than one time.

## data-type

The schema is SYSIBM.

### CONTENT

Specifies that any XML value can be specified and the result of the serialization is based on this input value.

### XML-expression

An expression that returns an XML value that is not an attribute node. The atomic values in the input sequence must be able to be cast to xs:string.  
XML-expression is the input to the serialization process.

### AS data type

Specifies the data type of the result. The implicit or explicit length attribute for the specified result data type must be sufficient to contain the serialized output.

The CCSID of a resulting character or graphic string is determined by the data type of the result:

- If the result is a CLOB, the CCSID for mixed Unicode data (1208).
- If the result is a DBCLOB, the CCSID for graphic Unicode data (1200).

**VERSION '1.0'**

Specifies the XML version of the serialized value. The only version that is supported is '1.0', which must be specified as a string constant.

**EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION**

Specifies whether an XML declaration is included in the result.

**EXCLUDING XMLDECLARATION**

Specifies that an XML declaration is not included in the result.

EXCLUDING XMLDECLARATION is the default.

**INCLUDING XMLDECLARATION**

Specifies that an XML declaration is included in the result. The XML declaration contains values for XML serialization version 1.0 and an encoding specification of UTF-8. An XML sequence is effectively converted to have a single document node by applying the XMLELEMENT function to *XML-expression* prior to serializing the resulting XML nodes.

The data type and length attribute of the result are determined from the specified *data-type*. The result can be null; if the *XML-expression* argument is null, the result is the null value.

*Serializing a sequence:* The value of the input argument to XMLSERIALIZE is a sequence. Before a sequence is serialized, it is normalized. The purpose of sequence normalization is to create a sequence that can be serialized as a well-formed XML document or external general parsed entity, that also reflects the content of the input sequence to the extent possible. If the input sequence is an XML empty string, the result of serialization is an empty string. Otherwise, the result is constructed as follows:

- For each item in the sequence, if the item is atomic, the lexical representation of the item is obtained by casting it to an xs:string
- Each subsequence of adjacent strings in the sequence is merged into a single string with the values of the adjacent strings separated by a single space.
- For each item in the sequence, if the item is a string, a text node is created with a value that is equal to the string.
- For each node in the sequence, if the node is a document node, it is replaced it by its children.
- Each node must not be an attribute node.
- Each subsequence of adjacent text nodes in the sequence are merged into a single text node that with the values of the adjacent text nodes concatenated in order without a space between each node. Any text nodes of zero length are dropped.
- A document node is created and the sequence of nodes that was generated is copied as the children of the new document node.

Let *S* be any sequence, the normalization described in the preceding list is equivalent to XMLELEMENT(*S*). Therefore, the following two expressions produce the same result:

- XMLSERIALIZE(*S* AS CLOB)
- XMLSERIALIZE(XMLELEMENT(*S*) AS CLOB)

Each instance of the following characters that appear in the content of a text node or in the value of an attribute node is mapped as following during serialization:

Character in content of text node	during serialization, the character is mapped to
'&' (X'26')	'&amp;'
'<'(X'3C')	'&lt;'
'>'(X'3E')	'&gt;'
carriage return (X'0D')	'&#x0d;'
quote (X'22') <sup>1</sup>	'&quot;'

**Note:** The quote character is only mapped if it is inside of an attribute value.

*Syntax alternatives:* XML2CLOB(*XML-expression*) can be specified as an alternative to XMLSERIALIZE(*XML-expression AS CLOB(2G)*). XML2CLOB is supported only for compatibility with previous releases of DB2.

*Example 1:* Serialize into CLOB of UTF-8, the XML value that is returned by the XMLEMENT function, which is a simple XML element with "Emp" as the element name, and an employee name as the element content:

```
SELECT e.id, XMLSERIALIZE(XMLELEMENT ( NAME "Emp",
                                         e.fname || ' ' || e.lname)
                                         AS CLOB(100)) AS "result"
      FROM employees e;
```

The result looks similar to the following results:

ID	result
1001	<Emp>John Smith</Emp>
1206	<Emp>Mary Martin</Emp>

*Example 2:* Serialize into a string of BLOB type, the XML value that is returned by the XMLEMENT function:

```
SELECT XMLSERIALIZE(XMLELEMENT(NAME "emp",
                                 e.fname || ' ' || e.lname))
                                 AS BLOB(1K)
                                 VERSION '1.0') AS result
      FROM employee e WHERE e.id = '1001';
```

The result looks similar to the following results:

result
<emp>John Smith</emp>

## XMLTEXT

The XMLTEXT function returns an XML value with a single text node that contains the value of the argument.

```
►►—XMLTEXT—(—string-expression—)—————►►
```

The schema is SYSIBM.

*string-expression*

An expression that returns a value of a built-in character or graphic string that is not bit data. Any character in the resulting string must be a valid XML 1.0 character when it is converted to UTF-8.

If *string-expression* is an empty string, an empty text node is returned.

The result of the function is an XML value. The result can be null; if the argument is null, the result is the null value.

*Example 1:* The following example returns an XML value with a single text node that contains the specified value:

```
SELECT XMLTEXT('The stock symbol for Johnson&Johnson is JNJ.') AS "Result"  
FROM SYSIBM.SYSDUMMY1;
```

The result looks similar to the following results:

Result

```
-----  
The stock symbol for Johnson&Johnson is JNJ.
```

*Example 2:* The XMLTEXT function enables the XMLAGG function to construct mixed content, as in the following example:

```
SELECT XMLEMENT(NAME "para",  
                XMLAGG(XMLCONCAT( XMLTEXT( plaintext ),  
                               XMLEMENT( NAME "emphasis",  
                                         emphtext ) ))  
                ORDER BY seqno ), '.' ) as "result"  
FROM T;
```

Suppose that the content of the table T is as the following:

seqno	plaintext	emphtext
1	This query shows how to construct	mixed content
2	using XMLAGG and XMLTEXT. Without	XMLTEXT
3	XMLAGG cannot group text nodes with other nodes, therefore, cannot generate	mixed content

The result looks like the following result:

```
result  
-----  
<para>This query shows how to construct <emphasis>mixed content</emphasis>  
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>, XMLAGG  
cannot group text nodes with other nodes, therefore, cannot generate  
<emphasis>mixed content</emphasis>. </para>
```

## YEAR

The YEAR function returns the year part of a value that is a character or graphic string. The value must be a valid string representation of a date or timestamp.

```
►►YEAR(expression)—►►
```

The schema is SYSIBM.

The argument must be an expression that returns one of the following built-in data types: a date, a timestamp, a character string, a graphic string, or a numeric data type.

- If *expression* is a character or graphic string, it must not be a CLOB or DBCLOB, and its value must be a valid string representation of a date or timestamp with an actual length of not greater than 255 bytes. For the valid formats of string representations of dates and timestamps, see “String representations of datetime values” on page 89.
- If *expression* is a number, it must be a date or timestamp duration. For the valid formats of date and timestamp durations, see “Datetime operands” on page 121.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument specified:

**If the argument is a date, a timestamp, or a string representation of either,** the result is the year part of the value, which is an integer between 1 and 9999.

**If the argument is a date duration or a timestamp duration,** the result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.

*Example 1:* From the table DSN8910.EMP, select all rows for employees who were born in 1941.

```
SELECT *
  FROM DSN8910.EMP
 WHERE YEAR(BIRTHDATE) = 1941;
```

---

## Table functions

A table function can be used only in the FROM clause of a statement. Table functions return columns of a table and resemble a table created through a CREATE TABLE statement. Table functions can be qualified with a schema name.

## ADMIN\_TASK\_LIST

The ADMIN\_TASK\_LIST function returns a table with one row for each of the tasks that are defined in the administrative scheduler task list.

```
►►ADMIN_TASK_LIST()►►
```

The schema is DSNADM.

The result of the function is a table with the format shown in the following table. All the columns are nullable except TASK\_NAME.

*Table 68. Format of the resulting table for ADMIN\_TASK\_LIST*

Column name	Data type	Contains
BEGIN_TIMESTAMP	TIMESTAMP	Contains the timestamp of when the task can first run. When the task begins to run depends on what values this and other columns contain: <ul style="list-style-type: none"><li>• If BEGIN_TIMESTAMP contains a non-null value:<ul style="list-style-type: none"><li>- If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run at the timestamp in BEGIN_TIMESTAMP</li><li>- If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined at or after the timestamp in BEGIN_TIMESTAMP</li><li>- If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes or after the timestamp in BEGIN_TIMESTAMP</li></ul></li><li>• If BEGIN_TIMESTAMP contains a null value:<ul style="list-style-type: none"><li>- If POINT_IN_TIME and TRIGGER_TASK_NAME contain null values, the task begins to run immediately</li><li>- If POINT_IN_TIME contains a non-null value, the task begins to run at the next point in time that is defined</li><li>- If TRIGGER_TASK_NAME is a non-null value, the task begins to run at the next time that the task identified in TRIGGER_TASK_NAME completes</li></ul></li></ul>
END_TIMESTAMP	TIMESTAMP	Contains the timestamp of when the task is last able to run. If this column is NULL, there are no restrictions as to when the task must not run.

*Table 68. Format of the resulting table for ADMIN\_TASK\_LIST (continued)*

Column name	Data type	Contains
MAX_INVOCATIONS	INTEGER	Contains the maximum number of times the task can run. The maximum number applies to all types of schedules: triggered by events, scheduled by time interval, or by point in time. If this column is null, the task has no limit on the number of times it can be run.
INTERVAL	INTEGER	If both END_TIMESTAMP and MAX_INVOCATIONS contain values, the value in END_TIMESTAMP takes precedence over the value for MAX_INVOCATIONS. That is, if the value in END_TIMESTAMP is reached, even though the number of times the task has run has not reached the value for MAX_INVOCATIONS, the task will not run again.
POINT_IN_TIME	VARCHAR(400)	Contains an integer that indicates the duration between the start of one instance of a task and the start of the next instance of the same task. If the value of this column is NULL, the task is not scheduled to run at a regular interval.
TRIGGER_TASK_NAME	VARCHAR(128)	Contains one or more points in time (in UNIX cron format) for which the task is scheduled to run. If the value of this column is NULL, the task is not scheduled to run at a specific point in time.
		The format contains the following pieces of information separated by blanks: given hour, given minute, given day of the week, given day of the month, given month of the year.
		Contains the task name of the task that, when its execution is complete, will trigger the running of the task that is described in the row.
		Task name DB2STOP is reserved for DB2 stop events and task name DB2START is reserved for DB2 start events. Those events are handled by the administrative scheduler that is associated with the DB2 subsystem that is starting or stopping.
		If the value of this column is NULL, the task that is described in this row will not be triggered to run by another task.

*Table 68. Format of the resulting table for ADMIN\_TASK\_LIST (continued)*

Column name	Data type	Contains												
TRIGGER_TASK_COND	CHAR(2)	<p>Contains the type of comparison that is to be made to the return code after the running of task that is indicated in TRIGGER_TASK_NAME. The following values are possible:</p> <table> <tr> <td><b>GT</b></td><td>Greater than</td></tr> <tr> <td><b>GE</b></td><td>Greater than or equal to</td></tr> <tr> <td><b>EQ</b></td><td>Equal to</td></tr> <tr> <td><b>LT</b></td><td>Less than</td></tr> <tr> <td><b>LE</b></td><td>Less than or equal to</td></tr> <tr> <td><b>NE</b></td><td>Not equal to</td></tr> </table> <p>If this column contains NULL, the task is triggered to run without consideration of the return code of the task that is indicated in TRIGGER_TASK_NAME.</p>	<b>GT</b>	Greater than	<b>GE</b>	Greater than or equal to	<b>EQ</b>	Equal to	<b>LT</b>	Less than	<b>LE</b>	Less than or equal to	<b>NE</b>	Not equal to
<b>GT</b>	Greater than													
<b>GE</b>	Greater than or equal to													
<b>EQ</b>	Equal to													
<b>LT</b>	Less than													
<b>LE</b>	Less than or equal to													
<b>NE</b>	Not equal to													
TRIGGER_TASK_CODE	INTEGER	<p>Contains the return code from running the task indicated in TRIGGER_TASK_NAME.</p> <p>If the running of this task is triggered by a stored procedure, TRIGGER_TASK_CODE contains the SQLCODE that must be returned by the stored procedure in order for this task to run.</p> <p>If the running of this task is triggered by a JCL job, TRIGGER_TASK_CODE contains the MAXRC that must be returned by the job in order for this task to run.</p> <p>“ADMIN_TASK_STATUS” on page 606 returns the SQLCODE or MAXRC value in the SQLCODE or MAXRC column.</p> <p>If TRIGGER_TASK_COND is NULL, this column will also be NULL.</p>												

*Table 68. Format of the resulting table for ADMIN\_TASK\_LIST (continued)*

Column name	Data type	Contains
DB2_SSID	VARCHAR(4)	Contains the DB2 subsystem ID of the DB2 subsystem that is associated with the administrative scheduler that should run this task.
		The value in this column is used in a data sharing environment where, for example different DB2 members have different configurations and running the task relies on a certain environment. A value in DB2_SSID will prevent an administrative scheduler of other members to run this task, so that the task can only be run as long as the administrative scheduler of the subsystem indicated in DB2_SSID is running.
		For a task that is being triggered by a DB2 start or DB2 stop event as indicated in the TRIGGER_TASK_NAME column, a value in DB2_SSID will allow the task to be run only when the indicated subsystem is starting or stopping. If no value is indicated in DB2_SSID, each subsystem that starts or stops will trigger a the task to be run locally, provided that the triggered task is run serially.
		If this column is NULL, any administrative scheduler can run this task.
PROCEDURE_SCHEMA	VARCHAR(128)	Contains the schema of the DB2 stored procedure that this task will run. If the value of this column is null, DB2 uses a default schema.
PROCEDURE_NAME	VARCHAR(128)	Contains the name of the DB2 stored procedure that this task will run. If the value of this column is NULL, no stored procedure will be called when this task is run.
PROCEDURE_INPUT	VARCHAR(4096)	Contains a statement that returns one row of data. The returned value will be used as the input parameter of the stored procedure that this task will run. If this column contains the null value, no parameters are passed to the stored procedure when this task is run.
JCL_LIBRARY	VARCHAR(44)	Contains the name of the data set that contains the JCL job that is run when this task is run. If the value of this column is the null value, no JCL job will be run when this task is run.
JCL_MEMBER	VARCHAR(8)	Contains the name of the library member that contains the JCL job that is run when this task is run. If the value of this column is the null value, the data set that is specified in JCL_LIBRARY is sequential and contains the JCL job that is run when this task is run.

*Table 68. Format of the resulting table for ADMIN\_TASK\_LIST (continued)*

Column name	Data type	Contains
JOB_WAIT	VARCHAR(8)	Contains one of the following values, which indicates whether the JCL job can be run synchronously. If the value in the column is not null, this column contains one of the following values:  NO Runs asynchronously YES Runs synchronously <b>PURGE</b> Runs synchronously and then the job status in z/OS is purged
TASK_NAME	VARCHAR(128)	Contains the unique name that is assigned to this task.
DESCRIPTION	VARCHAR(128)	Contains a description of the task if one exists.
USERID	VARCHAR(128)	Contains the authorization ID of the user under which the task will be invoked. If this column is NULL, the task is invoked by the default authorization ID that is associated with the administrative scheduler.
CREATOR	VARCHAR(128)	Contains the authorization ID that added the task to the administrative scheduler task list.
LAST_MODIFIED	TIMESTAMP	Timestamp of when the task was added or last modified.

*Example 1:* Retrieve information about all of the tasks that are defined in the administrative scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_LIST()) AS T;
```

## ADMIN\_TASK\_STATUS

The ADMIN\_TASK\_STATUS function returns a table with one row for each task that is defined in the administrative scheduler task list. Each row indicates the status of the task for the last time it was run.

```
►►ADMIN_TASK_STATUS()--►►
```

The schema is DSNADM.

The result of the function is a table with the format shown in the following table.

*Table 69. Format of the resulting table for ADMIN\_TASK\_STATUS*

Column name	Data type	Contains
TASK_NAME	VARCHAR(128)	Contains the name of the task that has run, is running, or has been bypassed.
STATUS	VARCHAR(10)	Contains one of the following values that indicates task status:  <b>RUNNING</b> The task is currently running  <b>COMPLETED</b> The task has finished running.  For asynchronous tasks (JCL jobs), this column contains COMPLETED whenever the job is submitted to be run. Otherwise, this column contains COMPLETED only after the task has finished running.  <b>NOTRUN</b> The task was not run at the scheduled invocation time. The MSG column contains the error or warning message that indicates why the task was not run.  <b>UNKNOWN</b> The scheduler shut down while the task was running. The scheduler is started again but cannot know the execution status of this interrupted task.
NUM_INVOCATIONS	INTEGER	Contains the number of times the administrative scheduler attempted to run the task, including the current time if the task is currently running. The values in this column does not indicate if the task was successfully run.
START_TIMESTAMP	TIMESTAMP	Contains the time when the task started running if the STATUS column contains COMPLETED, RUNNING, or UNKNOWN. Otherwise, this column contains the time that the task should have started to run but could not.
END_TIMESTAMP	TIMESTAMP	Contains the time when the task finished running.

*Table 69. Format of the resulting table for ADMIN\_TASK\_STATUS (continued)*

Column name	Data type	Contains
JOB_ID	CHAR(8)	Contains the job ID that is assigned to the JCL job submitted by the administrative scheduler. This column contains NULL if the task is a stored procedure or if the STATUS column does not contain COMPLETED.
MAXRC	INTEGER	Contains the highest return code from submitting a JCL job. If the task is synchronous, the value in this column is changed to the return code that is returned when the job finishes running.
COMPLETION_TYPE	INTEGER	This column is set to NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if a synchronous task is finished and has run with JES3 in a z/OS 1.7 or earlier system.  Contains one of the following values that indicates the completion type of the JCL job submitted by the administrative scheduler:  0 No completion information 1 Job ended normally 2 Job ended by completion code 3 Job had a JCL error 4 Job was canceled 5 Job abended 6 Converter abended while processing the job 7 Job failed security checks 8 Job failed in end-of-memory
SYSTEM_ABENDCD	INTEGER	This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.  Contains the system abend code returned by a failed JCL job that was submitted by the administrative scheduler.
USER_ABENDCD	INTEGER	This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.  Contains the user abend code returned by a failed JCL job that was submitted by the administrative scheduler.
MSG	VARCHAR(128)	This column contains NULL if the task is a stored procedure, if the STATUS column does not contain COMPLETED, or if the JCL job is run with JES3 in a z/OS 1.7 or earlier system.  Contains the error or warning message from the last time the task was run.

*Table 69. Format of the resulting table for ADMIN\_TASK\_STATUS (continued)*

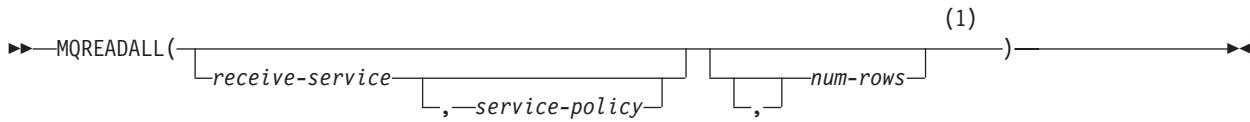

Column name	Data type	Contains
SQLCODE	INTEGER	Contains the SQLCODE set by DB2 when a stored procedure was called by the administrative scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
SQLSTATE	CHAR(5)	Contains the SQLSTATE set by DB2 when a stored procedure was called by the administrative scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
SQLERRP	VARCHAR(8)	Contains the SQLERRP set by DB2 when a stored procedure was called by the administrative scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
SQLERRMC	VARCHAR(70)	Contains the SQLERRMC set by DB2 when a stored procedure was called by the administrative scheduler. This column contains NULL if the task is a JCL job or if the STATUS column does not contain COMPLETED.
DB2_SSID	VARCHAR(4)	Contains the DB2 subsystem ID that is associated with the administrative scheduler that ran the task or should have run the task.
USERID	VARCHAR(128)	Contain the user ID that the task ran under.

*Example 1:* Retrieve status information about all of the tasks that have run in the administrative scheduler task list:

```
SELECT *
  FROM TABLE (DSNADM.ADMIN_TASK_STATUS()) AS T;
```

## MQREADALL

The MQREADALL function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

### Notes:

- 1 The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ1N or DB2MQ2N.

The MQREADALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

#### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *num-rows*

An expression that specifies the maximum number of messages to return. It must be an expression that returns a built-in integer data type.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns are nullable.

*Table 70. Format of the resulting table for MQREADALL*

Column name	Data type	Contains
MSG	VARCHAR(4000)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALL()) T;
```

The messages and all the metadata are returned as a table.

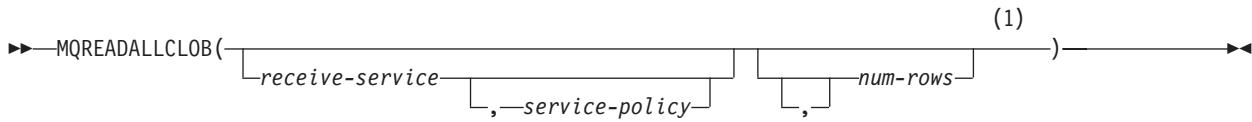

*Example 2:* Retrieve the first 10 messages from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALL(10)) T;
```

The first 10 messages and all the columns are returned as a table.

## MQREADALLCLOB

The MQREADALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

### Notes:

- 1 The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ1N or DB2MQ2N.

The MQREADALLCLOB function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

#### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

#### *num-rows*

An expression that specifies the maximum number of messages to return. It must be an expression that returns a built-in integer data type.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns in the table are nullable.

*Table 71. Format of the resulting table for MQREADALLCLOB*

Column name	Data type	Contains
MSG	CLOB(1M)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALLCLOB()) T;
```

The messages and all the metadata are returned as a table.

*Example 2:* Retrieve all the messages from the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID
  FROM TABLE (MQREADALLCLOB('MYSERVICE')) T;
```

Only the MSG and CORRELID columns are returned as a table.

## MQREADALLXML

The MQREADALLXML function returns a table that contains the messages and message metadata from a specified MQSeries location without removing the messages from the queue.

```
►►—MQREADALLXML—(—  
    |—————receive-service—————|—————num-rows—————|—————  
    |—————,—————service-policy—————|—————  
    )—————►►
```

The schema is DMQXML1C or DMQXML2C.

The MQREADALLXML function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation does not remove the messages from the queue that is associated with *receive-service*.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAME repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAME repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *num-rows*

An expression that specifies the maximum number of messages to return. It must be an integer that is greater than or equal to zero.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All the columns in the table are nullable.

*Table 72. Format of the resulting table for MQREADALLXML*

Column name	Data type	Contains
MSG	DB2XML.XMLVARCHAR	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), and read using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALLXML()) T;
```

The messages and all the metadata are returned as a table.

*Example 2:* Retrieve all the messages from the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Have only the MSG and CORRELID columns of the table returned.

```
SELECT T.MSG, T.CORRELID
  FROM table (MQREADALLXML('MYSERVICE')) T;
```

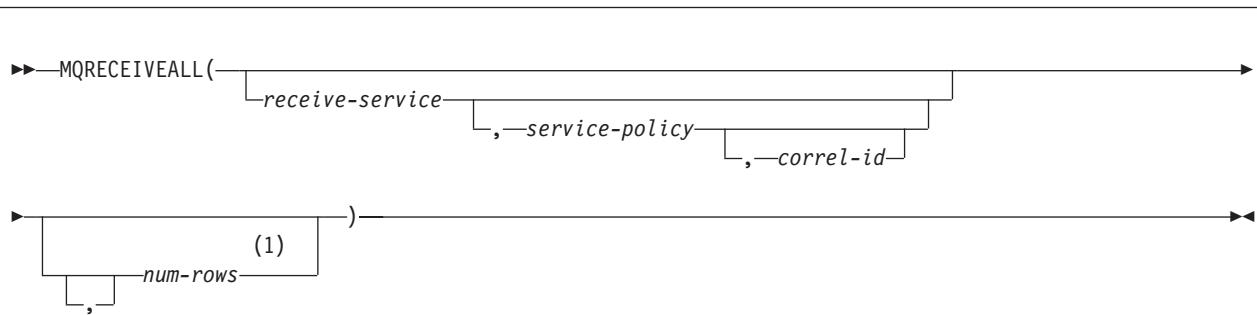

*Example 3:* Retrieve the first 10 messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQREADALLXML(10)) T;
```

The first 10 messages and all the columns are returned as a table.

## **MQRECEIVEALL**

The MQRECEIVEALL function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

### Notes:

- 1 The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ1N or DB2MQ2N.

The MQRECEIVEALL function returns a table containing the messages and message meta-data from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

*receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAME repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAME repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

*correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEALL does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

*num-rows*

An expression that specifies the maximum number of messages to return. It must be an expression that returns a built-in integer data type.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

*Table 73. Format of resulting table for MQRECEIVEALL*

Column name	Data type	Contains
MSG	VARCHAR(4000)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQRECEIVEALL()) T;
```

The messages and all the metadata are returned as a table and deleted from the queue.

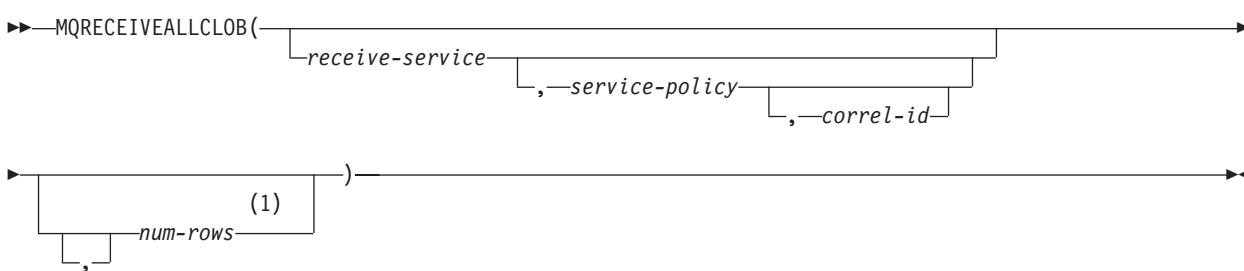

*Example 2:* Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy MYPOLICY.

```
SELECT T.MSG, T.CORRELID  
FROM TABLE (MQRECEIVEALL('MYSERVICE','MYPOLICY','1234')) T;
```

Only messages with CORRELID of '1234' and only the MSG and CORRELID columns are returned as a table and removed from the queue.

## MQRECEIVEALLCLOB

The MQRECEIVEALLCLOB function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

### Notes:

- 1 The comma is required before *num-rows* when any of the preceding arguments to the function are specified.

The schema is DB2MQ1N or DB2MQ2N.

The MQRECEIVEALLCLOB function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

#### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

#### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

*correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the correlation identifier that is associated with this message. A correlation identifier is often specified in request-and-reply scenarios to associate requests with replies. Only those messages with a matching correlation identifier are returned.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSEND, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEALLCLOB does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSEND request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

*num-rows*

An expression that specifies the maximum number of messages to return. It must be an expression that returns a built-in integer data type.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

Table 74. Format of resulting table for MQRECEIVEALLCLOB

Column name	Data type	Contains
MSG	CLOB(1M)	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

The CCSID of the result is the system CCSID that was in effect at the time that the MQSeries function was installed into DB2.

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQRECEIVEALLCLOB()) T;
```

The messages and all the metadata are returned as a table and deleted from the queue.

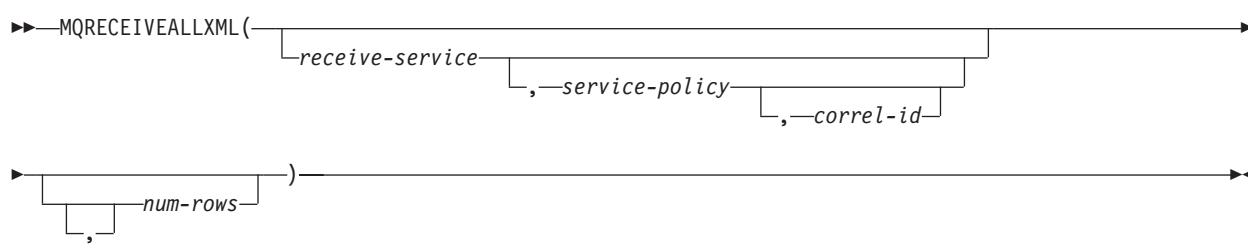

*Example 2:* Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the policy (DB2.DEFAULT.POLICY).

```
SELECT T.MSG, T.CORRELID  
  FROM TABLE (MQRECEIVEALLCLOB('MYSERVICE')) T;
```

Only the MSG and CORRELID columns are returned as a table and removed from the queue.

## MQRECEIVEALLXML

The MQRECEIVEALLXML function returns a table that contains the messages and message metadata from a specified MQSeries location and removes the messages from the queue.

The schema is DMQXML1C or DMQXML2C.

The MQRECEIVEALLXML function returns a table containing the messages and message metadata from the MQSeries location that is specified by *receive-service*, using the quality-of-service policy that is defined in *service-policy*. Performing this operation removes the messages from the queue that is associated with *receive-service*.

### *receive-service*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to a service point that is the logical MQSeries destination from which the message is read. A service point is defined in the DSNAMT repository file, and it represents a logical end-point from which a message is sent or received. A service point definition includes the name of the MQSeries queue manager and the name of the queue. See *MQSeries Application Messaging Interface* for more details.

If *receive-service* is not specified, DB2.DEFAULT.SERVICE is used.

### *service-policy*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The value of the expression must not be the null value, an empty string, or a string with trailing blanks. The expression must have an actual length that is no greater than 48 bytes. The value of the expression refers to an MQSeries AMI service policy that is used in handling this message. A service policy is defined in the DSNAMT repository file, and it specifies a set of quality-of-service options that are to be applied to this messaging operation. These options include message priority and message persistence. See *MQSeries Application Messaging Interface* for more details.

If *service-policy* is not specified, DB2.DEFAULT.POLICY is used.

### *correl-id*

An expression that returns a value that is a built-in character string or graphic string data type that is not a LOB. The expression must have an actual length that is no greater than 24 bytes. The value of the expression specifies the

correlation identifier to be associated with this message. The *correl-id* is often specified in request-and-reply scenarios to associate requests with replies.

A null value, an empty string, and a fixed length string with trailing blanks are all considered valid values. However, when the *correl-id* is specified on another request such as MQSENDXML, the *correl-id* must be specified the same to be recognized as a match. For example, specifying a value of 'test' for *correl-id* on MQRECEIVEALLXML does not match a *correl-id* value of 'test ' (with trailing blanks) specified earlier on an MQSENDXML request.

If *correl-id* is not specified, a correlation identifier is not used, and the message at the beginning of the queue is returned.

*num-rows*

An expression that specifies the maximum number of messages to return. It must be an integer that is greater than or equal to zero.

If *num-rows* is not specified or the value of expression is zero, all available messages are returned.

The result of the function is a table with the format shown in the following table. All of the columns are nullable.

*Table 75. Format of resulting table for MQRECEIVEALLXML*

Column name	Data type	Contains
MSG	DB2XML.XMLVARCHAR	The contents of the MQSeries message
CORRELID	VARCHAR(24)	The correlation ID that is used to relate messages
TOPIC	VARCHAR(40)	The topic that the message was published with, if available
QNAME	VARCHAR(48)	The name of the queue from which the message was received
MSGID	CHAR(24)	The unique, MQSeries-assigned identifier for the message
MSGFORMAT	VARCHAR(8)	The format of the message, as defined by MQSeries

*Example 1:* Retrieve all the messages from the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM TABLE (MQRECEIVEALLXML()) T;
```

The messages and all the metadata are returned as a table. The messages are deleted from the queue.

*Example 2:* Retrieve all the messages from the beginning of the queue specified by the service MYSERVICE, using the default policy (DB2.DEFAULT.POLICY). Have only the MSG and CORRELID columns returned.

```
SELECT T.MSG, T.CORRELID
  FROM TABLE (MQRECEIVEALLXML('MYSERVICE')) T;
```

The messages and the data for the CORRELID column are returned as a table. The messages are deleted from the queue.

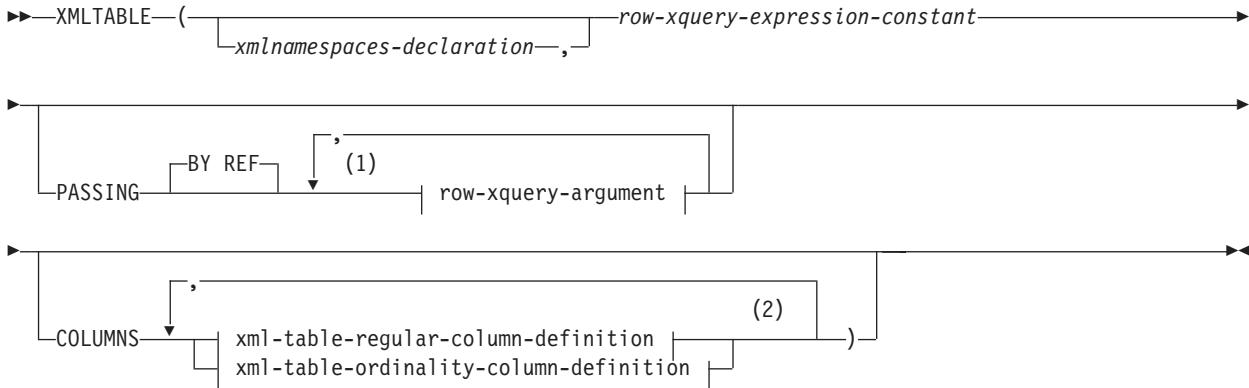

*Example 3:* Retrieve the first 10 the messages from the beginning of the queue specified by the default service (DB2.DEFAULT.SERVICE), using the default policy (DB2.DEFAULT.POLICY).

```
SELECT *
  FROM table (MQRECEIVEALLXML(10)) T;
```

The messages and all the metadata for the first 10 messages are returned as a table.  
The messages are deleted from the queue.

## XMLTABLE

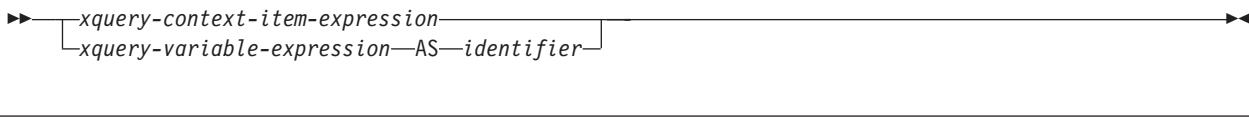

The XMLTABLE function returns a result table from the evaluation of XPath expressions, possibly by using specified input arguments as XPath variables. Each item in the result sequence of the row XPath expression represents one row of the result table.

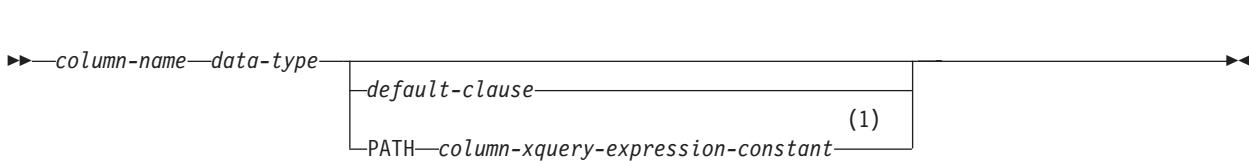

### Notes:

- 1 *xquery-context-item-expression* must not be specified more than one time.
- 2 The *xml-table-ordinality-column-definition* clause must not be specified more than one time.

## row-xquery-argument

## xml-table-regular-column-definition

### Notes:

- 1 Neither the *default-clause* or the **PATH** clause can be specified more than one time.

## xml-table-ordinality-column-definition

►►—*column-name*—FOR ORDINALITY—►►

The schema is SYSIBM. The function name cannot be specified as a qualified name.

### *xmlnamespaces-declaration*

Specifies one or more XML namespace declarations, using the XMLNAMESPACES function, that become part of the static context of the *row-xquery-expression-constant* and the *column-xquery-expression-constant*. The set of statically known namespaces for XPath expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XPath prolog within an XPath expression can override these namespaces.

If *xmlnamespaces-declaration* is not specified, only the pre-established set of statically known namespaces apply to the XPath expressions.

### *row-xquery-expression-constant*

Specifies an SQL character string constant that is interpreted as an XPath expression using supported XPath language syntax. This expression determines the number of rows in the result table. The expression is evaluated using the optional set of input XML values that is specified in *row-xquery-argument*, and returns an output XPath sequence where one row is generated for each item in the sequence. If the sequence is empty, the result of XMLTABLE is an empty table. *row-xquery-expression-constant* must not contain an empty string or a string of all blanks.

### PASSING

Specifies input values and the manner in which these values are passed to *row-xquery-expression-constant*.

#### BY REF

Specifies that any XML input arguments are, by default, passed by reference. When XML values are passed by reference, the XPath evaluation uses the input node trees, if any exist, directly from the specified input expressions and preserves all properties, including the original node identities and document order.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

### *row-xquery-argument*

Specifies an argument that is to be passed to the XPath expression specified by *row-xquery-expression-constant*. *row-xquery-argument* is an SQL expression that returns a value that is not a ROWID, LOB, DATE, TIME, TIMESTAMP, BINARY, VARBINARY, REAL, DECFLOAT, or character string with FOR BIT DATA attribute.

How *row-xquery-argument* is used in the XPath expression depends on whether the argument is specified as an *xquery-context-item-expression* or an *xquery-variable-expression*.

If the data type of *row-xquery-argument* is not XML, the result of the expression for the argument is implicitly cast to XML. A null value is converted to an XML empty sequence if the argument is *xquery-variable-expression*.

*row-xquery-argument* must not contain NEXT VALUE or PREVIOUS VALUE expressions or OLAP specifications.

*xquery-context-item-expression*

An expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-context-item-expression* must not be a character string that is bit data.

*xquery-context-item-expression* specifies the initial context item for the *row-xquery-expression*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

*xquery-variable-expression*

Specifies an SQL expression whose value is available to the XPath expression specified by *row-xquery-expression-constant* during execution. The expression must return a value that is XML, integer, decimal, or a character or graphic string that is not a LOB.

*xquery-variable-expression* specifies an argument that will be passed to *row-xquery-expression-constant* as an XPath variable. If *xquery-variable-expression* is a null value, the XPath variable is set to an XML empty sequence. The scope of the XPath variables that are created from the PASSING clause is the XPath expression specified by *row-xquery-expression-constant*.

**AS** *identifier*

Specifies that the value generated by *xquery-variable-expression* will be passed to *row-xquery-expression-constant* as an XPath variable. The variable name will be *identifier*. The leading dollar sign (\$) that precedes variable names in the XPath language is not included in *identifier*. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier.

**COLUMNS**

Specifies the output columns of the result table including the column name, data type, and how the column value is computed for each row. If this clause is not specified, a single unnamed column of data type XML is returned, with the value based on the sequence item from evaluating the XPath expression in the *row-xquery-expression-constant* (equivalent to specifying PATH '.'). To reference the result column, a *column-name* must be specified in the *correlation-clause* following the function.

*xml-table-regular-column-definition*

Specifies one output column of the result table including the column name, data type, and an XPath expression to extract the value from the sequence item for the row.

*column-name*

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

*data-type*

Specifies the data type of the column. See CREATE TABLE for the syntax and a description of types available. A *data-type* can be used in XMLTABLE if there is a supported XMLCAST from the XML data type to the specified *data-type*.

*default-clause*

Specifies a default value for the column. See CREATE TABLE for the syntax and a description of the *default-clause*. For XMLTABLE result columns, the default is applied when the processing of the XPath expression contained in *column-xquery-expression-constant* returns an empty sequence. This default value will not be inherited by declared global temporary tables even when the INCLUDING COLUMN DEFAULTS clause is specified in the definition of the declared global temporary table.

**PATH** *column-xquery-expression-constant*

Specifies an SQL character string constant that is interpreted as an XPath expression using supported XPath language syntax. The *column-xquery-expression-constant* specifies an XPath expression that determines the column value with respect to an item that is the result of evaluating the XPath expression in *row-xquery-expression-constant*. Given an item from the result of processing the *row-xquery-expression-constant* as the externally provided context item, the *column-xquery-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows.

- If the output sequence contains zero items, the *default-clause* provides the value of the column.
- If an empty sequence is returned and no *default-clause* was specified, a null value is assigned to the column.
- If a non-empty sequence is returned, the value is cast to the *data-type* specified for the column using the XMLCAST expression. An error could be returned from processing this XMLCAST.

The value for *column-xquery-expression-constant* must not be an empty string or a string of all blanks. If this clause is not specified, the default XPath expression is simply the *column-name*.

*xml-table-ordinality-column-definition*

Specifies the ordinality column of the result table.

*column-name*

Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table.

**FOR ORDINALITY**

Specifies that *column-name* is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XPath expression in *row-xquery-expression-constant*.

The result of the function is a table. The encoding scheme of the table is Unicode. If the evaluation of any of the XPath expressions results in an error, the XMLTABLE function returns the XPath error.

*Example:* List as a table result the purchase order items for orders with a status of 'NEW':

```
SELECT U."PO ID", U."Part #", U."Product Name",
       U."Quantity", U."Price", U."Order Date"
  FROM PURCHASEORDER P,
       XMLTABLE(XMLNAMESPACES('http://podemo.org' AS "pod"),
```

```
'$po/PurchaseOrder/itemlist/item' PASSING P.PORDER as "po"
COLUMNS "PO ID"          INTEGER      PATH '../@POid',
        "Part #"        CHAR(6)      PATH 'product/@pid',
        "Product Name"   CHAR(50)     PATH 'product/pod:name',
        "Quantity"       INTEGER      PATH 'quantity',
        "Price"          DECIMAL(9,2) PATH 'product/pod:price',
        "Order Date"     TIMESTAMP    PATH '../dateTime'
)
AS U
WHERE P.STATUS = 'NEW'
```

---

## Chapter 4. Queries

A *query* specifies a result table or an intermediate table. A query is a component of certain SQL statements. There are three forms of a query.

- A “[subselect](#)” on page 632
- A “[fullselect](#)” on page 662
- A “[select-statement](#)” on page 669

A subselect is a subset of a fullselect, and a fullselect is a subset of a *select-statement*.

“[Authorization](#)” on page 630 describes the privilege set that is required to use any form of a query.

Another SQL statement that can be used to retrieve at most a single row is described in “[SELECT INTO](#)” on page 1471. SELECT INTO is not a subselect, fullselect, or a *select-statement*.

---

## Authorization

For any form of a query, the privilege set that is defined below must include one of the following:

- For each table or view identified in the statement, the privilege set must include one of the following:
  - Ownership of the table or view
  - The SELECT privilege on the table or view
  - DBADM authority for the database (tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

- SYSADM authority
- SYSCTRL authority (catalog tables only)

If a query includes a user-defined function, the privileges that are held by the authorization ID of the statement must include at least one of the following:

- For each user-defined function that is identified in the statement, one of the following:
  - The EXECUTE privilege on the function
  - Ownership of the function
- SYSADM authority

If the *select-statement* is part of a DECLARE CURSOR statement, the privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

If the *select-statement* contains an SQL data change statement, the privilege set must include the SELECT privilege and the appropriate privileges for the SQL data change statement (insert, update, or delete privileges) on the target table or view.

For dynamically prepared statements, the privilege set depends on the dynamic SQL statement behavior, which is specified by option DYNAMICRULES:

### Run behavior

The privilege set is the union of the privilege sets that are held by each authorization ID of the process.

### Bind behavior

The privilege set is the privileges that are held by the authorization ID of the owner of the plan or package.

### Define behavior

The privilege set is the privileges that are held by the authorization ID of the owner of the stored procedure or user-defined function.

### Invoke behavior

The privilege set is the privileges that are held by the authorization ID of the invoker of the stored procedure or user-defined function.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.

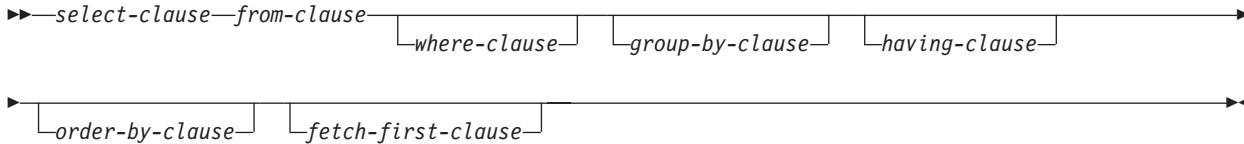

When any form of a query is used as a component of another statement, the authorization rules that apply to the query are specified in the description of that

statement. For example, see “CREATE VIEW” on page 1184 for the authorization rules that apply to the subselect component of CREATE VIEW.

If your installation uses the access control authorization exit (DSNX@XAC), that exit might be controlling the authorization rules instead of the rules that are listed here.

## subselect

The *subselect* is a component of the fullselect. A subselect specifies a result table that is derived from the tables or views that are identified in the FROM clause.

The derivation of the result table can be described as a sequence of operations in which the result of each operation is input for the next. (This is only a way of describing the subselect. The method that is used to perform the derivation might be quite different from this description. If portions of the subselect do not actually need to be executed for the correct result to be obtained, they might not be executed.)

A *scalar-subselect* is a subselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the subselect is no rows, the null value is returned. An error is returned if the result contains more than one row.

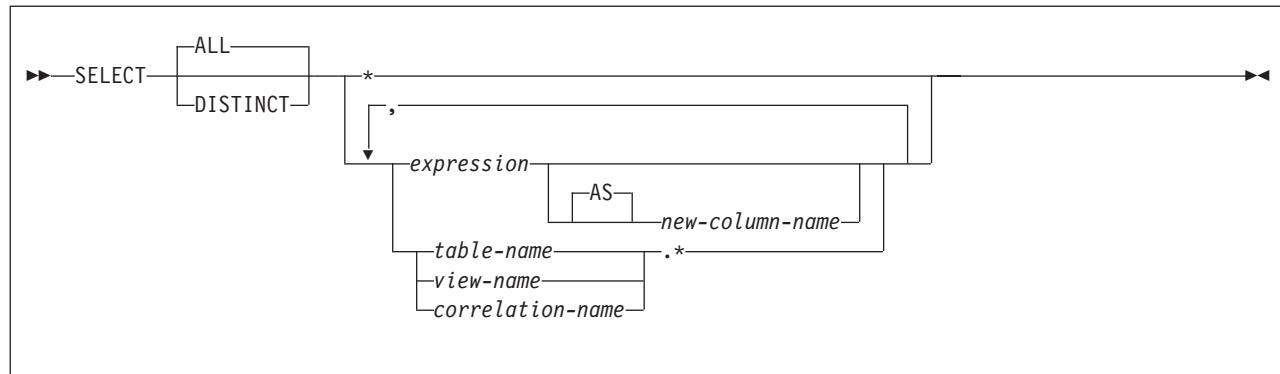

The clauses of the subselect are processed in the following sequence:

1. FROM clause
2. WHERE clause
3. GROUP BY clause
4. HAVING clause
5. SELECT clause
6. ORDER BY clause
7. FETCH FIRST clause

## select-clause

The SELECT clause specifies the columns of the final result table. The column values are produced by the application of the *select list* to R. The select list is a list of names and expressions specified in the SELECT clause, and R is the result of the previous operation of the subselect. For example, if SELECT, FROM, and WHERE are the only clauses specified, then R is the result of that WHERE clause.

### select-clause

#### ALL

Retains all rows of the final result table and does not eliminate redundant duplicates. This is the default.

#### DISTINCT

Eliminates all but one of each set of duplicate rows of the final result table.

Two rows are duplicates of one another only if each value in the first row is equal to the corresponding value in the second row. For determining duplicate rows, two null values are considered equal.

When SELECT DISTINCT is specified, no column or expression in the implicit or explicit list can return a value that is a LOB or XML data type. When a column or expression in the list returns a value that is a DECFLOAT data type and multiple bit representations of the same number exists in the intermediate result, the value that is returned is unpredictable. See "Numeric comparisons" on page 114 for additional information.

#### Select list notation:

- \* Represents a list of columns of table R, excluding any columns that are defined as implicitly hidden. The list of names is established when the statement containing the SELECT clause is prepared. Therefore, \* does not identify any columns that have been added to a table after the statement has been prepared.

A column that is defined as implicitly hidden can be explicitly referenced in the select list.

#### expression

Specifies the values of a result column. Each *column-name* in the expression must unambiguously identify a column of the intermediate result table.

**AS *new-column-name***

Names or renames the result column. The name must not be qualified and does not have to be unique. *new-column-name* is an SQL identifier of 128 UTF-8 bytes or less.

***name.\****

Represents a list of columns of *name*, excluding any columns that are defined as implicitly hidden, in the order the columns are produced by the FROM clause. *name* can be a table name, view name, or correlation name, and must designate an exposed table, view, or correlation name in the FROM clause that immediately follows the SELECT clause. The first name in the list identifies the first column of the table or view, the second name in the list identifies the second column of the table or view, and so on.

The list of names is established when the statement that contains the SELECT clause is prepared. Therefore, \* does not identify any columns that have been added to a table after the statement has been prepared.

SQL statements can be implicitly or explicitly prepared again. The effect of another prepare on statements that include \* or *name.\** is that the list of names is re-established. Therefore, the number of columns returned by the statement might change.

The number of columns in the result of SELECT is the same as the number of expressions in the operational form of the select list (that is, the list established at the time the statement is prepared), and cannot exceed 750. The result of a subquery must be a single column unless the subquery is used in an EXISTS predicate.

**If the FROM clause contains a MERGE statement:** The SELECT list must not implicitly or explicitly refer to a column that has a LOB data type, a ROWID data type (or a distinct type that is based on a LOB, or ROWID), or an XML data type.

**Implicitly hidden ROWID columns in the select list:** The result for SELECT \* does not include any implicitly hidden ROWID columns. To be included in the result, implicitly hidden ROWID columns must be explicitly specified in the select list.

**VARBINARY data:** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To query the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

**Applying the select list:** Some of the results of applying the select list to R depend on whether GROUP BY or HAVING is used. The following three lists describe the results.

**IF neither GROUP BY nor HAVING is used:**

- The select list can include aggregate functions only if it includes other aggregate functions, constants, or expressions that only involve constants.
- If the select list does not include aggregate functions, it is applied to each row of R and the result contains as many rows as there are rows in R.
- If the select list includes aggregate functions, R is the source of the arguments of the functions and the result of applying the select list is one row, even when R has no rows.

|

| **If HAVING is used and GROUP BY is not used:**

| | Each expression or *column-name* in an expression in the select list must be specified within an aggregate function. Constants or expressions that involve only constants can also be in the select list.

| | **If GROUP BY is used:**

- | | • Each expression in the select list must use one or more grouping expressions. Or, each expression or *column-name* in an expression must:
  - | – Unambiguously identify a grouping column of R.
  - | – Be specified within an aggregate function.
  - | – Be a correlated reference. (A column-name is a correlated reference if it identifies a column of a table or view identified in an outer subselect.)
- | | • If an expression in the select list is a scalar fullselect, a correlated reference from the scalar fullselect to a group R must either identify a grouping column or be contained within an aggregate function. For example, the following query fails because the correlated reference T1.C1 || T1.C2 in the select list of the scalar fullselect does not match a grouping column from the outer subselect. (Matching the grouping expression T1.C1 || T1.C2 is not supported.)

```
| | | SELECT MAX(T1.C2) AS X1,  
| | |         (SELECT T1.C1 || T1.C2 FROM T2 GROUP BY T2.C1) AS Y1  
| | |     FROM T1  
| | |     GROUP BY T1.C1, T1.C1 || T1.C2;
```

- | | | • You cannot use GROUP BY with a name defined using the AS clause unless the name is defined in a nested table expression. Example 6 demonstrates the valid use of AS and GROUP BY in a SELECT statement.

In either case, the *n*th column of the result contains the values specified by applying the *n*th expression in the operational form of the select list.

**Null attributes of result columns:** Result columns allow null values if they are derived from one of the following:

- Any aggregate function except COUNT or COUNT\_BIG
- A column that allows null values
- A view column in an outer select list that is derived from an arithmetic expression
- An arithmetic expression in an outer select list
- An arithmetic expression that allows nulls
- A scalar function or string expression that allows null values
- A host variable that has an indicator variable, or in the case of Java, a host variable or expression whose type is able to represent a Java null value
- A result of a set operator if at least one of the corresponding items in the select list is nullable

**Names of result columns:** In the following cases a result column is considered a named column:

- If the AS clause is specified, the name of the result column is the name specified on the AS clause.
- If the AS clause is not specified and a column list is specified in the correlation clause, the name of the result column is the corresponding name in the correlation column list.

- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single column (without any functions or operators), the result column name is the unqualified name of that column.
- If neither an AS clause nor a column list in the correlation clause is specified and the result column is derived only from a single SQL variable or SQL parameter (without any functions or operators), the result column name is the unqualified name of that SQL variable or SQL parameter.

In all other cases, a result column is an unnamed column.

Names of result columns are placed into the SQL descriptor area (SQLDA) when the DESCRIBE statement is executed. This allows an interactive SQL processor such as SPUFI, the command line processor, or DB2 QMF to use the column names when displaying the results. The names in the SQLDA include those specified by the AS clause.

**Data types of result columns:** Each column of the result of SELECT acquires a data type from the expression from which it is derived. Table 76 shows the data types of result columns.

*Table 76. Data types of result columns*

When the expression is...	The data type of the result column is...
The name of any numeric column	The same as the data type of the column, with the same precision and scale for decimal columns.
An integer constant	INTEGER.
A decimal or floating-point constant	The same as the data type of the constant, with the same precision and scale for decimal constants. For floating-point constants, the data type is DOUBLE PRECISION.
A decimal floating point constant	DECFLOAT(34)
The name of any numeric host variable	The same as the data type of the variable, with the same precision and scale for decimal variables. The result is decimal if the data type of the host variable is not an SQL data type; for example, DISPLAY SIGN LEADING SEPARATE in COBOL.
An arithmetic or string expression	The same as the data type of the result, with the same precision and scale for decimal results as described in “Expressions” on page 180.
Any function	The data type of the result of the function. For a built-in function, see Chapter 3, “Functions,” on page 259 to determine the data type of the result. For a user-defined function, the data type of the result is what was defined in the CREATE FUNCTION statement for the function.
The name of any string column	The same as the data type of the column, with the same length attribute.
The name of any string host variable	The same as the data type of the variable, with a length attribute equal to the length of the variable. The result is a varying-length character string if the data type of the host variable is not an SQL data type; for example, a NUL-terminated string in C.
A character string constant of length $n$	VARCHAR( $n$ ).
A binary string constant of length $n$	VARBINARY( $n$ )
A graphic string constant of length $n$	VARGRAPHIC( $n$ ).
The name of a datetime column	The same as the data type of the column.
The name of a ROWID column	Row ID.

*Table 76. Data types of result columns (continued)*

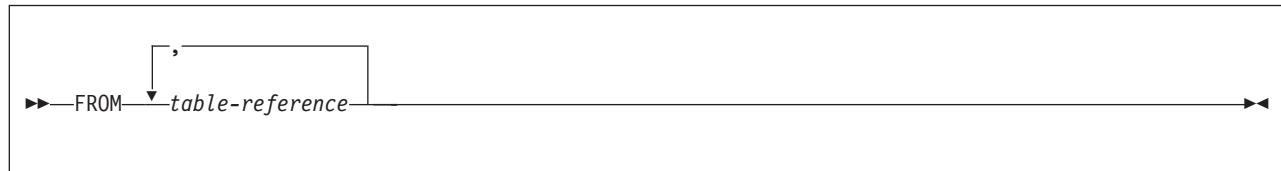

<b>When the expression is...</b>	<b>The data type of the result column is...</b>
The name of a distinct type column	The same as the distinct type of the column, with the same length, precision, and scale attributes, if any.

For information about the CCSID of the result column, see “Rules for result data types” on page 119.

## **from-clause**

The FROM clause specifies an intermediate result table.

### **from-clause**

If only one *table-reference* is specified, the intermediate result table is simply the result of that *table-reference*. If more than one *table-reference* is specified, the intermediate result table consists of all possible combinations of the rows of the result of each specified *table-reference*.

Each row of the result is a row from the result of the first *table-reference* concatenated with a row from the result of the second *table-reference*, concatenated with a row from the result of the third *table-reference*, and so on. The number of rows in the result is the product of the number of rows in the result of each *table-reference*. Thus, if the result of any *table-reference* is empty, the result is empty.

If a *table-reference* contains a security label column, DB2 compares the security label of the user to the security label of each row. Results are returned according to the following rules:

- If the security label of the user dominates the security label of the row, DB2 returns the row.
- If the security label of the user does not dominate the security label of the row, DB2 does not return the data from that row, and DB2 does not generate an error report.

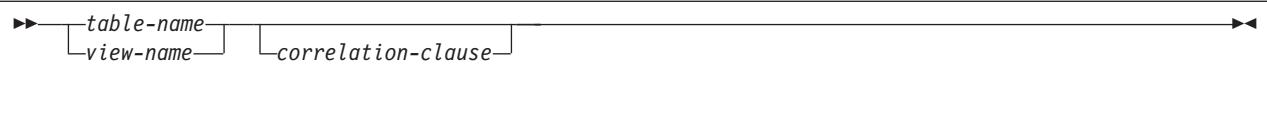

## **table-reference**

A *table-reference* specifies a result table as either a table or view, or an intermediate table.

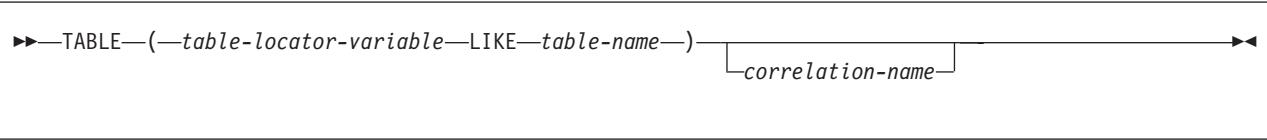

### **table-reference:**

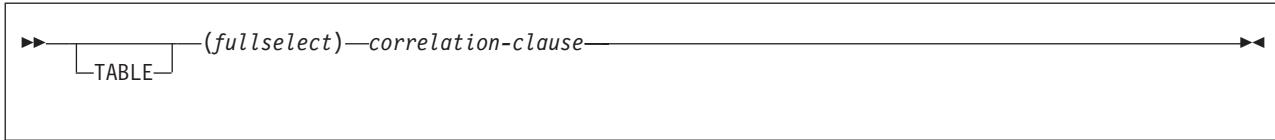

**single-table:**

## table-locator-reference:

### **nested-table-expression:**

## table-function-reference:

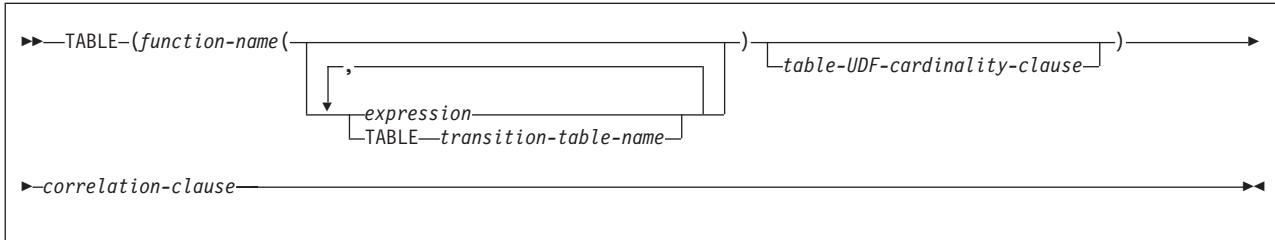

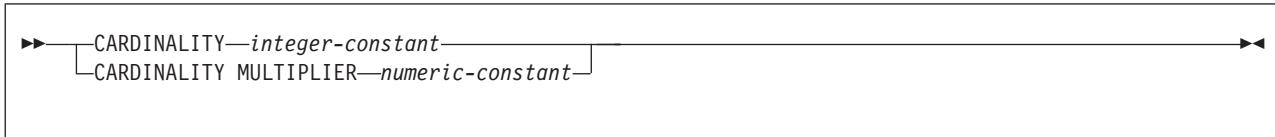

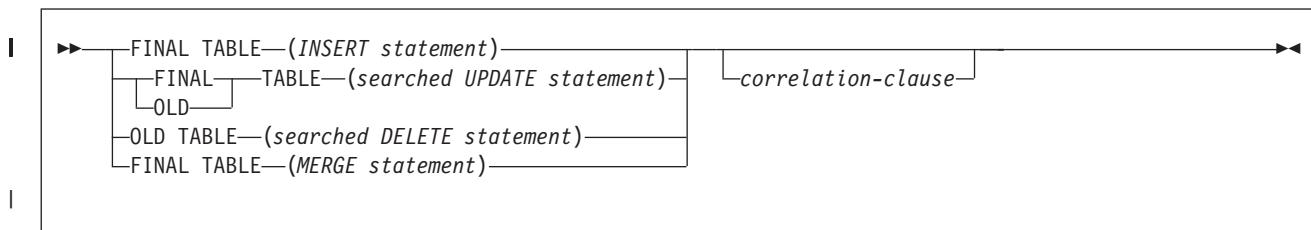

table-UDF-cardinality-clause:

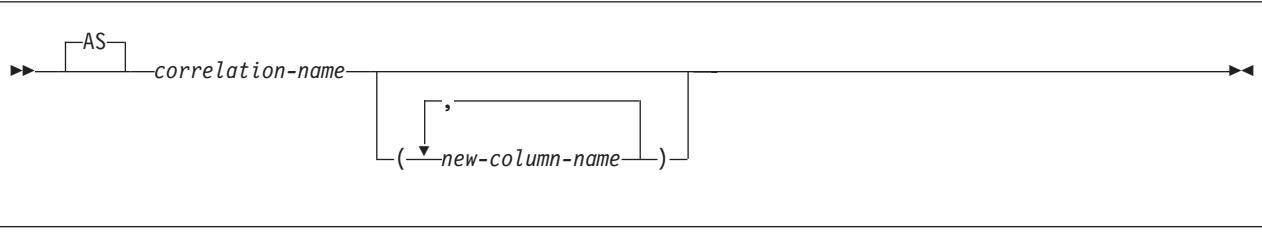

## **data-change-table-reference:**

## xmltable-expression:

►►—xmltable-function—correlation clause—►►

**correlation-clause:**

- If a single table or view is identified, the result table is simply that table or view.
- If a table locator is identified, the host variable represents the intermediate table. The intermediate table has the same structure as the table identified in *table-name*.

Each *table-name* or *view-name* specified in every **FROM** clause of the same SQL statement must identify a table or view that exists at the same DB2 subsystem. If a **FROM** clause is specified in a subquery of a basic predicate, a view that includes **GROUP BY** or **HAVING** must not be identified.

A *table-reference* must not identify a table that was implicitly created for an XML column.

**table-locator-reference**

Each *table-locator-variable* must specify a host variable with a table locator type. The only way to assign a value to a table locator is to pass the old or new transition table of a trigger to a user-defined function or stored procedure. A table locator host variable must not have a null indicator and must not be a parameter marker. In addition, a table locator can be used only in a manipulative SQL statement.

**nested-table-expression**

A *fullselect* in parentheses is called a *nested table expression*. If a nested table expression is specified, the result table is the result of that *nested-table-expression*. The columns of the result do not need unique names, but a column with a non-unique name cannot be referenced. At any time, the table consists of the rows that would result if the *fullselect* were executed.

**table-function-reference**

If a *function-name* is specified, the result table is the set of rows returned by the table function.

Each *function-name*, together with the types of its arguments, must resolve to a table function that exists at the same DB2 subsystem. An algorithm called function resolution, which is described in “Function resolution” on page 175, uses the function name and the arguments to determine the exact function to use. Unless given column names in the *correlation-clause*, the column names for a table function are those specified on the **RETURNS** clause of the **CREATE FUNCTION** statement. This is analogous to the column names of a table, which are defined in the **CREATE TABLE**.

**table-UDF-cardinality-clause**

The *table-UDF-cardinality clause* can be specified to each user-defined table function reference within the table spec of the **FROM** clause in a subselect.

This option indicates the expected number of rows to be returned only for the SELECT statement that contains it.

**CARDINALITY** *integer-constant* specifies an estimate of the expected number of rows returned by the reference to the user-defined function. The value of *integer-constant* must range from 0 to 2147483647.

The value set in the CARDINALITY field of SYSIBM.SYSROUTINES for the table function name is used as the reference cardinality value. The product of the specified **CARDINALITY MULTIPLIER** *numeric-constant* and the reference cardinality value are used by DB2 as the expected number of rows returned by the table function reference.

In this case, the *numeric-constant* can be in the integer, decimal, or floating-point format. The value must be greater than or equal to zero. If the decimal number notation is used, the number of digits can be up to 31. An integer value is treated as a decimal number with no fraction. The maximum value allowed for a floating-point number is about 7.237E + 75. If no value has been set in the CARDINALITY field of SYSIBM.SYSROUTINES, its default value is used as the reference cardinality value. If zero is specified or the computed cardinality is less than 1, DB2 assumes that the cardinality of the reference to the user-defined table function is 1.

Only a numeric constant can follow the keyword **CARDINALITY** or **CARDINALITY MULTIPLIER**. No host variable or parameter marker is allowed in a cardinality option. Specifying a cardinality option in a table function reference does not change the corresponding CARDINALITY field in SYSIBM.SYSROUTINES. The CARDINALITY field value in SYSIBM.SYSROUTINES can be initialized by the **CARDINALITY** option in the CREATE FUNCTION (external table) statement when a user-defined table function is created. It can be changed by the **CARDINALITY** option in the ALTER FUNCTION statement or by a direct update operation to SYSIBM.SYSROUTINES.

#### *data-change-table-reference*

A *data-change-table-reference* clause specifies an intermediate result table. This table is based on the rows that are directly changed by the SQL data change statement that is included in the clause. A *data-change-table-reference* can only be specified as the only *table-reference* in the FROM clause of the outer fullselect that is used in a select-statement and that fullselect must be in a subselect, or a SELECT INTO statement. A *data-change-table-reference* in a SELECT statement of a cursor makes the cursor read only. The target table or view of the SQL data change statement is a table or view that is reference in the query. The privileges that are held by the authorization ID of the statement must include the SELECT privilege on that target table or view.

Expressions in the select list of a view in a table reference can only be selected if OLD TABLE is specified or if the expression does not include any of the following objects:

- a function that is defined to read or modify SQL data
- a function that is defined as not deterministic or has an external action
- a NEXT VALUE expression for a sequence

#### **FINAL TABLE**

Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement as they appear at the completion of the SQL data change statement. If there are AFTER triggers that result in further operations on the table that is the target of

the SQL data change statement, an error is returned. If the target of the SQL data change statement is a view that is defined with an INSTEAD OF trigger for the type of data change, an error is returned.

#### **OLD TABLE**

The rows of the intermediate result table represent the set of affected rows as they exist prior to the application of the SQL data change statement. If OLD TABLE is specified, the select list cannot contain an XML column.

#### *INSERT statement*

Specifies an INSERT statement as described in “[INSERT](#)” on page 1367. A fullselect in the INSERT statement cannot contain correlated references to columns that are outside of the fullselect of the INSERT statement. The target of the INSERT statement must be a base table, a view that is defined with the **WITH CASCDED CHECK** clause, or a view where the view definition has no **WHERE** clause. If there are input variables elsewhere in the fullselect, the INSERT statement cannot be a multiple row not atomic insert, or a multiple row atomic insert that specifies the **USING DESCRIPTOR** clause.

#### *MERGE statement*

Specifies a MERGE statement as described in “[MERGE](#)” on page 1388. A table reference in the MERGE statement must not contain correlated references to columns that are outside of the table reference in the MERGE statement.

If the MERGE statement is used in the SELECT statement and the MERGE statement references a view, the view must be defined using the **WITH CASCDED CHECK OPTION** clause.

The target table or view of the MERGE statement must not have a column with a ROWID, LOB, or XML data type.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

#### *searched UPDATE statement*

Specifies a searched UPDATE statement as described in “[UPDATE](#)” on page 1521. A WHERE clause or a SET clause in the UPDATE statement cannot contain correlated references to columns that are outside of the UPDATE statement. The target of the UPDATE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched UPDATE statement is used in the SELECT statement and the UPDATE statement references a view, the view must be defined using the **WITH CASCDED CHECK OPTION** clause.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

#### *searched DELETE statement*

Specifies a searched DELETE statement as described in “[DELETE](#)” on page 1224. A WHERE clause in the DELETE statement cannot contain correlated references to columns that are outside of the DELETE statement. The target of the DELETE statement must be a base table, a symmetric view, or a view where the view definition has no WHERE clause.

If the searched DELETE statement is used in the SELECT statement and the DELETE statement references a view, the view must be defined using the **WITH CASCDED CHECK OPTION** clause.

AFTER triggers that result in further operations on the target table cannot exist on the target table.

The content of the intermediate result table for a table reference that contains an SQL data change statement is determined when the cursor is opened. The intermediate result table includes a column for each of the columns of the target table (including implicitly hidden columns) or view. All of the columns of the target table or view of an SQL data change statement are accessible by using the names of the columns from the target table or view unless the columns are renamed by using the correlation clause. If a *correlation-name* is not specified, the column names can be qualified by the target table or view name of the SQL data change statement. If an INCLUDE clause is specified as part of the SQL data change statement, the intermediate result table will contain these additional columns.

#### *joined-table*

If a *joined-table* is specified, the result table is the result of one or more join operations as explained in “joined-table” on page 645.

#### *correlation-clause*

Each *correlation-name* in a *correlation-clause* defines a designator for the immediately preceding result table (*table-name*, *view-name*, *nested-table-expression*, or *function-name* reference), which can be used to qualify references to the columns of the table. *new-column-names* is an SQL identifier of 128 UTF-8 bytes or less. Using *new-column-names* to list and rename the columns is optional. A correlation name must be specified for nested table expressions and references to table functions.

If no *correlation-name* is specified for *data-change-table-references*, the *correlation-name* is the name of the target table or view of the SQL data change statement. Otherwise, the correlation name is the *correlation-name*.

If a list of *new-column-names* is specified in a *correlation-clause*, the number of names must be the same as the number of columns in the corresponding table, view, nested table expression, or table function. Each name must be unique and unqualified. If columns are added to an underlying table of a *table-reference*, the number of columns in the result of the *table-reference* no longer matches the number of names in its *correlation-clause*. Therefore, when a rebind of a package containing the query in question is attempted, DB2 returns an error and the rebind fails. At that point, change the *correlation-clause* of the embedded SQL statement in the application program so that the number of names matches the number of columns. Then, precompile, compile, bind, and link-edit the modified program.

An exposed name is a *correlation-name* or a *table-name* or view name that is not followed by a *correlation-name*. The exposed names in a FROM clause should be unique, and only exposed names should be used as qualifiers of column names. Thus, if the same table name is specified twice, at least one specification of the table name should be followed by a unique correlation name. That correlation name should be used to qualify references to columns of that instance of the table. In addition, if column names are listed for the correlation name in the FROM clause, those column names should be used to reference the columns. For more information, see “Column name qualifiers in correlated references” on page 157.

#### *xmltable-function*

Specifies an invocation of the built-in XMLTABLE function. See “XMLTABLE” on page 624 for more information.

**Correlated references in *table-references*:** In general, nested table expressions and table functions can be specified in any FROM clause. Columns from the nested table expressions and table functions can be referenced in the select list and in the rest of the fullselect using the correlation name. The scope of this correlation name is the same as correlation names for other table or view names in the FROM clause. The basic rule that applies for both these cases is that the correlated reference must be from a *table-reference* at a higher level in the hierarchy of subqueries.

Nested table expressions can be used in place of a view to avoid creating a view when general use of the view is not required. They can also be used when the desired result table is based on host variables.

For table functions, an additional capability exists. A table function can contain one or more correlated references to other tables in the same FROM clause if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause. The same capability exists for nested table expressions if the optional keyword TABLE is specified; otherwise, only references to higher levels in the hierarchy of subqueries is allowed.

A nested table expression or table function that contains correlated references to other tables in the same FROM clause:

- Cannot participate in a FULL OUTER JOIN or a RIGHT OUTER JOIN
- Can participate in LEFT OUTER JOIN or an INNER JOIN if the referenced tables precede the reference in the left-to-right order of the tables in the FROM clause

The following table shows some examples of valid and invalid correlated references. TABF1 and TABF2 represent table functions.

Table 77. Examples of correlated references

Subselect	Valid	Reason
<pre>SELECT T.C1, Z.C5 FROM TABLE( TABF1(T.C2) ) AS Z, T WHERE T.C3 = Z.C4;</pre>	No	T.C2 cannot be resolved because T does not precede TABF1 in FROM
<pre>SELECT T.C1, Z.C5 FROM T, TABLE( TABF1(T.C2) ) AS Z WHERE T.C3 = Z.C4;</pre>	Yes	T precedes TABF1 in FROM, making T.C2 known
<pre>SELECT A.C1, B.C5 FROM TABLE( TABF2(B.C2) ) AS A,       TABLE( TABF1(A.C6) ) AS B WHERE A.C3 = B.C4;</pre>	No	B in B.C2 cannot be resolved because the table function that would resolve it, TABF1, follows its reference in TABF2 in FROM
<pre>SELECT D.DEPTNO, D.DEPTNAME,       EMPINFO.AVGSA, EMPINFO.EmpCount FROM DEPT D,       (SELECT AVG(E.SALARY) AS AVGSA,               COUNT(*) AS EmpCount        FROM EMP E        WHERE E.WORKDEPT = D.DEPTNO)       AS EMPINFO;</pre>	No	DEPT precedes nested table expression, but keyword TABLE is not specified, making D.DEPTNO unknown

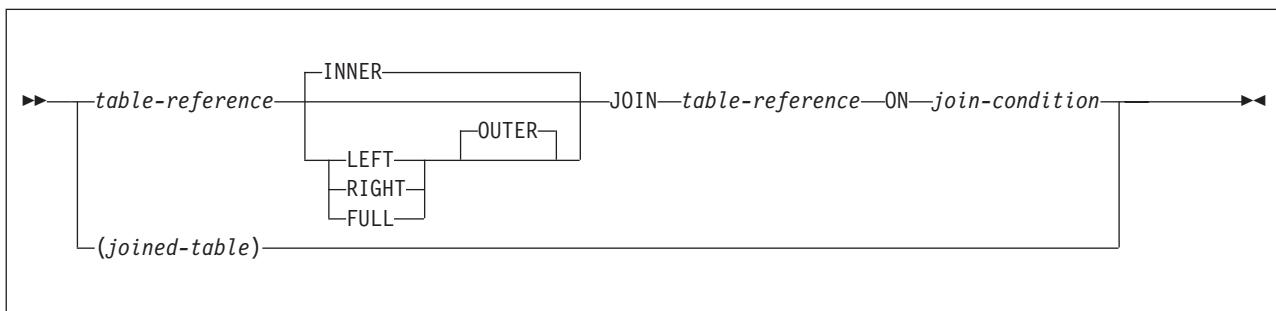

Table 77. Examples of correlated references (continued)

Subselect	Valid	Reason
<pre>SELECT D.DEPTNO, D.DEPTNAME,        EMPINFO.AVGSAL, EMPINFO.EmpCount   FROM DEPT D,        TABLE (SELECT AVG(E.Salary) AS AVGSAL,                     COUNT(*) AS EmpCount                FROM EMP E               WHERE E.WorkDept = D.DeptNo)       AS EMPINFO;</pre>	Yes	DEPT precedes nested table expression and keyword TABLE is specified, making D.DEPTNO known

### joined-table

A *joined-table* specifies a result table that is the result of either an inner equi-join or an outer join. The table is derived by applying one of the join-operators: INNER, RIGHT OUTER, LEFT OUTER, or FULL OUTER to its operands. If a join-operator is not specified, INNER is implicit. The order in which a LEFT OUTER JOIN or RIGHT OUTER JOIN is performed can affect the result.

#### joined-table

As described in more detail under “Join operations” on page 647 an inner join combines each row of the left table with every row of the right table keeping only the rows where the join-condition is true. Thus, the result table might be missing rows from either or both of the joined tables. Outer joins include the rows produced by the inner join as well as the missing rows, depending on the type of outer join as follows:

*Left outer*. Includes the rows from the left table that were missing from the inner join.

*Right Outer*. Includes the rows from the right table that were missing from the inner join.

*Full Outer*. Includes the rows from both tables that were missing from the inner join.

A *joined-table* can be used in any context in which any form of the SELECT statement is used. Both a view and a cursor is read-only if its SELECT statement includes a *joined-table*. If LEFT OUTER JOIN, RIGHT OUTER JOIN, or FULL OUTER JOIN is specified, the RID built-in function and the ROW CHANGE expression must not be specified in the subselect that contains the FROM clause.

## **join-condition**

*join-condition* specifies the conditions of a join that is used in a query.

### **join-condition**

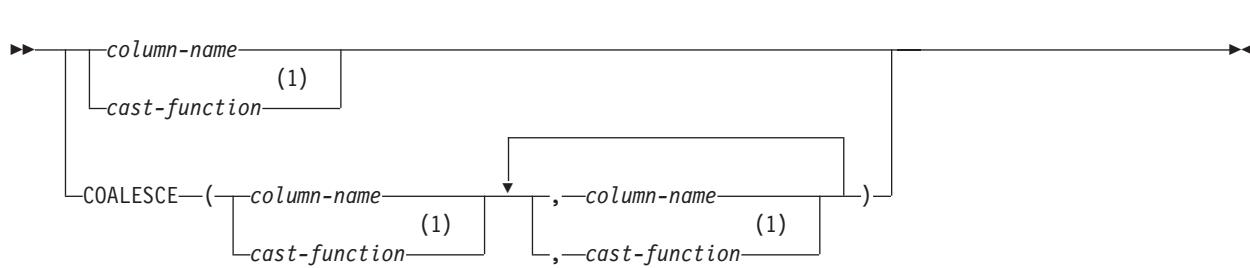

For INNER, LEFT OUTER, and RIGHT OUTER joins:

For FULL OUTER joins:

### **full-join-expression:**

#### **Notes:**

- 1    *cast-function* must only contain a column and the casting data type must be a distinct type or the data type upon which the distinct type was based.

For INNER, LEFT OUTER, and RIGHT OUTER joins, the *join-condition* is a *search-condition* that must conform to these rules:

- With one exception, It cannot contain any subqueries. If the *join-table* that contains the *join-condition* in the associated FROM clause is composed of only INNER joins, the *join-condition* can contain subqueries.
- Any column that is referenced in an expression of the *join-condition* must be a column of one of the operand tables of the associated join operator (in the scope of the same *joined-table* clause).

For a FULL OUTER (or FULL) join, the *join-condition* is a search condition in which the predicates can only be combined with AND. In addition, each predicate must have the form 'expression = expression', where one expression references only columns of one of the operand tables of the associated join operator, and the other expression references only columns of the other operand table. The values of the expressions must be comparable.

Each *full-join-expression* in a FULL OUTER join must include a column name or a cast function that references a column. The COALESCE function is allowed.

For any type of join, column references in an expression of the *join-condition* are resolved using the rules for resolution of column name qualifiers specified in "Resolution of column name qualifiers and column names" on page 158 before any rules about which tables the columns must belong to are applied.

## Join operations

A *join-condition* specifies pairings of T1 and T2, where T1 and T2 are the left and right operand tables of its associated JOIN operator. For all possible combinations of rows T1 and T2, a row of T1 is paired with a row of T2 if the join-condition is true. When a row of T1 is joined with a row of T2, a row in the result consists of the values of that row of T1 concatenated with the values of that row of T2. The execution might involve the generation of a "null row". The null row of a table consists of a null value for each column of the table, regardless of whether the columns allow null values.

The following summarizes the results of the join operations:

- The result of T1 INNER JOIN T2 consists of their paired rows.
- The result of T1 LEFT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2. All columns derived from T2 allow null values.
- The result of T1 RIGHT OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1. All columns derived from T1 allow null values.
- The result of T1 FULL OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T1, the concatenation of that row with the null row of T2, and for each unpaired row of T2, the concatenation of that row with the null row in T1. All columns of the result table allow null values.

A join operation is part of a FROM clause; therefore, for the purpose of predicting which rows will be returned from a SELECT statement containing a join operation, assume that the join operation is performed before the other clauses in the statement.

## **where-clause**

The WHERE clause specifies a result table that consists of those rows of R for which the search condition is true. R is the result of the FROM clause of the subselect.

### **where-clause**

```
►►—WHERE—search-condition—►►
```

The search condition must conform to the following rules:

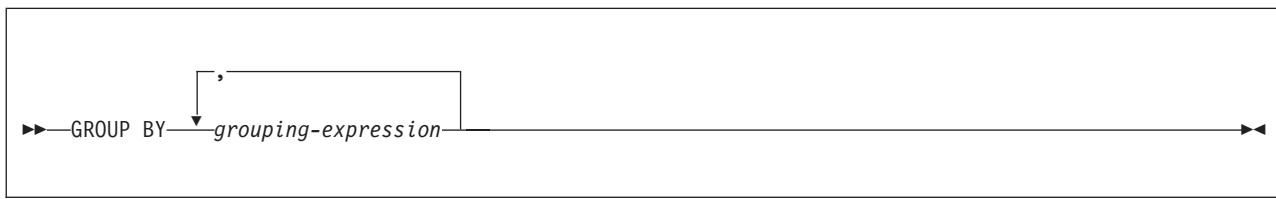

- Each column name must unambiguously identify a column of R or be a correlated reference. A column name is a correlated reference if it identifies a column of a table or view that is identified in an outer subselect.
- An aggregate function must not be specified unless the WHERE clause is specified in a subquery of a HAVING clause and the argument of the function is a correlated reference to a group.

Any subquery in the *search-condition* is effectively executed for each row of R and the results are used in the application of the *search-condition* to the given row of R. A subquery is actually executed for each row of R only if it includes a correlated reference. In fact, a subquery with no correlated references is executed just one time, whereas a subquery with a correlated reference might have to be executed one time for each row.

## group-by-clause

The GROUP BY clause specifies a result table that consists of a grouping of the rows of intermediate result table that is the result of the previous clause.

### group-by-clause

*grouping-expression* is an expression that defines the grouping of R. The following restrictions apply to *grouping-expression*:

- If *grouping-expression* is a single column, the column name must unambiguously identify a column of R.
- The result of *grouping-expression* cannot be a LOB data type (or a distinct type that is based on a LOB) or an XML data type.
- *grouping-expression* cannot include any of the following items:
  - A correlated column
  - A host variable
  - An aggregate function
  - Any function or expression that is not deterministic or that is defined to have an external action
  - A scalar fullselect
  - A CASE expression whose *searched-when-clause* contains a quantified predicate, an IN predicate using a fullselect, or an EXISTS predicate

The result of GROUP BY is a set of groups of rows. In each group of more than one row, all values of each *grouping-expression* are equal, and all rows with the same set of values of the *grouping-expression* are in the same group. For grouping, all null values for a *grouping-expression* are considered equal.

If a *grouping-expression* contains DECFLOAT values, the DECFLOAT values with the same value will be in the same group. But the number of digits returned for each group is unpredictable.

Because every row of a group contains the same value of any *grouping-expression*, *grouping-expression* can be used in a search condition in a HAVING clause or an expression in a SELECT clause, or in a *sort-key-expression* of an ORDER BY clause. In each case, the reference specifies only one value for each group. For example, if *grouping-expression* is col1+col2, col1+col2+3 would be an allowed expression in the select list. Associative rules for expressions do not allow the similar expression of 3+col1+col2, unless parentheses are used to ensure that the corresponding expression is evaluated in the same order. Thus, 3+(col1+col2) would also be allowed in the select list. If the concatenation operator is used, *grouping-expression* must be used exactly as the expression was specified in the select list.

If a *grouping-expression* contains varying-length strings with trailing blanks, the values in the group can differ in the number of trailing blanks and might not all

have the same length. In that case, a reference to *grouping-expression* still specifies only one value for each group, but the value for a group is chosen arbitrarily from the available set of values. Thus, the actual length of the result value is unpredictable.

## having-clause

The HAVING clause specifies a result table that consists of those groups of the intermediate result table for which the search-condition is true. The intermediate result table is the result of the previous clause. If this clause is not GROUP BY, the intermediate result table is considered a single group with no grouping columns of the previous clause of the subselect.

### having-clause

►►—HAVING—*search-condition*—►►

Each *column-name* in *search-condition* must be one of the following:

- Unambiguously identify a grouping column of the intermediate result table
- Be specified within an aggregate function<sup>22</sup>
- Be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a table, view, *common-table-expression*, or *nested-table-expression* that is identified in an outer subselect

A group of the intermediate result table to which the search condition is applied supplies the argument for each function in the search condition, except for any function whose argument is a correlated reference.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a group of the intermediate result table, and the results used in applying the search condition. In actuality, the subquery is executed for each group only if it contains a correlated reference. For an illustration of the difference, see Example 4 and Example 5 in “Examples of subselects” on page 657 below.

A correlated reference to a group of the intermediate result table must either identify a grouping column or be contained within an aggregate function.

When HAVING is used without GROUP BY, any expression or column name in the select list must appear within an aggregate function.

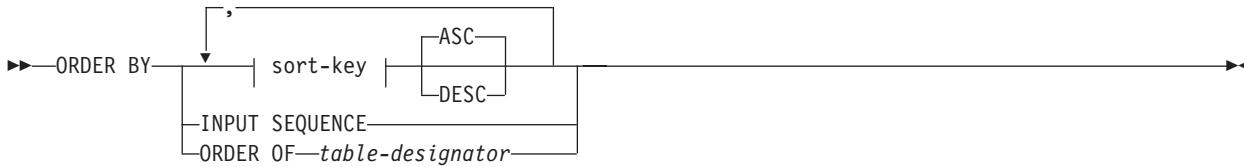

The RID built-in function and the ROW CHANGE expression cannot be specified in a HAVING clause unless they are within an aggregate function.

22. See Chapter 3, “Functions,” on page 259 for restrictions that apply to the use of aggregate functions.

## order-by-clause

The ORDER BY clause specifies an ordering of the rows of the result table.

### order-by-clause

### sort-key:

A subselect that contains an ORDER BY clause cannot be specified in the outermost fullselect of a view

If the subselect is not enclosed within parentheses and is not the outermost fullselect, the ORDER BY clause cannot be specified. The ORDER BY clause cannot be used in an outermost fullselect that contains a FOR UPDATE clause.

An ORDER BY clause that is specified in a subselect only effects the order of the rows that returned by the query if the subselect is the outermost fullselect, except when a nested subselect includes an ORDER BY clause and the outermost fullselect specifies that the ordering of the rows should be retained (by using the ORDER OF *table-designator* clause).

Multiple ORDER BY clauses can be specified in the same subselect if each clause is separated with parentheses.

#### INPUT SEQUENCE

Indicates that the result table reflects the input order of the rows specified in the VALUES clause of an INSERT statement. INPUT SEQUENCE ordering can be specified only when an INSERT statement is specified in a *from-clause*.

#### ORDER OF *table-designator*

Specifies that the same ordering of the rows for the result table that is designated by *table-designator* should be applied to the result table of the subselect (or fullselect) that contains the ORDER OF specification. There must be a table reference in the FROM clause of the subselect (or fullselect) that specifies this clause and matches *table-designator*.

*sort-key*

A *column-name*, *integer*, or *sort-key-expression* that specifies the value that is to be used to order the rows of the subselect.

If a single *sort-key* is identified, the rows are ordered by the values of that *sort-key*. If more than one *sort-key* is identified, the rows are ordered by the values of the first *sort-key*, then by the values of the second *sort-key*, and so on. A *sort-key* cannot be a LOB or XML expression.

The result table can be ordered by a named column in the select list by specifying a *sort-key* that is an integer or the column name. The result table can be ordered by an unnamed column in the select list by specifying a *sort-key* that is an integer or, in some cases, by a *sort-key-expression* that matches the expression in the select list.

*column-name*

An identifier that usually identifies a column of the result table. In this case, *column-name* must be the name of a named column in the select list. If the *fullselect* includes a set operator, the column name cannot be qualified.

If the query is a *subselect*, the *column-name* can also identify a column name of a table, view, or nested table expression identified in the FROM clause, including a column that is defined as implicitly hidden. The subselect must not include any of the following:

- DISTINCT in the select list
- Aggregate functions in the select list
- GROUP BY clause

*integer*

Must be greater than 0 and not greater than the number of columns in the result table. The integer *n* identifies the *n*th column of the result table.

*sort-key-expression*

Specifies an expression with operators (that is, not simply a *column-name* or *integer*). The query to which ordering is applied must be a *subselect* to use this form of the *sort-key*.

The *sort-key-expression* cannot include an expression that is not deterministic or a function that is defined to have an external action except for the RID built-in function and the ROW CHANGE expression. Any column name in the expression must conform to the rules described Column names in sort keys. If *sort-key-expression* includes an aggregate function, the input arguments to that function must not reference a named column in the select list that is derived from an aggregate function. An expression cannot be specified if DISTINCT is used in the select list of the *subselect*.

If the *subselect* is grouped, the *sort-key-expression* might or might not be in the select list of the *subselect*. When *sort-key-expression* is not in the select list the following rules apply:

- Each expression in the ORDER BY clause must either:
  - Use one or more grouping expressions
  - Use a column name that either unambiguously identifies a grouping column of R or is specified within a aggregate function.
- Each expression in the ORDER BY clause must not contain a scalar fullselect.

**ASC**

Uses the values of the *sort-key* in ascending order.

ASC is the default.

**DESC**

Uses the values of the *sort-key* in descending order.

Ordering is performed in accordance with the comparison rules described in Chapter 2, “Language elements,” on page 47, beginning on page “Numeric comparisons” on page 114. The null value is higher than all other values. If your ordering specification does not determine a complete ordering, rows with duplicate values of the last identified *sort-key* have an arbitrary order. If you do not specify ORDER BY, the rows of the result table have an arbitrary order.

**Column names in sort keys:** A column name in a *sort-key* must conform to the following rules:

- If the column name is qualified, the query must be a *subselect*. The column name must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect; its value is used to compute the value of the sort specification.
- If the column name is unqualified and the query is a *subselect*:
  - If the column name is identical to the name of more than one column of the result table, the column name must unambiguously identify a column of some table, view, or nested table expression in the FROM clause of the ordering subselect.
  - If the column name is identical to one column of the result table, its value is used to compute the value of the sort specification.
  - If the column name is not identical to a column in the result table, it must unambiguously identify a column of a table, view, or nested table expression in the FROM clause of the subselect. If the column name is identical to one column of a table, view, or nested table expression in the FROM clause of the subselect, its value is used to compute the value of the sort specification.

## fetch-first-clause

The **FETCH FIRST** clause limits the number of rows that can be fetched. It improves the performance of queries with potentially large result tables when only a limited number of rows are needed.

### fetch-first-clause

The **FETCH FIRST** clause sets a maximum number of rows that can be retrieved. **FETCH FIRST** specifies that only *integer* rows should be made available to be retrieved, regardless of how many rows there might be in the result table when this clause is not specified. An attempt to fetch beyond *integer* rows is handled the same way as normal end of data. The value of *integer* must be a positive integer (not zero). The default is 1.

The **FETCH FIRST** clause specifies an ordering of the rows of the result table. A subselect that contains a **FETCH FIRST** clause cannot be specified in the following objects:

- The outermost fullselect of a view
- The definition of a materialized query table

Limiting the result table to the first *n* rows can improve performance. The DB2 system will cease processing the query when it has determined the first *n* rows. If both the **FETCH FIRST** clause and the **OPTIMIZE FOR** clause are specified, the lower of the *integer* values from these clause will be used to influence the buffer size. The values are considered independently for optimization purposes. If the **OPTIMIZE FOR** clause is not specified, a default of **OPTIMIZE FOR integer ROWS**, where *integer* is the value that is specified in the **FETCH FIRST** clause, is assumed. The DB2 system uses this value for access path optimization.

Specification of the **FETCH FIRST** clause in an outermost fullselect makes the result table read-only. A read-only result table must not be referenced in an **UPDATE**, **MERGE**, or **DELETE** statement. The **FETCH FIRST** clause cannot be used in an outermost fullselect that contains a **FOR UPDATE** clause.

If the **FETCH FIRST** clause is specified in a subselect, and the subselect is not the outermost fullselect, the subselect must be enclosed in parentheses.

If both the **FETCH FIRST** clause and the **ORDER BY** clause are specified, the ordering is performed on the entire result table prior to returning the first *n* rows.

Multiple **FETCH FIRST** clauses can be specified in the same subselect if each clause is separated with parentheses.

If the **FETCH FIRST** clause is specified in the outermost fullselect of a **SELECT** statement that contains a data change statement (an **INSERT**, **DELETE**, **UPDATE**,

| or MERGE statement), all rows are processed by the specified data change  
| statement, but only the number of rows that is specified in the FETCH FIRST  
| clause are returned in the final result table.

## Examples of subselects

Examples of subselects can illustrate how to use the various clauses of the subselect to construct queries.

*Example 1:* Show all rows of the table DSN8910.EMP.

```
SELECT * FROM DSN8910.EMP;
```

*Example 2:* Show the job code, maximum salary, and minimum salary for each group of rows of DSN8910.EMP with the same job code, but only for groups with more than one row and with a maximum salary greater than 50000.

```
SELECT JOB, MAX(SALARY), MIN(SALARY)
  FROM DSN8910.EMP
 GROUP BY JOB
 HAVING COUNT(*) > 1 AND MAX(SALARY) > 50000;
```

*Example 3:* For each employee in department E11, get the following information from the table DSN8910.EMPPROJACT: employee number, activity number, activity start date, and activity end date. Using the CHAR function, convert the start and end dates to their USA formats. Get the needed department information from the table DSN8910.EMP.

```
SELECT EMPNO, ACTNO, CHAR(EMSTDATE,USA), CHAR(EMENDATE,USA)
  FROM DSN8910.EMPPROJACT
 WHERE EMPNO IN (SELECT EMPNO FROM DSN8910.EMP
                  WHERE WORKDEPT = 'E11');
```

*Example 4:* Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for all employees. (In this example, the subquery would be executed only one time.)

```
SELECT WORKDEPT, MAX(SALARY)
  FROM DSN8910.EMP
 GROUP BY WORKDEPT
 HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                           FROM DSN8910.EMP);
```

*Example 5:* Show the department number and maximum departmental salary for all departments whose maximum salary is less than the average salary for employees in all other departments. (In contrast to Example 4, the subquery in this statement, containing a correlated reference, would need to be executed for each group.)

```
SELECT WORKDEPT, MAX(SALARY)
  FROM DSN8910.EMP Q
 GROUP BY WORKDEPT
 HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                           FROM DSN8910.EMP
                           WHERE NOT WORKDEPT = Q.WORKDEPT);
```

*Example 6:* For each group of employees hired during the same year, show the year-of-hire and current average salary. (This example demonstrates how to use the AS clause in a FROM clause to name a derived column that you want to refer to in a GROUP BY clause.)

```
SELECT HIREYEAR, AVG(SALARY)
  FROM (SELECT YEAR(HIREDATE) AS HIREYEAR, SALARY
            FROM DSN8910.EMP) AS NEWEMP
 GROUP BY HIREYEAR;
```

*Example 7:* For an example of how to group the results of a query by an expression in the SELECT clause without having to retype the expression, see Example 4 for CASE expressions.

*Example 8:* Get the employee number and employee name for all the employees in DSN8910.EMP. Order the results by the date of hire.

```
SELECT EMPNO, FIRSTNAME, LASTNAME  
  FROM DSN8910.EMP  
 ORDER BY HIREDATE;
```

*Example 9:* Select all the rows from tables T1 and T2 and order the rows such that the rows from table T1 are first and are ordered by column C1, followed by the rows from T2, which are ordered by column C2. The rows of T1 are retrieved by one subselect which is connected to the results of another subselect that retrieves the rows from T2. Each subselect specifies the ordering for the rows from the referenced table. Note that both subselects need to be enclosed in parenthesis because each subselect is not the outermost fullselect.

```
(SELECT * FROM T1 ORDER BY C1)  
UNION  
(SELECT * FROM T2 ORDER BY C2);
```

*Example 10:* Specify the ORDER BY clause to order the results of a union using the second column of the result table if the union. In this example, the second ORDER BY clause applies to the results of the outermost fullselect (the result of the union) rather than to the second subselect. If the intent is to apply the second ORDER BY clause to the second subselect, the second subselect should be enclosed within parentheses as shown in Example 9.

```
(SELECT * FROM T1 ORDER BY C1)  
UNION  
SELECT * FROM T2 ORDER BY C2
```

*Example 11:* Retrieve all rows of table T1 with no specific ordering) and connect the result table to the rows of table T2, which have been ordered by the first column of table T2. The ORDER BY ORDER OF clause in the fullselect specifies that the order of the rows in the result table of the union is to be inherited by the final result.

```
SELECT *  
  FROM (SELECT * FROM T1  
        UNION ALL  
        (SELECT * FROM T2 ORDER BY 1)  
      ) AS UTABLE  
ORDER BY ORDER OF UTABLE;
```

*Example 12:* The following example uses a query to join data from a table to the result table of a nested table expression. The query uses the ORDER BY ORDER OF clause to order the rows of the result table using the order of the rows of the nested table expression.

```
SELECT T1.C1, T1.C2, TEMP.Cy, TEMP.Cx  
  FROM T1,  
       (SELECT T2.C1, T2.C2 FROM T2 ORDER BY 2) AS TEMP(Cx, Cy)  
 WHERE Cy = T1.C1  
 ORDER BY ORDER OF TEMP;
```

*Example 13:* Using the EMP\_ACT table, find the project numbers that have an employee whose salary is in the top three salaries for all employees.

```
SELECT EMP_ACT.EMPNO, PROJNO  
  FROM EMP_ACT  
 WHERE EMP_ACT.EMPNO IN  
   (SELECT EMPLOYEE.EMPNO  
     FROM EMPLOYEE  
    ORDER BY SALARY DESC  
   FETCH FIRST 3 ROWS ONLY);
```

| Example 14: Assume that an external function named ADDYEARS exists. For a given date, the function adds a given number of years and returns a new date. (The data types of the two input parameters to the function are DATE and INTEGER.) Get the employee number and employee name for all employees who have been hired within the last 5 years.

```
SELECT EMPNO, FIRSTNME, LASTNAME
  FROM DSN8910.EMP
 WHERE ADDYEARS(HIREDATE, 5) > CURRENT DATE;
```

To distinguish the different types of joins, to show nested table expressions, and to demonstrate how to combine join columns, the remaining examples use these two tables:

The PARTS table

PART	PROD#	SUPPLIER
WIRE	10	ACWF
OIL	160	WESTERN_CHEM
MAGNETS	10	BATEMAN
PLASTIC	30	PLASTIK_Corp
BLADES	205	ACE_STEEL

The PRODUCTS table

PROD#	PRODUCT	PRICE
505	SCREWDRIVER	3.70
30	RELAY	7.55
205	SAW	18.90
10	GENERATOR	45.75

Example 15: Join the tables on the PROD# column to get a table of parts with their suppliers and the products that use the parts:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
  FROM PARTS, PRODUCTS
 WHERE PARTS.PROD# = PRODUCTS.PROD#;
```

or

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
  FROM PARTS INNER JOIN PRODUCTS
    ON PARTS.PROD# = PRODUCTS.PROD#;
```

Either one of these two statements give this result:

PART	SUPPLIER	PROD#	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
BLADES	ACE_STEEL	205	SAW

Notice two things about the example:

- There is a part in the parts table (OIL) whose product (#160) is not listed in the products table. There is a product (SCREWDRIVER, #505) that has no parts listed in the parts table. Neither OIL nor SCREWDRIVER appears in the result of the join.

An *outer join*, however, includes rows where the values in the joined columns do not match.

- There is explicit syntax to express that this familiar join is not an outer join but an inner join. You can use INNER JOIN in the FROM clause instead of the comma. Use ON when you explicitly join tables in the FROM clause.

You can specify more complicated join conditions to obtain different sets of results. For example, eliminate the suppliers that begin with the letter A from the table of parts, suppliers, product numbers and products:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT
  FROM PARTS INNER JOIN PRODUCTS
    ON PARTS.PROD# = PRODUCTS.PROD#
   AND SUPPLIER NOT LIKE 'A%';
```

The result of the query is all rows that do not have a supplier that begins with A:

PART	SUPPLIER	PROD#	PRODUCT
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY

*Example 16:* Join the tables on the PROD# column to get a table of all parts and products, showing the supplier information, if any.

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT  
FROM PARTS FULL OUTER JOIN PRODUCTS  
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

PART	SUPPLIER	PROD#	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
BLADES	ACE_STEEL	205	SAW
OIL	WESTERN_CHEM	160	(null)
(null)	(null)	(null)	SCREWDRIVER

The clause FULL OUTER JOIN includes unmatched rows from both tables. Missing values in a row of the result table are filled with nulls.

*Example 17:* Join the tables on the PROD# column to get a table of all parts, showing what products, if any, the parts are used in:

```
SELECT PART, SUPPLIER, PARTS.PROD#, PRODUCT  
FROM PARTS LEFT OUTER JOIN PRODUCTS  
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

PART	SUPPLIER	PROD#	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
BLADES	ACE_STEEL	205	SAW
OIL	WESTERN_CHEM	160	(null)

The clause LEFT OUTER JOIN includes rows from the table identified before it where the values in the joined columns are not matched by values in the joined columns of the table identified after it.

*Example 18:* Join the tables on the PROD# column to get a table of all products, showing the parts used in that product, if any, and the supplier.

```
SELECT PART, SUPPLIER, PRODUCTS.PROD#, PRODUCT  
FROM PARTS RIGHT OUTER JOIN PRODUCTS  
ON PARTS.PROD# = PRODUCTS.PROD#;
```

The result is:

PART	SUPPLIER	PROD#	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
BLADES	ACE_STEEL	205	SAW
(null)	(null)	505	SCREWDRIVER

The clause RIGHT OUTER JOIN includes rows from the table identified after it where the values in the joined columns are not matched by values in the joined columns of the table identified before it.

*Example 19:* The result of Example 16 (a full outer join) shows the product number for SCREWDRIVER as null, even though the PRODUCTS table contains a product number for it. This is because PRODUCTS.PROD# was not listed in the SELECT list of the query. Revise the query using COALESCE so that all part numbers from both tables are shown.

```
SELECT PART, SUPPLIER,
       COALESCE(PARTS.PROD#, PRODUCTS.PROD#) AS PRODNUM, PRODUCT
    FROM PARTS FULL OUTER JOIN PRODUCTS
      ON PARTS.PROD# = PRODUCTS.PROD#;
```

In the result, notice that the AS clause (AS PRODNUM), provides a name for the result of the COALESCE function:

PART	SUPPLIER	PRODNUM	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
BLADES	ACE_STEEL	205	SAW
OIL	WESTERN_CHEM	160	(null)
(null)	(null)	505	SCREWDRIVER

*Example 20:* For all parts that are used in product numbers less than 200, show the part, the part supplier, the product number, and the product name. Use a nested table expression.

```
SELECT PART, SUPPLIER, PRODNUM, PRODUCT
  FROM (SELECT PART, PROD# AS PRODNUM, SUPPLIER
         FROM PARTS
        WHERE PROD# < 200) AS PARTX
  LEFT OUTER JOIN PRODUCTS
    ON PRODNUM = PROD#;
```

The result is:

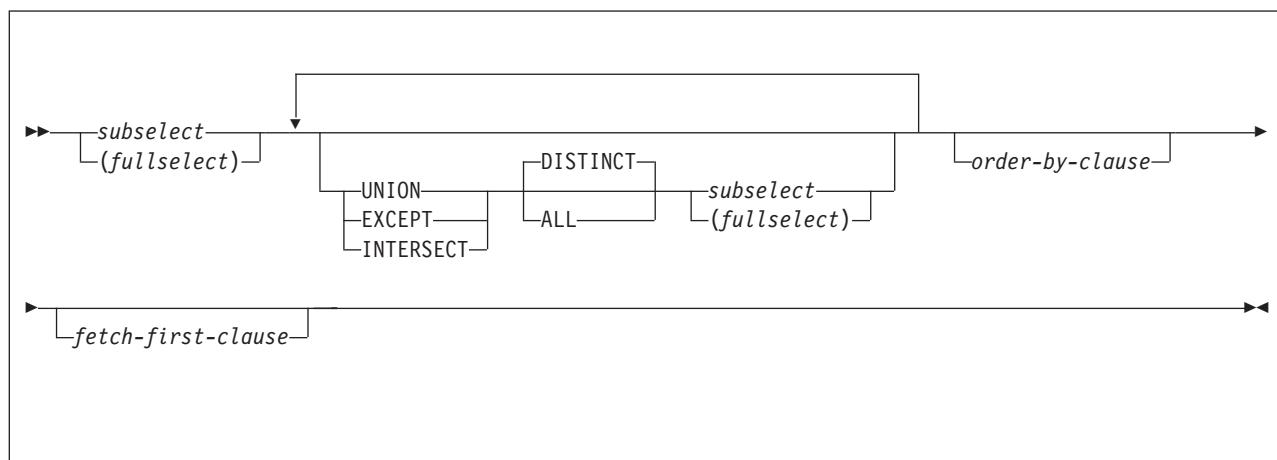

PART	SUPPLIER	PRODNUM	PRODUCT
WIRE	ACWF	10	GENERATOR
MAGNETS	BATEMAN	10	GENERATOR
PLASTIC	PLASTIK_Corp	30	RELAY
OIL	WESTERN_CHEM	160	(null)

*Example 21:* Examples of statements with DISTINCT specified more than once in a subselect:

```
SELECT DISTINCT COUNT(DISTINCT A1), COUNT(A2)
  FROM T1;
SELECT COUNT(DISTINCT A)
  FROM T1
 WHERE A3 > 0
 HAVING AVG(DISTINCT A4) >1;
```

## fullselect

The fullselect is a component of the *select-statement*, ALTER TABLE statement for the definition of a materialized query table, CREATE TABLE statement, CREATE VIEW statement, DECLARE GLOBAL TEMPORARY TABLE statement, and INSERT statement.

A fullselect that is enclosed in parentheses is called a *subquery*. For example, a subquery can be used in a search condition.

A *scalar-fullselect* is a fullselect, enclosed in parentheses, that returns a single result row and a single result column. If the result of the fullselect is no rows, then the null value is returned. An error is returned if there is more than one row in the result. For example, a scalar-fullselect can be used in the assignment clause of the DELETE, UPDATE and MERGE statements.

A *row-fullselect* is a fullselect that returns a single row. An error is returned if there is more than one row in the result. For example, a row-fullselect can be used in the assignment clause of the DELETE and UPDATE statements.

### UNION, EXCEPT, or INTERSECT

The set operators, UNION, EXCEPT, and INTERSECT, correspond to the relational operators union, difference, and intersection. A *fullselect* specifies a result table. If a set operator is not used, the result of the fullselect is the result of the specified subselect. Otherwise, the result table is derived by combining the two other result tables (R1 and R2) subject to the specified set operator.

### UNION DISTINCT or UNION ALL

If UNION ALL is specified, the result consists of all rows in R1 and R2. With UNION DISTINCT, the result is the set of all rows in either R1 or R2 with the redundant duplicate rows eliminated. In either case, each row of the result table of the union is either a row from R1 or a row from R2.

### EXCEPT DISTINCT or EXCEPT ALL

If EXCEPT ALL is specified, the result consists of all rows from only R1, including significant redundant duplicate rows. With EXCEPT DISTINCT, the result consists of all rows that are only in R1, with redundant duplicate rows eliminated. In either case, each row in the result table of the difference is a row from R1 that does not have a matching row in R2.

### **INTERSECT DISTINCT or INTERSECT ALL**

If INTERSECT ALL is specified, the result consists of all rows that are both in R1 and R2, including significant redundant duplicate rows. With INTERSECT DISTINCT, the result consists of all rows that are in both R1 and R2, with redundant duplicate rows eliminated. In either case each row of the result table of the intersection is a row that exists in both R1 and R2.

#### **Rules for columns:**

- R1 and R2 must have the same number of columns, and the data type of the *n*th column of R1 must be compatible with the data type of the *n*th column of R2.
- R1 and R2 must not include columns having a data type of CLOB, BLOB, DBCLOB, XML, or a distinct type that is based on any of these types. However, this rule is not applicable when UNION ALL is used with the set operator.
- If the *n*th column of R1 and the *n*th column of R2 have the same result column name, the *n*th column of the result table of the set operation has the same result column name. Otherwise, the *n*th column of the result table of the set operation is unnamed.
- Qualified column names cannot be used in the ORDER BY clause when the set operators are specified.

For information on the valid combinations of operand columns and the data type of the result column, see “Rules for result data types” on page 119.

**Duplicate rows:** Two rows are duplicates if the value in each column in the first row is equal to the corresponding value of the second row. For determining duplicates, two null values are considered equal.

The DECFLOAT data type allows for multiple bit representations of the same number. For example 2.00 and 2.0 are two numbers with the same coefficient, but different exponent values. See “Numeric comparisons” on page 114 section for more information. So if the result table of UNION contains a DECFLOAT column and multiple bit representations of the same number exist, the one returned is unpredictable.

**Operator precedence:** When multiple set operations are combined in an expression, set operations within parentheses are performed first. If the order is not specified by parentheses, set operations are performed from left to right with the exception that all INTERSECT operations are performed before any UNION or any EXCEPT operations.

**Results of set operators:** The following table illustrates the results of all set operations, with rows from result table R1 and R2 as the first two columns and the result of each operation on R1 and R2 under the corresponding column heading.

*Table 78. Example of UNION, EXCEPT, and INTERSECT set operations on result tables R1 and R2.*

Rows in R1	Rows in R2	Result of UNION ALL	Result of UNION DISTINCT	Result of EXCEPT ALL	Result of EXCEPT DISTINCT	Result of INTERSECT ALL	Result of INTERSECT DISTINCT
1	1	1	1	1	2	1	1
1	1	1	2	2	5	1	3
1	3	1	3	2		3	4
2	3	1	4	2		4	
2	3	1	5	4			

| Table 78. Example of UNION, EXCEPT, and INTERSECT set operations on result tables R1 and R2. (continued)

Rows in R1	Rows in R2	Result of UNION ALL	Result of UNION DISTINCT	Result of EXCEPT ALL	Result of EXCEPT DISTINCT	Result of INTERSECT ALL	Result of INTERSECT DISTINCT
2	3	2		5			
3	4	2					
4		2					
4		3					
5		3					
		3					
		3					
		4					
		4					
		4					
		5					

## Examples of fullselects

*Example 1:* A query specifies the union of result tables R1 and R2. A column in R1 has the data type CHAR(10) and the subtype BIT. The corresponding column in R2 has the data type CHAR(15) and the subtype SBCS. Hence, the column in the union has the data type CHAR(15) and the subtype BIT. Values from the first column are converted to CHAR(15) by adding five trailing blanks.

*Example 2:* Show all the rows from DSN8910.EMP.

```
SELECT * FROM DSN8910.EMP;
```

*Example 3:* Using sample tables DSN8910.EMP and DSN8910.EMPPROJECT, list the employee numbers of all employees for which either of the following statements are true:

- Their department numbers begin with 'D'.
- They are assigned to projects whose project numbers begin with 'AD'.

```
SELECT EMPNO FROM DSN8910.EMP
  WHERE WORKDEPT LIKE 'D%'
UNION
SELECT EMPNO FROM DSN8910.EMPPROJECT
  WHERE PROJNO LIKE 'AD'
```

The result is the union of two result tables, one formed from the sample table DSN8910.EMP, the other formed from the sample table DSN8910.EMPPROJECT. The result—a one-column table—is a list of employee numbers. Because UNION, rather than UNION ALL, was used, the entries in the list are distinct. If instead UNION ALL were used, certain employee numbers would appear in the list more than once. These would be the numbers for employees in departments that begin with 'D' while their projects begin with 'AD'.

*Example 4:* Specify a series of unions and order the results by the first column of the final result table.

```
|   SELECT * FROM T1  
|   UNION  
|   SELECT * FROM T2  
|   UNION  
|   SELECT * FROM T3  
|   ORDER BY 1;
```

*Example 5:* Specify a series of unions and order the results by the first column of the final result table. The first ORDER BY clause order the rows of the result of the first union by the first column of that result table. The second ORDER BY clause is applied as part of the outer fullselect and it causes the rows of the final result table to be ordered by the first column of the final result table.

```
|   (SELECT * FROM T1  
|   UNION  
|   SELECT * FROM T2  
|   ORDER BY 1)  
|   UNION  
|   SELECT * FROM T3  
|   ORDER BY 1;
```

*Example 6:* Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the EXCEPT operator produces all rows that are in T1 but not in T2, with duplicate rows removed:

```
|   (SELECT * FROM T1)  
|   EXCEPT DISTINCT  
|   (SELECT * FROM T2)
```

*Example 7:* Assume that tables T1 and T2 exist and each contain the same number of columns named C1, C2, and so on. This example of the INTERSECT operator produces all rows that are in both table T1 and table T2, with duplicate rows removed:

```
|   (SELECT * FROM T1)  
|   INTERSECT DISTINCT  
|   (SELECT * FROM T2)
```

## Character conversion in set operations and concatenations

The SQL operations that combine strings include concatenation, set operators, and the IN list of an IN predicate. Within an SQL statement, concatenation combines two or more strings into a new string. Within a fullselect, set operation, or the IN list of an IN predicate combine two or more string columns resulting from the subselects into results column.

All such operations have the following in common:

- The choice of a result CCSID for the string or column
- The possible conversion of one or more of the component strings or columns to the result CCSID

For all such operations, the rules for those two actions are the same, as described in “Selecting the result CCSID” on page 667. These rules also apply to the COALESCE scalar function.

## Selecting the result CCSID

The result CCSID is selected at package prepare time. The result CCSID is the CCSID of one of the operands.

**Two operands:** When two operands are used, the result CCSID is determined by the operand types, their CCSIDs, and their relative positions in the operation. When a CCSID is X'FFFF', the result CCSID is always X'FFFF', and no character conversions take place. When neither CCSID is X'FFFF', the rules for selecting the result CCSID are identical to the ones for string comparison. See "String comparisons" in Chapter 3, "Functions," on page 259.

**Three or more operands:**

If all the operands have the same CCSID, the result CCSID is the common CCSID.

If at least one of the CCSIDs has the value X'FFFF', the result CCSID also has the value X'FFFF'.

Otherwise, selection proceeds as follows:

1. The rules for a pair of operands are applied to the first two operands. This picks a "candidate" for the second step. The candidate is the operand that would furnish the result CCSID if just the first two operands were involved in the operation.
2. The rules are applied to the Step 1 candidate and the third operand, thereby selecting a second candidate.
3. If a fourth operand is involved, the rules are applied to the second candidate and fourth operand, to select a third candidate, and so on.

The process continues until all operands have been used. The remaining candidate is the one that furnishes the result CCSID. Whenever the rules for a pair are applied to a candidate and an operand, the candidate is considered to be the first operand.

Consider, for example, the following concatenation:

A CONCAT B CONCAT C

Here, the rules are first applied to the strings A and B. Suppose that the string selected as candidate is A. Then the rules are applied to A and C. If the string selected is again A, then A furnishes the result CCSID. Otherwise, C furnishes the result CCSID.

**Character conversion of components:** An operand of concatenation or the selected argument of the COALESCE scalar function is converted, if necessary, to the coded character set of the result string. Each string of an operand of a set operation is converted, if necessary, to the coded character set of the result column. In either case, the coded character set is the one identified by the result CCSID. Character conversion is necessary only if all of the following are true:

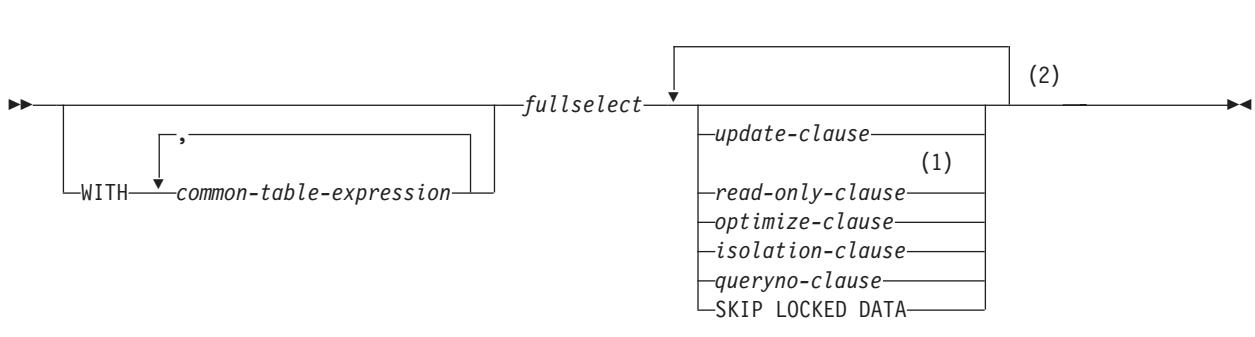

- The result and operand CCSIDs are different.
- Neither CCSID is X'FFFF' (neither string is defined as BIT data).
- The string is neither null nor empty.
- The SYSSTRINGS catalog table indicates that conversion is necessary.

An error occurs if a character of a string cannot be converted, SYSSTRINGS is used but contains no information about the CCSID pair, or DB2 cannot do the

conversion through z/OS support for Unicode. A warning occurs if a character of a string is converted to the substitution character.

## select-statement

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR statement or FOR statement, prepared and then referenced in a DECLARE CURSOR statement, or directly specified in an SQLJ assignment clause. It can also be issued using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the result table specified by a *select-statement* is the result of the *fullselect*.

### Notes:

- 1 The *read-only-clause* must not be specified if *update-clause* is specified.
- 2 The same clause must not be specified more than one time.

The tables and view identified in a select statement can be at the current server or any DB2 subsystem with which the current server can establish a connection.

For local queries on DB2 for z/OS or remote queries in which the server and requester are DB2 for z/OS, if a table is encoded as ASCII or Unicode, the retrieved data is encoded in EBCDIC. For information on retrieving data encoded in ASCII or Unicode, see *DB2 Application Programming and SQL Guide*.

A select statement can implicitly or explicitly invoke user-defined functions or implicitly invoke stored procedures. This technique is known as *nesting* of SQL statements. A function or procedure is implicitly invoked in a select statement when it is invoked at a lower level. For instance, if you invoke a user-defined function from a select statement and the user-defined function invokes a stored procedure, you are implicitly invoking the stored procedure. When a SELECT statement refers to a table, any SQL statements that are implicitly invoked (as a result of nested functions or procedures) must not result in an SQL data change statement that modifies the same table.

For example, suppose that you execute this SQL statement at level 1 of nesting:  
SELECT UDF1(C1) FROM T1;

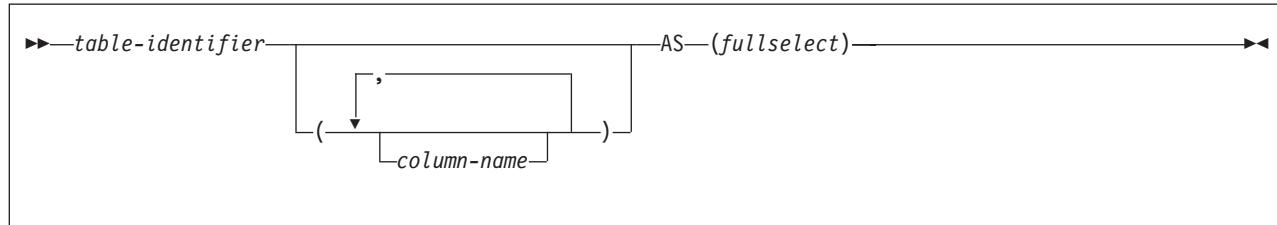

You cannot execute this SQL statement at a lower level of nesting:  
INSERT INTO T1 VALUES(...);

## common-table-expression

A *common table expression* defines a result table with *table-identifier* that can be referenced in any FROM clause of the *fullselect* that follows.

Multiple common table expressions can be specified following the single WITH keyword. Each specified common table expression can also be referenced by name in the FROM clause of subsequent common table expressions.

### common-table-expression

If a list of columns is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If these column names are not specified, the names are derived from the select list of the *fullselect* used to define the common table expression.

*table-identifier* must be an unqualified SQL identifier, and it must be different from any other *table-identifier* in the same statement. If the common table expression is specified in an INSERT statement, the *table-identifier* must not be the same as the table or view name that is the object of the insert. If the common table expression is specified in a CREATE VIEW statement, the *table-identifier* must not be the same as the view name that is created. A common table expression *table-identifier* can be specified as a table name in any FROM clause throughout the *fullselect*.

If more than one common table expression is defined in the same statement, cyclic references between the common table expressions are not permitted. A *cyclic reference* occurs when two common table expressions *dt1* and *dt2* are created such that *dt1* refers to *dt2* and *dt2* refers to *dt1*. Furthermore, a common table expression defined before cannot refer to subsequent common table expressions.

A common table expression name can only be referenced in the *select-statement*, SELECT INTO statement, INSERT statement, CREATE VIEW statement, or RETURN statement that defines it.

If a *select-statement*, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is not contained in a trigger definition refers to a unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the *select-statement*, the name identifies the common table expression that is in the innermost scope.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

If a *select-statement*, SELECT INTO statement, INSERT statement, or CREATE VIEW statement that is contained in a trigger definition refers to a unqualified table name, the following rules are applied to determine which table is actually being referenced:

- If the unqualified name corresponds to one or more common table expression names that are specified in the *select-statement*, the name identifies the common table expression that is in the innermost scope.
- If the unqualified name corresponds to a transition table name, the name identifies that transition table.
- Otherwise, the name identifies a persistent table, a temporary table, or a view that is present in the default schema.

The common table expression is also optional prior to the *fullselect* in the CREATE VIEW and INSERT statements. However, the use of common table expressions is not allowed in a INSERT within SELECT statement.

A common table expression can be used:

- In place of a view to avoid creating the view (when general use of the view is not required and positioned updates or deletes are not used)
- When the desired result table is based on host variables
- When the same result table needs to be shared in a *fullselect*
- When the result needs to be derived using recursion

If a *fullselect* of a common table expression contains a reference to itself in a FROM clause, the common table expression is a *recursive common table expression*. Queries using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The following must be true of a recursive common table expression:

- Each *fullselect* that is part of the recursion cycle must start with SELECT or SELECT ALL. Use of SELECT DISTINCT is not allowed. Furthermore, the set operators must use the ALL keyword.
- The column names must be specified following the *table-name* of the common table expression.
- The first *fullselect* of the first set operator (the initialization *fullselect*) must not include a reference to the common table expression itself in any FROM clause).
- If a column name of the common table expression is referred to in the iterative *fullselect*, the data type, length, and CCSID for the column are determined based on the initialization *fullselect*. The corresponding column in the iterative *fullselect* must have the same data type and length as the data type and length determined based on the initialization *fullselect* and the CCSID must match. However, for character string types, the length of the two data types can differ. In this case, the column in the iterative *fullselect* must have a length that would always be assignable to the length determined from the initialization *fullselect*. If a column of a recursive common table expression is not used recursively in its definition, the data type, length, and CCSID for the column are determined by applying rules associated with non-recursive queries.
- Each *fullselect* that is part of the recursion cycle must not include any aggregate functions, GROUP BY clauses, or HAVING clauses. The FROM clauses of these *fullselects* can include at most one reference to a common table expression that is part of a recursion cycle.
- Subqueries (scalar or quantified) must not be part of any recursion cycles.

- Outer join must not be part of any recursion cycles.

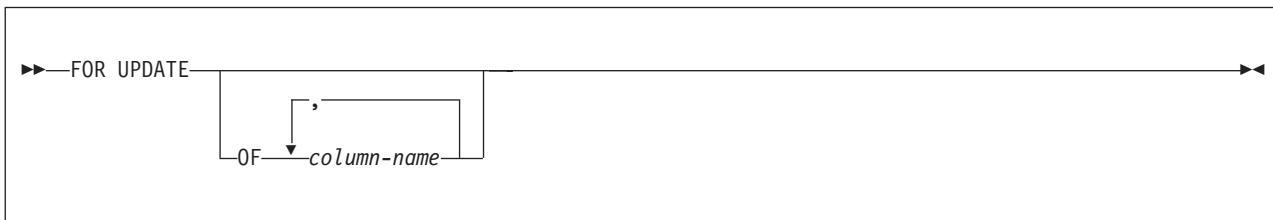

When developing recursive common table expressions, remember that an infinite recursion cycle (loop) can be created. Check that recursion cycles will terminate. This is especially important if the data involved is cyclic. A recursive common table expression is expected to include a predicate that will prevent an infinite loop. The recursive common table expression is expected to include:

- In the iterative *fullselect*, an integer column incremented by a constant.
- A predicate in the WHERE clause of the iterative *fullselect* in the form of "*counter\_col < constant*" or "*counter\_col < :hostvar*". A warning is issued if this syntax is not found.

## update-clause

The optional FOR UPDATE clause identifies the columns that can be updated in a later positioned UPDATE statement.

### update-clause

Each column name must be unqualified and must identify a column of the table or view identified in the first **FROM** clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only. For a discussion of read-only result tables, see “DECLARE CURSOR” on page 1191. The clause must also not be specified if a created temporary table is referenced in the first **FROM** clause of the *select-statement*.

If the **FOR UPDATE** clause is specified without a *column-name* list, the columns that can be updated will include all the updatable columns of the table or view that is identified in the first **FROM** clause of the fullselect.

The declaration of a cursor referred to in a positioned UPDATE statement need not include an **UPDATE** clause if the STDSQL(YES) or NOFOR option is specified when the program is precompiled. For more on the subject, see “Positioned updates of columns” on page 256.

When **FOR UPDATE** is used, FETCH operations referencing the cursor acquire U or X locks rather than S locks when:

- The isolation level of the statement is cursor stability.
- The isolation level of the statement is repeatable read or read stability and field U LOCK FOR RR/RS on installation panel DSNTIPI is set to get U locks.
- The isolation level of the statement is repeatable read or read stability and USE AND KEEP EXCLUSIVE LOCKS or USE AND KEEP UPDATE LOCKS is specified in the SQL statement, an X lock or a U lock, respectively, is acquired at fetch time.

No locks are acquired on declared temporary tables. For a discussion of U locks and S locks, see *DB2 Performance Monitoring and Tuning Guide*.

## **read-only-clause**

The read-only clause specifies that the result table is read-only. Therefore, the cursor cannot be referred to in positioned UPDATE or DELETE statements.

### **read-only-clause**

►►—FOR READ ONLY————►►

Some result tables are read-only by nature (for example, a table based on a read-only view.) FOR READ ONLY can still be specified for such tables, but the specification has no effect.

For tables in which updates and deletes are allowed, specifying FOR READ ONLY can possibly improve the performance of FETCH operations as DB2 can do blocking and avoid exclusive locks. For example, in programs that contain dynamic SQL statements without the FOR READ ONLY or ORDER BY clause, DB2 might open cursors as if the UPDATE clause was specified.

A read-only result table must not be referred to in an UPDATE or DELETE statement, whether it is read-only by nature or specified as FOR READ ONLY.

To take advantage of the possibly improved performance of FETCH operations while guaranteeing that selected data is not modified and preventing some types of deadlocks, you can specify FOR READ ONLY in combination with the optional syntax of USE AND KEEP ... LOCKS on the *isolation-clause*.

***Alternative syntax and synonyms:*** FOR FETCH ONLY can be specified as a synonym for FOR READ ONLY.

## **optimize-clause**

The OPTIMIZE clause requests special optimization of the *select-statement*.

### **optimize-clause**

```
►►—OPTIMIZE FOR—integer—ROWS  
          |  
          | ROW
```

The *optimize-clause* tells DB2 to assume that the program does not intend to retrieve more than *integer* rows from the result table. Without this clause, DB2 assumes that all rows of the result table will be retrieved, unless the FETCH FIRST clause is specified. Optimizing for *integer* rows can improve performance. If this clause is omitted and the FETCH FIRST is specified, OPTIMIZE FOR *integer* ROWS is assumed, where *integer* is the value that is specified in the FETCH FIRST clause. DB2 will optimize the query based on the specified number of rows.

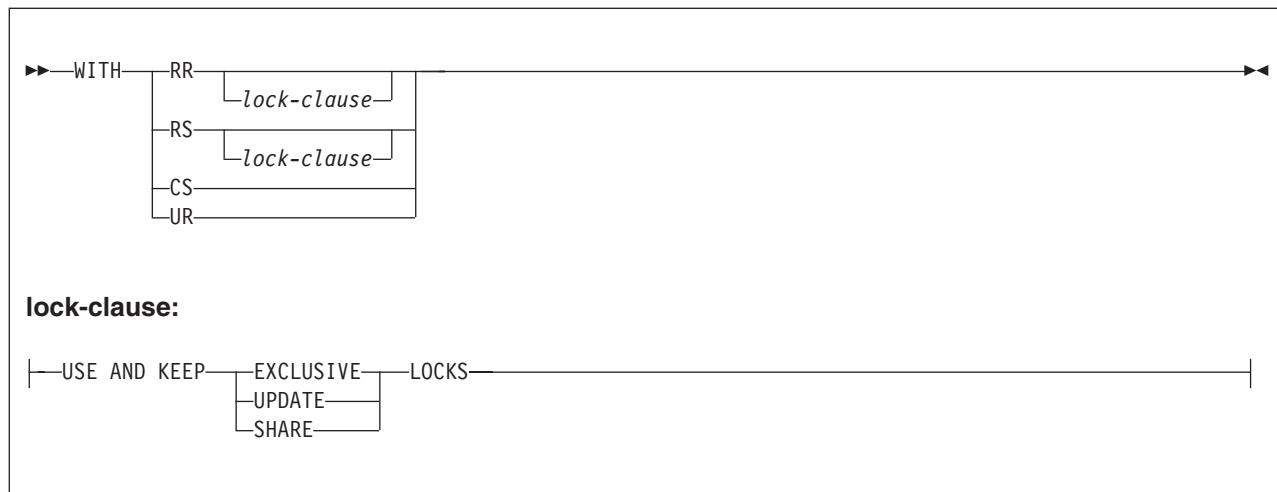

The clause does not limit the number of rows that can be fetched, change the result table, or change the order in which the rows are fetched. Any number of rows can be fetched, but performance can possibly degrade after *integer* fetches. In general, if you are retrieving only a few rows, specify OPTIMIZE FOR 1 ROW to influence the access path that DB2 selects. For more information about using this clause, see *DB2 Application Programming and SQL Guide*.

The value of *integer* must be a positive integer (not zero).

## isolation-clause

The *isolation-clause* specifies the isolation level at which the statement is executed. (Isolation level does not apply to declared temporary tables because no locks are acquired.)

### isolation-clause

**RR**      Repeatable read

**RR lock-clause**

Repeatable read, using and keeping the type of lock that is specified in *lock-clause* on all accessed pages and rows

**RS**      Read stability

**RS lock-clause**

Read stability, using and keeping the type of lock that is specified in *lock-clause* on all accessed pages and rows

**CS**      Cursor stability

**UR**      Uncommitted read

*lock-clause*

Specifies the type of lock.

**USE AND KEEP EXCLUSIVE LOCKS**

**USE AND KEEP UPDATE LOCKS**

**USE AND KEEP SHARE LOCKS**

Specifies that DB2 is to acquire and hold X, U, or S locks, respectively.

WITH UR can be specified only if the result table of the fullselect or the SELECT INTO statement is read-only.

In an ODBC application, the SQLSetStmtAttr function can be used to set statement attributes that interact with the *lock-clause*. If SQLSetStmtAttr is invoked with a cursor's statement handle and specifying that its SQL\_ATTR\_CLOSE\_BEHAVIOR is SQL\_CC\_RELEASE (locks are to be released when the cursor is closed), then irrespective of any *lock-clause*, lock used by the cursor that are not needed to protect the integrity of changed data are released. For more information on SQLSetStmtAttr, see *DB2 ODBC Guide and Reference*.

Although requesting an UPDATE or EXCLUSIVE LOCK can reduce concurrency, it can prevent some types of deadlocks.

The **default** isolation level of the statement depends on:

- The isolation of the package or plan that the statement is bound in
- Whether the result table is read-only

Table 79 shows the default isolation level of the statement.

*Table 79. Default isolation level based on the isolation level of the package or plan and whether the result table is read-only*

If package isolation is:	And plan isolation is:	And the result table is:	Then the default isolation is:
RR	Any	Any	RR
RS	Any	Any	RS
CS	Any	Any	CS
UR	Any	Read-only	UR
		Not read-only	CS
Not specified	Not specified	Any	RR
	RR	Any	RR
	RS	Any	RS
	CS	Any	CS
	UR	Read-only	UR
		Not read-only	CS

A simple way to ensure that a result table is read-only is to specify FOR READ ONLY in the SQL statement.

*Alternative syntax and synonyms:* KEEP UPDATE LOCKS can be specified as a synonym for USE AND KEEP EXCLUSIVE LOCKS. However, KEEP UPDATE LOCKS can be specified only if FOR UPDATE OF is specified, and it is not supported in the SELECT INTO statement.

## queryno-clause

The QUERYNO clause specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

### queryno-clause

```
►►QUERYNO—integer————►►
```

*integer* is the value to be used to identify this SQL statement in EXPLAIN output and trace records.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

## SKIP LOCKED DATA

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only with isolation CS or RS and applies only to row level or page level locks.

►►—SKIP LOCK DATA—►►

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, and whether the result table is read-only.

## Examples of select statements

Examples of SELECT statements.

*Example 1:* Select all the rows from DSN8910.EMP.

```
SELECT * FROM DSN8910.EMP;
```

*Example 2:* Select all the rows from DSN8910.EMP, arranging the result table in chronological order by date of hiring.

```
SELECT * FROM DSN8910.EMP  
ORDER BY HIREDATE;
```

*Example 3:* Select the department number (WORKDEPT) and average departmental salary (SALARY) for all departments in the table DSN8910.EMP. Arrange the result table in ascending order by average departmental salary.

```
SELECT WORKDEPT, AVG(SALARY)  
FROM DSN8910.EMP  
GROUP BY WORKDEPT  
ORDER BY 2;
```

*Example 4:* Change various salaries, bonuses, and commissions in the table DSN8910.EMP. Confine the changes to employees in departments D11 and D21. Use positioned updates to do this with a cursor named UP\_CUR. Use a FOR UPDATE clause in the cursor declaration to indicate that all updatable columns are updated. Below is the declaration for a PL/I program.

```
EXEC SQL DECLARE UP_CUR CURSOR FOR  
SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM  
FROM DSN8910.EMP  
WHERE WORKDEPT IN ('D11','D21')  
FOR UPDATE;
```

Beginning where the cursor is declared, all updatable columns would be updated. If only specific columns needed to be updated, such as only the salary column, the FOR UPDATE clause could be used to specify the salary column (FOR UPDATE OF SALARY).

*Example 5:* Find the maximum, minimum, and average bonus in the table DSN8910.EMP. Execute the statement with uncommitted read isolation, regardless of the value of ISOLATION with which the plan or package containing the statement is bound. Assign 13 as the query number for the SELECT statement.

```
EXEC SQL  
SELECT MAX(BONUS), MIN(BONUS), AVG(BONUS)  
INTO :MAX, :MIN, :AVG  
FROM DSN8910.EMP  
WITH UR  
QUERYNO 13;
```

If bind option EXPLAIN(YES) is specified, rows are inserted into the plan table. The value used for the QUERYNO column for these rows is 13.

*Example 6:* The cursor declaration shown below is in a PL/I program. In the query within the declaration, X.RMT\_TAB is an alias for a table at some other DB2. Hence, when the query is used, it is processed using DRDA access. See "Distributed data" on page 31.

The declaration indicates that no positioned updates or deletes will be done with the query's cursor. It also specifies that the access path for the query be optimized for the retrieval of at most 50 rows. Even so, the program can retrieve more than

50 rows from the result table, which consists of the entire table identified by the alias. However, when more than 50 rows are retrieved, performance could possibly degrade.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT * FROM X.RMT_TAB
  OPTIMIZE FOR 50 ROWS
  FOR READ ONLY;
```

The `FETCH FIRST` clause could be used instead of the `OPTIMIZE FOR` clause to ensure that only 50 rows are retrieved as in the following example:

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT * FROM X.RMT_TAB
  FETCH FIRST 50 ROWS ONLY;
```

*Example 7:* Assume that table DSN8810.EMP has 1000 rows and you wish to see the first five `EMP_ROWID` values that were inserted into DSN8810.EMP\_PHOTO\_RESUME.

```
EXEC SQL DECLARE CS1 CURSOR FOR
  SELECT EMP_ROWID
    FROM FINAL TABLE (INSERT INTO DSN8910.EMP_PHOTO_RESUME (EMPNO)
                      SELECT EMPNO FROM DSN8810.EMP)
  FETCH FIRST 5 ROWS ONLY;
```

All 1000 rows are inserted into DSN8810.EMP\_PHOTO\_RESUME, but only the first five are returned.

---

## Chapter 5. Statements

This section contains syntax diagrams, semantic descriptions, rules, and examples of the use of the SQL statements.

*Table 80. SQL statements*

SQL statement	Function	Topic
ALLOCATE CURSOR	Defines and associates a cursor with a result set locator variable	"ALLOCATE CURSOR" on page 696
ALTER DATABASE	Changes the description of a database	"ALTER DATABASE" on page 698
ALTER FUNCTION (external)	Changes the description of a user-defined external scalar or table function	"ALTER FUNCTION (external)" on page 701
ALTER FUNCTION (SQL scalar)	Changes the description of an SQL scalar function	"ALTER FUNCTION (SQL scalar)" on page 719
ALTER INDEX	Changes the description of an index	"ALTER INDEX" on page 725
ALTER PROCEDURE (external)	Changes the description of an external procedure	"ALTER PROCEDURE (external)" on page 741
ALTER PROCEDURE (SQL - external)	Changes the description of an external SQL procedure	"ALTER PROCEDURE (SQL - external)" on page 752
ALTER PROCEDURE (SQL - native)	Changes the description of or defines additional versions for a native SQL procedure	"ALTER PROCEDURE (SQL - native)" on page 758
ALTER SEQUENCE	Changes the description of a sequence	"ALTER SEQUENCE" on page 781
ALTER STOGROUP	Changes the description of a storage group	"ALTER STOGROUP" on page 786
ALTER TABLE	Changes the description of a table	"ALTER TABLE" on page 789
ALTER TABLESPACE	Changes the description of a table space	"ALTER TABLESPACE" on page 841
ALTER TRUSTED CONTEXT	Changes the description of a trusted context	"ALTER TRUSTED CONTEXT" on page 855
ALTER VIEW	Regenerates a view	"ALTER VIEW" on page 867
ASSOCIATE LOCATORS	Gets the result set locator value for each result set returned by a stored procedure	"ASSOCIATE LOCATORS" on page 868
BEGIN DECLARE SECTION	Marks the beginning of a host variable declaration section	"BEGIN DECLARE SECTION" on page 872
CALL	Calls a stored procedure	"CALL" on page 874
CLOSE	Closes a cursor	"CLOSE" on page 885
COMMENT	Replaces or adds a comment to the description of an object	"COMMENT" on page 887
COMMIT	Ends a unit of recovery and commits the database changes made by that unit of recovery	"COMMIT" on page 896
CONNECT	Connects the process to a server	"CONNECT" on page 899
CREATE ALIAS	Defines an alias	"CREATE ALIAS" on page 905

*Table 80. SQL statements (continued)*

SQL statement	Function	Topic
CREATE AUXILIARY TABLE	Defines an auxiliary table for storing LOB data	"CREATE AUXILIARY TABLE" on page 908
CREATE DATABASE	Defines a database	"CREATE DATABASE" on page 912
CREATE FUNCTION (external scalar)	Defines a user-defined external scalar function	"CREATE FUNCTION (external scalar)" on page 916
CREATE FUNCTION (external table)	Defines a user-defined external table function	"CREATE FUNCTION (external table)" on page 940
CREATE FUNCTION (sourced)	Defines a user-defined function that is based on an existing scalar or aggregate function	"CREATE FUNCTION (sourced)" on page 958
CREATE FUNCTION (SQL scalar)	Defines a user-defined SQL scalar function	"CREATE FUNCTION (SQL scalar)" on page 972
CREATE GLOBAL TEMPORARY TABLE	Defines a created temporary table	"CREATE GLOBAL TEMPORARY TABLE" on page 982
CREATE INDEX	Defines an index on a table	"CREATE INDEX" on page 988
CREATE PROCEDURE (external)	Defines an external stored procedure	"CREATE PROCEDURE (external)" on page 1016
CREATE PROCEDURE (SQL - external)	Defines an external SQL procedure	"CREATE PROCEDURE (SQL - external)" on page 1035
CREATE PROCEDURE (SQL - native)	Defines a native SQL procedure	"CREATE PROCEDURE (SQL - native)" on page 1046
CREATE ROLE	Defines a role	"CREATE ROLE" on page 1065
CREATE SEQUENCE	Defines a sequence	"CREATE SEQUENCE" on page 1066
CREATE STOGROUP	Defines a storage group	"CREATE STOGROUP" on page 1074
CREATE SYNONYM	Defines an alternate name for a table or view	"CREATE SYNONYM" on page 1077
CREATE TABLE	Defines a table	"CREATE TABLE" on page 1079
CREATE TABLESPACE	Defines a table space, which includes allocating and formatting the table space	"CREATE TABLESPACE" on page 1128
CREATE TRIGGER	Defines a trigger	"CREATE TRIGGER" on page 1151
CREATE TRUSTED CONTEXT	Defines a trusted context	"CREATE TRUSTED CONTEXT" on page 1167
CREATE TYPE	Defines a type (user-defined data type)	"CREATE TYPE" on page 1177
CREATE VIEW	Defines a view of one or more tables or views	"CREATE VIEW" on page 1184
DECLARE CURSOR	Defines an SQL cursor	"DECLARE CURSOR" on page 1191

*Table 80. SQL statements (continued)*

SQL statement	Function	Topic
DECLARE GLOBAL TEMPORARY TABLE	Defines a declared temporary table	"DECLARE GLOBAL TEMPORARY TABLE" on page 1202
DECLARE STATEMENT	Declares names used to identify prepared SQL statements	"DECLARE STATEMENT" on page 1216
DECLARE TABLE	Provides the programmer and the precompiler with a description of a table or view	"DECLARE TABLE" on page 1217
DECLARE VARIABLE	Defines a CCSID for a host variable	"DECLARE VARIABLE" on page 1221
DELETE	Deletes one or more rows from a table	"DELETE" on page 1224
DESCRIBE CURSOR	Puts information about the result set associated with a cursor into a descriptor	"DESCRIBE CURSOR" on page 1238
DESCRIBE INPUT	Puts information about the input parameter markers of a prepared statement into a descriptor	"DESCRIBE INPUT" on page 1240
DESCRIBE OUTPUT	Describes the result columns of a prepared statement	"DESCRIBE OUTPUT" on page 1243
DESCRIBE PROCEDURE	Puts information about the result sets returned by a stored procedure into a descriptor	"DESCRIBE PROCEDURE" on page 1250
DESCRIBE TABLE	Describes the columns of a table or view	"DESCRIBE TABLE" on page 1253
DROP	Deletes objects	"DROP" on page 1256
END DECLARE SECTION	Marks the end of a host variable declaration section	"END DECLARE SECTION" on page 1273
EXCHANGE	Exchanges data between the specified base table and an associated clone table	"EXCHANGE" on page 1274
EXECUTE	Executes a prepared SQL statement	the EXECUTE statement
EXECUTE IMMEDIATE	Prepares and executes an SQL statement	"EXECUTE IMMEDIATE" on page 1280
EXPLAIN	Obtains information about how an SQL statement would be executed	"EXPLAIN" on page 1283
FETCH	Positions the cursor, returns data, or both positions the cursor and returns data	"FETCH" on page 1290
FREE LOCATOR	Removes the association between a LOB locator variable and its value	"FREE LOCATOR" on page 1316
GET DIAGNOSTICS	Provides diagnostic information about the last SQL statement that was executed	"GET DIAGNOSTICS" on page 1317
GRANT	The GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of the classes of privilege.	"GRANT" on page 1333
GRANT (collection privileges)	Grants authority to create a package in a collection	"GRANT (collection privileges)" on page 1336
GRANT (database privileges)	Grants privileges on a database	"GRANT (database privileges)" on page 1337
GRANT (type or JAR file privileges)	Grants the usage privilege on a type (user-defined data type) or a JAR file	"GRANT (type or JAR file privileges)" on page 1359

Table 80. SQL statements (continued)

SQL statement	Function	Topic
GRANT (function or procedure privileges)	Grants privileges on a user-defined function or a stored procedure	"GRANT (function or procedure privileges)" on page 1340
GRANT (package privileges)	Grants authority to bind, execute, or copy a package	"GRANT (package privileges)" on page 1345
GRANT (plan privileges)	Grants authority to bind or execute an application plan	"GRANT (plan privileges)" on page 1348
GRANT (schema privileges)	Grants privileges on a schema	"GRANT (schema privileges)" on page 1349
GRANT (sequence privileges)	Grants privileges on a user-defined sequence	"GRANT (sequence privileges)" on page 1351
GRANT (system privileges)	Grants system privileges	"GRANT (system privileges)" on page 1352
GRANT (table or view privileges)	Grants privileges on a table or view	"GRANT (table or view privileges)" on page 1355
GRANT (use privileges)	Grants authority to use specified buffer pools, storage groups, or table spaces	"GRANT (use privileges)" on page 1361
HOLD LOCATOR	Allows a LOB locator variable to retain its association with its value beyond a unit of work	"HOLD LOCATOR" on page 1363
INCLUDE	Inserts declarations into a source program	"INCLUDE" on page 1365
INSERT	Inserts one or more rows into a table	"INSERT" on page 1367
LABEL	Replaces or adds a label on the description of a table, view, alias, or column	"LABEL" on page 1384
LOCK TABLE	Locks a table or table space partition in shared or exclusive mode	"LOCK TABLE" on page 1386
MERGE	Updates and/or inserts one or more rows of a table	"MERGE" on page 1388
OPEN	Opens a cursor	"OPEN" on page 1400
PREPARE	Prepares an SQL statement (with optional parameters) for execution	"PREPARE" on page 1405
REFRESH TABLE	Refreshes the data in a materialized query table	"REFRESH TABLE" on page 1422
RELEASE (connection)	Places one or more connections in the release pending status	"RELEASE (connection)" on page 1424
RELEASE SAVEPOINT	Releases a savepoint and any subsequently set savepoints within a unit of recovery	"RELEASE SAVEPOINT" on page 1427
RENAME	Renames an existing table or index	"RENAME" on page 1428
REVOKE	Revokes privileges from authorization IDs. There is a separate form of the statement for each of the classes of privilege	"REVOKE" on page 1432
REVOKE (collection privileges)	Revokes authority to create a package in a collection	"REVOKE (collection privileges)" on page 1437
REVOKE (database privileges)	Revokes privileges on a database	"REVOKE (database privileges)" on page 1439
REVOKE (type or JAR file privileges)	Revokes the usage privilege on a type (user-defined data type) or a JAR file	"REVOKE (type or JAR file privileges)" on page 1461

*Table 80. SQL statements (continued)*

SQL statement	Function	Topic
REVOKE (function or procedure privileges)	Revokes privileges on a user-defined function or a stored procedure	"REVOKE (function or procedure privileges)" on page 1442
REVOKE (package privileges)	Revokes authority to bind, execute, or copy a package	"REVOKE (package privileges)" on page 1447
REVOKE (plan privileges)	Revokes authority to bind or execute an application plan	"REVOKE (plan privileges)" on page 1449
REVOKE (schema privileges)	Revokes privileges on a schema	"REVOKE (schema privileges)" on page 1451
REVOKE (sequence privileges)	Revokes privileges on a user-defined sequence	"REVOKE (sequence privileges)" on page 1453
REVOKE (system privileges)	Revokes system privileges	"REVOKE (system privileges)" on page 1455
REVOKE (table or view privileges)	Revokes privileges on a table or view	"REVOKE (table or view privileges)" on page 1458
REVOKE (use privileges)	Revokes authority to use specified buffer pools, storage groups, or table spaces	"REVOKE (use privileges)" on page 1463
ROLLBACK	Ends a unit of recovery and backs out the changes to the database made by that unit of recovery, or partially rolls back the changes to a savepoint within the unit of recovery	"ROLLBACK" on page 1465
SAVEPOINT	Sets a savepoint within a unit of recovery	"SAVEPOINT" on page 1468
SELECT	Specifies the SELECT statement of the cursor	"SELECT" on page 1470
SELECT INTO	Specifies a result table of no more than one row and assigns the values to host variables	"SELECT INTO" on page 1471
SET CONNECTION	Establishes the database server of the process by identifying one of its existing connections	"SET CONNECTION" on page 1475
SET CURRENT APPLICATION ENCODING SCHEME	Assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register	"SET CURRENT APPLICATION ENCODING SCHEME" on page 1477
SET CURRENT DEBUG MODE	Assigns a value to the CURRENT DEBUG MODE special register	"SET CURRENT DEBUG MODE" on page 1478
SET CURRENT DECFLOAT ROUNDING MODE	Assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register	"SET CURRENT DECFLOAT ROUNDING MODE" on page 1480
SET CURRENT DEGREE	Assigns a value to the CURRENT DEGREE special register	"SET CURRENT DEGREE" on page 1482
SET CURRENT LOCALE LC_CTYPE	Assigns a value to the CURRENT LOCALE LC_CTYPE special register	"SET CURRENT LOCALE LC_CTYPE" on page 1483
SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION	Assigns a value to the CURRENT MAINTAINED TABLE TYPES FOR MAINTAINED TABLE TYPES special register	"SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION" on page 1485
SET CURRENT OPTIMIZATION HINT	Assigns a value to the CURRENT OPTIMIZATION HINT special register	"SET CURRENT OPTIMIZATION HINT" on page 1487
SET CURRENT PACKAGE PATH	Assigns a value to the CURRENT PACKAGE PATH special register	"SET CURRENT PACKAGE PATH" on page 1488

Table 80. SQL statements (continued)

SQL statement	Function	Topic
SET CURRENT PACKAGESET	Assigns a value to the CURRENT PACKAGESET special register	"SET CURRENT PACKAGESET" on page 1492
SET CURRENT PRECISION	Assigns a value to the CURRENT PRECISION special register	"SET CURRENT PRECISION" on page 1494
SET CURRENT REFRESH AGE	Assigns a value to the CURRENT REFRESH AGE special register	"SET CURRENT REFRESH AGE" on page 1495
SET CURRENT ROUTINE VERSION	Assigns a value to the CURRENT ROUTINE VERSION special register	"SET CURRENT ROUTINE VERSION" on page 1497
SET CURRENT RULES	Assigns a value to the CURRENT RULES special register	"SET CURRENT RULES" on page 1499
SET CURRENT SQLID	Assigns a value to the CURRENT SQLID special register	"SET CURRENT SQLID" on page 1500
SET ENCRYPTION PASSWORD	Assign a value for the ENCRYPTION PASSWORD and, optionally, a hint for the password	"SET host-variable assignment" on page 1504
SET host-variable Assignment	Assigns values to host variables	"SET host-variable assignment" on page 1504
SET PATH	Assigns a value to the CURRENT PATH special register	"SET PATH" on page 1507
SET SCHEMA	Assigns a value to the CURRENT SCHEMA special register	"SET SCHEMA" on page 1510
SET transition-variable Assignment	Assigns values to transition variables	"SET transition-variable assignment" on page 1513
SIGNAL	Signals an error or warning condition and optionally returns the specified message text	"SIGNAL statement" on page 1582
TRUNCATE	Deletes all rows from a table	"TRUNCATE" on page 1517
UPDATE	Updates the values of one or more columns in one or more rows of a table	"UPDATE" on page 1521
VALUES	Provides a way to invoke a user-defined function from a trigger	"VALUES" on page 1536
VALUES INTO	Assigns values to host variables	"VALUES INTO" on page 1537
WHENEVER	Defines actions to be taken on the basis of SQL return codes	"WHENEVER" on page 1539

## How SQL statements are invoked

SQL statements are invoked in different ways depending on whether the statement is an executable or nonexecutable statement or the *select-statement*.

The SQL statements are classified as *executable* or *nonexecutable*. The description of each statement includes a heading on invocation that indicates whether or not the statement is executable.

*Executable statements* can be invoked in the following ways:

- Embedded in an application program
- Dynamically prepared and executed
- Dynamically prepared and executed using DB2 ODBC function calls

- Issued interactively

Depending on the statement, you can use some or all of these methods. The section on invocation in the description of each statement tells you which methods can be used.

A *nonexecutable statement* can only be embedded in an application program.

The *select-statement* is an additional SQL statement construct. (See “*select-statement*” on page 669.) It is used in a different way from other statements.

A *select-statement* can be invoked in the following ways:

- Included in DECLARE CURSOR and implicitly executed by OPEN
- Dynamically prepared, referred to in DECLARE CURSOR, and implicitly executed by OPEN
- Dynamically executed (no PREPARE required) using a DB2 ODBC function call
- Issued interactively

The first two methods are called, respectively, the *static* and the *dynamic* invocation of *select-statement*.

## Embedding a statement in an application program

You can include SQL statements in a source program that will be submitted to the precompiler. Such statements are said to be *embedded* in the application program.

An embedded statement can be placed anywhere in the application program where a host language statement is allowed. Each embedded statement must be preceded by a keyword (or keywords) to indicate that the statement is an SQL statement.

- In C and COBOL, each embedded statement must be preceded by the keywords EXEC SQL.
- In Java, each embedded statement must be preceded by the keywords #sql.
- In REXX, each embedded statement must be preceded by the keyword EXECSQL.

**Executable statements:** An executable statement embedded in an application program is executed every time a statement of the host language would be executed if specified in the same place. (Thus, for example, a statement within a loop is executed every time the loop is executed, and a statement within a conditional construct is executed only when the condition is satisfied.)

An embedded statement can contain references to host variables. A host variable referred to in this way can be used in one of two ways:

### As input

The current value of the host variable is used in the execution of the statement.

### As output

The variable is assigned a new value as a result of executing the statement.

In particular, all references to host variables in expressions and predicates are effectively replaced by current values of the variables; that is, the variables are used as input. The treatment of other references is described individually for each statement.

The successful or unsuccessful execution of the statement is indicated by setting the SQLCODE and SQLSTATE fields in the SQLCA.<sup>23</sup> You must therefore follow all executable statements by a test of SQLCODE or SQLSTATE. Alternatively, you can use the WHENEVER statement (which is itself nonexecutable) to change the flow of control immediately after the execution of an embedded statement.

**Nonexecutable statements:** An embedded nonexecutable statement is processed only by the precompiler. The precompiler reports any errors encountered in the statement. The statement is never executed, and acts as a no-operation if placed among executable statements of the application program. Therefore, do not follow such statements with a test of an SQL return code.

## Dynamic preparation and execution

Your application program can dynamically build an SQL statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, input from a workstation).

In non-Java languages, the statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE and executed by means of the (embedded) statement EXECUTE, as described in *DB2 Application Programming and SQL Guide*. Alternatively, you can use the (embedded) statement EXECUTE IMMEDIATE to prepare and execute a statement in one step. In Java, the statement can be prepared for execution by means of the Statement, PreparedStatement, and CallableStatement classes, and executed by means of their respective execute() methods.

The statement can also be prepared by calling the DB2 ODBC SQLPrepare function and then executed by calling the DB2 ODBC SQLExecute function. In both cases, the application does not contain an embedded PREPARE or EXECUTE statement. You can execute the statement, without preparation, by passing the statement to the DB2 ODBC SQLExecDirect function. *DB2 ODBC Guide and Reference* describes the APIs supported with this interface.

A statement that is going to be prepared must not contain references to host variables. It can instead contain parameter markers. (See Parameter markers in the description of the PREPARE statement for rules concerning parameter markers.) When the prepared statement is executed, the parameter markers are effectively replaced by current values of the host variables specified in the EXECUTE statement. (See the EXECUTE statement for rules concerning this replacement.) After it is prepared, a statement can be executed several times with different values of host variables. Parameter markers are not allowed in the SQL statement prepared and executed using EXECUTE IMMEDIATE.

In non-Java languages, the successful or unsuccessful execution of the statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the EXECUTE (or EXECUTE IMMEDIATE) statement. You should check the fields as described above for embedded statements. In Java, the successful or unsuccessful execution of the statement is handled by Java Exceptions.

---

23. SQLCODE and SQLSTATE cannot be in the SQLCA when the precompiler option STDSQL(YES) is in effect. See "SQL standard language" on page 255.

As explained in “Authorization IDs and dynamic SQL” on page 64, the DYNAMICRULES behavior in effect determines the privilege set that is used for authorization checking when dynamic SQL statements are processed. The following table summarizes those privilege sets. (See Table 6 on page 64 for a list of the DYNAMICRULES bind option values that determine which behavior is in effect).

*Table 81. DYNAMICRULES behaviors and authorization checking*

DYNAMICRULES behavior	Privilege set
Run behavior	The union of the set of privileges held by each authorization ID of the process if the dynamically prepared statement is other than an ALTER, CREATE, DROP, GRANT, RENAME, or REVOKE statement.
	The privileges that are held by the SQL authorization ID of the process or the role of the primary authorization ID (if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause), if the dynamic SQL statement is a CREATE, GRANT, or REVOKE statement.
Bind behavior	The privileges that are held by the primary authorization ID of the owner of the package or plan.
Define behavior	The privileges that are held by the authorization ID of the stored procedure or user-defined function owner (definer).
Invoke behavior	The privileges that are held by the authorization ID of the stored procedure or user-defined function invoker. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked if they are needed for the required authorization. Therefore, in that case, the privilege set is the union of the set of privileges that are held by each authorization ID or role (if running in a trusted context).

## Static invocation of a SELECT statement

A SELECT statement can be invoked statically in different ways.

You can include a SELECT statement as a part of the (nonexecutable) statement DECLARE CURSOR. Such a statement is executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

If the application is using DB2 ODBC, the SELECT statement is first prepared with the SQLPrepare function call. It is then executed with the SQLExecute function call. Data is then fetched with the SQLFetch function call. The application does not explicitly open the cursor.

The SELECT statement used in this way can contain references to host variables. These references are effectively replaced by the values that the variables have at the moment of executing OPEN.

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

If the application is using DB2 ODBC, the successful execution of the SELECT statement is indicated by the return code from the SQLExecute function call. If necessary, the application can retrieve the SQLCA by calling the SQLGetSQLCA function.

## Dynamic invocation of a SELECT statement

Your application program can dynamically build a SELECT statement in the form of a character string placed in a host variable. In general, the statement is built from some data available to the application program (for example, a query obtained from a terminal).

The statement so constructed can be prepared for execution by means of the (embedded) statement PREPARE, and referred to by a (nonexecutable) statement DECLARE CURSOR. The statement is then executed every time you open the cursor by means of the (embedded) statement OPEN. After the cursor is open, you can retrieve the result table a row at a time by successive executions of the (embedded) SQL FETCH statement.

The SELECT statement used in that way must not contain references to host variables. It can instead contain parameter markers. (See "Notes" in "PREPARE" on page 1405 for rules concerning parameter markers.) The parameter markers are effectively replaced by the values of the host variables specified in the OPEN statement. (See "OPEN" on page 1400 for rules concerning this replacement.)

The successful or unsuccessful execution of the SELECT statement is indicated by the values returned in the SQLCODE and SQLSTATE fields in the SQLCA after the OPEN. You should check the fields as described above for embedded statements.

## Interactive invocation

An SQL statement submitted to DB2 from a terminal is said to be issued interactively.

IBM relational database management systems allow you to enter SQL statements from a terminal. DB2 for z/OS provides SPUFI to prepare and execute SQL statements. Other products are also available. A statement entered in this way is said to be issued interactively.

A statement issued interactively must not contain parameter markers or references to host variables, because these make sense only in the context of an application program. For the same reason, there is no SQLCA involved.

## SQL diagnostics information

DB2 uses a diagnostics area to store status information and diagnostics information about the execution of an executable SQL statement.

When an SQL statement other than GET DIAGNOSTICS or *compound-statement* is processed, the current diagnostics area is cleared before processing the SQL statement. As each SQL statement is processed, information about the execution of that SQL statement is recorded in the current diagnostics area as one or more completion conditions or exception conditions.

A completion condition indicates that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the statement was not successful. The GET

DIAGNOSTICS statement can be executed in most languages to return conditions and other information about the previously executed SQL statement from the diagnostics area. Additionally, the condition information is provided through language specific mechanisms:

- For SQL procedures, see “Notes” on page 1546 in “SQL-procedure-statement” on page 1546 for information about detecting and processing error and warning conditions.
- For host language applications, see “Detecting and processing error and warning conditions in host language applications.”

#### Related reference

“GET DIAGNOSTICS” on page 1317

## Detecting and processing error and warning conditions in host language applications

Errors and warnings conditions in host language applications can be checked by using the SQLCODE or SQLSTATE host variables or by using the SQLCA.

Each host language provides a mechanism for handling diagnostic information.

- In Assembler, C, COBOL, Fortran, and PL/I, an application program that contains executable SQL statements must provide at least one of the following:
  - A structure named SQLCA, which can be provided by using the INCLUDE SQLCA statement
  - A stand-alone CHAR(5) (CHAR(6) in C) variable named SQLSTATE (SQLSTT in Fortran)
  - A stand-alone integer variable named SQLCODE (SQLCOD in Fortran)
- In Java, for error conditions, the getSQLState method of the JDBC SQLException class can be used to get the SQLSTATE and the getErrorCode method can be used to get the SQLCODE.
- In REXX, an SQLCA is provided automatically.

Whether you define stand-alone SQLCODE and SQLSTATE host variables or an SQLCA in your program depends on the DB2 precompiler option you choose.

If the application is using DB2 ODBC and it calls the SQLGetSQLCA function, it need only include an SQLCA. Otherwise, all notification of success or errors is specified with return codes for the various function calls.

When you specify STDSQL(YES), which indicates conformance to the SQL standard, you should not define an SQLCA. The stand-alone variable for SQLCODE must be a valid host variable in the DECLARE SECTION of a program. It can also be declared outside of the DECLARE SECTION when no variable is defined for SQLSTATE. The stand-alone variable for SQLSTATE must be declared in the DECLARE SECTION. It must not be declared as an element of a structure.

Use a stand-alone SQLSTATE to conform with the SQL 2003 Core standard. When you specify STDSQL(NO), which indicates conformance to DB2 rules, you must include an SQLCA explicitly to have access to the SQLSTATE and SQLCODE information.

### SQLSTATE

DB2 sets SQLSTATE after each SQL statement (other than GET DIAGNOSTICS or a compound statement) is executed. DB2 returns values that conform to the error

specification in the SQL standard. Thus, application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE.

SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors. The coding scheme is the same for all IBM implementations of SQL. The SQLSTATE values are based on the SQLSTATE specifications contained in the SQL standard. Error messages and the tokens that are substituted for variables in error messages are associated with SQLCODE values, not SQLSTATE values.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

If the application is using DB2 ODBC, the SQLSTATE returned conforms to the ODBC Version 2.0 specification.

## **SQLCODE**

The SQLCODE is also set by DB2 after each SQL statement is executed as follows:

DB2 conforms to the SQL standard as follows:

- If SQLCODE = 0 and SQLWARN0 is blank, execution was successful.
- If SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data because the cursor was positioned after the last row of the result table.
- If SQLCODE > 0 and not = 100, execution was successful with a warning.
- If SQLCODE = 0 and SQLWARN0 = 'W', execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.

In the case of a LOOP statement, the SQLSTATE is set after the END LOOP portion of the LOOP statement completes. With the REPEAT statement, the SQLSTATE is set after the UNTIL and END REPEAT portions of the REPEAT statement completes.

The SQL standard does not define the meaning of any other specific positive or negative values of SQLCODE, and the meaning of these values is not the same in all implementations of SQL.

If the application is using DB2 ODBC, an SQLCODE is only returned if the application issues the SQLGetSQLCA function.

## SQL comments

Static SQL statements can include host language or SQL comments. Dynamic SQL statements can include SQL comments. There are two types of SQL comments, simple comments and bracketed comments.

### simple comments

Simple comments are introduced with two consecutive hyphens (--) and end with the end of a line. The following rules apply to the use of simple comments:

- The two hyphens must be on the same line and must not be separated by a space.
- Simple comments can be started whenever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Simple comments cannot be continued to the next line.
- In COBOL, the hyphen must be preceded by a space.

### bracketed comments

Bracketed comments are introduced with /\* and end with \*/. The following rules apply to the use of bracketed comments:

- The /\* must be on the same line and not separated by a space.
- The \*/ must be one the same line and not separated by a space.
- Bracketed comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Bracketed comments can be continued to the next line.
- Bracketed comments can be nested within other bracketed comments. However, nested bracketed comments are not supported by DSNTEP2, DSNTEP4, SPUFI, or the command line processor.
- Bracketed comments are not allowed in static SQL statements in a COBOL, Fortran, or Assembler program.

*Example:* This example shows how to include comments in an SQL statement within a C program. The example uses both simple and bracketed comments:

```
EXEC SQL
  CREATE VIEW PRJ_MAXPER      --projects with most support personnel
  /*
   * Returns number and name of the project
   */
  AS SELECT PROJNO, PROJNAME    -- number and name of project
       FROM DSN8910.PROJ
  /*
   * E21 is the systems support dept code
   */
  WHERE DEPTNO = 'E21'          -- systems support dept code
    AND PRSTAFF > 1;
```

For information about host language comments, refer to *DB2 Application Programming and SQL Guide*.

## ALLOCATE CURSOR

The ALLOCATE CURSOR statement defines a cursor and associates it with a result set locator variable.

### Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

### Authorization

None required.

### Syntax

```
►►—ALLOCATE—cursor-name—CURSOR FOR RESULT SET—rs-locator-variable—►►
```

### Description

#### *cursor-name*

Names the cursor. The name must not identify a cursor that has already been declared in the source program.

#### **CURSOR FOR RESULT SET *rs-locator-variable***

Specifies a result set locator variable that has been declared in the application program according to the rules for declaring result set locator variables.

The result set locator variable must contain a valid result set locator value, as returned by the ASSOCIATE LOCATORS or DESCRIBE PROCEDURE SQL statement. The value of the result set locator variable is used at the time the cursor is allocated. Subsequent changes to the value of the result set locator have no affect on the allocated cursor. The result set locator value must not be the same as a value used for another cursor allocated in the source program.

### Notes

**Dynamically prepared ALLOCATE CURSOR statements:** The EXECUTE statement with the USING clause must be used to execute a dynamically prepared ALLOCATE CURSOR statement. In a dynamically prepared statement, references to host variables are represented by parameter markers (question marks). In the ALLOCATE CURSOR statement, *rs-locator-variable* is always a host variable. Thus, for a dynamically prepared ALLOCATE CURSOR statement, the USING clause of the EXECUTE statement must identify the host variable whose value is to be substituted for the parameter marker that represents *rs-locator-variable*.

You cannot prepare an ALLOCATE CURSOR statement with a statement identifier that has already been used in a DECLARE CURSOR statement. For example, the following SQL statements are invalid because the PREPARE statement uses STMT1 as an identifier for the ALLOCATE CURSOR statement and STMT1 has already been used for a DECLARE CURSOR statement.

```
DECLARE CURSOR C1 FOR STMT1;
PREPARE STMT1 FROM      INVALID
'ALLOCATE C2 CURSOR FOR RESULT SET ?';
```

**Rules for using an allocated cursor:** The following rules apply when you use an allocated cursor:

- You cannot open an allocated cursor with the OPEN statement.
- You can close an allocated cursor with the CLOSE statement. Closing an allocated cursor closes the associated cursor defined in the stored procedure.
- You can allocate only one cursor to each result set.

**The life of an allocated cursor:** A rollback operation, an implicit close, or an explicit close destroy allocated cursors. A commit operation destroys allocated cursors that are not defined WITH HOLD by the stored procedure. Destroying an allocated cursor closes the associated cursor defined in the stored procedure.

**Considerations for scrollable cursors:** Following an ALLOCATE CURSOR statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see “GET DIAGNOSTICS” on page 1317):

- DB2\_SQL\_ATTR\_CURSOR\_HOLD. Whether the cursor was defined with the WITH HOLD attribute.
  - DB2\_SQL\_ATTR\_CURSOR\_SCROLLABLE. Scrollability of the cursor.
  - DB2\_SQL\_ATTR\_CURSOR\_SENSITIVITY. Effective sensitivity of the cursor.
- The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.
- DB2\_SQL\_ATTR\_CURSOR\_ROWSET. Whether the cursor can be used to access rowsets.
  - DB2\_SQL\_ATTR\_CURSOR\_TYPE. Whether a cursor type is forward-only, static, or dynamic.

In addition, if subsystem parameter DISABSCL is set to NO, a subset of the above information is returned in the SQLCA:

- The scrollability of the cursor is in SQLWARN1.
- The sensitivity of the cursor is in SQLWARN4.
- The effective capability of the cursor is in SQLWARN5.

## Example

The statement in the following example is assumed to be in a PL/I program.

Define and associate cursor C1 with the result set locator variable LOC1 and the related result set returned by the stored procedure:

```
EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :LOC1;
```

# ALTER DATABASE

The ALTER DATABASE statement changes the description of a database at the current server.

## Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

## Authorization

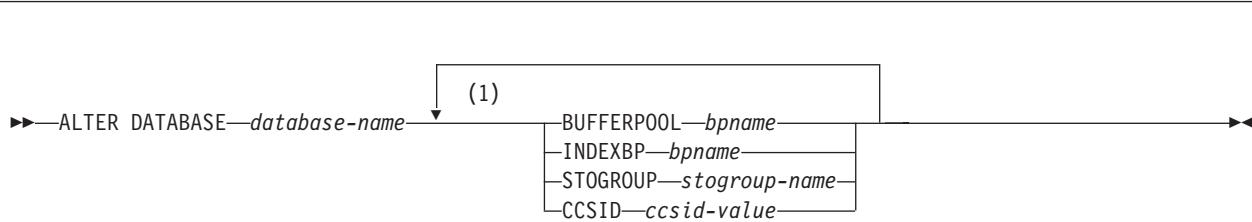

The privilege set that is defined below must include at least one of the following:

- The DROP privilege on the database
- Ownership of the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

## Syntax

### Notes:

- 1 The same clause must not be specified more than one time.

## Description

### DATABASE *database-name*

Identifies the database that is to be altered. The name must identify a database that exists at the current server and must not identify an implicitly created system database.

### BUFFERPOOL *bpname*

Identifies the default buffer pool for the table spaces within the database. It does not apply to table spaces that already exist within the database.

If the database is a work file database, 8 KB and 16 KB buffer pools cannot be specified.

See “Naming conventions” on page 51 for more details about *bpname*.

**INDEXBP** *bpname*

Identifies the default buffer pool for the indexes within the database. It does not apply to indexes that already exist within the database. The name can identify a 4 KB, 8 KB, 16 KB, or 32 KB buffer pool. See “Naming conventions” on page 51 for more details about *bpname*.

**STOGROUP** *stogroup-name*

Identifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. It does not apply to table spaces and indexes that already exist within the database.

**CCSID** *ccsid-value*

Identifies the default CCSID for table spaces within the database. It does not apply to existing table spaces in the database. *ccsid-value* must identify a CCSID value that is compatible with the current value of the CCSID for the database. “Notes” contains a list that shows the CCSID to which a given CCSID can be altered.

CCSID cannot be specified for a work file database.

## Notes

**Altering the CCSID:** The ability to alter the default CCSID enables you to change to a CCSID that supports the Euro symbol. You can only convert between specific CCSIDs that do and do not define the Euro symbol. In most cases, the code point that supports the Euro symbol replaces an existing code point, such as the International Currency Symbol (ICS).

Changing a CCSID can be disruptive to the system and requires several steps. For each encoding scheme of a system (ASCII, EBCDIC, and Unicode), DB2 supports SBCS, DBCS, and mixed CCSIDs. Therefore, the CCSIDs for all databases and all table spaces within an encoding scheme should be altered at the same time. Otherwise, unpredictable results might occur.

The recommended method for changing the CCSID requires that the data be unloaded and reloaded. See *DB2 Installation Guide* for the steps needed to change the CCSID, such as running an installation CLIST to modify the CCSID data in DSNHDECP, when to drop and recreate views, and when to rebind invalidated plans and packages.

The following lists show the CCSIDs that can be converted. The second CCSID in each pair is the CCSID with the Euro symbol. The CCSID can be changed from the CCSID that does not support the Euro symbol to the CCSID that does, and vice versa. For example, if the current CCSID is 500, it can be changed to 1148.

**EBCDIC CCSIDs**

-----	
37	1140
273	1141
277	1142
278	1143
280	1144
284	1145
285	1146
297	1147
500	1148
871	1149

ASCII CCSIDs

850	858
874	4970
1250	5346
1251	5347
1252	5348
1253	5349
1254	5350

1257	5353

## Example

Change the default buffer pool for both table spaces and indexes within database ABCDE to BP2.

```
ALTER DATABASE ABCDE
  BUFFERPOOL BP2
  INDEXBP BP2;
```

## ALTER FUNCTION (external)

The ALTER FUNCTION statement changes the description of a user-defined external scalar function or external table function at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

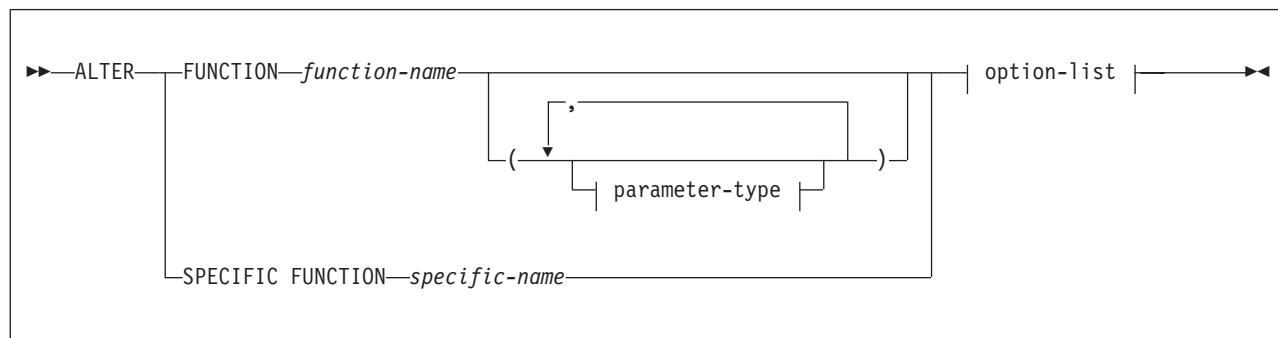

If the statement is dynamically prepared, the privilege set is the privileges that are held by the authorization IDs of the process. The specified function name can include a schema name (a qualifier). However, if the schema name is not the same as one of these authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- An authorization ID of the process has the ALTERIN privilege on the schema.

If the environment in which the function is to be run is being changed, the authorization ID must have authority to use the WLM environment specified. The required authorization is obtained from an external security product, such as RACF.

For *external scalar functions*, when LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

### Syntax

**parameter-type:**

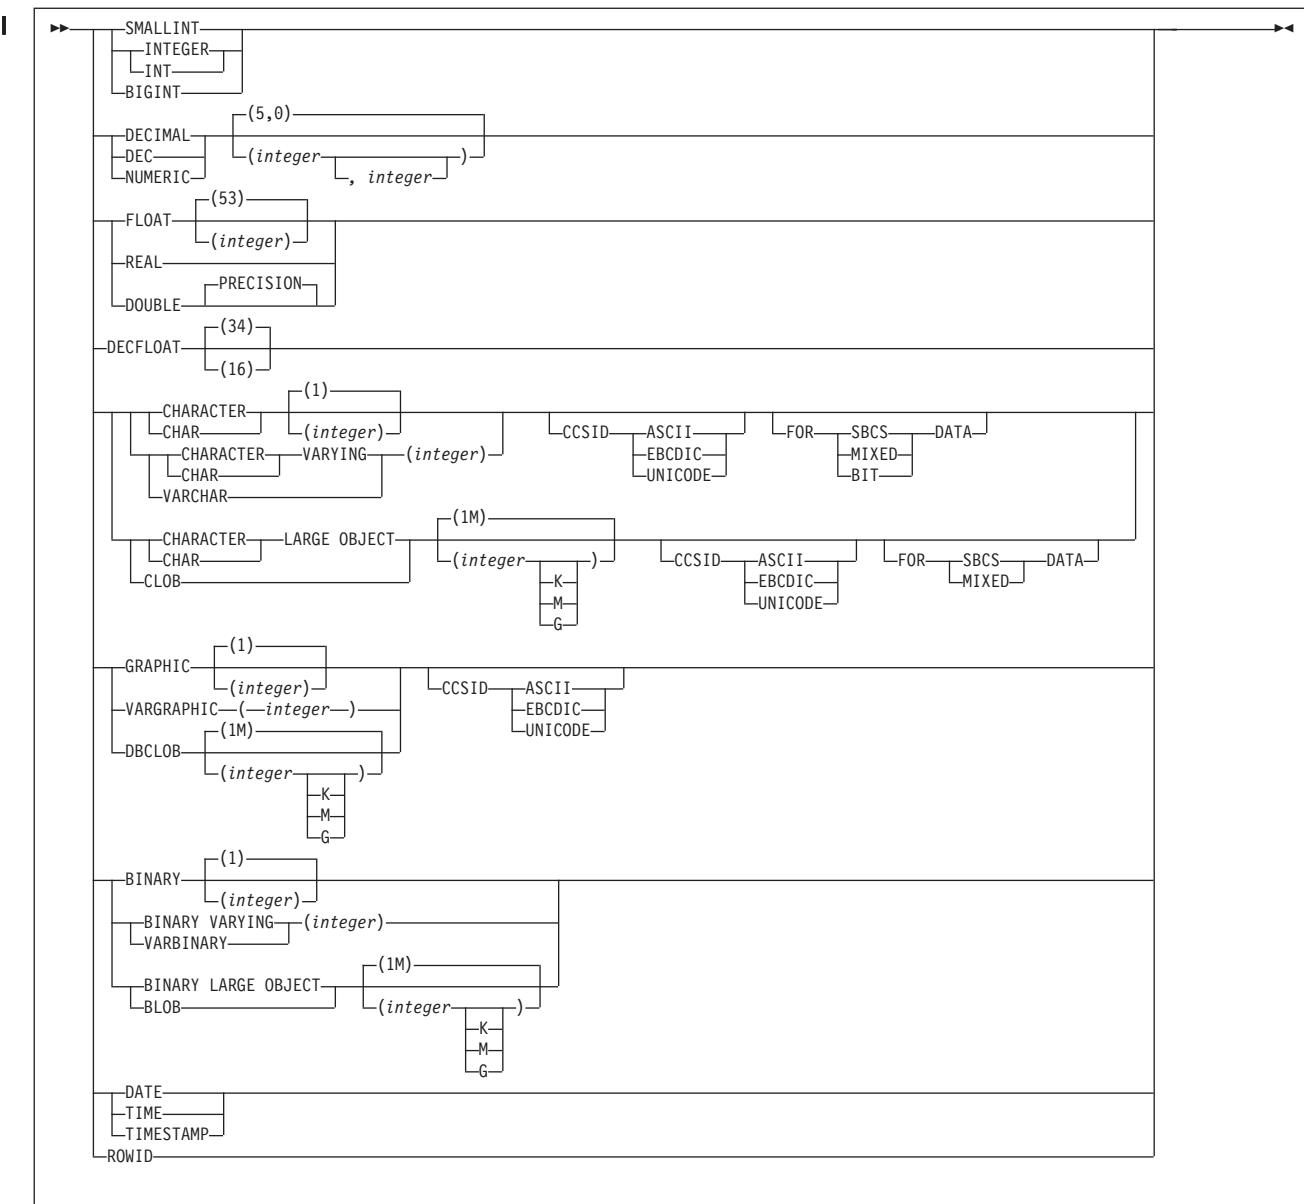

**Notes:**

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

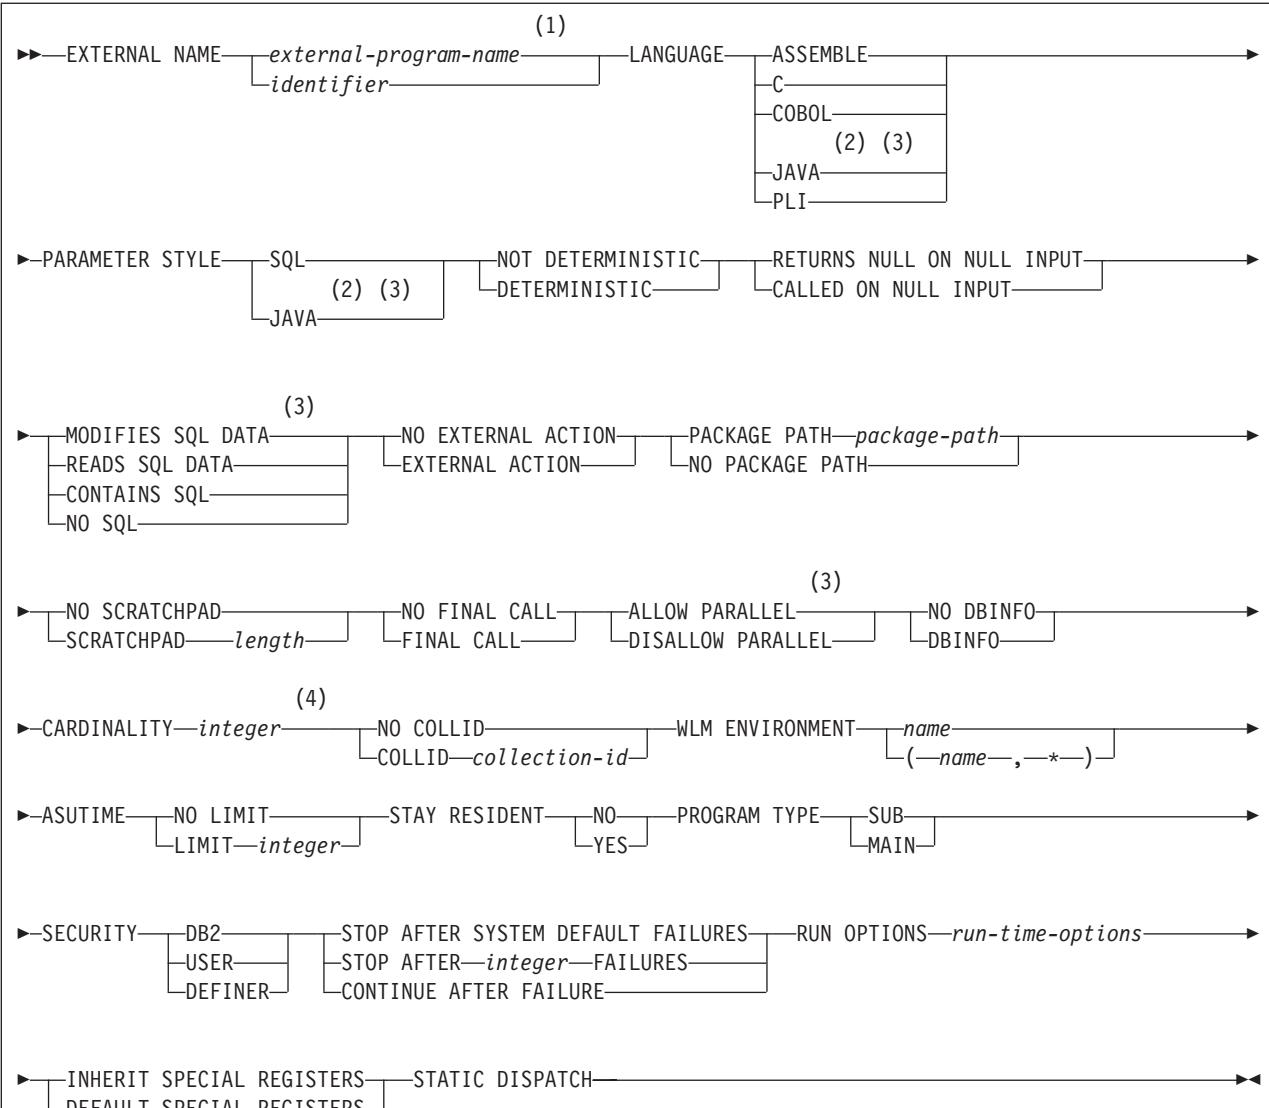

**data-type:**

**built-in-type:**

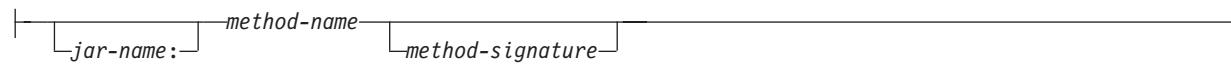

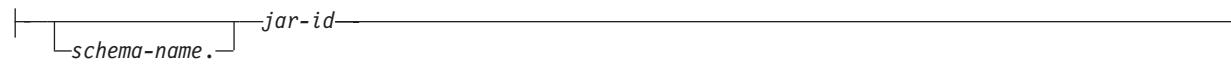

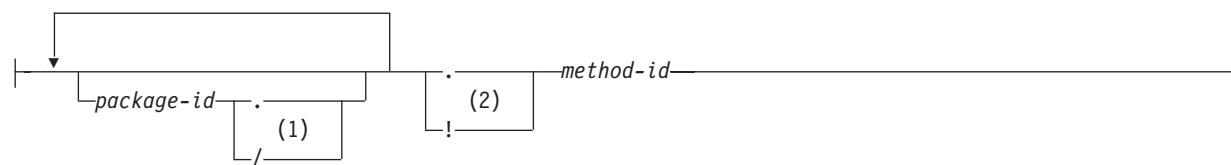

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

#### Notes:

- 1 If **LANGUAGE** is **JAVA**, **EXTERNAL NAME** must be specified with a valid *external-java-routine-name*.
- 2 When **LANGUAGE JAVA** is specified, **PARAMETER STYLE JAVA** must also be specified. When **PARAMETER STYLE JAVA** is specified, **LANGUAGE JAVA** must also be specified.
- 3 **LANGUAGE JAVA**, **PARAMETER STYLE JAVA**, **MODIFIES SQL DATA**, and **ALLOW PARALLEL** are not supported for *external table functions*.
- 4 **CARDINALITY** is not supported for *external scalar functions*.

**external-java-routine-name:****jar-name:****method-name:****method-signature:****Notes:**

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

## Description

One of the following three clauses identifies the function to be changed.

**FUNCTION *function-name***

Identifies the external function by its function name. *function-name* must identify a function that exists at the current server. The function must be a user-defined external function, and there must be exactly one function with *function-name* in the schema.

The function can have any number of input parameters. If the schema does not contain a function with *function-name* or contains more than one function with this name, an error occurs.

**FUNCTION *function-name* (*parameter-type*,...)**

Identifies the external function by its function signature, which uniquely identifies the function.

***function-name***

Identifies the function by its name.

If *function-name()* is specified, the function that is identified must have zero parameters.

*(parameter-type,...)*

Identifies the number of input parameters of the function and their data types.

The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

If the function was defined with a table parameter (the **LIKE TABLE** *name AS LOCATOR* clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because 1<=n<=21 indicates REAL and 22<=n<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR** *subtype DATA* clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 915 for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

**SPECIFIC FUNCTION** *specific-name*

Identifies the external function by its specific name. A function with the specific name must exist in the schema.

The following clauses change the description of the function that has been identified to be changed.

**EXTERNAL NAME** *external-program-name* **or** *identifier*

Identifies the user-written code (program) that runs when the function is invoked.

If **LANGUAGE** is **JAVA**, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-name* values are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a Java function for which **NO SQL** is in effect.

An *external-java-routine-name* contains the following parts:

*jar-name*

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the **QUALIFIER** option of the **BIND** subcommand for a package or plan when the package or plan was created or last changed. The schema name can also be the authorization ID in the **QUALIFIER** option of the **CREATE PROCEDURE** or **ALTER PROCEDURE** statement for a native SQL procedure when the procedure was created or last changed. If the **QUALIFIER** is not specified, the schema name is the owner of the package, plan, or native SQL procedure.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the **CURRENT SCHEMA** special register.

If *jar-name* is specified, it must exist when the **ALTER FUNCTION** statement is processed.

If *jar-name* is not specified, the function is loaded from the class file directly. DB2 searches the directories in the **CLASSPATH** associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a **JAVAENV** DD card on the **JCL** used to start the address space for a WLM-managed function.

*method-name*

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method IDs are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what method IDs can contain are not necessarily the same as the rules for an SQL ordinary identifier.

*package-id*

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

*class-id*

Identifies the class identifier of the Java object.

*method-id*

Identifies the method identifier with the Java class to be invoked.

*method-signature*

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the user-defined function involves any input or output parameters that can be NULL. When the function that is being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements that are specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER FUNCTION statement.

For other values of **LANGUAGE**, the value must conform to the naming conventions for load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

**LANGUAGE**

Specifies the application programming language in which the function is written. All programs must be designed to run in IBM's Language Environment® environment.

**ASSEMBLE**

The function is written in Assembler.

**C** The function is written in C or C++.

**COBOL**

The function is written in COBOL, including the object-oriented language extensions.

**JAVA**

The user-defined function is written in Java and is executed in the Java virtual machine. If the ALTER FUNCTION statement results in changing **LANGUAGE** to **JAVA**, **PARAMETER STYLE JAVA** and an **EXTERNAL NAME** clause must be specified to provide the appropriate values. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid *external-java-routine-name* and **PARAMETER STYLE** must be specified with **JAVA**.

Do not specify **LANGUAGE JAVA** when **SCRATCHPAD**, **FINAL CALL**, **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is specified. Do not specify **LANGUAGE JAVA** for a table function.

**PLI**

The function is written in PL/I.

**PARAMETER STYLE**

Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

**SQL**

Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- Input parameters. The first  $n$  parameters are the input parameters that are specified for the function.
- Result parameters. For an external scalar function, a parameter for the result of the function. For an external table function, the next  $m$  parameters that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
- Input parameter indicator variables.  $n$  parameters for the indicator variables for the input parameters.
- Result parameter indicator variables. For an external scalar function, a parameter for the indicator variable for the result of the function that is specified on the RETURNS clause of the CREATE statement that defined the function. For an external table function,  $m$  parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause of the CREATE statement that defined the function.
- The SQLSTATE to be returned to DB2.
- The qualified name of the function.
- The specific name of the function.
- The SQL diagnostic string to be returned to DB2.
- The scratchpad, if SCRATCHPAD is specified.
- The call type. For an external scalar function, the call type is passed only if FINAL CALL is specified. The call type is always passed for an external table function.
- The DBINFO structure, if DBINFO is specified.

#### JAVA

Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications. If the ALTER FUNCTION statement results in changing LANGUAGE to JAVA, PARAMETER STYLE JAVA and an EXTERNAL NAME clause must be specified to provide the appropriate values. PARAMETER STYLE JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

Do not specify PARAMETER STYLE JAVA for a table function.

#### NOT DETERMINISTIC or DETERMINISTIC

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

#### NOT DETERMINISTIC

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

Some SQL functions that invoke functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

If a view or a materialized query table definition refers to the function, the function cannot be changed to **NOT DETERMINISTIC**. To change the function, drop any views or materialized query tables that refer to the function first.

#### **DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

#### **RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**

Specifies whether the function is called if any of the input arguments is null at execution time.

#### **RETURNS NULL ON NULL INPUT**

The function is not called if any of the input arguments is null. For an external scalar function, the result is the null value. For an external table function, the result is an empty table, which is a table with no rows.

#### **CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. For an external scalar function, the function can return a null or nonnull value. For an external table function, the function can return an empty table, depending on its logic.

#### **MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function.

#### **MODIFIES SQL DATA**

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify **MODIFIES SQL DATA** when **ALLOW PARALLEL** is in effect.

#### **READS SQL DATA**

Specifies that the function can execute statements with a data access indication of **READS SQL DATA**, **CONTAINS SQL**, or **NO SQL**. The function cannot execute SQL statements that modify data.

#### **CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data classification of **CONTAINS SQL** or **NO SQL**. SQL statements that neither read nor modify SQL data can be executed by the function. Statements that are not supported in any function return a different error.

#### **NO SQL**

Specifies that the function can execute only SQL statements with a data access classification of **NO SQL**. Do not specify **NO SQL** for a Java function that uses a JAR file.

**NO EXTERNAL ACTION or EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for external functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

**NO EXTERNAL ACTION**

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **NO EXTERNAL ACTION** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

**EXTERNAL ACTION**

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the **DISALLOW PARALLEL** clause for functions that do not work correctly with parallelism.

If you specify **EXTERNAL ACTION**, DB2:

- Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify **EXTERNAL ACTION** if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared **WITH HOLD**.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

If a view or a materialized query table definition refers to the function, the function cannot be changed to **EXTERNAL ACTION**. To change the function, drop any views or materialized query tables that refer to the function first.

DB2 does not verify that the function program is consistent with the specification of **EXTERNAL ACTION** or **NO EXTERNAL ACTION**.

**NO PACKAGE PATH or PACKAGE PATH *package-path***

Identifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM that is associated with the function is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the function is the same as

the list of package collections for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

**PACKAGE PATH** *package-path*

Specifies a list of package collections, in the same format as used in the SET CURRENT PACKAGE PATH statement.

If the **COLLID** clause is specified with PACKAGE PATH, the **COLLID** clause is ignored when the function is invoked.

The *package-path* value that is associated with the function definition is checked when the function is invoked. If *package-path* contains SESSION\_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether DB2 is to provide a scratchpad for the function. Using reentrant external functions and a scratchpad (which provides an area for the function to save information from one invocation to the next) is strongly recommended.

**NO SCRATCHPAD**

A scratchpad is not allocated and passed to the function.

**SCRATCHPAD** *length*

When the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00').
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad.

For example, assuming that user-defined function UDFX is a scalar function that is defined with the **SCRATCHPAD** option, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A) FROM TABLEB  
      WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

For another example, assume that UDFX is a user-defined table function that is defined with the **SCRATCHPAD** option. Two scratchpads are allocated for the two references to function UDFX in the following SQL statement:

```
SELECT *  
      FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the SQL statement. Specify the **DISALLOW PARALLEL** clause for functions that do not work correctly with parallelism.

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2

initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify **FINAL CALL** to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time that the function is invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify **SCRATCHPAD**, DB2:

- Does not move the function from one TCB or address space to another between **FETCH** operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared **WITH HOLD**.

Do not specify **SCRATCHPAD** when **LANGUAGE JAVA** is specified.

#### **NO FINAL CALL or FINAL CALL**

Specifies whether a final call is made to the function. A *final call* enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the **SCRATCHPAD** keyword and the function acquires system resource and anchors them in the scratchpad.

The effect of **NO FINAL CALL** or **FINAL CALL** depends on whether the external function is a scalar function or a table function.

**For an external scalar function:**

##### **NO FINAL CALL**

A final call is not made to the external scalar function. The function does not receive an additional argument that specifies the type of call.

##### **FINAL CALL**

A final call is made to the external scalar function. See the following description of call types for the characteristics of a final call. When **FINAL CALL** is specified, the function receives an additional argument that specifies the type of call to enable the function to differentiate between a final call and another type of call. Do not specify **FINAL CALL** when **LANGUAGE JAVA** is specified.

For more information on **NO FINAL CALL** and **FINAL CALL** for external scalar functions, including the types of calls, see the description of the option for “**CREATE FUNCTION** (external scalar)” on page 916.

**For an external table function:**

##### **NO FINAL CALL**

A first and final call are not made to the external table function.

##### **FINAL CALL**

A first call and final call are made to the external table function in addition to one or more other types of calls.

For both **NO FINAL CALL** and **FINAL CALL**, the function receives an additional argument that specifies the type of call. For more information on

NO FINAL CALL and FINAL CALL for external table functions, including the types of calls, see the description of the option for “CREATE FUNCTION (external table)” on page 940.

**ALLOW or DISALLOW PARALLEL**

Specifies whether, for a single reference to the function, the function can be executed in parallel. If the function is defined with **MODIFIES SQL DATA**, specify **DISALLOW PARALLEL**, not **ALLOW PARALLEL**.

**ALLOW PARALLEL**

Specifies that DB2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

See **SCRATCHPAD**, **EXTERNAL ACTION**, and **FINAL CALL** for considerations when specifying **ALLOW PARALLEL**.

**DISALLOW PARALLEL**

Specifies that DB2 does not consider parallelism for the function.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the function when it is invoked.

**NO DBINFO**

Additional information is not passed.

**DBINFO**

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

Do not specify **DBINFO** when **LANGUAGE JAVA** is specified.

**CARDINALITY** *integer*

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of *integer* must range from 0 to 2147483647.

If a function has an infinite cardinality (which means that the function never returns the “end-of-table” condition and always returns a row), a query that requires the end-of-table condition to work correctly needs to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

Do not specify **CARDINALITY** for external scalar functions.

**NO COLLID or COLLID** *collection-id*

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function is bound.

**NO COLLID**

Specifies the package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET

special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

**COLLID** *collection-id*

Specifies the name of the package collection that is to be used when the function is executed.

**WLM ENVIRONMENT**

An SQL identifier that identifies the *name* of the WLM (workload manager) application environment in which the function is to run.

*name*

The WLM environment in which the function must run. If the user-defined function is nested and if the calling stored procedure or invoking user-defined function is not running in an address space associated with the specified WLM environment, DB2 routes the function request to a different address space.

*(name,\*)*

When an SQL application program calls the function, *name* specifies the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in the same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

The *name* of the WLM environment is an SQL identifier.

To change the environment in which the function is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the service units.

**LIMIT** *integer*

The limit on the service units is a positive integer in the range of 1 to 2 147 483 647. If the function uses more service units than the specified value, DB2 cancels the function.

**STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends.

**NO** The load module is deleted from memory after the function ends. Use **NO** for non-reentrant functions.

**YES**

The load module remains resident in memory after the function ends. Use **YES** for reentrant functions.

**PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.

**SUB**

The function runs as a subroutine.

**MAIN**

The function runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is in effect.

**SECURITY**

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID associated with the WLM-established stored procedure address space.

**USER**

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**

An external security environment should be used with the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures. The following options must not be specified for SQL functions or sourced functions.

**STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

**STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

**RUN OPTIONS *run-time-options***

Specifies the Language Environment runtime options to be used for the function. You must specify *run-time-options* as a character string that is no longer than 254 bytes. To replace any existing runtime options with no options, specify an empty string with **RUN OPTIONS**. When you specify an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

Do not specify **RUN OPTIONS** when **LANGUAGE JAVA** is specified.

#### **INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

##### **INHERIT SPECIAL REGISTERS**

Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in "Using special registers in a user-defined function or a stored procedure" on page 151.

##### **DEFAULT SPECIAL REGISTERS**

Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in "Using special registers in a user-defined function or a stored procedure" on page 151.

#### **STATIC DISPATCH**

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

## **Notes**

***Changes are immediate:*** Any changes that the ALTER FUNCTION statement causes to the definition of an external function take effect immediately. The changed definition is used the next time that the function is invoked.

***Invalidation of plans and packages:*** When an external function is altered, all the plans and packages that refer to that function are marked invalid.

***LANGUAGE C and the PARAMETER VARCHAR clause:*** The ALTER statement does not allow you to alter the value of the **PARAMETER VARCHAR** or **PARAMETER CCSID** clauses that are associated with the function definition. However, you can alter the **LANGUAGE** clause for the function. If the **PARAMETER VARCHAR** clause is specified for the creation of a LANGUAGE C function, the catalog information for that option is not affected by a subsequent ALTER function statement. The function might be changed to a language other than C, in which case the **PARAMETER VARCHAR** setting is ignored. If the function is later changed back to LANGUAGE C, the setting of the **PARAMETER VARCHAR** option that was specified during the CREATE FUNCTION statement will be used.

***Alternative syntax and synonyms:*** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- **VARIANT** as a synonym for **NOT DETERMINISTIC**
- **NOT VARIANT** as a synonym for **DETERMINISTIC**
- **NOT NULL CALL** as a synonym for **RETURNS NULL ON NULL INPUT**
- **NULL CALL** as a synonym for **CALLED ON NULL INPUT**
- **PARAMETER STYLE DB2SQL** as a synonym for **PARAMETER STYLE SQL**

## **Examples**

**Example 1:** Assume that two functions CENTER are in the PELLOW schema. The first function has two input parameters with INTEGER and FLOAT data types,

respectively. The specific name for the first function is FOCUS1. The second function has three parameters with CHAR(25), DEC(5,2), and INTEGER data types.

Using the specific name to identify the function, change the WLM environment in which the first function runs from WLMENVNAME1 to WLMENVNAME2:

```
ALTER SPECIFIC FUNCTION ENGLS.FOCUS1 WLM ENVIRONMENT WLMENVNAME2;
```

*Example 2:* Change the second function that is described in *Example 1* so that it is not invoked when any of the arguments are null. Use the function signature to identify the function:

```
ALTER FUNCTION ENGLS.CENTER (CHAR(25), DEC(5,2), INTEGER)
RETURNS NULL ON NULL INPUT;
```

You can also code the ALTER FUNCTION statement without the exact values for the CHAR and DEC data types:

```
ALTER FUNCTION ENGLS.CENTER (CHAR(), DEC(), INTEGER)
RETURNS NULL ON NULL INPUT;
```

If you use empty parentheses, DB2 is to ignore the length, precision, and scale attributes when looking for matching data types to find the function.

## ALTER FUNCTION (SQL scalar)

The ALTER FUNCTION (SQL scalar) statement changes the description of a user-defined SQL scalar function at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- Ownership of the function
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority

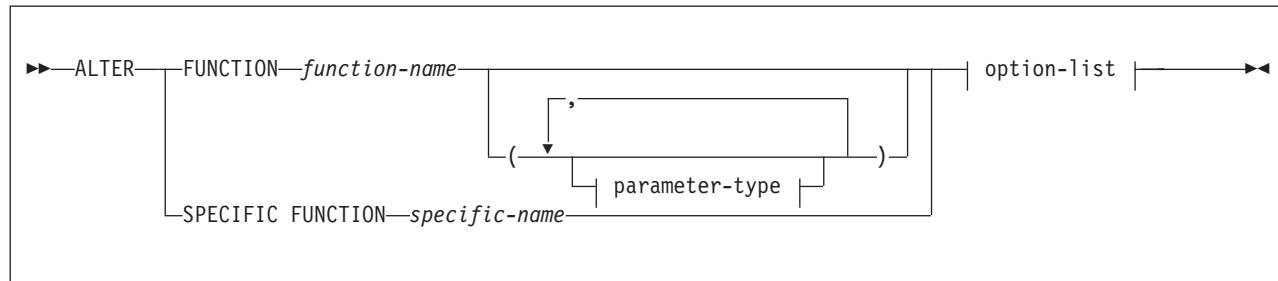

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

|  
| **Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

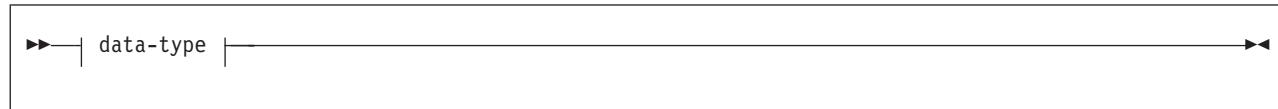

If the statement is dynamically prepared, the privilege set is the privileges that are held by the authorization IDs of the process. The specified function name can include a schema name (a qualifier). However, if the schema name is not the same as one of these authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- An authorization ID of the process has the ALTERIN privilege on the schema.

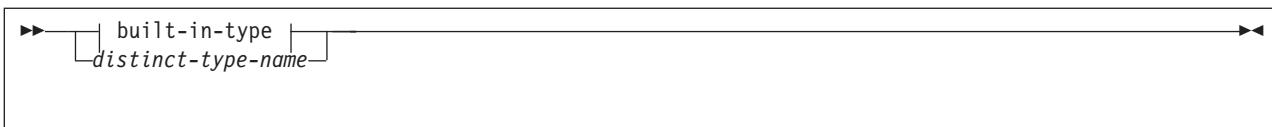

### Syntax

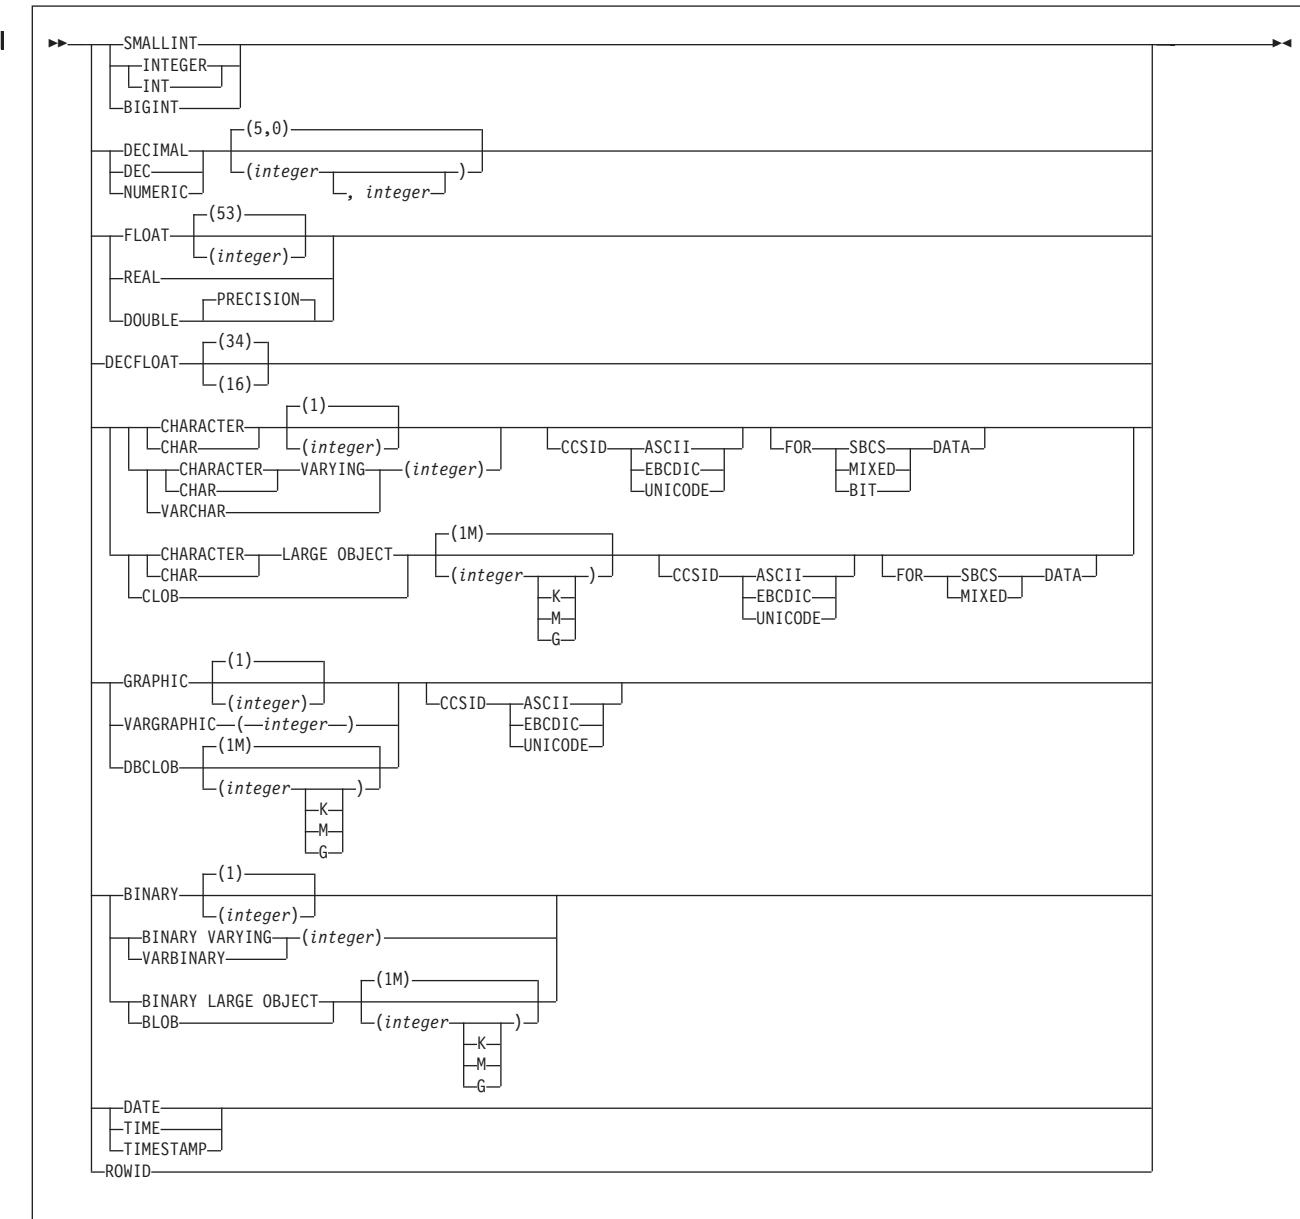

**parameter-type:**

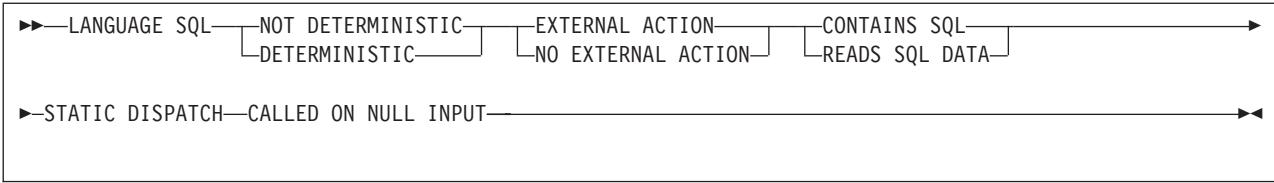

**data-type:**

**built-in-type:**

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

## Description

One of the following three clauses identifies the function to be changed.

**FUNCTION** *function-name*

Identifies the SQL function by its function name.

The identified function must be an SQL scalar function. There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters. If the schema does not contain a function with *function-name* or contains more than one function with this name, an error occurs.

**FUNCTION** *function-name* (*parameter-type*,...)

Identifies the SQL function by its function signature, which uniquely identifies the function.

*function-name*

Gives the function name of the SQL function.

If *function-name()* is specified, the function that is identified must have zero parameters.

(*parameter-type*,...)

Identifies the number of input parameters of the function and the data type of each parameter. The data type of each parameter must match the data type that was specified in the CREATE FUNCTION statement for the parameter in the corresponding position. The number of data types and the logical concatenation of the data types are used to uniquely identify the function. Therefore, you cannot change the number of parameters or the data types of the parameters.

For data types that have a length, precision, or scale attribute, you can use a set of empty parentheses, specify a value, or accept the default values:

If the function was defined with a table parameter (the **LIKE TABLE** *name* **AS LOCATOR** clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function.

Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

- Empty parentheses indicate that DB2 is to ignore the attribute when determining whether the data types match.

For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34).

FLOAT cannot be specified with empty parentheses because its parameter value indicates different data types (REAL or DOUBLE).

- If you use a specific value for a length, precision, or scale attribute, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

The specific value for FLOAT(*n*) does not have to exactly match the defined value of the source function because 1<=n<= 21 indicates REAL and 22<=n<=53 indicates DOUBLE. Matching is based on whether the data type is REAL or DOUBLE.

- If length, precision, or scale is not explicitly specified and empty parentheses are not specified, the default length of the data type is implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the **FOR subtype DATA** clause or the **CCSID** clause is optional. Omission of either clause indicates that DB2 is to ignore the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

See “CREATE FUNCTION” on page 915 for more information on the specification of the parameter list.

A function with the function signature must exist in the explicitly or implicitly specified schema.

#### **SPECIFIC FUNCTION** *function-name*

Identifies a particular user-defined function by its specific name. The name is implicitly or explicitly qualified with a schema name. A function with the specific name must exist in the schema. If the specific name is not qualified, it is implicitly qualified with a schema name as described in the preceding description for **FUNCTION** *function-name*.

#### **LANGUAGE SQL**

Specifies the application programming language in which the stored function is written. The value of the function is written as DB2 SQL in the *expression* of the RETURN clause in the CREATE FUNCTION statement.

#### **NOT DETERMINISTIC** or **DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

#### **NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

**NOT DETERMINISTIC** must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic.

#### **DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **DETERMINISTIC** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

#### **EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

#### **EXTERNAL ACTION**

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

If you specify **EXTERNAL ACTION**, DB2:

- Materializes the views and table expressions in SELECT or SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify **EXTERNAL ACTION** if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

**EXTERNAL ACTION** must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with **EXTERNAL ACTION**.

#### **NO EXTERNAL ACTION**

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function. If applicable, specify **NO EXTERNAL ACTION** to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of **EXTERNAL ACTION** or **NO EXTERNAL ACTION**.

#### **READS SQL DATA or CONTAINS SQL**

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function. The default is **READS SQL DATA**.

#### **READS SQL DATA**

Specifies that function can execute statements with a data access indication of **READS SQL DATA**, **CONTAINS SQL**, or **NO SQL**. The function cannot execute SQL statements that modify data.

#### **CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data classification of **CONTAINS SQL**. SQL statements that neither read nor

modify SQL data can be executed by the function. Statements that are not supported in any function return a different error.

#### **STATIC DISPATCH**

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters.

#### **CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null arguments. The function can return null.

### **Notes**

*Changes are immediate:* Any changes that the ALTER FUNCTION statement causes to the definition of an SQL function take effect immediately. The changed definition is used the next time that the function is invoked.

*Invalidation of plans and packages:* When an SQL function is altered, all the plans and packages that refer to that function are marked invalid.

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT

### **Examples**

*Example 1:* Modify the definition for an SQL function to indicate that the function is deterministic.

```
ALTER FUNCTION MY_UDF1  
DETERMINISTIC;
```

## ALTER INDEX

The ALTER INDEX statement changes the description of an index at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include one of the following:

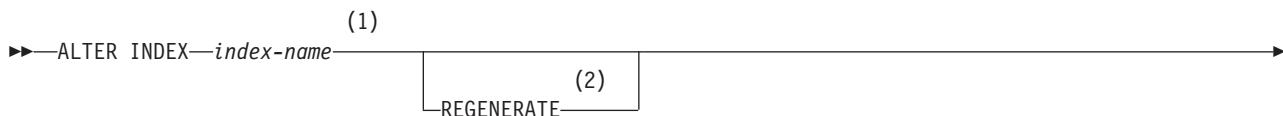

- Ownership of the index
- Ownership of the table on which the index is defined
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority

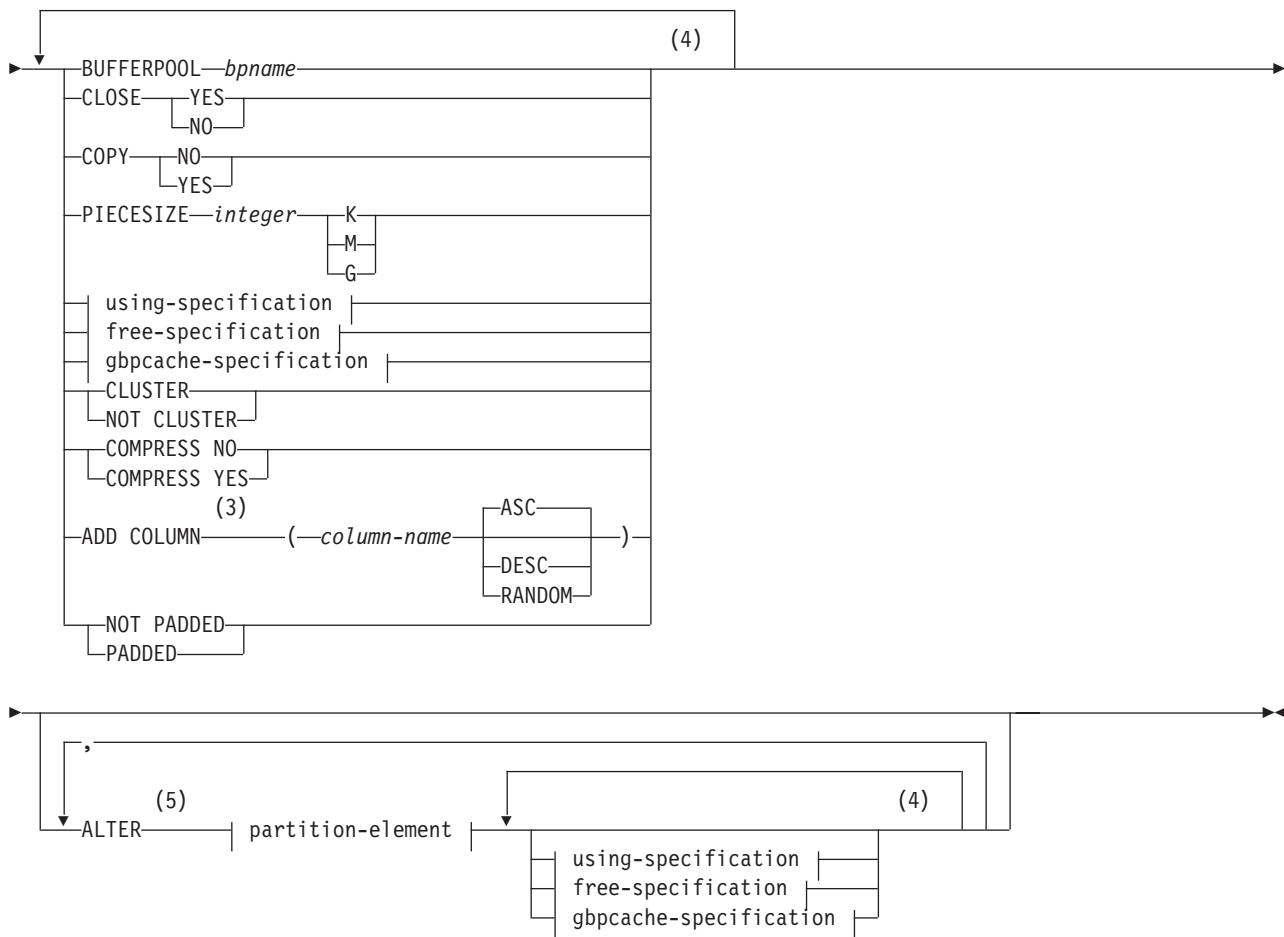

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If **BUFFERPOOL** or **USING STOGROUP** is specified, additional privileges could be needed, as explained in the description of those clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

### Syntax

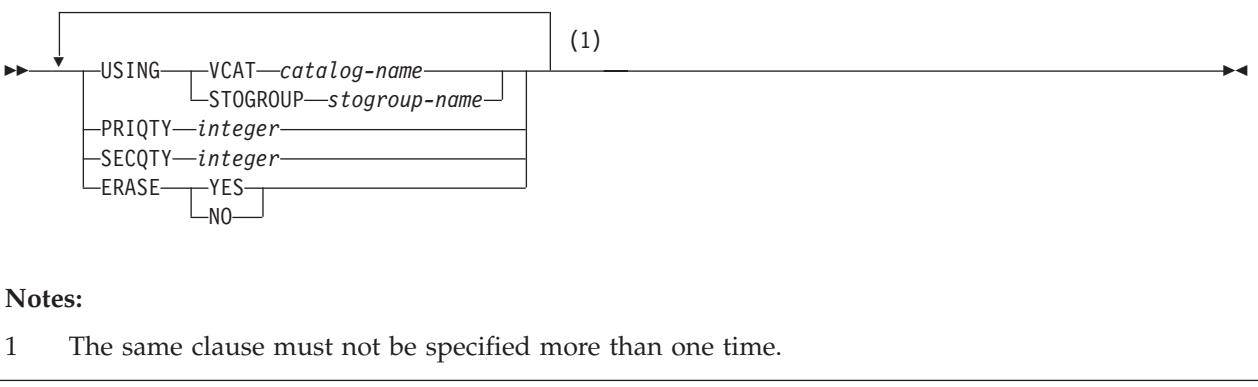

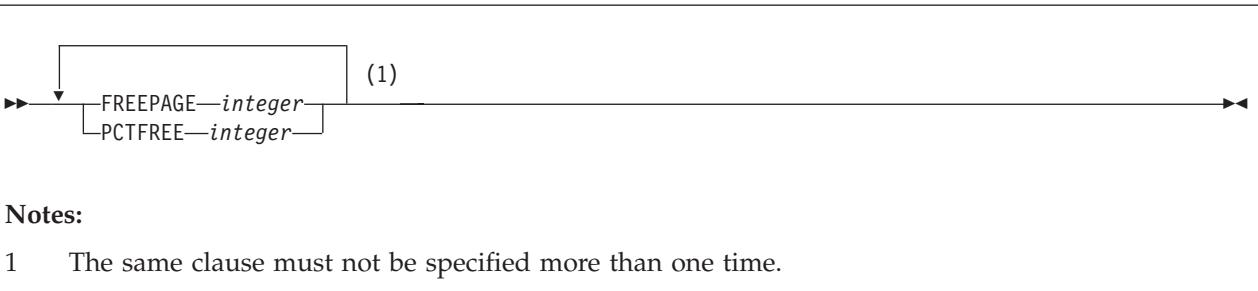

#### Notes:

- 1 At least one clause must be specified after *index-name*. It can be from the optional list or it can be **ALTER PARTITION**.
- 2 If **REGENERATE** is specified, it must be the only clause specified on the **ALTER INDEX** statement.
- 3 If **ADD COLUMN** and **PADDED** or **NOT PADDED** are specified, **ADD COLUMN** must be specified before **PADDED** or **NOT PADDED**.
- 4 The same clause must not be specified more than one time.
- 5 The **ALTER** clause can only be specified for partitioned indexes. The **ALTER** clause must be specified last.

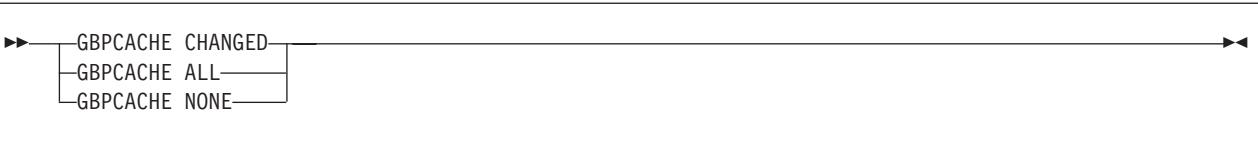

**using-specification:**

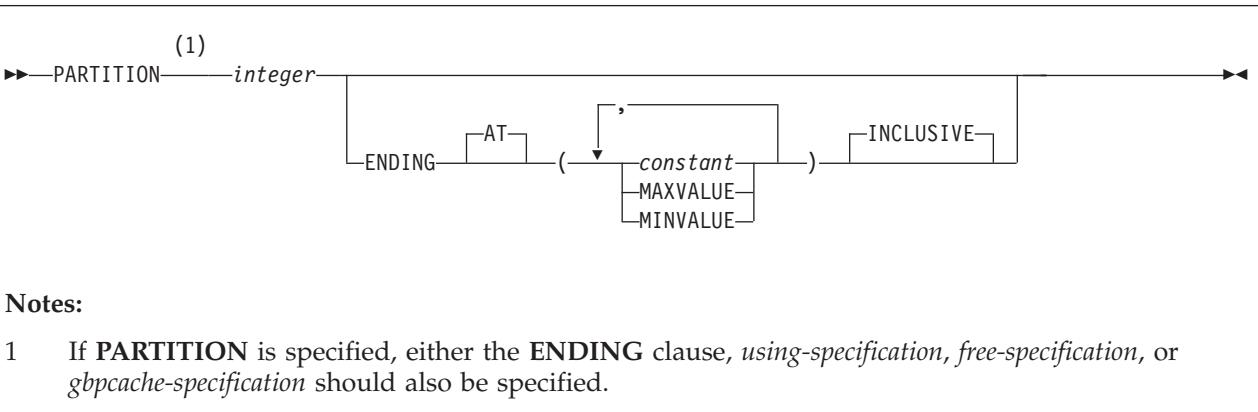

#### free-specification:

#### gbpcache-specification:

#### partition-element:

## Description

*index-name*

Identifies the index to be changed or regenerated. The name must identify a

user-created index that exists at the current server. The name must not identify an index that is defined on a declared temporary table.

#### **REGENERATE**

Specifies that the index will be regenerated. The structure that represents the index definition is regenerated. The index definition will be composed from the catalog. Existing authorities and dependencies, if any, are retained. The catalog is updated with the regenerated index definition. The index is put into rebuild-pending state, all packages that depend on the index are invalidated, and catalog entries for the index statistics are deleted.

If the index cannot be successfully regenerated, an error is returned. In this case, the index must be dropped and recreated.

#### **BUFFERPOOL *bpname***

Identifies the buffer pool that is to be used for the index. *bpname* must identify an activated 4K, 8 KB, 16 KB, or 32 KB buffer pool, and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the buffer pool.

A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

If the index is changed to use index compression (the **COMPRESS YES** clause), the buffer pool must be greater than 4 KB in size.

The change to the description of the index takes effect the next time the data sets of the index space are opened. The data sets can be closed and reopened by a STOP DATABASE command to stop the index followed by a START DATABASE command to start the index.

If the buffer pool is changed to a buffer pool with a different page size, the index is placed into REBUILD-pending status.

In a data sharing environment, if you specify **BUFFERPOOL**, the index space must be in the stopped state when the ALTER INDEX statement is executed.

#### **CLOSE**

Specifies whether the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached. The change to the close rule takes effect the next time the data sets of the index space are opened.

##### **YES**

Eligible for closing.

**NO** Not eligible for closing.

If DSMAX is reached and there are no CLOSE YES page sets to close, CLOSE NO page sets will be closed.

#### **COPY**

Indicates whether the COPY utility is allowed for the index.

**NO** Does not allow full image or concurrent copies or the use of the RECOVER utility on the index.

##### **YES**

Allows full image or concurrent copies and the use of the RECOVER utility on the index. For data sharing, changing **COPY** to **YES** causes additional SCA (Shared Communications Area) storage to be used until the next full or incremental image copy is taken or until **COPY** is set back to **NO**.

**PIECESIZE** *integer*

Specifies the maximum addressability of each data set for a secondary index. The **PIECESIZE** clause can only be specified for secondary indexes.

Be aware that when you alter the **PIECESIZE** value, the index is placed into page set REBUILD-pending (PSRBD) status. The entire index space becomes inaccessible. You must run the REBUILD INDEX or the REORG TABLESPACE utility to remove that status.

The subsequent keyword **K**, **M**, or **G**, indicates the units of the value that is specified in *integer*.

- K** Indicates that the *integer* value is to be multiplied by 1024 to specify the maximum data set size in bytes. The integer must be a power of two between 256 and 67 108 864.
- M** Indicates that the *integer* value is to be multiplied by 1 048 576 to specify the maximum data set size in bytes. The integer must be a power of two between 1 and 65 536.
- G** Indicates that the *integer* value is to be multiplied by 1 073 741 824 to specify the maximum data set size in bytes. The integer must be a power of two between 1 and 64.

Table 82 shows the valid values for data set size, which depend on the size of the table space.

Table 82. Valid values of **PIECESIZE** clause

K units	M units	G units	Size attribute of table space
256K			
512K			
1024K	1M		
2048K	2M		
4096K	4M		
8192K	8M		
16384K	16M		
32768K	32M		
65536K	64M		
131072K	128M		
262144K	256M		
524288K	512M		
1048576K	1024M	1G	
2097152K	2048M	2G	
4194304K	4096M	4G	LARGE, DSSIZE 4G (or greater)
8388608K	8192M	8G	DSSIZE 8G (or greater)
16777216K	16384M	16G	DSSIZE 16G (or greater)
33554432K	32768M	32G	DSSIZE 32G (or greater)
67108864K	65536M	64G	DSSIZE 64G

The data set size limit for partitioned table spaces with more than 256 partitions is 4096.

### begin using-specification block

The components of the *using-specification* are discussed below, first for non-partitioned indexes and then for partitioned indexes.

#### **USING (specification for nonpartitioned indexes)**

For nonpartitioned indexes, the **USING** clause specifies whether the data sets for the index are to be managed by the user or managed by DB2. The **USING** clause applies to every data set that can be used for the index.

If you specify **USING**, the index must be in the stopped state when the **ALTER INDEX** statement is executed. See *Altering storage attributes* to determine how and when changes take effect.

#### **VCAT catalog-name**

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify the catalog name in the form of an SQL identifier. Thus, you must specify an alias if the name of the integrated catalog facility catalog is longer than eight characters. When the new description of the index is applied, the integrated catalog facility catalog must contain an entry for the data set that conforms to the DB2 naming conventions described in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

#### **STOGROUP stogroup-name**

Specifies using a DB2-managed data set that resides on a volume of the specified storage group. *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the index is applied, the description of the storage group must include at least one volume serial number. Each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify **USING STOGROUP** and the current data set is DB2-managed, omission of the **PRIQTY**, **SECQTY**, or **ERASE** clause is an implicit specification of the current value of the omitted clause.

If you specify **USING STOGROUP** to convert from user-managed data sets to DB2-managed data sets:

- Omission of the **PRIQTY** clause is an implicit specification of the default value. For information on how DB2 determines the default value, see *Rules for primary and secondary space allocation*.
- Omission of the **SECQTY** clause is an implicit specification of the default value. For information on how DB2 determines the default value, see *Rules for primary and secondary space allocation*.
- Omission of the **ERASE** clause is an implicit specification of **ERASE NO**.

#### **PRIQTY integer**

Specifies the minimum primary space allocation for a DB2-managed data set. This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified.

If **PRIQTY** is specified (with a value other than -1), the primary space allocation is at least  $n$  kilobytes, where  $n$  is:

**12** If *integer* is less than 12

*integer*

If *integer* is between 12 and 4194304

**2097152**

If both of the following conditions are true:

- *integer* is greater than 2097152.
- The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.

**4194304**

If *integer* is greater than 4194304

If **PRIQTY** -1 is specified, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If **USING STOGROUP** is specified and **PRIQTY** is omitted, the value of **PRIQTY** is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of **USING STOGROUP**.)

If you specify **PRIQTY** and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of 4 KB not less than  $n$ . The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see the description of the **DEFINE CLUSTER** command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

When determining a suitable value for **PRIQTY**, be aware that two of the pages of the primary space could be used by DB2 for purposes other than storing index entries.

#### **SECQTY** *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set. This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified.

If **SECQTY** -1 is specified, DB2 uses a default value for the secondary space allocation.

If **USING STOGROUP** is specified and **SECQTY** is omitted, the value of **SECQTY** is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of **USING STOGROUP**.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or DB2 uses a default value, see Rules for primary and secondary space allocation.

If you specify **SECQTY** and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of 4 KB not less than  $n$ . The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see the description of the **DEFINE CLUSTER** command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

## **ERASE**

Indicates whether the DB2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index. Refer to for more information.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2.

## **YES**

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is currently managed by DB2 and **USING VCAT** is not specified. If you specify **ERASE**, the index must be in the stopped state when the **ALTER INDEX** statement is executed. See Altering storage attributes to determine how and when changes take effect.

## **USING (specification for partitioned indexes:)**

For a partitioned index, there is an optional **PARTITION** clause for each partition. A *using-specification* can be specified at the global level or at the partition level. A *using-specification* within a **PARTITION** clause applies only to that partition. A *using-specification* specified before any **PARTITION** clauses applies to every partition except those with a **PARTITION** clause with a *using-specification*.

For DB2-managed data sets, the values of **PRIQTY**, **SECQTY**, and **ERASE** for each partition are given by the first of these choices that applies:

- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* within the **PARTITION** clause for the partition. Do not use more than one *using-specification* in any **PARTITION** clause.
- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* before any **PARTITION** clause
- The current values of **PRIQTY**, **SECQTY**, and **ERASE**

For data sets that are being changed from user-managed to DB2-managed, the values of **PRIQTY**, **SECQTY**, and **ERASE** for each partition are given by the first of these choices that applies:

- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in the *using-specification* within the **PARTITION** clause for the partition. Do not use more than one *using-specification* in any **PARTITION** clause.
- The values of **PRIQTY**, **SECQTY**, and **ERASE** given in a *using-specification* before any **PARTITION** clauses
- The default values of **PRIQTY**, **SECQTY**, and **ERASE**, which are:
  - **PRIQTY** 12
  - **SECQTY** 12, if **PRIQTY** is not specified in either *using-specification*, or 10% of **PRIQTY** or 3 times the index page size (whichever is larger) when **PRIQTY** is specified
  - **ERASE NO**

Any partition for which **USING** or **ERASE** is specified (either explicitly at the partition level or implicitly at the global level) must be in the stopped state when the **ALTER INDEX** statement is executed. See Altering storage attributes to determine how and when changes take effect.

## **VCAT catalog-name**

Specifies a user-managed data set with a name that starts with the

specified catalog name. You must specify the catalog name in the form of an SQL identifier. Thus, you must specify an alias if the name of the integrated catalog facility catalog is longer than eight characters.

If *n* is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the *vth* data set of the index, conforming to the DB2 naming convention for data sets described in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

**STOGROUP** *stogroup-name*

If **USING STOGROUP** is used, *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group.

DB2 assumes one and only one data set for each partition.

For information on the **PRIQTY**, **SECQTY**, and **ERASE** clauses, see the description of those clauses in the *using-specification* for secondary indexes.

**end using-specification block**

**begin free-specification block**

**FREEPAGE** *integer*

Specifies how often to leave a page of free space when index entries are created as the result of executing a DB2 utility. One free page is left for every *integer* pages. The value of *integer* can range from 0 to 255. The change to the description of the index or partition has no effect until it is loaded or reorganized using a DB2 utility. Do not specify **FREEPAGE** for an implicitly created XML index.

**PCTFREE** *integer*

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or partition as the result of executing a DB2 utility. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as *integer*.

The value of *integer* can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The change to the description of the index or partition has no effect until it is loaded or reorganized using a DB2 utility. Do not specify **PCTFREE** for an implicitly created XML index.

**If the index is partitioned, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:**

- The values of **FREEPAGE** and **PCTFREE** given in the **PARTITION** clause for that partition. Do not use more than one *free-specification* in any **PARTITION** clause.
- The values given in a *free-specification* before any **PARTITION** clauses.
- The current values of **FREEPAGE** and **PCTFREE** for that partition.

```
end free-specification block  
begin gbpcache-specification block
```

#### **GBPCACHE**

Specifies what index pages are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify this option, but it is ignored.

#### **CHANGED**

When there is inter-DB2 read-write interest on the index or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 read-write interest, the group buffer pool is not used. Inter-DB2 read-write interest exists when more than one member in the data sharing group has the index or partition open, and at least one member has it open for update.

If the index is in a group buffer pool that is defined as **GBPCACHE(NO)**, **CHANGED** is ignored and no pages are cached to the group buffer pool.

#### **ALL**

Indicates that pages are to be cached to the group buffer pool as they are read in from DASD, with one exception. When the page set is not GBP-dependent and one DB2 data sharing member has exclusive read-write interest in that page set (no other group members have any interest in the page set), no pages are cached in the group buffer pool.

If the index is in a group buffer pool that is defined as **GBPCACHE(NO)**, **ALL** is ignored and no pages are cached to the group buffer pool.

#### **NONE**

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-validation.

If you specify **NONE**, the index or partition must not be in group buffer pool recover-pending (GRECP) status.

If the index is partitioned, the value of **GBPCACHE** for a particular partition is given by the first of these choices that applies:

1. The value of **GBPCACHE** given in the **PARTITION** clause for that partition. Do not use more than one *gbpcache-specification* in any **PARTITION** clause.
2. The value given in a *gbpcache-specification* before any **PARTITION** clauses.
3. The current value of **GBPCACHE** for that partition.

If you specify **GBPCACHE** in a data sharing environment, the index or partition must be in the stopped state when the **ALTER INDEX** statement is executed. You cannot alter the **GBPCACHE** value for certain indexes on DB2 catalog tables; for more information, see “SQL statements allowed on the catalog” on page 1689.

```
end gbpcache-specification block
```

#### **CLUSTER or NOT CLUSTER**

Specifies whether the index is the clustering index for the table.

#### **CLUSTER**

The index is used as the clustering index for the table. This change takes effect immediately. Any subsequent insert operations will use the new

clustering index. Existing data remains clustered by the previous clustering index until the table space is reorganized.

The implicit or explicit clustering index is ignored when data is inserted into a table space that is defined with **MEMBER CLUSTER**. Instead of using cluster order, DB2 chooses where to locate the data based on available space. The **MEMBER CLUSTER** attribute affects only data that is inserted with an insert operation; data is always loaded and reorganized in cluster order.

Do not specify **CLUSTER** in the following cases:

- The index is for an auxiliary table.
- **CLUSTER** was used already for a different index on the table.
- The index is an XML index.
- The index includes expressions.

#### **NOT CLUSTER**

The index is not used as the clustering index of the table. If the index is already defined as the clustering index, it continues to be used as the clustering index by DB2 and the REORG utility until clustering is explicitly changed by specifying **CLUSTER** for a different index.

Specifying **NOT CLUSTER** for an index that is not a clustering index is ignored.

If the index is the partitioning index for a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

#### **COMPRESS NO or COMPRESS YES**

Specifies whether the index data will be compressed. If the index is partitioned, this option will apply to all partitions.

##### **COMPRESS NO**

Specifies that index compression will be turned off. If the index was created using the **COMPRESS YES** clause, changing to **COMPRESS NO** will place the index in advisory reorg-pending state.

##### **COMPRESS YES**

Specifies that the index will use index compression. The index must be in a buffer pool that has a page size greater than 4 KB. Index compression will not take place immediately and the index will be placed in advisory reorg-pending state. Index compression will not be in effect until the REORG INDEX, REBUILD INDEX, or REORG TABLESPACE utility is run.

**COMPRESS YES** can be specified for user-managed data sets only if the control interval size is 4K.

#### **NOT PADDED or PADDED**

Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned.

##### **NOT PADDED**

Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

**NOT PADDED** is ignored and has no effect if the index is on an auxiliary table. Indexes on auxiliary tables are always padded.

When **PADDED** is changed to **NOT PADDED**, the maximum key length is recalculated with the varying-length formula  $(2000 - n - 2m$ , where  $n$  is the number of columns that can contain null values and  $m$  is the number of varying-length columns in the key). If it is possible that the index key length might exceed the maximum length (because when it was padded, the formula  $2000 - n$  was used), an error occurs.

#### **PADDED**

Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length.

When an index with at least one varying-length column is changed from **PADDED** to **NOT PADDED**, or vice versa, the index is placed in restricted rebuild-pending status (RBDP). The index cannot be accessed until it is rebuilt from the table (using the REBUILD INDEX, REORG TABLESPACE, or LOAD REPLACE utility). For nonpartitioned secondary indexes (NPSIs), the index is placed in page set rebuild-pending status (PSRBD), and the entire index must be rebuilt. In addition, plans and packages that are dependent on the table are quiesced, and dynamically cached statements that are dependent on the index are invalidated.

Do not specify **PADDED** if the index is an XML index.

#### **ADD COLUMN** *column-name*

Adds *column-name* to the index. *column-name* must be unqualified, must identify a column of the table, must not be one of the existing columns of the index, and must not be a LOB column, a DECFLOAT column, or a distinct-type column that is based on a LOB or DECFLOAT data type. The column cannot be a VARBINARY column or a distinct-type column that is based on a VARBINARY data type if the column is defined with the DESC attribute. The total number of columns for the index cannot exceed 64.

For PADDED indexes, the sum of the length attributes of the columns must not be greater than  $2000 - n$ , where  $n$  is the number of columns that can contain null values. For NOT PADDED indexes, the sum of the length attributes of the columns must not be greater than  $2000 - n - 2m$ , where  $n$  is the number of nullable columns and  $m$  is the number of varying-length columns.

The index cannot be any of the following types of indexes:

- A system-defined catalog index
- An index that enforces a primary key, unique key, or referential constraint, or matches a foreign key
- A partitioning index when index-controlled partitioning is being used
- A unique index required for a ROWID column defined as GENERATED BY DEFAULT
- An auxiliary index
- An XML index
- An index that includes expressions

If a column is added to both a table and an associated index within the same commit scope, the index is put into rebuild-pending (RBDP) status if rows are inserted into the table within the same commit scope or the column is a ROWID column; otherwise, the index is put into an advisory reorg-pending (AREO\*) state.

**ASC**

Index entries are put in ascending order by the column.

**DESC**

Index entries are put in descending order by the column.

**RANDOM**

Index entries are put in a random order by the column. **RANDOM** cannot be specified for an index key column that is varying length in an index that is created with the **NOT PADDED** option.

**ALTER PARTITION *integer***

Identifies the partition of the index to be altered. For an index that has *n* partitions, you must specify an integer in the range 1 to *n*. You must not use this clause if the index is nonpartitioned. You must use this clause if the index is partitioned and you specify the **ENDING AT** clause.

**ENDING AT(*constant*), MAXVALUE, or MINVALUE**

Specifies the highest value of the index key for the identified partition of the partitioning index. In this context, highest means highest in the sorting sequence of the index columns. In a column defined as ascending (ASC), highest and lowest have the usual meanings. In a column defined as descending (DESC), the lowest actual value is highest in the sorting sequence.

You must use at least one value (*constant*, **MAXVALUE**, or **MINVALUE**) after **ENDING AT** in each **PARTITION** clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index. The length of each highest key value (also called the limit key) is the same as the length of the partitioning index

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the **MINVALUE** clause cannot be specified following **MAXVALUE**. After **MAXVALUE** is specified, all subsequent columns must be **MAXVALUE**.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the **MAXVALUE** clause cannot be specified following **MAXVALUE**. After **MINVALUE** is specified, all subsequent columns must be **MINVALUE**.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on.
- If a key includes a ROWID column (or a column with a distinct type that is based on a ROWID data type), the values of the ROWID column are assumed to be in the range of X'000...00' to X'FFF...FF'. Only the first 17 bytes of the value that is specified for the corresponding ROWID column are considered.
- Using fewer values than there are columns in the key has the same effect as using the highest possible values for all omitted columns for an ascending index.
- If the key exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The highest value of the key in the last partition depends on how the table space was defined. For table spaces created without the LARGE or DSSIZE option, the constants you specify after **ENDING AT** are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For table spaces created with the LARGE or DSSIZE options, the constants you specify after **ENDING AT** are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any keys that are made invalid after the **ALTER TABLE** statement is executed are placed in a discard data set when you run the REORG utility. If the last partition is in reorg-pending status, regardless of whether you changed its limiting key values, you must specify a discard data set when you run the REORG utility.

**ENDING AT** must not be specified for any indexes defined on a table that uses table-controlled partitioning. Use **ALTER TABLE ALTER PARTITION** to modify the partitioning boundaries for a table that uses table-controlled partitioning.

#### INCLUSIVE

Specifies that the specified range values are included in the data partition.

#### Notes

**Altering storage attributes:** The **USING**, **PRIQTY**, **SECQTY**, and **ERASE** clauses define the storage attributes of the index or partition. If you specify the **USING** or **ERASE** clause when altering storage attributes, the index or partition must be in the stopped state when the **ALTER INDEX** statement is executed. A **STOP DATABASE...SPACENAM...** command can be used to stop the index or partition.

If the catalog name changes, the changes take effect after you move the data and start the index or partition using the **START DATABASE...SPACENAM...** command. The catalog name can be implicitly or explicitly changed by the **ALTER INDEX** statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *DB2 Administration Guide*.

Changes to the secondary space allocation (**SECQTY**) take effect the next time DB2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the index or partition. Changes to the other storage attributes take effect the next time you use the REORG, RECOVER, or LOAD REPLACE utility on the index or

partition. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the index or partition.

**Altering indexes on DB2 catalog tables:** For details on altering options on catalog tables, see “SQL statements allowed on the catalog” on page 1689.

**Altering limit keys:** If you specify **ALTER PARTITION integer ENDING AT** to change the limit key values of a partitioning index, the plans and packages that are dependent on that index are marked invalid and go through automatic rebind the next time they are run.

**Invalidation of plans and packages:** When an index is altered, all the plans and packages that refer to that index are marked invalid if one of the following conditions is true:

- A column is added to the index.
- The index is altered to be **PADDED** or **NOT PADDED**.
- The index is a partitioning index on a table that uses index-controlled partitioning, and one or more limit key values is altered.
- The index is altered to **REGENERATE**.

**Restrictions on SQL data change statements in the same commit scope as ALTER INDEX:** SQL data change statements that affect an index cannot be performed in the same commit scope as **ALTER INDEX** statements that affect that index.

**Altering indexes for tables that are involved in a clone relationship:** You cannot change any index for a table that is involved in a clone relationship (base table or clone table). If a change to an index is required, the clone table must be dropped, than the index can be changed. After the index is changed, the clone table can be created again.

**Running utilities:** You cannot execute the **ALTER INDEX** statement while a DB2 utility has control of the index or its associated table space.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when altering the partitions of a partitioned index:

- **PART** can be specified as a synonym for **PARTITION**. In addition, the **ALTER** keyword that precedes **PARTITION** is optional. In addition, if you alter more than one partition, specifying a comma between each **ALTER PARTITION integer** clause is optional.
- **VALUES** can be specified as a synonym for **ENDING AT**.

Although these keywords are supported as alternatives, they are not the preferred syntax.

## Examples

**Example 1:** Alter the index DSN8910.XEMP1. Indicate that DB2 is not to close the data sets that support the index when there are no current users of the index.

```
ALTER INDEX DSN8910.XEMP1  
CLOSE NO;
```

*Example 2:* Alter the index DSN8910.XPROJ1. Use BP1 as the buffer pool that is to be associated with the index, indicate that full image or concurrent copies on the index are allowed, and change the maximum size of each data set to 8 megabytes.

```
ALTER INDEX DSN8910.XPROJ1  
  BUFFERPOOL BP1  
  COPY YES  
  PIECESIZE 8M;
```

*Example 3:* Assume that index X1 contains at least one varying-length column and is a padded index. Alter the index to an index that is not padded.

```
ALTER INDEX X1  
  NOT PADDED;
```

The index is placed in restricted rebuild-pending status (RBDP) and cannot be accessed until it is rebuilt from the table

*Example 4:* Alter partitioned index DSN8910.DEPT1. For partition 3, leave one page of free space for every 13 pages and 13 percent of free space per page. For partition 5, leave one page for every 25 pages and 25 percent of free space. For all the other partitions, leave one page of free space for every 6 pages and 11 percent of free space. Ensure that index pages are cached to the group buffer pool for all partitions except partition 4. For partition 4, write pages only when there is inter-DB2 read-write interest on the partition.

```
ALTER INDEX DSN8910.XDEPT1  
  BUFFERPOOL BP1  
  CLOSE YES  
  COPY YES  
  USING VCAT CATLGG  
  FREEPAGE 6  
  PCTFREE 11  
  GBPCACHE ALL  
  ALTER PARTITION 3  
    USING VCAT CATLGG  
    FREEPAGE 13  
    PCTFREE 13,  
  ALTER PARTITION 4  
    USING VCAT CATLGG  
    GBPCACHE CHANGED,  
  ALTER PARTITION 5  
    USING VCAT CATLGG  
    FREEPAGE 25  
    PCTFREE 25;
```

## ALTER PROCEDURE (external)

The ALTER PROCEDURE statement changes the description of an external stored procedure at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

|      **Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the authorization IDs of the process. The specified procedure name can include a schema name (a qualifier). However, if the schema name is not the same as one of these authorization IDs, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- An authorization ID of the process has the ALTERIN privilege on the schema.

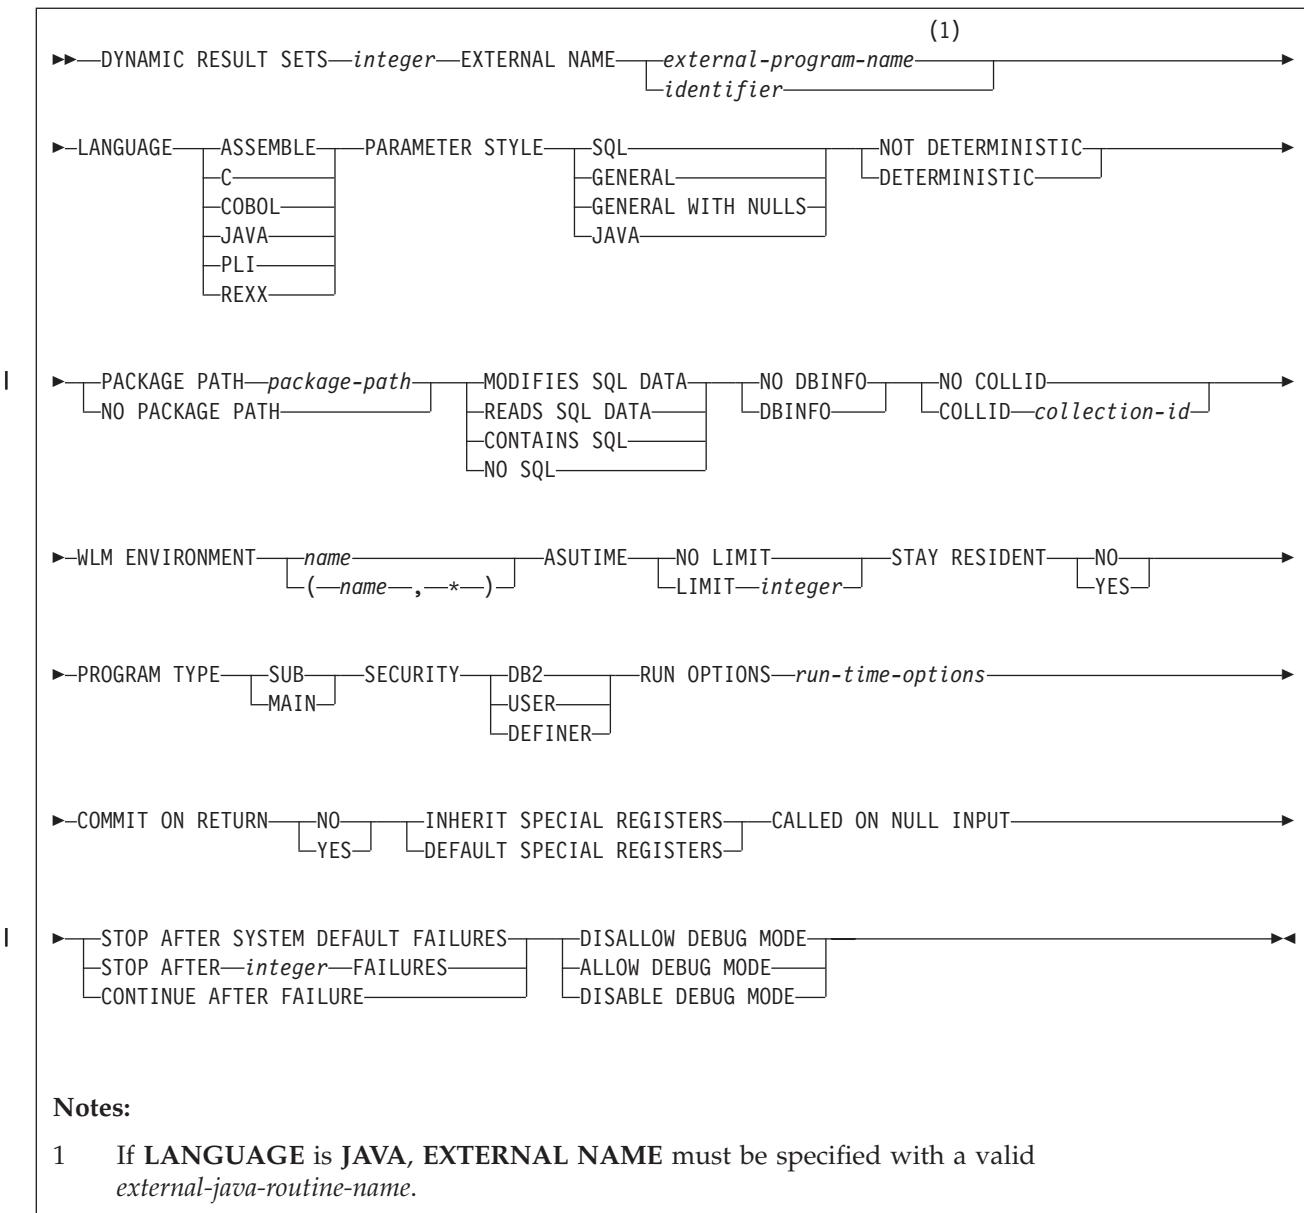

|      If the environment in which the stored procedure is to run is being changed, the authorization ID must have authority to use the WLM environment. This authorization is obtained from an external security product, such as RACF.

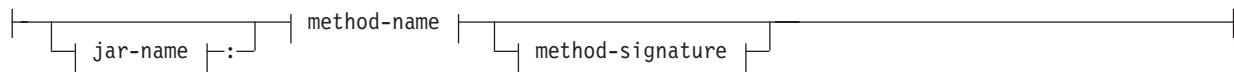

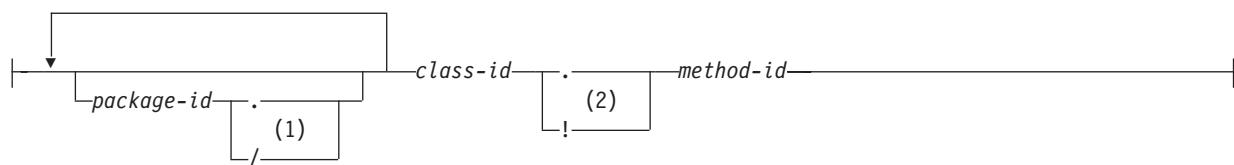

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

### Syntax

```
►—ALTER PROCEDURE—procedure-name—| option-list |————►
```

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

**external-java-routine-name:****jar-name:****method-name:****method-signature:****Notes:**

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

## Description

**procedure-name**

Identifies the stored procedure to be altered.

**DYNAMIC RESULT SETS integer**

Specifies the maximum number of query result sets that the stored procedure can return. The value must be between 0 and 32767.

**EXTERNAL NAME external-program-name or identifier**

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement.

If **LANGUAGE** is **JAVA**, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-name* values are specified, the total length of all of the values must not be greater than 1305 bytes and each value must be separated by a space or a line break. Do not specify a JAR file for a Java procedure for which **NO SQL** is in effect.

An *external-java-routine-name* contains the following parts:

*jar-name*

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the ALTER PROCEDURE statement is processed.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

*method-name*

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

*package-id*

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

*class-id*

Identifies the class identifier of the Java object.

*method-id*

Identifies the method identifier with the Java class to be invoked.

*method-signature*

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the ALTER PROCEDURE statement.

For other values of LANGUAGE, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8

bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

#### **LANGUAGE**

Specifies the application programming language in which the stored procedure is written. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

#### **ASSEMBLE**

The stored procedure is written in Assembler.

**C** The stored procedure is written in C or C++.

#### **COBOL**

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

#### **JAVA**

The stored procedure is written in Java and is executed in the Java Virtual Machine. When **LANGUAGE JAVA** is specified, the **EXTERNAL NAME** clause must also be specified with a valid *external-java-routine-name* and **PARAMETER STYLE** must be specified with **JAVA**. The procedure must be a public static method of the specified Java class.

Do not specify **LANGUAGE JAVA** when **DBINFO**, **PROGRAM TYPE MAIN**, or **RUN OPTIONS** is in effect.

#### **PLI**

The stored procedure is written in PL/I.

#### **REXX**

The stored procedure is written in REXX. Do not specify **LANGUAGE REXX** when **PARAMETER STYLE SQL** is specified.

#### **PARAMETER STYLE**

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *DB2 Application Programming and SQL Guide*.

#### **SQL**

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first *n* parameters that are specified on the CREATE PROCEDURE statement.
- *n* parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If **DBINFO** is specified, the **DBINFO** structure.

Do not specify **PARAMETER STYLE SQL** when **LANGUAGE REXX** is specified.

**GENERAL**

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

**GENERAL WITH NULLS**

Specifies that, in addition to the parameters on the CALL statement as specified in **GENERAL**, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short integers. The indicator array enables the stored procedure to accept or return null parameter values.

**JAVA**

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. **PARAMETER STYLE JAVA** can be specified only if **LANGUAGE** is **JAVA**. If the **ALTER PROCEDURE** statement results in changing **LANGUAGE** to **JAVA**, **PARAMETER STYLE JAVA**, and an **EXTERNAL NAME** clause might need to be specified to provide appropriate values. **JAVA** must be specified for **PARAMETER STYLE** when **LANGUAGE** is **JAVA**.

**INOUT** and **OUT** parameters are passed as single-entry arrays. The **INOUT** and **OUT** parameters are declared in the Java method as single-element arrays of the Java type.

**PARAMETER STYLE SQL** cannot be used with **LANGUAGE REXX**.

**DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same **IN** and **INOUT** arguments.

**DETERMINISTIC**

The stored procedure always returns the same results each time the stored procedure is called with the same **IN** and **INOUT** arguments, if the referenced data in the database has not changed.

**NOT DETERMINISTIC**

The stored procedure might not return the same result each time the procedure is called with the same **IN** and **INOUT** arguments, even when the referenced data in the database has not changed.

DB2 does not verify that the stored procedure code is consistent with the specification of **DETERMINISTIC** or **NOT DETERMINISTIC**.

**NO PACKAGE PATH or PACKAGE PATH *package-path***

Identifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the procedure is the same as the list of package collections for the calling program. If the calling program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

**PACKAGE PATH** *package-path*

Specifies a list of package collections, in the same format as used in the CURRENT PACKAGE PATH special register.

If the **COLLID** clause is specified with **PACKAGE PATH**, the **COLLID** clause is ignored when the routine is invoked.

The *package-path* value that is associated with the procedure definition is checked when the procedure is invoked. If *package-path* contains SESSION\_USER, USER, PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies which SQL statements, if any, can be executed in the procedure or any routine that is called from this procedure. For the data access classification of each statement, see Table 138 on page 1605.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

**READS SQL DATA**

Specifies that procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**NO SQL**

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify **NO SQL** for a Java procedure that uses a JAR file.

**NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the stored procedure when it is invoked.

**NO DBINFO**

Additional information is not passed.

**DBINFO**

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the application run-time authorization ID, the schema name, the name of a table or column that the procedure might be inserting into or updating, and identification of the database server that invoked the procedure. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

**DBINFO** can be specified only if **PARAMETER STYLE SQL** is specified.

**NO COLLID or COLLID** *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

**NO COLLID**

Specifies that the package collection for the stored procedure is the same as the package collection of the calling program. If the invoking program does

not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

**COLLID** *collection-id*

Identifies the package collection that is to be used when the stored procedure is executed. It is the name of the package collection into which the DBRM associated with the stored procedure is bound.

For REXX stored procedures, *collection-id* can be DSNREXR, DSNREXRS, DSNREXCR, or DSNREXCS.

**WLM ENVIRONMENT**

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

*name*

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

(*name* , \*)

When the stored procedure is called directly by an SQL application program, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column in the resource limit specification table.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on CPU service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the service units.

**LIMIT** *integer*

The limit on the service units is a positive *integer* in the range of 1 to 2 147 483 647. If the stored procedure uses more service units than the specified value, DB2 cancels the stored procedure.

**STAY RESIDENT**

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends.

**NO** The load module is deleted from memory after the stored procedure ends. Use **NO** for non-reentrant stored procedures.

**YES**

The load module remains resident in memory after the stored procedure ends.

**PROGRAM TYPE**

Specifies whether the stored procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

**SUB**

The stored procedure runs as a subroutine.

Do not specify **PROGRAM TYPE SUB** for stored procedures with a **LANGUAGE** value of **REXX**.

**MAIN**

The stored procedure runs as a main routine.

Do not specify **PROGRAM TYPE MAIN** when **LANGUAGE JAVA** is specified.

**SECURITY**

Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space.

**USER**

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

**DEFINER**

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

**RUN OPTIONS** *run-time-options*

Specifies the Language Environment run-time options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment run-time options to be passed to the REXX language interface to DB2. You must specify *run-time-options* as a character string that is no longer than 254 bytes. To replace any existing run-time options with no options, specify an empty string with **RUN OPTIONS**. When you specify an empty string, DB2 does not pass any run-time options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment run-time options, see *z/OS Language Environment Programming Reference*.

Do not specify **RUN OPTIONS** when **LANGUAGE JAVA** is specified.

**COMMIT ON RETURN**

Indicates whether DB2 is to commit the transaction immediately on return from the stored procedure.

**NO** DB2 does not issue a commit when the stored procedure returns.

**YES**

DB2 issues a commit when the stored procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Indicates that values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 37 on page 151.

**DEFAULT SPECIAL REGISTERS**

Indicates that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 37 on page 151.

**CALLED ON NULL INPUT**

Specifies that the procedure is to be called even if any or all of the argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures.

**STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation field DSNTIPX.

**STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Specifies whether the procedure can be run in debugging mode.

Do not specify this option unless the procedure is defined with **LANGUAGE JAVA**.

**ALLOW DEBUG MODE**

Specifies that the procedure can be run in debugging mode.

**DISALLOW DEBUG MODE**

Specifies that the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to **ALLOW DEBUG MODE**.

#### **DISABLE DEBUG MODE**

Specifies that the procedure can never be run in debugging mode.

The procedure cannot be changed to specify **ALLOW DEBUG MODE** or **DISALLOW DEBUG MODE** when the procedure has been created or altered to use **DISABLE DEBUG MODE**. To change this option, you must drop and recreate the procedure using the desired option.

### **Notes**

**Changes are immediate:** Any changes that the ALTER PROCEDURE statement causes to the definition of a procedure take effect immediately, with the exception of changes to the PROGRAM TYPE clause. If PROGRAM TYPE is changed, the stored procedure needs to be re-compiled for the change to take effect. The changed definition is used the next time that the procedure is called.

**Invalidation of plans and packages:** When an external procedure is altered, all the plans and packages that refer to that procedure are marked invalid.

**LANGUAGE C and the PARAMETER VARCHAR clause:** The ALTER PROCEDURE statement does not allow you to alter the value of the **PARAMETER VARCHAR** or **PARAMETER CCSID** clauses that are associated with the procedure definition. However, you can alter the **LANGUAGE** clause for the procedure. If the **PARAMETER VARCHAR** clause is specified for the creation of a LANGUAGE C procedure, the catalog information for that option is not affected by subsequent ALTER PROCEDURE statements. The procedure might be changed to a language other than C, in which case the **PARAMETER VARCHAR** setting is ignored. If the procedure is later changed back to LANGUAGE C, the setting of the **PARAMETER VARCHAR** option that was specified for the CREATE PROCEDURE statement (which is still in the catalog) will be used.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- DYNAMIC RESULT SET, RESULT SET, and RESULT SETS as synonyms for **DYNAMIC RESULT SETS**
- STANDARD CALL as a synonym for **DB2SQL**
- SIMPLE CALL as a synonym for **GENERAL**
- SIMPLE CALL WITH NULLS as a synonym for **GENERAL WITH NULLS**
- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**
- NULL CALL as a synonym for **CALLED ON NULL INPUT**
- PARAMETER STYLE DB2SQL as a synonym for **PARAMETER STYLE SQL**

### **Example**

Assume that stored procedure SYSPROC.MYPROC is currently defined to run in WLM environment PARTSA and that you have appropriate authority on that WLM environment and WLM environment PARTSEC. Change the definition of the stored procedure so that it runs in PARTSEC.

```
ALTER PROCEDURE SYSPROC.MYPROC WLM ENVIRONMENT PARTSEC;
```

## ALTER PROCEDURE (SQL - external)

The ALTER PROCEDURE statement changes the description, at the current server, of an external SQL procedure.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the stored procedure
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. The specified procedure name can include a schema name (a qualifier). However, if the schema name is not the same as the SQL authorization ID, one of the following conditions must be met:

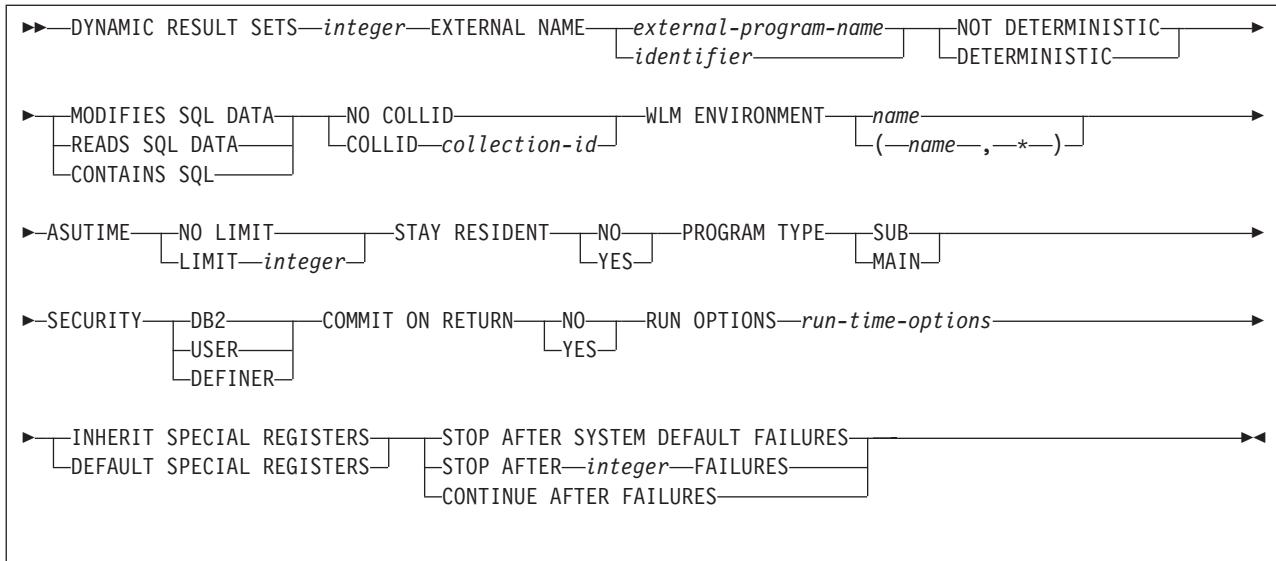

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the ALTERIN privilege on the schema.

The SQL authorization ID that is used to alter the procedure definition must have appropriate authority for the WLM environment in which the procedure is currently defined to run. This authorization is obtained from an external security product, such as RACF.

### Syntax

```
►►ALTER PROCEDURE—procedure-name—| option-list |————►►
```

**option-list:** (Specify options in any order. Specify at least one option. Do not specify the same option more than once.)

## Description

*procedure-name*

Identifies the stored procedure to be altered.

**DYNAMIC RESULT SETS** *integer*

Specifies the maximum number of query result sets that the procedure can return. The value must be between 0 and 32767.

**EXTERNAL NAME** *external-program-name or identifier*

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

**NOT DETERMINISTIC**

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

**DETERMINISTIC**

The procedure always returns the same results each time the procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements that the procedure can execute. For the data access classification of each statement, see Table 138 on page 1605. Statements that are not supported in any procedure will return an error.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

**READS SQL DATA**

Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**NO COLLID or COLLID *collection-id***

Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

**NO COLLID**

Indicates that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

**COLLID *collection-id***

Specifies the package collection for the procedure.

**WLM ENVIRONMENT *name* or (*name*,\*)**

Identifies the WLM (workload manager) environment in which the procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

***name***

Specifies the WLM environment in which the procedure must run. If another routine calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

**(*name*,\*)**

When an SQL application program directly calls a procedure, *name* specifies the WLM environment in which the stored procedure runs.

If another routine calls the procedure, the procedure runs in the same WLM environment that the calling routine uses.

To change the environment in which the procedure is to run, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the number of CPU service units that the procedure can run.

**LIMIT integer**

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure.

**STAY RESIDENT**

Specifies whether the load module for the procedure is to remain resident in memory when the procedure ends.

**NO** The load module is deleted from memory after the procedure ends.

**YES**

The load module remains resident in memory after the procedure ends.

**PROGRAM TYPE**

Specifies whether the procedure runs as a main routine or a subroutine. If PROGRAM TYPE is altered, the stored procedure needs to be re-compiled for the change to take effect.

**SUB**

The procedure runs as a subroutine.

**MAIN**

The procedure runs as a main routine.

**SECURITY**

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

**USER**

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

**DEFINER**

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

**RUN OPTIONS *run-time-options***

Specifies the Language Environment runtime options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

#### **COMMIT ON RETURN**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**NO** DB2 does not issue a commit when the procedure returns.

#### **YES**

DB2 issues a commit when the procedure returns if the following statements are true:

- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

#### **INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

##### **INHERIT SPECIAL REGISTERS**

Specifies that special registers should be inherited according to the rules listed in the table for characteristics of special registers in a procedure in Table 37 on page 151.

##### **DEFAULT SPECIAL REGISTERS**

Specifies that special registers should be initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 37 on page 151.

#### **STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies if the routine is stopped after failures.

##### **STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

##### **STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

##### **CONTINUE AFTER FAILURES**

Specifies that this routine should not be placed in a stopped state after any failure.

## **Notes**

**Changes are immediate:** Any changes that the ALTER PROCEDURE statement causes to the definition of a procedure take effect immediately, with the exception of changes to the PROGRAM TYPE clause. If PROGRAM TYPE is changed, the stored procedure needs to be re-compiled for the change to take effect. The changed definition is used the next time that the procedure is called.

**Changing to a native SQL procedure:** You cannot change an external SQL procedure to a native SQL procedure. You can drop the procedure that you want to

| change using the DROP statement and create a native SQL procedure with a  
| similar definition using the CREATE PROCEDURE statement. Alternatively, you  
| can create a native SQL procedure using a different schema.

*Invalidation of plans and packages:* When an SQL procedure is altered, all the plans and packages that refer to that procedure are marked invalid.

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 UDB family, DB2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for **DYNAMIC RESULT SETS**.
- VARIANT as a synonym for **NOT DETERMINISTIC**
- NOT VARIANT as a synonym for **DETERMINISTIC**

## Example

Modify the definition for an SQL procedure so that SQL changes are committed on return from the SQL procedure and the SQL procedure runs in the WLM environment named WLMSQLP.

```
ALTER PROCEDURE UPDATE_SALARY_1
  COMMIT ON RETURN YES
  WLM ENVIRONMENT WLMSQLP;
```

## ALTER PROCEDURE (SQL - native)

The ALTER PROCEDURE statement changes the definition of an SQL procedure at the current server. The procedure options, parameter names, and routine body can be changed and additional versions of the procedure can be defined and maintained using the ALTER PROCEDURE statement.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 6, “SQL control statements for native SQL procedures,” on page 1541.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

If the ALTER statement contains either a **REPLACE VERSION** or **ADD VERSION** clause, the statement can only be dynamically prepared.

### Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the procedure
- The ALTERIN privilege on the schema
- SYSADM authority
- SYSCTRL authority

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the procedure.

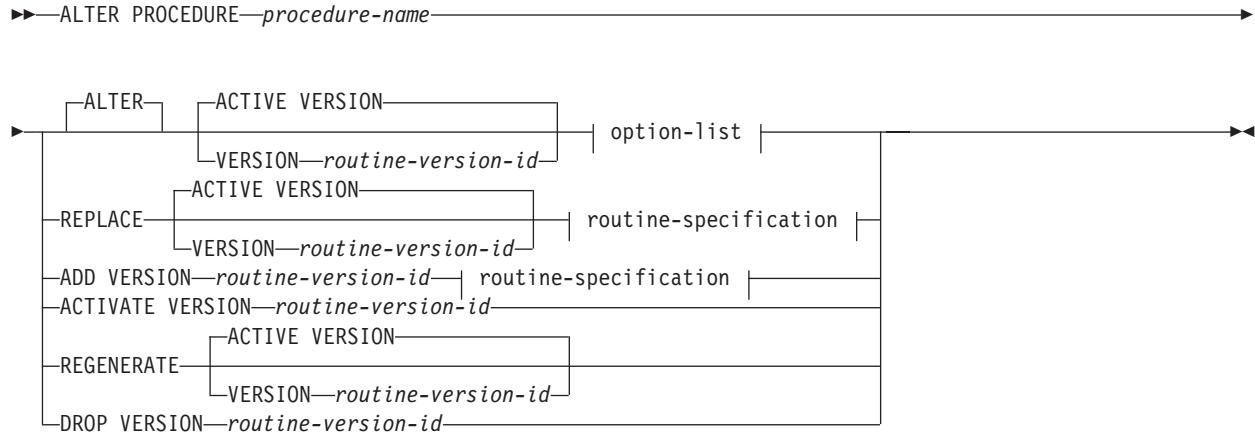

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. The specified procedure name can include a schema name (a qualifier). However, if the schema name is not the same as the SQL authorization ID, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the ALTERIN privilege on the schema.

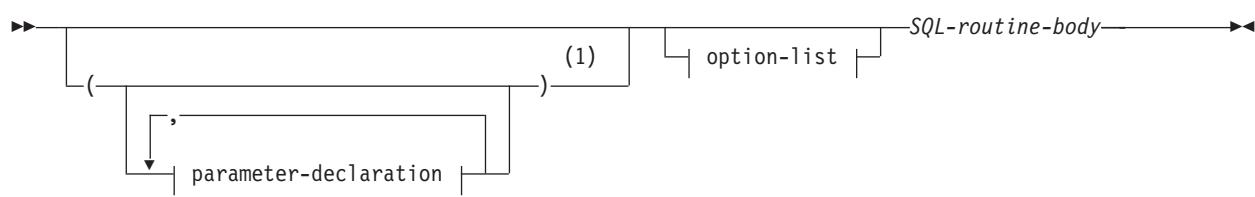

Additional privileges might be required in the following situations:

- If *SQL-routine-body* is specified, the privilege set must include the privileges that are required to execute the statements in *SQL-routine-body*.
- If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must include the authority to define programs that run in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.
- When defining a new version of a procedure (using the ADD VERSION clause) or when replacing an existing version (using the REPLACE VERSION clause), the privilege set must include the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP, or the privilege set must include SYSADM or SYSCTRL authority.

## Syntax

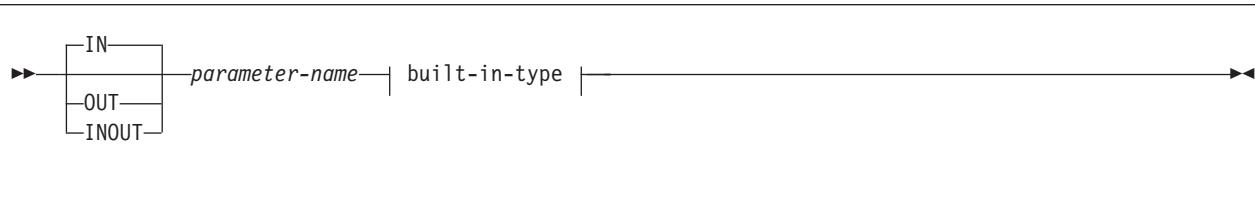

**routine-specification:**

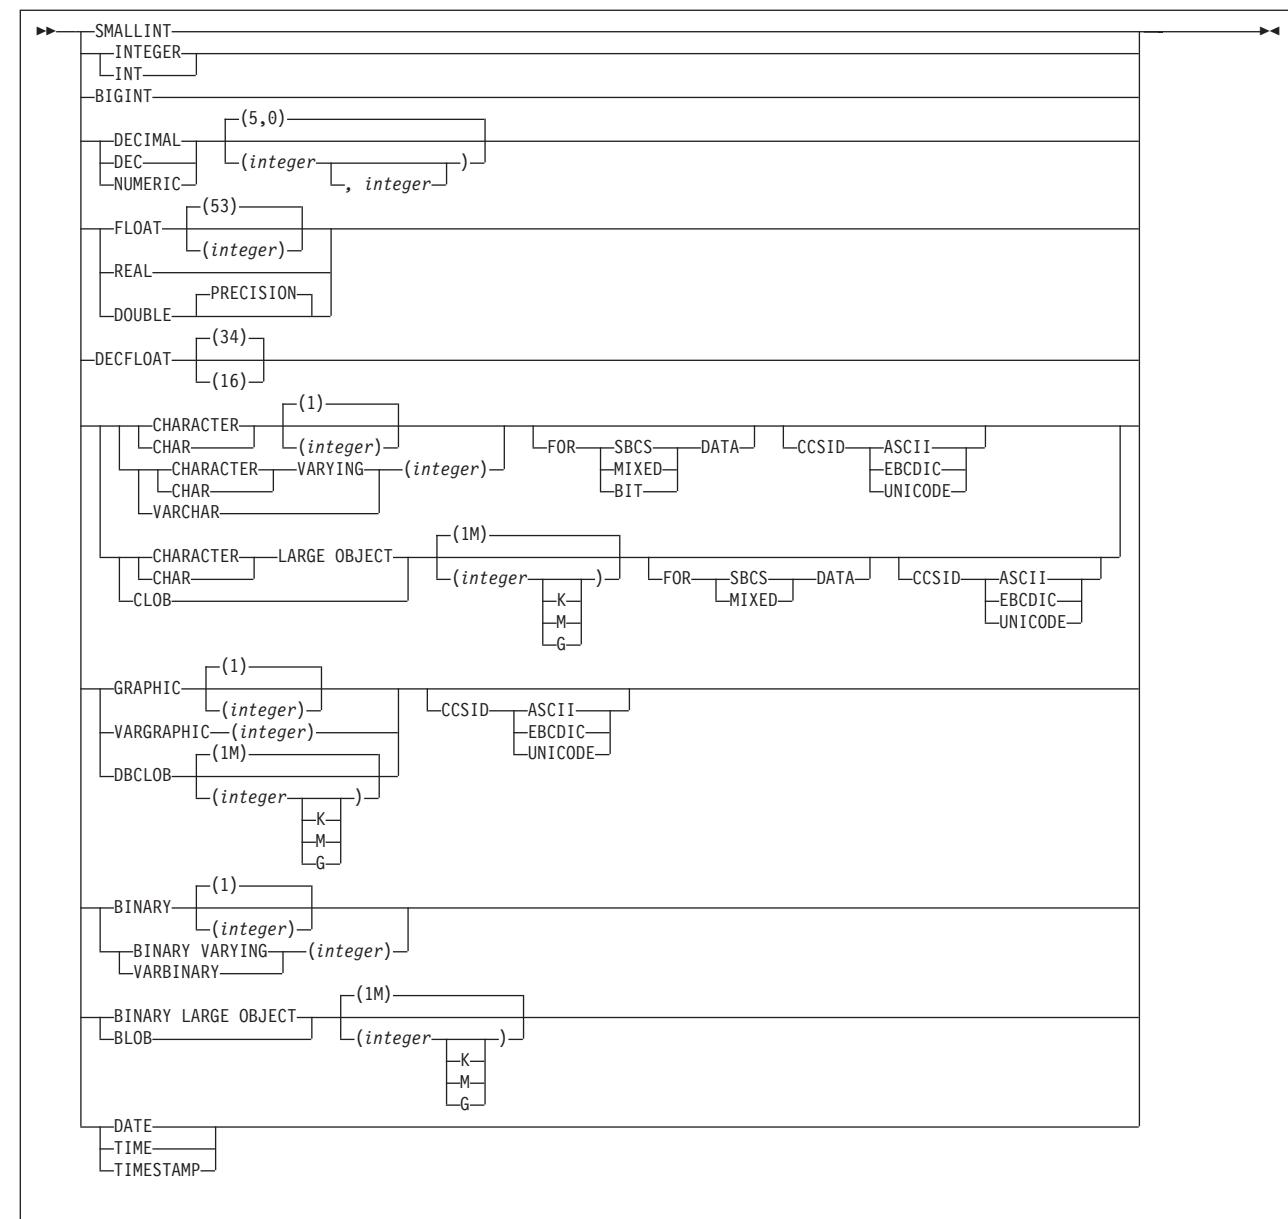

**Notes:**

- 1 All versions of the procedure must have the same number of parameters.

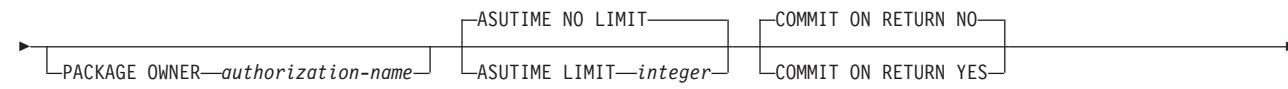

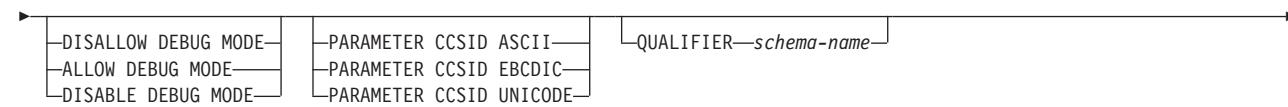

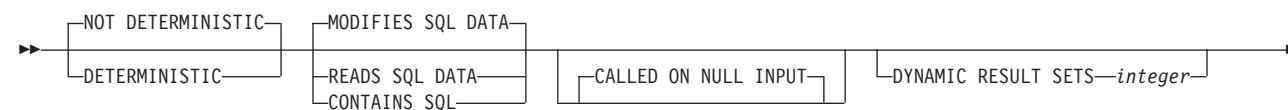

**parameter-declaration:**

**built-in-type:**

**option-list:** (The options can be specified in any order, but each option can be specified only one time.)

## Description

*procedure-name*

Identifies the procedure to alter. The procedure that is identified in *procedure-name* must exist at the current server.

**ACTIVE VERSION or VERSION *routine-version-id***

Identifies the version of the procedure that is to be changed, replaced, or regenerated depending on whether the ALTER, REPLACE, or REGENERATE keyword is specified.

**ACTIVE VERSION**

Specifies that the currently active version of the procedure is to be changed, replaced, or regenerated.

**VERSION *routine-version-id***

Identifies the version of the procedure that is to be changed, replaced, or regenerated. *routine-version-id* is the version identifier that is assigned when

the version is defined. *routine-version-id* must identify a version of the specified procedure that exists at the current server.

#### **ALTER**

Specifies that a version of the procedure is to be changed.

When you change a procedure to add or replace a version of the procedure, any option that is not explicitly specified will use the existing value from the version of the procedure that is being changed.

#### **REPLACE**

Specifies that a version of the procedure is to be replaced.

Binding the replaced version of the procedure might result in a new access path even if the routine body is not changed.

When you replace a procedure, the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. For options that are not explicitly specified, the system default values for those options are used, even if those options were explicitly specified for the version of the procedure that is being replaced. This is not the case for versions of the procedure that specified DISABLE DEBUG MODE. If DISABLE DEBUG MODE is specified for a version of a procedure, it cannot be changed by the REPLACE clause.

#### **ADD VERSION *routine-version-id***

Specifies that a new version of the procedure is to be created. *routine-version-id* is the version identifier for the new version of the procedure. *routine-version-id* must not identify a version of the specified procedure that already exists at the current server.

When a new version of a procedure is created, the comment that is recorded in the catalog for the new version will be the same as the comment that is in the catalog for the currently active version.

When you add a new version of a procedure the data types, CCSID specifications, and character data attributes (FOR BIT/SBCS/MIXED DATA) of the parameters must be the same as the attributes of the corresponding parameters for the currently active version of the procedure. The parameter names can differ from the other versions of the procedure. For options that are not explicitly specified, the system default values will be used.

#### **ACTIVATE VERSION *routine-version-id***

Specifies the version of the procedure that is to be the currently active version of the procedure. *routine-version-id* is the version identifier that is assigned when the version of the procedure is defined. The version that is specified with *routine-version-id* is the version that will be invoked by the CALL statement, unless the value of the CURRENT ROUTINE VERSION special register overrides the currently active version of the procedure when the procedure is invoked. *routine-version-id* must identify a version of the procedure that already exists at the current server.

#### **REGENERATE**

Regenerates a version of the procedure. When DB2 maintenance is applied that changes how an SQL procedure is generated, the procedure might need to be regenerated to process the maintenance changes.

REGENERATE automatically rebinds, at the local server, the package for the SQL control statements for the procedure and rebinds the package for the SQL

statements that are included in the procedure body. If a remote bind is also needed, the BIND PACKAGE COPY command must be explicitly done for all of the remote servers.

REGENERATE is different from a REBIND PACKAGE command where the SQL statements are rebound (i.e. to generate better access paths for those statements), but the SQL control statements in the procedure definition remain the same.

**DROP VERSION** *routine-version-id*

Drops the version of the procedure that is identified with *routine-version-id*. *routine-version-id* is the version identifier that is assigned when the version is defined. *routine-version-id* must identify a version of the procedure that already exists at the current server and must not identify the currently active version of the procedure. Only the identified version of the procedure is dropped.

When only a single version of the procedure exists at the current server, use the DROP PROCEDURE statement to drop the procedure. A version of the procedure for which the version identifier is the same as the contents of the CURRENT ROUTINE VERSION special register can be dropped if that version is not the currently active version of the procedure.

*(parameter-declaration, ...)*

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined or changed. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

**IN** Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

**INOUT**

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

*parameter-name*

Names the parameter for use as an SQL variable. The name cannot be the same as the name of any other *parameter-name* for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

*built-in-type*

Specifies the data type of the parameter. See “CREATE PROCEDURE (SQL - native)” on page 1046 for more information on data type specifications.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

**NOT DETERMINISTIC**

The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements that the procedure can execute.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

**READS SQL DATA**

Specifies that procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**CALLED ON NULL INPUT**

Specifies that the procedure will be called if any, or even if all parameter values are null.

**DYNAMIC RESULT SETS *integer***

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Specifies whether the version of the procedure can be run in debugging mode. The default for a new version of a procedure is determined using the value of the CURRENT DEBUG MODE special register.

**ALLOW DEBUG MODE**

Specifies that this version of the procedure can be run in debugging mode. When this version of the procedure is invoked and debugging is attempted, a WLM environment must be available.

**DISALLOW DEBUG MODE**

Specifies that the version of the procedure cannot be run in debugging mode.

You can use a subsequent ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

**DISABLE DEBUG MODE**

Specifies that the version of the procedure can never be run in debugging mode.

The version of the procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after the version of the procedure has been created, replaced, or altered to use DISABLE DEBUG MODE. To change DEBUG MODE for a version of a procedure that specifies DISABLE DEBUG MODE, you must drop and recreate the version of the procedure using the desired option.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE option is ignored.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or Unicode. The value must be the same as the PARAMETER CCSID value determined when the procedure was created. The default value is the same as the PARAMETER CCSID value that was determined when the procedure was created.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in all of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER *schema-name***

Specifies the implicit qualifier that is used for unqualified names of tables, views, indexes, and aliases that are referenced in the procedure body. The default value is determined from the CURRENT SCHEMA special register.

**PACKAGE OWNER *authorization-name***

Specifies the owner of the package that is associated with the version of the procedure. The SQL authorization ID of the process is the default value.

This authorization ID must have the privileges required to execute the SQL statements that are contained in the body of the routine. The value of the PACKAGE OWNER option is subject to translation when sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

Specifies that there is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

**LIMIT** *integer*

Specifies that the limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure.

**COMMIT ON RETURN NO** or **COMMIT ON RETURN YES**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**COMMIT ON RETURN NO**

DB2 does not issue a commit when the procedure returns. NO is the default.

**COMMIT ON RETURN YES,**

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS** or **DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 37 on page 151.

INHERIT SPECIAL REGISTERS is the default.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 37 on page 151.

**WLM ENVIRONMENT FOR DEBUG MODE** *name*

Specifies the WLM (workload manager) application environment used by DB2 when debugging the procedure. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space that is specified at installation time.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

To change the environment that DB2 uses for debugging this procedure, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**DEFER PREPARE** or **NODEFER PREPARE**

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value that is specified for the REOPT option. If REOPT NONE is specified, the default is NODEFER PREPARE. Otherwise, the default is DEFER PREPARE.

#### **DEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in *DB2 Command Reference* for considerations with distributed processing.

#### **NODEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

#### **CURRENT DATA**

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors. For more information about updating the current row of a cursor, block fetch, and data currency, see *DB2 Application Programming and SQL Guide*.

##### **YES**

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquired page or row locks to ensure data currency. Block fetch is not allowed for distributed, ambiguous cursors.

**NO** Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of CURRENT DATA(NO) is not recommended if the procedure attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your procedure attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch
- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

No is the default.

#### **DEGREE**

Specifies whether to attempt to run a query using parallel processing to maximize performance.

**1** Specifies that parallel processing should not be used.

1 is the default.

#### **ANY**

Specifies that parallel processing can be used.

#### **DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the runtime environment of a native SQL procedure controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the runtime environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

**RUN**

Specifies that dynamic SQL statements are to be processed using run behavior.

RUN is the default.

**BIND**

Specifies that dynamic SQL statements are to be processed using bind behavior.

**DEFINEBIND**

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

**DEFINERUN**

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

**INVOKEBIND**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

**INVOKERUN**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See “Authorization IDs and dynamic SQL” on page 64 for information on the effects of these options.

**APPLICATION ENCODING SCHEME**

Specifies the default encoding scheme for SQL variables in static SQL statements in the procedure body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

**ASCII**

Specifies that the data is encoded using the ASCII CCSIDs of the server.

**EBCDIC**

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

**UNICODE**

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

**WITH EXPLAIN or WITHOUT EXPLAIN**

Specifies whether information will be provided about how SQL statements in the procedure will execute.

#### **WITHOUT EXPLAIN**

Specifies that information will not be provided about how SQL statements in the procedure will execute.

You can get EXPLAIN output for a statement that is embedded in a native SQL procedure that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the procedure body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the procedure body, and to the fullselect portion of any DECLARE CURSOR statements.

WITHOUT EXPLAIN is the default.

#### **WITH EXPLAIN**

Specifies that information will be provided about how SQL statements in the procedure will execute. Information is inserted into the table *owner.PLAN\_TABLE*. *owner* is the authorization ID of the owner of the procedure package. Alternatively, the authorization ID of the owner of the procedure can have an alias as *owner.PLAN\_TABLE* that points to the base table, PLAN\_TABLE. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. PLAN\_TABLE must have a base table and can have multiple aliases with the same table name, PLAN\_TABLE, but have different schema qualifiers; it cannot be a view or a synonym. It should exist before the version is added or replaced. In all inserts to *owner.PLAN\_TABLE*, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables, if they exist: DSN\_STATEMENT\_TABLE and DSN\_FUNCTION\_TABLE.

DSN\_STATEMENT\_TABLE contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. DSN\_FUNCTION\_TABLE contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1283.

#### **WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. *DB2 Command Reference* shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this procedure option) as it affects run time.

#### **WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

WITHOUT IMMEDIATE WRITE is the default.

#### **WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. WITH IMMEDIATE WRITE might impact performance.

**ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the procedure from the effects of other running applications. For information about isolation levels, see *DB2 Performance Monitoring and Tuning Guide*.

**RR** Specifies repeatable read.

**RS** Specifies read stability.

**CS** Specifies cursor stability. CS is the default.

**UR** Specifies uncommitted read.

**WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC**

Specifies whether DB2 keeps dynamic SQL statements after commit points.

**WITHOUT KEEP DYNAMIC**

Specifies that DB2 does not keep dynamic SQL statements after commit points.

WITHOUT KEEP DYNAMIC is the default.

**WITH KEEP DYNAMIC**

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify WITH KEEP DYNAMIC, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify WITH KEEP DYNAMIC, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread time outs, as described in *DB2 Installation Guide* for install panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The DB2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

**OPTHINT *string-constant***

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the procedure.

*string-constant* is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN\_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *DB2 Installation Guide* for information about enabling optimization hints.

#### **SQL PATH**

Specifies the SQL path that the DB2 subsystem uses to resolve unqualified user-defined distinct types, functions, and procedure names (in CALL statements) in the body of the procedure.

The maximum length of the SQL path is 2048 bytes. DB2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed 2048 bytes.

*schema-name*

Specifies a schema. DB2 does not validate that the specified schema actually exists when the ALTER statement is processed.

*schema-name-list*

Specifies a comma separated list of schema names. The same schema name should not appear more than one time in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

#### **SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (or USER) special register. At the time the ALTER statement is processed, the actual length is included in the total length of the list of schema names that is specified for the PATH option. If you specify SESSION\_USER (or USER) in a list of schema names, do not use delimiters around the SESSION\_USER (or USER) keyword.

#### **DEFAULT**

Specifies that the SQL Path should be set to "SYSIBM", "SYSFUN", "SYSPROC", *procedure-schema*. *procedure-schema* is the schema qualifier for the procedure that is being altered.

If you specify DEFAULT, you do not need to explicitly specify the SYSIBM, SYSFUN, and SYSPROC schemas; these schemas are implicitly added to the beginning of the SQL path in the order listed. If you do not specify the SYSIBM, SYSFUN, and SYSPROC, schemas, they are not included in the length of the SQL path.

#### **RELEASE AT**

Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

#### **COMMIT**

Specifies that resources will be released at each commit point.

COMMIT is the default.

#### **DEALLOCATE**

Specifies that resources will be released only when the procedure terminates. DEALLOCATE has no effect on packages that run on a DB2 server through a DRDA connection with a client system. DEALLOCATE also has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC

SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and SQL data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package size because additional items become resident in the package. For more information about how the RELEASE clause affects locking and concurrency, see *DB2 Performance Monitoring and Tuning Guide*.

#### **REOPT**

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

#### **NONE**

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

NONE is the default.

#### **ALWAYS**

Specifies that DB2 always determine the access path at run time each time an SQL statement is run.

#### **ONCE**

Specifies that DB2 determine the access path for any dynamic SQL statements only one time, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and needs to be prepared again.

#### **VALIDATE RUN or VALIDATE BIND**

Specifies whether to recheck, at run time, errors of the type "OBJECT not FOUND" and NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

#### **VALIDATE RUN**

Specifies that if needed objects or privileges do not exist when the ALTER PROCEDURE statement is processed, warning messages are returned, but the ALTER PROCEDURE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the ALTER PROCEDURE statement. The authorization checks the use of the authorization ID of the owner of the procedure package.

VALIDATE RUN is the default.

**VALIDATE BIND**

Specifies that if needed objects or privileges do not exist at the time the ALTER PROCEDURE statement is processed, an error is issued and the ALTER PROCEDURE statement fails.

**ROUNDING**

Specifies the desired rounding mode for manipulation of DECFLOAT data.

**DEC\_ROUND\_CEILING**

Specifies numbers are rounded towards positive infinity.

**DEC\_ROUND\_DOWN**

Specifies numbers are rounded towards 0 (truncation).

**DEC\_ROUND\_FLOOR**

Specifies numbers are rounded towards negative infinity.

**DEC\_ROUND\_HALF\_DOWN**

Specifies numbers are rounded to nearest; if equidistant, round down.

**DEC\_ROUND\_HALF\_EVEN**

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

**DEC\_ROUND\_HALF\_UP**

Specifies numbers are rounded to nearest; if equidistant, round up.

**DEC\_ROUND\_UP**

Specifies numbers are rounded away from 0.

**DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the date format for result values that are string representations of date or time values. See “String representations of datetime values” on page 89 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the procedure is defined. You cannot use the LOCAL option unless you have a date exit routine.

**DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**

Specifies the maximum precision that is to be used for decimal arithmetic operations. See “Arithmetic with two decimal operands” on page 183 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the procedure is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

**FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

**FOR UPDATE CLAUSE REQUIRED**

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

FOR UPDATE CLAUSE REQUIRED is the default.

**FOR UPDATE CLAUSE OPTIONAL**

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The procedure body can include positioned UPDATE statements that update columns that the user is authorized to update.

If the resulting DBRM for the procedure is very large, you might need extra storage when you specify FOR UPDATE CLAUSE OPTIONAL.

The FOR UPDATE clause of the select-statement with no column list applies to static or dynamic SQL statements. You can specify the FOR UPDATE OF clause of the select-statement with a column list to restrict updates to only the columns that are named in the column list and to specify the acquisition of update locks.

#### **TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 89 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the procedure is defined. You cannot use the LOCAL option unless you have a date exit routine.

#### *SQL-routine-body*

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 6, “SQL control statements for native SQL procedures,” on page 1541. If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon. For information on the SQL statements that are allowed in SQL procedures, see “SQL statements allowed in SQL procedures” on page 1608.

## **Notes**

***Changes are immediate:*** Any changes that the ALTER PROCEDURE statement causes to the definition of a procedure take effect immediately. The changed definition is used the next time that the procedure is called.

***Considerations for altering a version of a procedure:*** To alter a version of a procedure, the environment settings that are in effect when the ALTER PROCEDURE statement is issued must be the same as the environment settings that are in effect when the version of the procedure is first created using the CREATE PROCEDURE or ALTER PROCEDURE statements if one of the following options is specified:

- **QUALIFIER**
- **PACKAGE OWNER**
- **WLM ENVIRONMENT FOR DEBUG MODE**
- **OPTHINT**
- **SQL PATH**
- **DECIMAL** (if the value includes a comma)

***Changing to a native SQL procedure:*** You cannot change an external SQL procedure to a native SQL procedure. You can drop the external SQL procedure that you want to change by using the DROP statement and create a native SQL procedure with a similar definition using the CREATE PROCEDURE statement. Alternatively, you can create a native SQL procedure using a different schema.

***Identifier resolution:*** See Chapter 6, “SQL control statements for native SQL procedures,” on page 1541 for information on how names are resolved to columns, SQL variables, or SQL routines for native SQL procedures. Name resolution is unchanged for external SQL procedures.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the procedure name for parameters, and the label name for SQL variables.

*Characteristics of the package that is generated for a version of a procedure:* The package that is associated with a version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See Table 83 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(\*)

*Considerations for a procedure that is defined using a TABLE LIKE name AS LOCATOR clause:* If a procedure is defined with a table parameter (the TABLE LIKE *name* AS LOCATOR clause was specified in the CREATE PROCEDURE statement to indicate that one of the input parameters is a transition table), the procedure cannot be changed with an ALTER PROCERDURE statement if the change requires that the parameter list be specified. For example, to add or replace a version of a native SQL procedure, the procedure must be dropped and recreated.

*Correspondence of procedure options to BIND options:* The following table lists options for CREATE PROCEDURE and ALTER PROCEDURE and the corresponding options for the bind commands. See *DB2 Command Reference* for more information about the effects of the options of the bind commands.

*Table 83. Correspondence of procedure options to bind options*

CREATE PROCEDURE or ALTER PROCEDURE option	bind commands option
APPLICATION ENCODING SCHEME	ENCODING(ASCII) ENCODING(EBCDIC) ENCODING(UNICODE)
CURRENT DATA NO	CURRENTDATA(NO)
CURRENT DATA YES	CURRENTDATA(YES)
DEFER PREPARE	DEFER(PREPARE)
NODEFER PREPARE	NODEFER(PREPARE)
DEGREE	DEGREE(ANY) DEGREE(1)

*Table 83. Correspondence of procedure options to bind options (continued)*

CREATE PROCEDURE or ALTER PROCEDURE option	bind commands option
DYNAMICRULES	DYNAMICRULES(RUN) DYNAMICRULES(BIND) DYNAMICRULES(DEFINEBIND) DYNAMICRULES(DEFINERUN) DYNAMICRULES(INVOKEBIND) DYNAMICRULES(INVOKERUN)
ISOLATION LEVEL	ISOLATION(RR) ISOLATION(RS) ISOLATION(CS) ISOLATION(UR)
OPTHINT	OPTHINT
PACKAGE OWNER	OWNER
QUALIFIER	QUALIFIER
RELEASE AT COMMIT	RELEASE(COMMIT)
RELEASE AT DEALLOCATE	RELEASE(DEALLOCATE)
REOPT ALWAYS	REOPT(ALWAYS)
REOPT NONE	REOPT(NONE)
REOPT ONCE	REOPT(ONCE)
ROUNDING DEC_ROUND_CEILING	ROUNDING(CEILING)
ROUNDING DEC_ROUND_DOWN	ROUNDING(DOWN)
ROUNDING DEC_ROUNDING_FLOOR	ROUNDING(FLOOR)
ROUNDING DEC_ROUNDING_HALF_DOWN	ROUNDING(HALFDOWN)
ROUNDING DEC_ROUNDING_HALF_EVEN	ROUNDING(HALFEVEN)
ROUNDING DEC_ROUNDING_HALF_UP	ROUNDING(HALFUP)
ROUNDING DEC_ROUNDING_UP	ROUNDING(UP)
SQL PATH	PATH
VALIDATE BIND	VALIDATE(BIND)
VALIDATE RUN	VALIDATE(RUN)
WITH EXPLAIN	EXPLAIN(YES)
WITHOUT EXPLAIN	EXPLAIN(NO)
WITH IMMEDIATE WRITE	IMMEDWRITE(YES)
WITHOUT IMMEDIATE WRITE	IMMEDWRITE(NO)
WITH KEEPDYNAMIC	KEEPDYNAMIC(YES)
WITHOUT KEEPDYNAMIC	KEEPDYNAMIC(NO)

**Invalidation of plans and packages:** When a version of an SQL procedure is altered to change any option that is specified for the active version, all the plans and packages that refer to that procedure are marked invalid. Additionally, when

certain attributes of a native SQL procedure are changed, the body of the procedure might be rebound or regenerated. The following table summarizes when implicit rebind and regeneration occurs when specific options are changed. A value of Y in a row indicates that a rebind or regeneration will occur if the option is changed for a version of the procedure.

*Table 84. CREATE PROCEDURE and ALTER PROCEDURE options that result in rebind or regeneration when changed.*

CREATE PROCEDURE or ALTER PROCEDURE option	Change requires rebind of invoking applications?	Change results in implicit rebind of the non-control statements of the body of the procedure?	Change results in implicit regeneration of the entire body of the procedure?
ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE	Y <sup>1, 2</sup>	Y <sup>1</sup>	Y
APPLICATION ENCODING SCHEME	Y	Y	Y
ASUTIME	Y		
COMMIT ON RETURN	Y		
CURRENT DATA		Y	
DATE FORMAT	Y	Y	Y
DECIMAL	Y	Y	Y
DEFER PREPARE or NODEFER PREPARE		Y	
DEGREE		Y	
DYNAMIC RESULT SETS	Y		
DYNAMICRULES		Y	
FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED	Y	Y	Y
INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS	Y		
ISOLATION LEVEL		Y	
MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL	Y	Y	Y
NOT DETERMINISTIC or DETERMINISTIC			
OPTHINT		Y	
PACKAGE OWNER		Y	
QUALIFIER		Y	
RELEASE AT COMMIT or RELEASE AT DEALLOCATE		Y	
REOPT		Y	
SQL PATH		Y	

| Table 84. *CREATE PROCEDURE* and *ALTER PROCEDURE* options that result in rebind or regeneration when  
| changed. (continued)

CREATE PROCEDURE or ALTER PROCEDURE option	Change requires rebind of invoking applications?	Change results in implicit rebind of the non-control statements of the body of the procedure?	Change results in implicit regeneration of the entire body of the procedure?
STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER nn FAILURES, or CONTINUE AFTER FAILURES	Y		
TIME FORMAT	Y	Y	Y
VALIDATE RUN or VALIDATE BIND		Y	
WITH EXPLAIN or WITHOUT EXPLAIN		Y	
WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE		Y	
WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC		Y	
WLM ENVIRONMENT FOR DEBUG MODE	Y		

| **Note:**

| 1. The procedure package is rebound or regenerated if a value of ALLOW DEBUG MODE is changed to DISALLOW DEBUG MODE.

| 2. Invoking applications are invalidated if a value of DISALLOW DEBUG MODE is changed to DISABLE DEBUG MODE.

| **Compatibilities:** For compatibility with previous versions of DB2, the following clauses can be specified, but they will be ignored and an error or a warning will be issued. If ALTER is implicitly or explicitly specified with one of these options specified as part of *option-list*, a warning is issued and the option is ignored. If REPLACE or ADD VERSION is specified with one of these options specified as part of *option-list*, an error is issued. For example, ADD VERSION is specified and STAY RESIDENT is specified as part of *option-list* and an error is issued.

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER *nn* FAILURES
- CONTINUE AFTER FAILURES

| If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

For compatibility with the CREATE PROCEDURE statement, the following clause can be specified, but will be ignored:

- LANGUAGE SQL

*Considerations for SYSENVIRONMENTS catalog table:* An ALTER statement that specifies a new environment settings will result in a new row being added to the SYSENVIRONMENTS catalog table. The new row will be added even if an error is subsequently encountered during processing of the ALTER statement. Thus, a new SYSENVIRONMENTS row might be added even for an ALTER statement that fails.

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET, RESULT SETS, and DYNAMIC RESULT SET as synonyms for DYNAMIC RESULT SETS.
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

## Example

*Example 1:* The following statement changes the existing procedure options for the active version of the UPDATE\_SALARY\_1 native SQL procedure. If you need to change a different version of the procedure, you would specify VERSION *routine-version-id* in place of ACTIVE VERSION. Note that the ALTER clause that precedes the version specification can be omitted.

```
ALTER PROCEDURE UPDATE_SALARY_1
    ALTER ACTIVE VERSION
    NOT DETERMINISTIC
    CALLED ON NULL INPUT
    ALLOW DEBUG MODE
    ASUTIME LIMIT 10
```

*Example 2:* To change the procedure body of any existing version of a procedure, you need to use the REPLACE clause. The following statement changes both the procedure body and the existing SQL data access option for version V2 of the UPDATE\_SALARY\_1 SQL procedure. Note that the list of parameters is specified even though no changes are made to the list. To replace an existing version of a procedure, you must specify the list of parameters, any options that are to have non-default values (even if those options are specified in the version of the procedure that you are replacing), and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
    REPLACE VERSION V2 (P1 INTEGER, P2 CHAR(5))
    MODIFIES SQL DATA
    UPDATE EMP SET SALARY = SALARY * RATE
        WHERE EMPNO = EMPLOYEE_NUMBER;
```

*Example 3:* To add a new version of an existing procedure, use the ADD VERSION clause. The following statement adds a new version of the UPDATE\_SALARY\_1 procedure to apply a larger salary increase. Note that the list of parameters is specified even though the new version of the procedure uses the same parameters as the existing version of the procedure. To add a new version of a procedure, you must specify the list of parameters, any options that will have non-default values, and the body of the procedure.

```
ALTER PROCEDURE UPDATE_SALARY_1
    ADD VERSION V3 (P1 INTEGER, P2 CHAR(5))
    UPDATE EMP SET SALARY = SALARY * (RATE*10)
        WHERE EMPNO = EMPLOYEE_NUMBER;
```

*Example 4:* When the new version of the procedure has been defined, as in Example 3, you must use the ALTER PROCEDURE statement with the ACTIVATE VERSION clause if the new version of the procedure is to be the currently active version, as in the following example.

```
ALTER PROCEDURE UPDATE_SALARY_1  
    ACTIVATE VERSION V3;
```

*Example 5:* To regenerate the currently active version of a procedure, use the following statement.

```
ALTER PROCEDURE UPDATE_SALARY_1  
    REGENERATE ACTIVE VERSION;
```

## ALTER SEQUENCE

The ALTER SEQUENCE statement changes the attributes of a sequence at the current server. Only future values of the sequence are affected by the ALTER SEQUENCE statement.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

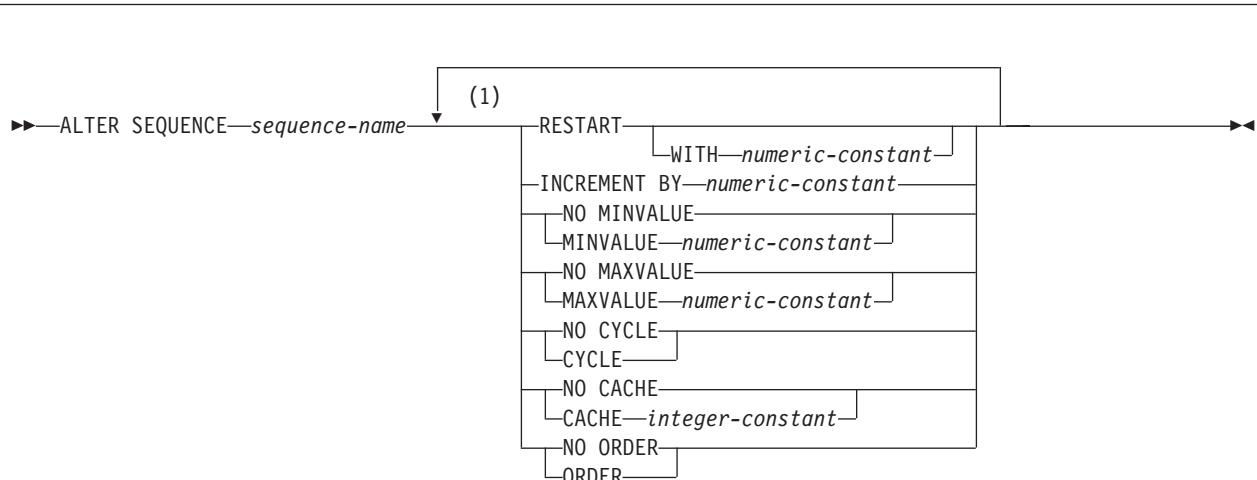

The privilege set that is defined below must include at least one of the following:

- Ownership of the sequence
- The ALTER privilege for the sequence
- The ALTERIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the ALTERIN privilege on the schema.

| **Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process.

### Syntax

#### Notes:

- 1 At least one option must be specified and the same clause must not be specified more than once. Separator commas can be specified between sequence attributes when a sequence is defined.

### Description

*sequence-name*

| Identifies the sequence. The combination of sequence name and the implicit or

explicit qualifier must identify an existing sequence at the current server. *sequence-name* must not identify a sequence that is generated by DB2 for an identity column or a DB2\_GENERATED\_DOCID\_FOR\_XML column.

#### **RESTART**

Restarts the sequence. If *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the CREATE SEQUENCE statement that originally created the sequence.

#### **WITH *numeric-constant***

Specifies the value at which to restart the sequence. The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values in effect for all the options after the ALTER statement is issued.

After a sequence is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated by the sequence previously.

#### **INCREMENT BY *numeric-constant***

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point.

If INCREMENT BY *numeric-constant* is positive, the sequence ascends. If INCREMENT BY *numeric-constant* is negative, the sequence descends. If INCREMENT BY *numeric-constant* is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

#### **NO MINVALUE or MINVALUE**

Specifies whether or not there is a minimum end point of the range of values for the sequence.

#### **NO MINVALUE**

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the original starting value.
- For a descending sequence, the value is the minimum of the data type that is associated with the sequence.

#### **MINVALUE *numeric-constant***

Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value.

MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

**NO MAXVALUE or MAXVALUE**

Specifies whether or not there is a maximum end point of the range of values for the sequence.

**NO MAXVALUE**

Specifies either explicitly or implicitly that the minimum end point of the range of values for the sequence has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence
- For a descending sequence, the value is the original starting value.

If NO MAXVALUE is explicitly specified in the ALTER SEQUENCE statement, the value of the MAXVALUE column in the catalog table is reset to the maximum value of the data type associated with the sequence if the sequence is ascending or the value stored in the START column of the catalog table if the sequence is descending. Whether the sequence is ascending or descending depends on whether or not the INCREMENT BY option is reset. If it is, the new INCREMENT BY VALUE determines if the sequence is ascending or descending. If it is not explicitly reset, the value stored in the INCREMENT column of the catalog table determines if the sequence is ascending or descending.

**MAXVALUE *numeric-constant***

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or a descending sequence cycles to after reaching the minimum value. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value.

MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

**NO CYCLE or CYCLE**

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it.

**NO CYCLE**

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached.

**CYCLE**

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application

conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

#### **NO CACHE or CACHE**

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

##### **NO CACHE**

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure. When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O.

##### **CACHE *integer-constant***

Specifies the maximum number of sequence values that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

#### **NO ORDER or ORDER**

Specifies whether the sequence numbers must be generated in order of request.

##### **NO ORDER**

Specifies that the sequence numbers do not need to be generated in order of request.

##### **ORDER**

Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested for next value first, then DB2B requested, and then DB2A again requested. Therefore, to

guarantee that sequence numbers are generated in strict numeric order among multiple DB2 members using the same sequence concurrently, specify the ORDER option.

## Notes

*Altering a sequence:* The changes to the attributes of a sequence take effect after the ALTER SEQUENCE statement is committed. Only future sequence numbers are affected by the ALTER SEQUENCE statement. If the ALTER SEQUENCE request results in an error or is rolled back, nothing is changed; however, unused cache values might be lost.

- The data type of a sequence cannot be changed. Instead, drop and recreate the sequence specifying the desired data type for the new sequence.
- All cached values are lost when a sequence is altered.
- After restarting a sequence or changing it to cycle, it is possible that a generated value will duplicate a value previously generated for that sequence.

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- NOCACHE (single key word) as a synonym for NO CACHE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOORDER (single key word) as a synonym for NO ORDER

## Examples

*Example 1:* Reset a sequence to the START WITH value to generate the numbers from 1 up to the number of rows in the table:

```
ALTER SEQUENCE org_seq
  RESTART;
```

# ALTER STOGROUP

The ALTER STOGROUP statement changes the description of a storage group at the current server.

# Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

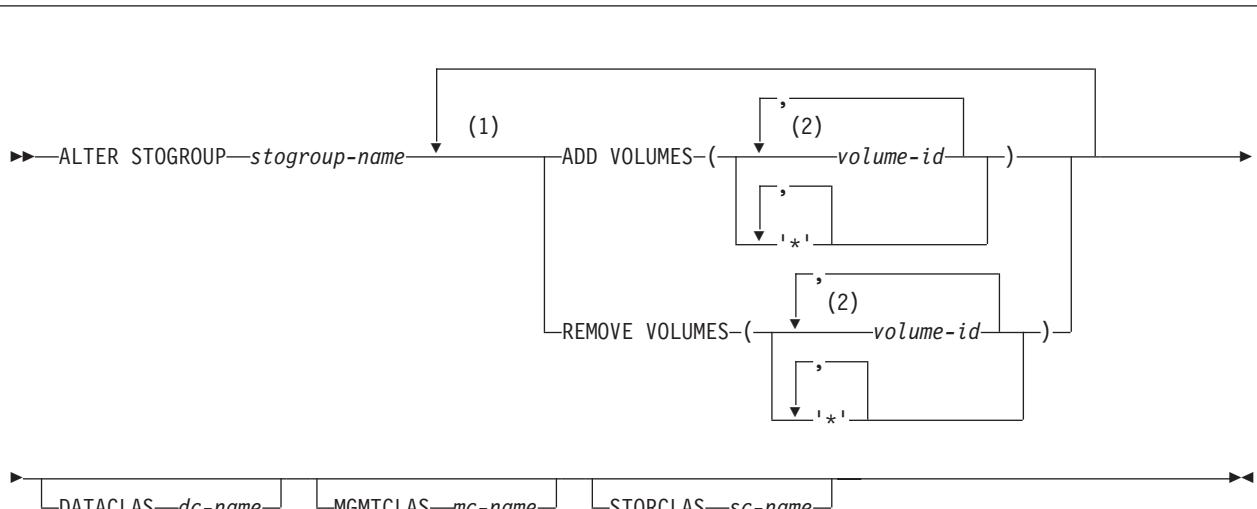

## Authorization

The privilege set that is defined below must include one of the following:

- Ownership of the storage group
  - SYSADM or SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

## Syntax

#### **Notes:**

- 1 The same clause must not be specified more than once.
  - 2 The same *volume-id* must not be specified more than once in the same clause.

## Description

*storagegroup-name*

Identifies the storage group to be altered. The name must identify a storage group that exists at the current server.

**ADD VOLUMES(*volume-id*,...)** or **ADD VOLUMES('\*',...)**

Adds volumes to the storage group. Each *volume-id* is the volume serial number of a storage volume to be added. It can have a maximum of six characters and is specified as an identifier or a string constant.

A *volume-id* must not be specified if any volume of the storage group is designated by an asterisk (\*). An asterisk must not be specified if any volume of the storage group is designated by a *volume-id*.

You cannot add a volume that is already in the storage group unless you first remove it with REMOVE VOLUMES.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

**REMOVE VOLUMES(*volume-id*,...)** or **REMOVE VOLUMES('\*',...)**

Removes volumes from the storage group. Each *volume-id* is the volume serial number of a storage volume to be removed. Each *volume-id* must identify a volume that is in the storage group.

The REMOVE VOLUMES clause is applied to the current list of volumes before the ADD VOLUMES clause is applied. Removing a volume from a storage group does not affect existing data, but a volume that has been removed is not used again when the storage group is used to allocate storage for table spaces or index spaces.

Asterisks are recognized only by Storage Management Subsystem (SMS). If the data set that is associated with the storage group is non SMS managed, either ADD VOLUMES or REMOVE VOLUMES must be specified. Neither ADD VOLUMES or REMOVE VOLUMES is required if DATACLAS, MGMTCLAS, or STORCLAS is specified.

**DATACLAS *dc-name***

Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

**MGMTCLAS *mc-name***

Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

**STORCLAS *sc-name***

Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The

| SMS storage administrator defines the storage class that can be used.  
| STORCLAS must not be specified more than one time.

## Notes

**Work file databases:** If the storage group altered contains data sets in a work file database, the database must be stopped and restarted for the effects of the ALTER to be recognized. To stop and restart a database, issue the following commands:

```
-STOP DATABASE(database-name)
-START DATABASE(database-name)
```

**Device types:** When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

**Number of volumes:** There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

| If the VOLUMES clause is specified, the maximum number of volumes is 59.

| **Verifying the existence of volumes and classes:** When processing the VOLUMES, DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the  
| existence of the volumes or classes or determine the types of devices that are  
| identified or if SMS is active. Later, when the storage group allocates data sets, the  
| list of volumes is passed in the specified order to Data Facilities (DFSMSdfp). See  
| *DB2 Administration Guide* for more information about creating DB2 storage groups.

**SMS data set management:** You can have Storage Management Subsystem (SMS) manage the storage needed for the objects that the storage group supports. To do so, specify ADD VOLUMES('\*') and REMOVE VOLUMES(*current-vols*) in the ALTER statement, where *current-vols* is the list of the volumes currently assigned to the storage group. SMS manages every data set created later for the storage group. SMS does not manage data sets created before the execution of the statement.

You can also specify ADD VOLUMES(*volume-id*) and REMOVE VOLUMES('\*') to make the opposite change.

See *DB2 Administration Guide* for considerations for using SMS to manage data sets.

## Examples

*Example 1:* Alter storage group DSN8G910. Add volumes DSNV04 and DSNV05.

```
ALTER STOGROUP DSN8G910
    ADD VOLUMES (DSNV04,DSNV05);
```

*Example 2:* Alter storage group DSN8G910. Remove volumes DSNV04 and DSNV05.

```
ALTER STOGROUP DSN8G910
    REMOVE VOLUMES (DSNV04,DSNV05);
```

## ALTER TABLE

The ALTER TABLE statement changes the description of a table at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The ALTER privilege on the table
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

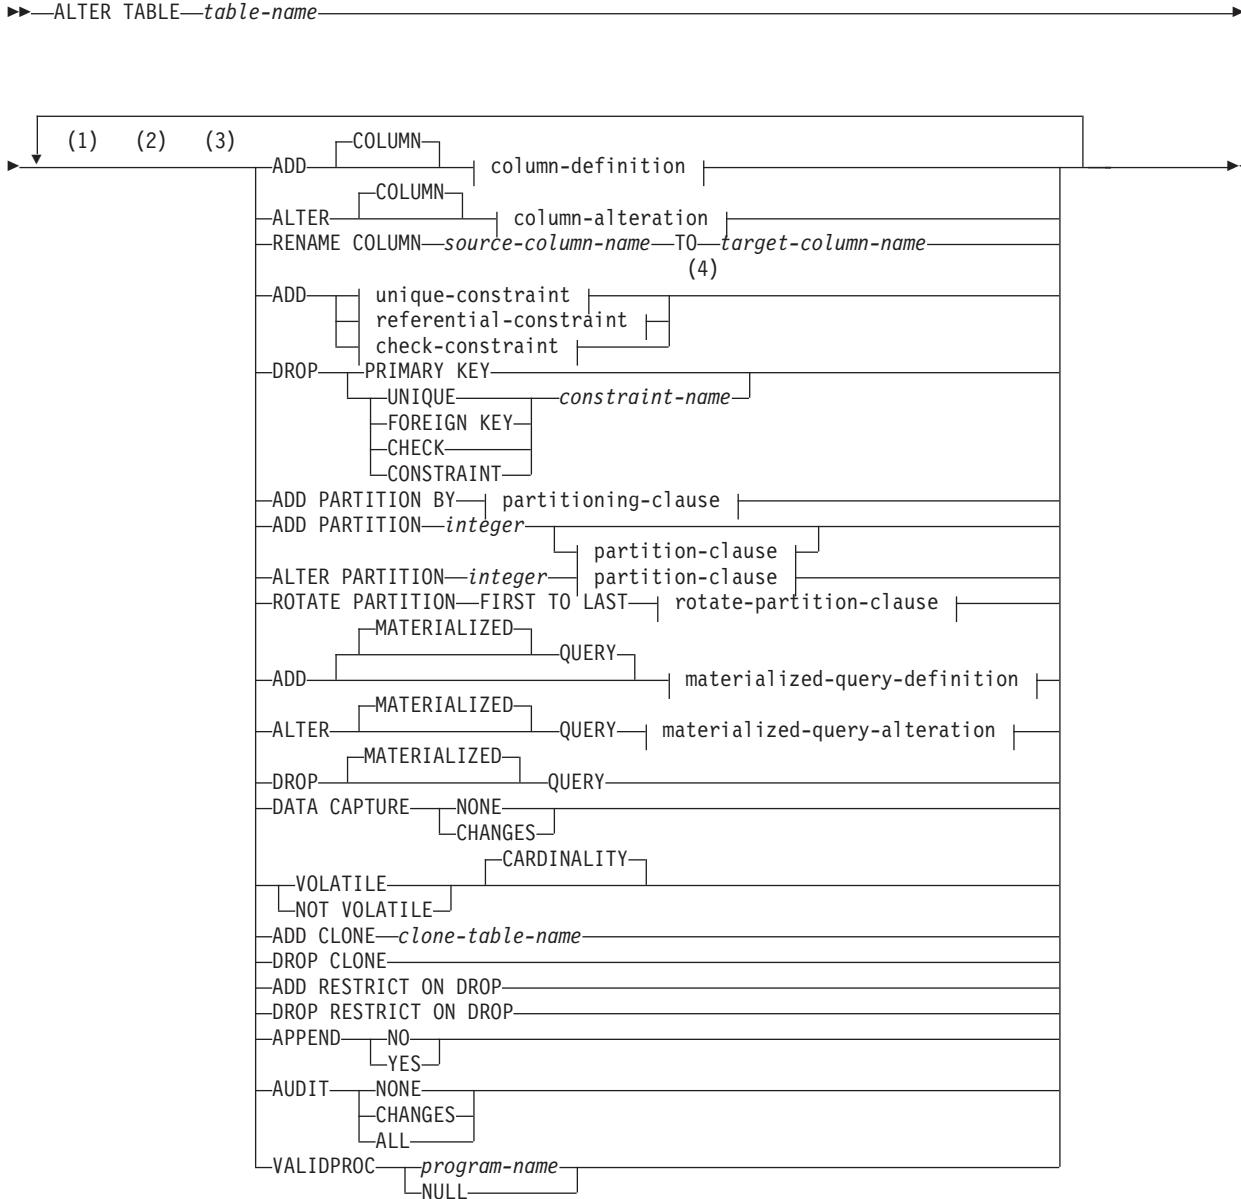

Additional privileges might be required in the following situations:

- FOREIGN KEY, ADD PRIMARY KEY, ADD UNIQUE, DROP PRIMARY KEY, DROP FOREIGN KEY, or DROP CONSTRAINT is specified.
- The data type of a column that is added to the table is a distinct type.
- A fullselect is specified.
- A column is defined as a security label column.
- A column is defined as ROWID GENERATED BY DEFAULT.

See the description of the appropriate clauses for the details about these privileges.

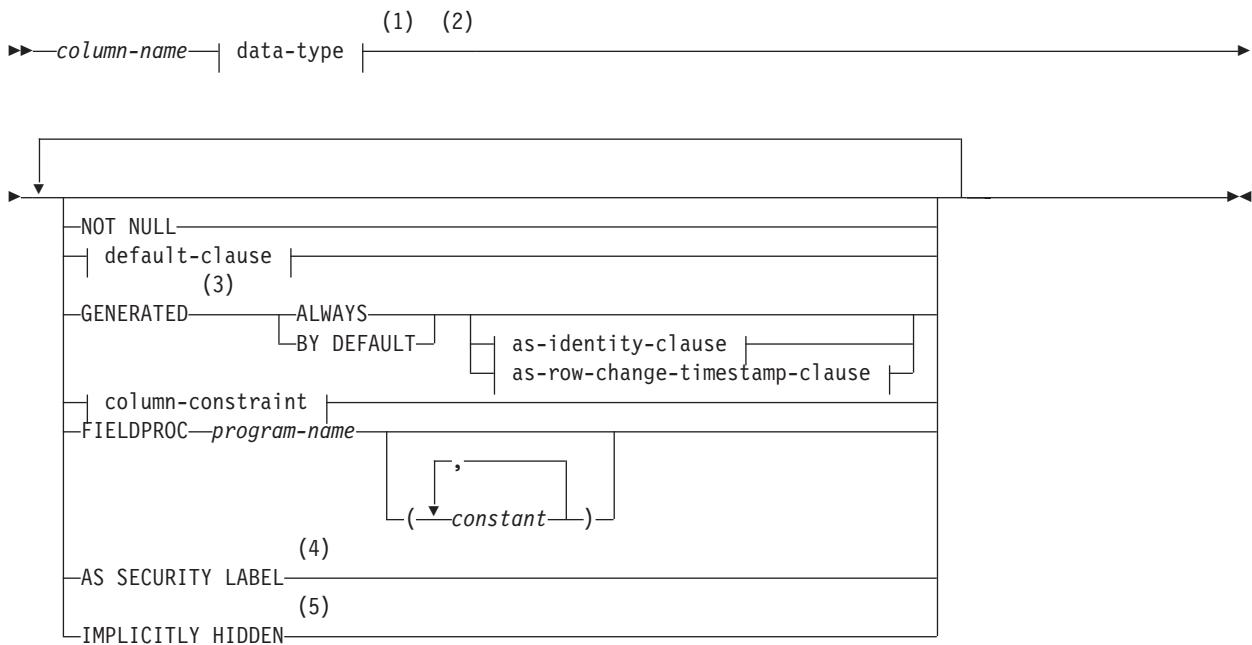

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and each role of the process.

## Syntax

### Notes:

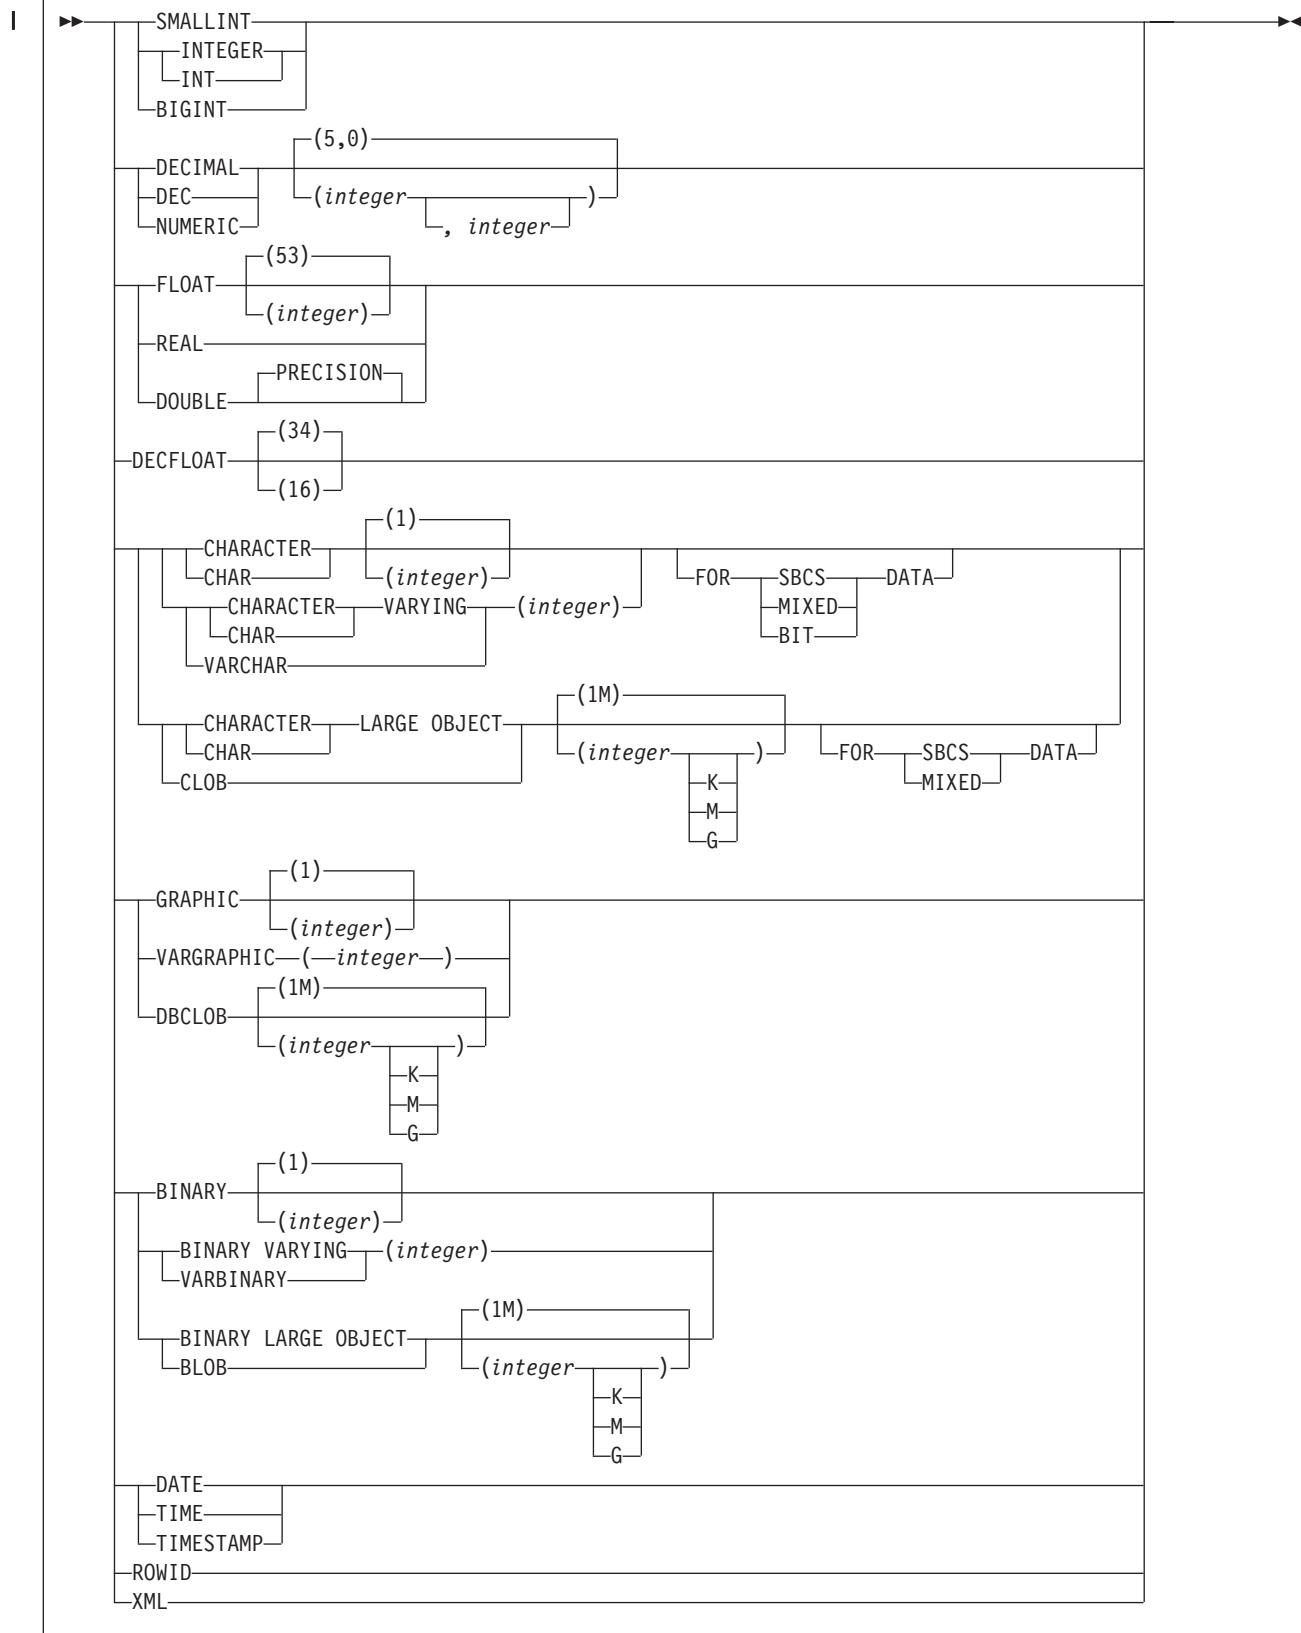

- 1 The same clause must not be specified more than one time, except for the ALTER COLUMN clause. If ALTER COLUMN SET DATA TYPE is specified, it must be specified first.
- 2 The ADD PARTITION, ALTER COLUMN, ALTER PARTITION, and ROTATE PARTITION FIRST TO LAST clauses are mutually exclusive with each other.
- 3 If ADD CLONE, DROP CLONE, or RENAME COLUMN is specified, no other clause is allowed on the ALTER TABLE statement.
- 4 The ADD keyword is optional for *referential-constraint* or *unique-constraint* if it is the first clause specified in the statement. Otherwise, ADD is required.

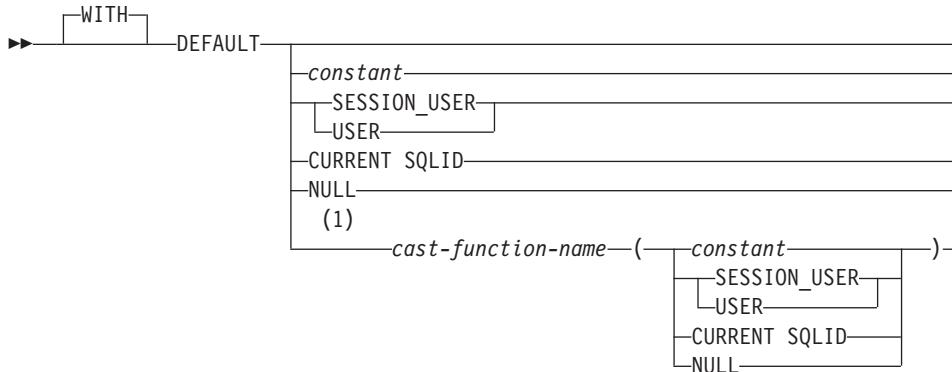

**column-definition:****Notes:**

- 1 *data-type* is optional if *as-row-change-timestamp-clause* is specified
- 2 The same clause must not be specified more than one time.
- 3 GENERATED must be specified if the column is to be an identity column. A column that has a ROWID data type (or a distinct type that is based on a ROWID data type) defaults to GENERATED ALWAYS.
- 4 AS SECURITY LABEL can be specified only for a CHAR(8) data type and requires that the NOT NULL and WITH DEFAULT clauses be specified.
- 5 IMPLICITLY HIDDEN must not be specified for a column defined as a ROWID, or a distinct type that is based on a ROWID.

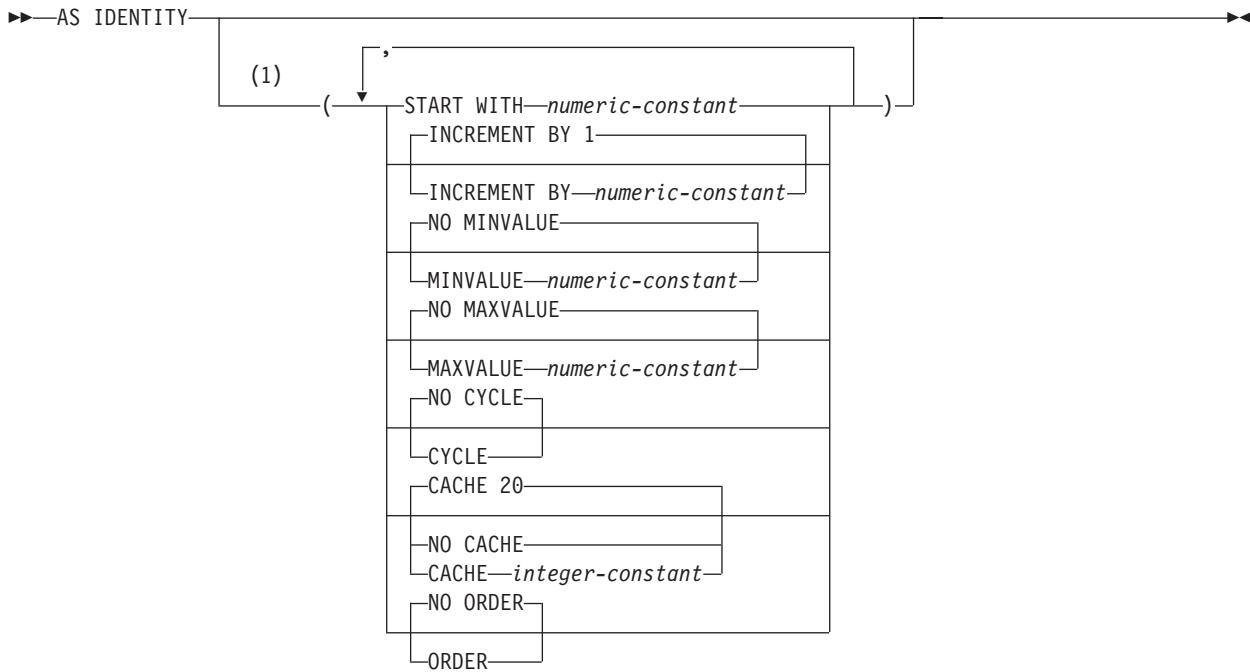

**data-type:**

**built-in-type:**

**default-clause:****Notes:**

- 1 The *cast-function-name* form of the DEFAULT value can only be used with a column that is defined as a distinct type.

**as-identity-clause:****Notes:**

- 1 Separator commas can be specified between attributes when an identity column is defined.

| **as-row-change-timestamp-clause:**

| ►►—FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP—►►

**column-constraint**

►►— references-clause | check-constraint —►►

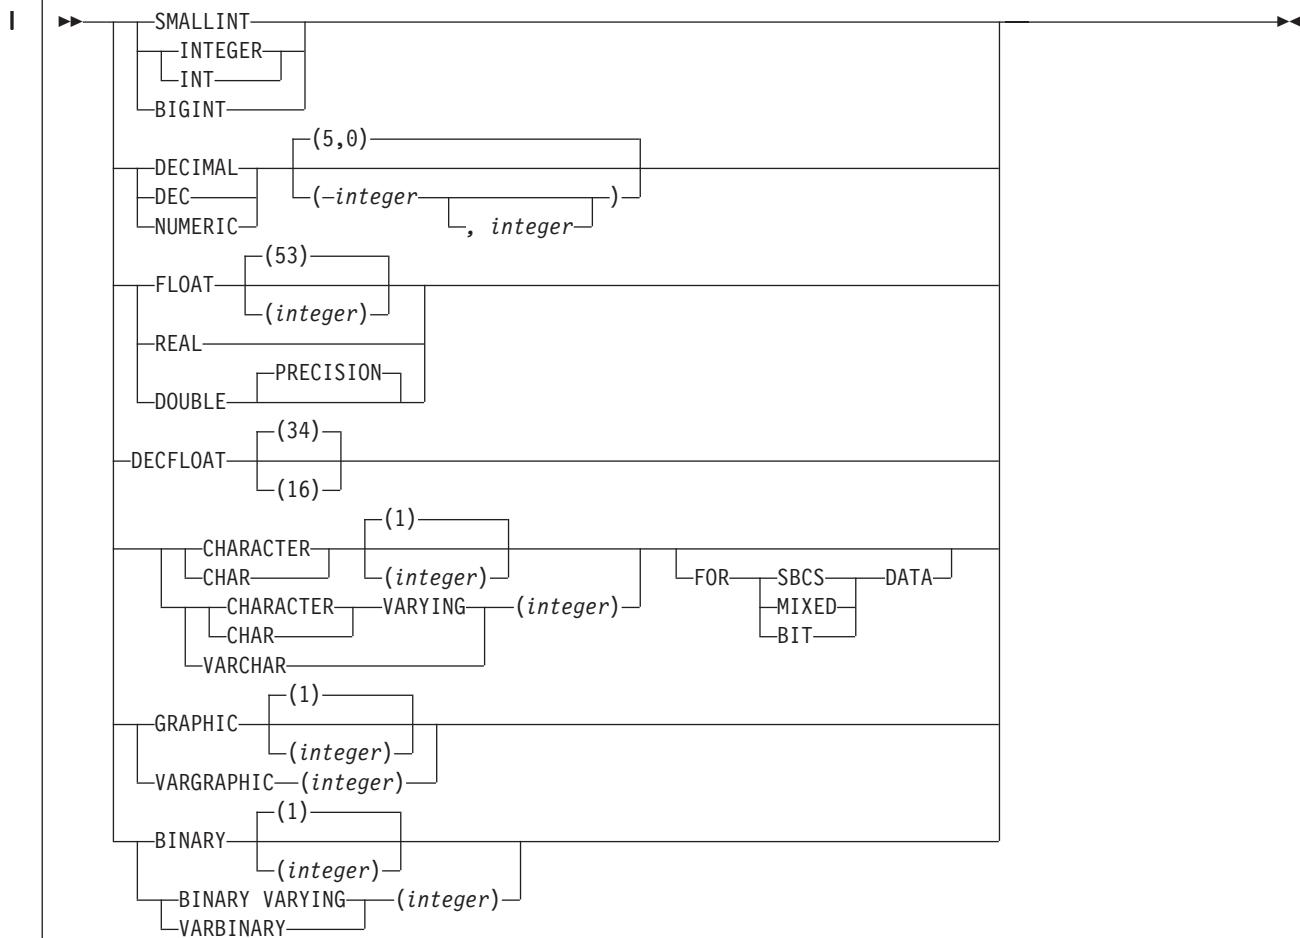

**column-alteration:**

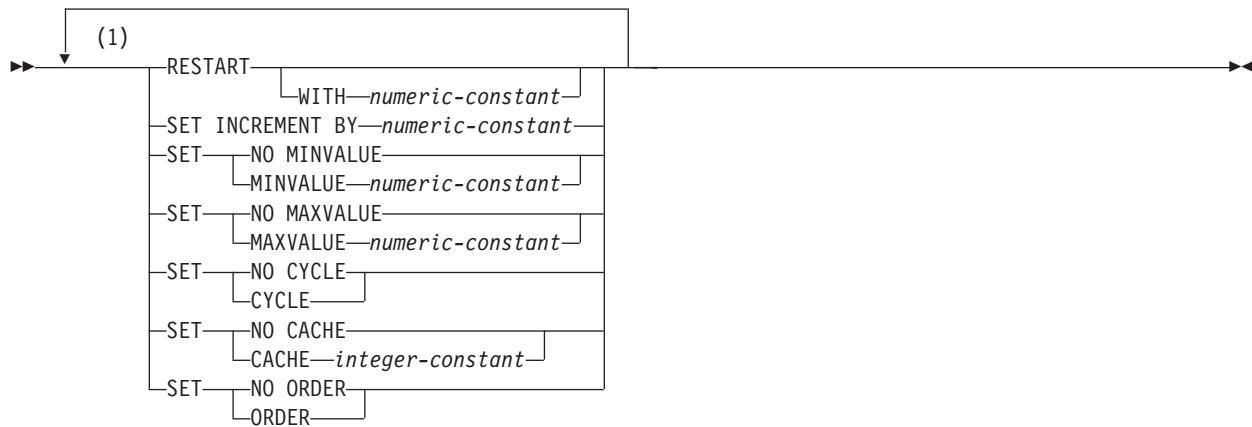

| ►►—column-name—SET—DATA TYPE— altered-data-type (1)  
| | | | default-clause |  
| | | | DROP DEFAULT |  
| | | | SET GENERATED—ALWAYS—  
| | | | | BY DEFAULT |  
| | | | SET GENERATED—ALWAYS— identity-alteration  
| | | | | BY DEFAULT |

**Notes:**

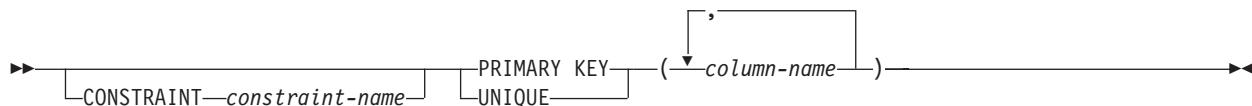

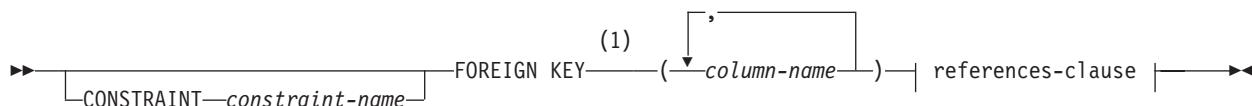

- 1 Each clause can be specified only one time. If DATA TYPE is specified, it must be specified first.

**altered-data-type:**

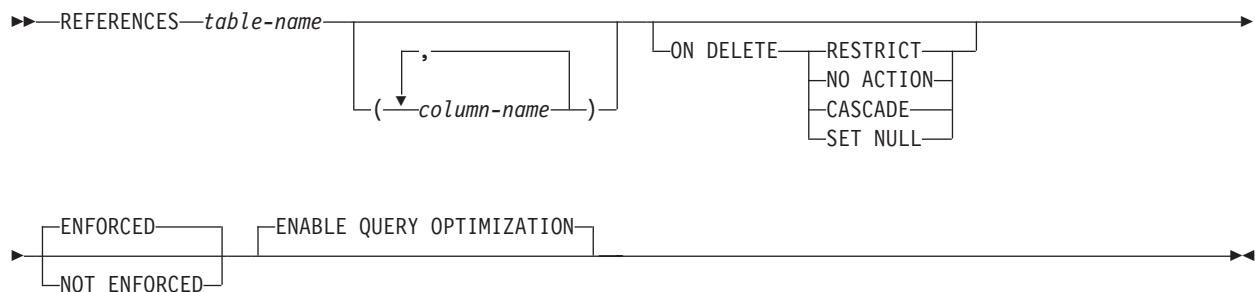

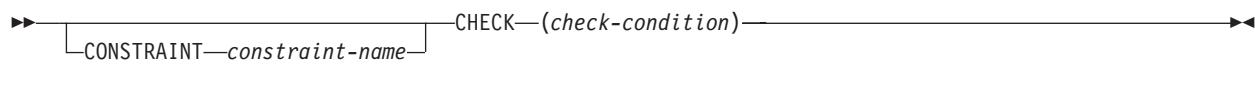

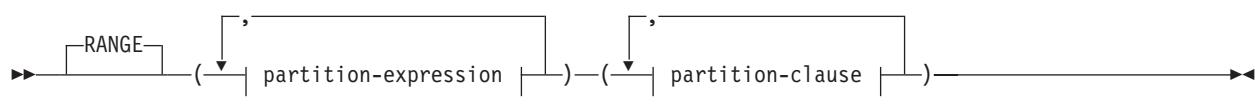

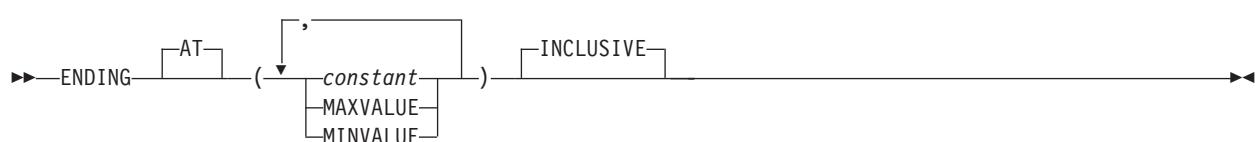

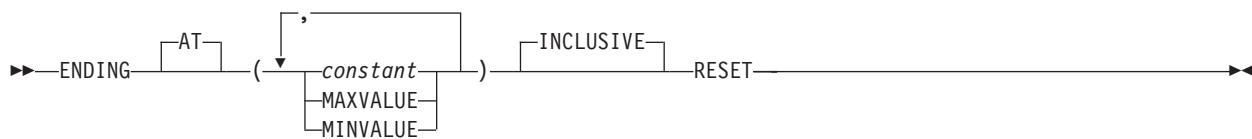

**identity-alteration:****Notes:**

- 1 At least one option must be specified and the same clause must not be specified more than once.

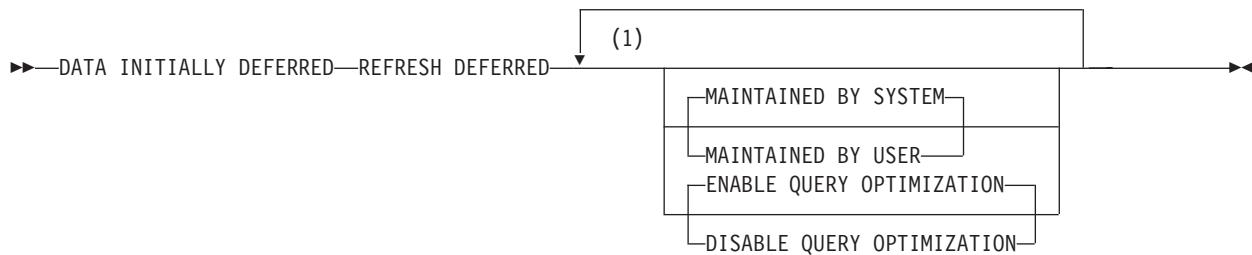

**unique-constraint:****referential-constraint:****Notes:**

- 1 For compatibility with prior releases, when the CONSTRAINT clause (shown above) is not specified, a *constraint-name* can be specified following FOREIGN KEY.

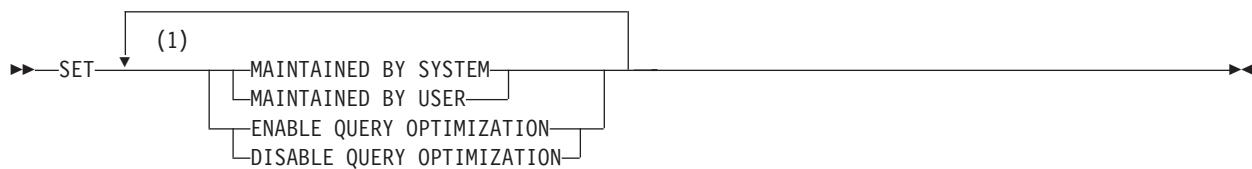

**references-clause:****check-constraint:****partitioning-clause:****partition-expression:****partition-clause:**

**partition-rotation:****materialized-query-definition:**

```
▶▶ (—fullselect—) refreshable-table-options
```

**refreshable-table-options:****Notes:**

- 1 The same clause must not be specified more than one time.

**materialized-query-table-alteration:****Notes:**

- 1 The same clause must not be specified more than one time.

**Description**

*table-name*

Identifies the table to be altered. The name must identify a table that exists at the current server. The name must not identify a declared temporary table,

view, or a table that was implicitly created for an XML column. If the name identifies a catalog table, DATA CAPTURE CHANGES is the only clause that can be specified.

If *table-name* identifies an auxiliary table, alterations are limited to the following clauses:

- APPEND

If *table-name* identifies a materialized query table, alterations are limited to the following clauses:

- AUDIT
- DATA CAPTURE
- ALTER MATERIALIZED QUERY
- DROP MATERIALIZED QUERY
- ADD RESTRICT ON DROP
- DROP RESTRICT ON DROP

## ADD COLUMN:

### **ADD** *column-definition*

Adds a column to the table. Except for a ROWID column and an identity column, all values of the column in existing rows are set to its default value. If the table has *n* columns, the ordinality of the new column is *n*+1. The value of *n* cannot be greater than 749. For a dependent table, *n* cannot be greater than 748.

The column cannot be added if the increase in the total byte count of the columns exceeds the maximum row size. The maximum row size for the table is eight less than the maximum record size as described in Maximum record size.

If you add a LOB column and the table does not already have a ROWID column, DB2 creates an implicitly hidden ROWID column. For details about adding a LOB column, such as the other objects that might be implicitly created or need to be explicitly created, see Creating a table with LOB columns. For more information about adding a ROWID column, see Adding a ROWID column.

For implicitly created LOB objects, the privilege set requires CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created) and the USE privilege on the buffer pool and the storage group that is used by the auxiliary table and the LOB table space. The implicitly created objects are owned by the owner of the base table.

If you add an XML column, the privilege set requires the CREATETAB and CREATETS privileges on the database that contains the table (DSNDB04 if the database is implicitly created), INDEX on the base table for the first DOCID column that is added, and USE privilege on the buffer pool and the storage group that is used by the XML objects. These privileges are required for implicitly created XML objects. The implicitly created objects are owned by the owner of the base table.

When you add a column to a table, the table space is placed into advisory REORG-pending status.

You cannot add the following columns:

- A column to a table that has an edit procedure that is defined as WITH ROW ATTRIBUTES.

- A ROWID column to a table that already has an explicitly defined ROWID column
- An identity column to a table that has an identity column
- A security label column to a table that already has a security label column
- A row change timestamp column to a table that already has a row change timestamp column
- A LOB, ROWID, identity column, or row change timestamp column to a created temporary table
- A GRAPHIC, VARGRAPHIC, DBCLOB, or CHAR FOR MIXED DATA column, when the setting for installation option MIXED DATA is NO

*column-name*

Names of the column you want to add to the table. Do not use the name of an existing column of the table. Do not qualify *column-name*.

*built-in-type*

Specifies the data type of the column is one of the built-in data types. See built-in-type for information about the built-in data types that can be used when adding a column to a table.

*distinct-type-name*

Specifies the distinct type (user-defined data type) of the column. The length and scale of the column are respectively the length and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

**DEFAULT**

The default value assigned to the column in the absence of a value specified in a data change statement, or LOAD. Do not specify DEFAULT for the following types of columns:

- A ROWID column (DB2 generates default values)
- An identity column (DB2 generates default values)
- An XML column
- A row change timestamp column

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default for a security label column.

If a value is not specified after the DEFAULT keyword, the default value depends on the data type of the column as indicated in the following table:

<b>Data Type</b>	<b>Default Value</b>
------------------	----------------------

**Numeric**

0

**Fixed-length character or graphic string**

Blanks

**Fixed-length binary string**

Hexadecimal zeros

**Varying-length string**

A string of length 0

- Date** For existing rows, a date corresponding to 1 January 0001. For added rows, CURRENT DATE.
- Time** For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, CURRENT TIME.

#### **Timestamp**

For existing rows, a date corresponding to 1 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and 0 microseconds. For added rows, CURRENT TIMESTAMP.

In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.
- Omission of NOT NULL and DEFAULT for a column other than an identity column is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

A default value other than the one that is listed above can be specified in one of the following forms, except for a LOB column. The only form that can be specified for a LOB column is DEFAULT NULL. Unlike other varying-length strings, a LOB column can have the default value of only a zero-length string or null. Specify:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

#### *constant*

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or string constant must be short enough so that its UTF-8 representation requires no more than 1536 bytes. A hexadecimal graphic string (GX) constant cannot be specified.

#### **SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register at the time of an SQL data change statement or LOAD, as the default for the column. If SESSION\_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37. For existing rows, the value is that of the SESSION\_USER special register at the time the ALTER TABLE statement is processed.

#### **CURRENT\_SQLID**

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or LOAD, as the default for the column. If CURRENT\_SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT\_SQLID special register. For existing rows, the value is the SQL authorization ID of the process at the time the ALTER TABLE statement is processed.

#### **NULL**

Specifies null as the default value for the column.

#### *cast-function-name*

The name of the cast function that matches the name of the distinct

type for the column. A cast function can be specified only if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

*constant*

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type.

**SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the SESSION\_USER special register.

**CURRENT\_SQLID**

Specifies the value of the CURRENT\_SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the CURRENT\_SQLID special register.

**NULL**

Specifies the NULL value as the argument.

**GENERATED**

Specifies that DB2 generates values for the column. GENERATED is applicable only to ROWID columns, identity columns, and row change timestamp columns. If the data type of the column is a ROWID (or a distinct type that is based on a ROWID), the default is GENERATED ALWAYS.

**ALWAYS**

Specifies that DB2 will generate a value for the column when a row is inserted into the table. ALWAYS is the recommended value unless you are using data propagation.

**BY DEFAULT**

Specifies that DB2 will generate a value for the column when a row is inserted unless a value was specified for the column on the data change statement.

If a user-supplied value is specified for a ROWID column, DB2 uses the value only if it is a valid row ID value that was previously generated by DB2 and the column has a unique, single-column index. Until this index is created on the ROWID column, the insert, and update operations and the LOAD utility cannot be used to add rows to the table. If the table space name is not specified on the CREATE TABLE statement, DB2 implicitly creates the necessary object to make the table complete, including the index. The name of this index is 'T' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

|  
|  
For an identity column, DB2 inserts a specified value but does not verify that it is a unique value for the column unless the identity column has a unique, single-column index.

If a user-supplied value is specified for an identity column, DB2 inserts the specified value but does not perform any special validation on that value beyond the normal validation that is performed for any column. DB2 does not check how the specified value affects the sequential properties that are defined for the identity column. To ensure the uniqueness of an identity column that is defined as GENERATED BY DEFAULT, define a unique index on the identity column.

BY DEFAULT is the recommended value only when you are using data propagation.

#### **AS IDENTITY**

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a distinct type based on one of these types). Separator commas between identity column attribute specifications are optional when the identity column is defined.

An identity column is implicitly NOT NULL. When adding an identity column to a table, you must also specify GENERATED ALWAYS or GENERATED BY DEFAULT.

Defining a column AS IDENTITY does not necessarily guarantee uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

#### **START WITH *numeric-constant***

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

#### **INCREMENT BY *numeric-constant***

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant and could be assigned to the column without any non-zero digits existing to the right of the decimal point. The default is 1.

If the value is positive or zero, the sequence of values for the identity column ascends. If the value is negative, the sequence of values descends.

#### **MINVALUE or NO MINVALUE**

Specifies the minimum value at which a descending identity

column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

#### **NO MINVALUE**

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH was not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

#### **MINVALUE *numeric-constant***

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

#### **MAXVALUE or NO MAXVALUE**

Specifies the maximum value at which a ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

#### **NO MAXVALUE**

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending identity column, the value is the maximum value of the data type of the column.
- For a descending identity column, the value is the START WITH value or -1 if START WITH is not specified.

#### **MAXVALUE *numeric-constant***

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

#### **CYCLE or NO CYCLE**

Specifies whether this identity column should continue to generate values after reaching either its maximum or minimum value.

#### **NO CYCLE**

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached. This is the default.

#### **CYCLE**

Specifies that values continue to be generated for this column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it

generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

#### **CACHE or NO CACHE**

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is CACHE 20.

#### **NO CACHE**

Specifies that values for the identity column are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column results in synchronous I/O.

#### **CACHE *integer-constant***

Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a system failure, all cached identity column values that are yet to be assigned might be lost and will not be used. Therefore, the value that is specified for CACHE also represents the maximum number of values for the identity column that could be lost during a system failure.

The minimum value is 2.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

#### **ORDER or NO ORDER**

Specifies whether the identity column values must be generated in order of request. The default is NO ORDER.

#### **NO ORDER**

Specifies that the values do not need to be generated in order of request.

#### **ORDER**

Specifies that the values are generated in order of request. Specifying ORDER might disable the caching of values. ORDER applies only to a single-application process.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the identity column, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested a value first, then DB2B requested, and then DB2A again requested.

Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the ORDER option.

**FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**

Specifies that the column is a timestamp and the values will be generated by DB2. DB2 generates a value for the column for each row as a row is inserted, and for any row for which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the time of the insert or update of the row. If multiple rows are inserted or updated with a single statement, the value of the row change timestamp column might be different for each row.

If *data-type* is specified, it must be TIMESTAMP. You must specify NOT NULL with a row change timestamp column.

**NOT NULL**

Prevents the column from containing null values. If NOT NULL is specified, the DEFAULT clause must be used to specify a nonnull default value for the column unless the column has a row ID data type or is an identity column. For a ROWID column, NOT NULL must be specified, and DEFAULT must not be specified. For an identity column, although NOT NULL can be specified, DEFAULT must not be specified.

**IMPLICITLY HIDDEN**

Specifies that the column is not visible in the results of SQL statements unless you refer explicitly to the column by name. For example, assume that table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause. The result of SELECT \* FROM T1 would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID.

*references-clause*

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if *references-clause* is specified in the definition of column C, the effect is the same as if that *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column.

Do not specify *references-clause* in the definition of a LOB, ROWID, XML, DECFLOAT column, or a row change timestamp column, or a security label column because these types of columns cannot be a foreign key.

*check-constraint*

The *check-constraint* of a *column-definition* has the same effect as specifying a check constraint in a separate ADD *check-constraint* clause. For conformance with the SQL standard, a check constraint specified in the definition of column C should not reference any columns other than C.

Do not specify a check constraint in the definition of a LOB, ROWID, DECFLOAT, XML, or security label column.

**FIELDPROC *program-name***

Designates *program-name* as the field procedure exit routine for the column. Writing a field procedure exit routine is described in *DB2 Administration Guide*. A field procedure can be specified only for a column with a length

attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data type that is not a LOB. The column must not be one of the following:

- a security label column
- a row change timestamp column

The field procedure encodes and decodes column values. Before a value is inserted in the column, it is passed to the field procedure for encoding. Before a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the ALTER TABLE statement. When so invoked, the procedure provides DB2 with the column's *field description*. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the ALTER TABLE statement defines the data characteristics of the decoded values.

*constant*

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The *n*th parameter specified in the FIELDPROC clause on ALTER TABLE corresponds to the *n*th parameter of the specified field procedure. The maximum length of the parameter list is 255 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

If you omit FIELDPROC, the column has no field procedure.

**AS SECURITY LABEL**

Specifies that the table is defined with multilevel security with row level granularity and specifies that the column will contain the security label values. A table can have only one security label column. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column does not have any field procedures, check constraints, or referential constraints.
- The column must be defined as NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not be specified with a default value (DB2 provides the default value).
- The table does not have an edit procedure that is defined as WITH ROW ATTRIBUTES.
- The table is not the source table for a materialized query table.

For existing rows in the table, the value of the security label column defaults to the security label of the user at the time the ALTER statement is executed.

## **ALTER COLUMN:**

**ALTER COLUMN** *column-alteration*

Alters the definition of an existing column, including the attributes of an existing identity column. Only the attributes specified are altered. Other attributes remain unchanged. Only future values of the column are affected by the changes made with an ALTER TABLE ALTER COLUMN statement.

The table being altered must not be in an incomplete state because of a missing unique index on a unique constraint (primary or unique key). An ALTER TABLE ALTER COLUMN statement might not be processed in the same unit of work as a data change statement. A column cannot be altered if any of the following conditions are true:

- The table has an edit procedure that is defined as WITH ROW ATTRIBUTES or a validation exit procedure
- The table is used in a materialized query table definition
- The table is a materialized query table
- There is an extended index that depends on that column
- The column is referenced in a field procedure
- The column is referenced in a referential constraint
- The column is a LOB column
- The column is defined as a security label column
- The column is defined as a row change timestamp column

You can modify all the attributes of an existing identity column, except for the data type of the column. To change the data type of an identity column, drop the table containing the column and recreate it. When the attributes of an identity column are altered, the column of the specified *column-name* must exist in the specified table and must have been defined with the IDENTITY attribute.

*column-name*

Identifies the column to be altered. The name must not be qualified and must identify an existing column in the table being altered when the ALTER statement is processed. The name must not identify a column that is being added in the same ALTER TABLE statement.

A column can only be referenced in one ALTER COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

**SET DATA TYPE** (*altered-data-type*)

Specifies the new data type of the column to be altered. For a character column, you can also use the clause to change the definition of the subtype that is stored in the DB2 catalog and OBD.

The column cannot be an identity column. The new data type must be compatible with the existing data type of the column. The existing data type of the column cannot be a ROWID, LOB, date, time, timestamp, or distinct type. If the column is a partitioning column, and the existing data type is CHAR or VARCHAR FOR BIT DATA, the new data type cannot be VARBINARY or BINARY. If the column is CHAR FOR BIT DATA, VARCHAR FOR BIT DATA, or BINARY, the new data type cannot be VARBINARY if the column is part of an index and is defined with the DESC attribute. For more information on the compatibility of data types, see "Assignment and comparison" on page 102.

If any numeric data type is being converted to DECFLOAT, the ALTER statement will fail if there is a partitioning key, check constraints, index, or a unique constraint on the column.

If the data type is a character or graphic string, the new length attribute must be at least as large as the existing length attribute of the column. If the data type is a numeric data type, the specified precision and scale must

be at least as large as the existing precision and scale. If a decimal fraction is being converted to floating point, the ALTER statement will fail if there is a unique index or a unique constraint on the column.

If the specified column has a default value, the existing default value must represent a value that could be assigned to a column with the new data type in accordance with the rules for assignment. The default value is updated to reflect the new data type.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the new column length must not exceed the limit on an index size. For PADDED indexes, the sum of the length attributes of the columns must not be greater than  $2000-n$ , where  $n$  is the number of columns that can contain null values. For NOT PADDED indexes, the sum of the length attributes of the columns must not be greater than  $2000-n-2m$ , where  $n$  is the number of nullable columns and  $m$  is the number of varying length columns.

The total byte count of columns after the alteration must not exceed the maximum row size. If the column is in the partitioning key, the new partitioning key cannot exceed  $255-n$ .

Table 85 shows the numeric data type alterations that are supported for SET DATA TYPE:

*Table 85. Supported numeric data type alterations for SET DATA TYPE*

From/To	SMALLINT	INTEGER	BIGINT	DECIMAL (q,t)	REAL	DOUBLE	DECFLOAT (16)	DECFLOAT (34)
SMALLINT	Y	Y	Y	(q-t)>4	Y	Y	Y	Y
INTEGER	N	Y	Y	(q-t)>9	N	Y	Y	Y
BIGINT	N	N	Y	(q-t)>18	N	N	N	Y
DECIMAL (p,s)	s=0 p<5	s=0 p<10	s=0 p<=19	q>=p (q-t)>=(p-s)	p<7	p<16	p<17	Y
DECFLOAT (16)	N	N	N	N	N	N	Y	Y
DECFLOAT (34)	N	N	N	N	N	N	N	Y
FLOAT (1-21)	N	N	N	N	Y	Y	Y	Y
FLOAT (22-53)	N	N	N	N	N	Y	Y	Y

When a SMALLINT, INTEGER, or DECIMAL column is altered to a BIGINT data type, and there is an index defined on that column, the index will be put in RBDP status.

In releases of DB2 prior to Version 9.1, use of the DECIMAL(19,0) data type for applications that work with BIGINT data was encouraged. For performance reasons, the DECIMAL(19,0) columns should be altered to BIGINT. Note that altering from DECIMAL(19,0) to BIGINT is provided only for DECIMAL(19,0) columns that are used for applications that work with BIGINT (thus, the data in those columns is within the range of the BIGINT).

When altering from DECIMAL(19,0) to BIGINT you should ensure that all values in the DECIMAL(19,0) column are within the range of BIGINT

before the alter. The following query or a similar query can be run to determine which rows (if any) contain values that are outside of the range of BIGINT:

```
SELECT * FROM table_name
  WHERE dec19_0_column > 9223372036854775807
    OR dec19_0_column < -9223372036854775808;
```

When a partitioning key column with a numeric data type is altered to a larger numeric data type, and the limit key value for the original numeric data type of the column is X'FF', the limit key value for the new numeric data type of the column is left-padded with X'FF'. For example, if a column is converted from SMALLINT to INTEGER, and a limit key value for the SMALLINT column is 32767 (which is 2 bytes of X'FF'), the limit key for the INTEGER column is 2147483647 (which is 4 bytes of X'FF').

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is neither all X'FF' nor all X'00', the limit key value for the new character data type of the column is right-padded with blank(s) of the encoding scheme of the table. For example, if a column is converted from CHAR(1) to VARCHAR(2), and a limit key value for the CHAR(1) column is 'A' (which is X'C1'), the limit key for the VARCHAR(2) column is 'A ' (which is X'C140' when the encoding scheme of the table is EBCDIC, or is X'C120' when the encoding scheme of the table is UNICODE or ASCII).

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'FF', the limit key value for the new character data type of the column is right-padded with X'FF' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

When a partitioning key column with a character data type is altered to a longer character data type, and the limit key value for the original character data type of the column (excluding the first NULL byte if the column is nullable) is all X'00', the limit key value for the new character data type of the column is right-padded with X'00' and the table space that contains the table being altered is left in REORG-pending (REORP) status.

Table 86 shows the character data type alterations that are supported for SET DATA TYPE:

*Table 86. Supported character data type alterations for SET DATA TYPE (x > =0).*

From/To	CHARACTER (n+x)	VARCHAR (n+x)	LONG VARCHAR	GRAPHIC (n+x)	VARGRAPHIC (n+x)	LONG VARGRAPHIC
CHARACTER(n)	Y	Y	N	N	N	N
VARCHAR(n)	Y	Y	N	N	N	N
LONG VARCHAR	N	Y	N	N	N	N
GRAPHIC(n)	N	N	N	Y	Y	N
VARGRAPHIC(n)	N	N	N	Y	Y	N
LONG VARGRAPHIC	N	N	N	N	Y	N

When columns are converted from CHAR to VARCHAR, normal assignment rules apply, which means that trailing blanks are kept instead of being stripped out. If you want varying length character strings without trailing blanks, use the STRIP function for data in the column after changing the data type to VARCHAR.

When a CHAR FOR BIT DATA column is converted to a BINARY data type, the following applies:

- The existing space characters in the table will not be changed to hexadecimal zeros (X'00')
- If the new length attribute is greater than current length attribute of the column, the values in the table are padded with hexadecimal zeros (X'00')

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, the existing default value will be cast as a binary string. The resulting binary string will be at least twice the original size. The alter will fail if the resulting binary string length exceeds 1536 UTF-8 bytes.

When a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA column is converted to a BINARY or VARBINARY data type, and there is an index defined on that column, the index will be put in RBDP.

*Table 87. Supported binary data type alterations for SET DATA TYPE (x >= 0)*

From/To	BINARY(n+x)	VARBINARY(n+x)
CHAR(n) FOR BIT DATA	Y	Y
VARCHAR(n) FOR BIT DATA	Y	Y
BINARY(n)	Y	Y
VARBINARY(n)	Y <sup>1</sup>	Y

**Note:** ALTER from VARBINARY to BINARY is not allowed when the column is part of a unique index.

The table being altered must not be defined with an edit procedure that is defined as WITH ROW ATTRIBUTES or a valid procedure. There must not be a materialized query table defined on this table, and this table must not be defined as a materialized query table.

If the alteration results in the generation of a new table version, the table space that contains the table that is being changed is left in an advisory REORG-pending (AREO) status. If the column that is being changed is part of an index, an exception state might be set for the index as shown in Table 88:

*Table 88. Informational settings for ALTER COLUMN when the column is in an index*

Alteration type	Exception state for index	Plans and packages invalidation
VARCHAR to CHAR	AREO*	Yes
VARGRAPHIC to GRAPHIC	AREO*	Yes
CHAR to VARCHAR	AREO*	Yes
GRAPHIC to VARGRAPHIC	AREO*	Yes
VARCHAR to VARCHAR	AREO* (for padded only)	No
VARGRAPHIC to VARGRAPHIC	AREO* (for padded only)	No
CHAR to CHAR	AREO*	Yes

*Table 88. Informational settings for ALTER COLUMN when the column is in an index (continued)*

Alteration type	Exception state for index	Plans and packages invalidation
GRAPHIC to GRAPHIC	AREO*	Yes
DECIMAL to DECIMAL	RBDP	Yes

For information on resetting informational or restrictive exception states, see *DB2 Utility Guide and Reference*.

#### **FOR subtype DATA**

Alters the *subtype* of a character column. This clause does not change the data. The clause only updates the definition of the subtype as it is stored in the DB2 catalog and the OBD. The length and data type that are specified must match the existing length and data type of the column.

Only character strings are valid when subtype is BIT.

For more information on the subtype values (SBCS, MIXED, and BIT), see the subtype information under built-in-type.

#### **SET default-clause**

Specifies the new default value of the column to be altered. The new default value must conform to the current rules for assigning that value to the column. Existing rows will retain their current value. The new default value will only be reflected in the rows that are inserted after the alter. Sections that are dependent on the table that is being altered will be invalidated.

The table must not be referenced by a view.

If the column is specified in a unique constraint (unique key or primary key) or unique index, the default value might be altered to the same value as an existing row of that column. However, subsequent data change operations will fail in the absence of a value specified for that column on the insert operation.

#### **DROP DEFAULT**

Drops the current default value of the column. For columns that are not nullable, the specified column must be defined with a default value. For columns that are nullable, the specified column cannot have a null default value. For columns that are nullable, the new default value is the null value.

The table that contains the specified column must not be referenced in a view.

Follow these steps to remove the default value for a column that was defined using ALTER TABLE with the ADD COLUMN clause:

1. Run the REORG utility on the table space that contains the table
2. Issue the ALTER TABLE statement that specifies the DROP DEFAULT clause

If the REORG is not processed, an error is returned for the ALTER TABLE statement.

#### **SET GENERATED ALWAYS or BY DEFAULT**

Specifies when DB2 is to generate values for the column. GENERATED BY DEFAULT specifies that a value is only to be generated when a value is not provided. or the DEFAULT keyword is used in an assignment to the

column. GENERATE ALWAYS specifies that DB2 is to always generate a value for the column. This clause can only be specified for an identity column.

#### **RESTART**

Specifies the next value for the identity column. If *numeric-constant* is not specified, the sequence is restarted at the value that is specified implicitly or explicitly as the starting value when the identity column was originally created.

#### **WITH *numeric-constant***

Specifies that, when it is time to generate the next value for this identity column, *numeric-constant* will be used as the next value for the column. This value can be any positive or negative value (including 0) that could be assigned to this column without nonzero digits existing to the right of the decimal point.

If RESTART is not specified, the sequence is not restarted. Instead, it resumes with the current values that are in effect for all the options after the ALTER statement is issued.

After an identity column is restarted or changed to allow cycling, sequence numbers might be duplicates of values generated previously.

#### **SET INCREMENT BY *numeric-constant***

For a definition, see the description of INCREMENT BY *numeric-constant* for defining an identity column.

#### **SET MINVALUE or NO MINVALUE**

For a definition, see the description of MINVALUE or NO MINVALUE for defining an identity column.

#### **SET MAXVALUE or NO MAXVALUE**

For a definition, see the description of MAXVALUE or NO MAXVALUE for defining an identity column.

#### **SET CYCLE or NO CYCLE**

For a definition, see the description of CYCLE or NO CYCLE for defining an identity column.

#### **SET CACHE or NO CACHE**

For a definition, see the description of CACHE or NO CACHE for defining an identity column.

#### **SET ORDER or NO ORDER**

For a definition, see the description of ORDER or NO ORDER for defining an identity column.

## **RENAME COLUMN:**

### **RENAME COLUMN *source-column-name* TO *target-column-name***

Renames the specified column. The names must not be qualified.

*source-column-name*

Identifies the column that is to be renamed. The name must identify an existing column of the table.

*target-column-name*

Specifies the new name for the column. The name must not identify a column that already exists in the table.

You cannot rename a column if any of the following conditions apply:

- The column is referenced in a view
- The column is referenced in the expression of an index definition
- The column has a check constraint defined
- The column has a field procedure defined
- The table has a trigger
- The table is a materialized query table or is referenced by a materialized query table
- The table has a valid procedure, or an edit procedure that is defined as WITH ROW ATTRIBUTES
- The table is a DB2 catalog table

## **ADD unique-constraint:**

### **CONSTRAINT *constraint-name***

Names the primary key or unique key constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table. If the table space is implicitly created, the enforcing primary key and unique key indexes are also implicitly created.

### **PRIMARY KEY(*column-name*,...)**

Defines a primary key composed of the identified columns. Each column name must be an unqualified name that identifies a column of the table except a LOB, ROWID, DECFLOAT (including a distinct type that is based on a LOB, ROWID, or DECFLOAT data type), XML column, or a row change timestamp column, and the same column must not be identified more than one time. The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than  $2000 - 2m$ , where  $m$  is the number of varying-length columns in the key. The table must not have a primary key and the identified columns must be defined as NOT NULL.

The set of columns in the primary key cannot be the same as the set of columns of another unique key.

The table must have a unique index with a unique key that is identical to the primary key. The keys are identical only if they have the same number of columns and the  $n$ th column name of one is the same as the  $n$ th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, DB2 will automatically create a primary index. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created primary key index is owned by the owner of the base table.

The identified columns are defined as the primary key of the table. The description of the index is changed to indicate that it is a primary index. If the table has more than one unique index with a key that is identical to the primary key, the selection of the primary index is arbitrary.

### **UNIQUE(*column-name*,...)**

Defines a unique key composed of the identified columns with the specified *constraint-name*. If a *constraint-name* is not specified, a name is generated. Each column name must be an unqualified name that identifies a column of the table except a LOB, ROWID, XML, or DECFLOAT column (including a distinct type that is based on a LOB, ROWID, or DECFLOAT data type), and the same column must not be identified more than one time. Each identified column must be defined as NOT NULL. The number of identified columns must not

exceed 64. In addition, the sum of the length attributes of the columns must not be greater than  $2000 - n$  for padded indexes and  $2000 - n - 2m$  for nonpadded indexes, where  $n$  is the number of columns that can contain null values and  $m$  is the number of varying-length columns in the key.

The set of columns in the unique key cannot be the same as the set of columns of the primary key or another unique key. A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table must have a unique index with a key that is identical to the unique key. The keys are identical only if they have the same number of columns and the  $n$ th column name of one is the same as the  $n$ th column name of the other. If the table is in a table space that is implicitly created, and no unique index is defined on the identified columns, DB2 will automatically create a unique index to enforce the unique key constraint. The privilege set must include the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created unique key index is owned by the owner of the base table.

The identified columns are defined as a unique key of the table. The description of the index is changed to indicate that it is enforcing a unique key constraint. If the table has more than one unique index with a key that is identical to the unique key, the selection of the enforcing index is arbitrary.

## ADD referential-constraint:

### **CONSTRAINT** *constraint-name*

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

### **FOREIGN KEY** (*column-name*,...) *references-clause*

Specifies a referential constraint with the specified *constraint-name*.

Let T1 denote the object table of the ALTER TABLE statement.

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T1 except a LOB, ROWID, XML, DECFLOAT column, security label column, or a row change timestamp column, and the same column must not be identified more than one time. The number of identified columns must not exceed 64 and the sum of their length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and the parent table are the same as the FOREIGN KEY and parent table of an existing referential constraint on T1. The specification of a duplicate referential constraint is ignored with a warning.

### **REFERENCES** *table-name* (*column-name*,...)

The table name specified after REFERENCES must identify a table that exists at the current server, but it must not identify a catalog table or a declared global temporary table. Let T2 denote the identified parent table and let T1 denote the table that is being changed (T1 and T2 can be the same table).

T2 must have a unique index and the privilege set on T2 must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key.

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a

column of T2. The identified column cannot be a LOB, ROWID, XML, DECFLOAT, security label, or row change timestamp column. The same column must not be identified more than one time.

The list of column names in the parent key must be identical to the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the *same order* as in the primary key or unique key. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, then T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the *n*th column of the foreign key must be identical to the description of the *n*th column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A *field description* is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

The table space that contains T1 must be available to DB2. If T1 is populated, its table space is placed in a check pending status. A table in a segmented table space is populated if the table is not empty. A table in a table space that is not segmented is considered populated if the table space has ever contained any records.

The referential constraint specified by the FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

#### ON DELETE

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see “Referential constraints” on page 20.

If T1 and T2 are the same table, CASCADE or NO ACTION must be specified. SET NULL must not be specified unless some column of the foreign key allows null values. Also, SET NULL must not be specified if any nullable column of the foreign key is a column of the key of a partitioning index. The default value for the rule depends on the value of the CURRENT RULES special register when the ALTER TABLE statement is processed. If the value of the register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'SQL', the delete rule defaults to NO ACTION.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let *p* denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of *p* in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of *p* in T1 is set to null.

A cycle involving two or more tables must not cause a table to be delete-connected to itself. Thus, if the relationship would form a cycle:

- The referential constraint cannot be defined if each of the existing relationships that would be part of the cycle have a delete rule of CASCADE.
- CASCADE must not be specified if T2 is delete-connected to T1.

If T1 is delete-connected to T2 through multiple paths, those relationships in which T1 is a dependent and which form all or part of those paths must have the same delete rule and it must not be SET NULL. For example, assume that T1 is a dependent of T3 in a relationship with a delete rule of *r* and that one of the following is true:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendants of the same table and the deletion of rows from that table cascades to both T2 and T3.

In this case, the referential constraint cannot be defined when *r* is SET NULL. When *r* is other than SET NULL, the referential constraint can be defined, but the delete rule that is implicitly or explicitly specified in the FOREIGN KEY clause must be the same as *r*.

#### **ENFORCED or NOT ENFORCED**

Indicates whether or not the referential constraint is enforced by DB2 during normal operations, such as insert, update, or delete.

##### **ENFORCED**

Specifies that the referential constraint is enforced by DB2 during normal operations (such as data change operations) and that it is guaranteed to be correct. ENFORCED is the default.

##### **NOT ENFORCED**

Specifies that the referential constraint is not enforced by DB2 during normal operations (such as data change operations). NOT ENFORCED should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on DB2.

#### **ENABLE QUERY OPTIMIZATION**

Specifies that the constraint can be used for query optimization. DB2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

### **ADD check-constraint:**

#### **CONSTRAINT *constraint-name***

Names the check constraint. If *constraint-name* is not specified, a unique constraint name is derived from the name of the first column in the *check-condition* specified in the definition of the check constraint. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

#### **CHECK (*check-condition*)**

Defines a check constraint. At any time, *check-condition* must be true or unknown for every row of the table. A *check-condition* can evaluate to unknown if a column that is an operand of the predicate is null. A *check-condition* that evaluates to unknown does not violate the check constraint. A *check-condition* is a search condition, with the following restrictions:

- It can refer only to the columns of table *table-name*; however, the columns cannot be LOB, ROWID, XML, DECFLOAT, or security label columns (including distinct types that are based on LOB, ROWID, and DECFLOAT data types).
- It can be up to 7400 bytes long, not including redundant blanks.
- It must not contain any of the following:
  - Subselects
  - Built-in or user-defined functions
  - CAST specifications
  - Cast functions other than those created when the distinct type was created
  - Host variables
  - Parameter markers
  - Special registers
  - Columns that include a field procedure
  - CASE expressions
  - ROW CHANGE expressions
  - row expressions
  - DISTINCT predicates
  - GX constants (hexadecimal graphic string constants)
  - sequence references
  - OLAP specifications
- If a *check-condition* refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the *check-condition* must be either a constant or a column name of a column in the table.
  - If the second operand of a predicate is a constant, and if the constant is:
    - A floating-point number, then the column data type must be floating point.
    - A decimal number, then the column data type must be either floating point or decimal.
    - A big integer number, then the column data type must not be an integer or a small integer
    - An integer number, then the column data type must not be a small integer.
    - A small integer number, then the column data type must be small integer.
    - A decimal constant, then its precision must not be larger than the precision of the column.
  - If the second operand of a predicate is a column, then both columns of the predicate must have:
    - The same data type
    - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes

**Effects of defining a check constraint on a populated table:** When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'DB2', the check constraint is not immediately enforced on the table. The check constraint is added to the description of the table, and

the table space that contains the table is placed in a check pending status. For a description of the check pending status and the implications for utility operations, see *DB2 Utility Guide and Reference*.

When a check constraint is defined on a populated table and the value of the special register CURRENT RULES is 'STD', the check constraint is checked against all rows of the table. If no violations occur, the check constraint is added to the table. If any rows violate the new check constraint, an error occurs and the description of the table is unchanged.

## DROP constraint:

### DROP PRIMARY KEY

Drops the definition of the primary key and all referential constraints in which the primary key is a parent key. The table must have a primary key and the privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table.

The description of the primary index is changed to indicate that it is not a primary index. If the table space was implicitly created, the corresponding enforcing index is dropped if the primary key is dropped.

### DROP UNIQUE *constraint-name*

Drops the definition of the unique key constraint and all referential constraints in which the unique key is a parent key. The table must have a unique key. The privilege set must include the ALTER or REFERENCES privilege on every dependent table of the table. The description of the enforcing index is changed to indicate that it is not enforcing a unique key constraint. If the table space is implicitly created, the corresponding enforcing index is dropped if the unique key is dropped.

### DROP FOREIGN KEY *constraint-name*

Drops the referential constraint *constraint-name*. The *constraint-name* must identify a referential constraint in which the table is the dependent table, and the privilege set must include the ALTER or REFERENCES privilege on the parent table of that relationship, or the REFERENCES privilege on the columns of the parent table of that relationship.

### DROP CHECK *constraint-name*

Drops the check constraint *constraint-name*. The *constraint-name* must identify an existing check constraint defined on the table.

### DROP CONSTRAINT *constraint-name*

Drops the constraint *constraint-name*. The *constraint-name* must identify an existing primary key, unique key, check, or referential constraint defined on the table.

DROP CONSTRAINT must not be used on the same ALTER TABLE statement as DROP PRIMARY KEY, DROP UNIQUE KEY, DROP FOREIGN KEY or DROP CHECK.

## ADD partitioning:

### ADD PARTITION BY RANGE

Specifies the range partitioning scheme for the table (the columns used to partition the data). When this clause is specified, the table uses table-controlled partitioning. The number of partitions specified in the ADD PARTITION BY RANGE clause has to be the same as the number of partitions defined in the table space.

This clause applies only to tables in a partitioned table space. If the table is already complete by having established either table-controlled partitioning or index-controlled partitioning, the ADD PARTITION BY RANGE clause is not allowed. If this clause is used, then the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

*partition-expression*

Specifies the key data over which the range is defined to determine the target data partition of the data.

*column-name*

Specifies the columns of the key. Each *column-name* must identify a column of the table. Do not specify more than 64 columns, the same column more than one time, a BINARY, VARBINARY, LOB, XML, or DECFLOAT column, a column with a distinct type that is based on a these data type, a qualified column name, or a row change timestamp column. The sum of length attributes of the columns must not be greater than 255 -  $n$ , where  $n$  is the number of columns that can contain null values.

**NULLS LAST**

Specifies that null values are treated as positive infinity for purposes of comparison.

**ASC**

Puts the entries in ascending order by the column. ASC is the default.

**DESC**

Puts the entries in descending order by the column.

*partition-element*

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

**PARTITION** *integer*

Specifies a number of a physical partition in the table space. A PARTITION clause must be specified for every partition of the table space. In the context, highest means highest in the sorting sequence of the columns. In a column that is defined as ascending (ASC), highest and lowest have the usual meanings. In a column that is defined as descending (DESC), the lowest actual value is the highest in the sorting sequence.

**ENDING AT** (*constant*, MAXVALUE, or MINVALUE...)

Specifies the limit key for a partition boundary. Specify at least one value (constant, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key for ascending and the lowest for descending.

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant

must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

#### **MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

#### **MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

#### **INCLUSIVE**

Specifies that the specified range values are included in the data partition.

### **ADD PARTITION:**

#### **ADD PARTITION**

Specifies that a partition is added to the table and each partitioned index on the table. The new partition is the next physical partition not being used until the maximum for the table space has been reached. ADD PARTITION must not be specified for nonpartitioned tables or for tables in a partition-by-growth table space. Adding a partition is not allowed if the table is a materialized query table or a materialized query table is defined on the table. However, adding a partition is allowed if an accelerated query table is defined on the table. A partition cannot be added if the table space definition is incomplete because a partitioning key or partitioning index is missing. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

The maximum number of partitions allowed depends on how the table space was originally created. If DSSIZE was specified when the table space was created, it is non-zero in the catalog. The maximum number of partitions allowed is shown in Table 89.

*Table 89. Maximum number of partitions allowed*

DSSIZE	Page size 4		Page size 16	
	KB	Page size 8 KB	KB	Page size 32 KB
1GB-4GB	4096	4096	4096	4096
8GB	2048	4096	4096	4096
16GB	1024	2048	4096	4096
32GB	512	1024	2048	4096
64GB	256	512	1024	2048

If LARGE was specified when the table space was created, the maximum number of partitions is shown in the fourth row of Table 90. For more than 254 partitions when LARGE or DSSIZE is not specified, the maximum number of partitions is determined by the page size of the table space.

*Table 90. Maximum number of partitions when DSSIZE = 0*

Type of table space	Number of existing partitions	Maximum partitions
non-large	1 to 16	16
non-large	17 to 32	32
non-large	33 to 64	64
large	N/A	4096

The existing table space PRIQTY and SECQTY attributes of the previous logical partition are used for the space attributes of the new partition. For each partitioned index, the existing PRIQTY and SECQTY attributes of the previous partition are used.

To specify specific space attributes for the new partition, use additional ALTER TABLESPACE and ALTER INDEX statements.

**ENDING AT (*constant*, MAXVALUE, or MINVALUE, ...)**

Specifies the high key limit for the new partition. The new partition's key limit must be higher when partitioning is ascending and lower when it is descending. Specify at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in the PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition of the index.

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. If the limit was not previously enforced, any existing key values that are greater than the value that is specified for the added partition are placed into the discard data set when REORG is run.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions \* (106 + limit key size in bytes) < 65394
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.

#### **INCLUSIVE**

Specifies that the specified range values are included in the data partition.

### **ALTER PARTITION:**

#### **ALTER PARTITION**

Specifies that the partitioning limit key for the identified partition is to be changed.

This clause applies only to tables in a partitioned table space. ALTER PARTITION must not be specified for a table in a partition-by-growth table space or for tables that have XML columns or LOB columns (or distinct type columns that are based on LOBs). ALTER PARTITION must also not be specified if the table is a materialized query table or if a materialized query table is defined on the specified table. However, adding a partition is allowed if an accelerated query table is defined on the table.

#### *integer*

If *integer* is specified, it must be in the range 1 to *n*, where *n* is the number of partitions in the table. Changing a partition boundary is not allowed if the table is a materialized query table or if a materialized query table is defined from this table. When this option is specified for any partition except for the last, both the identified partition and the partition following are placed in REORG-pending (REORP) status.

#### **ENDING AT (*constant, MAXVALUE, or MINVALUE...*)**

Specifies the highest value of the partitioning key for the identified partition.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT in each ALTER PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the

corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

***constant***

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

The value that is specified must not be equal to or beyond the range of the partition boundaries of the adjacent partitions.

**INCLUSIVE**

Specifies that the specified range values are included in the data partition.

If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

## **ROTATE PARTITION:**

### **ROTATE PARTITION FIRST TO LAST**

Specifies that the first logical partition should be rotated to become the last logical partition. The table definition must be complete and must contain more than one partition. This clause must be followed by the ENDING AT clause, which specifies the new high key limit for this partition, which is now logically last. The new partitioning key value must be higher than the current high key limit if partition values are ascending. If partition values are descending, the new key limit must be lower than the current low key limit.

Rotating a partition occurs immediately. If there is a referential constraint with DELETE RESTRICT on the table, the ROTATE might fail. If the table uses index-controlled partitioning, it is converted to use table-controlled partitioning.

After an ALTER TABLE statement with the ROTATE PARTITION clause is run, the RUNSTATS utility with REORG should be run on the table space to ensure effective access paths are available for selection.

If the table has a security label column, the user must have a valid security label to rotate partitions. In addition, if write-down is in effect, the user must have the write-down privilege.

| ROTATE PARTITION must not be specified in the following situations:

- The table is a materialized query table or a materialized query table is defined on the table
- The table is in a partition-by-growth table space
- The table that has XML columns

#### **ENDING AT (constant, MAXVALUE, or MINVALUE...)**

The ENDING AT clause specifies the new high key limit for the existing partition holding the oldest data.

In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC) the lowest actual value is highest in the sorting sequence.

Specify at least one value after ENDING AT. You can use as many values as there are columns in the key. The concatenation of all the values is the highest value of the key in the corresponding partition. The length of each highest key value (the limit key) is the same as the length of the partitioning key.

##### *constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

##### **MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must specify MAXVALUE.

##### **MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the rules listed for the ENDING AT clause for a partition definition. See list of rules.

#### **INCLUSIVE**

Specifies that the specified range values are included in the data partition.

## RESET

Specifies that the existing data in the oldest partition is deleted. In a partitioned table with limit values that are in ascending sequence, ALTER TABLE ROTATE PARTITION FIRST TO LAST logically operates as if the partition with the lowest high key limit were dropped and then a new partition was added with the specified high key limit. The new key limit for the partition must be higher than any other partition in the table. For descending limit keys, the rotation operates as the partition with the highest limit values becomes the partition with the lowest limit values.

If the partition contains referential integrity parent relationships, has DATA CAPTURE logging enabled, or has a delete row trigger, then each data row in the partition must be deleted individually. If a table does not have any of these attribute settings, then the data rows are removed by deleting and redefining the underlying data sets.

## ADD MATERIALIZED QUERY:

### ADD MATERIALIZED QUERY *materialized-query-definition*

Changes a base table to a materialized query table. Supplies a definition for a regular table to make it a materialized query table. The table specified by *table-name* and the result columns of the fullselect must not have the following characteristics:

- Be already defined as a materialized query table
- Have any primary keys, unique constraints (unique indexes), referential constraints (foreign keys), check constraints, or triggers defined
- Be referenced in the definition of another materialized query table
- Be directly or indirectly referenced in the *fullselect*
- Be in an incomplete state

If *table-name* does not meet these criteria, an error occurs.

The **ADD MATERIALIZED QUERY** clause cannot be specified in a Common Criteria environment.

### *fullselect*

Defines the query on which the table is based. The columns of the existing table must meet the following characteristics:

- Have the same number of columns
- Have exactly the same column definitions
- Have the same column names in the same ordinal positions

If fullselect is specified, the owner of the table being altered must have the SELECT privilege on the tables or views referenced in the fullselect.

Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the table of the fullselect reside

If the owner of the table does not have the SELECT privilege, the following authorization IDs must have SYSADM authority or DBADM authority for the database in which the tables of the fullselect reside:

- For embedded statements, the authorization ID of the owner of the plan or package
- For dynamically prepared statements, the SQL authorization ID of the process

For details about specifying *fullselect* for a materialized query table, see the definition of *fullselect* in the “CREATE TABLE” on page 1079 statement.

Altering a table to change it from a base table to a materialized query table with REFRESH DEFERRED causes any plans and packages dependent on the table to be invalidated.

#### *refreshable-table-options*

Specifies the materialized query table options for altering a regular table to a materialized query table. The ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

#### **DATA INITIALLY DEFERRED**

Specifies that the data in the table is not validated as part of the ALTER TABLE statement. A REFRESH TABLE statement can be used to make sure the data in the materialized query table is the same as the result of the query in which the table is based.

#### **REFRESH DEFERRED**

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or as updated by the user for a user-maintained materialized query table.

#### **MAINTAINED BY SYSTEM or MAINTAINED BY USER**

Specifies how the data in the materialized query table is maintained.

##### **MAINTAINED BY SYSTEM**

Specifies that the data in the materialized query table *table-name* is to be maintained by the system. Only the REFRESH TABLE statement is allowed on the table.

##### **MAINTAINED BY USER**

Specifies that the data in materialized query table *table-name* is to be maintained by the user, who can use LOAD utility or SQL data change statements and REFRESH TABLE statements on the table.

#### **ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION**

Specifies whether this materialized query table can be used for optimization.

##### **ENABLE QUERY OPTIMIZATION**

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs. For detailed rules to satisfy query optimization, see *materialized-query-definition* in the “CREATE TABLE” on page 1079 statement.

##### **DISABLE QUERY OPTIMIZATION**

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

## **ALTER MATERIALIZED QUERY:**

### **ALTER MATERIALIZED QUERY** *materialized-query-table-alteration*

Changes attributes of a materialized query table. The *table-name* must identify a materialized query table.

#### **SET** *refreshable-table-alteration*

Changes how the table is maintained or whether the table can be used in query optimization.

##### **MAINTAINED BY SYSTEM**

Specifies that the data in a materialized query table *table-name* is to be maintained by the system.

##### **MAINTAINED BY USER**

Specifies that the data in the materialized query table *table-name* is to be maintained by the user.

##### **ENABLE QUERY OPTIMIZATION**

Specifies that materialized query table *table-name* can be used in query optimization. If the fullselect specified for the materialized query table does not satisfy the restrictions for automatic query optimization, an error occurs. For detailed rules to satisfy query optimization, see "CREATE TABLE" on page 1079.

##### **DISABLE QUERY OPTIMIZATION**

Specifies that materialized query table *table-name* cannot be used for query optimization. The table can still be queried directly.

## **DROP MATERIALIZED QUERY:**

### **DROP MATERIALIZED QUERY**

Changes a materialized query table so that it is no longer considered a materialized query table. The table specified by *table-name* must be defined as a materialized query table. The definition of columns and data of the name are not changed, but the table can no longer be used for query optimization and is no longer valid for use with the REFRESH TABLE statement.

Altering a table to change from a materialized query table to a base table with the DROP MATERIALIZED QUERY clause causes any plans and packages dependent on the table to be invalidated.

## **DATA CAPTURE:**

### **DATA CAPTURE**

Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause)
- Changing columns (using the ALTER COLUMN clause)

For guidance on intended uses of the expanded log records, see:

- The description of data propagation to IMS in *IMS DataPropagator: An Introduction*
- The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*
- The instructions for reading log records in *DB2 Administration Guide*

### **NONE**

Do not record additional information to the log.

## **CHANGES**

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

For details about the recording of additional data for logged updates to catalog tables, see "Notes" on page 785.

## **VOLATILE:**

### **VOLATILE or NOT VOLATILE**

Specifies how DB2 is to choose access to the table.

#### **VOLATILE**

Specifies that DB2 is to use index access to the table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques are disabled when VOLATILE is used.

One instance in which use of VOLATILE might be desired is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows. Another instance in which use of VOLATILE might be desired is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation.

#### **NOT VOLATILE**

Specifies that DB2 is to base SQL access to the table on the current statistics.

### **CARDINALITY**

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

## **ADD CLONE:**

### **ADD CLONE *clone-table-name***

Specifies that a clone table, identified by *clone-table-name*, is created for the table that is being altered. The clone table is created in the same table space as the base table and has the same structure as the base table. This includes, but is not limited to, column names, data types, null attributes, check constraints, indexes. When ADD CLONE is used to create a clone of the specified base table, the base table must conform to the following rules:

- Reside in a DB2-managed universal table space
- Be the only table in the table space
- Not be defined with a clone table
- Not be involved in any referential constraint
- Not be defined with any after triggers
- Not be a materialized query table
- If the table space is created with the DEFINE NO clause, all data sets must already be created
- Not have any pending changes

- Not have any active versioning
- Not have an incomplete definition
- Not be a created global temporary table or a declared global temporary table

## **DROP CLONE:**

### **DROP CLONE**

Specifies that the clone table that is associated with the specified base table is dropped. *table-name* must identify a base table that exists at the current server and the table must have a clone table defined.

## **RESTRICT ON DROP:**

### **ADD RESTRICT ON DROP**

Restricts dropping the table and the database and table space that contain the table.

### **DROP RESTRICT ON DROP**

Removes the restriction on dropping the table and the database and table space that contain the table.

## **APPEND:**

### **APPEND NO or APPEND YES**

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition by growth table space, the APPEND attributes of LOB table will be inherited by each partition.

**NO** Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

### **YES**

Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

## **AUDIT:**

### **AUDIT**

Alters the auditing attribute of the table. For information about audit trace classes, see *DB2 Administration Guide*.

### **NONE**

Specifies that no auditing is to be done when the table is accessed.

### **CHANGES**

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

### **ALL**

Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

The ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- AUDIT attribute is changed to NONE, CHANGES, or ALL on an audited or non-audited table.
- AUDIT CHANGES or AUDIT ALL is in effect.

## VALIDPROC:

### VALIDPROC

Names a validation procedure for the table or inhibits the execution of any existing validation procedure.

*program-name*

Designates *program-name* as the new validation exit routine for the table. Validation exit routines are described in *DB2 Administration Guide*.

The validation procedure can inhibit a data change operation on any row of the table. Before the operation takes place, the row is passed to the procedure. The values that are represented by any LOB or XML columns in the table are not passed to the validation procedure. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. When you name a new procedure, any existing procedure is no longer used. The new procedure is not used to validate existing table rows. It is used only to validate rows that are loaded, inserted, updated, or deleted after execution of the ALTER TABLE statement.

### NULL

Discontinues the use of any validation routine for the table.

## Notes

*Order of processing of clauses:* When there is more than one clause, they are processed in the following order:

1. VALIDPROC
2. AUDIT
3. DATA CAPTURE
4. ROTATE
5. VOLATILE clauses
6. APPEND clauses
7. DROP clauses
8. ALTER clauses
9. RENAME clause
10. ADD clauses

Within each of these stages, the order in which the user specifies the clauses is the order in which they are performed.

*Altering the data type, length, precision, or scale of a column:* When you change the data type, length, precision, or scale of a column, the following information applies to indexes, limit keys, check constraints, and invalidation:

- *Restrictions.* The ALTER TABLE statement is not allowed if any of the following conditions are true:
  - The column is referenced in a referential constraint.
  - The column has a field procedure routine.
  - The column is defined as an identity column.
  - The column is defined as an security label column
  - The table has an edit or validation routine.
  - The table is defined with DATA CAPTURE CHANGES and the ALTER TABLE statement causes a new version of the table to be generated.
  - The table is a created temporary table.
  - The table is a materialized query table or the table is referenced by a materialized query table.
  - The data type changed is not to a compatible data type.
  - The new length or data type specification could result in a loss of significance because of a shorter length or less precision in the data type.
  - For a conversion from decimal to float, a unique index or a unique constraint exists on the column.
  - For a conversion from other numeric data type to DECFLOAT, a partitioning key, check constraint, index, or a unique constraint exists on the column.
  - The existing default value for a column cannot be assigned to the new data type.
  - Increasing the column length results in an existing index that references the column exceeding the maximum size of an index.
  - Increasing the column length results in the partitioning key using that column exceeding the maximum size for a partitioning key.
  - Table definition is incomplete because unique index for enforcing a unique constraint (primary key or unique key) is missing.
- *Indexes.*
  - If the index has a changed character column, the index is in advisory REORG-pending (AREO\*) status.
  - If the index has a changed numeric column, the index remains in REBUILD-pending (RBDP) status.
- *Length of partitioned index keys.* When a table is altered and the length of a column in the PARTITIONING KEY is changed, DB2 changes the length of the limit key (the highest key value) for a partition too. The length of the limit key is increased by the same amount that the length of the column is increased.
- *Check constraints.* If a check constraint refers to the column being altered, the length of the column is also changed in the check constraint.
- *Statistics.* The RUNSTATS utility should be run to collect new COLUMN statistics for all altered columns. Even though the COLCARDF value is valid, the HIGH2KEY and LOW2KEY values are invalid, and any SYSCOLSTATS catalog entries for the column are removed. Any frequencies or histogram statistics which include this column should also be collected again.

When you change a column from a fixed to varying length or change the length of a varying-length column, process the ALTER TABLE statements in the same unit of

work or do a reorganization between the ALTER TABLE statements to avoid anomalies with the lengths and padding of individual values.

**Referencing columns in ADD, ALTER, and RENAME clauses:** A column can only be referenced once in an ADD COLUMN, an ALTER COLUMN, or a RENAME COLUMN clause in a single ALTER TABLE statement. However, that same column can be referenced multiple times for adding or dropping constraints in the same ALTER TABLE statement.

Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB, ROWID, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, if a table has an explicitly created ROWID column, you cannot add a column with a distinct type that is sourced on a row ID.

Adding a column to table T only changes the description of T. If the catalog description of T is used to create a table T' and a facility such as DSN1COPY is used to effectively copy T into T', queries that refer to the added column in T' will fail because the data does not match its description. To avoid this problem, run the REORG utility against the table space of T before making the copy.

**Restrictions on a clone table:** Tables that are involved in a clone relationship (base tables and their associated clone tables) have the following restrictions:

- You cannot use the RUNSTATS utility on a clone table. When a data exchange is done using the EXCHANGE statement, real time statistics for the base table are invalidated.
- Objects that are involved in a clone relationship do not use the FASTSWITCH naming convention when the REORG utility is run. This includes both the base table and the clone table objects (data and index), as well as LOB and XML objects.
- For a partitioned table, if a mixture of 'T' and 'J' data sets exists when a clone table is created, the mixture of 'T' and 'J' data sets can be changed only by first dropping the clone table.
- Catalog and directory tables cannot have clone tables.
- Indexes cannot be created on a clone table. When an index is created on a base table that is involved in a clone relationship, the index on the clone table will be created implicitly and will be put into rebuild-pending status.
- Before triggers cannot be created on a clone table. Before triggers that are created on a base table apply to both the base table and the clone table.
- You cannot rename a base table that has a clone and you cannot rename a clone table.
- Real time statistics tables cannot have clone tables.
- You cannot drop an auxiliary table or an auxiliary index of an object that is involved in a clone relationship.

If the table is involved in a clone relationship, no other table altering can take place. If a table change is required, the clone table objects must be dropped so that the base table object attributes can be modified. After the desired table, index, etc. changes are completed, the clone table objects can be recreated.

**Altering the attributes of an existing identity column:** Existing values for the identity column are unaffected by the ALTER TABLE statement. The changed identity column attributes affect values generated after the ALTER statement has executed. DB2 does not validate any of the existing identity column values against

the new identity column attributes. For example, duplicate values might be generated even if NO CYCLE is in effect, such as when an ascending identity column altered to become a descending identity column.

Any existing values in the cache that have not yet been used might be lost. Loss of cached values can also occur if the ALTER statement returns an error or is rolled back.

**Adding a LOB column:** If the table space that contains the table is implicitly created and you add a LOB column to the table, the following object are implicitly created:

- A LOB table space
- An auxiliary table
- An auxiliary index

**Adding a ROWID column:** When you add a ROWID column to an existing table, DB2 ensures that the same, unique row ID value is returned for a row whenever it is accessed. If the table already has an implicitly hidden ROWID column, DB2 also ensures that the values in the two ROWID columns are identical.

If the table space that contains the table is implicitly created and you add a ROWID column that is defined as GENERATED BY DEFAULT to the table, an enforcing index for the ROWID column is implicitly created. If the table already has an implicitly hidden ROWID column and the ROWID column that you add is defined as GENERATED BY DEFAULT, DB2 changes the implicitly hidden ROWID column to have the GENERATED BY DEFAULT attribute and does not implicitly create an enforcing index for the ROWID column.

When you add a ROWID column that is defined as GENERATED BY DEFAULT and the ROWID index is implicitly created, the privilege set requires the INDEX privilege on the table and the USE privilege on the buffer pool and the storage group. The implicitly created ROWID index is owned by the owner of the table.

Reorganizing a table space has no effect on the values in a ROWID column.

**Adding an identity column:** When you add an identity column to a table that is not empty, DB2 places the table space that contains the table in the REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the identity column in all existing rows and then removes the REORG pending status. These values are guaranteed to be unique, and their order is system-determined.

**Adding a row change timestamp column:** When you add a row change timestamp column to an existing table, the initial value for existing rows is not stored at the time of the ALTER statement. DB2 places the table space into an advisory-REORG pending state. When the REORG utility is subsequently run, DB2 generates the values for the row change timestamp column in all existing rows and then removes the REORG pending status. These values will not change unless the row is updated.

**Effect of adding a column on views:** Adding a column to a table has no effect on existing views.

**Considerations for implicitly hidden columns:** A column that is defined as implicitly hidden can be explicitly referenced on the ALTER statement. For

example, an implicitly hidden column can be altered, can be specified as part of a referential constraint or a check constraint, or a materialized query table definition.

**Cascaded effects of adding or altering a column:** Adding a column to a table has no cascaded effects to views that reference the table. For example, adding a column to a table does not cause the column to be added to any dependent views, even if those views were created with a SELECT clause. But altering a column can cause other cascaded effects. Table 91 lists the cascaded effect of altering the data type, precision, scale, or length of a column.

*Table 91. Cascaded effect of altering a column's data type, precision, scale, or length*

Operation	Effect
Alter of a column referenced by a view	If the data type, length, precision, or scale for a column is altered, all the views that are dependent on the altered table are reevaluated at alter time with the new column attributes. If errors are encountered during the view regeneration process, the ALTER TABLE statement fails. The new internal structure of each dependent view is not saved at alter time, and subsequent references to a dependent view will cause the view to be regenerated again. Use the ALTER VIEW statement to regenerate a dependent view and have the new internal structure saved.
Alter of a column referenced in the key of an index or a unique constraint (unique key or primary key)	The alter is allowed unless DECIMAL with a fraction is being converted to a floating value. In this case, the loss of precision can result in a loss of uniqueness. For numeric data type conversions, the index is placed in REBUILD-pending status. For character data type conversions, the index key columns are converted on first-write access. The index is not placed in REBUILD-pending status.
Alter of a column referenced in a package or plan	The alter is allowed. All plans and packages dependent on the table in which the column is being altered are invalidated.
Alter of a column referenced in the body of a user-defined function or procedure	Alter is allowed. If there is a package associated with the function or procedure, it is invalidated.
Alter of a column referenced in the parameter list of a user-defined function or procedure	Alter is allowed. The attributes of the existing function or procedure are unchanged. To access the new definition of the column, the function or procedure must be dropped and recreated.
Alter of a column referenced by a trigger	Alter is allowed. All trigger packages dependent on the table of the column are invalidated.
Alter of a column referenced in a CHECK constraint	Alter is not allowed.

**Adding a partition:** When you add a partition to a table, if the boundary for the last partition was not previously enforced, it is enforced after the partition is added, and the last two logical partitions are left in REORG-pending (REORP).

status. If the last partition before the new one is added was in REORG-pending status, the added partition is also placed in REORG-pending status.

**Row format for newly added partitions:** When the value of the SPRMRRF subsystem parameter is ENABLE, newly added partitions that are created using the ADD PARTITION clause (or partitions that are added because the table space is partition-by-growth) will be created in re-ordered row format. When the value of the SPRMRRF subsystem parameter is DISABLE, newly added partitions will be created in basic row format, except for the following:

- For table spaces that are already using basic row format and that contain tables with edit procedures, newly created partition will always be in basic row format regardless of value of the SPRMRRF parameter.
- For table spaces that are already using re-ordered row format and that contain tables with edit procedures, newly created partition will always be in re-ordered row format regardless of value of the SPRMRRF parameter.
- Newly created partitions of an XML table space will always be in re-ordered format.

**Rotating a partition from first to last:** Running ALTER TABLE to rotate the first logical partition to become the last logical partition can be very time consuming. During the reset operation, all rows from the partition are deleted. In addition, the keys for the deleted rows are also deleted from all nonpartitioned indexes, which requires that each nonpartitioned index must be scanned.

When you rotate partitions, if the boundary for the last partition was not previously enforced, it is enforced after ROTATE FIRST TO LAST is issued, and the last two logical partitions are left in REORG-pending (REORP) status. If the last partition before ROTATE FIRST TO LAST was issued was in REORG-pending status, the last two logical partitions are left in REORG-pending status.

**Effect of changes on applications:** Applications might need to be changed to correspond to changes to the columns in a table. For example, if you increase the length of a column, you need to increase the length of host variables into which that column is fetched. If you change the data type of a column, you also might need to change the data type of the corresponding host variable to avoid performance degradation. If you rename a column, you need to change any references to that column to avoid unexpected results.

**Invalidation of plans and packages:** When a table is altered, all the plans, packages, and dynamic cached statements that refer to the table are invalidated if any one of the following conditions is true:

- The table is a created temporary table or a materialized query table.
- The table is changed to add or drop a materialized query definition.
- The AUDIT attribute of the table is changed.
- A DATE, TIME, or TIMESTAMP column is added and its default value for added rows is CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP, respectively.
- A security label is added.
- The length attribute of a CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, BINARY, or VARBINARY column has changed. See Table 88 on page 811.
- The column data type, precision, scale, or subtype is changed.
- The column is renamed.

- The table is partitioned and a partition is added or one of the existing partitions is changed or rotated
- An identity attribute of an identity column has changed

When a referential constraint is defined with a delete rule of CASCADE or SET NULL, all plans and packages that refer to the parent table of the constraint are invalidated. Furthermore, all plans and packages that refer to tables from which deletes cascade to this parent table are also invalidated.

Altering a base table or a user-maintained materialized query table to change it to a system-maintained materialized query table causes any plans and packages dependent on the table to be invalidated because data change statements are not allowed on system-maintained materialized query tables. Altering a materialized query table to change it to a base table causes any plans and packages dependent on the table to be invalidated because the REFRESH TABLE statement is invalid on a base table.

#### **Invalidation of plans and packages by RENAME COLUMN:**

ALTER TABLE RENAME COLUMN will invalidate any plan or package that is dependent on the table in which the column is renamed. Any attempt to execute the invalidated plan or package will trigger an automatic rebind of the plan or package.

The automatic rebind will fail if the column is referenced in the plan or package because the referenced column no longer exists in the table. In this case, applications that reference the plan or package need to be modified, recompiled, and rebound to return the expected result.

The automatic rebind will succeed in either of the following cases:

- The plan or package does not reference the column. In this case, the renaming of the column does not affect the query results that are returned by the plan or package. The application does not need to be modified as a result of renaming the column.
- The plan or package does reference the column, but after the column is renamed, another column with the name of the original column is added to the table. In this case, any query that references the name of the original column might return a different result set. In order to restore the expected results, the application would need to be modified to specify the new column name.

**Example:** The following scenario shows how renaming a column can cause a plan or package to return unexpected results:

```

CREATE TABLE MYTABLE (MYCOL1 INT);
INSERT INTO TABLE MYTABLE
VALUES (1);
SELECT MYCOL1 FROM MYTABLE -- this is the statement in the package MYPACKAGE,
-- the query returns a value of 1
ALTER TABLE MYTABLE
RENAME MYCOL1 TO MYCOL2; -- MYPACKAGE is invalidated and automatic rebind
-- of MYPACKAGE will fail at this point
ALTER TABLE MYTABLE
ADD COLUMN MYCOL1 VARCHAR(10); -- automatic rebind of MYPACKAGE
-- will be successful

INSERT INTO TABLE MYTABLE (MYCOL1)
VALUES ('ABCD');
-- at this point an application executes MYPACKAGE which results in a
-- successful automatic rebind. However, the statement in the package
-- will return 'ABCD' instead of the expected '1'

```

**Dropping constraints and check pending status:** If a table space or partition is in check pending status because it contains a table with rows that violate constraints, dropping the constraints removes the check pending status.

**Altering materialized query tables:** The ALTER TABLE statement can be used to register an existing table at the current server as a materialized query table, change the attributes of an existing materialized query table, or change an existing materialized query table into a base table.

The isolation level at the time when a base table is first altered to become a materialized query table by the ALTER TABLE statement is the isolation level for the materialized query table.

Altering a table to change it to a materialized query table with query optimization enabled makes the table eligible for use in query rewrite immediately. Therefore, pay attention to the accuracy of the data in the table. If necessary, the table should be altered to a materialized query table with query optimization disabled, and then the table should be refreshed and enabled with query optimization.

When a base table is altered into a materialized query table or a user-maintained query table is altered into a system-maintained one, the REFRESH\_TIME column of the row for the table in SYSIBM.SYSVIEWS contains the current timestamp. When a system-maintained materialized query table is altered into a user-maintained materialized query table, the REFRESH\_TIME column of the row for the table in SYSIBM.SYSVIEWS does not change.

The LOAD utility is not allowed on a system-maintained query table, but it is allowed on a user-maintained materialized query table.

**Considerations for running utilities while altering tables:** You cannot execute the ALTER TABLE statement while a utility has control of the table space that contains the table.

**Restrictions on field procedures, edit procedures, and validation exit procedures:** Field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures that are defined as WITH ROW ATTRIBUTES, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

**Restrictions on SQL data change statements in the same commit scope as ALTER TABLE:** SQL data change statements that affect an index cannot be performed in the same commit scope as ALTER TABLE statements that affect that index.

**Restrictions on DATA CAPTURE CHANGES:** If the table is in advisory REORG-pending state, you cannot alter the table to use the DATA CAPTURE CHANGES clause.

**Capturing changes to the DB2 catalog:** To have logged changes to a DB2 catalog table augmented with information for data capture, specify ALTER TABLE *xxx* DATA CAPTURE CHANGES where *xxx* is the name of a catalog table

(SYSIBM.xxx). Data capture of catalog table changes provides the possibility of creating and managing a shadow of the catalog.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART *integer* VALUES can be specified as an alternative to PARTITION *integer* ENDING AT.
- VALUES as a synonym for ENDING AT
- DEFINITION ONLY as a synonym for WITH NO DATA
- SET MATERIALIZED QUERY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
- SET SUMMARY AS DEFINITION ONLY as a synonym for DROP MATERIALIZED QUERY
- SET MATERIALIZED QUERY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)
- SET SUMMARY AS (fullselect) as a synonym for ADD MATERIALIZED QUERY (fullselect)

## Examples

*Example 1:* Column DEPTNAME in table DSN8910.DEPT was created as a VARCHAR(36). Increase its length to 50 bytes. Also, add the column BLDG to the table DSN8910.DEPT. Describe the new column as a character string column that holds SBCS data.

```
ALTER TABLE DSN8910.DEPT  
    ALTER COLUMN DEPTNAME SET DATA TYPE VARCHAR(50)  
    ADD BLDG CHAR(3) FOR SBCS DATA;
```

*Example 2:* Assign a validation procedure named DSN8EAEM to the table DSN8910.EMP.

```
ALTER TABLE DSN8910.EMP  
    VALIDPROC DSN8EAEM;
```

*Example 3:* Disassociate the current validation procedure from the table DSN8910.EMP. After the statement is executed, the table no longer has a validation procedure.

```
ALTER TABLE DSN8910.EMP  
    VALIDPROC NULL;
```

*Example 4:* Define ADMRDEPT as the foreign key of a self-referencing constraint on DSN8910.DEPT.

```
ALTER TABLE DSN8910.DEPT  
    FOREIGN KEY(ADMRDEPT) REFERENCES DSN8910.DEPT ON DELETE CASCADE;
```

*Example 5:* Add a check constraint to the table DSN8910.EMP which checks that the minimum salary an employee can have is \$10,000.

```
ALTER TABLE DSN8910.EMP  
    ADD CHECK (SALARY >= 10000);
```

*Example 6:* Alter the PRODINFO table to define a foreign key that references a non-primary unique key in the product version table (PRODVER\_1). The columns of the unique key are VERNAME, RELNO.

```
ALTER TABLE PRODINFO
  FOREIGN KEY (PRODNAME,PRODVERNO)
    REFERENCES PRODVER_1 (VERNAME,RELNO) ON DELETE RESTRICT;
```

*Example 7:* Assume that table DEPT has a unique index defined on column DEPTNAME. Add a unique key constraint named KEY\_DEPTNAME consisting of column DEPTNAME to the DEPT table:

```
ALTER TABLE DSN8910.DEPT
  ADD CONSTRAINT KEY_DEPTNAME UNIQUE( DEPTNAME );
```

*Example 8:* Register the base table TRANSCOUNT as a materialized query table. The result of the fullselect must provide a set of columns that match the columns in the existing table (same number of columns, same column definitions, and same names). So that you can maintain the table with insert, update, and delete operations as well as the REFRESH TABLE statement, define the materialized query table as user-maintained.

```
ALTER TABLE TRANSCOUNT ADD MATERIALIZED QUERY
  (SELECT ACCTID, LOCID, YEAR, COUNT(*) as cnt
   FROM TRANS
   GROUP BY ACCTID, LOCID, YEAR )
  DATA INITIALLY DEFERRED
  REFRESH DEFERRED
  MAINTAINED BY USER;
```

*Example 9:* Assume that table TB1 has a column, COL1 that is defined as CHAR(4) FOR BIT DATA WITH DEFAULT 'AB'. The value that is stored in the table will be XC1C24040. After the following ALTER TABLE statement is run, the resulting value that is stored in the table will be BX'C1C240400000'.

```
ALTER TABLE TB1
ALTER COLUMN COL1
SET DATA TYPE BINARY(6);
```

## ALTER TABLESPACE

The ALTER TABLESPACE statement changes the description of a table space at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

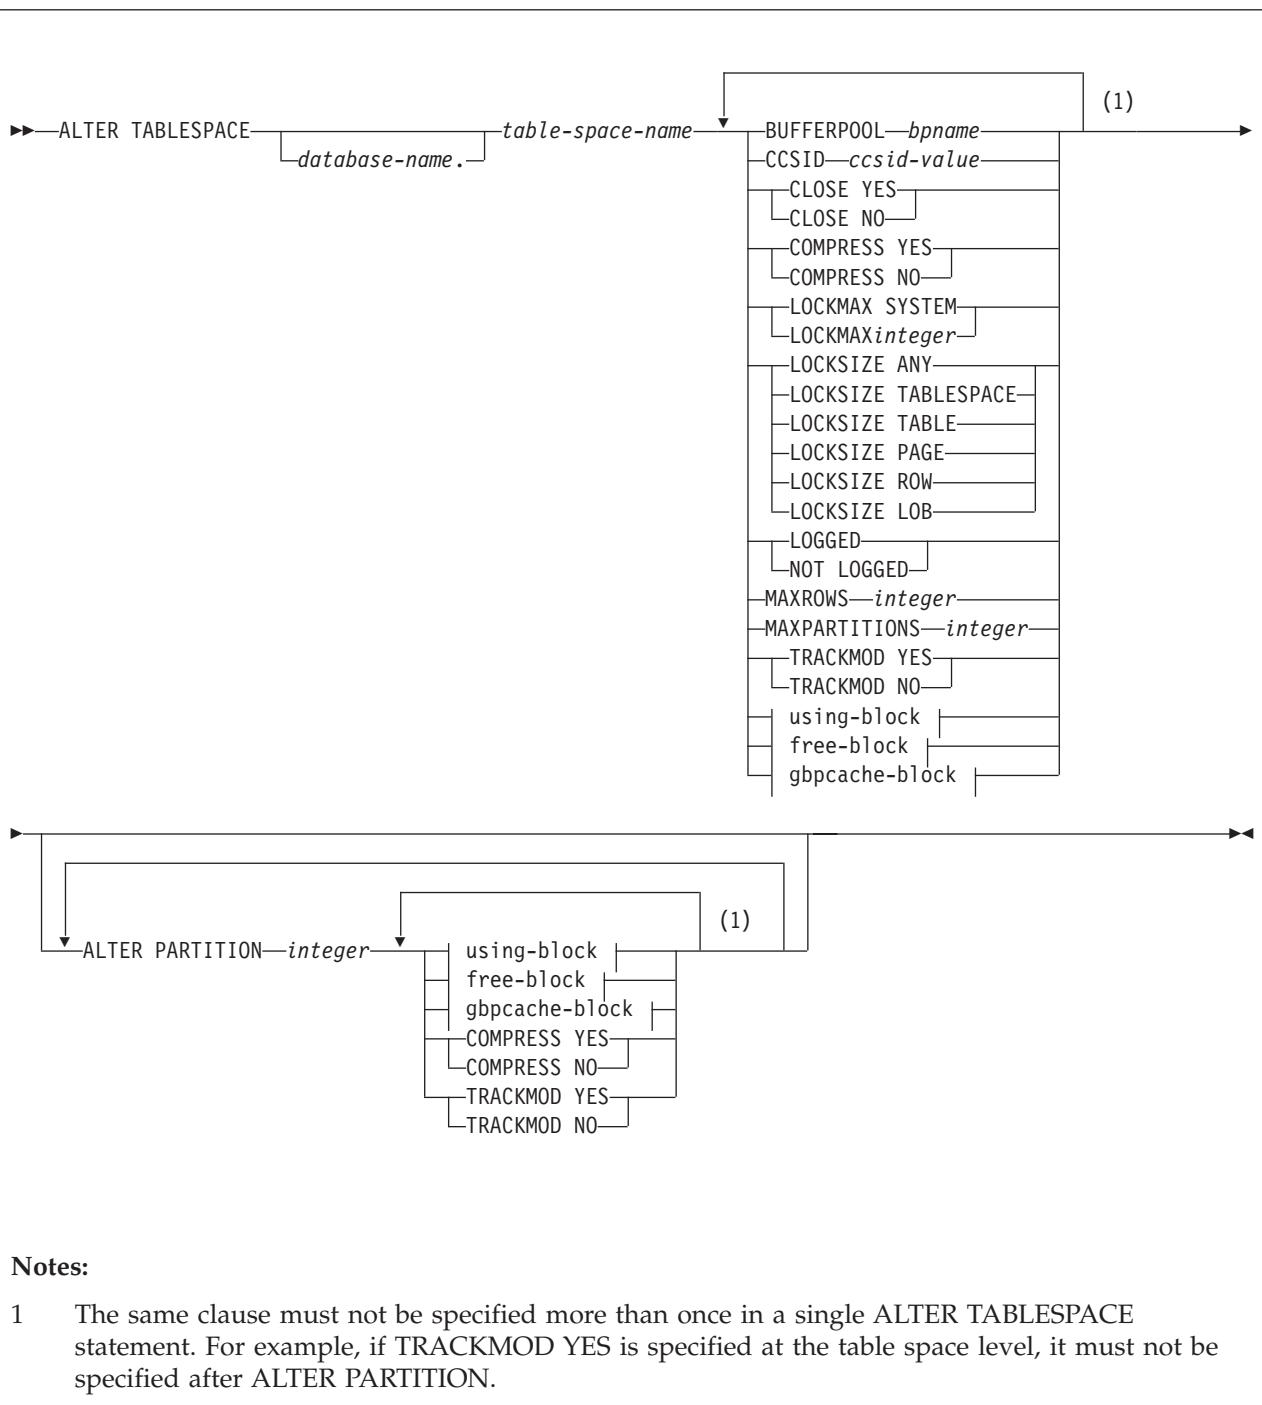

- Ownership of the table space
- DBADM authority for its database
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

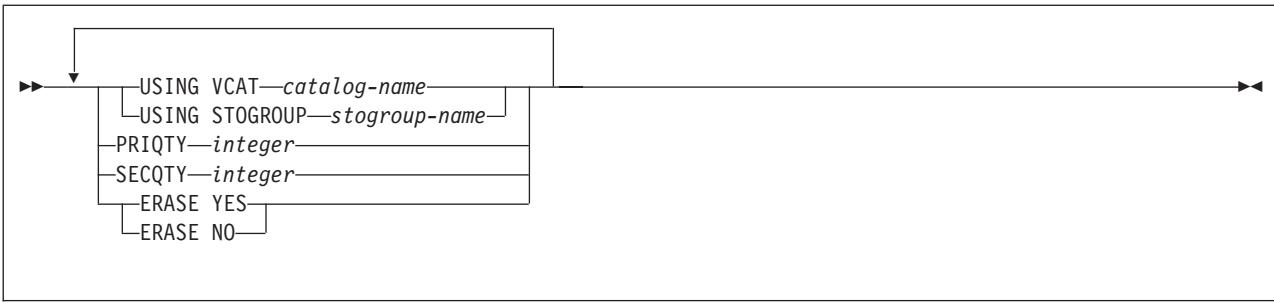

If BUFFERPOOL or USING STOGROUP is specified, additional privileges might be required, as explained in the description of those clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID and role of the process.

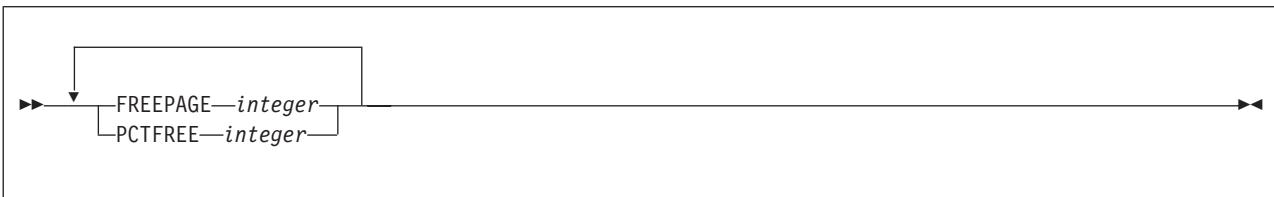

## Syntax

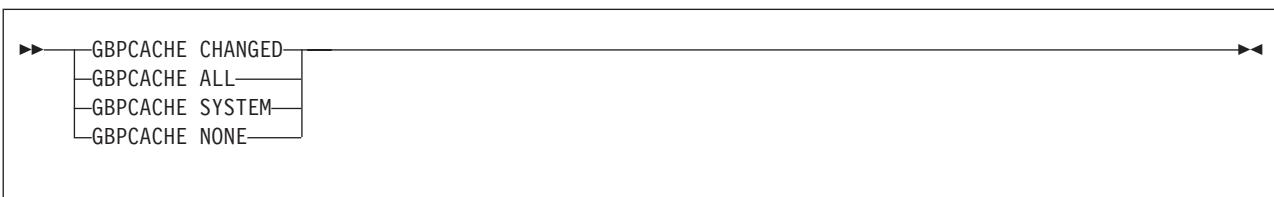

using-block:

**free-block:**

**gbpcache-block:**

## Description

*database-name.table-space-name*

Identifies the table space that is to be altered. The name must identify a table space that exists at the current server. Omission of *database-name* is an implicit specification of DSNDB04.

If you identify a partitioned table space, you can use the PARTITION clause.

**BUFFERPOOL** *bpname*

Identifies the buffer pool that is to be used for the table space. *bpname* must identify an activated buffer pool with the same page size as the table space.

The privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

The change to the description of the table space takes effect the next time the data sets of the table space are opened. The data sets can be closed and reopened by using a STOP DATABASE command to stop the table space followed by a START DATABASE command to start the table space.

In a data sharing environment, if you specify BUFFERPOOL, the table space must be in the stopped state when the ALTER TABLESPACE statement is executed.

**CCSID** *ccsid-value*

Identifies the CCSID value to be used for the table space. *ccsid-value* must identify a CCSID value that is compatible with the current value of the CCSID

for the table space. See “Notes” on page 699 for a list that shows the CCSID to which a given CCSID can be changed and details about changing it.

| Do not specify CCSID for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

| The CCSID of a table space cannot be changed if the table space contains any table that has an index that contains expressions.

#### CLOSE

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

##### YES

Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

**NO** Eligible for closing after all eligible CLOSE YES data sets are closed.

| For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified

#### COMPRESS

Specifies whether data compression applies to the rows of the table space or partition. Do not specify COMPRESS for a LOB table space or a table space in a work file database.

##### YES

Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition.

**NO** Specifies no data compression. Inserted rows will not be compressed. Updated rows will be decompressed. The dictionary used for compression will be erased when the LOAD REPLACE, LOAD RESUME NO, or REORG utility is run. See *DB2 Performance Monitoring and Tuning Guide* for more information about the dictionary and data compression.

#### LOCKMAX

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX a for table space in a work file database, DB2 ignores the value because these types of locks are not used.

| For an application that uses Sysplex query parallelism, a lock count is maintained on each member.

##### *integer*

Specifies the number of locks allowed before escalating, in the range 0 to 2 147 483 647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

#### SYSTEM

Indicates that the value of field LOCKS PER TABLE(SPACE) on installation panel DSNTIPJ specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

If you change LOCKSIZE and omit LOCKMAX, the following results occur:

<b>LOCKSIZE</b>	<b>Resultant LOCKMAX</b>
TABLESPACE or TABLE	0
PAGE, ROW, or LOB	Unchanged
ANY	SYSTEM

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

#### **LOCKSIZE**

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not specify LOCKSIZE for a table space in a work file database.

#### **ANY**

Specifies that DB2 can use any lock size. Currently, DB2 never chooses row locks, but reserves the right to do so.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (an installation parameter), the page or LOB locks are released and locking is set at the next higher level. If the table space is segmented, the next higher level is the table. If the table space is not segmented, the next higher level is the table space.

#### **TABLESPACE**

Specifies table space locks.

#### **TABLE**

Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

#### **PAGE**

Specifies page locks. Do not use PAGE for a LOB table space.

#### **ROW**

Specifies row locks. Do not use ROW for a LOB table space.

#### **LOB**

Specifies LOB locks. Use LOB only for a LOB table space.

Let S denote an SQL statement that refers to a table in the table space:

- The LOCKSIZE change affects S if S is prepared and executed after the change. This includes dynamic statements and static statements that are not bound because of VALIDATE(RUN).
- If the size specified by the new LOCKSIZE is greater than the size of the old LOCKSIZE, the change affects S if S is a static statement that is executed after the change.

The hierarchy of lock sizes, starting with the largest, is as follows:

- table space lock
- table lock (only for segmented table spaces)
- page lock, row lock, and LOB lock (which are at the same level)

#### **LOGGED or NOT LOGGED**

Specifies whether changes that are made to the data in the specified table space are recorded in the log.

**LOGGED**

Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This can affect the logging attribute of associated LOB table spaces. See "Notes" on page 852 for more information.

If the base table space is in informational copy-pending status (meaning updates have been made to the table space) when you change from NOT LOGGED to LOGGED, the base table space is placed in copy-pending status. All indexes of tables in the table space are unchanged from their current state; that is, if an index is currently in informational copy-pending status, it will remain in information copy-pending status.

Specifying LOGGED for a LOB table space requires that the base table space also specifies the LOGGED parameter.

LOGGED cannot be specified for XML table spaces. The logging attribute of an XML table space is inherited from its base table space.

LOGGED cannot be specified for table spaces in DSNDB06 (the DB2 catalog) or in a work file database.

**NOT LOGGED**

Specifies that changes that are made to data in the specified table space are not recorded in the log. This applies to all tables in the specified table space and to all indexes of those tables. Table spaces and indexes that are created for XML columns inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space. This parameter can affect the logging attribute of associated LOB table spaces. See "Notes" on page 852 for more information.

NOT LOGGED prevents undo and redo information from being recorded in the log for the base table space; however, control information for the specified base table space will continue to be recorded in the log. For a LOB table space, changes to system pages and to auxiliary indexes are logged.

NOT LOGGED is mutually exclusive with the DATA CAPTURE CHANGES parameter of CREATE TABLE and ALTER TABLE. NOT LOGGED will not be applied to the table space if any table in the table space specifies DATA CAPTURE CHANGES.

NOT LOGGED cannot be specified for XML table spaces.

NOT LOGGED cannot be specified for table spaces in the following databases:

- DSNDB06 (the DB2 catalog)
- a work file database

**MAXROWS *integer***

Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255.

The change takes effect immediately for new rows added. However, the space class settings for some pages might be incorrect and could cause unproductive page visits. It is highly recommended to reorganize the table space after altering MAXROWS.

If you specify MAXROWS, the table space must be in the stopped state when the ALTER TABLESPACE statement is executed. Do not specify MAXROWS for a LOB table space, a table space that is implicitly created for an XML column, a table space in a work file database, or the DB2 catalog table spaces that are listed under “SQL statements allowed on the catalog” on page 1689.

#### **MAXPARTITIONS** *integer*

Specifies that the table space is partition-by-growth. *integer* specifies the maximum number of partitions to which the table space can grow. *integer* must be in the range of 1 to 4096, depending on the value that is in effect for DSSIZE and the page size of the table space, and must not be less than the current maximum number of partitions for the table space. See “CREATE TABLESPACE” on page 1128 for more information about how DSSIZE and the page size are related.

MAXPARTITIONS can only be specified for a partition-by-growth table space, including XML partition-by-growth table spaces.

#### **TRACKMOD**

Specifies whether DB2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space or a table space in a work file database.

##### **YES**

DB2 tracks changed pages in the space map pages to improve the performance of incremental image copy. For data sharing, changing TRACKMOD to YES causes additional SCA (shared communication area) storage to be used until after the next full or incremental image copy is taken or until TRACKMOD is set back to NO.

**NO** DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

#### **FREEPAGE** *integer*

Specifies how often to leave a page of free space when the table space is loaded or reorganized. One free page is left after every *integer* pages; *integer* can range from 0 to 255. FREEPAGE 0 leaves no free pages. Do not specify FREEPAGE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

#### **PCTFREE** *integer*

Specifies what percentage of each page to leave as free space when the table space is loaded or reorganized. The first record on each page is loaded without restriction. When additional records are loaded, at least *integer* percent of free space is left on each page. *integer* can range from 0 to 99. Do not specify PCTFREE for a LOB table space, a table space that is implicitly created for an XML column, or a table space in a work file database.

This change to the description of the table space or partition has no effect until data in the table space or partition is loaded or reorganized. For XML table spaces, this change has no effect until data in the table space is reorganized.

#### **USING**

Specifies whether a data set for the table space or partition is managed by the user or is managed by the DB2 system. If the table space is partitioned, USING applies to the data set for the partition that is identified in the PARTITION clause. If the table space is a partition-by-growth table space, USING can only be specified at the table space level. If the table space is not partitioned, USING applies to every data set that is eligible for the table space. (A nonpartitioned table space can have more than one data set if PRIQTY+118 × SECQTY is at least 2 gigabytes.)

If the USING clause is specified, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. See Altering storage attributes to determine how and when changes take effect. Do not specify the USING clause if the table space is in a work file database.

#### **VCAT *catalog-name***

Specifies a user-managed data set with a name that starts with *catalog-name*. The VCAT clause must not be specified if the table space is a partition-by-growth table space. You must specify the catalog name in the form of an SQL identifier. You must specify an alias<sup>24</sup> if the name of the integrated catalog facility catalog is longer than eight characters. When the new description of the table space is applied, the integrated catalog facility catalog must contain an entry for the data set that conforms to the DB2 naming conventions set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

#### **STOGROUP *stogroup-name***

Specifies a DB2-managed data set that resides on a volume of the identified storage group. *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. When the new description of the table space is applied, the description of the storage group must include at least one volume serial number, each volume serial number must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type. Furthermore, the integrated catalog facility catalog used for the storage group must not contain an entry for the data set.

If you specify USING STOGROUP and the current data set for the table space or partition is managed by DB2:

- Omission of the PRIQTY clause is an implicit specification of the current PRIQTY value.
- Omission of the SECQTY clause is an implicit specification of the current SECQTY value.
- Omission of the ERASE clause is an implicit specification of the current ERASE rule.

---

24. The alias of an integrated catalog facility catalog

If you specify USING STOGROUP to convert from user-managed data sets to DB2-managed data sets:

- Omission of the PRIQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the SECQTY clause is an implicit specification of the default value. For information on how DB2 determines the default value, see Rules for primary and secondary space allocation.
- Omission of the ERASE clause is an implicit specification of ERASE NO.

**PRIQTY** *integer*

Specifies the minimum primary space allocation for a DB2-managed data set of the table space or partition. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If PRIQTY is specified (with a value other than -1), the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer* with the following exceptions:

- For 4 KB page sizes, if *integer* is less than 12, *n* is 12.
- For 8 KB page sizes, if *integer* is less than 24, *n* is 24.
- For 16 KB page sizes, if *integer* is less than 48, *n* is 48.
- For 32 KB page sizes, if *integer* is less than 96, *n* is 96.
- For any page size, if *integer* is greater than 4194304, *n* is 4194304.

For LOB table spaces, the exceptions are:

- For 4 KB pages sizes, if *integer* is less than 200, *n* is 200.
- For 8 KB pages sizes, if *integer* is less than 400, *n* is 400.
- For 16 KB pages sizes, if *integer* is less than 800, *n* is 800.
- For 32 KB pages sizes, if *integer* is less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 4194304, *n* is 4194304.

If the DB2 subsystem is under DFP 1.5, the maximum value allowed for PRIQTY is 64GB (67108864 kilobytes). Otherwise, the existing maximum value of 4GB (4194304 kilobytes) applies.

If PRIQTY -1 is specified, DB2 uses a default value for the primary space allocation. For information on how DB2 determines the default value for primary space allocation, see Rules for primary and secondary space allocation.

If PRIQTY is omitted and USING STOGROUP is specified, the value of PRIQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)

If you specify PRIQTY and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of *p* KB not less than *n*, where *p* is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

At least one of the volumes of the identified storage group must have enough available space for the primary quantity. Otherwise, the primary space allocation will fail.

See Altering storage attributes to determine how and when changes to PRIQTY take effect.

**SECQTY** *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set of the table space or partition. This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If SECQTY -1 is specified, DB2 uses a default value for the secondary space allocation.

If USING STOGROUP is specified and SECQTY is omitted, the value of SECQTY is its current value. (However, if the current data set is being changed from being user-managed to DB2-managed, the value is its default value. See the description of USING STOGROUP.)

For information on the actual value that is used for secondary space allocation, whether you specify a value or DB2 uses a default value, see Rules for primary and secondary space allocation.

If you specify SECQTY and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of  $p$  KB not less than  $n$ , where  $p$  is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command for z/OS DFSMS Access Method Services for Catalogs.

See Altering storage attributes to determine how and when changes to SECQTY take effect.

**ERASE**

Indicates whether the DB2-managed data sets for the table space or partition are to be erased before they are deleted during the execution of a utility or an SQL statement that drops the table space.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2.

**YES**

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

This clause can be specified only if the data set is managed by DB2, and if one of the following is true:

- USING STOGROUP is specified.
- A USING clause is not specified.

If you specify ERASE, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. If you specify ERASE for a partitioned table space, you must also specify the ALTER PARTITION clause. See Altering storage attributes to determine how and when changes take effect.

**GBPCACHE**

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In

a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or not). In addition, you cannot alter the GBPCACHE value of some DB2 catalog table spaces; for a list of these table spaces, see “SQL statements allowed on the catalog” on page 1689.

#### **CHANGED**

When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update.

If the table space is in a group buffer pool that is defined to be used only for cross-validation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

#### **ALL**

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating DB2 when no other DB2 subsystems have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-validation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

#### **SYSTEM**

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

SYSTEM is the default for a LOB table space. Use SYSTEM only for a LOB table space.

#### **NONE**

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-validation.

If you specify NONE, the table space or partition must not be in recover pending status when the ALTER TABLESPACE statement is executed.

If you specify GBPCACHE in a data sharing environment, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed.

#### **ALTER PARTITION *integer***

Specifies that the identified partition of the table space is to be changed. For a table space that has *n* partitions, you must specify an integer in the range 1 to *n*. You must not use this clause for a nonpartitioned table space, for a LOB table space, or a partition-by-growth table space. At least one of the following clauses must be specified:

- COMPRESS
- ERASE
- FREEPAGE
- GBPCACHE
- PCTFREE

- PRIQTY
- SECQTY
- TRACKMOD
- USING

The changes specified by these clauses affect only the identified partition.

Do not specify the following clauses for ALTER PARTITION for partitions of a table space that is implicitly created for an XML column.

- CCSID
- FREEPAGE
- MAXROWS
- PCTFREE

## Notes

**Running utilities:** You cannot execute the ALTER TABLESPACE statement while a DB2 utility has control of the table space.

**Altering more than one partition:** To change FREEPAGE, PCTFREE, USING, PRIQTY, SECQTY, COMPRESS, ERASE, or GBPCACHE for more than one partition, you must use separate ALTER TABLESPACE statements.

**Altering storage attributes:** The USING, PRIQTY, SECQTY, and ERASE clauses define the storage attributes of the table space or partition. If you specify USING or ERASE when altering storage attributes, the table space or partition must be in the stopped state when the ALTER TABLESPACE statement is executed. You can use a STOP DATABASE...SPACENAM... command to stop the table space or partition.

If the catalog name changes, the changes take effect after you move the data and start the table space or partition using the START DATABASE...SPACENAM... command. The catalog name can be implicitly or explicitly changed by the ALTER TABLESPACE statement. The catalog name also changes when you move the data to a different device. See the procedures for moving data in *DB2 Administration Guide*.

Changes to the secondary space allocation (SECQTY) take effect the next time DB2 extends the data set; however, the new value is not reflected in the integrated catalog until you use the REORG, RECOVER, or LOAD REPLACE utility on the table space or partition. The changes to the other storage attributes take effect the next time the page set is reset. For a non-LOB table space, the page set is reset when you use the REORG, RECOVER, or LOAD REPLACE utilities on the table space or partition. For a LOB table space, the page set is reset when RECOVER is run on the LOB table space or LOAD REPLACE is run on its associated base table space. If there is not enough storage to satisfy the primary space allocation, a REORG might fail. If you change the primary space allocation parameters or erase rule, you can have the changes take effect earlier if you move the data before you start the table space or partition.

**Recommended GBPCACHE setting for LOB table spaces:** For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

*Altering the logging attribute of a table space:* If the logging attribute (specified with the LOGGED or NOT LOGGED parameter) of a table space is altered frequently, the size of SYSIBM.SYSCOPY might need to be increased.

The logging attribute of the table space cannot be altered if the table space has been updated in the same unit of recovery.

A full image copy of the table space should be taken:

- Before altering a table space to NOT LOGGED
- After altering a table space to LOGGED

If a table space has data changes after an image copy is taken (the table space is in informational COPY-pending state), and the table space is altered from NOT LOGGED to LOGGED, the table space is marked COPY-pending and a full image copy of the table space must be taken.

An XML table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the XML table space is said to be *linked* to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated XML table spaces are altered back to LOGGED, and all of these links are dissolved.

A LOB table space with the LOGGED logging attribute has its logging attribute altered to NOT LOGGED when the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When this happens, the logging attribute of the LOB table space is said to be *linked* to the logging attribute of the base table space. When the logging attribute of the base table space is altered back to LOGGED, all logging attributes that are linked for the associated LOB table spaces are altered back to LOGGED, and all of these links are dissolved.

You can dissolve the link between these logging attributes by altering the logging attribute of the LOB table space to NOT LOGGED, even though it has already been implicitly given this logging attribute. After such an alter, the logging attribute of the LOB table space is unaffected when the logging attribute of the base table is altered back to LOGGED. A LOB table space with the NOT LOGGED logging attribute does not have this attribute changed in any way if the logging attribute of the associated base table space is altered from LOGGED to NOT LOGGED. When altered in this way, the logging attributes of the LOB table space and the base table space are not linked. If the base table space is altered back to LOGGED, the logging attribute of any LOB table spaces that are not linked to the logging attribute of the base table space remain unchanged.

*Altering table spaces for DB2 catalog tables:* For details on altering options on catalog tables, see “SQL statements allowed on the catalog” on page 1689.

*Invalidation of plans and packages:* All of the plans and packages that refer to that table space are invalidated when the SBCS CCSID attribute of a table space is changed. When the SBCS CCSID attribute of a table space is altered, all the plans and packages that refer to that table space are marked invalid.

*Alternative syntax and synonyms:* For compatibility with previous releases of DB2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. DB2 treats all partitioned table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space.
- When altering the partitions of a partitioned table space, the ALTER keyword that precedes PARTITION keyword is optional and if ALTER keyword is omitted, then you can specify PART as a synonym for PARTITION.
- You can specify LOG YES as a synonym for LOGGED and LOG NO as a synonym for NOT LOGGED.

## Examples

*Example 1:* Alter table space DSN8S91D in database DSN8D91A. BP2 is the buffer pool associated with the table space. PAGE is the level at which locking is to take place.

```
ALTER TABLESPACE DSN8D91A.DSN8S91D
  BUFFERPOOL BP2
  LOCKSIZE PAGE;
```

*Example 2:* Alter table space DSN8S91E in database DSN8D91A. The table space is partitioned. Indicate that the data sets of the table space are not to be closed when there are no current users of the table space. Also, change all of the partitions so that DB2 will use a formula to determine any secondary space allocations, and change partition 1 to use a PCTFREE value of 20.

```
ALTER TABLESPACE DSN8D91A.DSN8S91E
  CLOSE NO
  SECQTY -1
  ALTER PARTITION 1 PCTFREE 20;
```

*Example 3:* The following statement changes the maximum number of partitions in a partition-by-growth table space:

```
ALTER TABLESPACE TS01DB.TS01TS
  MAXPARTITIONS 30;
```

---

## ALTER TRUSTED CONTEXT

The ALTER TRUSTED CONTEXT statement modifies the definition of a trusted context at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

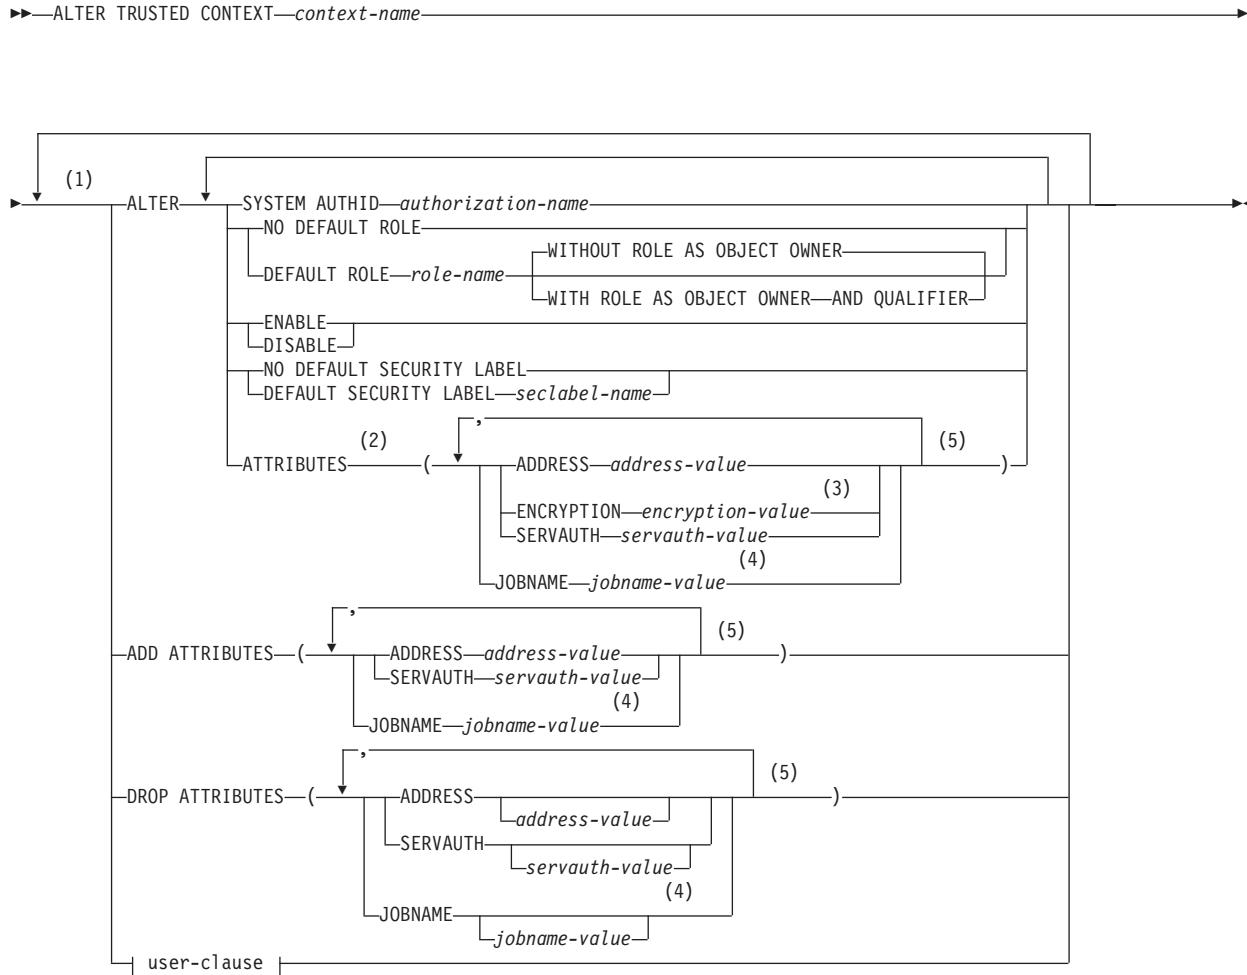

### Authorization

The privilege set that is defined below must include SYSADM authority.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the union of the set of privileges that are held by each authorization ID of the process. If the statement is run in a trusted context with a role, the privilege set is the union of the set of privileges that are held by the role that is associated with the primary authorization ID and the set of privileges that are held by each authorization ID of the process.

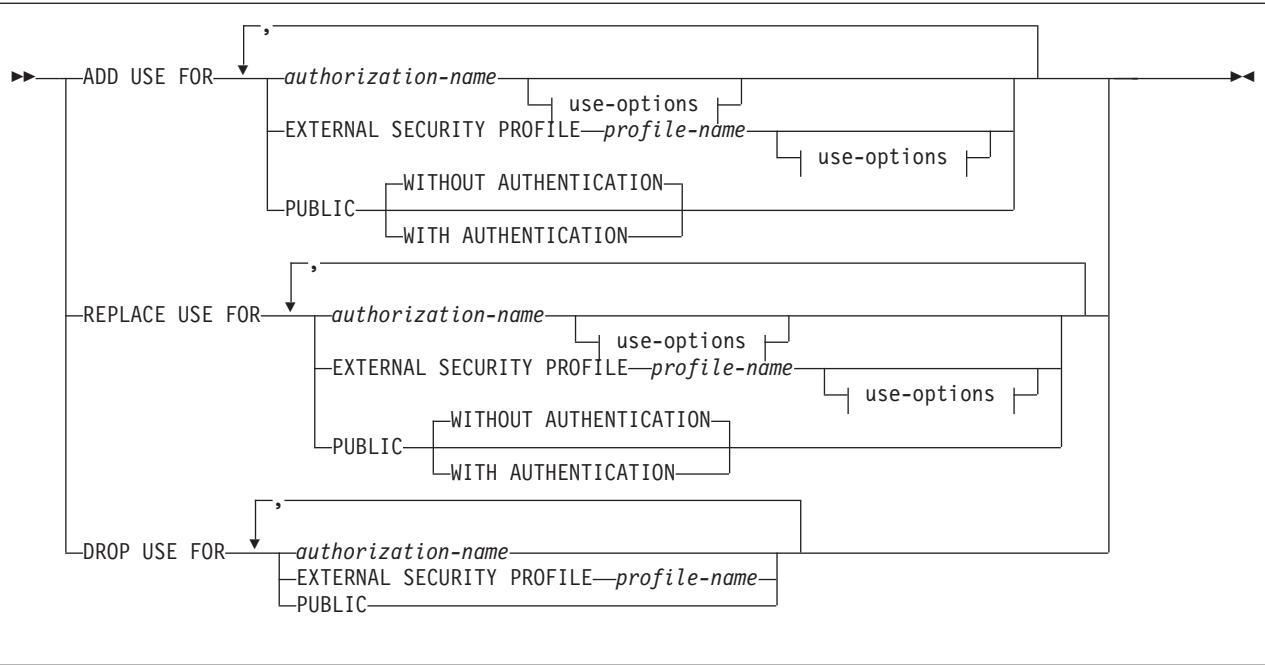

## Syntax

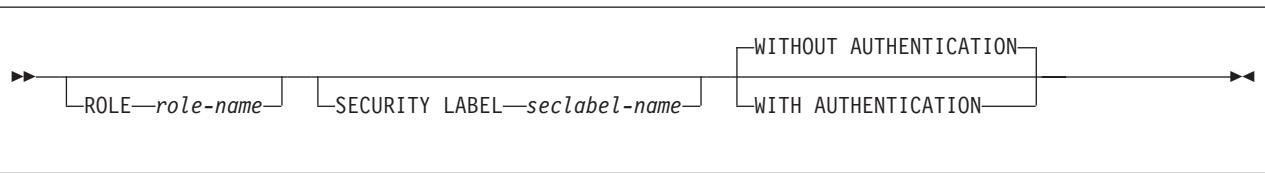

### Notes:

- 1 These clauses can be specified in any order. Each clause must not be specified more than one time.
- 2 This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.
- 3 ENCRYPTION must not be specified more than one time.
- 4 JOBNAME must not be specified with ADDRESS, ENCRYPTION, or SERVAUTH.
- 5 Each pair of attribute name and corresponding value must be unique.

**user-clause:**

**use-options:**

## Description

*context-name*

Identifies the trusted context to alter. *context-name* must refer to a trusted context that exists at the current server.

**ALTER**

Specifies that changes are to be made to the definition of an existing trusted context.

**SYSTEM AUTHID** *authorization-name*

Specifies that *authorization-name* is the system authorization ID for the trusted context. The system authorization ID is the primary authorization ID of the DB2 system that establishes the connection. For a remote connection, the authorization ID is derived from the system used ID that is provided by the external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 92.

*Table 92. System authorization ID for a local connection*

Source of local connection	System authorization ID
Started task (RRSAF)	USER parameter on JOB statement or RACF USER.
TSO	TSO logon ID
BATCH	USER parameter on JOB statement

*authorization-name* must not be associated with an existing trusted context.

**NO DEFAULT ROLE or DEFAULT ROLE *role-name***

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

**NO DEFAULT ROLE**

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

**DEFAULT ROLE *role-name***

Specifies that *role-name* is the role for the trusted context. *role-name* must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

**WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

**WITHOUT ROLE AS OBJECT OWNER**

Specifies that a role is not used as the owner of the objects that are created using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

**WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context. That role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

**AND QUALIFIER**

Specifies that the *role-name* will be used as the default for the CURRENT SCHEMA special register. The *role-name* will also be included in the SQL PATH (in place of CURRENT SQLID).

When **WITH ROLE AS OBJECT OWNER AND QUALIFIER** is not specified, there is no change to the default of the CURRENT SCHEMA special register and SQL PATH.

**DISABLE or ENABLE**

Specifies whether the trusted context is in the enabled or disabled state.

**DISABLE**

Specified that the trusted context is disabled. A trusted context that is disabled is not considered when a trusted connection is established.

**ENABLE**

Specifies that the trusted context is enabled.

**NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL *seclabel-name***

Specifies whether a default security label is associated with a trusted connection that is based on this trusted context. If a trusted connection for the specified context is active, the change goes into effect at the next connection reuse attempt or when a new connection is requested.

**NO DEFAULT SECURITY LABEL**

Specifies that the trusted context does not have a default security label.

**DEFAULT SECURITY LABEL *seclabel-name***

Specifies that *seclabel-name* is the default security label for the trusted context. *seclabel-name* is the security label that is used for multilevel security verification. *seclabel-name* must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used in a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, *seclabel-name* must also identify one of the RACF SECLABEL values that is defined for the user.

**ALTER ATTRIBUTES or ADD ATTRIBUTES**

Specifies a list of one or more connection trust attributes to change or add to the definition of a trusted context. The connection trust attributes are used to define the trusted context. If ALTER ATTRIBUTES is specified and the attribute is not currently part of the definition of the specified trusted context, an error is returned. Existing specifications for the specified attributes are changed to the new value if ALTER is specified. Attributes that are not specified retain the previously specified values.

**ADDRESS *address-value***

Specifies the actual communication address that is used by the connection to communicate with the database manager. The protocol supported is only for TCP/IP. Previously specified ADDRESS values are removed when ALTER ATTRIBUTES is specified. The ADDRESS attribute can be specified multiple times, but each *address-value* must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the values that are defined for the ADDRESS attribute of the trusted context.

*address-value* specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of *address-value* is done at the time the ALTER TRUSTED CONTEXT statement is processed. *address-value* must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111.

- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. This address can also be expressed in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

**ENCRYPTION** *encryption-value*

Specifies the minimum level of encryption of the data stream (network encryption) for the connection.

*encryption-value* specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

ENCRYPTION cannot be specified if ADD ATTRIBUTES is specified. See “CREATE TRUSTED CONTEXT” on page 1167 for more information about the ENCRYPTION attribute.

**JOBNAME** *jobname-value*

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. Previously specified values for JOBNAME are removed when ALTER ATTRIBUTES is specified. The JOBNAME attribute can be specified multiple times, but each *jobname-value* must be unique.

*jobname-value* specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte job name or started task name. *jobname-value* must be left justified within the string constant. The last character in the name can be a wildcard character (\*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that match the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space).

Table 93. Job name for local connection

Source of the address space	Job name
RRSAF	Job name or started task name
TSO	TSO logon ID
BATCH	Job name on JOB statement

**SERVAUTH** *servauth-value*

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2. Previously specified values for SERVAUTH are removed when ALTER

ATTRIBUTES is specified. The SERVAUTH attribute can be specified multiple times but each *servauth-value* must be unique.

*servauth-value* specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. *servauth-value* is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. *servauth-value* must be left justified in the string constant. No validation of *servauth-value* is done at the time the ALTER TRUSTED CONTEXT statement is processed.

#### **DROP ATTRIBUTES**

Specifies that one or more attributes are dropped from the definition of a trusted context. If the attribute is not currently specified as part of the definition of a trusted context, an error is returned. The specification of DROP ATTRIBUTES must not attempt to drop all of the existing attributes for a trusted context.

#### **ADDRESS *address-value***

Specifies that the identified communication address is removed from the definition of the trusted context. *address-value* specifies a string constant that contains the value of an existing ADDRESS trust attribute.

#### **JOBNAME *jobname-value***

Specifies that the identified job name is removed from the definition of the trusted context. *jobname-value* specifies a string constant that contains the value of an existing JOBNAME trust attribute.

#### **SERVAUTH *servauth-value***

Specifies that the identified servauth that is removed from the definition of the trusted context. *servauth-value* specifies a string constant that contains the value of an existing SERVAUTH trust attribute.

#### **ADD USE FOR**

Specifies additional users who can use a trusted connection that is based on the specified trusted context.

##### *authorization-name*

Specifies that the trusted connection can be used by the specified *authorization-name*. This is the DB2 primary authorization ID. The *authorization-name* must not identify an authorization ID that is already defined to use the trusted context, and must not be specified more than one time in the ADD USE FOR clause.

##### **ROLE *role-name***

Specifies that *role-name* is the role that is used when a trusted connection is used by the specified *authorization-name*. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

##### **SECURITY LABEL *seclabel-name***

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

##### **EXTERNAL SECURITY PROFILE *profile-name***

Specifies that the trusted connection can be used by the DB2 primary authorization IDs that are permitted to use the specified *profile-name* in RACF. The *profile-name* must not already be defined to use the trusted

context and must not be specified more than one time in the **ADD USE FOR** clause. After you specify an external security profile, any user who is permitted access to the RACF profile can use the trusted context in addition to any users that are specified using the **ADD USE FOR authorization-name** clause.

**ROLE** *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL** *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

**PUBLIC**

Specifies that a trusted connection that is based on the specified trusted context can be used by any user. PUBLIC must not already be defined to use the trusted context and must not be specified more than one time in the **ADD USE FOR** clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- EXTERNAL SECURITY PROFILE *profile-name*
- PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION (with JOE and SAM permitted to use the RACF PROFILE SPROFILE), and PUBLIC WITH AUTHENTICATION. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if the trusted connection is used by SALLY, authentication is required.

**REPLACE USE FOR**

Specifies a change to the specified user or PUBLIC for who can use the trusted context.

*authorization-name*

Specifies the *authorization-name* that is changed for use of the trusted context. The trusted context must already be defined to allow use by *authorization-name*, and *authorization-name* must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with *authorization-name* is changed as indicated.

**ROLE** *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is using the specified trusted context. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

**SECURITY LABEL** *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

**EXTERNAL SECURITY PROFILE** *profile-name*

Specifies the *profile-name* to change attributes for use of the trusted connection. The trusted context must already be defined to allow the use of *profile-name*. *profile-name* must not be specified more than one time in the REPLACE USE FOR clause. The information that is associated with the profile name is changed as indicated.

**ROLE** *role-name*

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The role name must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL** *seclabel-name*

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

**PUBLIC**

Specifies that the attributes for use of the trusted connection by PUBLIC are to be changed. PUBLIC must already be defined to use the trusted context, and PUBLIC must not be specified more than one time in the REPLACE USE FOR clause.

All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of

the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

#### **WITHOUT AUTHENTICATION or WITH AUTHENTICATION**

Specifies whether use of the trusted connection requires authentication of the user.

##### **WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

##### **WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user.

#### **DROP USE FOR**

Specifies who can no longer use the trusted context. The users that are removed from the definition of the trusted context are the specified users (or PUBLIC) that are currently allowed to use the trusted context. If multiple users are specified to be dropped, and one or more of those users cannot be dropped, those users that can be dropped are dropped and a warning is returned. If none of the specified users can be removed from the definition of the trusted context, an error is returned.

##### *authorization-name*

Specifies the *authorization-name* that will no longer be able to use this trusted context.

##### **EXTERNAL SECURITY PROFILE *profile-name***

Removes the ability for the specified *profile-name* to use the trusted context.

##### **PUBLIC**

Specifies that PUBLIC users will no longer be able to use this trusted context. The system authorization ID and individual authorization IDs that have been explicitly enabled can still use the trusted context.

### **Notes**

**Precedence for *authorization-name* and authentication requirements:** If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same authorization name that is specified in the ADD or REPLACE USE FOR *authorization-name* clauses, the role or the security label that is specified for the *authorization-name* takes precedence over the default value and the value that is specified for the EXTERNAL SECURITY PROFILE *profile-name* (if one is specified). If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the specified profile names and is not specified in ADD or REPLACE USE for *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

Authentication is required for SYSTEM AUTHID if the AUTHENTICATION clause is specified in the ADD or REPLACE USE FOR clauses, or if the subsystem parameter TCP/IP Already Verified is set to NO. For example, if *authorization-name* is the same as the authorization name that is specified in the SYSTEM AUTHID clause and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, authentication is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to

YES, authentication is still required for SYSTEM AUTHID.

*Order of precedence for users of a trusted connection:* The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- EXTERNAL SECURITY PROFILE *profile-name*
- PUBLIC

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

*User-clause SYSTEM AUTHID considerations:* If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same as the *authorization-name* that is specified in the user-clause *authorization-name*, the role or the security label that is specified for *authorization-name* takes precedence over the default value. The value that is specified for the *profile-name*, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the *user-clause* or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if *authorization-name* is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

*Order of operations:* The order in which the clauses of the ALTER TRUSTED CONTEXT statement are applied are as follows:

- DROP ATTRIBUTES
- DROP USE FOR
- ALTER
- ADD ATTRIBUTES
- ADD USE FOR
- REPLACE USE FOR

*Effect of changes on existing trusted connections:* If trusted connections exist for the trusted context that is changed, the connections continue to use the unchanged definition of the trusted context until the connection is terminated or an attempt at reuse is made. If the trusted context is disabled while there are active trusted connections that are based on this trusted context, the connections continue to be

used until terminated or an attempt at reuse is made. If the trust attributes are changed, trusted connections that exist at the time that the trusted context is changed will continue to be used.

**When changes to a trusted context take place:** The changes to the definition of a trusted context take effect after the ALTER TRUSTED CONTEXT statement is committed. If the ALTER TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not changed.

**Role privileges:** If no role is associated with the user or the trusted context, only the privileges that are associated with the user are applicable. This is the same as not using a trusted context.

## Examples

**Example 1:** The following statement updates the default role of the trusted context CTX1:

```
ALTER TRUSTED CONTEXT CTX1  
    ALTER DEFAULT ROLE CTXROLE2;
```

**Example 2:** The following statement changes the CTX3 trusted context to allow use for BILL, and it also puts the trusted context into the disabled state:

```
ALTER TRUSTED CONTEXT CTX3  
    DISABLE  
    ADD USE FOR BILL;
```

**Example 3:** The following statement changes the CTX4 trusted context to allow the previously defined user JOE to use the trusted context without authentication. The statement also adds use for PUBLIC with authentication and TOM with a role of SPLROLE:

```
ALTER TRUSTED CONTEXT CTX4  
    REPLACE USE FOR JOE WITHOUT AUTHENTICATION  
    ADD USE FOR PUBLIC WITH AUTHENTICATION,  
        TOM ROLE SPLROLE;
```

**Example 4:** The following statement changes the REMOTECTX to use a different IPv4 address than it was originally defined to use. It also changes the encryption settings from NONE to LOW. After the ALTER statement is processed, the connection will be considered trusted only when it is established from 9.12.155.200 with low encryption. The connection will no longer be considered trusted if it is established from the previously defined addresses:

```
ALTER TRUSTED CONTEXT REMOTECTX  
    ALTER ATTRIBUTES (ADDRESS '9.12.155.200',  
        ENCRYPTION 'LOW');
```

## ALTER VIEW

The ALTER VIEW statement regenerates a view using an existing view definition at the current server. ALTER VIEW is primarily used during DB2 migration or when DB2 maintenance is applied. To change a view definition (for example, to add additional columns), you must drop the view and create a new view using the CREATE VIEW statement.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the view
- SYSADM authority
- SYSCTRL authority

| **Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

### Syntax

```
►►—ALTER VIEW—view-name—REGENERATE—►►
```

### Description

*view-name*

Identifies the view to be regenerated. The name must identify a view that exists at the current server.

#### REGENERATE

Specifies that the view is to be regenerated. The view definition in the catalog is used, and existing authorizations and dependent views are retained. The catalog is updated with the regenerated view definition. If the view cannot be successfully regenerated, an error is returned.

### Examples

Check the catalog to find any views that were marked with view regeneration errors during catalog migration:

```
SELECT CREATOR,NAME FROM SYSIBM.SYSTABLES  
WHERE TYPE = 'V' AND STATUS = 'R' AND TABLESTATUS = 'V';
```

Assume that the query returned MYVIEW as the name of a view with a regeneration error. Issue an ALTER VIEW statement to regenerate the view:

```
ALTER VIEW MYVIEW REGENERATE;
```

## ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a stored procedure.

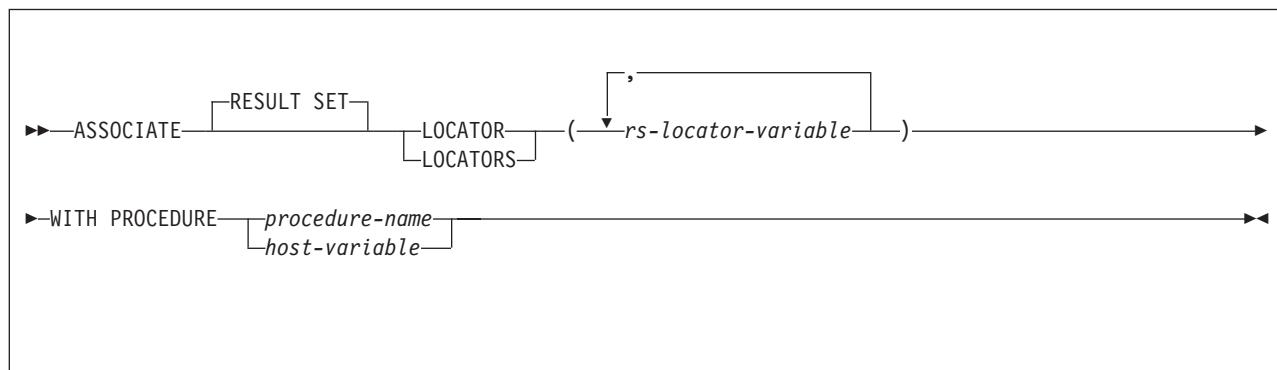

### Invocation

This statement can be embedded in an application program. It is an executable statement that can be dynamically prepared. It cannot be issued interactively.

### Authorization

None required.

### Syntax

### Description

#### *rs-locator-variable*

Identifies a result set locator variable that has been declared according to the rules for declaring result set locator variables.

#### **WITH PROCEDURE** *procedure-name or host-variable*

Identifies the stored procedure that returned one or more result sets. When the ASSOCIATE LOCATORS statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one-part, two-part, or three-part name. The procedure name in the ASSOCIATE LOCATORS statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the ASSOCIATE LOCATORS statement.

If a host variable is used to specify the name:

- It must be a character string variable with a length attribute that is not greater than 255.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

## Notes

**Assignment of locator values:** If the ASSOCIATE LOCATORS statement specifies multiple locator variables, locator values are assigned to the locator variables in the order that the associated cursors are opened regardless of whether they are still open or not at runtime. Locator values are assigned to the locator variables in the same order that they would be placed in the SQLVAR entries in the SQLDA as a result of a DESCRIBE PROCEDURE statement.

Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later opened again before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values assigned for the following ASSOCIATE LOCATORS statement will be in the order A, C, B:

```
ASSOCIATE RESULT SET LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P1;
-- assigns locators for result set cursors A, C, and B
```

More than one locator can be associated with a result set. You can issue multiple ASSOCIATE LOCATORS statements for the same stored procedure with different result set locator variables to associate multiple locators with each result set.

- If the number of result set locator variables specified in the ASSOCIATE LOCATORS statement is less than the number of result sets returned by the stored procedure, all locator variables specified in the statement are assigned a value, and a warning is issued. For example, assume procedure P1 exists and returns four result sets. Each of the following ASSOCIATE LOCATORS statement returns information on the first result set along with a warning that not enough locators were provided to obtain information about all the result sets.

```
CALL P1;
ASSOCIATE RESULT SET LOCATORS (:loc1) WITH PROCEDURE P1;
-- :loc1 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc2) WITH PROCEDURE P1;
-- :loc2 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc3) WITH PROCEDURE P1;
-- :loc3 is assigned a value for first result set, and a warning is returned
ASSOCIATE RESULT SET LOCATORS (:loc4) WITH PROCEDURE P1;
-- :loc4 is assigned a value for first result set, and a warning is returned
```

- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the stored procedure, the extra locator variables are assigned a value of 0.

**Accessing result sets from multiple CALL statements:** An application can access to result sets created by multiple CALL statements. The result sets can be created by different procedure or by the same procedure invoked multiple times.

- *Invoking different procedures:* Invoking different procedures with the same name can be done either explicitly by specifying the different collections or implicitly with the use of the PACKAGE PATH. For example, to identify the different collections explicitly, specify qualified names on the CALL statement. Although both procedures are named P2, they are different procedures. After the second CALL statement, result sets from both procedures are accessible to the application.

```
CALL X.P2;  
CALL Y.P2;
```

The collections for the two different procedures can also be determined implicitly from the PACKAGE PATH when unqualified procedure names are specified as part of the CALL statement. For example, assume that procedure P4 exists in collections X and Z. An application contains two CALL statements to invoke procedure P4. The references to procedure P4 in the CALL statements are unqualified. So, the PACKAGE PATH special register is used to resolve the procedure name. Procedure X.P4 is invoked for the first CALL statement and procedure Z.P4 is invoked by the second CALL statement. Following the second CALL statement, result sets from both procedures are accessible to the application.

```
SET CURRENT PACKAGE PATH = X, Y, Z;  
CALL P4;  
SET CURRENT PACKAGE PATH = PATH Z, Y, X;  
CALL P4;
```

- *Invoking the same procedure multiple times:* If the server and requester are both the same version of DB2, you can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors. For more information on this situation, see Multiple calls to the same stored procedure.

When a procedure is invoked multiple times in an application and there is a need to process the result sets from the different instances at the same time, be sure to use the ASSOCIATE LOCATORS statement after each CALL statement to capture the locator values returned from each invocation of the procedure. For example, assume that procedure P exists in collection Z and that an application contains two CALL statements to invoke procedure P. The PACKAGE PATH is used to determine the collection for the procedure in the first CALL statement, and the collection is explicitly specified in the second CALL statement. Result sets from both procedures can be accessible to the application following both CALL statements if the locators for the result sets produced by the first CALL statement are captured with an ASSOCIATE LOCATOR statement before invoking the procedure the second time.

```
SET CURRENT PACKAGE PATH = X, Y, Z;  
CALL P3;  
ASSOCIATE LOCATORS ...  
CALL Z.P3;  
ASSOCIATE LOCATORS ...  
-- process the result sets using the locators
```

**Using host variables:** If the ASSOCIATE LOCATORS statement contains host variables, the following conditions apply:

- If the statement is executed statically, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.
- If the statement is executed dynamically, the contents of the host variables are assumed to be in the encoding scheme that is specified in the APPLICATION ENCODING bind option.

## Examples

The statements in the following examples are assumed to be in PL/I programs.

*Example 1:* Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets returned by stored procedure P1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL P1;
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE P1;
```

*Example 2:* Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHHEMA is used.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL MYSCHHEMA.P1;
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE MYSCHHEMA.P1;
```

*Example 3:* Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets that are returned by the stored procedure named by host variable HV1. Assume that host variable HV1 contains the value SITE2.MYSCHHEMA.P1 and the stored procedure is called with a three-part name.

```
EXEC SQL CALL SITE2.MYSCHHEMA.P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE :HV1;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSCHHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the ASSOCIATE LOCATORS statement.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL SITE2.MYSCHHEMA.P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE :HV1;
```

## BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of an SQL declare section. An SQL declare section contains declarations of host variables that are eligible to be used as host variables in SQL statements in a program.

### Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

### Authorization

None required.

### Syntax

```
►►BEGIN DECLARE SECTION—————►►
```

### Description

The BEGIN DECLARE SECTION statement can be coded in the application program wherever variable declarations can appear in accordance with the rules of the host language. It is used to indicate the beginning of a host variable declaration section. A host variable section ends with an END DECLARE SECTION statement, described in "END DECLARE SECTION" on page 1273.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) precompiler option is specified:

- A variable referred to in an SQL statement must be declared within a host variable declaration section of the source program in all host languages, other than Java and REXX. Furthermore, the declaration of each variable must appear before the first reference to the variable. Host variables are declared without the use of these statements in Java, and they are not declared at all in REXX.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- Host variable declaration sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

### Notes

Host variable declaration sections are only required if the STDSQL(YES) option is specified or the host language is C. However, declare sections can be specified for any host language so that the source program can conform to IBM SQL. If declare sections are used, but not required, variables declared outside a declare section must not have the same name as variables declared within a declare section.

## **Example**

```
EXEC SQL BEGIN DECLARE SECTION;  
    -- host variable declarations  
EXEC SQL END DECLARE SECTION;
```

---

## CALL

The CALL statement invokes a stored procedure.

### Invocation

This statement can be embedded in an application program. This statement can be executed interactively using the command line processor. Refer to *DB2 Application Programming and SQL Guide* for information about using the command line processor with the CALL statement. This statement can also be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements. IBM's ODBC and CLI drivers provide this capability.

### Authorization

Invoking a stored procedure requires the EXECUTE privilege on the following:

- The stored procedure  
You do not need the EXECUTE privilege on a stored procedure that was created prior to Version 6 of DB2 for z/OS.
- For external procedures (including external SQL procedures), additional authority is needed for the stored procedure package and most packages that run in the stored procedure.  
The authorization that is required for which packages is explained in detail in Authorization to execute packages under the stored procedure.

#### Authorization to execute the stored procedure

The authorization ID or role that must have the EXECUTE privilege on the stored procedure depends on the form of the CALL statement:

- For static SQL programs that use the syntax CALL *procedure*, the owner of the plan or package that contains the CALL statement must have one of the following:
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - SYSADM authority
- For static SQL programs that use the syntax CALL *:host-variable*, the authorization ID or role of the plan or package that contains the CALL statement must have one of the following:
  - The EXECUTE privilege on the stored procedure
  - Ownership of the stored procedure
  - SYSADM authority

The DYNAMICRULES behavior for the plan or package that contains the CALL statement determines both the authorization ID or role and the privilege set that is held by that authorization ID or role:

#### Run behavior

The privilege set is the union of the set of privileges that are held by the SQL authorization ID and each authorization ID or role of the process.

#### Bind behavior

The privilege set is the privileges that are held by the primary authorization ID of the owner of the package or plan.

### Define behavior

The privilege set is the privileges that are held by the authorization ID or role of the owner (definer) of the stored procedure or user-defined function that issued the CALL statement.

### Invoke behavior

The privilege set is the privileges that are held by the authorization ID or role of the invoker of the stored procedure or user-defined function that issued the CALL statement. However, if the invoker is the primary authorization ID of the process or the CURRENT SQLID value, the privilege set is the union of the set of privileges that are held by each authorization ID or role.

For a list of the DYNAMICRULES values that specify run, bind, define, or invoke behavior, see Table 6 on page 64.

## Authorization to execute packages under the stored procedure (including nested stored procedures)

The authorization that is required to run the stored procedure package and any packages that are used under the stored procedure (including nested stored procedures) apply to any form of the CALL statement as follows:

- *Stored procedure package*: One of the authorization IDs or roles that are defined in Set of authorization IDs must have at least one of the following privileges or authorities on the stored procedure package:
  - The EXECUTE privilege
  - Ownership of the package
  - PACKADM authority for the package's collection
  - SYSADM authority

A PKLIST entry is not required for the stored procedure package.

- *User-defined function packages and trigger packages*: If a stored procedure or any application under the stored procedure invokes a user-defined function, DB2 requires only the owner (the definer), and not the invoker of the user-defined function, to have EXECUTE authority on the user-defined function package. However, the authorization ID or role of the SQL statement that invokes the user-defined function must have EXECUTE authority on the function.

Similarly, if a trigger is used under a stored procedure, DB2 does not require EXECUTE authority on the trigger package; however, the authorization ID or role of the SQL statement that activates the trigger must have EXECUTE authority on the trigger.

For more information about the EXECUTE authority for user-defined functions, triggers, and user-defined function packages, see *DB2 Administration Guide*.

PKLIST entries are not required for any user-defined function packages or trigger packages that are used under the stored procedure.

- *Packages other than user-defined function, trigger, and stored procedure packages*: One of the authorization IDs or roles that is defined below under Set of authorization IDs must have at least one of the following privileges or authorities on any packages other than user-defined function and trigger packages that are used under the stored procedure:
  - The EXECUTE privilege
  - Ownership of the package
  - PACKADM authority for the package's collection

- SYSADM authority

PKLIST entries are required for any of these packages that are used under the stored procedure.

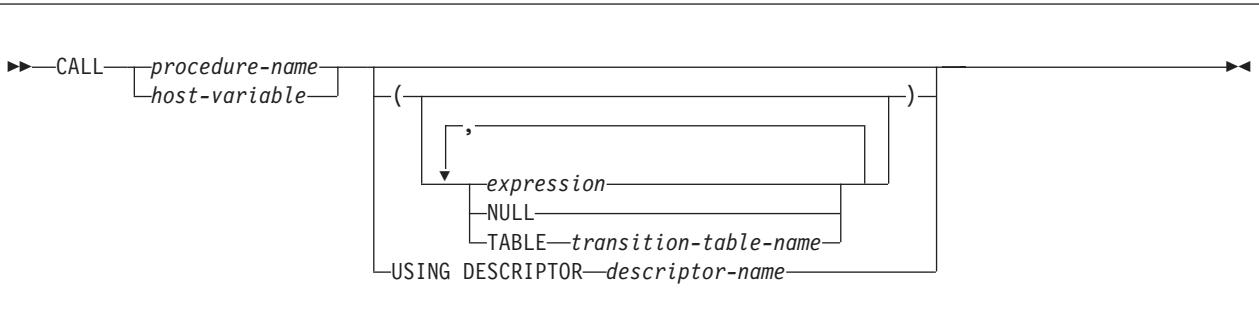

For improved performance and simplicity, consider granting the EXECUTE ON PACKAGE privilege for the stored procedure package, and for any packages that run under the stored procedure, to the owner of the stored procedure.

**Set of authorization IDs:** DB2 checks the following authorization IDs, in the order in which they are listed, for the required authorization to execute the stored procedure package and any packages that run under the stored procedure other than user-defined function and trigger packages as described previously.

Authorization checking ends after the first authorization ID that has EXECUTE ON PACKAGE privileges for the target package is found:

- The owner (the definer) of the stored procedure.
- The owner of the plan that contains the CALL statement that invokes the stored procedure if the calling application (a package or a DBRM that is bound directly to the plan) is local or if the calling application is distributed and DB2 for z/OS is both the requester and the server.
- The owner of the package that contains the CALL statement that invokes the stored procedure if the calling application is distributed and DB2 for z/OS is the server but not the requester, or if the calling application uses Recoverable Resources Management Services attachment facility (RRSAF) and has no plan.
- The authorization ID as determined by the value of the DYNAMICRULES bind option for the plan or package that contains the CALL statement if the CALL statement is in the form of CALL *:host-variable*.
  - If the calling application is bound with the DYNAMICRULES(RUN) option, DB2 checks either the authorization ID of the process at run time and its secondary authorization IDs or the single authorization ID that is determined by the other DYNAMICRULES bind option values.
  - If the calling application is bound with a value other than DYNAMICRULES(RUN), DB2 checks only a single authorization ID, even if that ID fails the EXECUTE ON PACKAGE authorization check.
  - If the calling application is a package and is bound with DYNAMICRULES(BIND), DB2 checks the authorization ID of the package owner. DB2 does not check the authorization ID of the plan owner.

## Syntax

## Description

*procedure-name or host-variable*

Identifies the procedure to call by the specified *procedure-name* or the procedure name contained in the *host-variable*. The identified procedure must exist at the current server.

If *procedure-name* specifies any of the three special characters that are alphabetic extenders for national languages, \$#@, specify the procedure name with a *host-variable*.

If a host variable is used:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

In addition, the specification can:

- Contain upper and lowercase characters. Lowercase characters are not folded to uppercase.
- Use a delimited identifier for any part of a three-part procedure name.

If the server is DB2 for z/OS, the specification must be a procedure name as defined above.

When the CALL statement is executed, the procedure name or specification must identify a stored procedure that exists at the server.

When the package that contains the CALL statement is bound, the stored procedure that is invoked must be created if VALIDATE(BIND) is specified. Although the stored procedure does not need to be created at bind time if VALIDATE(RUN) is specified, it must be created when the CALL statement is executed.

*expression, NULL, or TABLE transition-table-name*

Identifies a list of values to be passed as parameters to the stored procedure. If USING DESCRIPTOR is specified, each host variable described by the identified SQLDA is a parameter, or part of an expression that is a parameter, of the CALL statement. If host structures are not specified in the CALL statement, the *n*th parameter of the CALL statement corresponds to the *n*th parameter in the stored procedure, and the number of parameters in each must be the same. Otherwise, each reference to a host structure is replaced by a reference to each of the variables contained in that host structure, and the resulting number of parameters must be the same as the number of parameters defined for the stored procedure.

However, a character FOR BIT DATA parameter cannot be passed as input for a parameter that is not defined as character FOR BIT DATA. Likewise, a character argument that is not FOR BIT DATA cannot be passed as input for a parameter that is defined as character FOR BIT DATA.

Each parameter of a stored procedure is described at the server. In addition to attributes such as data type and length, the description of each parameter indicates how the stored procedure uses it.

- IN means as an input value
- OUT means as an output value
- INOUT means both as an input and an output value

When the CALL statement is executed, the value of each of its parameters is assigned to the corresponding parameter of the stored procedure. In cases where the parameters of the CALL statement are not an exact match to the data types of the parameters of the stored procedure, each parameter specified in the CALL statement is converted to the data type of the corresponding parameter of the stored procedure at execution. The conversion occurs according to the same rules as assignment to columns. For details on the rules used to assign parameters, see “Assignment and comparison” on page 102.

Conversion can occur when precision, scale, length, encoding scheme, or CCSID differ between the parameter specified in the CALL statement and the data type of the corresponding parameter of the stored procedure. Conversion might occur for a character string parameter specified in the CALL statement when the corresponding parameter of the stored procedure has a different encoding scheme or CCSID. For example, an error occurs when the CALL statement passes mixed data that actually contains DBCS characters as input to a parameter of the stored procedure that is declared with an SBCS subtype. Likewise, an error occurs when the stored procedure returns mixed data that actually contains DBCS characters in the parameter of the CALL statement that has an SBCS subtype.

Control is passed to the stored procedure according to the calling conventions of the host language. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

#### *expression*

The parameter is the result of the specified expression, which is evaluated before the stored procedure is invoked.

If *expression* is a single host variable, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. In addition, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables. A reference to a host structure is replaced by a reference to each of the variables contained in the host structure.

If the result of the expression can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple host variables. In addition to the rules stated in “Expressions” on page 180 for *expression*, *expression* cannot include a column name, a scalar subselect, a file reference variable, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single host variable. *expression* cannot include a file reference variable.

## **NULL**

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

## **TABLE *transition-table-name***

The parameter is a transition table, and it is passed to the procedure as a table locator. You can use the CALL statement with the TABLE clause only within the definition of the triggered action of a trigger. The name of a transition table must be specified in the CALL statement if the corresponding parameter of the procedure was defined in the TABLE LIKE clause of the CREATE PROCEDURE statement. For information about creating a trigger, see “CREATE TRIGGER” on page 1151 and *DB2 Application Programming and SQL Guide*.

There is no effect on the transition table on the return from the procedure regardless of whether the parameter was defined as IN, INOUT, or OUT.

## **USING DESCRIPTOR *descriptor-name***

Identifies an SQLDA that contains a valid description of the host variables that are to be passed as parameters to the stored procedure. If the stored procedure has no parameters, an SQLDA is ignored.

Before the CALL statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA. This number must not be less than SQLD. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA. This number must be not be less than SQLN\*44+16. This field is not part of the REXX SQLDA and therefore does not need to be set for REXX programs.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement. This number must be the same as the number of parameters of the stored procedure.
- SQLVAR occurrences to indicate the attributes of the variables.

There are additional considerations for setting the fields of the SQLDA when a variable that is passed as a parameter to the stored procedure has a LOB data type or is a LOB locator. For more information, see “SQL descriptor area (SQLDA)” on page 1656.

The SQL CALL statement ignores distinct type information in the SQLDA. Only the base SQL type information is used to process the input and output parameters described by the SQLDA.

See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

## **Notes**

**Procedure signatures:** A procedure is identified by its schema, a procedure name, and its number of parameters. This is called a procedure signature, which must be unique within the database. DB2 for z/OS does not support overloaded procedure names (procedures with the same schema and procedure name, but with different numbers of parameters).

**SQL path:** A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments that are enclosed in parentheses. A procedure can also be invoked without the schema name, which results in a choice of possible procedures in different schemas that have the same procedure name and same number of parameters. In this case, the SQL path is used to assist in procedure resolution. The SQL path is a list of schemas that is searched to identify a procedure with the same name and number of parameters as the procedure in the CALL statement. For CALL statements that explicitly specify a procedure name, the SQL path is specified by using the platform-specific bind option. For CALL *host-variable* statements, the SQL path is the value of the CURRENT PATH special register when the procedure is invoked.

**Procedure resolution:** Given a procedure invocation, the database manager must decide which of the possible procedures that has the same name to call.

A procedure name is a qualified or unqualified name. Each part of the name must be composed of SBCS characters:

- A fully qualified procedure name is a three-part name. The first part is an SQL identifier that contains the location name that identifies the DBMS at which the procedure is stored. The second part is an SQL identifier that contains the schema name of the stored procedure. The last part is an SQL identifier that contains the name of the stored procedure. A period must separate each of the parts. Any or all of the parts can be a delimited identifier.
- A two-part procedure name has one implicit qualifier. The implicit qualifier is the location name of the current server. The two parts identify the schema name and the name of the stored procedure. A period must separate the two parts.
- An unqualified procedure name is a one-part name with two implicit qualifiers. The first implicit qualifier is the location name of the current server. The second implicit qualifier depends on the server. If the server is DB2 for z/OS, the implicit qualifier is the schema name. DB2 uses the SQL path to determine the value of the schema name.
  - If the procedure name is specified as a string constant on the CALL statement (CALL *procedure-name*), the SQL path is the value of the PATH bind option that is associated with the calling package or plan.
  - If a host variable is specified for the procedure name on the CALL statement (CALL *host-variable*), the SQL path is the value of the CURRENT PATH special register.

DB2 searches the schema names in the SQL path from left to right until a stored procedure with the specified schema name is found in the DB2 catalog. When a matching *schema.procedure-name* is found, the search stops only if the following conditions are true:

- The user is authorized to call the stored procedure.
- The number of parameters in the definition of the stored procedure matches the number of parameters specified on the CALL statement.

If the list of schemas in the SQL path is exhausted before the procedure name is resolved, an error is returned.

When the procedure is resolved depends on how the procedure name is specified. For a CALL statement that specifies the procedure name using a host variable, procedure resolution occurs at runtime. For a CALL statement that contains the name of the procedure as an identifier, procedure resolution occurs when the CALL statement is bound.

Procedure resolution is done by the database manager using the following steps:

1. Find all procedures from the catalog where all of the following conditions are true:
  - For invocations where the schema name is specified (qualified references), the schema name and the procedure name match the invocation name.
  - For invocations where the schema name is not specified (unqualified references), the procedure name matches the invocation name, and the procedure has a schema name that matches one of the schemas in the SQL path.
  - The number of defined parameters matches the number of arguments that are specified in the invocation.
  - The invoker has the EXECUTE privilege on the procedure.
2. Of the candidate procedures that remain from step 1, choose the procedure whose schema is first in the SQL path. If no candidate procedures remain after step 1, an error is returned.
3. For CALL statements that use a host variable to specify the procedure name, the CURRENT ROUTINE VERSION special register can affect which version of the native SQL procedure is invoked. If the CURRENT ROUTINE VERSION special register is set, check if there is a version of the procedure with that version name. If not, choose the currently active version of the procedure.  
For CALL statements that do not use a host variable to specify the procedure name, choose the currently active version of the procedure.

**Version resolution:** Normally, the currently active version of a native SQL procedure will be used on a CALL statement. However, if the CALL statement is a recursive call inside the body of the same stored procedure, and the original CALL statement uses a version that is different from the currently active version, the active version will not be used. The version from the original CALL statement will be used for any recursive CALL statements until the entire stored procedure finishes executing. This preserves the semantics of the version that is used by the original CALL statement. This includes the case where the recursive call is indirect. For example, assume that procedure SP1 call procedure SP2, which in turn recursively calls SP1. The second invocation of procedure SP1 will use the version of the procedure that is active at the time of the original CALL statement that invoked procedure SP1.

Since the currently active version can be used at the next CALL statement, it is possible that two or more versions of the same procedure can run at the same time. There could be different versions of an SQL procedure loaded by a given thread. For example, a CALL SP1 statement in an application will cause the currently active version, SP1\_V1, to load and execute. After this CALL statement has completed, an ALTER PROCEDURE ALTER ACTIVE VERSION could execute and change the active version of the procedure SP1 to version SP1\_V2. Subsequent CALL SP1 statements from the same thread will load the currently active version of the procedure, SP1\_V2, and execute it.

**Parameter assignments:** When the CALL statement is executed, the value of each of its parameters is assigned with storage assignment rules to the corresponding parameter of the procedure. Control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned with storage assignment rules to the corresponding parameter of the CALL statement defined as OUT or INOUT. If an error is returned by the procedure, OUT arguments are

undefined and INOUT arguments are unchanged. For details on the assignment rules, see “Assignment and comparison” on page 102.

**Cursors and prepared statements in procedures:** All cursors opened in the called procedure that are not result set cursors are closed and all statements prepared in the called procedure are destroyed when the procedure ends.

**Result sets from procedures:** Any cursors specified using the WITH RETURN clause that the procedure leaves open when it returns identifies a result set. In a procedure written in Java, all cursors are implicitly defined WITH RETURN.

Results sets are returned only when the procedure is called from CLI, JDBC, or SQLJ. If the procedure was invoked from CLI or Java, and more than one cursor is left open, the result sets can only be processed in the order in which the cursors were opened. Only unread rows are available to be fetched. For example, if the result set of a cursor has 500 rows, and 150 of those rows have been read by the procedure at the time the procedure is terminated, then rows 151 through 500 will be returned to the procedure.

**Errors from procedures:** A procedure can return errors or warnings using an SQLSTATE-like SQL statement. Applications should be aware of the possible SQLSTATES that can be expected when a procedure is invoked. The possible SQLSTATES depend on how the procedure is coded. Procedures might also return SQLSTATES such as those that begin with '38' or '39' if DB2 encounters problems executing the procedure. Applications should therefore be prepared to handle any error SQLSTATE that can result from issuing a CALL statement.

**Improving performance:** The capability of calling stored procedures is provided to improve the performance of DRDA distributed access(DB2 private protocol access is not supported). The capability is also useful for local operations. The server can be the local DB2. In which case, packages are still required.

All values of all parameters are passed from the requester to the server. To improve the performance of this operation, host variables that correspond to OUT parameters and have lengths of more than a few bytes should be set to null before the CALL statement is executed.

**Using the CALL statement in a trigger:** When a trigger issues a CALL statement to invoke a stored procedure, the parameters that are specified in the CALL statement cannot be host variables and the USING DESCRIPTOR clause cannot be specified.

**Nesting CALL statements:** A program that is executing as a stored procedure, a user-defined function, or a trigger can issue a CALL statement. When a stored procedure, user-defined function, or trigger calls a stored procedure, user-defined function, or trigger, the call is considered to be nested. Stored procedures, user-defined functions, and triggers can be nested up to 16 levels deep on a single system. Nesting can occur within a single DB2 subsystem or when a stored procedure or user-defined function is invoked at a remote server.

If a stored procedure returns any query result sets, the result sets are returned to the caller of the stored procedure. If the SQL CALL statement is nested, the result sets are visible only to the program that is at the previous nesting level. For example, Figure 18 on page 883 illustrates a scenario in which a client program calls stored procedure PROCA, which in turn calls stored procedure PROCB. Only PROCA can access any result sets that PROCB returns; the client program has no access to the query result sets. The number of query result sets that PROCB returns

does not count toward the maximum number of query results that PROCA can return.

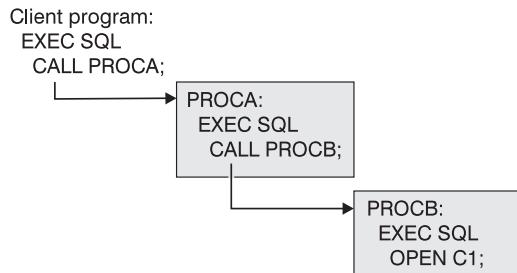

Figure 18. Nested CALL statements

Some stored procedures cannot be nested. A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN attribute.

**Multiple calls to the same stored procedure:** If the server and requester are both Version 8 or later of DB2 for z/OS (running in new-function mode), you can call a stored procedure multiple times within an application and at the same nesting level. Each call to the same stored procedure causes a unique instance of the stored procedure to run. If the stored procedure returns result sets, each instance of the stored procedure opens its own set of result set cursors.

The application might receive a "resource unavailable message" if the CALL statement causes the values of the maximum number of active stored procedures or maximum number open cursors to be exceeded. The value of field MAX STORED PROCEDURES (on installation panel DSNTIPX) defines the maximum number of active stored procedures that are allowed per thread. The value of field MAX OPEN CURSORS (on installation panel DSNTIPX) defines the maximum number of open cursors (both result set cursors and regular cursors) that are allowed per thread.

If you make multiple calls to the same stored procedure within an application, be aware of the following considerations:

- A DESCRIBE PROCEDURE statement describes the last instance of the stored procedure.
- The ASSOCIATE LOCATORS statement works on the last instance of the stored procedure.
- The ALLOCATE CURSOR statement must specify a unique cursor name for a result set returned from an instance of the stored procedure. Otherwise, you will lose the data from the result sets that are returned from prior instances or calls to the stored procedure.

You should issue an ASSOCIATE LOCATORS statement (or DESCRIBE PROCEDURE statement) after each call to the stored procedure to get a unique locator value for each result set.

**Using host variables:** If the CALL statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Examples

*Example 1:* A PL/I application has been precompiled on DB2 ALPHA and a package was created at DB2 BETA with the BIND subcommand. A CREATE PROCEDURE statement was issued at BETA to define the procedure SUMARIZE, which allows nulls and has two parameters. The first parameter is defined as IN and the second parameter is defined as OUT. Some of the statements that the application that runs at DB2 ALPHA might use to call stored procedure SUMARIZE include:

```
EXEC SQL CONNECT TO BETA;
V1 = 528671;
IV = -1;
EXEC SQL CALL SUMARIZE(:V1,:V2 INDICATOR :IV);
```

*Example 2:* Assume that stored procedure MYPROC exists and produces several result sets. An application might include statements like the following to access the result sets produced by MYPROC:

```
-- Invoke stored procedure MYPROC that returns several result sets
EXEC SQL CALL MYPROC (...);
-- Copy the locator values for the result sets into result set locator variables
EXEC SQL ASSOCIATE RESULT SET LOCATORS (:RS1, :RS2, :RS3) WITH PROCEDURE MYPROC;
-- Allocate cursors for the result set cursors
EXEC SQL ALLOCATE CSR1 CURSOR FOR RESULT SET :RS1;
EXEC SQL ALLOCATE CSR2 CURSOR FOR RESULT SET :RS2;
EXEC SQL ALLOCATE CSR3 CURSOR FOR RESULT SET :RS3;
-- Process data returned with the result set cursors
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH CSR1 INTO .....
END;
EXEC SQL CLOSE CSR1;
-- do similar processing with other result sets
...
```

## CLOSE

The CLOSE statement closes a cursor. If a temporary copy of a result table was created when the cursor was opened, that table is destroyed.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

### Authorization

See “DECLARE CURSOR” on page 1191 for the authorization required to use a cursor.

### Syntax

```
►►CLOSE—cursor-name—————►►
```

### Description

*cursor-name*

Identifies the cursor to be closed. The cursor name must identify a declared cursor as explained in “DECLARE CURSOR” on page 1191. When the CLOSE statement is executed, the cursor must be in the open state.

### Notes

*Implicit cursor close:* At the end of a unit of work, all open cursors declared without the WITH HOLD option that belong to an application process are implicitly closed.

*Close cursors for performance:* Explicitly closing cursors as soon as possible can improve performance.

*Procedure considerations:* Special rules apply to cursors within procedures that have not been closed before returning to the calling program. For more information, see “CALL” on page 874.

*Allocated cursors:* The cursor could have been allocated. See “ALLOCATE CURSOR” on page 696.

### Example

A cursor is used to fetch one row at a time into the application program variables DNUM, DNAME, and MNUM. Finally, the cursor is closed. If the cursor is reopened, it is again located at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DSN8910.DEPT
      WHERE ADMRDEPT = 'A00'
      END-EXEC.
```

```
EXEC SQL OPEN C1 END-EXEC.  
  
EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.  
  
IF SQLCODE = 100  
    PERFORM DATA-NOT-FOUND  
ELSE  
    PERFORM GET-REST-OF-DEPT  
    UNTIL SQLCODE IS NOT EQUAL TO ZERO.  
  
EXEC SQL CLOSE C1 END-EXEC.  
  
GET-REST-OF-DEPT.  
    EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM END-EXEC.
```

---

## COMMENT

The COMMENT statement adds or replaces comments in the descriptions of various objects in the DB2 catalog at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

For a comment on a table, view, alias, index, or column, the privilege set that is defined below must include at least one of the following:

- Ownership of the table, view, alias, or index
- DBADM authority for its database (tables and indexes only)
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

For a comment on a distinct type, stored procedure, trigger, or user-defined function, the privilege set that is defined below must include at least one of the following:

- Ownership of the distinct type, stored procedure, trigger, or user-defined function
- The ALTERIN privilege on the schema (for the addition of comments)
- SYSADM or SYSCTRL authority

For a comment on a package, the privilege set that is defined below must include at least one of the following:

- Ownership of the plan or package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

For a comment on a plan, the privilege set that is defined below must include at least one of the following:

- Ownership of the plan or package
- The BINDAGENT privilege granted from the plan owner
- SYSADM or SYSCTRL authority

For a comment on a role or a trusted context, the privilege set that is defined below must include at least one of the following:

- Ownership of the object
- SYSADM or SYSCTRL authority

For a comment on a sequence, the privilege set that is defined below must include at least one of the following:

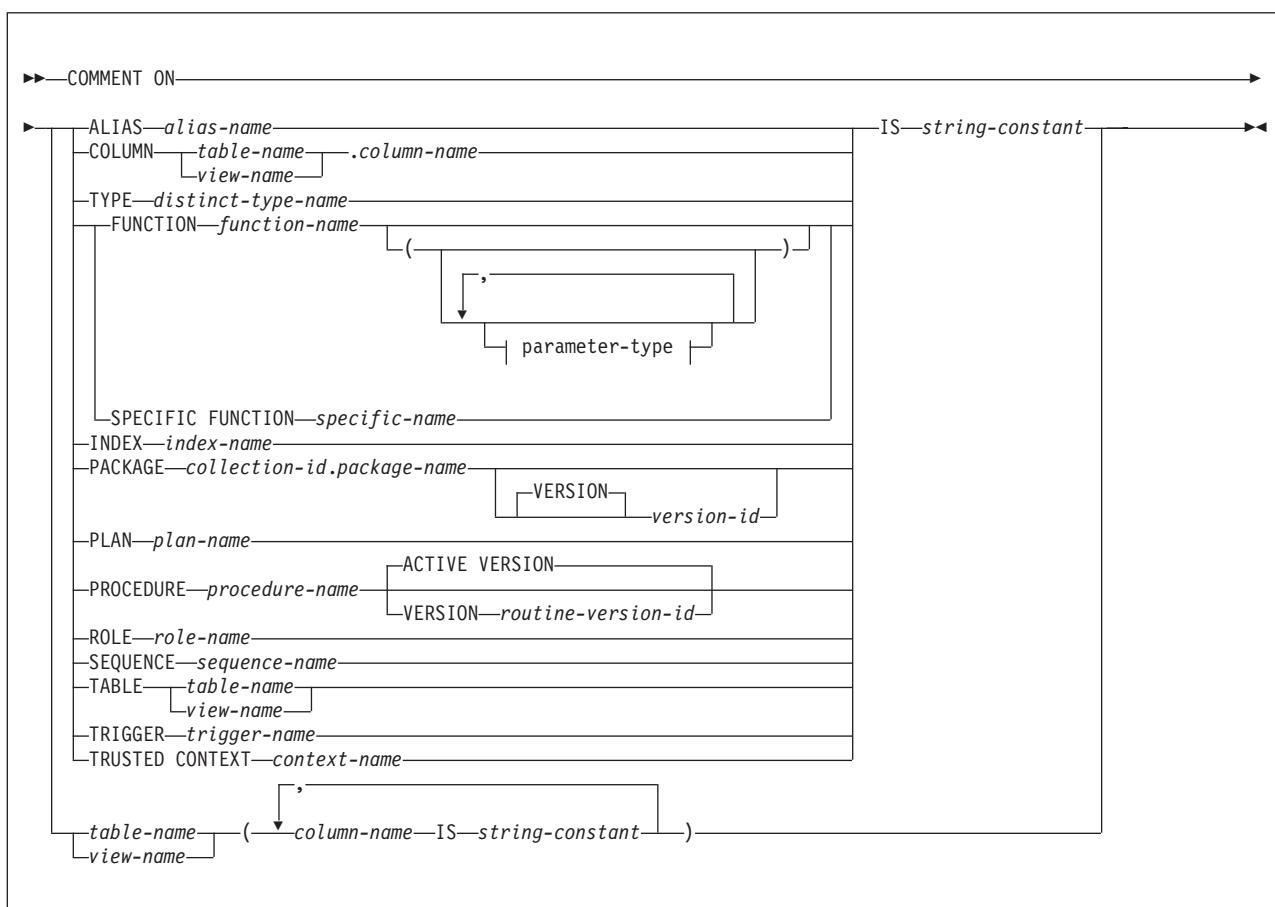

- Ownership of the sequence
- The ALTER privilege for the sequence

- The ALTERIN privilege on the schema
  - SYSADM or SYSCTRL authority

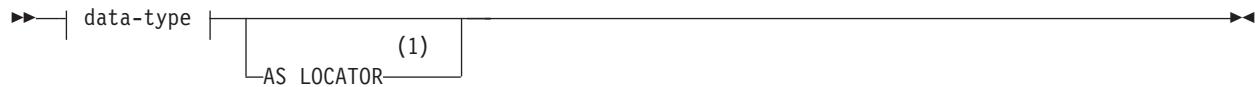

The authorization ID that matches the schema name implicitly has the `ALTERIN` privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

## Syntax

## parameter-type

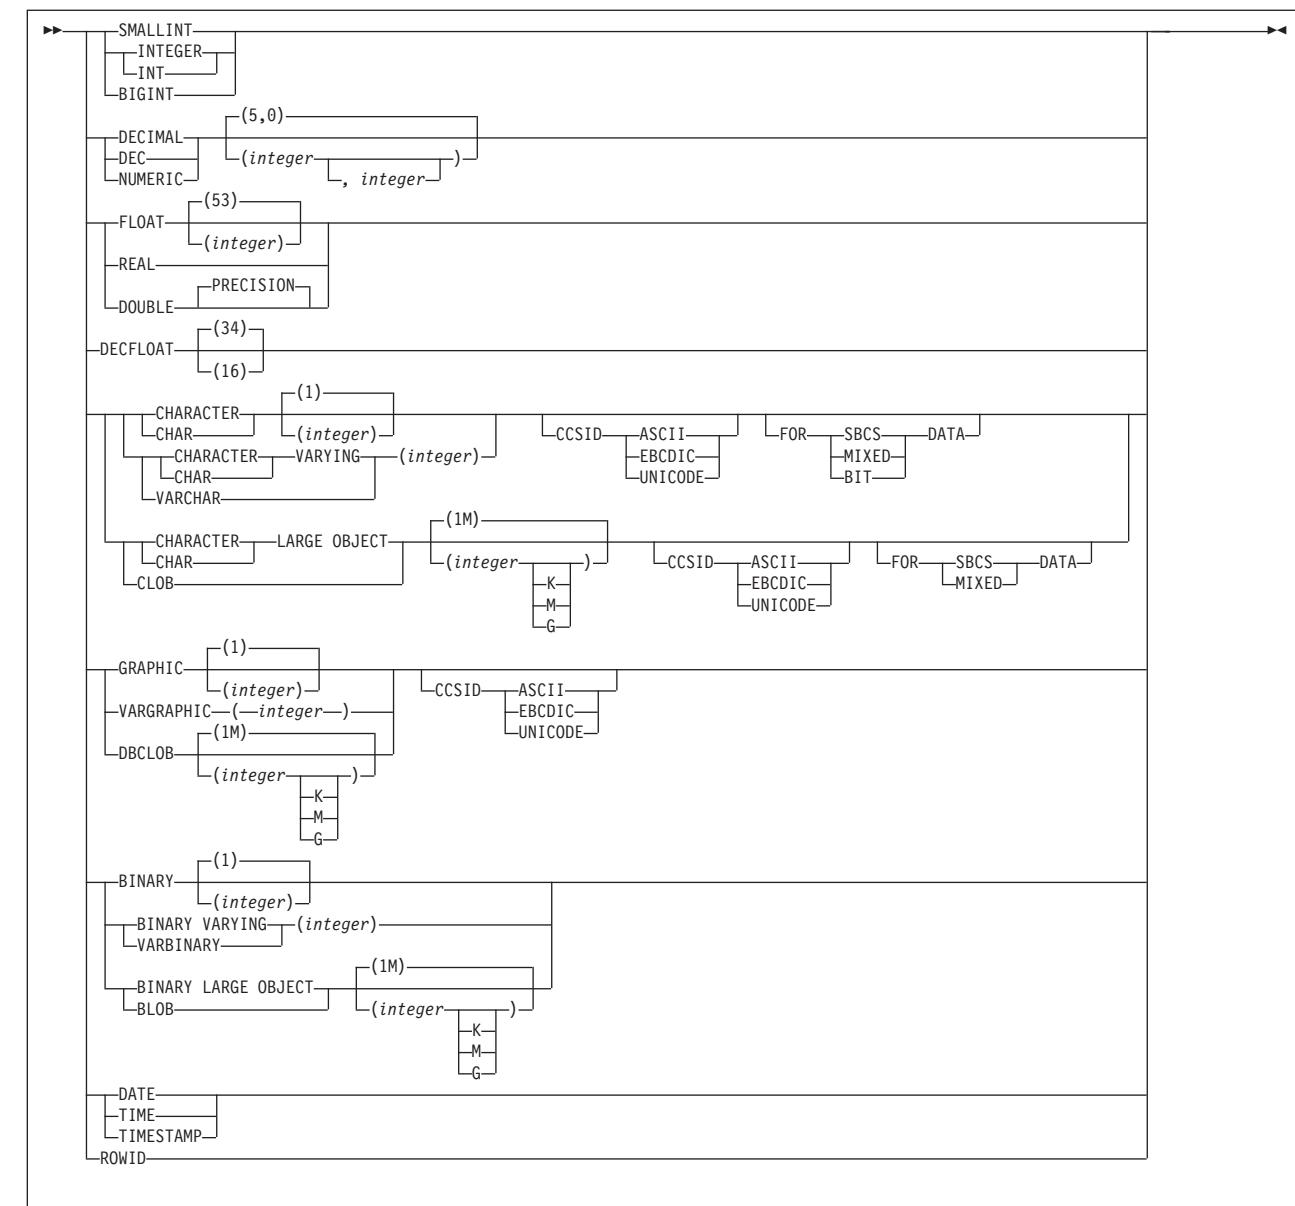

**Notes:**

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type that is based on a LOB data type.

**data-type**

**built-in-type**

## Description

### **ALIAS** *alias-name*

Identifies the alias to which the comment applies. *alias-name* must identify an alias that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.

### **COLUMN** *table-name.column-name or view-name.column-name*

Identifies the column to which the comment applies. The name must identify a column of a table or view that exists at the current server. The name must not identify a column of a declared temporary table. The comment is placed into the REMARKS column of the SYSIBM.SYSCOLUMNS catalog table, for the row that describes the column.

**Do not use TABLE or COLUMN to comment on more than one column in a table or view.** Give the table or view name and then, in parentheses, a list in the form:

```
column-name IS string-constant,  
column-name IS string-constant,...
```

The column names must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

#### **FUNCTION or SPECIFIC FUNCTION**

Identifies the function to which the comment applies. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The comment is placed in the REMARKS column of the SYSIBM.SYSROUTINES catalog table for the row that describes the function.

The function can be identified by its name, function signature, or specific name. If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), you must identify the function with its function name, if it is unique, or with its specific name.

#### **FUNCTION *function-name***

Identifies the function by its function name. There must be exactly one function with *function-name* in the schema. The function can have any number of input parameters. If the schema does not contain a function with *function-name*, or if the schema contains more than one function with this name, an error is returned.

#### **FUNCTION *function-name* (*parameter-type*,...)**

Identifies the function by its function signature, which uniquely identifies the function. The *function-name* (*parameter-type*,...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types and the logical concatenation of the data types is used to identify the specific function instance to which the comment applies. Synonyms for data types are considered a match. The rules for function resolution (and the SQL path) are not used.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name()* is specified, the function that is identified must have zero parameters.

#### *function-name*

Identifies the name of the function.

#### *(parameter-type*,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parenthesis indicates that the data base manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional. Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

#### **AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

#### **SPECIFIC FUNCTION *specific-name***

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

#### **INDEX *index-name***

Identifies the index to which the comment applies. *index-name* must identify an index that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSINDEXES catalog table for the row that describes the index.

#### **PACKAGE *collection-id.package-name***

Identifies the package to which the comment applies. You must qualify the package name with a collection ID. *collection-id.package-name* must identify a package that exists at the current server. The name plus the implicitly or explicitly specified *version-id* must identify a package that exists at the current server. Omission of the *version-id* is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. Specify this clause to comment on a package that was created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

#### **VERSION *version-id***

*version-id* is the version identifier that was assigned to the package's DBRM when the DBRM was created. If *version-id* is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in *DB2 Application Programming and SQL Guide*.

**PLAN** *plan-name*

Identifies the plan to which the comment applies. *plan-name* must identify a plan that exists at the current server.

**PROCEDURE** *procedure-name*

Identifies the procedure to which the comment applies. *procedure-name* must identify a procedure that exists at the current server.

**ACTIVE VERSION**

Specifies that the comment applies to the currently active version of the routine that is specified by *procedure-name*.

**ACTIVE VERSION** is the default.

**VERSION** *routine-version-id*

Specifies that the comment applies only to the version of the routine that is identified by *routine-version-id*. *routine-version-id* must identify a version of the specified routine that already exists at the current server. If *routine-version-id* is not specified, a null string is used as the version identifier.

**ROLE** *role-name*

Identifies the role to which the comment applies. *role-name* must identify a role that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSROLES catalog table for the row that describes the role.

**SEQUENCE** *sequence-name*

Identifies the sequence to which the comment applies.

*sequence-name* must identify a sequence that exists at the current server.

*sequence-name* must not be the name of an internal sequence object that is used by DB2. The comment is placed in the REMARKS column of the SYSIBM.SYSSEQUENCES catalog table for the row that describes the sequence.

**TABLE** *table-name or view-name*

Identifies the table or view to which the comment applies. *table-name or view-name* must identify a table, auxiliary table, or view that exists at the current server. *table-name* must not identify a declared temporary table. The comment is placed in the REMARKS column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

**TRIGGER** *trigger-name*

Identifies the trigger to which the comment applies. *trigger-name* must identify a trigger that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSTRIGGERS catalog table for the row that describes the trigger.

**TRUSTED CONTEXT** *context-name*

Identifies the trusted context to which the comment applies. *context-name* must identify a trusted context that exists at the current server. The comment is

placed in the REMARKS column of the SYSIBM.SYSCONTEXT catalog table for the row that describes the trusted context.

**TYPE** *distinct-type-name*

Identifies the distinct type to which the comment applies. *distinct-type-name* must identify a distinct type that exists at the current server. The comment is placed in the REMARKS column of the SYSIBM.SYSDATATYPES catalog table for the row that describes the distinct type.

**IS** *string-constant*

Introduces the comment that you want to make. *string-constant* can be any SQL character string constant of up to 762 bytes.

## Notes

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

## Examples

*Example 1:* Enter a comment on table DSN8910.EMP.

```
COMMENT ON TABLE DSN8910.EMP  
IS 'REFLECTS 1ST QTR 81 REORG';
```

*Example 2:* Enter a comment on view DSN8910.VDEPT.

```
COMMENT ON TABLE DSN8910.VDEPT  
IS 'VIEW OF TABLE DSN8910.DEPT';
```

*Example 3:* Enter a comment on the DEPTNO column of table DSN8910.DEPT.

```
COMMENT ON COLUMN DSN8910.DEPT.DEPTNO  
IS 'DEPARTMENT ID - UNIQUE';
```

*Example 4:* Enter comments on the two columns in table DSN8910.DEPT.

```
COMMENT ON DSN8910.DEPT  
(MGRNO IS 'EMPLOYEE NUMBER OF DEPARTMENT MANAGER',  
ADMREPT IS 'DEPARTMENT NUMBER OF ADMINISTERING DEPARTMENT');
```

*Example 5:* Assume that you are SMITH and that you created the distinct type DOCUMENT in schema SMITH. Enter comments on DOCUMENT.

```
COMMENT ON TYPE DOCUMENT  
IS 'CONTAINS DATE, TABLE OF CONTENTS, BODY, INDEX, and GLOSSARY';
```

*Example 6:* Assume that you are SMITH and you know that ATOMIC\_WEIGHT is the only function with that name in schema CHEM. Enter comments on ATOMIC\_WEIGHT.

```
COMMENT ON FUNCTION CHEM.ATOMIC_WEIGHT  
IS 'TAKES ATOMIC NUMBER AND GIVES ATOMIC WEIGHT';
```

*Example 7:* Assume that you are SMITH and that you created the function CENTER in schema SMITH. Enter comments on CENTER, using the signature to uniquely identify the function instance.

```
COMMENT ON FUNCTION CENTER (INTEGER, FLOAT)  
IS 'USES THE CHEBYCHEV METHOD';
```

*Example 8:* Assume that you are SMITH and that you created another function named CENTER in schema JOHNSON. You gave the function the specific name FOCUS97. Enter comments on CENTER, using the specific name to identify the function instance.

```
COMMENT ON SPECIFIC FUNCTION JOHNSON.FOCUS97  
IS 'USES THE SQUARING TECHNIQUE';
```

*Example 9:* Assume that you are SMITH and that procedure OSMOSIS is in schema BIOLOGY. Enter comments on OSMOSIS. Your comments will apply to the currently active version of the procedure OSMOSIS.

```
COMMENT ON PROCEDURE BIOLOGY.OSMOSIS  
IS 'CALCULATIONS THAT MODEL OSMOSIS';
```

*Example 11:* Assume that you are SMITH and that trigger BONUS is in your schema. Enter comments on BONUS.

```
COMMENT ON TRIGGER BONUS  
IS 'LIMITS BONUSES TO 10% OF SALARY';
```

*Example 12:* Provide a comment for package MYPKG, which is in collection COLLIDA.

```
COMMENT ON COLLIDA.MYPKG  
IS 'THIS IS MY PACKAGE';
```

*Example 14:* Provide a comment on role ROLE1:

```
COMMENT ON ROLE ROLE1  
IS 'Role defined for trusted context, ctx1';
```

*Example 15:* Provide a comment on trusted context CTX1:

```
COMMENT ON TRUSTED CONTEXT CTX1  
IS 'WEBSPHERE SERVER';
```

## COMMIT

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work.

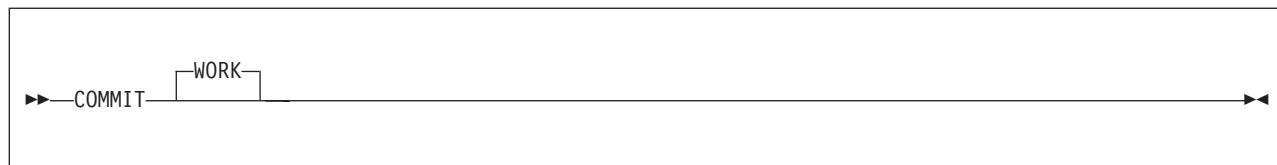

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It cannot be used in the IMS or CICS environment.

### Authorization

None required.

### Syntax

### Description

The COMMIT statement ends the unit of recovery in which it is executed and a new unit of recovery is started for the process. The statement commits all changes made by SQL schema statements and SQL data change statements during the unit of work. For more information see Chapter 5, "Statements," on page 683.

### Notes

**Recommended coding practices:** Code an explicit COMMIT or ROLLBACK statement at the end of an application process. Either an implicit commit or rollback operation will be performed at the end of an application process depending on the application environment. Thus, a portable application should explicitly execute a COMMIT or ROLLBACK statement before execution ends in those environments where explicit COMMIT or ROLLBACK is permitted.

**Effect of COMMIT:** All savepoints that are set within the unit of recovery are released, and all changes are committed for the following statements that are executed during the unit of recovery:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL

- MERGE
- RENAME
- REVOKE
- UPDATE
- SELECT INTO with an SQL data change statement
- subselect with an SQL data change statement

SQL connections are ended when any of the following conditions apply:

- The connection is in the release pending status
- The connection is not in the release pending status but it is a remote connection and:
  - The DISCONNECT(AUTOMATIC) bind option is in effect, or
  - The DISCONNECT(CONDITIONAL) bind option is in effect and an open WITH HOLD cursor is not associated with the connection.

For existing connections, all LOB locators are disassociated, except for those locators for which a HOLD LOCATOR statement has been issued without a corresponding FREE LOCATOR statement. All open cursors that were declared without the WITH HOLD option are closed. All open cursors that were declared with the WITH HOLD option are preserved, along with any SELECT statements that were prepared for those cursors. All other prepared statements are destroyed unless dynamic caching is enabled for your system. In that case, all prepared SELECT and data change statements that are bound with DYNAMICKEEP(YES) are kept past the commit.

Prepared statements cannot be kept past a commit if any of the following conditions is true:

- SQL RELEASE has been issued for that site.
- Bind option DISCONNECT(AUTOMATIC) was used.
- Bind option DISCONNECT(CONDITIONAL) was used and there are no hold cursors for that site.

All implicitly acquired locks are released, except for the following locks:

- Locks that are required for the cursors that were not closed
- Table and table space locks when the RELEASE parameter on the bind command was not RELEASE(COMMIT)
- LOB locks and LOB table space locks that are required for held LOB locators

For an explanation of the duration of explicitly acquired locks, see *DB2 Performance Monitoring and Tuning Guide*.

All rows of every created temporary table of the application process are deleted with the exception that the rows of a created temporary table are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table. In addition, if RELEASE(COMMIT) is in effect, the logical work files for the created temporary tables whose rows are deleted are also deleted.

All rows of every declared temporary table of the application process are deleted with these exceptions:

- The rows of a declared temporary table that is defined with the ON COMMIT PRESERVE ROWS attribute are not deleted.

- The rows of a declared temporary table that is defined with the ON COMMIT DELETE ROWS attribute are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on that table.

***Implicit commit operations:*** In all DB2 environments, the normal termination of a process is an implicit commit operation.

***Restrictions on the use of COMMIT:*** The COMMIT statement cannot be used in the IMS or CICS environment. To cause a commit operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these commit operations on DB2 data is the same as that of the SQL COMMIT statement.

The COMMIT statement cannot be used in a stored procedure if the procedure is in the calling chain of a user-defined function or a trigger or DB2 is not the commit coordinator.

***Effect of commit on special registers:*** Issuing a COMMIT statement may cause special registers to be re-initialized. Whether one of these special registers is affected by a commit depends on whether the special register has been explicitly set within the application process. For example, assume that the PATH special register has not been explicitly set with a SET PATH statement in the application process. After a commit, the value of PATH is re-initialized. For information on the initialization of PATH, which can take the current value of CURRENT SQLID into consideration, see “CURRENT PATH” on page 142.

## Example

Commit all DB2 database changes made since the unit of recovery was started.

```
COMMIT WORK;
```

## CONNECT

The CONNECT statement connects an application process to a database server. This server becomes the *current server* for the process. The CONNECT statement of DB2 for z/OS is equivalent to CONNECT (Type 2) in IBM DB2 SQL Reference for Cross-Platform Development.

Refer to “Distributed data” on page 31 for complete information about connections, the current server, commit processing, and distributed and remote units of work.

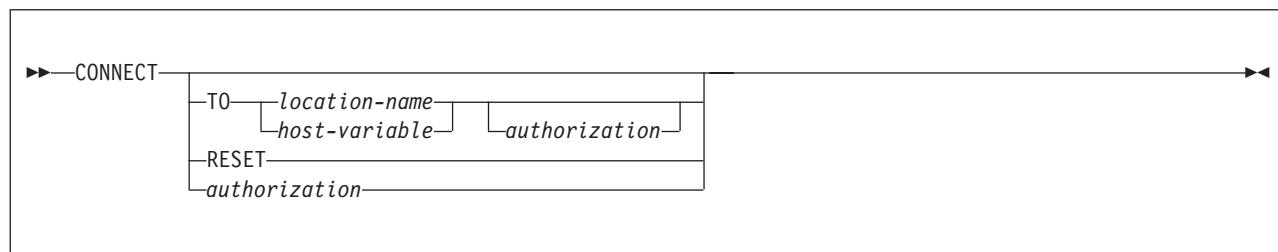

### Invocation

This statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

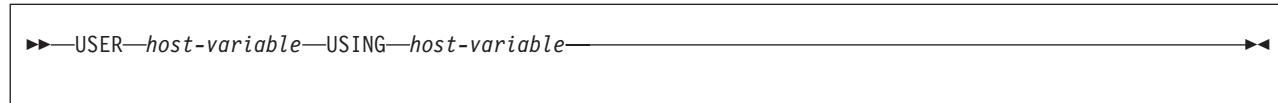

### Authorization

The primary authorization ID of the process or the authorization ID that is specified in this statement must be authorized to connect to the specified server. The server performs the authorization check when the statement is executed, and determines the specific authorization that is required. See *DB2 Administration Guide* for further information.

### Syntax

**authorization:**

### Description

#### TO *location-name* or *host-variable*

Identifies the server by the specified location name or by the location name that is contained in the host variable. If a host variable is specified:

- It must be a CHAR or VARCHAR variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes long.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

- It must not contain lowercase characters.
- If used with an SQL procedure language application, host variable must be a qualified SQL-variable name or a qualified SQL-parameter name.

When the CONNECT statement is executed:

- The location name must identify a server known to the local DB2 subsystem. Hence, the location name must be the location name of the local DB2 subsystem or it must appear in the LOCATION column of the SYSIBM.LOCATIONS table.
- The application process must not have an existing connection to the specified server, if the SQLRULES(STD) bind option is in effect.
- The application process must be in a connectable state, if the transaction is participating in a remote unit of work.

#### **RESET**

CONNECT RESET is equivalent to CONNECT TO *x* where *x* is the location name of the local DB2 subsystem.

- If the SQLRULES(DB2) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection.
- If the SQLRULES(STD) bind option is in effect, CONNECT RESET establishes the local DB2 subsystem as the current SQL connection only if the connection does not exist.

#### *authorization*

Specifies an authorization ID and a password that is used to verify that the authorization ID is authorized to connect to the server. Authorization cannot be specified when the connection type is IMS or CICS for a connection to the local DB2 subsystem. An attempt to do so causes an SQL error.

#### **USER** *host-variable*

Identifies the authorization name to use when connecting to the server. The value of *host-variable* must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified within the host variable and must conform to the rules for forming an authorization name.
- The value must not be followed by an indicator variable.
- The value must be padded on the right with blanks if the length of the authorization name is less than the length of the host variable.

For a connection to the local DB2 subsystem, a user ID that is longer than 8 characters causes an SQL error.

#### **USING** *host-variable*

Identifies the password of the authorization name to use when connecting to the server. The value of *host-variable* must satisfy the following rules:

- The value must be a CHAR or VARCHAR variable with a length attribute that is not greater than 128.
- The value must be left-justified.
- The value must not include an indicator variable.
- The value must be padded on the right with blanks if the length of the password is less than the length of the host variable.
- The value must not contain lowercase characters.

For a connection to a DB2 subsystem, a password that is longer than 8 characters causes an SQL error.

CONNECT USER/USING is equivalent to CONNECT TO *x* USER/USING where *x* is the location name of the local DB2 subsystem (which has the semantic of CONNECT RESET).

#### CONNECT with no operand

This form of the CONNECT statement returns information about the current server in the SQLERRP field of the SQLCA. SQLERRP returns blanks if the application process is in the unconnected state.

Executing a CONNECT with no operand has no effect on connection states.

In a remote unit of work, this form of CONNECT does not require the application process to be in a connectable state.

#### Notes

**Successful connection:** With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is successful:

- One of the following scenarios takes place in a **distributed unit of work**:
  - If the location name does not identify a server to which the application process is already connected, an SQL connection to the server is created and placed in the current and held state. The previously current SQL connection, if any, is placed in the dormant state.
  - If the location name identifies a server to which the application process is already connected, the associated SQL connection is dormant, and the SQLRULES(DB2) option is in effect, the SQL connection is placed in the current state. The previously current SQL connection, if any, is placed in the dormant state.
  - If the location name identifies a server to which the application process is already connected, the associated SQL connection is current, and the SQLRULES(DB2) option is in effect, the states of all SQL connections of the application process are unchanged.
- The following actions occur in a **remote unit of work**:
  - The application process is connected to the specified server.
  - An existing SQL connection of the application process is ended. As a result, all cursors of that SQL connection are closed, all prepared statements of that connection are destroyed, and so on.
- The location name is placed in the CURRENT SERVER special register.
- When CONNECT is used to connect back to the local DB2 subsystem, the CURRENT SQLID special register is reinitialized if the USER/USING clause is specified.
- Information about the server is placed in the SQLERRP field of the SQLCA. If the server is a DB2 product, the information has the form *pppvrrm*, where:
  - *ppp* is:
    - ARI for DB2 Server for VSE & VM
    - DSN for DB2 for z/OS
    - QSQ for DB2 for i
    - SQL for DB2 for LUW
  - *vv* is a two-digit version identifier such as '09'.
  - *rr* is a two-digit release identifier such as '01'.
  - *m* is a one-digit maintenance level. Values 0, 1, 2, 3, and 4 are reserved for maintenance levels in compatibility and enabling-new-function mode. Values 5, 6, 7, 8, and 9 are for maintenance levels in new-function mode.

For example, if the server is Version 9 of DB2 for z/OS in new-function mode with the first level of maintenance, the value of SQLERRP is 'DSN09015'.

- Additional information about the connection is placed in the SQLERRMC field of the SQLCA. The contents are product-specific.

**Tip:** Use the GET DIAGNOSTICS statement to get detailed diagnostic information about the last SQL statement that was executed.

**Unsuccessful connection:** With the exception of a CONNECT with no operand statement, if execution of the CONNECT statement is unsuccessful:

- In a **distributed unit of work**, the connection state of the application process and the states of its SQL connections are unchanged unless the failure was because an authorization check failed. If this is the case, the connection is placed in the connectable and unconnected state.
- In a **remote unit of work**, the SQLERRP field of the SQLCA is set to the name of the DB2 requester module that detected the error.

If execution of the CONNECT statement is unsuccessful because the application process is not in the connectable state, the connection state of the application process is unchanged. If execution of the CONNECT statement is unsuccessful for any other reason, CURRENT SERVER is set to blanks and the application process is placed in the connectable and unconnected state.

**Authorization:** If the server is a DB2 subsystem, a user is authenticated in the following way:

- DB2 invokes RACF via the RACROUTE macro with REQUEST=VERIFY to verify the password.
- If the password is verified, DB2 then invokes RACF again via the RACROUTE macro with REQUEST=AUTH, to check whether the authorization ID is allowed to use DB2 resources defined to RACF.
- DB2 then invokes the connection exit routine if one has been defined.
- The connection then has a primary authorization ID, possibly one or more secondary IDs, and an SQL ID.

If the server is a remote DB2 subsystem, the requester generates authentication tokens and sends them to the remote site in the following way:

- The SECURITY\_OUT column in SYSIBM.LUNAMES for SNA or the SECURITY\_OUT column in SYSIBM.IPNAME for TCP/IP must have one of the following values:
  - 'A' (already verified)
  - 'D' (userid and security-sensitive data encryption; TCP/IP only)
  - 'E' (userid, password, and security-sensitive data encryption; TCP/IP only)
  - 'P' (password)

When the value is 'A', the user ID and password specified on the CONNECT is still sent.

When the value is 'D', 'E', or 'P', the requester encrypts the user ID and password specified on the CONNECT for TCP/IP. However, if the Integrated Cryptographic Service Facility (ICSF) is not configured at the requester or if the server does not support encryption, one of the following actions occurs:

- If the value of SECURITY\_OUT in SYSIBM.IPNAME is 'D' or 'E', SQLCODE -904 is returned if ICSF is not configured at the requester, and SQLCODE -30082 is returned if the server does not support encryption.

- If the value of SECURITY\_OUT in SYSIBM.IPNAMES is 'P', the requester does not encrypt the user ID and password and flows the tokens in clear text.
- For SNA, the ENCRYPTIONSWDS column in SYSIBM.SYSLUNAMES must be not contain 'Y'.
- The authorization ID and password are verified at the server.
- In all cases, outbound translation—as specified in SYSIBM.USERNAMES—is not done.

**Distributed unit of work:** In general, the following are true:

- A CONNECT statement with the TO clause and the USER/USING clause can be executed only if no current or dormant connection to the named server exists. However, if the named server is the local DB2 subsystem and the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.
- A CONNECT statement without the TO clause but with the USER/USING clause can be executed only if no current or dormant connection to the local DB2 subsystem exists. However, if the CONNECT statement is the first SQL statement that is executed after the DB2 thread is created, the CONNECT statement executes successfully.

**Remote unit of work:** If the authorization check fails, the connection is placed in the connectable and unconnected state.

**Precompiler options:** Regardless of whether a program is precompiled with the CONNECT(1) or CONNECT(2) option, DB2 for z/OS negotiates with the remote server during the connection process to determine how to perform commits. If the remote server does not support the two-phase commit protocol, DB2 downgrades to perform one-phase commits.

Programs containing CONNECT statements that are precompiled with different CONNECT precompiler options cannot execute as part of the same application process. An error occurs when an attempt is made to execute the invalid CONNECT statement.

**Host variables:** If a CONNECT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Error processing:** A CONNECT statement can return and indicate a successful execution even when no physical connection yet exists. DB2 delays the physical connection process, when possible, to economize on the number of messages it sends to a server. Therefore, errors in CONNECT statement processing can be reported following the next executable SQL statement, not immediately following the CONNECT statement.

## Examples

*Example 1:* Connect an application to a DBMS. The location name is in the character-string variable *LOCNAME*, the authorization identifier is in the character-string variable *AUTHID*, and the password is in the character-string variable *PASSWORD*.

```
EXEC SQL CONNECT TO :LOCNAME USER :AUTHID USING :PASSWORD;
```

*Example 2:* Obtain information about the current server.

```
EXEC SQL CONNECT;
```

*Example 3:* Execute SQL statements in a distributed unit of work. The first CONNECT statement creates a connection to the EASTDB server. The second CONNECT statement creates a connection to the WESTDB server, and places the SQL connection to EASTDB in the dormant state.

```
EXEC SQL CONNECT TO EASTDB;
-- execute statements referencing objects at EASTDB
EXEC SQL CONNECT TO WESTDB;
-- execute statements referencing objects at WESTDB
```

*Example 4:* Connect the application to a DBMS whose location identifier is in the character-string variable LOC using the authorization identifier in the character-string variable AUTHID and the password in the character-string variable PASSWORD. Perform work for the user, and then release the connection and connect again using a different user ID and password.

```
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
-- execute SQL statements accessing data on the server
RELEASE :LOC;
EXEC SQL COMMIT;
-- set AUTHID and PASSWORD to new values
EXEC SQL CONNECT TO :LOC USER :AUTHID USING :PASSWORD;
-- execute SQL statements accessing data on the server
```

*Example 5:* Change servers in a remote unit of work. Assume that the application connected to a remote DB2 server, opened a cursor, and fetched rows from the cursor's result table. Subsequently, to connect to the local DB2 subsystem, the application executes the following statements:

```
EXEC SQL COMMIT WORK;
EXEC SQL CONNECT RESET;
```

The COMMIT is required because opening the cursor caused the application to enter the unconnectable and connected state.

If the cursor was declared with the WITH HOLD clause and was not closed with a CLOSE statement, it would still be open even after execution of the COMMIT statement. However, it would be closed with the execution of the CONNECT statement.

## CREATE ALIAS

The CREATE ALIAS statement defines an alias for a table or view. The definition is recorded in the DB2 catalog at the current server. The table or view does not have to be described in that catalog.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEALIAS privilege
- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner of the plan or package is a role, this role must hold the privileges for the privilege set. If the specified alias name includes a qualifier that is not the same as this authorization ID, the privilege set must include one of the following authorities:

- SYSADM or SYSCTRL authority
- DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. If the process is not running in a trusted context that is defined with the ROLE AS OBJECT OWNER clause and the specified alias name includes a qualifier that is not the same as this authorization ID:

- The privilege set must include SYSADM or SYSCTRL authority.

- The privilege set must include DBADM or DBCTRL authority on the database that contains the table, if the alias is for a table and the value of field DBADM CREATE AUTH on installation panel DSNTIPP is YES.
- The qualifier must be the same as one of the authorization IDs of the process and the privileges that are held by that authorization ID must include the CREATEALIAS privilege. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

## Syntax

```
►►CREATE ALIAS—alias-name—FOR table-name  
                          └─view-name┘
```

## Description

### *alias-name*

Names the alias. The name, including the implicit or explicit qualifier, must not identify a table, view, or alias that exists at the current server.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

### FOR *table-name* or *view-name*

Identifies the table or view for which the alias is defined. If a table is identified, it must not be an auxiliary table, a declared temporary table, or a table that is implicitly created for an XML column. The table or view need not exist at the time the alias is defined. If it does exist, it can be at the current server or at another server. The name must not be the same as the alias name and must not identify an alias that exists at the current server.

## Notes

**Owner privileges:** There are no specific privileges on an alias. For more information about ownership of an object, see “Authorization, privileges, and object ownership” on page 60.

An alias can be defined for a table, view, or alias that is not at the current server. When so defined, the existence of the referenced object is not verified at the time the alias is created. But the object must exist when a statement that contains the alias is executed. And if that object is also an alias, it must refer to a table or view at the server where that alias is defined.

A warning occurs if an alias is defined for a table or view that is local to the current server but does not exist.

When an application uses three-part name aliases for remote objects and DRDA access, the application program must be bound at each location that is specified in the three-part names. Also, you need to define the alias at the remote site as well as at the local site.

## **Example**

Create an alias for a catalog table at a DB2 with location name DB2USCALABOA5281.

```
CREATE ALIAS LATABLES FOR DB2USCALABOA5281.SYSIBM.SYSTABLES;
```

## CREATE AUXILIARY TABLE

The CREATE AUXILIARY TABLE statement creates an auxiliary table at the current server for storing LOB data.

### Invocation

This statement can be embedded in an application program or issued interactively if the value of special register CURRENT RULES is 'DB2' and the table space is explicitly created when the statement is executed. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Do not use this statement if the value of special register CURRENT RULES is 'STD' or if the table space is implicitly created. When the values of the CURRENT RULES special register is 'STD' and a base table is created with LOB columns or altered such that LOB columns are added, DB2 automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column. DB2 also automatically creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column if the table space is implicitly created. DB2 chooses the names and characteristics of these objects. For more information about the names and the characteristics, see [Creating a table with LOB columns](#).

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database implicitly or explicitly specified by the IN clause
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specifies, a role is the owner. Otherwise, an authorization ID is the owner. If the specified table name includes a qualifier that is not the same as this authorization ID, the privilege set must include SYSADM or SYSCTRL authority, DBADM authority for the database, or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

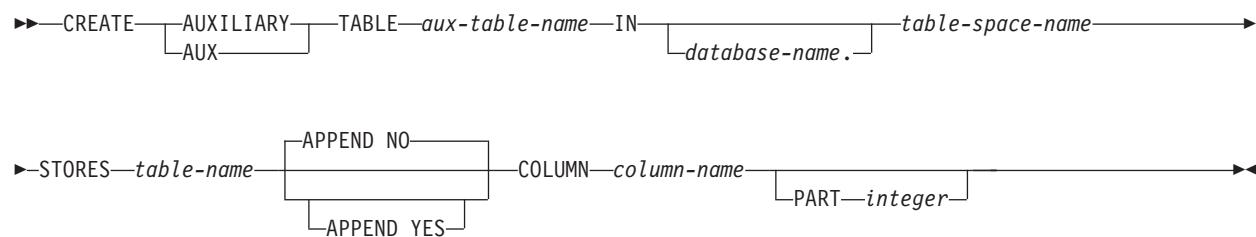

- If the privilege set lacks the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. If the process is in a trusted

context, any authorization ID can be the qualifier. However, if the process is not in a trusted context and if the specified table name includes a qualifier that is not the same as the SQL authorization ID of the process, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
- If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all<sup>25</sup> privileges needed to create the table.

## Syntax

## Description

### AUXILIARY or AUX

Specifies a table that is used to store the LOB data for a LOB column (or a column with a distinct type that is based on a LOB data type).

### *aux-table-name*

Names the auxiliary table. The name, including the implicit or explicit qualifiers, must not identify a table, view, alias, or synonym that exists at the current server. If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

### **IN** *database-name.table-space-name* or **IN** *table-space-name*

Identifies the table space in which the auxiliary table is created. The name must identify an empty LOB table space that currently exists at the current server. The LOB table space must be in the same database as the associated base table.

If you specify a database and a table space, the table space must belong to the specified database. If you specify only a table space, it must belong to the database that contains the specified table space. If you specify only a table space, this table space must belong to DSNDB04. This type of table space is only created when SET CURRENT RULES='DB2' is specified.

### **STORES** *table-name COLUMN column-name*

Identifies the base table and the column of that table that is to be stored in the

25. Exception: The CREATETAB privilege is checked on the SQL authorization ID of the process.

auxiliary table. If the base table is nonpartitioned, an auxiliary table must not already exist for the specified column. If the base table is partitioned, an auxiliary table must not already exist for the specified column and specified partition.

The encoding scheme for the LOB data stored in the auxiliary table is the same as the encoding scheme for the base table. It is either ASCII, EBCDIC, or UNICODE depending on the value of the CCSID clause when the base table was created.

#### **APPEND NO or APPEND YES**

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table in a work file table space.

If the base table is in a range-partitioned table space, the APPEND option on the LOB table might be different for each partition (depending if the LOB table space and associated objects for each partition are created explicitly or implicitly). If the base table is in a partition by growth table space, the APPEND attributes of LOB table will be inherited by each partition.

#### **APPEND NO**

Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key columns.

APPEND NO is the default

#### **APPEND YES**

Specifies that data rows are placed into the table without regard to clustering during the insert and LOAD operations.

#### **PART integer**

Specifies the partition of the base table for which the auxiliary table is to store the specified column. You can specify PART only if the base table is defined in a partitioned table space, and no other auxiliary table exists for the same LOB column of the base table.

### **Notes**

*Owner privileges:* There are no specific privileges on an auxiliary table. For more information about ownership of an object, see “Authorization, privileges, and object ownership” on page 60.

*Determining the number of auxiliary tables to create:* If the base table is nonpartitioned, you might need to create one LOB table space and one auxiliary table for each LOB column in the base table. If the base table is partitioned, for each LOB column, you might need to create one LOB table space and one auxiliary table for each partition. For example if your base table has three partitions and two LOB columns, you might need to create three LOB table spaces and three auxiliary tables for each LOB column. In other words, you might need a total of six LOB table spaces and six auxiliary tables.

*Auxiliary tables in LOB table spaces that are logged:* When you create an auxiliary table in a LOB table space that is LOGGED, and the associated base table space is NOT LOGGED, the logging attribute of the LOB table space is implicitly changed to NOT LOGGED and the logging attributes of the base table space and the LOB table space are linked.

*Append processing and unused free space in a table:* An update or delete of LOB data creates some free space in the LOB table that can be used by the next insert. If the table uses append processing, any free space that is not at the end of the table space will not be reused during the insert operation. Any unused free space in the table can be reclaimed by running the REORG utility with either the SHRELEVLRREFERENCE or SHRLEVEL CHANGE keywords. The REORG utility is not influenced by the APPEND option.

## Example

Assume that a column named EMP\_PHOTO with a data type of BLOB(110K) has been added to sample employee table DSN8910.EMP for each employee's photo. Create auxiliary table EMP\_PHOTO\_ATAB to store the BLOB data for the BLOB column in LOB table space DSN8D91A.PHOTOLTS.

```
CREATE AUX TABLE EMP_PHOTO_ATAB
  IN DSN8D91A.PHOTOLTS
  STORES DSN8910.EMP
  COLUMN EMP_PHOTO;
```

# CREATE DATABASE

The CREATE DATABASE statement defines a DB2 database at the current server.

## Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

## Authorization

The privilege set that is defined below must include at least one of the following:

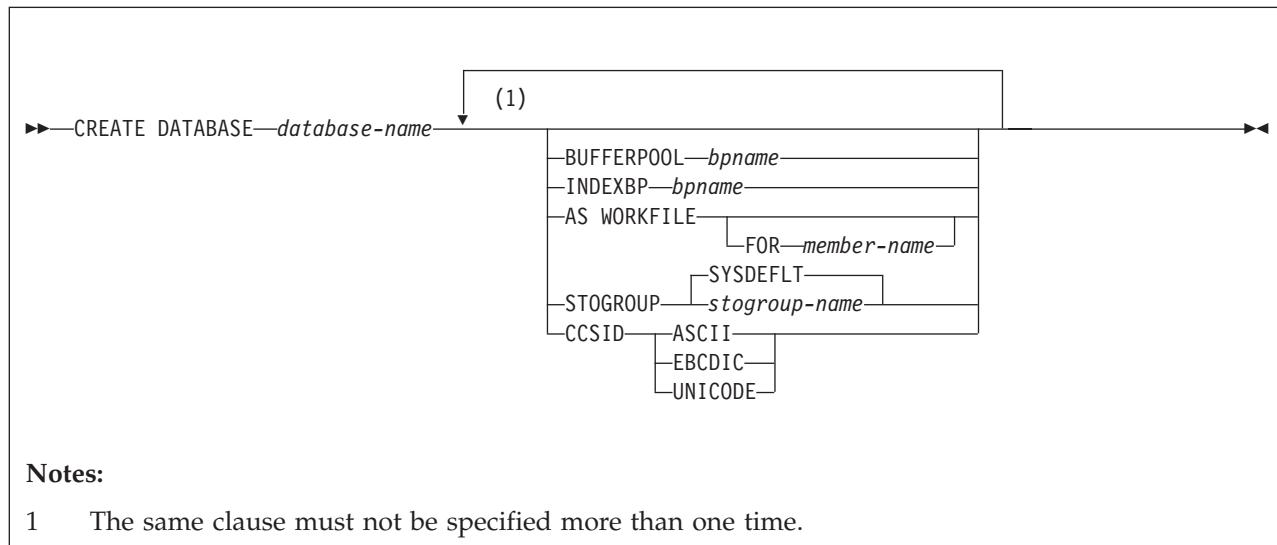

- The CREATEDBA privilege
- The CREATEDBC privilege
- SYSADM or SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process.

See “Notes” on page 914 for the authorization effect of a successful CREATE DATABASE statement.

## Syntax

## Description

*database-name*

Names the database. The name must not start with DSNDB and must not identify a database that exists at the current server. *database-name* must not be in the form of eight characters that start with DSN followed by exactly five

digits. If the database is to be a work file database in a data sharing environment, DSNDB07 is an acceptable work file database name. However, only one member of a data sharing group can use DSNDB07 as the name of its work file database.

**BUFFERPOOL** *bpname*

Specifies the default buffer pool name to be used for table spaces created within the database. If the database is a work file database, 8KB and 16KB buffer pools cannot be specified. See “Naming conventions” on page 51 for more details about *bpname*.

If you omit the BUFFERPOOL clause, the default 4-KB buffer pool for user data that is specified on installation panel DSNTIP1 is used.

**INDEXBP** *bpname*

Specifies the default buffer pool name to be used for the indexes created within the database. The name can identify a 4KB, 8KB, 16KB, or 32KB buffer pool. See “Naming conventions” on page 51 for more details about *bpname*.

If you omit the INDEXBP clause, the buffer pool specified for user indexes on installation panel DSNTIP1 is used. The default value for the user indexes field on that panel is BP0.

**AS WORKFILE**

Specifies the database is a work file database. AS WORKFILE can be specified only in a data sharing environment. Only one work file database can be created for each DB2 subsystem. The work file database is used for work files, created global temporary table, declared temporary tables, and sensitive static scrollable cursors.

PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority) to define a declared temporary table in the work file database. This implicit privilege is not recorded in the DB2 catalog and cannot be revoked.

The CCSID clause is not supported for a work file database. If you specify AS WORKFILE, do not use the CCSID clause.

**FOR** *member-name*

Specifies the member for which this database is to be created. Specify FOR *member-name* only in a data sharing environment.

If FOR *member-name* is not specified, the member is the DB2 subsystem on which the CREATE DATABASE statement is executed.

**STOGROUP** *stogroup-name*

Specifies the storage group to be used, as required, as a default storage group to support DASD space requirements for table spaces and indexes within the database. The default is SYSDEFLT.

**CCSID** *encoding-scheme*

Specifies the default encoding scheme for data stored in the database. The default applies to table spaces created in the database. All tables stored within a table space must use the same encoding scheme.

**ASCII** Specifies that the data must be encoded using the ASCII CCSIDs of the server.

**EBCDIC**

Specifies that the data must be encoded using the EBCDIC CCSIDs of the server.

## **UNICODE**

Specifies that the data must be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

The option defaults to the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

| Do not use the CCSID clause if you specify the AS WORKFILE clause.

## **Notes**

If the statement is embedded in an application program, the owner of the plan or package is the owner of the database. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the database.

If the owner of the database has the CREATEDBA, SYSADM, or SYSCTRL authority, the owner acquires DBADM authority for the database. DBADM authority for a database includes table privileges on all tables in that database. Thus, if a user with SYSCTRL authority creates a database, that user has table privileges on all tables in that database. This is an exception to the rule that SYSCTRL authority does not include table privileges.

If the owner of the database has the CREATEDBC privilege, but not the CREATEDBA privilege, the owner acquires DBCTRL authority for the database. In this case, no authorization ID has DBADM authority for the database until it is granted by an authorization ID with SYSADM authority.

## **Examples**

*Example 1:* Create database DSN8D91P. Specify DSN8G910 as the default storage group to be used for the table spaces and indexes in the database. Specify 8KB buffer pool BP8K1 as the default buffer pool to be used for table spaces in the database, and BP2 as the default buffer pool to be used for indexes in the database.

```
CREATE DATABASE DSN8D91P  
STOGROUP DSN8G910  
BUFFERPOOL BP8K1  
INDEXBP BP2;
```

*Example 2:* Create database DSN8TEMP. Use the defaults for the default storage group and default buffer pool names. Specify ASCII as the default encoding scheme for data stored in the database.

```
CREATE DATABASE DSN8TEMP  
CCSID ASCII;
```

## CREATE FUNCTION

---

The CREATE FUNCTION statement registers a user-defined function with a database server. You can register four different types of functions with this statement, each of which is described separately.

### External scalar

The function is written in a programming language and returns a scalar value. The external executable is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external scalar)” on page 916.

### External table

The function is written in a programming language and returns a complete table. The external executable is registered with a database server along with various attributes of the function. See “CREATE FUNCTION (external table)” on page 940.

### Sourced

The function is implemented by invoking another function (either built-in, external, SQL, or sourced) that already exists at the server. The function inherits the attributes of the underlying source function. See “CREATE FUNCTION (sourced)” on page 958.

### SQL scalar

The function is written exclusively in SQL statements and returns a scalar value. The body of an SQL scalar function is written in the SQL procedural language and is defined at the current server along with various attributes of the function. See “CREATE FUNCTION (SQL scalar)” on page 972.

## CREATE FUNCTION (external scalar)

This CREATE FUNCTION statement registers a user-defined external scalar function with a database server. A scalar function returns a single value each time it is invoked.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

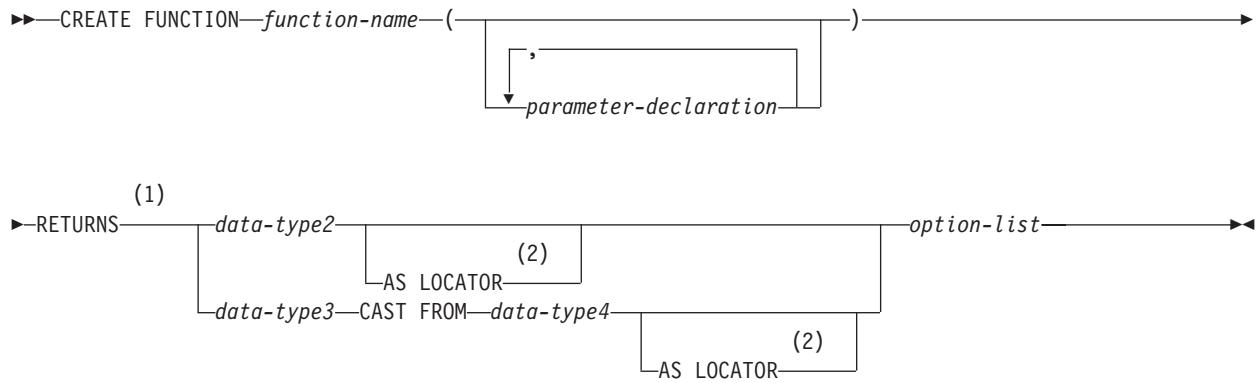

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file.

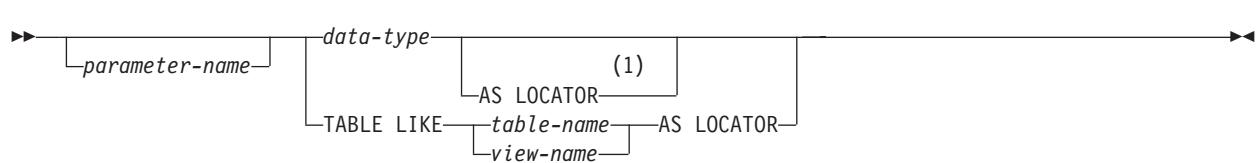

## Syntax

### Notes:

- 1 This clause and the clauses that follow in the *option-list* can be specified in any order.
- 2 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

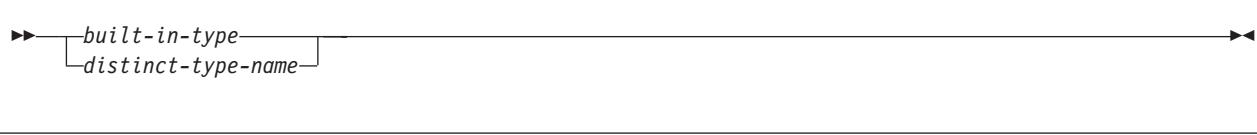

### parameter-declaration:

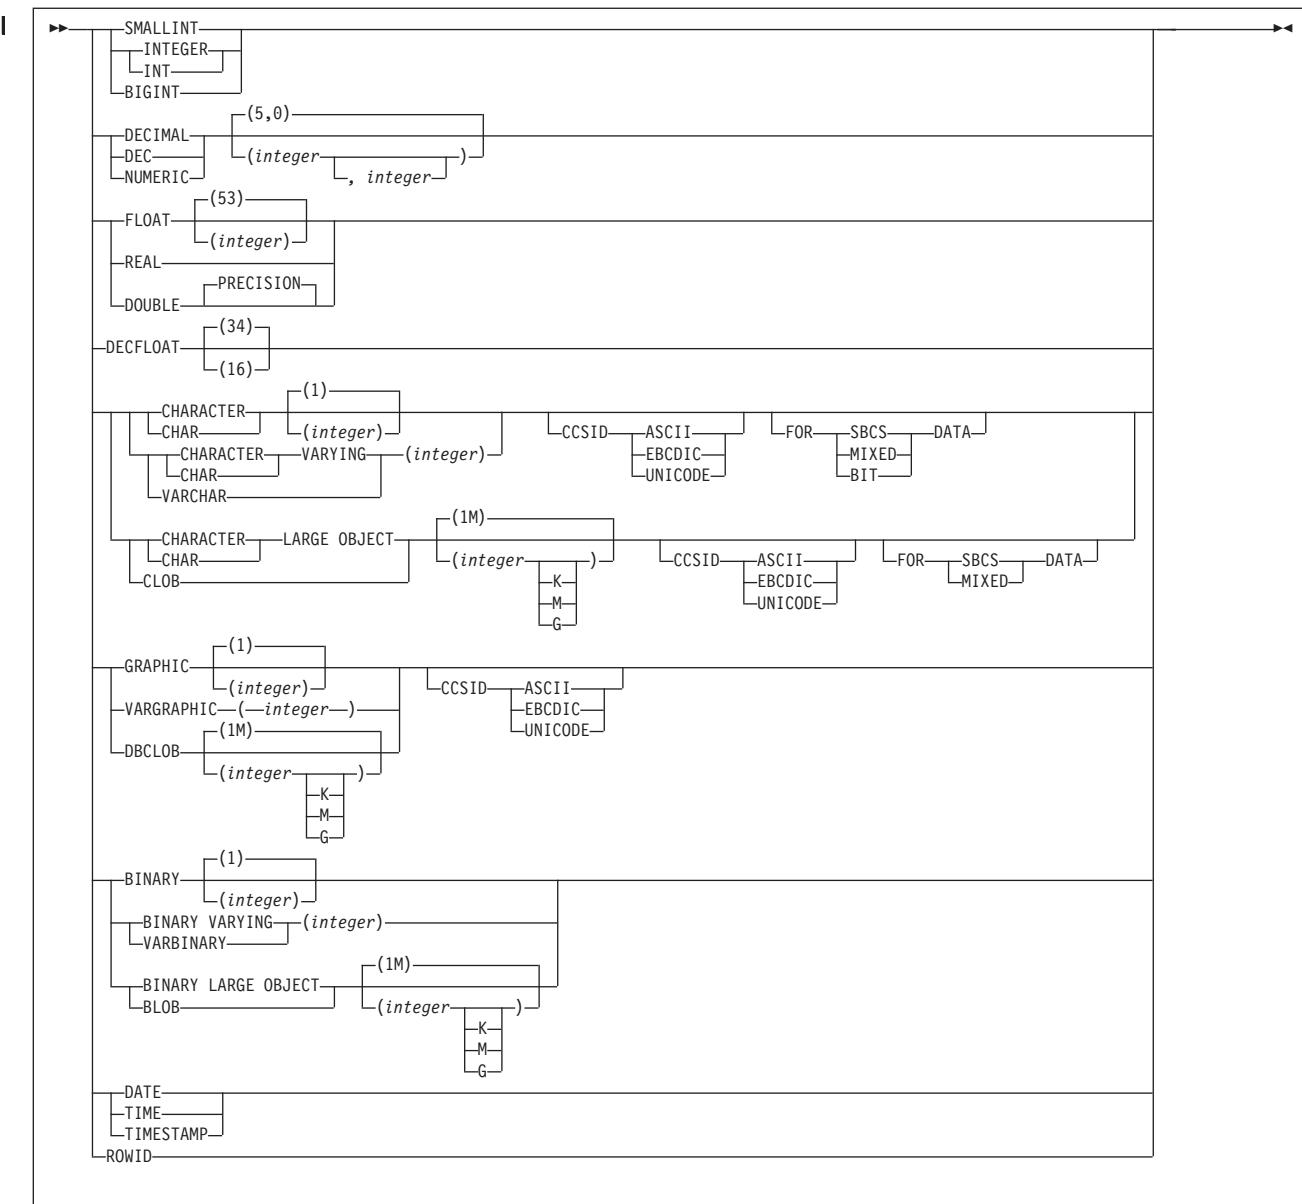

### Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

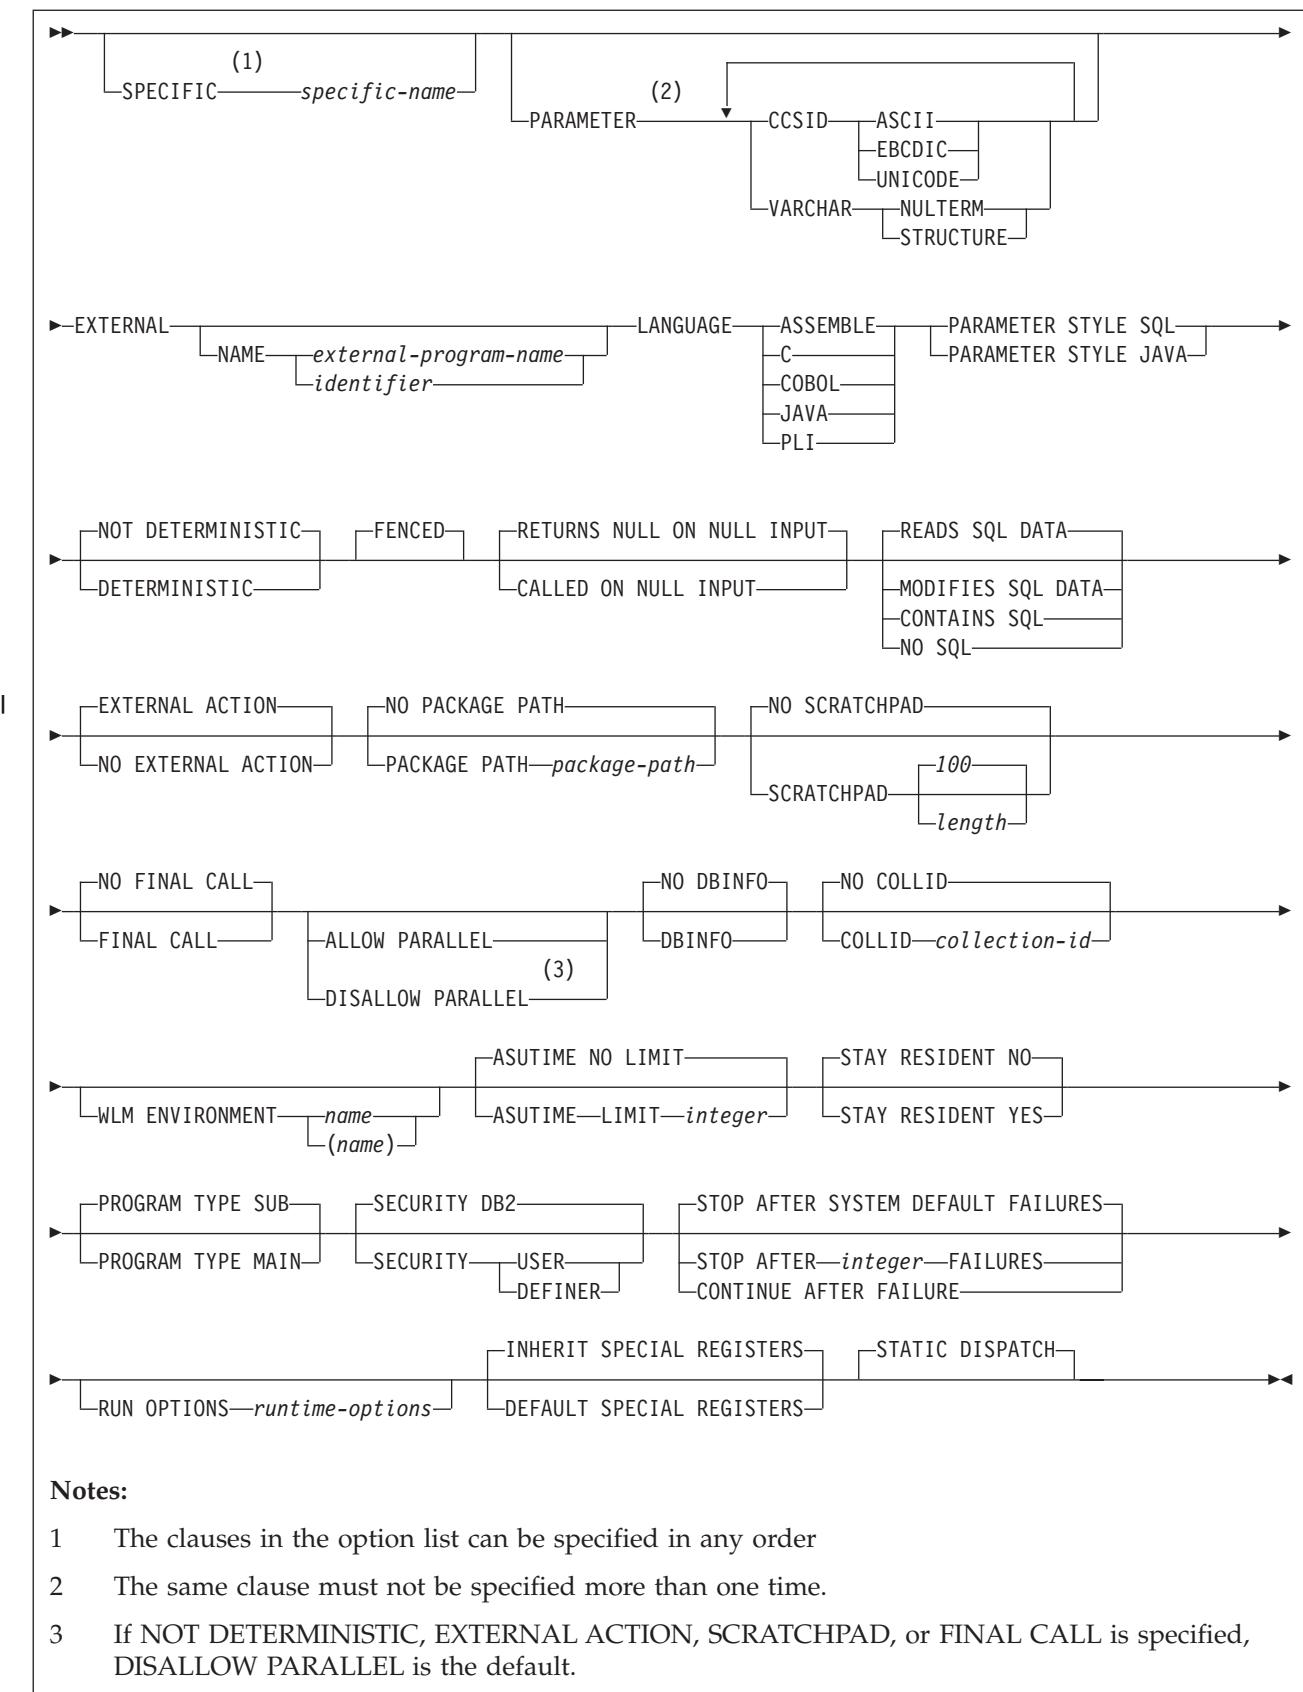

### data-type:

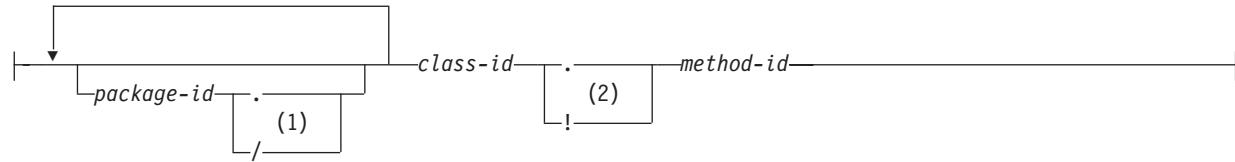

### built-in-type:

**option-list:**

**external-java-routine-name:****jar-name:****method-name:****method-signature:****Notes:**

- 1 The slash (/) is supported for compatibility with previous release of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

## Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

ALL	LIKE	UNIQUE
AND	MATCH	UNKNOWN
ANY	NOT	=
BETWEEN	NULL	~=
DISTINCT	ONLY	<

EXCEPT	OR	<=
EXISTS	OVERLAPS	<<
FALSE	SIMILAR	>
FOR	SOME	>=
FROM	TABLE	>>
IN	TRUE	<>
IS	TYPE	

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

*(parameter-declaration,...)*

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

*parameter-name*

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

*data-type*

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the input parameter is a built-in data type.

For information on the data types, see *built-in-type*.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

*distinct-type-name*

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

#### **AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

#### **TABLE LIKE *table-name* or *view-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name* or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.

- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

#### **RETURNS**

Specifies the data type for the result of the function. Consider this clause in conjunction with the optional CAST FROM clause.

*data-type2*

Specifies the data type of the output. The output parameter is nullable.

The same considerations that apply to the data type and nullability of input parameter, as described under *data-type*, apply to the data type of the result of the function.

#### **AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

*data-type3* **CAST FROM** *data-type4*

Specifies the data type of the output of the function (*data-type4*) and the data type in which that output is returned to the invoking statement (*data-type3*). The two data types can be different. For example, for the following definition, the function returns a DOUBLE value, which DB2 converts to a DECIMAL value and then passes to the statement that invoked the function:

```
CREATE FUNCTION SQRT(DECIMAL(15,0))
  RETURNS DECIMAL(15,0) CAST FROM DOUBLE
  ...
  
```

The value of *data-type4* must not be a distinct type and must be castable to *data-type3*. The value for *data-type3* can be any built-in data type other than a distinct type. (For information on casting data types, see “Casting between data types” on page 96.) The encoding scheme of the parameters, if they are string data types, must be the same.

If the PARAMETER VARCHAR clause is specified, *data-type3* and *data-type4* should be specified as VARCHAR.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the value. You can specify AS LOCATOR only if *data-type4* is a LOB data type or a distinct type based on a LOB data type.

**SPECIFIC *specific-name***

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

**PARAMETER CCSID or VARCHAR**

Specifies the encoding scheme for character and graphic string parameters, and in the case of LANGUAGE C, specifies that representation of variable length string parameters.

**CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for *all* string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

**VARCHAR**

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

#### NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

#### STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as there is with the PARAMETER CCSID clause. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

#### EXTERNAL

Specifies that the CREATE FUNCTION statement is being used to define a new function that is based on code that is written in an external programming language.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

```
EXTERNAL  
EXTERNAL NAME PKJVSP1  
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

```
EXTERNAL PKJVSP1
```

**NAME** *external-program-name or identifier*

Identifies the user-written code that implements the user-defined function.

If LANGUAGE is JAVA, *external-program-name* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *external-program-names* are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break. Do not specify a JAR file for a JAVA function for which NO SQL is also specified.

An *external-java-routine-name* contains the following parts:

*jar-name*

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified

with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the CREATE FUNCTION statement is processed.

If *jar-name* is not specified, the function is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed function.

*method-name*

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

*package-id*

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.UserFuncs." The Java virtual machine looks in the directory "/myPacks/UserFuncs/" for the classes.

*class-id*

Identifies the class identifier of the Java object.

*method-id*

Identifies the method identifier with the Java class to be invoked.

*method-signature*

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the user-defined function involves any input or output parameters that can be NULL. When the function being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE FUNCTION statement.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

If you do not specify the NAME clause, 'NAME *function-name*' is implicit. In this case, *function-name* must not be longer than 8 characters.

#### **LANGUAGE**

Specifies the language interface convention to which the body of the function is written. All programs must be designed to run in IBM's Language Environment environment.

#### **ASSEMBLE**

The function is written in Assembler.

**C** The function is written in C or C++.

#### **COBOL**

The function is written in COBOL, including the object-oriented language extensions.

#### **JAVA**

The user-defined function is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must also be specified with a valid *external-java-routine-name* and PARAMETER STYLE must be specified with JAVA.

Do not specify LANGUAGE JAVA when SCRATCHPAD, FINAL CALL, DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is in effect.

#### **PLI**

The function is written in PL/I.

#### **PARAMETER STYLE**

Specifies the conventions for passing parameters to and returning a value from the function.

#### **SQL**

Specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- *n* parameters for the input parameters that are specified for the function
- A parameter for the result of the function
- *n* parameters for the indicator variables for the input parameters
- A parameter for the indicator variable for the result
- The SQLSTATE to be returned to DB2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to DB2
- The function can also pass from zero to three additional parameters:
  - The scratchpad, if SCRATCHPAD is specified
  - The call type, if FINAL CALL is specified
  - The DBINFO structure, if DBINFO is specified

#### **JAVA**

Indicates that the user-defined function uses a convention for passing parameters that conforms to the Java and SQLJ specifications.

PARAMETER STYLE JAVA can be specified only if LANGUAGE is specified as JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE JAVA is specified.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

**NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT or SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

Some functions that are not deterministic can receive incorrect results if the function is executed by parallel tasks. Specify the DISALLOW PARALLEL clause for these functions.

**DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT or SQL data change statements that refer to this function.

DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**FENCED**

Specifies that the external function runs in an external address space to prevent the function from corrupting DB2 storage.

FENCED is the default.

**RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**

Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**

The function is not called if any of the input arguments is null. The result is the null value. RETURNS NULL ON INPUT is the default.

**CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return a null or nonnull value.

**MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies the classification of SQL statements that the function can execute. DB2 verifies that the SQL statements that the function issues are consistent with this specification. For the data access classification of each statement, see Table 138 on page 1605.

**MODIFIES SQL DATA**

Specifies that the function can execute any SQL statement except the statements that are not supported in functions. Do not specify MODIFIES SQL DATA when ALLOW PARALLEL is in effect.

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data. The default is **READS SQL DATA**.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

**NO SQL**

Specifies that the function can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA function that uses a JAR file.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for external functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

**EXTERNAL ACTION**

Specifies that the function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, DB2:

- Materializes the views and table expressions in SELECT or data change statements statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

**NO EXTERNAL ACTION**

Specifies that the function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and data change statements that refer to this function. NO EXTERNAL ACTION is

not the default. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

**NO PACKAGE PATH or PACKAGE PATH *package-path***

Specifies the package path to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

**PACKAGE PATH *package-path***

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The *package-path* value that is provided when the function is created is checked when the function is invoked. If *package-path* contains SESSION\_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether DB2 is to provide a scratchpad for the function. It is strongly recommended that external functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

**NO SCRATCHPAD**

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

**SCRATCHPAD *length***

Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00"s).
- The scope of a scratchpad is the SQL statement. For each reference to the function in an SQL statement, there is one scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, three scratchpads are allocated for the three references to UDFX in the following SQL statement:

```
SELECT A, UDFX(A) FROM TABLEB  
      WHERE UDFX(A) > 103 OR UDFX(A) < 19;
```

If the function is run under parallel tasks, one scratchpad is allocated for each parallel task of each reference to the function in the SQL statement. This can lead to unpredictable results. For example, if a function uses the scratchpad to count the number of times that it is invoked, the count reflects the number of invocations done by the parallel task and not the

SQL statement. Specify the DISALLOW PARALLEL clause for functions that will not work correctly with parallelism.

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2 initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.
- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, DB2:

- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

Do not specify SCRATCHPAD when LANGUAGE JAVA is in effect.

#### **NO FINAL CALL or FINAL CALL**

Specifies whether a *final call* is made to the function. A final call enables the function to free any system resources that it has acquired. A final call is useful when the function has been defined with the SCRATCHPAD keyword and the function acquires system resource and anchors them in the scratchpad.

#### **NO FINAL CALL**

Specifies that a final call is not made to the function. The function does not receive an additional argument that specifies the type of call. NO FINAL CALL is the default.

#### **FINAL CALL**

Specifies that a final call is made to the function. To differentiate between final calls and other calls, the function receives an additional argument that specifies the type of call. The types of calls are:

##### **First call**

Specifies that the first call to the function for this reference to the function in this SQL statement. A first call is a normal call—SQL arguments are passed and the function is expected to return a result.

##### **Normal call**

Specifies that SQL arguments are passed and the function is expected to return a result.

##### **Final call**

Specifies that the last call to the function to enable the function to free resources. A final call is not a normal call. If an error occurs, DB2 attempts to make the final call unless the function abended. A final call occurs at these times:

- *End of statement*: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.

- *End of a parallel task:* When the function is executed by parallel tasks.
- *End of transaction:* When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made when the cursor is closed or the application ends. If a commit occurs at the end of a parallel task, a final call is made regardless of whether a cursor defined as WITH HOLD is open.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.
