Some functions that use a final call can receive incorrect results if parallel tasks execute the function. For example, if a function sends a note for each final call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that have inappropriate actions when executed in parallel.

Do not specify FINAL CALL when LANGUAGE JAVA is in effect.

#### **ALLOW or DISALLOW PARALLEL**

For a single reference to the function, specifies whether parallelism can be used when the function is invoked. Although parallelism can be used for most scalar functions, some functions such as those that depend on a single copy of the scratchpad cannot be invoked with parallel tasks.

Consider these characteristics when determining which clause to use:

- If all invocations of the function are completely independent from one another, specify ALLOW PARALLEL.
- If each invocation of the function updates the scratchpad, providing values that are of interest to the next invocation, such as incrementing a counter, specify DISALLOW PARALLEL.
- If the scratchpad is used only so that some expensive initialization processing is performed a minimal number of times, specify ALLOW PARALLEL.
- If the function performs some external action that should apply to only one partition, specify DISALLOW PARALLEL.
- If the function is defined with MODIFIES SQL DATA, specify DISALLOW PARALLEL, not ALLOW PARALLEL.

ALLOW PARALLEL is the default unless NOT DETERMINISTIC, EXTERNAL ACTION, SCRATCHPAD, or FINAL CALL is specified, in which case, DISALLOW PARALLEL is the default.

#### **ALLOW PARALLEL**

Specifies that DB2 can consider parallelism for the function. Parallelism is not forced on the SQL statement that invokes the function or on any SQL statement in the function. Existing restrictions on parallelism apply.

#### **DISALLOW PARALLEL**

Specifies that DB2 does not consider parallelism for the function.

#### **NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the function when it is invoked.

**NO DBINFO**

No additional information is passed. NO DBINFO is the default.

**DBINFO**

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

Do not specify DBINFO when LANGUAGE JAVA is in effect.

**NO COLLID or COLLID collection-id**

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

**NO COLLID**

The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID collection-id**

The name of the package collection that is to be used when the function is executed.

**WLM ENVIRONMENT**

Identifies the WLM (workload manager) application environment in which the function is to run. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time. When LANGUAGE is JAVA, you must specify WLM ENVIRONMENT, and the WLM environment in which the function is to run must be Java-enabled.

**name**

The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

**(name,\*)**

When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see *Running external functions in WLM environments*.

#### **ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

#### **NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

#### **LIMIT integer**

The limit on the service units is a positive integer in the range of 1 to 2 147 483 647. If the function uses more service units than the specified value, DB2 cancels the function.

#### **STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends. This option is ignored if LANGUAGE JAVA is specified.

**NO** The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

#### **YES**

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

#### **PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.

#### **SUB**

The function runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option. SUB is the default.

#### **MAIN**

The function runs as a main routine.

#### **SECURITY**

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

#### **DB2**

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

DB2 is the default.

#### **USER**

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures.

**STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

**STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

**RUN OPTIONS *runtime-options***

Specifies the Language Environment runtime options to be used for the function. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults. For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 37 on page 151.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 37 on page 151.

**STATIC DISPATCH**

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

**Notes**

**Owner privileges:** The owner is authorized to execute the function (EXECUTE privilege) and has the ability to grant these privileges to others. For more information, see “GRANT (function or procedure privileges)” on page 1340. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

**Choosing data types for parameters:** When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 95).

For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

**Specifying the encoding scheme for parameters:** The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII or all EBCDIC.

**Determining the uniqueness of functions in a schema:** At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, scale, subtype or encoding scheme attributes in the comparison. DB2 considers the synonyms of data types (DECIMAL and NUMERIC, REAL and FLOAT, and DOUBLE and FLOAT) a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), or DECFLOAT(16) and DECFLOAT(34).

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

**Character string representation considerations:** The PARAMETER VARCHAR clause is specific to LANGUAGE C functions because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when

character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external function. For example, a CREATE FUNCTION statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the function, the specific name of the function, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

*Considerations for accessing message tokens and DBINFO:* DB2 returns system-generated parameters from a routine, such as message tokens and DBINFO. The message tokens and DBINFO are character string data. The CCSID for system-generated string parameters is determined from the CCSID that is in effect for string parameters that are defined for the routine. If the parameter list for the routine does not include any character or graphic string parameters, the CCSID for system-generated string parameters is determined from the PARAMETER CCSID option that is in effect for the routine. For example, with a Unicode database, you can specify PARAMETER CCSID EBCDIC to have the system-generated string parameters returned to the invoking application in EBCDIC.

*Overriding a built-in function:* Giving an external function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create an external function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

*Running external functions in WLM environments:* You can use the WLM ENVIRONMENT clause to identify the address space in which a function or is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with data, such as employee salaries.

To prevent a user from defining functions in sensitive WLM environments, DB2 invokes the external security manager to determine whether the user has authorization to issue CREATE FUNCTION statements that refer to the specified WLM environment. The following example shows the RACF command that authorizes DB2 user DB2USER1 to register a function on DB2 subsystem DB2A that runs in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

**Scrollable cursors specified with user-defined functions:** A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

## Examples

*Example 1:* Assume that you want to write an external function program in C that implements the following logic:

```
output = 2 * input - 4
```

The function should return a null value if and only if one of the input arguments is null. The simplest way to avoid a function call and get a null result when an input value is null is to specify RETURNS NULL ON NULL INPUT on the CREATE FUNCTION statement or allow it to be the default. Write the statement needed to register the function, using the specific name MINENULL1.

```
CREATE FUNCTION NTEST1 (SMALLINT)
  RETURNS SMALLINT
  EXTERNAL NAME 'NTESTMOD'
  SPECIFIC MINENULL1
  LANGUAGE C
  DETERMINISTIC
  NO SQL
  FENCED
  PARAMETER STYLE SQL
  RETURNS NULL ON NULL INPUT
  NO EXTERNAL ACTION;
```

*Example 2:* Assume that user Smith wants to register an external function named CENTER in schema SMITH. The function program will be written in C and will be reentrant. Write the statement that Smith needs to register the function, letting DB2 generate a specific name for the function.

```
CREATE FUNCTION CENTER (INTEGER, FLOAT)
  RETURNS FLOAT
  EXTERNAL NAME 'MIDDLE'
  LANGUAGE C
  DETERMINISTIC
  NO SQL
  FENCED
  PARAMETER STYLE SQL
  NO EXTERNAL ACTION
  STAY RESIDENT YES;
```

*Example 3:* Assume that user McBride (who has administrative authority) wants to register an external function named CENTER in the SMITH schema. McBride plans to give the function specific name FOCUS98. The function program uses a scratchpad to perform some one-time only initialization and save the results. The

function program returns a value with a FLOAT data type. Write the statement McBride needs to register the function and ensure that when the function is invoked, it returns a value with a data type of DECIMAL(8,4).

```
CREATE FUNCTION SMITH.CENTER (FLOAT, FLOAT, FLOAT)
    RETURNS DECIMAL(8,4) CAST FROM FLOAT
    EXTERNAL NAME 'CMOD'
    SPECIFIC FOCUS98
    LANGUAGE C
    DETERMINISTIC
    NO SQL
    FENCED
    PARAMETER STYLE SQL
    NO EXTERNAL ACTION
    SCRATCHPAD
    NO FINAL CALL;
```

*Example 4:* The following example registers a Java user-defined function that returns the position of the first vowel in a string. The user-defined function is written in Java, is to be run fenced, and is the FINDVWL method of class JAVAUDFS.

```
CREATE FUNCTION FINDV (CLOB(100K))
    RETURNS INTEGER
    FENCED
    LANGUAGE JAVA
    PARAMETER STYLE JAVA
    EXTERNAL NAME 'JAVAUDFS.FINDVWL'
    NO EXTERNAL ACTION
    CALLED ON NULL INPUT
    DETERMINISTIC
    NO SQL;
```

---

## CREATE FUNCTION (external table)

This CREATE FUNCTION statement registers a user-defined external table function with a database server. A user-defined external table function can be used in the FROM clause of a subselect. It returns a table to the subselect by returning one row at a time each time it is invoked.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

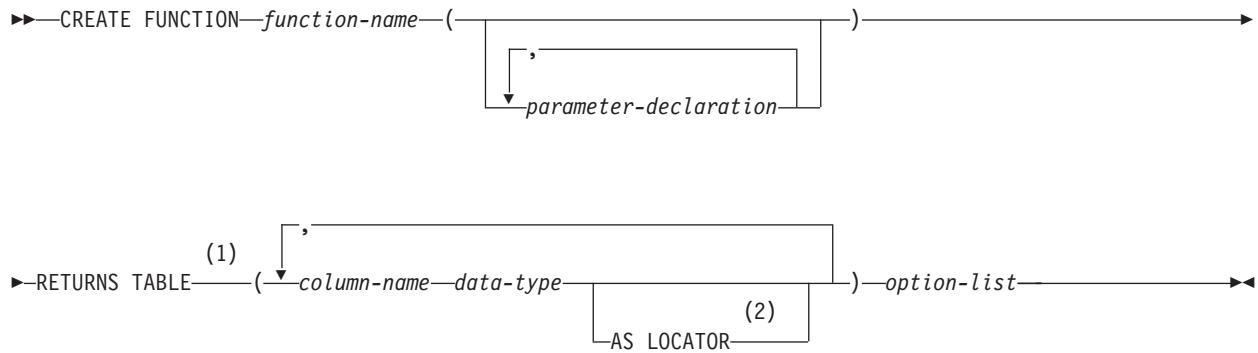

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Additional privileges are required if the function uses a table as a parameter, refers to a distinct type, or is to run in a WLM (workload manager) environment. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.
- Authority to create programs in the specified WLM environment. This authorization is obtained from an external security product, such as RACF.

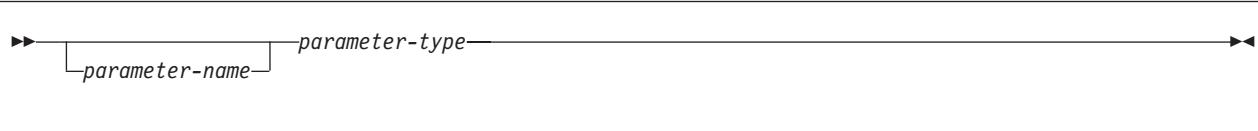

## Syntax

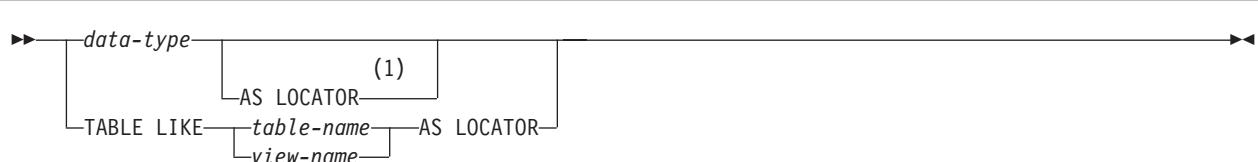

### Notes:

- 1 This clause and the clauses that follow in the *option-list* can be specified in any order.
- 2 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

### parameter-declaration:

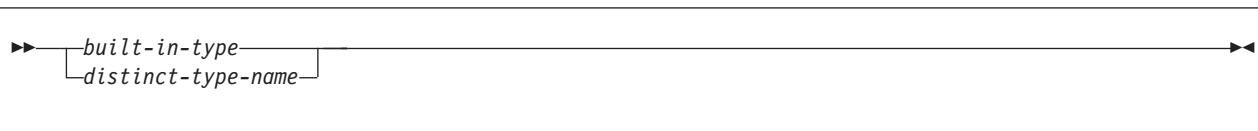

### parameter-type:

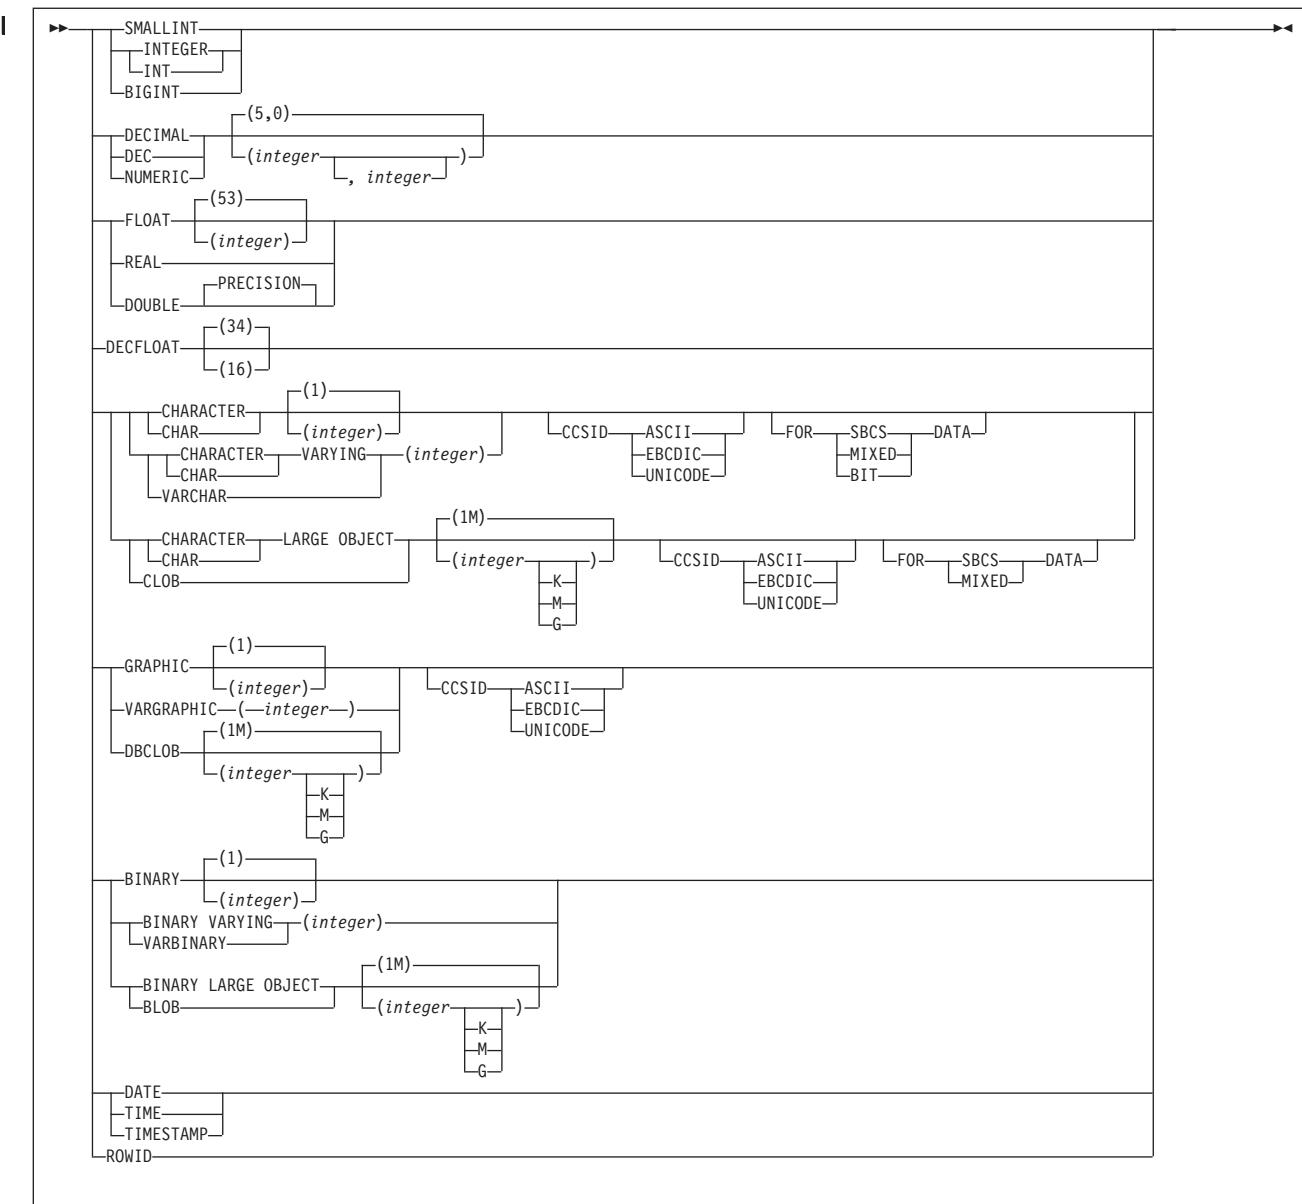

### Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

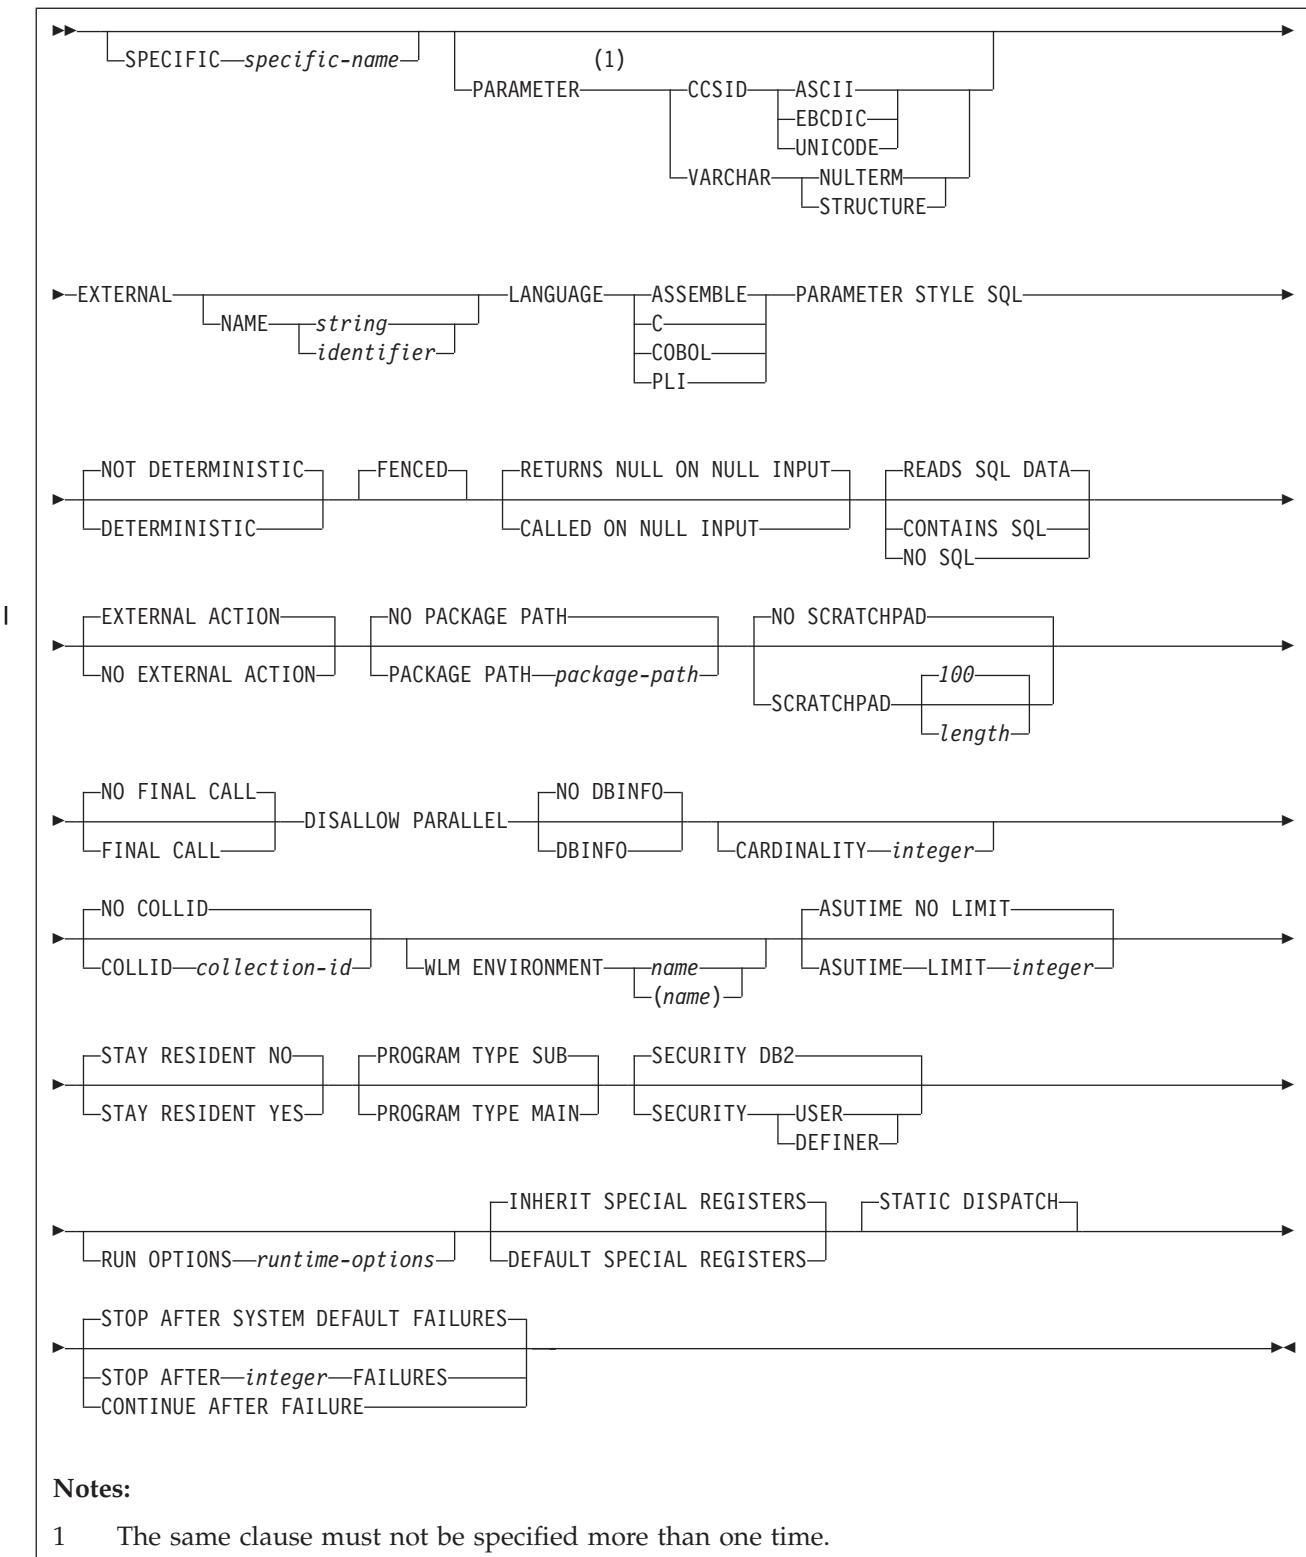

### data-type:

### built-in-type:

**option-list:** (The clauses in the *option-list* can be specified in any order.)

## Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter<sup>26</sup> (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

ALL	LIKE	UNIQUE
AND	MATCH	UNKNOWN
ANY	NOT	=
BETWEEN	NULL	≠
DISTINCT	ONLY	<
EXCEPT	OR	≤
EXISTS	OVERLAPS	⊓
FALSE	SIMILAR	>
FOR	SOME	≥
FROM	TABLE	→
IN	TRUE	↔
IS	TYPE	

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

*(parameter-declaration,...)*

Identifies the number of input parameters of the function, and specifies the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

*parameter-name*

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name. The same name cannot be used for a parameter name and a column name.

*data-type*

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the input parameter is a built-in data type.

For information on the data types, see *built-in-type*.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

*distinct-type-name*

The data type of the input parameter is a distinct type. Any length,

26. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

#### **AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type that is based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

#### **TABLE LIKE *table-name* or *view-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name* or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

**RETURNS TABLE(*column-name* *data-type* ...)**

Identifies that the output of the function is a table. The parentheses that follow the keyword enclose the list of names and data types of the columns of the table.

*column-name*

Specifies the name of the column. The name is an SQL identifier and must be unique within the RETURNS TABLE clause for the function.

*data-type*

Specifies the data type of the column. The column is nullable.

**AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only for a LOB data type or a distinct type based on a LOB data type.

**SPECIFIC *specific-name***

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

#### PARAMETER CCSID or VARCHAR

##### CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS TABLE clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

##### VARCHAR

Specifies that the representation of the values of varying length character string-parameters, including, if applicable, the output of the function, for functions which specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

##### NULTERM

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

##### STRUCTURE

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a function and in the RETURNS TABLE clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

#### **EXTERNAL**

Specifies that the function being registered is based on code that is written in an external programming language and adheres to the documented linkage conventions and interface of that language.

If you do not specify the NAME clause, 'NAME *function-name*' is implicit. In this case, *function-name* must not be longer than 8 characters.

#### **NAME *string or identifier***

Identifies the name of the load module that contains the user-written code that implements the logic of the function.

For other values of LANGUAGE, the name can be a string constant that is no longer than 8 characters. It must conform to the naming conventions for load modules. Alphabetical extenders for national languages can be used as the first character and as subsequent characters in the load module name.

DB2 loads the load module when the function is invoked. The load module is created when the program that contains the function body is compiled and link-edited. The load module does not need to exist when the CREATE FUNCTION statement is executed. However, it must exist and be accessible by the current server when the function is invoked.

You can specify the EXTERNAL clause in one of the following ways:

```
EXTERNAL  
EXTERNAL NAME PKJVSP1  
EXTERNAL NAME 'PKJVSP1'
```

If you specify an external program name, you must use the NAME keyword. For example, this syntax is not valid:

```
EXTERNAL PKJVSP1
```

#### **LANGUAGE**

Specifies the application programming language in which the function program is written. All programs must be designed to run in IBM's Language Environment environment.

#### **ASSEMBLE**

The function is written in Assembler.

- C** The function is written in C or C++. The VARCHAR clause can only be specified if LANGUAGE C is specified.

#### **COBOL**

The function is written in COBOL, including the object-oriented language extensions.

#### **PLI**

The function is written in PL/I.

#### **PARAMETER STYLE SQL**

Specifies the linkage convention that the function program uses to receive input parameters from and pass return values to the invoking SQL statement.

PARAMETER STYLE SQL specifies the parameter passing convention that supports passing null values both as input and for output. The parameters that are passed between the invoking SQL statement and the function include:

- $n$  parameters for the input parameters that are specified for the function
- $m$  parameters for the result columns of the function that are specified on the RETURNS TABLE clause
- $n$  parameters for the indicator variables for the input parameters
- $m$  parameters for the indicator variables of the result columns of the function that are specified on the RETURNS TABLE clause
- The SQLSTATE to be returned to DB2
- The qualified name of the function
- The specific name of the function
- The SQL diagnostic string to be returned to DB2
- The scratchpad, if SCRATCHPAD is specified
- The call type
- The DBINFO structure, if DBINFO is specified

For complete details about the structure of the parameter list that is passed, see *DB2 Application Programming and SQL Guide*.

#### **NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns function returns the same results each time that the function is invoked with the same input arguments.

##### **NOT DETERMINISTIC**

The function might not return the same results each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers, or any function that contains SQL statements.

NOT DETERMINISTIC is the default.

##### **DETERMINISTIC**

The function always returns the same result each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

#### **FENCED**

Specifies that the function runs in an external address space to prevent the function from corrupting DB2 storage.

FENCED is the default.

#### **RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT**

Specifies whether the function is called if any of the input arguments is null at execution time.

**RETURNS NULL ON NULL INPUT**

The function is not called if any of the input arguments is null. The result is an empty table, which is a table with no rows. RETURNS NULL ON INPUT is the default.

**CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null argument values. The function can return an empty table, depending on its logic.

**READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function. The default is READS SQL DATA. For the data access classification of each statement, see Table 138 on page 1605.

**READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the function can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The function cannot execute statements that read or modify data.

**NO SQL**

Specifies that the function can execute only SQL statements with a data access classification of NO SQL.

**EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

Because DB2 uses the RRS attachment for functions, DB2 can participate in two-phase commit with any other resource manager that uses RRS. For resource managers that do not use RRS, there is no coordination of commit or rollback operations on non-DB2 resources.

**EXTERNAL ACTION**

The function can take an action that changes the state of an object that DB2 does not manage.

If you specify EXTERNAL ACTION, DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION is the default.

**NO EXTERNAL ACTION**

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. NO EXTERNAL ACTION is not the default. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

**NO PACKAGE PATH or PACKAGE PATH *package-path***

Specifies the packagepath to use when the function is run. This is the list of the possible package collections into which the DBRM this is associated with the function is bound.

**NO PACKAGE PATH**

Specifies that the list of package collections for the function is the same as the list of package collection IDs for the program that invokes the function. If the program that invokes the function does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

**PACKAGE PATH *package-path***

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the function is invoked.

The *package-path* value that is provided when the function is created is checked when the function is invoked. If *package-path* contains SESSION\_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

**NO SCRATCHPAD or SCRATCHPAD**

Specifies whether DB2 provides a scratchpad for the function. It is strongly recommended that functions be reentrant, and a scratchpad provides an area for the function to save information from one invocation to the next.

**NO SCRATCHPAD**

Specifies that a scratchpad is not allocated and passed to the function. NO SCRATCHPAD is the default.

**SCRATCHPAD *length***

Specifies that when the function is invoked for the first time, DB2 allocates memory for a scratchpad. A scratchpad has the following characteristics:

- *length* must be between 1 and 32767. The default value is 100 bytes.
- DB2 initializes the scratchpad to all binary zeros (X'00's).
- The scope of a scratchpad is the SQL statement. Each reference to the function in an SQL statement has a scratchpad. For example, assuming that function UDFX was defined with the SCRATCHPAD keyword, two scratchpads are allocated for the two references to UDFX in the following SQL statement:

```
SELECT *
  FROM TABLE (UDFX(A)), TABLE (UDFX(B));
```

- The scratchpad is persistent. DB2 preserves its content from one invocation of the function to the next. Any changes that the function makes to the scratchpad on one call are still there on the next call. DB2

initializes the scratchpads when it begins to execute an SQL statement. DB2 does not reset scratchpads when a correlated subquery begins to execute.

- The scratchpad can be a central point for the system resources that the function acquires. If the function acquires system resources, specify FINAL CALL to ensure that DB2 calls the function one more time so that the function can free those system resources.

Each time the function invoked, DB2 passes an additional argument to the function that contains the address of the scratchpad.

If you specify SCRATCHPAD, DB2:

- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

#### **NO FINAL CALL or FINAL CALL**

Specifies whether a *first call* and a *final call* are made to the function.

##### **NO FINAL CALL**

A first call and final call are not made to the function. NO FINAL CALL is the default.

##### **FINAL CALL**

A first call and final call are made to the function in addition to one or more *open*, *fetch*, or *close calls*.

The types of calls are:

##### **First call**

An *first call* occurs only if the function was defined with FINAL CALL. Before a first call, the scratchpad is set to binary zeros. Argument values are passed to the function, and the function might acquire memory or perform other one-time only resource initialization. However, the function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments.

##### **Open call**

An *open call* occurs unless the function returns an error. The scratchpad is set to binary zeros only if the function was defined with NO FINAL CALL. Argument values are passed to the function, and the function might perform any one-time initialization actions that are required. However, the function should not return any data to DB2.

##### **Fetch call**

An *fetch call* occurs unless the function returns an error during the first call or open call. Argument values are passed to the function, and DB2 expects the function to return a row of data or the end-of-table condition. If a scratchpad is also passed to the function, it remains untouched from the previous call.

##### **Close call**

An *close call* occurs unless the function returns an error during the first call, open call, or fetch call. No SQL-argument or SQL-argument-ind values are passed to the function, and if the function attempts to

examine these values, unpredictable results might occur. If a scratchpad is also passed to the function, it remains untouched from the previous call.

The function should not return any data to DB2, but it can set return values for the SQL-state and diagnostic-message arguments. Also on close call, a function that is defined with NO FINAL CALL should release any system resources that it acquired. (A function that is defined with FINAL CALL should release any acquired resources on the final call.)

- Final** The *final call* balances the first call, and like the first call, occurs only if the function was defined with FINAL CALL. The function can set return values for the SQL-state and diagnostic-message arguments. The function should also release any system resources that it acquired. A final call occurs at these times:
- *End of statement*: When the cursor is closed for cursor-oriented statements, or the execution of the statement has completed.
  - *End of transaction*: When normal end of statement processing does not occur. For example, the logic of an application, for some reason, bypasses closing the cursor.

If a commit, rollback, or abort operation causes the final call, the function cannot issue any SQL statements when it is invoked.

#### **DISALLOW PARALLEL**

Specifies that DB2 does not consider parallelism for the function.

#### **NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the function when it is invoked.

#### **NO DBINFO**

No additional information is passed. NO DBINFO is the default.

#### **DBINFO**

An additional argument is passed when the function is invoked. The argument is a structure that contains information such as the application runtime authorization ID, the schema name, the name of a table or column that the function might be inserting into or updating, and identification of the database server that invoked the function. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

#### **CARDINALITY *integer***

Specifies an estimate of the expected number of rows that the function returns. The number is used for optimization purposes. The value of *integer* must range from 0 to 2147483647.

If you do not specify CARDINALITY, DB2 assumes a finite value. The finite value is the same value that DB2 assumes for tables for which the RUNSTATS utility has not gathered statistics.

If a function has an infinite cardinality—the function never returns the “end-of-table” condition and always returns a row, then a query that requires the “end-of-table” to work correctly will need to be interrupted. Thus, avoid using such functions in queries that involve GROUP BY and ORDER BY.

**NO COLLID or COLLID *collection-id***

Identifies the package collection that is to be used when the function is executed. This is the package collection into which the DBRM that is associated with the function program is bound.

**NO COLLID**

The package collection for the function is the same as the package collection of the program that invokes the function. If a trigger invokes the function, the collection of the trigger package is used. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID *collection-id***

The name of the package collection that is to be used when the external is executed.

**WLM ENVIRONMENT**

Identifies the WLM (workload manager) application environment in which the function is to run. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the function runs in the WLM-established stored procedure address space that is specified at installation time.

**name**

The WLM environment in which the function must run. If another user-defined function or a stored procedure calls the function and that calling routine is running in an address space that is not associated with the WLM environment, DB2 routes the function request to a different address space.

**(name,\*)**

When an SQL application program directly invokes the function, the WLM environment in which the function runs.

If another user-defined function or a stored procedure calls the function, the function runs in same environment that the calling routine uses. In this case, authorization to run the function in the WLM environment is not checked because the authorization of the calling routine suffices.

Users must have the appropriate authorization to execute functions in the specified WLM environment. For an example of a RACF command that provides this authorization, see *Running external functions in WLM environments*.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of the function can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a function, setting a limit can be helpful if the function gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

**LIMIT** *integer*

The limit on the service units is a positive integer in the range of 1 to 2 147 483 647. If the function uses more service units than the specified value, DB2 cancels the function.

**STAY RESIDENT**

Specifies whether the load module for the function is to remain resident in memory when the function ends.

**NO** The load module is deleted from memory after the function ends. Use NO for non-reentrant functions. NO is the default.

**YES**

The load module remains resident in memory after the function ends. Use YES for reentrant functions.

**PROGRAM TYPE**

Specifies whether the function program runs as a main routine or a subroutine.

**SUB**

The function runs as a subroutine. SUB is the default.

**MAIN**

The function runs as a main routine.

**SECURITY**

Specifies how the function interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The function does not require an external security environment. If the function accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the WLM-established stored procedure address space.

DB2 is the default.

**USER**

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the primary authorization ID of the process that invoked the function.

**DEFINER**

An external security environment should be established for the function. If the function accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the function.

**RUN OPTIONS** *runtime-options*

Specifies the Language Environment runtime options to be used for the function. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

#### **INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a user-defined function in Table 37 on page 151.

#### **DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a user-defined function in Table 37 on page 151.

#### **STATIC DISPATCH**

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. STATIC DISPATCH is the default.

#### **STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures.

#### **STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

#### **STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

#### **CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

### **Notes**

See "Notes" on page 935 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Determining the uniqueness of functions in a schema
- Character string representation considerations
- Overriding a built-in function
- Scrollable cursors specified with user-defined functions
- Restrictions on nesting

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

## Example

The following example registers a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

Within the context of a single session, the table function always returns the same table; therefore, it is defined as DETERMINISTIC. In addition, the DISALLOW PARALLEL keyword is added because table functions cannot operate in parallel.

Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value and is specified to help DB2.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
    RETURNS TABLE (DOC_ID CHAR(16))
    EXTERNAL NAME ABC
    LANGUAGE C
    PARAMETER STYLE SQL
    NO SQL
    DETERMINISTIC
    NO EXTERNAL ACTION
    FENCED
    SCRATCHPAD
    FINAL CALL
    DISALLOW PARALLEL
    CARDINALITY 20;
```

---

## CREATE FUNCTION (sourced)

This CREATE FUNCTION statement registers a user-defined function that is based on an existing scalar or aggregate function with a database server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

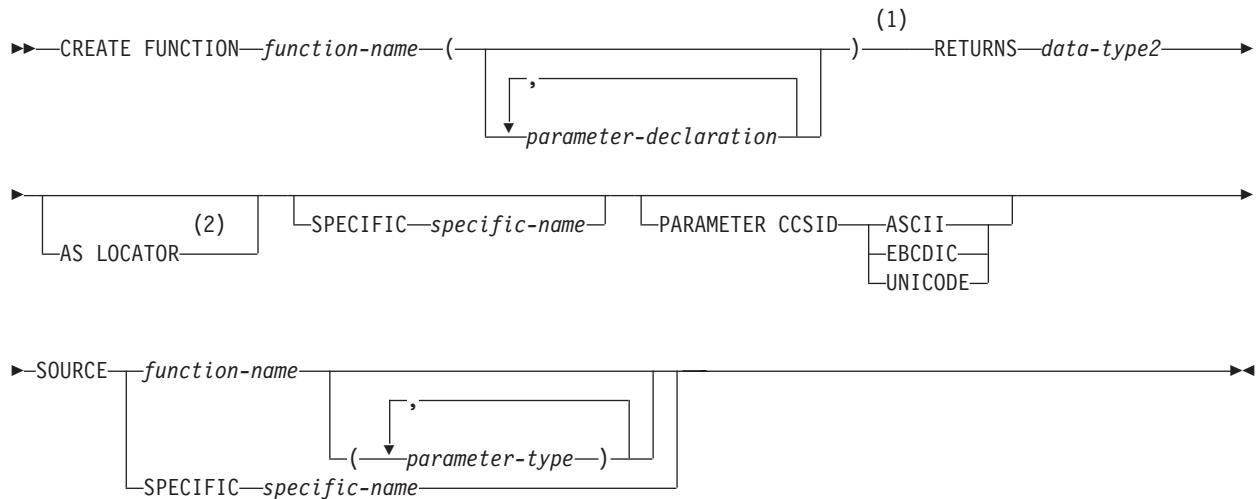

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Additional privileges are required for the source function, and other privileges are also needed if the function uses a table as a parameter, or refers to a distinct type. These privileges are:

- The EXECUTE privilege for the function that the SOURCE clause references.
- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

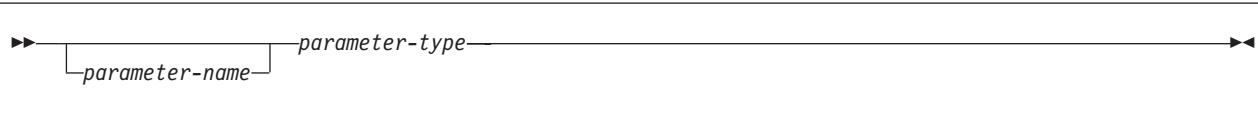

## Syntax

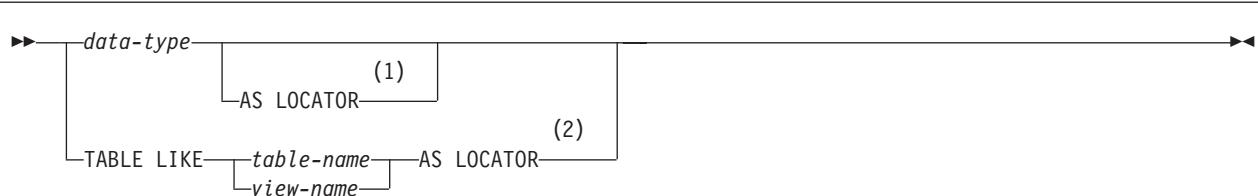

### Notes:

- 1 RETURNS, SPECIFIC, and SOURCE can be specified in any order.
- 2 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

### parameter-declaration:

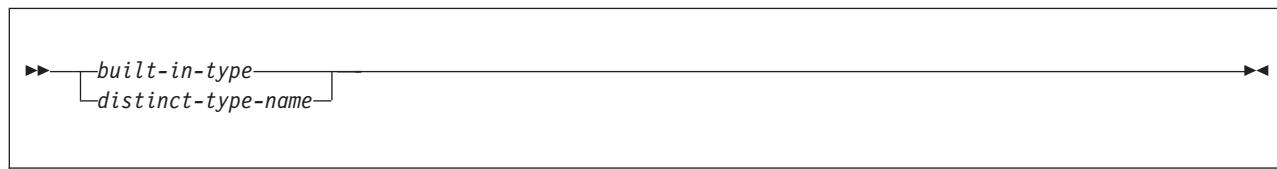

### parameter-type:

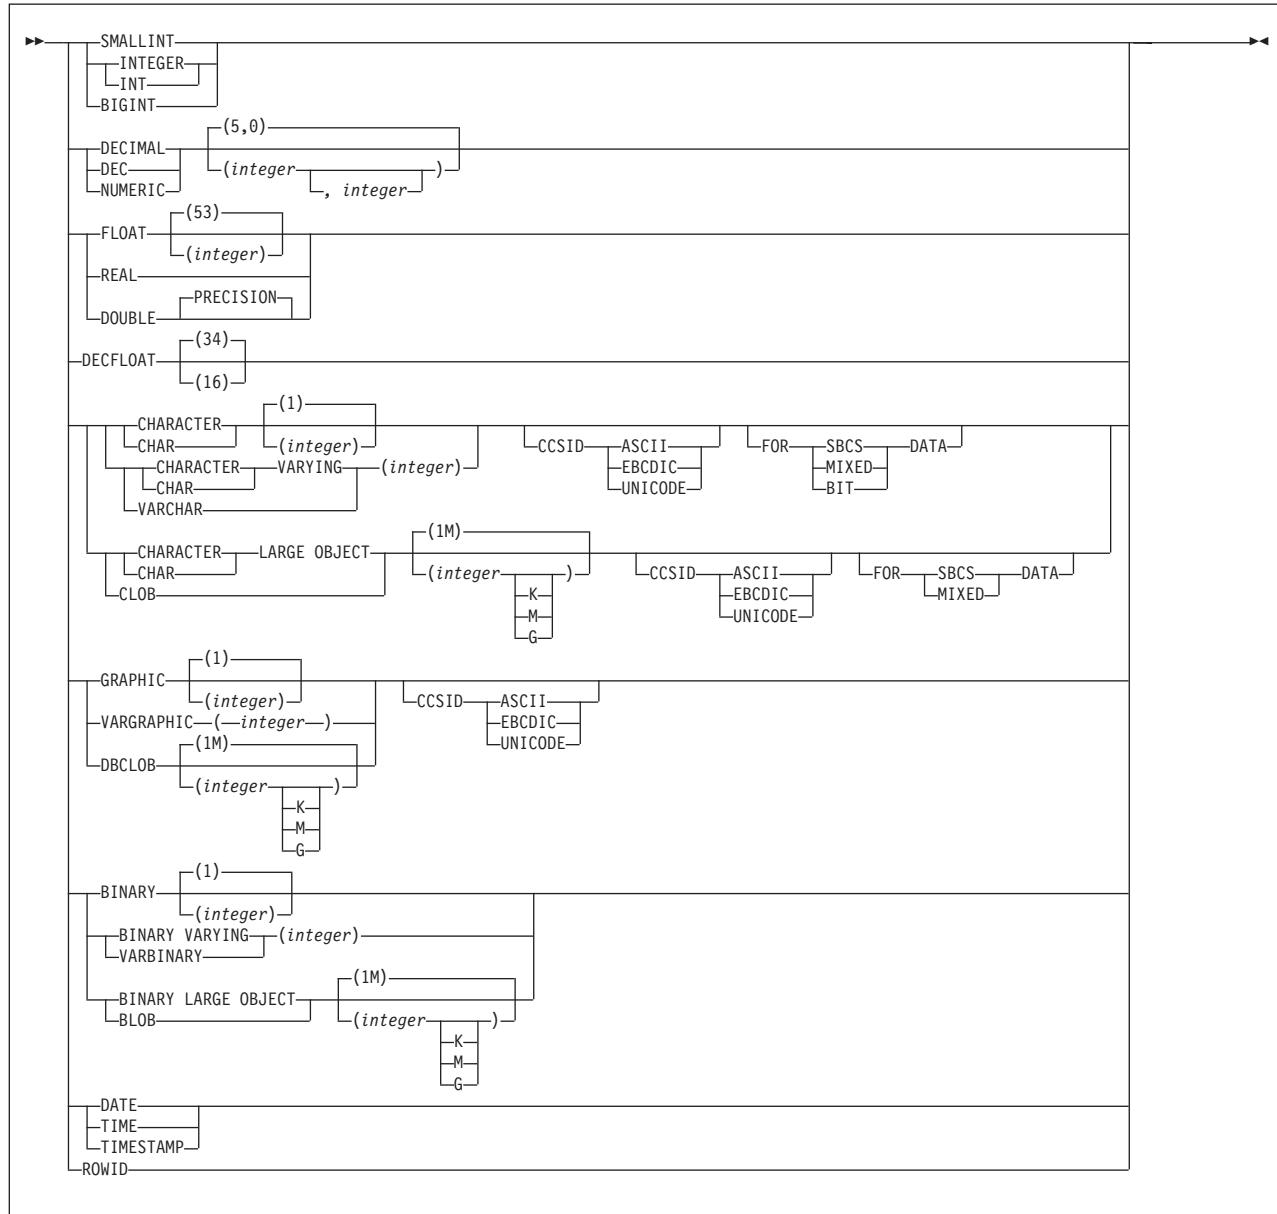

### Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
- 2 The TABLE LIKE name AS LOCATOR clause can only be specified for the parameter list of the function that is being defined.

**data-type:**

**built-in-type:**

## Description

*function-name*

Names the user-defined function. The name is implicitly or explicitly qualified by a schema name.

The combination of name, schema name, the number of parameters, and the data type of each parameter<sup>27</sup> (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

If the function is sourced on an existing function to enable the use of the existing function with a distinct type, the name can be the same name as the existing function. In general, more than one function can have the same name if the function signature of each function is unique.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

ALL	LIKE	UNIQUE
AND	MATCH	UNKNOWN
ANY	NOT	=
BETWEEN	NULL	~=
DISTINCT	ONLY	<
EXCEPT	OR	≤
EXISTS	OVERLAPS	~<
FALSE	SIMILAR	>
FOR	SOME	≥
FROM	TABLE	~>
IN	TRUE	~><
IS	TYPE	

The schema name can be 'SYSTOOLS' or 'SYSFUN' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

*(parameter-declaration,...)*

Specifies the number of input parameters of the function and the data type of each parameter. All of the parameters for a function are input parameters and are nullable. There must be one entry in the list for each parameter that the function expects to receive. Although not required, you can give each parameter a name.

A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

`CREATE FUNCTION WOOFER()`

*parameter-name*

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

*data-type*

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the input parameter is a built-in data type.

For information on the data types, see *built-in-type*.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding

27. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

*distinct-type-name*

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

You can specify any built-in data type or distinct type that matches or can be cast to the data type of the corresponding parameter of the source function (the function that is identified in the SOURCE clause). (For information on casting data types, see “Casting between data types” on page 96.) Length, precision, or scale attributes do not have to be specified for data types with these attributes. When specifying data types with these attributes, follow these rules:

- An empty set of parentheses can be used to indicate that the length, precision, or scale is the same as the source function.
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default values are used.

**AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

**TABLE LIKE *table-name* or *view-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the function is invoked, the actual values in the transition table are not passed

to the function. A single value is passed instead. This single value is a locator to the table, which the function uses to access the columns of the transition table. A function with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACE. The number of columns and the attributes of those columns are determined at the time the CREATE FUNCTION statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the function.

*table-name* or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the function cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE FUNCTION statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE FUNCTION statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the function is invoked, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE FUNCTION statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE FUNCTION statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

## RETURNS

Identifies the output of the function.

*data-type2*

Specifies the data type of the output. The output is nullable.

You can specify any built-in data type or distinct type that can be cast from the data type of the result of the source function. (For information on

casting data types, see “Casting between data types” on page 96.) For additional rules that apply to the data type that you can specify, see Rules for creating sourced functions.

#### **AS LOCATOR**

Specifies that the function returns a locator to the value rather than the actual value. You can specify AS LOCATOR only if the output from the function has a LOB data type or a distinct type based on a LOB data type.

#### **SPECIFIC *specific-name***

Provides a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

#### **PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

#### **SOURCE**

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The source function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the built-in functions shown in Table 94 (if a particular syntax is shown, only the indicated form cannot be specified).

*Table 94. Built-in functions that cannot be the source function.* When listed with specific conditions, the function cannot be a source function under those conditions. Otherwise, the function cannot be a source function regardless of its arguments.

Type of function	Restricted functions
Aggregate	COUNT(*) COUNT_BIG(*) XMLAGG

*Table 94. Built-in functions that cannot be the source function (continued).* When listed with specific conditions, the function cannot be a source function under those conditions. Otherwise, the function cannot be a source function regardless of its arguments.

Type of function	Restricted functions
Scalar function	<p>CHAR(datetime-expression, second-argument) where second-argument is ISO, USA, EUR, JIS, or LOCAL or if CHAR is specified with OCTETS, CODEUNITS16, or CODEUNITS32.</p> <p>CHARACTER_LENGTH</p> <p>CLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>COALESCE</p> <p>DBCLOB if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>DECRYPT_BIT where second argument is DEFAULT</p> <p>DECRYPT_CHAR where second argument is DEFAULT</p> <p>DECRYPT_DB where second argument is DEFAULT</p> <p>EXTRACT</p> <p>GETVARIABLE where second argument is DEFAULT</p> <p>GRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>INSERT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>LEFT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>LOCAL</p> <p>LOCATE if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>MAX</p> <p>MIN</p> <p>NULLIF</p> <p>POSITION</p> <p>RID</p> <p>RIGHT if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>STRIP where multiple arguments are specified</p> <p>SUBSTRING</p> <p>VARCHAR if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>VARGRAPHIC if OCTETS, CODEUNITS16, or CODEUNITS32 is specified</p> <p>XMLCONCAT</p> <p>XMLELEMENT</p> <p>XMLFOREST</p> <p>XMLNAMESPACES</p>

If you base the sourced function directly or indirectly on an external scalar function, the sourced function inherits the attributes of the external scalar function. This can involve several layers of sourced functions. For example, assume that function A is sourced on function B, which in turn is sourced on function C. Function C is an external scalar function. Functions A and B inherit all of the attributes that are specified on the EXTERNAL clause of the CREATE FUNCTION statement for function C.

*function-name*

Identifies the function that is to be used as the source function. The source

function can be defined with any number of parameters. If more than one function is defined with the specified name in the specified or implicit schema, an error is returned.

If you specify an unqualified *function-name*, DB2 searches the schemas of the SQL path. DB2 selects the first schema that has only one function with this name on which the user has EXECUTE authority. An error is returned if a function is not found or a schema has more than one function with this name.

*function-name (parameter-type,...)*

Identifies the function that is to be used as the source function by its function signature, which uniquely identifies the function. The *function-name (parameter-type,...)* must identify a function with the specified signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. DB2 uses the number of data types and the logical concatenation of the data types to identify the specific function instance. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name()* is specified, the identified function must have zero parameters.

*function-name*

Identifies the function name of the source function. If you specify an unqualified name, DB2 searches the schemas of the SQL path. Otherwise, DB2 searches for the function in the specified schema.

*parameter-type,...*

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

Empty parentheses are allowed for some data types that are specified in this context. For data types that have a length, precision, or scale attribute, use one of the following specifications:

- Empty parentheses indicate that DB2 ignores the attribute when determining whether the data types match. For example, DEC() is considered a match for a parameter of a function that is defined with a data type of DEC(7,2). However, FLOAT cannot be specified with empty parentheses because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not need to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type

are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

If you omit the FOR *subtype* DATA clause or the CCSID clause for data types with a subtype or encoding scheme attribute, DB2 is to ignore the attribute when determining whether the data types match. An exception to ignoring the attribute is FOR BIT DATA. A character FOR BIT DATA parameter of the new function cannot correspond to a parameter of the source function that is not defined as character FOR BIT DATA. Likewise, a character parameter of the new function that is not FOR BIT DATA cannot correspond to a parameter of the source function that is defined as character FOR BIT DATA.

The number of input parameters in the function that is being created must be the same as the number of parameters in the source function. If the data type of each input parameter is not the same as or castable to the corresponding parameter of the source function, an error occurs. The data type of the final result of the source function must match or be castable to the result of the sourced function.

#### **AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or distinct type that is based on a LOB.

#### **SPECIFIC *specific-name***

Identifies the function to be used as the source function by its specific name.

If you specify an unqualified *specific-name*, DB2 searches the SQL path to locate the schema. DB2 selects the first schema that contains a function with this specific name for which the user has EXECUTE authority. DB2 returns an error if it cannot find a function with the specific name in one of the schemas in the SQL path.

If you specify a qualified *specific-name*, DB2 searches the named schema for the function. DB2 returns an error if it cannot find a function with the specific name.

## **Notes**

**Owner privileges:** The owner is authorized to execute the function (EXECUTE privilege) in the following cases:

- If the underlying function is a user-defined function, and the owner is authorized with the grant option to execute the underlying function, the privilege on the new function includes the grant option. Otherwise, the owner can execute the new function but cannot grant others the privilege to do so.
- If the underlying function is a built-in function, the owner is authorized with the grant option to execute the underlying built-in function and the privilege on the new function includes the grant option.

For more information, see “GRANT (function or procedure privileges)” on page 1340. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

**Choosing data types for parameters:** When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can

affect the values of the parameters. (See “Promotion of data types” on page 95). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, we recommend using the following data types for parameters:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

*Specifying the encoding scheme for parameters:* The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE.

*Determining the uniqueness of functions in a schema:* At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a schema must not contain two functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, scale, subtype or encoding scheme attributes in the comparison. DB2 considers the synonyms of data types (DECIMAL and NUMERIC, REAL and FLOAT, and DOUBLE and FLOAT) a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), or DECFLOAT(16) and DECFLOAT(34).

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (INT, CHAR(15)) ...
CREATE FUNCTION PART (INTEGER, CHAR(40)) ...
CREATE FUNCTION ANGLE (DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (DEC(10,7)) ...
```

*Rules for creating sourced functions:* For the discussion in this section, assume that the function that is being created is named NEWF and the source function is named SOURCEF. Consider the following rules when creating a sourced function:

- The unqualified names of the sourced function and source function can be different (NEWF and SOURCEF).
- The number of input parameters for NEWF and SOURCEF must be the same.

- When specifying the input parameters and output for NEWF, you can specify a value for the precision, scale, subtype, or encoding scheme for a data type with any of these attributes or use empty parentheses.

Empty parentheses, such as VARCHAR(), indicate that the value of the attribute is the same as the attribute for the corresponding parameter of SOURCEF, or that is determined by data type promotion. If you specify any values for the attributes, DB2 checks the values against the corresponding input parameters and returned output of SOURCEF as described next.

- When the CREATE FUNCTION statement is executed, DB2 checks the input parameters of NEWF against those of SOURCEF. The data type of each input parameter of NEWF function must be either the same as, or promotable to, the data type of the corresponding parameter of SOURCEF. (For information on the promotion of data types, see “Casting between data types” on page 96.)

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, an argument that matches the data type and length or precision attributes of a NEWF parameter might not be promotable if the corresponding SOURCEF parameter has a shorter length or less precision. In general, do not define the parameters of a sourced function with length or precision attributes that are greater than the attributes of the corresponding parameters of the source function.

- When the CREATE FUNCTION statement is executed, DB2 checks the data type identified in the RETURNS clause of NEWF against the data type that SOURCEF returns. The data type that SOURCEF returns must be either the same as, or promotable to, the RETURNS data type of NEWF.

This checking does not guarantee that an error will not occur when NEWF is invoked. For example, the value of a result that matches the data type and length or precision attributes of those specified for SOURCEF's result might not be promotable if the RETURNS data type of NEWF has a shorter length or less precision. Consider the possible effects of defining the RETURNS data type of a sourced function with length or precision attributes that are less than the attributes defined for the data type returned by source function.

**Scrollable cursors specified with user-defined functions:** A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

## Examples

*Example 1:* Assume that you created a distinct type HATSIZE, which you based on the built-in data type INTEGER. You want to have an AVG function to compute the average hat size of different departments. Create a sourced function that is based on built-in function AVG.

```
CREATE FUNCTION AVE (HATSIZE) RETURNS HATSIZE
  SOURCE SYSIBM.AVG (INTEGER);
```

When you created distinct type HATSIZE, two cast functions were generated, which allow HATSIZE to be cast to INTEGER for the argument and INTEGER to be cast to HATSIZE for the result of the function.

*Example 2:* After Smith registered the external scalar function CENTER in his schema, you decide that you want to use this function, but you want it to accept

two INTEGER arguments instead of one INTEGER argument and one FLOAT argument. Create a sourced function that is based on CENTER.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
  RETURNS FLOAT
  SOURCE SMITH.CENTER (INTEGER, FLOAT);
```

---

## CREATE FUNCTION (SQL scalar)

The CREATE FUNCTION (SQL Scalar) statement defines an SQL scalar function at the current server. The function returns a single value each time it is invoked.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

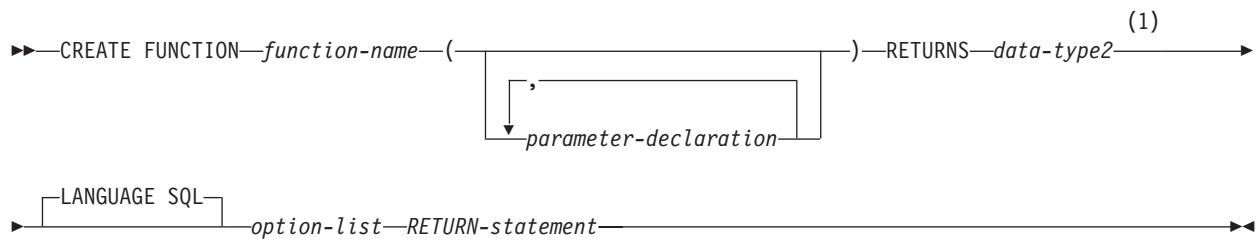

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

Additional privileges are required if the function uses a table as a parameter or refers to a distinct type. These privileges are:

- The SELECT privilege on any table that is an input parameter to the function.
- The USAGE privilege on each distinct type that the function references.

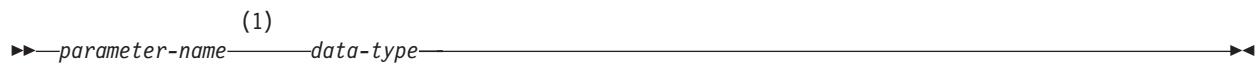

## Syntax

### Notes:

- 1 The RETURNS clause, the RETURN-statement, and the clauses in the option-list can be specified in any order. However, the same clause cannot be specified more than once.

### parameter-declaration:

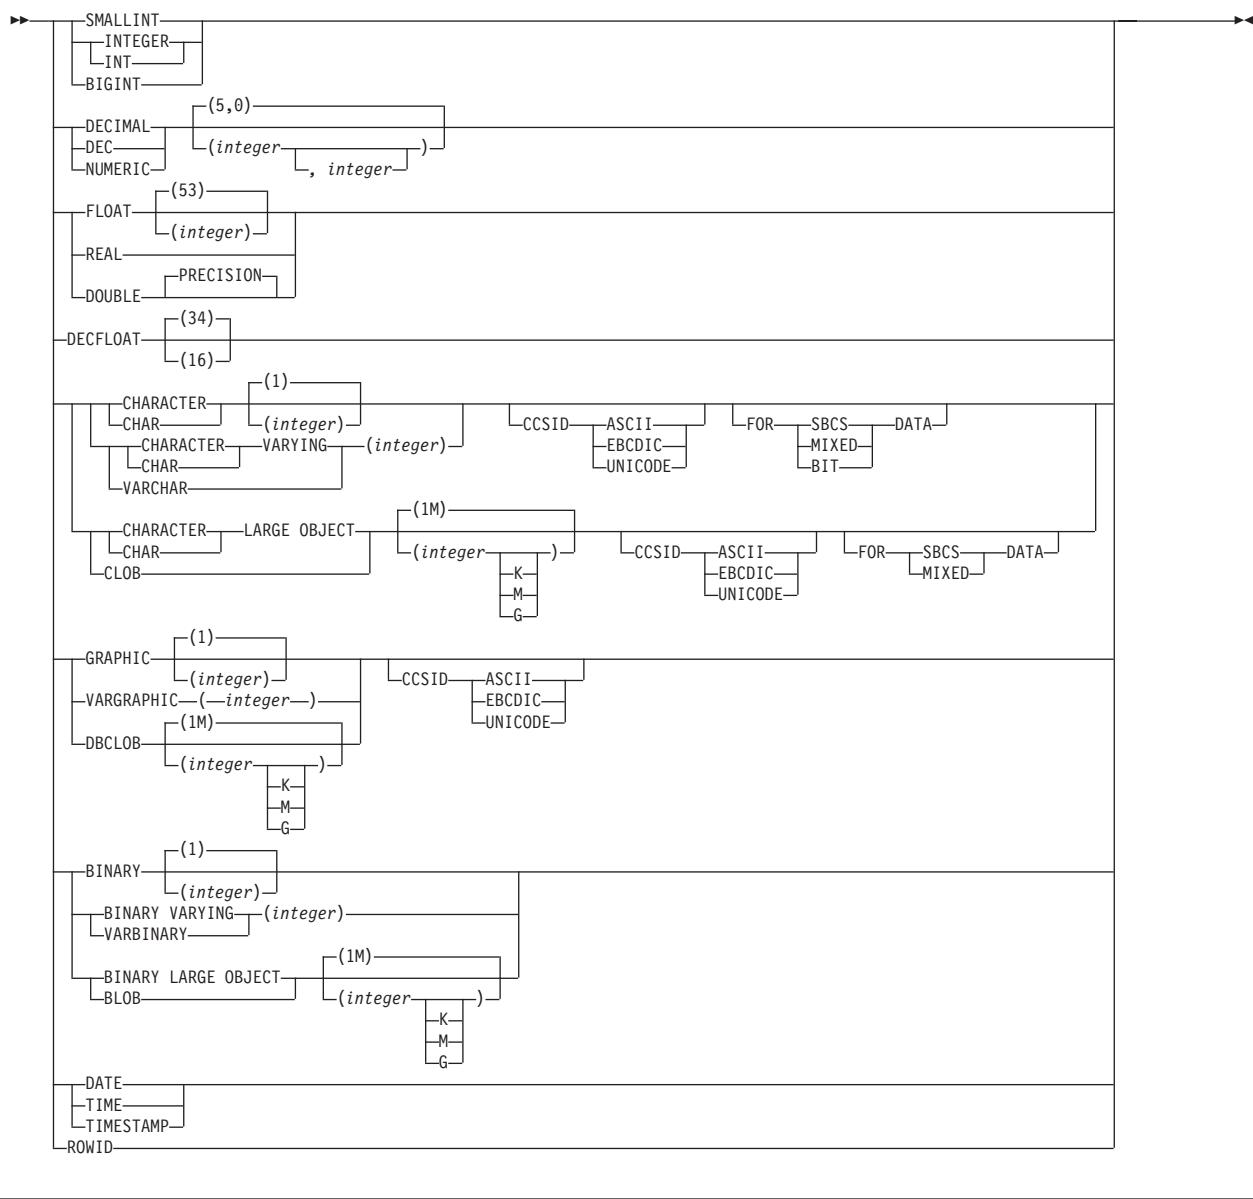

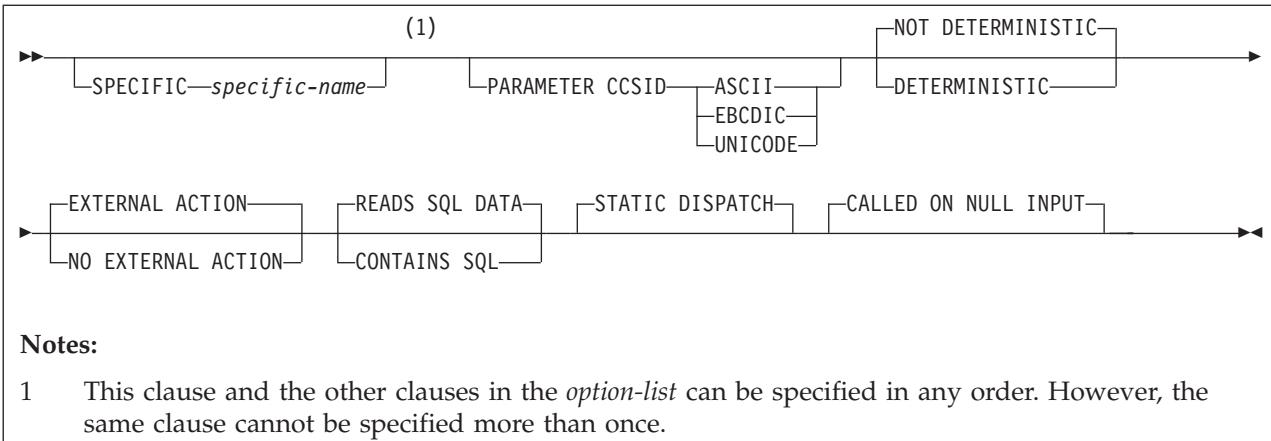

### Notes:

- 1 Note that the parameter-name is required for SQL functions.

### data-type:

**built-in-type:****option-list:**

## Description

*function-name*

NAMES the user-defined function. The name is implicitly or explicitly qualified by a schema name. The combination of name, schema name, the number of parameters, and the data type of each parameter<sup>28</sup> (without regard for any length, precision, scale, subtype or encoding scheme attributes of the data type) must not identify a user-defined function that exists at the current server.

You can use the same name for more than one function if the function signature of each function is unique.

- The unqualified form of *function-name* is an SQL identifier.

The name must not be any of the following system-reserved keywords even if you specify them as delimited identifiers:

ALL	LIKE	UNIQUE
AND	MATCH	UNKNOWN
ANY	NOT	=
BETWEEN	NULL	~=
DISTINCT	ONLY	<
EXCEPT	OR	≤
EXISTS	OVERLAPS	~<
FALSE	SIMILAR	>
FOR	SOME	≥
FROM	TABLE	→
IN	TRUE	↔
IS	TYPE	

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

*(parameter-declaration, ...)*

Identifies the number of input parameters of the function, and specifies the name and data type of each parameter. All of the parameters for a function are input parameters. There must be one entry in the list for each parameter that the function expects to receive. A function can have no parameters. In this case, you must code an empty set of parentheses, for example:

```
CREATE FUNCTION WOOFER()
```

28. If the function has more than 30 parameters, only the first 30 parameters are used to determine whether the function is unique.

*parameter-name*

Specifies the name of the input parameter. The name is an SQL identifier, and each name in the parameter list must not be the same as any other name.

*data-type*

Specifies the data type of the input parameter. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the input parameter is a built-in data type.

For information on the data types, see *built-in-type*.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

*distinct-type-name*

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type must be the same—either all ASCII, all EBCDIC, or all UNICODE.

Although parameters with a character data type have an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the function program can receive character data of any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the function is invoked. An error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

**RETURNS**

Identifies the output of the function.

*data-type2*

Specifies the data type of the output. The output is nullable.

The same considerations that apply to the data type of input parameter, as described under *data-type*, apply to the data type of the output of the function.

#### **LANGUAGE SQL**

Specifies that the function is written exclusively in SQL.

#### **SPECIFIC *specific-name***

Specifies a unique name for the function. The name is implicitly or explicitly qualified with a schema name. The name, including the schema name, must not identify the specific name of another function that exists at the current server.

The unqualified form of *specific-name* is an SQL identifier. The qualified form is an SQL identifier (the schema name) followed by a period and an SQL identifier.

If you do not specify a schema name, it is the same as the explicit or implicit schema name of the function name (*function-name*). If you specify a schema name, it must be the same as the explicit or implicit schema name of the function name.

If you do not specify the SPECIFIC clause, the default specific name is the name of the function. However, if the function name does not provide a unique specific name or if the function name is a single asterisk, DB2 generates a specific name in the form of:

SQLxxxxxxxxxxxx

where 'xxxxxxxxxxxx' is a string of 12 characters that make the name unique.

The specific name is stored in the SPECIFIC column of the SYSROUTINES catalog table. The specific name can be used to uniquely identify the function in several SQL statements (such as ALTER FUNCTION, COMMENT, DROP, GRANT, and REVOKE) and must be used in DB2 commands (START FUNCTION, STOP FUNCTION, and DISPLAY FUNCTION). However, the function cannot be invoked by its specific name.

#### **PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or RETURNS clause, or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

#### **NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the function returns the same results each time that the function is invoked with the same input arguments.

#### **NOT DETERMINISTIC**

The function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. DB2 uses this information to disable the merging of views and table expressions when processing SELECT and SQL data change statements that refer to this function. An example of a function that is not deterministic is one that generates random numbers.

NOT DETERMINISTIC must be specified explicitly or implicitly if the function program accesses a special register or invokes another function that is not deterministic. NOT DETERMINISTIC is the default.

#### **DETERMINISTIC**

The function always returns the same result function each time that the function is invoked with the same input arguments. An example of a deterministic function is a function that calculates the square root of the input. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. DETERMINISTIC is not the default. If applicable, specify DETERMINISTIC to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

#### **EXTERNAL ACTION or NO EXTERNAL ACTION**

Specifies whether the function takes an action that changes the state of an object that DB2 does not manage. An example of an external action is sending a message or writing a record to a file.

#### **EXTERNAL ACTION**

The function can take an action that changes the state of an object that DB2 does not manage.

Some SQL statements that invoke functions with external actions can result in incorrect results if parallel tasks execute the function. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

If you specify EXTERNAL ACTION, then DB2:

- Materializes the views and table expressions in SELECT and SQL data change statements that refer to the function. This materialization can adversely affect the access paths that are chosen for the SQL statements that refer to this function. Do not specify EXTERNAL ACTION if the function does not have an external action.
- Does not move the function from one task control block (TCB) to another between FETCH operations.
- Does not allow another function or stored procedure to use the TCB until the cursor is closed. This is also applicable for cursors declared WITH HOLD.

The only changes to resources made outside of DB2 that are under the control of commit and rollback operations are those changes made under RRS control.

EXTERNAL ACTION must be specified implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION. EXTERNAL ACTION is the default.

#### **NO EXTERNAL ACTION**

The function does not take any action that changes the state of an object that DB2 does not manage. DB2 uses this information to enable the merging of views and table expressions for SELECT and SQL data change statements that refer to this function. NO EXTERNAL ACTION is not the

default. If applicable, specify NO EXTERNAL ACTION to prevent non-optimal access paths from being chosen for SQL statements that refer to this function.

DB2 does not verify that the function program is consistent with the specification of EXTERNAL ACTION or NO EXTERNAL ACTION.

#### **READS SQL DATA or CONTAINS SQL**

Specifies which SQL statements, if any, can be executed in the function or any routine that is called from this function. The default is READS SQL DATA. For the data access classification of each statement, see Table 138 on page 1605.

##### **READS SQL DATA**

Specifies that the function can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The function cannot execute SQL statements that modify data.

##### **CONTAINS SQL**

Specifies that the function can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

#### **STATIC DISPATCH**

At function resolution time, DB2 chooses a function based on the static (or declared) types of the function parameters. **STATIC DISPATCH** is the default.

#### **CALLED ON NULL INPUT**

The function is called regardless of whether any of the input arguments are null, making the function responsible for testing for null arguments. The function can return null. **CALLED ON NULL INPUT**

#### **RETURN-*statement***

Specifies the return value of the function. For description of the statement, see "RETURN statement" on page 1580.

## **Notes**

**Choosing data types for parameters:** When you choose the data types of the input and output parameters for your function, consider the rules of promotion that can affect the values of the parameters. (See "Promotion of data types" on page 95). For example, a constant that is one of the input arguments to the function might have a built-in data type that is different from the data type that the function expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

**Specifying the encoding scheme for parameters:** The implicitly or explicitly specified encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII or all EBCDIC.

**Determining the uniqueness of functions in a schema:** At the current server, the function signature of each function, which is the qualified function name combined with the number and data types of the input parameters, must be unique. If the function has more than 30 input parameters, only the data types of the first 30 are used to determine uniqueness. This means that two different schemas can each contain a function with the same name that have the same data types for all of their corresponding data types. However, a single schema must not contain multiple functions with the same name that have the same data types for all of their corresponding data types.

When determining whether corresponding data types match, DB2 does not consider any length, precision, scale, subtype or encoding scheme attributes in the comparison. DB2 considers the synonyms of data types (DECIMAL and NUMERIC, REAL and FLOAT, and DOUBLE and FLOAT) a match. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), DECIMAL(4,3), or DECFLOAT(16) and DECFLOAT(34).

Assume that the following statements are executed to create four functions in the same schema. The second and fourth statements fail because they create functions that are duplicates of the functions that the first and third statements created.

```
CREATE FUNCTION PART (A INT, B CHAR(15)) ...
CREATE FUNCTION PART (A INTEGER, B CHAR(40)) ...
CREATE FUNCTION ANGLE (A DECIMAL(12,2)) ...
CREATE FUNCTION ANGLE (A DEC(10,7)) ...
```

**Overriding a built-in function:** Giving an SQL function the same name as a built-in function is not a recommended practice unless you are trying to change the functionality of the built-in function.

If you do intend to create an SQL function with the same name as a built-in function, be careful to maintain the uniqueness of its function signature. If your function has the same name and data types of the corresponding parameters of the built-in function but implements different logic, DB2 might choose the wrong function when the function is invoked with an unqualified function name. Thus, the application might fail, or perhaps even worse, run successfully but provide an inappropriate result.

**Resolution of function invocations:** DB2 resolves function invocations inside the body of the function according to the SQL path that is in effect for the CREATE FUNCTION statement. This SQL path does not change after the function is created.

**Referencing date and time special registers:** If an SQL function contains multiple references to any of the date or time special registers, all references return the same value. Further, this value is the same value returned by the register invocation in the statement that invoked the function.

**Self-referencing function:** The body of an SQL function (that is, the *expression* or NULL in the RETURN clause of the CREATE FUNCTION statement) cannot contain a recursive invocation of itself or to another function that invokes it, because such a function would not exist to be referenced.

**Scrollable cursors specified with user-defined functions:** A row can be fetched more than one time with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NOT NULL CALL as a synonym for RETURNS NULL ON NULL INPUT
- NULL CALL as a synonym for CALLED ON NULL INPUT

## Examples

*Example 1:* Define a scalar function that returns the tangent of a value using existing SIN and COS built-in functions:

```
CREATE FUNCTION TAN (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN SIN(X)/COS(X);
```

# CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server.

## Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

## Authorization

The privilege set that is defined below must include at least one of the following:

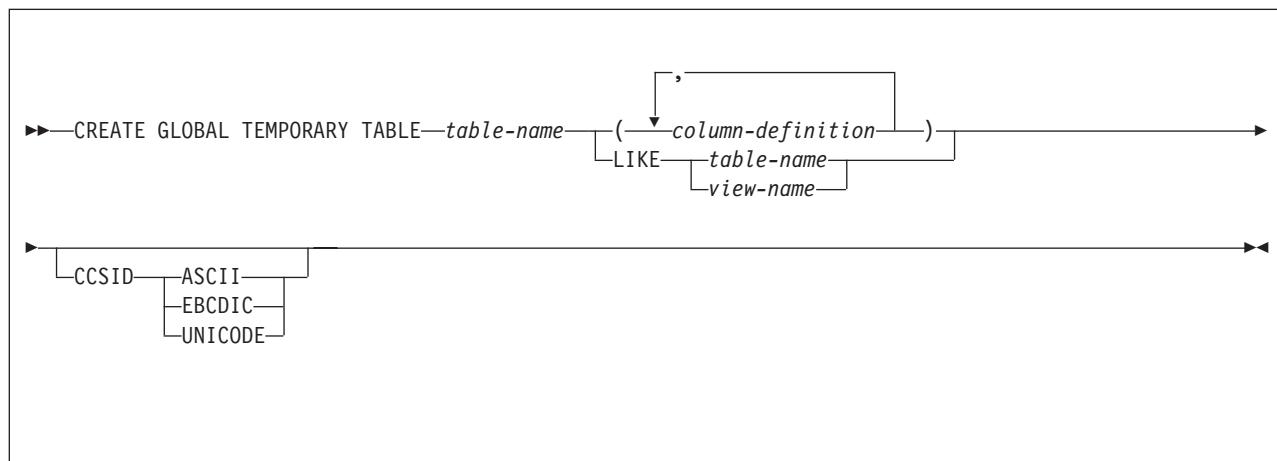

- The CREATETMTAB system privilege
  - The CREATETAB database privilege for any database
  - DBADM, DBCTRL, or DBMAINT authority for any database
  - SYSADM or SYSCTRL authority

However, DABADM, DBCTRL, or DBMAINT authority is not sufficient authority if you are creating a temporary table for someone else and the table qualifier is not your authorization ID.

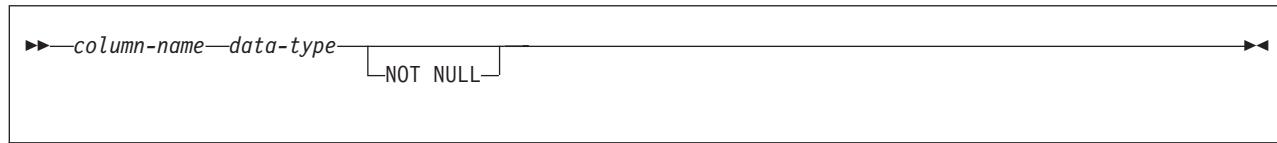

Additional privileges might be required when the data type of a column is a distinct type or the `LIKE` clause is specified. See the description of `distinct-type` and `LIKE` for the details.

**Privilege set:** The privilege set is the same as the privilege set for the CREATE TABLE statement. See Privilege Set for details.

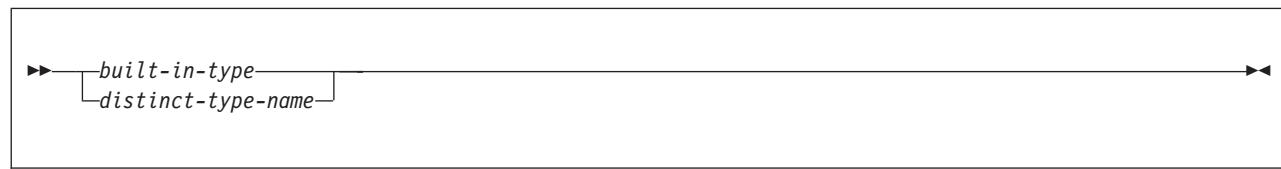

## Syntax

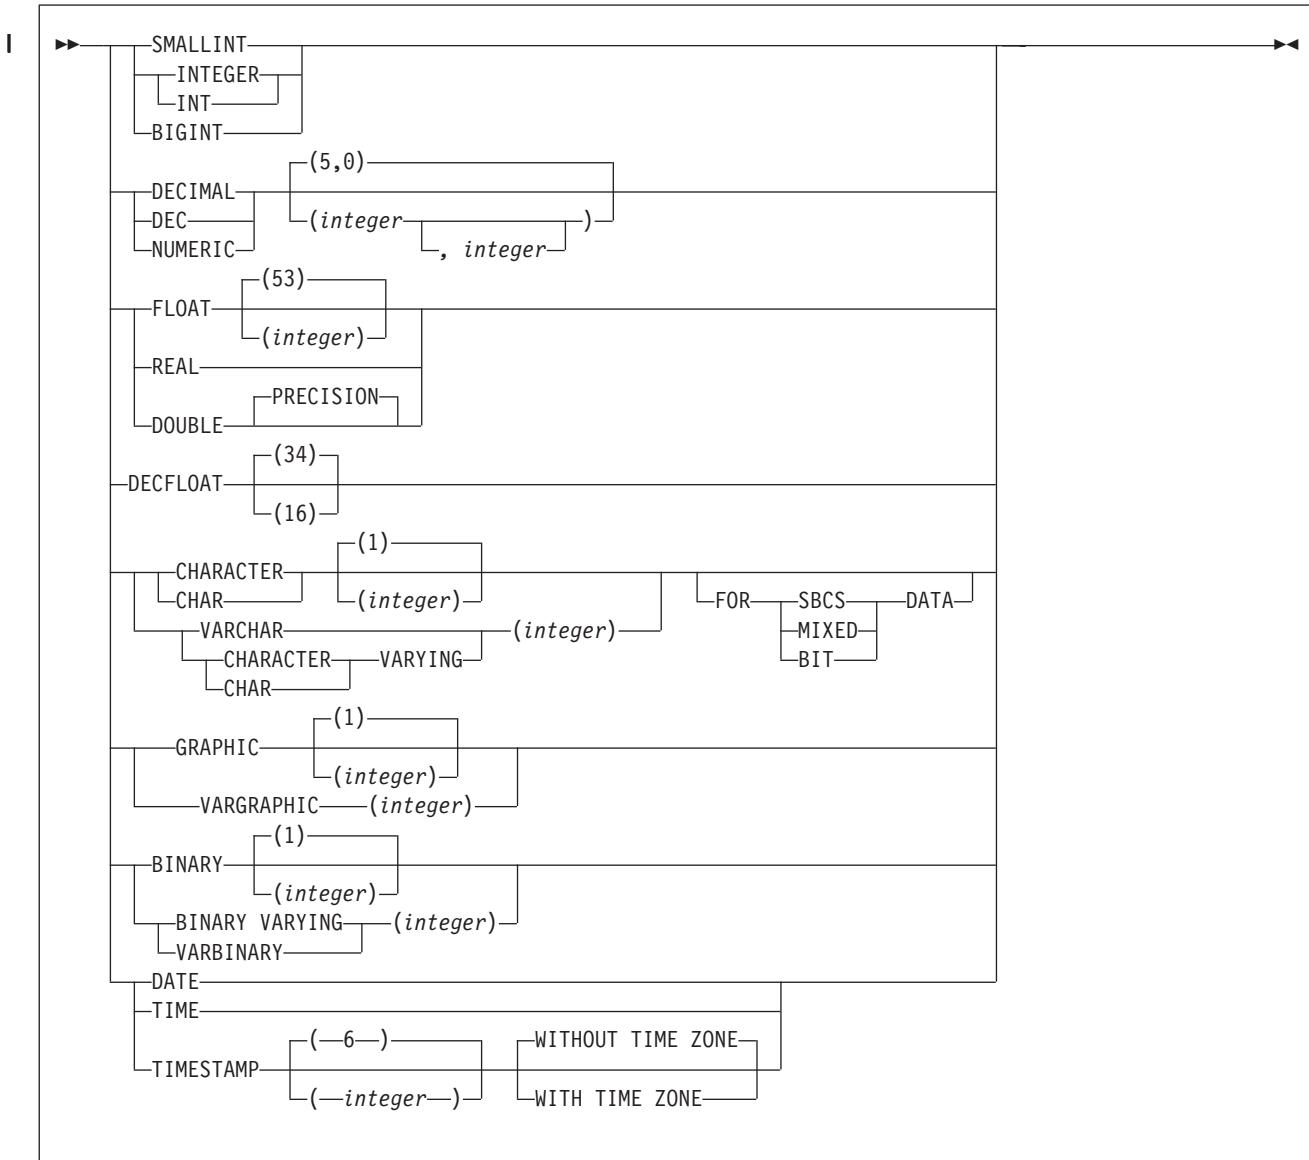

### column-definition:

**data-type:**

**built-in-type:**

## Description

*table-name*

Names the temporary table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, synonym, or temporary table that exists at the database server.

| The qualification rules for a temporary table are the same as for other tables.

The owner acquires ALL PRIVILEGES on the table WITH GRANT OPTION and the authority to drop the table.

*column-definition*

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32714 bytes. The maximum row size must not exceed 32706 bytes (8 bytes less than the maximum record size).

*column-name*

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

*data-type*

Specifies the data type of the column. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the column is a built-in data type.

For more information on and the rules that apply to the data types, see [built-in-type](#).

*distinct-type*

Any distinct type except one that is based on a LOB or ROWID data type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

**NOT NULL**

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

**LIKE** *table-name or view-name*

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table, view, or temporary table that exists at the current server. The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If any column of the identified table or view has an attribute value that is not allowed for a column in a temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.
- If any column of the identified table or view allows a default value other than null, that default value is ignored and the corresponding column in the new temporary table has no default value. A default value other than null is not allowed for any column in a temporary table.

**CCSID** *encoding-scheme*

Specifies the encoding scheme for string data stored in the table.

**ASCII** Specifies that the data must be encoded by using the ASCII CCSIDs of the server.

An error occurs if a valid ASCII CCSID has not been specified for the installation.

### **EBCDIC**

Specifies that data must be encoded by using the EBCDIC CCSIDs of the server.

An error occurs if a valid EBCDIC CCSID has not been specified for the installation.

### **UNICODE**

Specifies that data must be encoded by using the CCSIDs of the server for Unicode.

An error occurs if a valid CCSID for Unicode has not been specified for the installation.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used. An error occurs if CCSIDs have not been defined.

For the creation of temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause.

## **Notes**

*Owner privileges:* The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 1355) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

*Instantiation and termination:* Let T be a temporary table defined at the current server and let P denote an application process:

- An empty instance of T is created as a result of the first implicit or explicit reference to T in an OPEN, SELECT INTO or SQL data change operation that is executed by any program in P.
- Any program in P can reference T and any reference to T by a program in P is a reference to that instance of T.

When a commit operation terminates a unit of work in P and no program in P has an open WITH HOLD cursor that is dependent on T, the commit includes the operation DELETE FROM T.

- When a rollback operation terminates a unit of work in P, the rollback includes the operation DELETE FROM T.
- When the connection to the database server at which an instance of T was created terminates, the instance of T is destroyed. However, the definition of T remains. A DROP TABLE statement must be executed to drop the definition of T.

*Restrictions and extensions:* Let T denote a temporary table:

- Columns of T cannot have default values other than null.
- A column of T cannot have a LOB or ROWID data type (or a distinct type based on one).
- T cannot have unique constraints, referential constraints, or check constraints.
- T cannot be defined as the parent in a referential constraint.
- T cannot be referenced in:
  - A CREATE INDEX statement.

- A LOCK TABLE statement.
  - As the object of an UPDATE statement in which the object is T or a view of T. However, you can reference T in the WHERE clause of an UPDATE statement (including the update operation of the MERGE statement).
  - DB2 utility commands.
  - As with all tables stored in a work file, query parallelism cannot be considered for any query that references T.
  - If T is referenced in the *fullselect* of a CREATE VIEW statement, you cannot specify a WITH CHECK OPTION clause in the CREATE VIEW statement.
  - ALTER TABLE T is valid only if the statement is used to add a column to T. Any column that you add to T must have a default value of null.
- When you alter T, any plans and packages that refer to the table are invalidated, and DB2 automatically rebinds the plans and packages the next time they are run.
- DELETE FROM T or a *view of T* is valid only if the statement does not include a WHERE or WHERE CURRENT OF clause. In addition, DELETE FROM *view of T* is valid only if the view was created (CREATE VIEW) without the WHERE clause. A DELETE FROM statement deletes all the rows from the table or view.
  - You can refer to T in the FROM clause of any subselect. If you refer to T in the first FROM clause of a *select-statement*, you cannot specify a FOR UPDATE clause.
  - You cannot use a DROP DATABASE statement to implicitly drop T. To drop T, reference T in a DROP TABLE statement.
  - A temporary table instantiated by an SQL statement using a three-part table name can be accessed by another SQL statement using the same name in the same application process for as long as the DB2 connection which established the instantiation is not terminated.
  - GRANT ALL PRIVILEGES ON T is valid, but you cannot grant specific privileges on T.
- Of the ALL privileges, only the ALTER, INSERT, DELETE, and SELECT privileges can actually be used on T.
- REVOKE ALL PRIVILEGES ON T is valid, but you cannot revoke specific privileges from T.
  - A COMMIT operation deletes all rows of every temporary table of the application process, but the rows of T are not deleted if any program in the application process has an open WITH HOLD cursor that is dependent on T. In addition, if RELEASE(COMMIT) is in effect and no open WITH HOLD cursors are dependent on T, all logical work files for T are also deleted.
  - A ROLLBACK operation deletes all rows and all logical work files of every temporary table of the application process.
  - You can reuse threads when using a temporary table, and a logical work file for a temporary table name remains available until deallocation. A new logical work file is not allocated for that temporary table name when the thread is reused.
  - You can refer to T in the following statements:

ALTER FUNCTION	CREATE PROCEDURE	DECLARE TABLE
ALTER PROCEDURE	CREATE SYNONYM	DELETE (if it does not include a WHERE clause)
COMMENT	CREATE TABLE LIKE	DROP TABLE
CREATE ALIAS	CREATE VIEW	INSERT
CREATE FUNCTION	DESCRIBE TABLE	LABEL
		SELECT INTO

**Alternative syntax and synonyms:** For compatibility with previous releases of DB2, you can specify LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column. However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

## Examples

*Example 1:* Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, column MEANING has a subtype of SBCS:

```
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP  
  (CODE INTEGER NOT NULL, MEANING VARCHAR(254) NOT NULL);
```

*Example 2:* Create a temporary table, EMP:

```
CREATE GLOBAL TEMPORARY TABLE EMP  
  (TMPDEPTNO  CHAR(3)      NOT NULL,  
   TMPDEPTNAME VARCHAR(36)  NOT NULL,  
   TMPMGRNO    CHAR(6)      ,  
   TMPLOCATION CHAR(16)     );
```

## CREATE INDEX

The CREATE INDEX statement creates a partitioning index or a secondary index and an index space at the current server. The columns included in the key of the index are columns of a table at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The INDEX privilege on the table
- Ownership of the table
- DBADM authority for the database that contains the table
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the index is created using an expression, the EXECUTE privilege is required on any user-defined function that is invoked in the index expression.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the specified index name includes a qualifier that is not the same as this owner, the privilege set must include SYSADM or SYSCTRL authority, or DBADM or DBCTRL authority for the database.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

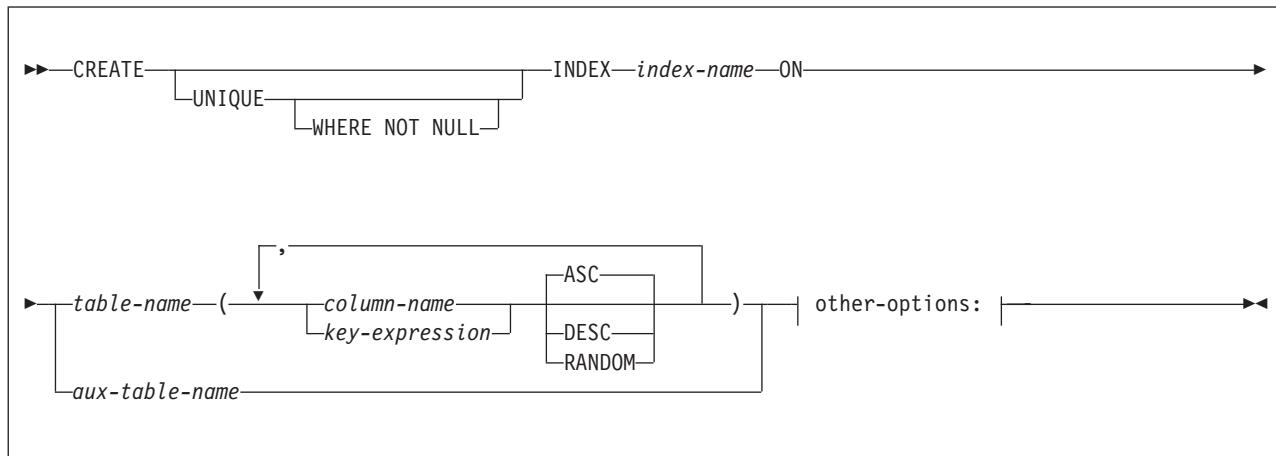

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

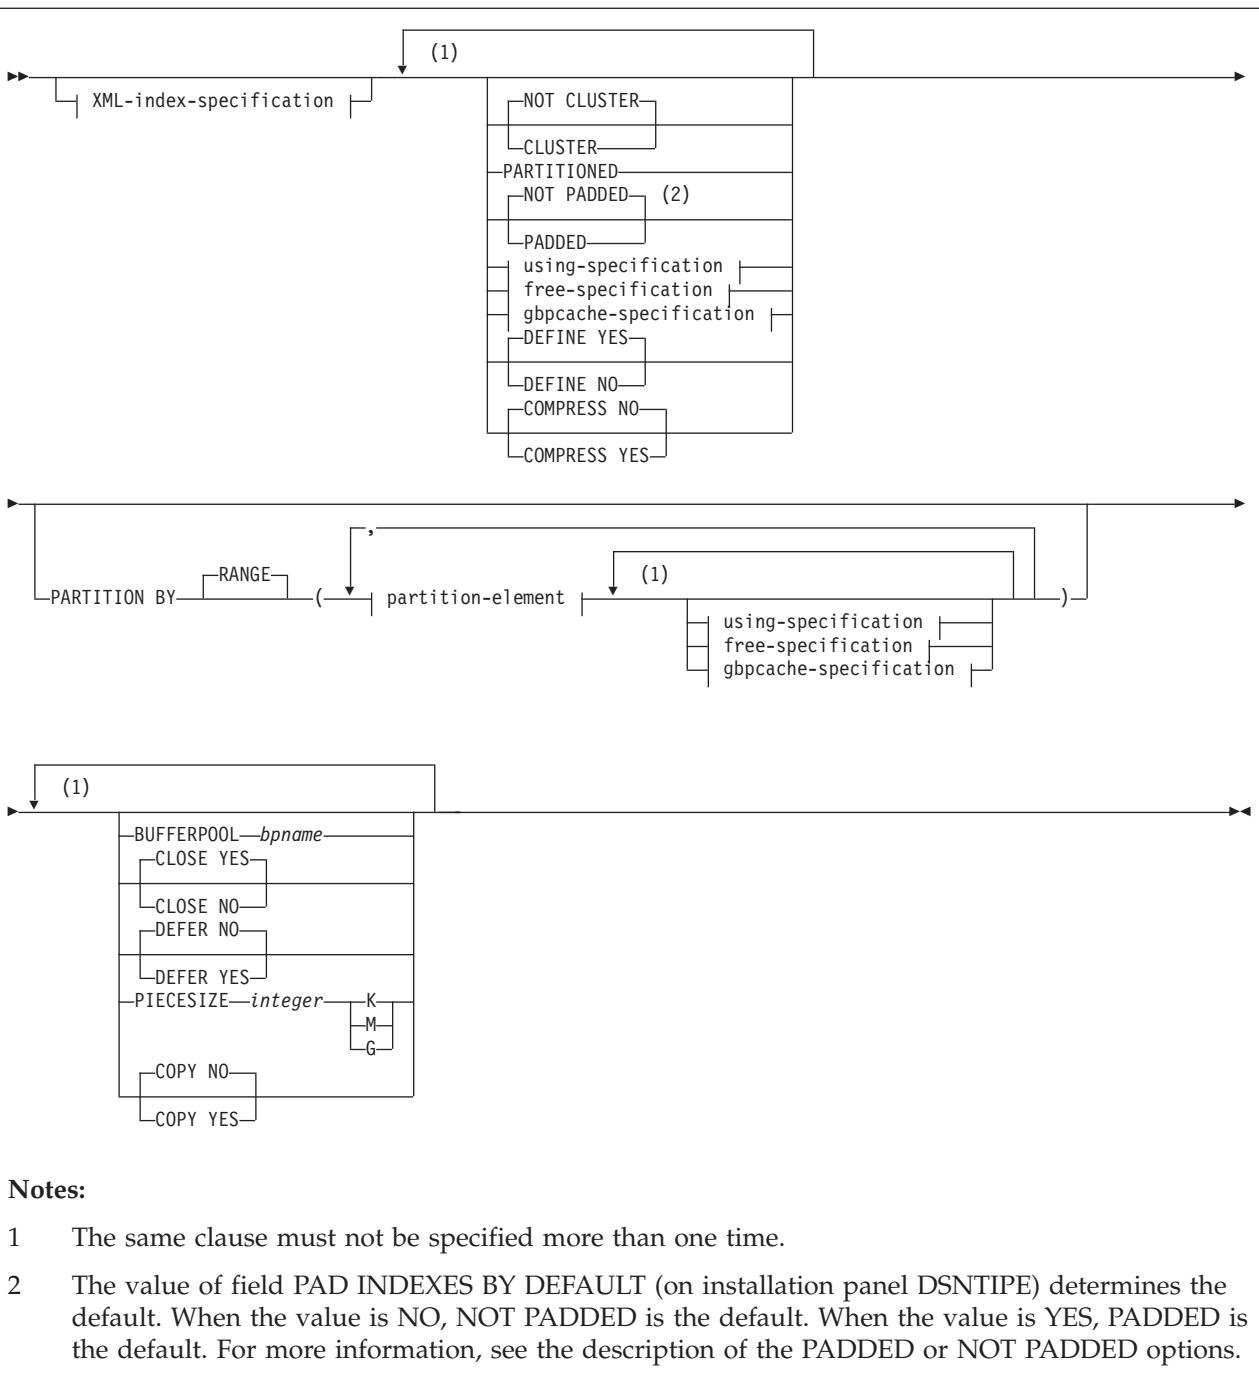

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the set of privileges that are held by the role that is associated with the primary authorization ID of the process. However, if the specified index name includes a qualifier that is not the same as this authorization ID, the following rules apply:

- If the privilege set includes SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier can be any valid schema name.
  - If the privilege set lacks SYSADM or SYSCTRL authority (or DBADM authority for the database, or DBCTRL authority for the database when creating a table), the schema qualifier is valid only if it is the same as one of the authorization IDs of the process and the privilege set that are held by that authorization ID includes all privileges needed to create the index. This is an exception to the rule that the privilege set is the privileges that are held by the SQL authorization ID of the process.

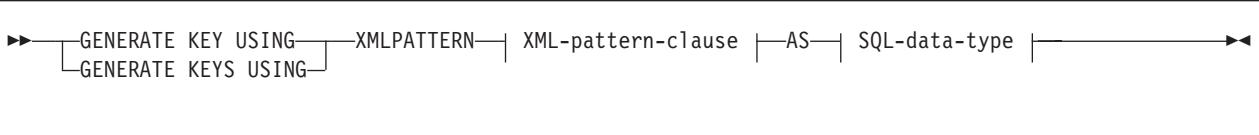

## Syntax

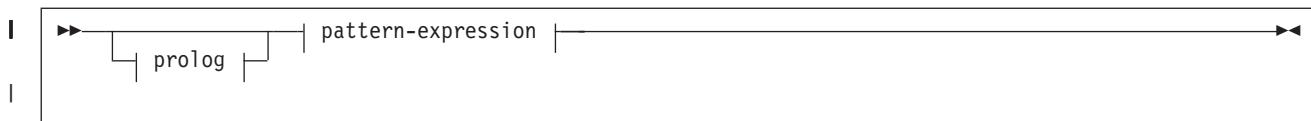

### **other-options:**

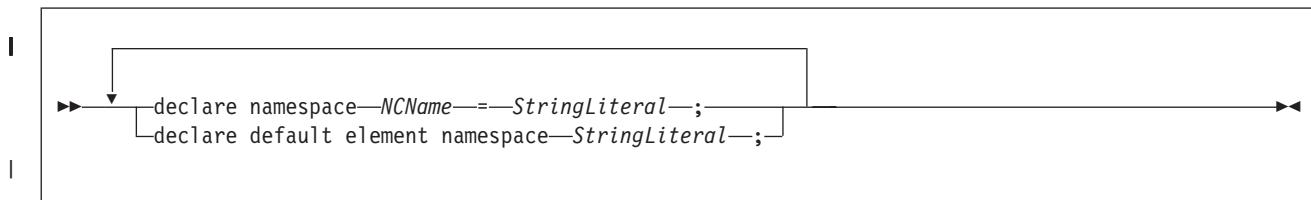

#### XML-index-specification:

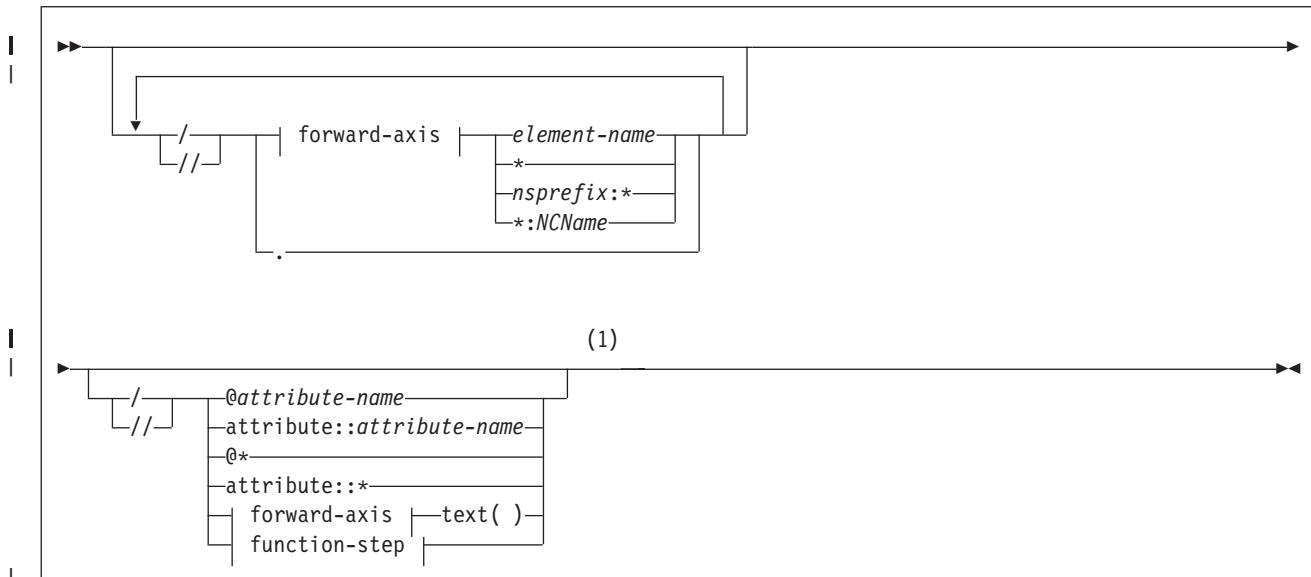

#### XML-pattern-clause:

**prolog:**

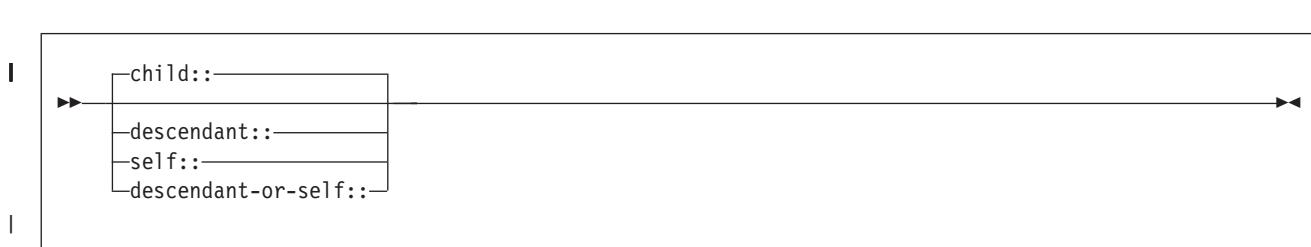

**pattern-expression:**

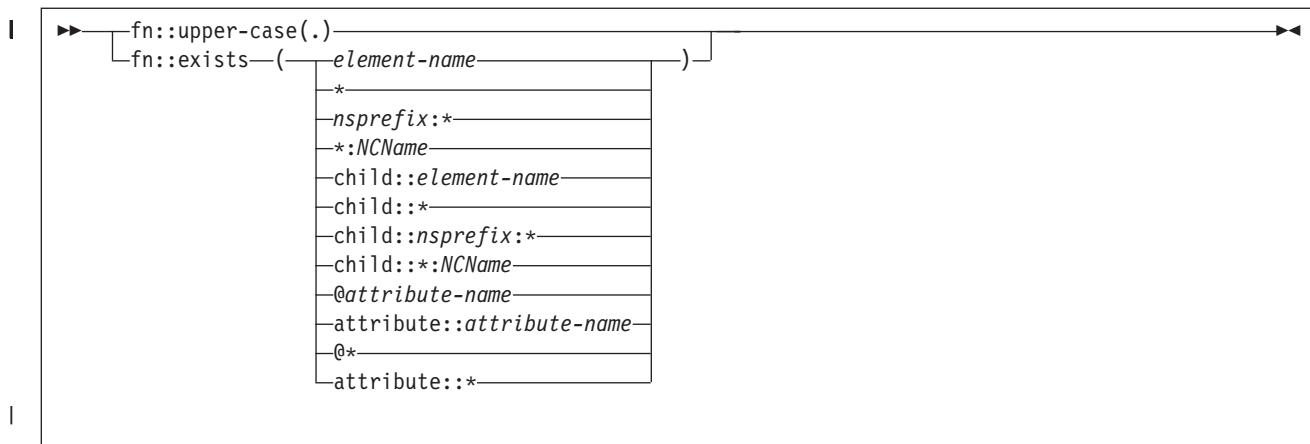

**Notes:**

- 1 *pattern-expression* cannot be an empty string.

**using-specification:**

**Notes:**

- 1 The same clause must not be specified more than once.

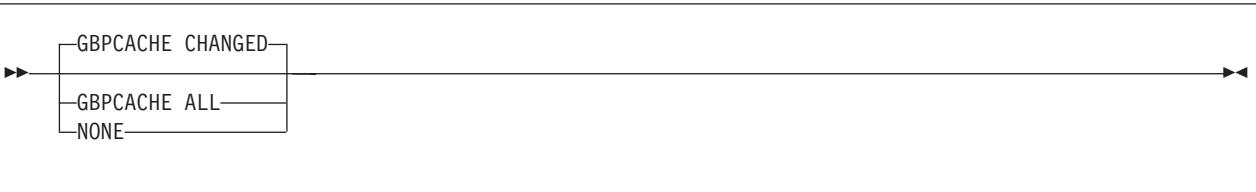

**free-specification:**

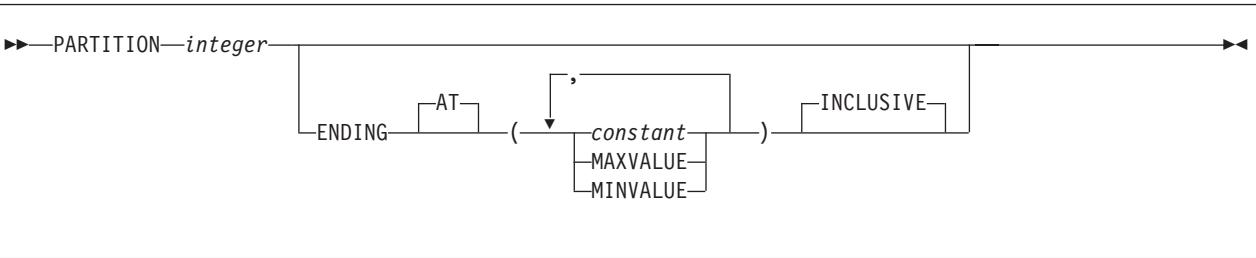

**Notes:**

- 1 The same clause must not be specified more than one time.

**gbpcache-specification:**

**partition-element:**

## Description

### UNIQUE

Prevents the table from containing two or more rows with the same value of the index key. When UNIQUE is used, all null values for a column are considered equal. For example, if the key is a single column that can contain null values, that column can contain only one null value. The constraint is enforced when rows of the table are updated or new rows are inserted.

The constraint is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

### UNIQUE WHERE NOT NULL

Prevents the table from containing two or more rows with the same value of the index key where all null values for a column are not considered equal. Multiple null values are allowed. Otherwise, this is identical to UNIQUE.

### INDEX *index-name*

Names the index. The name must not identify an index that exists at the current server.

The associated index space also has a name. That name appears as a qualifier in the names of data sets defined for the index. If the data sets are managed by

the user, the name is the same as the second (or only) part of *index-name*. If this identifier consists of more than eight characters, only the first eight are used. The name of the index space must be unique among the names of the index spaces and table spaces of the database for the identified table. If the data sets are defined by DB2, DB2 derives a unique name.

If the index is an index on a declared temporary table, the qualifier, if explicitly specified, must be SESSION. If the index name is unqualified, DB2 uses SESSION as the implicit qualifier.

**ON** *table-name* **or** *aux-table-name*

Identifies the table on which the index is created. The name can identify a base table, a materialized query table, a declared temporary table, or an auxiliary table.

*table-name*

Identifies the base table, materialized query table, or declared temporary table on which the index is created. The name must identify a table that exists at the current server. (The name of a declared temporary table must be qualified with SESSION.) The name must not identify a clone table. The name must not identify a created temporary table or a table that is implicitly created for an XML column. If the index that is being created is for XML values, the table can contain an XML column, otherwise, the table must not contain an XML column. The name cannot identify a catalog table or declared temporary table if the index is created using expressions.

*column-name*,...

Specifies the columns of the index key.

Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. Do not qualify *column-name*. Do not specify a column for *column-name* that is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- a BINARY or VARBINARY column (or a column with a distinct type that is based on a BINARY or VARBINARY data type)
- a row change timestamp column when the PARTITION BY RANGE clause is also specified.

A column with an XML type can only be specified if the XMLPATTERN clause is also specified. If the XMLPATTERN clause is specified, only one column can be identified and the column must be an XML type. The resulting index is an XML index.

The sum of the length attributes of the columns must not be greater than the following limits, where *n* is the number of columns that can contain null values and *m* is the number of varying-length columns in the key:

- $2000 - n$  for a padded, nonpartitioning index
- $2000 - n - 2m$  for a nonpadded, nonpartitioning index
- $255 - n$  for a partitioning index (padded or nonpadded)
- $255 - n - 2m$  for a nonpadded, partitioning index

**ASC**

Puts the index entries in ascending order by the column. ASC cannot be specified with the GENERATE KEY USING clause.

ASC is the default.

**DESC**

Puts the index entries in descending order by the column. DESC cannot be specified with the GENERATE KEY USING clause or if the ON clause contains *key-expression*.

**RANDOM**

Index entries are put in a random order by the column. RANDOM cannot be specified in the following cases:

- For an index key column that is varying length in an index that is created with the NOT PADDED option
- With the GENERATE KEY USING clause
- If the index is part of the partitioning key

***key-expression***

Specifies an expression that returns a scalar value. *key-expression* cannot be specified with the GENERATE KEY USING clause. *key-expression* has the following restrictions:

- Each *key-expression* must contain at least one reference to a column of *table-name*.  
All references to columns of *table-name* must be unqualified. Referenced columns cannot be LOB, XML, or DECFLOAT data types or a distinct type that is based on one of these data types. Referenced columns cannot include any FIELDPROCs or a SECURITY LABEL. Referenced columns cannot be implicitly hidden (that is, defined with the IMPLICITLY HIDDEN attribute).
- *key-expression* must not include the following:
  - A subquery
  - An aggregate function
  - A function that is not deterministic
  - A function that has an external action
  - A user-defined function
  - A sequence reference
  - A host variable
  - A parameter marker
  - A special register
  - A CASE expression
  - An OLAP specification
- If *key-expression* references a cast function, the privilege set must implicitly include EXECUTE authority on the generated cast functions for the distinct type.
- If *key-expression* references the LOWER or UPPER functions, the input *string-expression* cannot be FOR BIT DATA, and the function invocation must contain the *locale-name* argument.
- If *key-expression* references the TRANSLATE function, the function invocation must contain the *to-string* argument.
- The same expression cannot be used more than one time in the same index.
- The data type of the result of the expression (including the intermediate result) cannot be a LOB, XML, or DECFLOAT value.

- The CCSID encoding schema of the result of a *key-expression* must be the same encoding scheme as the table.

The maximum length of the text string of each *key-expression* is 4000 bytes after conversion to UTF-8. The maximum number of *key-expression* in an extended index is 64.

#### *aux-table-name*

Identifies the auxiliary table on which the index is created. The name must identify an auxiliary table that exists at the current server. If the auxiliary table already has an index, do not create another one. An auxiliary table can only have one index.

Do not specify any columns for the index key. The key value is implicitly defined as a unique 19 byte value that is system generated.

If qualified, *table-name* or *aux-table-name* can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.) Whether the name is two-part or three-part, the authorization ID that qualifies the name is the owner of the index.

The table space that contains the named table must be available to DB2 so that its data sets can be opened. If the table space is EA-enabled, the data sets for the index must be defined to belong to a DFSMS data class that has the extended format and addressability attributes.

#### **GENERATE KEY USING**

Along with XMLPATTERN, GENERATE KEY USING is required to generate an XML index.

#### **XMLPATTERN**

When an XML column is indexed, only parts of the documents will be indexed. To identify those parts, a path expression that follows the XMLPATTERN clause is specified. Only values of those element, attribute, or text nodes which match the specified pattern are indexed. An XML pattern can be specified using an optional namespace declaration where namespace prefixes are mapped to namespace URIs and by providing a path expression. The path expression is similar to a path expression in XQuery except that the paths that are specified for the XML index can support child axis, self-or-descendant axis, wildcard expressions, or attribute only. The maximum length of an XML pattern text is 4000 bytes after being converted to UTF-8. Refer to *DB2 XML Guide* for more information about XQuery.

#### *prolog*

To use qualified names in the *pattern-expression*, namespace prefixes need to be declared. A default namespace can also be declared for use with unqualified names.

#### **declare namespace *NCName*=*StringLiteral***

The namespace prefix, *NCName*, is mapped to a namespace URI that is identified in *StringLiteral*. Multiple namespaces can be declared, but each namespace prefix must be unique within the list of namespace declarations. *NCName* is an XML name as defined by the XML 1.0 standard. *NCName* cannot include a colon character. The namespace URI cannot be <http://www.w3.org/XML/1998/namespace> or <http://w3.org/2000/xmlns/>.

**declare default element namespace *StringLiteral***

Specifies the default namespace URI for unqualified names of elements and types. *StringLiteral* is a namespace URI. If no default element namespace is declared, unqualified names of element and types are in no namespace. Only one default namespace can be declared.

***pattern-expression***

*Pattern-expression* is used to identify those nodes in an XML document that are indexed. *Pattern-expression* cannot be an empty or invalid string, and the XPath expression cannot be nested more than 50 levels.

**/ (forward slash)**

Separates path expression steps.

**// (double forward slash)**

Abbreviated syntax for /descendant-or-self::node() /

**. (dot)**

Abbreviated syntax for /self::node() /

**child::**

Specifies children of the context node. child:: is the default if no forward axis is specified.

**descendant::**

Specifies the descendants of the context node.

**self::**

Specifies the current context node.

**descendant-or-self::**

Specifies the context node and the descendants of the context node.

***element-name***

Identifies an element in an XML document. *element-name* is an XML QName that can have one of the following forms:

***nsprefix:NCName***

*nsprefix* explicitly specifies a namespace prefix that must be declared.

***NCName***

An unqualified XML name that uses the default namespace.

**\* (an asterisk)**

Indicates any element name. If \* is prefixed by attribute:: or @, \* indicates any attribute name.

***nsprefix:\****

Indicates any NCName within the specified namespace.

***\*:NCName***

Indicates a specific XML name in any of the currently declared namespaces.

***attribute:: or @***

Specifies attributes of the context node.

***attribute-name***

Identifies an attribute in an XML document. *attribute-name* is an XML QName that can have one of the following forms:

*nsprefix:NCName*

*nsprefix* explicitly specifies a namespace prefix that must be declared.

*NCName*

An unqualified XML name that uses the default namespace.

**text( )**

Matches any text node.

**fn:upper-case(.)**

Specifies an element node or an attribute node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:upper-case).

The context step of fn:upper-case() must specify an element node or an attribute node. The argument of fn:upper-case() must be a self step. The key values of an XML value index must be specified as the SQL data type VARCHAR. The length of the VARCHAR value can be any value that is allowed in DB2.

**fn:exists()**

Specifies an element node that identifies the key value for the index for each node that is specified by the context step (the part of *pattern-expression* that is specified prior to fn:exists).

The context step of fn:exists() must specify an element node. The argument of fn:exists() must be either a single step of a child element node or an attribute node. The name test part can be a wildcard character for either the namespace prefix or NCName. The key values of an XML value index for an XPath expression that ends with fn:exists() must be specified as the SQL data type VARCHAR(1). The key value will be "T" or "F". "T" implies that fn:exists() evaluates to true and "F" implies that fn:exists() evaluates to false.

**AS SQL *data-type***

Specifies that indexed values are stored as an instance of the specified SQL data type. Casting to the specified data type can result in a loss of precision of the values. For example, a loss of precision can occur when an XML integer value is cast to the SQL data type DECFLOAT. If the cast causes a loss of precision, the result will be rounded to the approximate value when it is stored in the index. The cast result cannot be outside of the range that is supported by the SQL data type. If the value cannot be cast to the specified data type, the document is still inserted into the table, but the index entry for that value is not created. No error or warning code is returned.

If the index is unique, the uniqueness is enforced on the value after it is cast to the specified type. Because rounding can occur during the cast to the SQL data type, if a value is cast to the same key value as a document that the table already contains, DB2 will return duplicate key errors at insert time, or fail to create the index.

**VARCHAR (*integer*)**

The length *integer* is a value in the range of 1 to 1000 bytes. If VARCHAR is specified with a length, the specified length is treated as a constraint. If documents are inserted into a table (or exist in the table at create index time) that have nodes with values that are longer than the specified length, the insert or index creation will fail.

**DECFLOAT**

DECFLOAT can be specified to index numeric values. For the cast to

succeed, the string must be a valid XML numeric type. Otherwise the value will be ignored and no insert to the index will occur. The result of the cast cannot be outside of the range that DECFLOAT can represent. Because the XML Schema data type for numeric values allows greater precision than the SQL data type, the result might be rounded to fit into the SQL data type. The DECFLOAT values that are stored in the index are the normalized numeric values.

#### **CLUSTER or NOT CLUSTER**

Specifies whether the index is the clustering index for the table. This clause must not be specified for an index on an auxiliary table.

##### **CLUSTER**

The index is to be used as the clustering index of the table. CLUSTER cannot be specified if XMLPATTERN or *key-expression* is specified.

##### **NOT CLUSTER**

The index is not to be used as the clustering index of the table.

#### **PARTITIONED**

Specifies that the index is data partitioned (that is, partitioned according to the partitioning scheme of the underlying data). A partitioned index can be created only on a partitioned table space, not of a partition-by-growth table space. PARTITIONED cannot be specified if XMLPATTERN is specified. The types of partitioned indexes are partitioning and secondary.

An index is considered a partitioning index if the specified index key columns match or comprise a superset of the columns specified in the partitioning key, are in the same order, and have the same ascending or descending attributes.

If PARTITION BY was not specified when the table was created, the CREATE INDEX statement must have the ENDING AT clause specified to define a partitioning index and use index-controlled partitioning. This index is created as a partitioned index even if the PARTITIONED keyword is not specified. When a partitioning index is created, if both the PARTITIONED and ENDING AT keywords are omitted, the index will be nonpartitioned. If PARTITIONED is specified, the USING specification with PRIQTY and SECQTY specifications are optional. If these space parameters are not specified, default values are used.

A secondary index is any index defined on a partitioned table space that does not meet the definition of the partitioning index. For partitioned secondary indexes (data-partitioned secondary indexes), the ENDING AT clause is not allowed because the partitioning scheme of the index is predetermined by that of the underlying data. UNIQUE and UNIQUE WHERE NOT NULL are not allowed unless the columns in the index are a superset of the partitioning columns. If a partitioned secondary index is created on a table that uses index-controlled partitioning, the table is converted to use table-controlled partitioning.

#### **NOT PADDED or PADDED**

Specifies how varying-length string columns are to be stored in the index. If the index contains no varying-length columns, this option is ignored, and a warning message is returned. Indexes that do not have varying-length string columns are always created as physically padded indexes.

##### **NOT PADDED**

Specifies that varying-length string columns are not to be padded to their maximum length in the index. The length information for a varying-length column is stored with the key.

NOT PADDED is ignored and has no effect if the index is being created on an auxiliary table. Indexes on auxiliary tables are always padded.

#### PADDED

Specifies that varying-length string columns within the index are always padded with the default pad character to their maximum length. PADDED cannot be specified if XMLPATTERN is specified. PADDED cannot be specified for indexes that are defined on VARBINARY columns.

When the index contains at least one varying-length column, the default for the option depends on the value of field PAD INDEXES BY DEFAULT on installation panel DSNTIPE:

- When the value of this field is NO, new indexes are not padded unless PADDED is specified.
- When the value of this field is YES, new indexes are padded unless NOT PADDED is specified.

The components of the USING clause are discussed below, first for nonpartitioned indexes and then for partitioned indexes.

#### Using clause for nonpartitioned indexes

For nonpartitioned indexes, the USING clause indicates whether the data sets for the index are to be managed by the user or managed by DB2. If DB2 definition is specified, the clause also gives space allocation parameters (PRIQTY and SECQTY) and an erase rule (ERASE).

If you omit USING, the data sets will be managed by DB2 on volumes listed in the default storage group of the database that is associated with the table. That default storage group must exist. With no USING clause, PRIQTY, SECQTY, and ERASE assume their default values.

#### VCAT *catalog-name*

Specifies that the first data set for the index is managed by the user, and that following data sets, if needed, are also managed by the user.

The data sets defined for the index are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by *catalog-name*. An alias<sup>29</sup> must be used if *catalog-name* is longer than eight characters.

Conventions for index data set names are given in *DB2 Administration Guide*. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

Do not specify VCAT for an index on a declared temporary table or if the table space is partition-by-growth.

#### STOGROUP *stogroup-name*

Specifies that DB2 will define and manage the data sets for the index. Each data set will be defined on a volume listed in the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. If

29. The alias of an integrated catalog facility catalog

PRIQTY+118×SECQTY is 2 gigabytes or greater, more than one data set could eventually be used, but only the first is defined during execution of this statement.

To use USING STOGROUP, the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. Moreover, *stogroup-name* must identify a storage group that exists at the current server and includes in its description at least one volume serial number. The description can indicate that the choice of volumes will be left to Storage Management Subsystem (SMS). Each volume specified in the storage group must be accessible to z/OS for dynamic allocation of the data set, and all these volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must *not* contain an entry for the first data set of the index. If the catalog is password protected, the description of the storage group must include a valid password.

The storage group supplies the data set name. The first level qualifier is also the name of, or an alias for, the integrated catalog facility catalog on which the data set is to be catalogued. The naming convention for the data set is the same as if the data set is managed by the user.

**PRIQTY** *integer*

Specifies the minimum primary space allocation for a DB2-managed data set. When you specify PRIQTY (with a value other than -1), the primary space allocation is at least *n* kilobytes, where *n* is:

12    If *integer* is less than 12

*integer*

If *integer* is between 12 and 4194304

**2097152**

If both of the following conditions are true:

- *integer* is greater than 2097152.
- The index is a non-partitioned index on a table space that is not defined with the LARGE or DSSIZE attribute.

**4194304**

If *integer* is greater than 4194304

If you do not specify PRIQTY or specify PRIQTY -1, DB2 uses a default value for the primary space allocation; for information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of 4KB not less than *n*. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

When determining a suitable value for PRIQTY, be aware that two of the pages of the primary space could be used by DB2 for purposes other than storing index entries.

**SECQTY** *integer*

Specifies the minimum secondary space allocation for a DB2-managed data set. If you do not specify SECQTY, DB2 uses a formula to determine a value. For information on the actual value that is used for

secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of 4KB not less than  $n$ . The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the space requested. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command in .

#### **ERASE**

Indicates whether the DB2-managed data sets are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the index. Refer to for more information.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.

#### **YES**

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

#### **USING clause for partitioned indexes:**

If the index is partitioned, there is a PARTITION clause for each partition. Within a PARTITION clause, a USING clause is optional. If a USING clause is present, it applies to that partition in the same way that a USING clause for a secondary index applies to the entire index.

When a USING specification is absent from a PARTITION clause, the USING clause parameters for the partition depend on whether a USING clause is specified before the PARTITION clauses.

- If the USING clause is specified, it applies to every PARTITION clause that does not include a USING clause.
- If the USING clause is not specified, the following defaults apply to the partition:
  - Data sets are managed by DB2
  - The default storage group for the database is used
  - A value of 12 is used for PRIQTY and SECQTY
  - A value of NO is used for ERASE

#### **VCAT catalog-name**

Specifies a user-managed data set with a name that starts with the specified catalog name. You must specify an alias for the integrated catalog facility catalog if the name of the integrated catalog facility catalog is longer than eight characters.

If  $n$  is the number of the partition, the identified integrated catalog facility catalog must already contain an entry for the  $n$ th data set of the index, conforming to the DB2 naming convention for data sets set forth in *DB2 Administration Guide*.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

**STOGROUP** *stogroup-name*

If USING STOGROUP is used, explicitly or by default, for a partition *n*, DB2 defines the data set for the partition during the execution of the CREATE INDEX statement, using space from the named storage group. The privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for that storage group. The integrated catalog facility catalog used for the storage group must NOT contain an entry for the *n*th data set of the index.

*stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group.

If you omit PRIQTY, SECQTY, or ERASE from a USING STOGROUP clause for some partition, their values are given by the next USING STOGROUP clause that governs that partition: either a USING clause that is not in any PARTITION clause, or a default USING clause. DB2 assumes one and only one data set for each partition.

**FREEPAGE** *integer*

Specifies how often to leave a page of free space when index entries are created as the result of executing a DB2 utility or when creating an index for a table with existing rows. One free page is left for every *integer* pages. The value of *integer* can range from 0 to 255. The default is 0, leaving no free pages.

Do not specify FREEPAGE for an index on a declared temporary table.

**PCTFREE** *integer*

Determines the percentage of free space to leave in each nonleaf page and leaf page when entries are added to the index or index partition as the result of executing a DB2 utility or when creating an index for a table with existing rows. The first entry in a page is loaded without restriction. When additional entries are placed in a nonleaf or leaf page, the percentage of free space is at least as great as *integer*.

The value of *integer* can range from 0 to 99, however, if a value greater than 10 is specified, only 10 percent of free space will be left in nonleaf pages. The default is 10.

Do not specify PCTFREE for an index on a declared temporary table.

**If the index is partitioned , the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that applies:**

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition. Do not use more than one *free-specification* in any PARTITION clause.
- The values given in a *free-specification* that is not in any PARTITION clause.
- The default values FREEPAGE 0 and PCTFREE 10.

**GBPCACHE**

In a data sharing environment, specifies what index pages are written to the group buffer pool. In a non-data-sharing environment, the option is ignored unless the index is on a declared temporary table. Do not specify GBPCACHE for an index on a declared temporary table in either environment (data sharing or non-data-sharing).

**CHANGED**

Specifies that updated pages are written to the group buffer pool, when

there is inter-DB2 R/W interest on the index or partition. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the index or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), CHANGED is ignored and no pages are written to the group buffer pool.

#### ALL

Indicates that pages are written to the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating DB2 subsystem when no other DB2 subsystems have any interest in the page set, no pages are written to the group buffer pool.

If the index is in a group buffer pool that is defined as GBPCACHE(NO), ALL is ignored and no pages are written to the group buffer pool.

#### NONE

Indicates that no pages are written to the group buffer pool. DB2 uses the group buffer pool only for cross-validation.

If the index is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one *gbpcache-specification* in any PARTITION clause.
2. The value given in a *gbpcache-specification* that is not in any PARTITION clause.
3. GBPCACHE CHANGED is the default value.

#### DEFINE

Specifies when the underlying data sets for the index are physically created. The SPACE column in catalog table SYSINDEXPART is used to record the status of the data sets (undefined or allocated).

#### YES

The data sets are created when the index is created (the CREATE INDEX statement is executed). YES is the default.

**NO** The data sets are not created until data is inserted into the index.

DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). Use DEFINE NO especially when performance of the CREATE INDEX statement is important or DASD resource is constrained.

Do not use DEFINE NO on an index if you use a program outside of DB2 to propagate data into a table on which that index is defined. If you use DEFINE NO on an index of a table and data is then propagated into the table from a program that is outside of DB2, the index space data sets are allocated, but the DB2 catalog will not reflect this fact. As a result, DB2 treats the data sets for the index space as if they have not yet been allocated. The resulting inconsistency causes DB2 to deny application programs access to the data until the inconsistency is resolved.

DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DEFINE NO is also ignored if the index is being created on a table that is not empty or on an auxiliary table.

| Do not specify DEFINE NO if the index is created on a base table that is involved in a clone relationship.

| Do not specify DEFINE NO for an index on a declared temporary table.

| Do not specify DEFINE NO if XMLPATTERN is specified.

#### **COMPRESS NO or COMPRESS YES**

| Specifies whether compression for index data will be used. If the index is partitioned, the clause will apply to all partitions.

##### **COMPRESS NO**

| Specifies that no index compression will be used.

| COMPRESS NO is the default.

##### **COMPRESS YES**

| Specifies that index compression will be used. The bufferpool that is used to create the index must be 8K, 16K, or 32K in size. The physical page size on disk will be 4K. The index compression will take place immediately.

| Index compression is recommended for applications that do sequential insert operations with few or no delete operations. Random inserts and deletes can adversely effect compression. Index compress is also recommended for applications where the indexes are created primarily for scan operations.

#### **PARTITION BY RANGE**

| Specifies the partitioning index for the table, which determines the partitioning scheme for the data in the table.

| PARTITION BY RANGE should only be specified if the table space is partitioned and the partitioning schema has not already been established.

| PARTITION BY RANGE must not be specified if the index is an extended index or if the table is in a universal table space (ranged-partitioned or partition-by-growth table space).

##### *partition-element*

| Specifies the range for each partition.

##### **PARTITION *integer***

| A PARTITION clause specifies the highest value of the index key in one partition of a partitioning index. In this context, highest means highest in the sorting sequences of the index columns. In a column defined as *ascending* (ASC), highest and lowest have their usual meanings. In a column defined as *descending* (DESC), the lowest actual value is highest in the sorting sequence.

| If you use CLUSTER, and the table is contained in a partitioned table space, you must use exactly one PARTITION clause for each partition (defined with NUMPARTS on CREATE TABLESPACE). If there are *p* partitions, the value of *integer* must range from 1 through *p*.

| The length of the highest value of a partition (also called the limit key) is the same as the length of the partitioning index.

##### **ENDING AT(*constant*, MAXVALUE, or MINVALUE...)**

| Specifies that this is the partitioning index and indicates how the data will be partitioned. The table space is marked complete after this partitioning index is created. You must use at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many as there are columns in the key. The

concatenation of all the values is the highest value of the key in the corresponding partition of the index unless the VALUES statement was already specified when the table or previous index was created.

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

**MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

**MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MAXVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition.
- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions \* (106 + limit key size in bytes) <65394.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- The highest value of the key in the last partition depends on how the table space is defined. For table spaces that are created without the LARGE or DSSIZE options, the values that you specify after VALUES are not enforced. The highest value of the key that can be placed in the table is the highest possible value of the key.

For large partitioned table space, the values you specify are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value that is specified for the last partition are out of range.

ENDING AT can be specified only if the ENDING AT clause was not specified on a previous CREATE or ALTER TABLE statement for the underlying table.

#### **INCLUSIVE**

Specifies that the specified range values are included in the data partition.

#### **BUFFERPOOL *bpname***

Identifies the buffer pool that is to be used for the index. The *bpname* must identify an activated 4KB, 8KB, 16KB, or 32KB buffer pool and the privilege set must include SYSADM or SYSCTRL authority or the USE privilege for the buffer pool.

The default is the default 4KB buffer pool for indexes in the database. A buffer pool with a smaller size should be chosen for indexes with random insert patterns. A buffer pool with a larger size should be chosen for indexes with sequential insert patterns.

See “Naming conventions” on page 51 for more details about *bpname*. See *DB2 Command Reference* for a description of active and inactive buffer pools.

#### **CLOSE**

Specifies whether or not the data set is eligible to be closed when the index is not being used and the limit on the number of open data sets is reached.

##### **YES**

Eligible for closing. This is the default unless the index is on a declared temporary table.

##### **NO** Not eligible for closing.

If the limit on the number of open data sets is reached and there are no page sets that specify CLOSE YES to close, page sets that specify CLOSE NO will be closed.

For an index on a declared temporary table, DB2 uses CLOSE NO regardless of the value specified.

#### **DEFER**

Indicates whether the index is built during the execution of the CREATE INDEX statement. Regardless of the option specified, the description of the index and its index space is added to the catalog. If the table is determined to be empty and DEFER YES is specified, the index is neither built nor placed in a rebuild-pending status. Refer to *DB2 Administration Guide* for more information about using DEFER. Do not specify DEFER for an index on a declared temporary table or an auxiliary table.

##### **NO** The index is built. This is the default.

##### **YES**

The index is not built. If the table is populated, the index is placed in a rebuild-pending status and a warning message is issued; the index must be rebuilt by the REBUILD INDEX utility.

**PIECESIZE** *integer*

Specifies the maximum addressability of each data set for a secondary index. The subsequent keyword K, M, or G, indicates the units of the value that is specified in *integer*.

- K** Indicates that the *integer* value is to be multiplied by 1024 to specify the maximum data set size in bytes. *integer* must be a power of two between 256 and 67,108,864.
- M** Indicates that the *integer* value is to be multiplied by 1,048,576 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 65,536.
- G** Indicates that the *integer* value is to be multiplied by 1,073,741,824 to specify the maximum data set size in bytes. *integer* must be a power of two between 1 and 64.

Table 95 shows the valid values for the data set size, which depend on the size of the table space.

Table 95. Valid values of PIECESIZE clause

K units	M units	G units	Size attribute of table space
256K			
512K			
1024K	1M		
2048K	2M		
4096K	4M		
8192K	8M		
16384K	16M		
32768K	32M		
65536K	64M		
131072K	128M		
262144K	256M		
524288K	512M		
1048576K	1024M	1G	
2097152K	2048M	2G	
4194304K	4096M	4G	LARGE, DSSIZE 4G (or greater)
8388608K	8192M	8G	DSSIZE 8G (or greater)
16777216K	16384M	16G	DSSIZE 16G (or greater)
33554432K	32768M	32G	DSSIZE 32G (or greater)
67108864K	65536M	64G	DSSIZE 64G

PIECESIZE has no effect on primary and secondary space allocation as it is only a specification of the maximum amount of data that a data set can hold and not the actual allocation of storage.

The default for PIECESIZE size is 2G (2GB) for indexes that are backed by table spaces that were created without the LARGE or DSSIZE option. For tables spaces that were created with the LARGE or DSSIZE option, the index piece size is the result of the following:

$$\text{MIN}(x, 2^{32} / (\text{MIN}(4096, 2^{32} / (x / y))) * z)$$

where

*x* is the DSSIZE of the table space

*y* is the page size of the table space

*z* is the page size of the index

If you change the PIECESIZE value with the ALTER INDEX statement, note that the index is put into REBUILD-pending status.

#### COPY

Indicates whether the COPY utility is allowed for the index. Do not specify COPY for an index on a declared temporary table.

**NO** Does not allow full image or concurrent copies or the use of the RECOVER utility on the index. NO is the default.

#### YES

Allows full image or concurrent copies and the use of the RECOVER utility on the index.

### Notes

**Owner privileges:** The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 1355) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

**Effects of the DEFER clause:** If DEFER NO is implicitly or explicitly specified, the CREATE INDEX statement cannot be executed while a DB2 utility has control of the table space that contains the identified table.

If the identified table already contains data and if the index build is not deferred, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.

**Errors evaluating the expressions for an index:** Errors that occur during the evaluation of an expression for an index are returned when the expression is evaluated. This can occur on an SQL data change statement, SELECT from an SQL data change statement, or the REBUILD INDEX utility. For example, the evaluation of the expression  $10 / \text{column\_1}$  returns an error if the value in *column\_1* is 0. The error is returned during CREATE INDEX processing if the table is not empty and contains a row with a value of zero in *column\_1*, otherwise the error is returned during the processing of the insert or update operation when a row with a value of zero in *column\_1* is inserted or updated.

**Result length of expressions that return a string type:** If the result data type of *key-expression* is a string type and the result length cannot be calculated at bind time, the length is set to the maximum allowable length of that data type or the largest length that DB2 can estimate. In this case, the CREATE INDEX statement can fail because the total key length might exceed the limit of an index key.

For example, the result length of the expression `REPEAT('A', CEIL(1.1))` is `VARCHAR(32767)` and the result length of the expression `SUBSTR(DESCRIPTION,1,INTEGER(1.2))` is the length of the DESCRIPTION column. Therefore, a CREATE INDEX statement that uses any of these expressions as a *key-expression* might not be created because the total key length might exceed the limit of an index key.

**Use of ASC or DESC on key columns:** There are no restrictions on the use of ASC or DESC for the columns of a parent key or foreign key. An index on a foreign key does not have to have the same ascending and descending attributes as the index of the corresponding parent key.

**EBCDIC, ASCII, and UNICODE encoding schemes for an index:** An index has the same encoding scheme as its associated table.

**Choosing a value for PIECESIZE:** To choose a value for PIECESIZE, divide the size of the secondary index by the number of data sets that you want. For example, to ensure that you have five data sets for the secondary index, and your index is 10MB (and not likely to grow much), specify PIECESIZE 2 M. If your secondary index is likely to grow, choose a larger value.

Remember that 32 data sets is the limit if the underlying table space is not defined as LARGE (or as DSSIZE 4G or greater) and that the limit is 4096 for objects with greater than 254 parts.

Keep the PIECESIZE value in mind when you are choosing values for primary and secondary quantities. Ideally, the value of your primary quantity plus the secondary quantities should be evenly divisible into PIECESIZE.

**Dropping an index:** Partitioning indexes can be dropped. If the table space is using index-controlled partitioning, the table space is converted to table-controlled partitioning. Secondary indexes that are not indexes on auxiliary tables can be dropped simply by dropping the indexes. An empty index on an auxiliary table can be explicitly dropped; a populated index can be dropped only by dropping other objects. For details, see Dropping an index on an auxiliary table and an auxiliary table.

If the index is a unique index that enforces a primary key, unique key, or referential constraint, the constraint must be dropped before the index is dropped. See “DROP” on page 1256.

**Unique indexes and enforcement of UNIQUE or PRIMARY KEY specifications for a table:** A table requires a unique index (that is not defined as UNIQUE WHERE NOT NULL) if you use the UNIQUE or PRIMARY KEY clause in the CREATE or ALTER TABLE statements, or if there is a ROWID column that is defined as GENERATED BY DEFAULT. DB2 implicitly creates those unique indexes if the table space is explicitly created and the CREATE or ALTER TABLE statement is processed by the schema processor or if the table space is implicitly created; otherwise, you must explicitly create them. If any of the unique indexes that must be explicitly defined do not exist, the definition of the table is incomplete, and the following rules apply:

- Let K denote a key for which a required unique index does not exist and let  $n$  denote the number of unique indexes that remain to be created before the definition of the table is complete. (For a new table that has no indexes, K is its primary key or any of the keys defined in the CREATE or ALTER TABLE statement as UNIQUE and  $n$  is the number of such keys. After the definition of a table is complete, an index cannot be dropped if it is enforcing a primary key or unique key.)
- The creation of the unique index reduces  $n$  by one if the index key is identical to K. The keys are identical only if they have the same columns in the same order.
- If  $n$  is now zero, the creation of the index completes the definition of the table.

- If K is a primary key, the description of the index indicates that it is a primary index. If K is not a primary key, the description of the index indicates that it enforces the uniqueness of a key defined as UNIQUE in the CREATE or ALTER TABLE statement.

A unique index cannot be created on a materialized query table.

**Unique indexes and XML columns:** If the index is an XML index on a unique XML column, the uniqueness applies to values of the specified pattern across all documents of that column, and the uniqueness is enforced on the value after the value is cast to the specified SQL data type. Because the data type conversion might result in a loss of precision and normalization, multiple values that appear unique in the XML document might still result in duplicate errors. If the index is defined using an expression, the uniqueness is enforced against the values that are stored in the index, not against the original values of the columns. The WHERE NOT NULL specification is ignored with a warning if XMLPATTERN is also specified, and the index is treated as if UNIQUE had been specified.

**Defining an XML index using an XPath pattern-expression that includes functions:** An XPath pattern-expression that includes functions (including fn:exists() or fn:upper-case()) will have two parts. The first part is referred to as the *context step* and specifies the XPath of the element node or attribute node for which an index entry will be created (the element or attributes NodeID will be included in the index). The context step follows the same syntax as the XPath pattern-expression for an XML index, except that for fn:exists() it has to specify an element node, and for fn:upper-case() it has to specify an element node or an attribute node.

The second part is referred to as the *function expression step* and specifies the fn:exists() or fn:upper-case() XPath function. The function expression step is the right-most part of an XPath pattern-expression. For each node specified by the context step, the function expression step specifies the key value for the index. For example, in the XPath pattern-expression /purchaseOrder/items/item/fn:exists(shipDate), the context step is /purchaseOrder/items/item, and the function expression step is fn:exists(shipDate).

**Use of PARTITIONED keyword:** When a partitioned index is created and no additional keywords are specified, the index is nonpartitioned. If the keyword PARTITIONED is specified, the index is partitioned. If PARTITION BY RANGE is specified, the index is both data-partitioned and key-partitioned because it is defined on the partitioning columns of the table. Any index on a partitioned table space that does not meet the definition of a partitioning index is a secondary index. When a secondary index is created and no additional keywords are specified, the secondary index is nonpartitioned (NPSI). If the keyword PARTITIONED is specified, the index is a data-partitioned secondary index (DPSI).

**Creating a partitioning index for a table created without partition boundaries:** When a table is created without specifying partition boundaries using the ENDING AT clause, the table is incomplete until a partitioning index is created. The first index that is created for a table must specify both the PARTITION and the ENDING AT clauses.

When the PARTITION clause is specified while creating an index, either the PARTITIONED clause, or the ENDING AT clause must also be specified.

**Considerations for tables that are involved in a clone relationship:** If an index is created on a base table that is involved in a clone relationship, an index with the

same name is also created on the clone table. The index on the clone table will be placed in rebuild-pending status unless the clone table is empty when the index is created.

**Considerations for tables that contain a row change timestamp column:** To create an index that refers to a row change timestamp column in the table, values must already exist in the column for all rows. Values are stored in row change timestamp columns whenever a row is inserted or updated in the table. If the row change timestamp column is added to an existing table that contains rows, the values for the row change timestamp column is not materialized and stored at the time of the ALTER TABLE statement. Values are materialized for these rows when they are updated, or when a REORG or a LOAD REPLACE utility is run on the table or table space.

**Creating indexes on DB2 catalog tables:** For details on creating indexes on catalog tables, see “SQL statements allowed on the catalog” on page 1689.

**EA-enabled index data sets:** If an index is created for an EA-enabled table space, the data sets for the index must be set up to belong to a DFSMS data class that has the extended format and extended addressability attributes.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords when creating a partitioned index:

- **PART integer VALUES** as an alternative syntax for **PARTITION integer ENDING**. The **PARTITION BY RANGE** keyword that precedes the *partition-element* clause is optional.

Although these keywords are supported as alternatives, they are not the preferred syntax.

## Examples

*Example 1:* Create a unique index, named DSN8910.XDEPT1, on table DSN8910.DEPT. Index entries are to be in ascending order by the single column DEPTNO. DB2 is to define the data sets for the index, using storage group DSN8G910. Each data set should hold 1 megabyte of data at most. Use 512 kilobytes as the primary space allocation for each data set and 64 kilobytes as the secondary space allocation. These specifications enable each data set to be extended up to 8 times before a new data set is used—512KB + (8\*64KB)= 1024KB. Make the index padded.

The data sets can be closed when no one is using the index and do not need to be erased if the index is dropped.

```
CREATE UNIQUE INDEX DSN8910.XDEPT1
  ON DSN8910.DEPT
    (DEPTNO ASC)
  PADDED
  USING STOGROUP DSN8G910
    PRIQTY 512
    SECQTY 64
    ERASE NO
    BUFFERPOOL BP1
    CLOSE YES
    PIECESIZE 1M;
```

For the above example, the underlying data sets for the index will be created immediately, which is the default (DEFINE YES). Assuming that table DSN8910.DEPT is empty, if you wanted to defer the creation of the data sets until data is first inserted into the index, you would specify DEFINE NO instead of accepting the default behavior. Specifying PADDED ensures that the varying-length character string columns in the index are padded with blanks.

*Example 2:* Create a cluster index, named XEMP2, on table EMP in database DSN8910. Put the entries in ascending order by column EMPNO. Let DB2 define the data sets for each partition using storage group DSN8G910. Make the primary space allocation be 36 kilobytes, and allow DB2 to use the default value for SECQTY, which for this example is 12 kilobytes (3 times 4KB). If the index is dropped, the data sets need not be erased.

There are to be 4 partitions, with index entries divided among them as follows:

- Partition 1: entries up to H99
- Partition 2: entries above H99 up to P99
- Partition 3: entries above P99 up to Z99
- Partition 4: entries above Z99

Associate the index with buffer pool BP1 and allow the data sets to be closed when no one is using the index. Enable the use of the COPY utility for full image or concurrent copies and the RECOVER utility.

```
CREATE INDEX DSN8910.XEMP2
  ON DSN8910.EMP
    (EMPNO ASC)
  USING STOGROUP DSN8G910
    PRIQTY 36
    ERASE NO
    CLUSTER
    PARTITION BY RANGE
      (PARTITION 1 ENDING AT('H99'),
       PARTITION 2 ENDING AT('P99'),
       PARTITION 3 ENDING AT('Z99'),
       PARTITION 4 ENDING AT('999'))
    BUFFERPOOL BP1
    CLOSE YES
    COPY YES;
```

*Example 3:* Create a secondary index, named DSN8910.XDEPT1, on table DSN8910.DEPT. Put the entries in ascending order by column DEPTNO. Assume that the data sets are managed by the user with catalog name DSNCAT and each data set is to hold 1GB of data, at most, before the next data set is used.

```
CREATE UNIQUE INDEX DSN8910.XDEPT1
  ON DSN8910.DEPT
    (DEPTNO ASC)
  USING VCAT DSNCAT
  PIECESIZE 1048576K;
```

*Example 4:* Assume that a column named EMP\_PHOTO with a data type of BLOB(110K) was added to the sample employee table for each employee's photo and auxiliary table EMP\_PHOTO\_ATAB was created in LOB table space DSN8D91A.PHOTOLTS to store the BLOB data for the column. Create an index named XPHOTO on the auxiliary table. The data sets are to be user-managed with catalog name DSNCAT.

```
CREATE UNIQUE INDEX DSN8910.XPHOTO
  ON DSN8910.EMP_PHOTO_ATAB
  USING VCAT DSNCAT
  COPY YES;
```

In this example, no columns are specified for the key because auxiliary indexes have implicitly generated keys.

---

## CREATE PROCEDURE

The CREATE PROCEDURE statement registers a stored procedure with a database server. You can register the following types of procedures with this statement, each of which is described separately.

- External

The procedure is written in a programming language such as C, COBOL, or Java. The external executable is referenced by a procedure defined at the server along with various attributes of the procedure. See “CREATE PROCEDURE (external)” on page 1016.

- SQL (external)

The procedure is written exclusively in SQL statements, but is implemented as an external program. The body of an SQL procedure is written in the SQL procedural language. The procedure body is defined at the current server along with various attributes of the procedure. See “CREATE PROCEDURE (SQL - external)” on page 1035.

- SQL (native)

The procedure is written exclusively in SQL statements, but is implemented natively in DB2. The body of an SQL procedure is written in the SQL procedural language. The procedure body is defined at the current server along with various attributes of the procedure. See “CREATE PROCEDURE (SQL - native)” on page 1046.

---

## CREATE PROCEDURE (external)

The CREATE PROCEDURE statement defines an external stored procedure at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is specified implicitly or explicitly.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

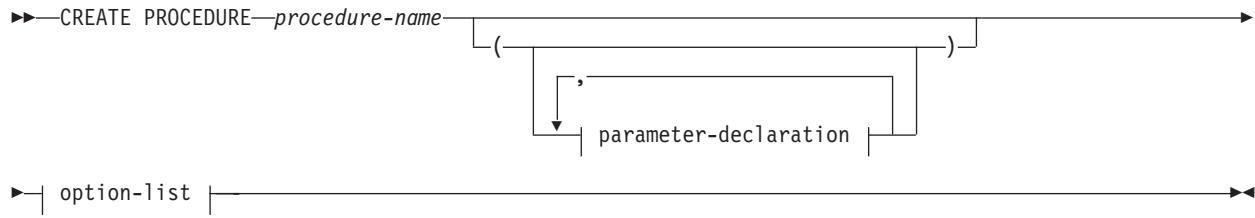

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

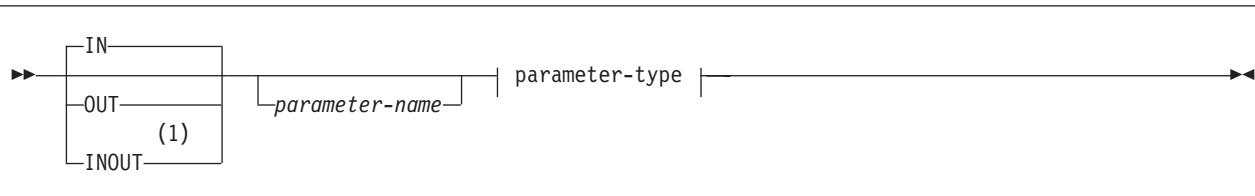

The authorization ID that is used to create the stored procedure must have authority to define programs that run in the specified WLM environment. In addition, if the stored procedure uses a distinct type as a parameter, this authorization ID must have the USAGE privilege on each distinct type that is a parameter.

When LANGUAGE is JAVA and a *jar-name* is specified in the EXTERNAL NAME clause, the privilege set must include USAGE on the JAR file, the Java archive file.

## Syntax

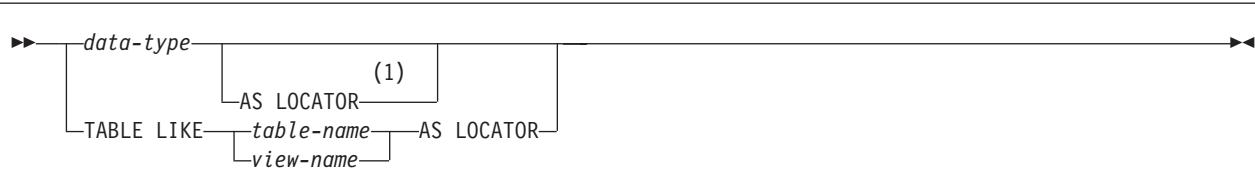

**parameter-declaration:**

**Notes:**

- 1 For a REXX stored procedure, only one parameter can have type OUT or INOUT. That parameter must be declared last.

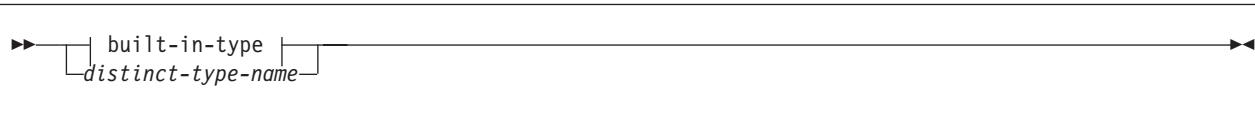

**parameter-type:**

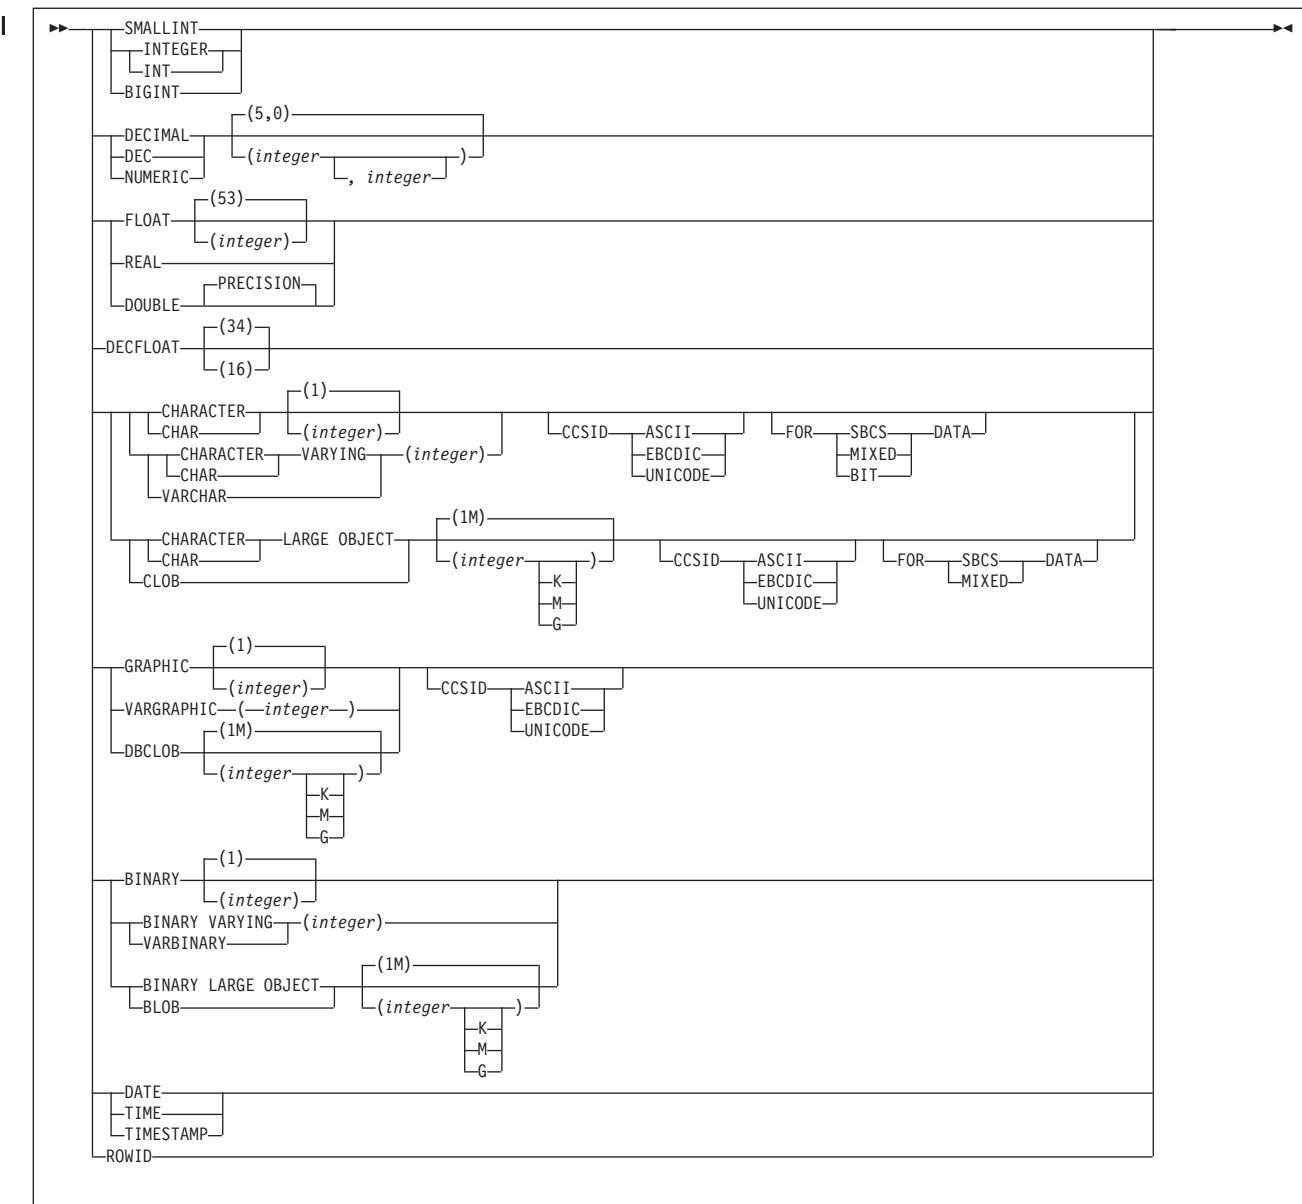

**Notes:**

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

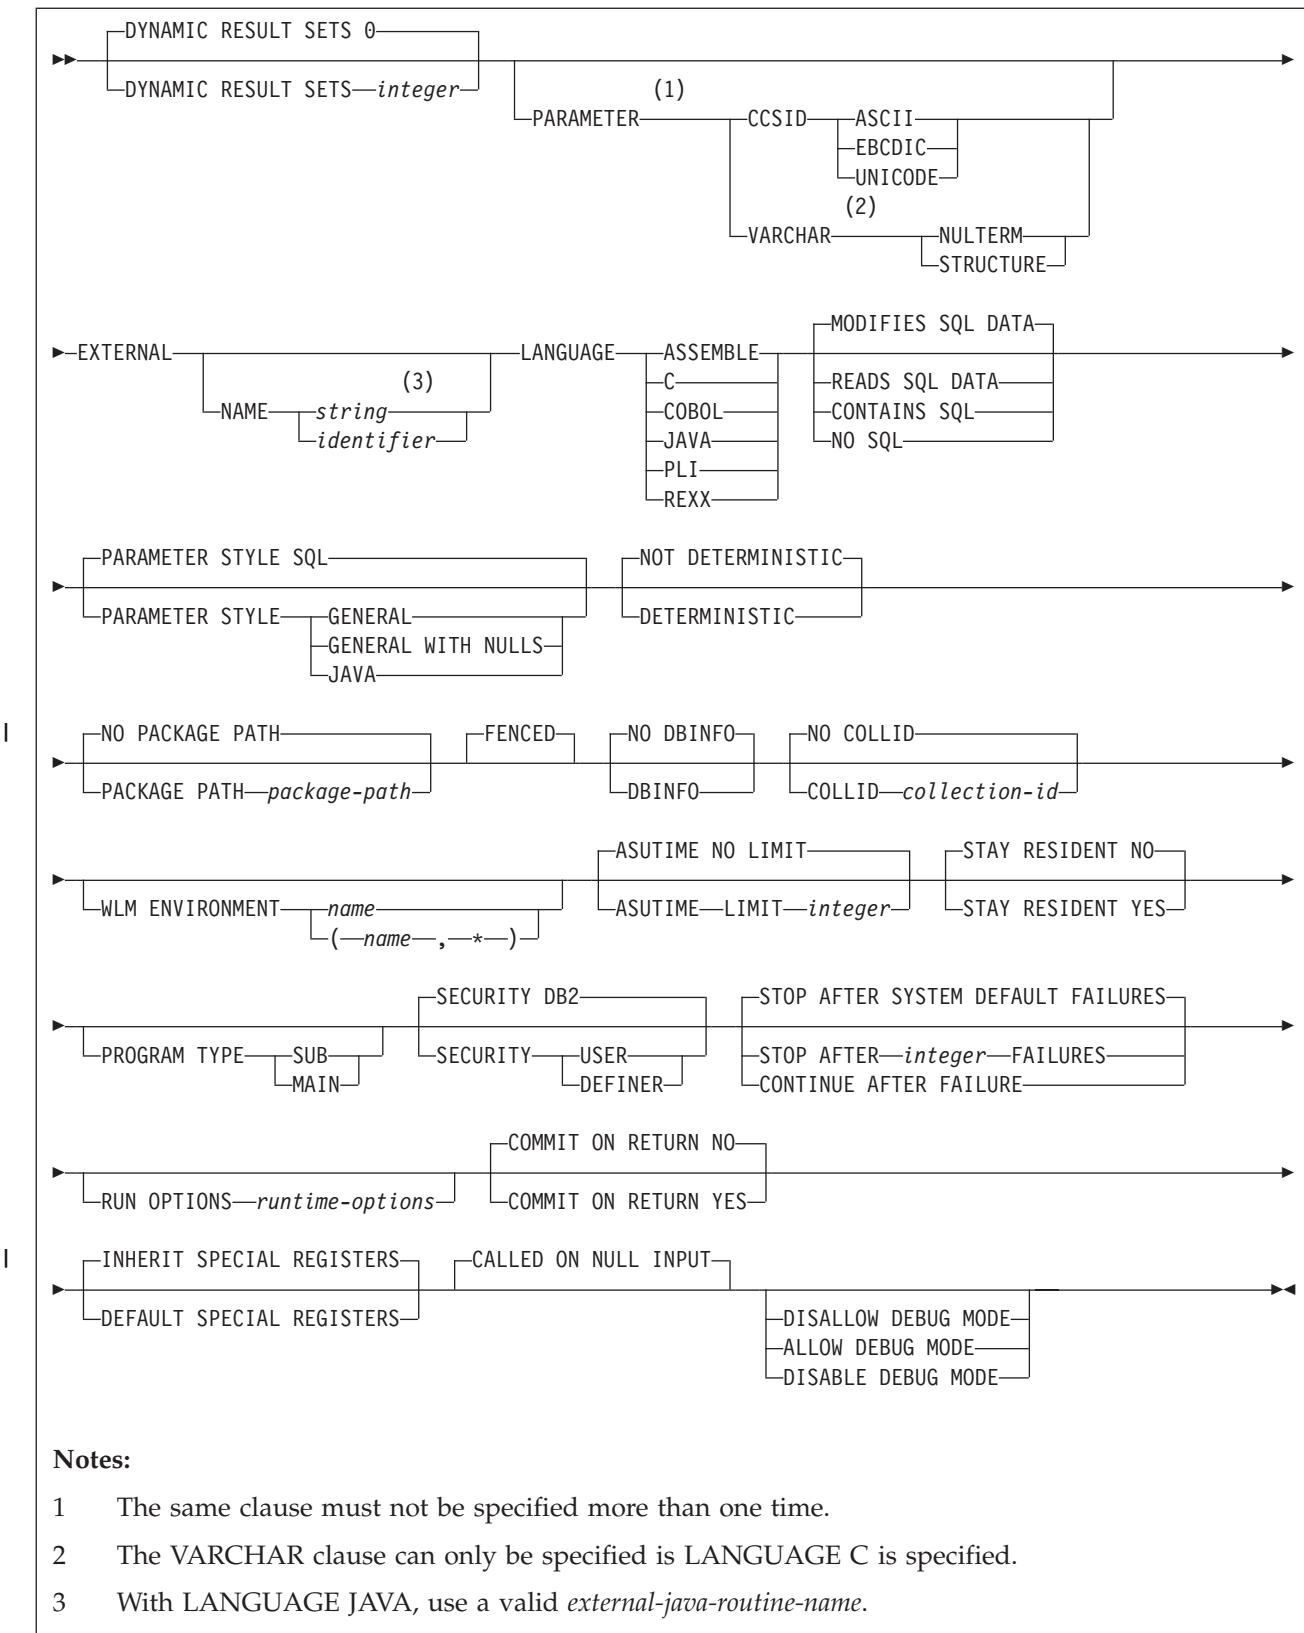

**data-type:**

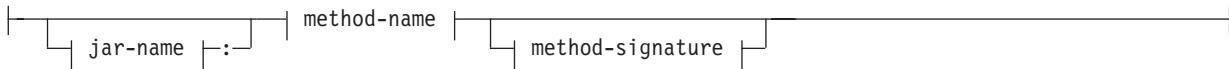

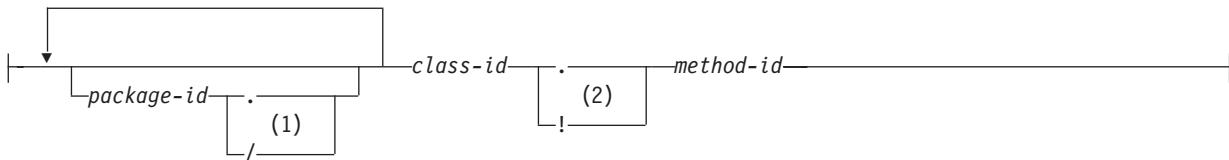

**built-in-type:**

**option-list:** (The options can be specified in any order.)

**external-java-routine-name:****jar-name:****method-name:****method-signature:****Notes:**

- 1 The slash (/) is supported for compatibility with previous releases of DB2 for z/OS.
- 2 The exclamation point (!) is supported for compatibility with other products in the DB2 family.

## Description

***procedure-name***

Names the stored procedure. The name cannot be a single asterisk, even if you specify it as a delimited identifier ("\*"). The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

The schema name can be 'SYSIBM' or 'SYSPROC'. It can also be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCtrl privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

***(parameter-declaration,...)***

Specifies the number of parameters of the stored procedure and the data type of each parameter, and optionally, the name of each parameter. A parameter for a stored procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.

All parameters are nullable except for numeric parameters in Java procedures, where numeric parameters, other than the DECIMAL types are not nullable in order to conform to the SQL/JRT standard.

**IN** Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**

Identifies the parameter as an output parameter that is returned by the stored procedure.

**INOUT**

Identifies the parameter as both an input and output parameter for the stored procedure.

*parameter-name*

Names the parameter for use as an SQL variable. The name cannot be the same as any other *parameter-name* for the procedure.

*data-type*

Specifies the data type of the parameter. The data type can be a built-in data type or a distinct type.

*built-in-type*

The data type of the parameter is a built-in data type.

For more information on the data types, see *built-in-type*.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

*distinct-type-name*

The data type of the input parameter is a distinct type. Any length, precision, scale, subtype, or encoding scheme attributes for the parameter are those of the source type of the distinct type.

If you specify the name of the distinct type without a schema name, DB2 resolves the schema name by searching the schemas in the SQL path.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input argument on the CALL statement can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

Parameters with a datetime data type or a distinct type are passed to the function as a different data type:

- A datetime type parameter is passed as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is the same as the implicitly or explicitly specified encoding scheme of any character or

graphic string parameters. If no character or graphic string parameters are passed, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

- A distinct type parameter is passed as the source type of the distinct type.

#### **AS LOCATOR**

Specifies that a locator to the value of the parameter is passed to the procedure instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type. Passing locators instead of values can result in fewer bytes being passed to the procedure, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted.

#### **TABLE LIKE *table-name* or *view-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the procedure is called, the actual values in the transition table are not passed to the stored procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The use of TABLE LIKE provides an implicit definition of the transition table. It specifies that the transition table has the same number of columns as the identified table or view. If a table is specified, the transition table includes columns that are defined as implicitly hidden in the table. The columns have the same data type, length, precision, scale, subtype, and encoding scheme as the identified table or view, as they are described in catalog tables SYSCOLUMNS and SYSTABLESPACES. The number of columns and the attributes of those columns are determined at the time the CREATE PROCEDURE statement is processed. Any subsequent changes to the number of columns in the table or the attributes of those columns do not affect the parameters of the procedure.

*table-name* or *view-name* must identify a table or view that exists at the current server. The name must not identify a declared temporary table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. The name does not have to be the same name as the table that is associated with the transition table for the trigger. An unqualified table or view name is implicitly qualified according to the following rules:

- If the CREATE PROCEDURE statement is embedded in a program, the implicit qualifier is the authorization ID in the QUALIFIER bind option when the plan or package was created or last rebound. If QUALIFIER was not used, the implicit qualifier is the owner of the plan or package.
- If the CREATE PROCEDURE statement is dynamically prepared, the implicit qualifier is the SQL authorization ID in the CURRENT SCHEMA special register.

When the procedure is called, the corresponding columns of the transition table identified by the table locator and the table or view identified in the TABLE LIKE clause must have the same definition. The data type, length, precision, scale, and encoding scheme of these columns must match exactly. The description of the table or view at the time the CREATE PROCEDURE statement was executed is used.

Additionally, a character FOR BIT DATA column of the transition table cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is not defined as character FOR BIT DATA. (The definition occurs with the CREATE PROCEDURE statement.) Likewise, a character column of the transition table that is not FOR BIT DATA cannot be passed as input for a table parameter for which the corresponding column of the table specified at the definition is defined as character FOR BIT DATA.

For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

#### FENCED

Specifies that the procedure runs in an external address space.

#### DYNAMIC RESULT SETS *integer*

Specifies the maximum number of query result sets that the stored procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

#### ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE

Specifies whether the procedure can be run in debugging mode. When DYNAMICRULES run behavior is in effect, the default is determined by using the value of the CURRENT DEBUG MODE special register. Otherwise the default is DISALLOW DEBUG MODE.

Do not specify this option unless LANGUAGE JAVA is in effect.

#### ALLOW DEBUG MODE

Specifies that the JAVA procedure can be run in debugging mode.

#### DISALLOW DEBUG MODE

Specifies that the JAVA procedure cannot be run in debugging mode.

You can use an ALTER PROCEDURE statement to change this option to ALLOW DEBUG MODE.

#### DISABLE DEBUG MODE

Specifies that the JAVA procedure can never be run in debugging mode.

The procedure cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE once the procedure has been created or altered using DISABLE DEBUG MODE. To change this option, you must drop and recreate the procedure using the desired option.

#### PARAMETER CCSID or PARAMETER VARCHAR

Specifies the encoding scheme for string parameters, and in the case of LANGUAGE C, specifies the representation of variable length string parameters.

#### CCSID

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme to be used for system-generated parameters of the routine such as message tokens and DBINFO.

#### **VARCHAR**

Specifies that the representation of the values of varying length character string-parameters for procedures that specify LANGUAGE C.

This option can only be specified if LANGUAGE C is also specified.

#### **NULTERM**

Specifies that variable length character string parameters are represented in a NUL-terminated string form.

#### **STRUCTURE**

Specifies that variable length character string parameters are represented in a VARCHAR structure form.

Using the PARAMETER VARCHAR clause, there is no way to specify the VARCHAR form of an individual parameter as these is with PARAMETER CCSID. The PARAMETER VARCHAR clause only applies to parameters in the parameter list of a procedure and in the RETURNS clause. It does not apply to system-generated parameters of the routine such as message tokens and DBINFO.

In a data sharing environment, you should not specify the PARAMETER VARCHAR clause until all members of the data sharing group support the clause. If some group members support this clause and others do not, and PARAMETER VARCHAR is specified in an external routine, the routine will encounter different parameter forms depending on which group member invokes the routine.

#### **EXTERNAL**

Specifies that the CREATE PROCEDURE statement is being used to define a new procedure that is based on code written in an external programming language. If the NAME clause is not specified, 'NAME *procedure-name*' is assumed. The NAME clause is required for a LANGUAGE JAVA procedure because the default name is not valid for a Java procedure. In some cases, the default name will not be valid. To avoid invalid names, specify the NAME clause for the following types of procedures:

- A procedure that is defined as LANGUAGE JAVA
- A procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

#### **NAME *string or identifier***

Identifies the user-written code that implements the stored procedure.

If LANGUAGE is JAVA, *string* must be specified and enclosed in single quotation marks, with no extraneous blanks within the single quotation marks. It must specify a valid *external-java-routine-name*. If multiple *strings* are specified, the total length of all of them must not be greater than 1305 bytes and they must be separated by a space or a line break.

An *external-java-routine-name* contains the following parts:

#### *jar-name*

Identifies the name given to the JAR file when it was installed in the database. The name contains *jar-id*, which can optionally be qualified

with a schema. Examples are "myJar" and "mySchema.myJar." The unqualified *jar-id* is implicitly qualified with a schema name according to the following rules:

- If the statement is embedded in a program, the schema name is the authorization ID in the QUALIFIER bind option when the package or plan was created or last rebound. If the QUALIFIER was not specified, the schema name is the owner of the package or plan.
- If the statement is dynamically prepared, the schema name is the SQL authorization ID in the CURRENT SCHEMA special register.

If *jar-name* is specified, it must exist when the CREATE PROCEDURE statement is processed. Do not specify a *jar-name* for a JAVA procedure for which NO SQL is also specified.

If *jar-name* is not specified, the procedure is loaded from the class file directly instead of being loaded from a JAR file. DB2 searches the directories in the CLASSPATH associated with the WLM Environment. Environmental variables for Java routines are specified in a data set identified in a JAVAENV DD card on the JCL used to start the address space for a WLM-managed stored procedure.

*method-name*

Identifies the name of the method and must not be longer than 254 bytes. Its package, class, and method ID's are specific to Java and as such are not limited to 18 bytes. In addition, the rules for what these can contain are not necessarily the same as the rules for an SQL ordinary identifier.

*package-id*

Identifies a package. The concatenated list of *package-ids* identifies the package that the class identifier is part of. If the class is part of a package, the method name must include the complete package prefix, such as "myPacks.StoredProcs." The Java virtual machine looks in the directory "/myPacks/StoredProcs/" for the classes.

*class-id*

Identifies the class identifier of the Java object.

*method-id*

Identifies the method identifier with the Java class to be invoked.

*method-signature*

Identifies a list of zero or more Java data types for the parameter list and must not be longer than 1024 bytes. Specify the *method-signature* if the procedure involves any input or output parameters that can be NULL. When the stored procedure being created is called, DB2 searches for a Java method with the exact *method-signature*. The number of *java-datatype* elements specified indicates how many parameters that the Java method must have.

A Java procedure can have no parameters. In this case, you code an empty set of parentheses for *method-signature*. If a Java *method-signature* is not specified, DB2 searches for a Java method with a signature derived from the default JDBC types associated with the SQL types specified in the parameter list of the CREATE PROCEDURE statement.

For other values of LANGUAGE, the value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

## **LANGUAGE**

This mandatory clause is used to specify the language interface convention to which the procedure body is written. All programs must be designed to run in the server's environment. Assembler, C, COBOL, and PL/I programs must be designed to run in IBM's Language Environment.

### **ASSEMBLE**

The stored procedure is written in Assembler.

### **C**

The stored procedure is written in C or C++.

### **COBOL**

The stored procedure is written in COBOL, including the OO-COBOL language extensions.

### **JAVA**

The stored procedure is written in Java and is executed in the Java Virtual Machine. When LANGUAGE JAVA is specified, the EXTERNAL NAME clause must be specified with a valid *external-java-routine-name* and PARAMETER STYLE must be specified with JAVA. The procedure must be a public static method of the specified Java class.

Do not specify LANGUAGE JAVA when DBINFO, PROGRAM TYPE MAIN, or RUN OPTIONS is specified.

### **PLI**

The stored procedure is written in PL/I.

### **REXX**

The stored procedure is written in REXX. Do not specify LANGUAGE REXX when PARAMETER STYLE SQL is in effect. When REXX is specified, the procedure must use PARAMETER STYLE GENERAL or GENERAL WITH NULLS.

## **MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL**

Specifies which SQL statements, if any, can be executed in the procedure or any routine that is called from this procedure. The default is MODIFIES SQL DATA. For the data access classification of each statement, see Table 138 on page 1605.

### **MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

### **READS SQL DATA**

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA, CONTAINS SQL, or NO SQL. The procedure cannot execute SQL statements that modify data.

### **CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with an access indication of CONTAINS SQL or NO SQL. The procedure cannot execute statements that read or modify data.

### **NO SQL**

Specifies that the procedure can execute only SQL statements with a data access classification of NO SQL. Do not specify NO SQL for a JAVA procedure that uses a JAR file.

## **PARAMETER STYLE**

Identifies the linkage convention used to pass parameters to and return values from the stored procedure. All of the linkage conventions provide arguments to

the stored procedure that contain the parameters specified on the CALL statement. Some of the linkage conventions pass additional arguments to the stored procedure that provide more information to the stored procedure. For more information on linkage conventions, see *DB2 Application Programming and SQL Guide*.

#### **SQL**

Specifies that, in addition to the parameters on the CALL statement, several additional parameters are passed to the stored procedure. The following parameters are passed:

- The first  $n$  parameters that are specified on the CREATE PROCEDURE statement.
- $n$  parameters for indicator variables for the parameters.
- The SQLSTATE to be returned.
- The qualified name of the stored procedure.
- The specific name of the stored procedure.
- The SQL diagnostic string to be returned to DB2.
- If DBINFO is specified, the DBINFO structure.

PARAMETER STYLE SQL is the default. Do not specify PARAMETER STYLE SQL when LANGUAGE REXX or LANGUAGE JAVA is in effect.

#### **GENERAL**

Specifies that the stored procedure uses a parameter passing mechanism where the stored procedure receives only the parameters specified on the CALL statement. Arguments to procedures defined with this parameter style cannot be null.

#### **GENERAL WITH NULLS**

Specifies that, in addition to the parameters on the CALL statement as specified in GENERAL, another argument is also passed to the stored procedure. The additional argument contains an indicator array with an element for each of the parameters on the CALL statement. In C, this is an array of short INTS. The indicator array enables the stored procedure to accept or return null parameter values.

#### **JAVA**

Specifies that the stored procedure uses a parameter passing convention that conforms to the Java and SQLJ Routines specifications. PARAMETER JAVA can be specified only if LANGUAGE is JAVA. JAVA must be specified for PARAMETER STYLE when LANGUAGE is JAVA.

INOUT and OUT parameters are passed as single-entry arrays. The INOUT and OUT parameters are declared in the Java method as single-element arrays of the Java type.

For REXX stored procedures (LANGUAGE REXX), GENERAL and GENERAL WITH NULLS are the only valid values for PARAMETER STYLE; therefore, specify one of these values and do not allow PARAMETER STYLE to default to SQL.

#### **DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the stored procedure returns the same results each time the stored procedure is called with the same IN and INOUT arguments.

#### **DETERMINISTIC**

The stored procedure always returns the same results each time the stored

procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

#### **NOT DETERMINISTIC**

The stored procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed. NOT DETERMINISTIC is the default.

DB2 does not verify that the stored procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

#### **NO PACKAGE PATH or PACKAGE PATH *package-path***

Specifies the package path to use when the procedure is run. This is the list of the possible package collections into which the DBRM this is associated with the procedure is bound.

#### **NO PACKAGE PATH**

Specifies that the list of package collections for the procedure is the same as the list of package collection IDs for the calling program. If the calling program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For information about how DB2 uses these three items, see *DB2 Application Programming and SQL Guide*.

#### **PACKAGE PATH *package-path***

Specifies a list of package collections, in the same format as the SET CURRENT PACKAGE PATH special register.

If the COLLID clause is specified with PACKAGE PATH, the COLLID clause is ignored when the routine is invoked.

The *package-path* value that is provided when the procedure is created is checked when the CALL statement is prepared. If *package-path* contains SESSION\_USER (or USER), PATH, or PACKAGE PATH, an error is returned when the *package-path* value is checked.

#### **NO DBINFO or DBINFO**

Specifies whether additional status information is passed to the stored procedure when it is invoked.

#### **NO DBINFO**

Additional information is not passed. NO DBINFO is the default.

#### **DBINFO**

An additional argument is passed when the stored procedure is invoked. The argument is a structure that contains information such as the name of the current server, the application runtime authorization ID and identification of the version and release of the database manager that invoked the procedure. For details about the argument and its structure, see *DB2 Application Programming and SQL Guide*.

DBINFO can be specified only if PARAMETER STYLE SQL is specified.

#### **NO COLLID or COLLID *collection-id***

Identifies the package collection that is to be used when the stored procedure is executed. This is the package collection into which the DBRM that is associated with the stored procedure is bound.

#### **NO COLLID**

The package collection for the stored procedure is the same as the package

collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID** *collection-id*

The package collection for the stored procedure is the one specified.

For REXX stored procedures, *collection-id* can be DSNREXR, DSNREXRS, DSNREXCR, or DSNREXCS.

**WLM ENVIRONMENT**

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the stored procedure runs in the default WLM-established stored procedure address space specified at installation time.

**name**

The WLM environment in which the stored procedure must run. If another stored procedure or a user-defined function calls the stored procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the stored procedure request to a different address space.

**(name,\*)**

When an SQL application program directly calls a stored procedure, the WLM environment in which the stored procedure runs.

If another stored procedure or a user-defined function calls the stored procedure, the stored procedure runs in the same WLM environment that the calling routine uses.

To define a stored procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a stored procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table. This option is ignored if LANGUAGE JAVA is specified.

When you are debugging a stored procedure, setting a limit can be helpful in case the stored procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the service units. NO LIMIT is the default.

**LIMIT** *integer*

The limit on the service units is a positive *integer* in the range of 1 to 2 147 483 647. If the stored procedure uses more service units than the specified value, DB2 cancels the stored procedure.

**STAY RESIDENT**

Specifies whether the stored procedure load module is to remain resident in memory when the stored procedure ends. This option is ignored if LANGUAGE JAVA is specified.

**NO** The load module is deleted from memory after the stored procedure ends.  
NO is the default.

**YES**

The load module remains resident in memory after the stored procedure ends.

**PROGRAM TYPE**

Specifies whether the stored procedure runs as a main routine or a subroutine.

**SUB**

The stored procedure runs as a subroutine. With LANGUAGE JAVA, PROGRAM TYPE SUB is the only valid option.

**MAIN**

The stored procedure runs as a main routine. With LANGUAGE REXX, PROGRAM TYPE MAIN is always in effect.

The default for PROGRAM TYPE is:

- MAIN with LANGUAGE REXX
- SUB with LANGUAGE JAVA
- For other languages, the default depends on the value of the CURRENT RULES special register:
  - MAIN when the value is DB2
  - SUB when the value is STD

**SECURITY**

Specifies how the stored procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The stored procedure does not require a special external security environment. If the stored procedure accesses resources that an external security product protects, the access is performed using the authorization ID associated with the stored procedure address space. DB2 is the default.

**USER**

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the stored procedure.

**DEFINER**

An external security environment should be established for the stored procedure. If the stored procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the stored procedure.

**STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies whether the routine is to be put in a stopped state after some number of failures.

**STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the

number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX. This is the default.

**STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

**CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

**RUN OPTIONS *runtime-options***

Specifies the Language Environment runtime options to be used for the stored procedure. For a REXX stored procedure, specifies the Language Environment runtime options to be passed to the REXX language interface to DB2. You must specify *runtime-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults.

Do not specify RUN OPTIONS when LANGUAGE JAVA is in effect.

For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

**COMMIT ON RETURN**

Indicates whether DB2 commits the transaction immediately on return from the stored procedure.

**NO** DB2 does not issue a commit when the stored procedure returns. NO is the default.

**YES**

DB2 issues a commit when the stored procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The stored procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the stored procedure.

If the stored procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine. The default is INHERIT SPECIAL REGISTERS.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited according to the rules listed in the table for characteristics of special registers in a stored procedure in Table 37 on page 151.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a stored procedure in Table 37 on page 151.

**CALLED ON NULL INPUT**

Specifies that the procedure is to be called even if any or all argument values

are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or nonnull values. CALLED ON NULL INPUT is the default.

## Notes

*Owner privileges:* The owner is authorized to call the procedure (EXECUTE privilege) and grant others the privilege to call the procedure. See “GRANT (function or procedure privileges)” on page 1340. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

*Choosing data types for parameters:* When you choose the data types of the parameters for your stored procedure, consider the rules of promotion that can affect the values of the parameters. (See “Promotion of data types” on page 95). For example, a constant that is one of the input arguments to the stored procedure might have a built-in data type that is different from the data type that the procedure expects, and more significantly, might not be promotable to that expected data type. Based on the rules of promotion, using the following data types for parameters is recommended:

- INTEGER instead of SMALLINT
- DOUBLE instead of REAL
- VARCHAR instead of CHAR
- VARGRAPHIC instead of GRAPHIC
- VARBINARY instead of BINARY

For portability of functions across platforms that are not DB2 for z/OS, do not use the following data types, which might have different representations on different platforms:

- FLOAT. Use DOUBLE or REAL instead.
- NUMERIC. Use DECIMAL instead.

*Specifying the encoding scheme for parameters:* The encoding scheme of all of the parameters with a character or graphic string data type (both input and output parameters) must be the same—either all ASCII, all EBCDIC, or all UNICODE. If you specify the encoding scheme on the individual parameters, instead of using the PARAMETER CCSID to specify it for all parameters at once or allowing the encoding scheme to default to the system value, ensure that they all agree.

*Character string representation considerations:* The PARAMETER VARCHAR clause is specific to LANGUAGE C routines because of the native use of NUL-terminated strings in C. VARCHAR structure representation is useful when character string data is known to contain embedded NUL-terminators. It is also useful when it cannot be guaranteed that character string data does not contain embedded NUL-terminators.

PARAMETER VARCHAR does not apply to fixed length character strings, VARCHAR FOR BIT DATA, CLOB, DBCLOB, or implicitly generated parameters. The clause does not apply to VARCHAR FOR BIT DATA because BIT DATA can contain X'00' characters, and its value representation starts with length information. It does not apply to LOB data because a LOB value representation starts with length information.

PARAMETER VARCHAR does not apply to optional parameters that are implicitly provided to an external procedure. For example, a CREATE PROCEDURE statement for LANGUAGE C must also specify PARAMETER STYLE SQL, which returns an SQLSTATE NUL-terminated character string; that SQLSTATE will not be represented in VARCHAR structured form. Likewise, none of the parameters that represent the qualified name of the procedure, the specific name of the procedure, or the SQL diagnostic string that is returned to the database manager will be represented in VARCHAR structured form.

**Running stored procedures:** You can use the WLM ENVIRONMENT clause to identify the address space in which a stored procedure is to run. Using different WLM environments lets you isolate one group of programs from another. For example, you might choose to isolate programs based on security requirements and place all payroll applications in one WLM environment because those applications deal with sensitive data, such as employee salaries.

Regardless of where the stored procedure is to run, DB2 invokes RACF to determine whether you have appropriate authorization. You must have authorization to issue CREATE PROCEDURE statements that refer to the specified WLM environment or the DB2-established stored procedure address space. For example, the following RACF command authorizes DB2 user DB2USER1 to define stored procedures on DB2 subsystem DB2A that run in the WLM environment named PAYROLL.

```
PERMIT DB2A.WLMENV.PAYROLL CLASS(DSNR) ID(DB2USER1) ACCESS(READ)
```

**Accessing result sets from nested stored procedures:** When another stored procedure or a user-defined function calls a stored procedure, only the calling routine can access the result sets that the stored procedure returns. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

When a stored procedure is nested, the result sets that are returned by the stored procedure are accessible only by the calling routine. The result sets are not returned to the application that contains the outermost stored procedure or user-defined function in the sequence of nested calls.

**Restrictions for nested stored procedures:** A stored procedure, user-defined function, or trigger cannot call a stored procedure that is defined with the COMMIT ON RETURN clause.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET as a synonym for DYNAMIC RESULT SET
- RESULT SETS as a synonym for DYNAMIC RESULT SETS
- STANDARD CALL as a synonym for DB2SQL
- SIMPLE CALL as a synonym for GENERAL
- SIMPLE CALL WITH NULLS as a synonym for GENERAL WITH NULLS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL INPUT
- PARAMETER STYLE DB2SQL as a synonym for PARAMETER STYLE SQL

## Examples

*Example 1:* Create the definition for a stored procedure that is written in COBOL. The procedure accepts an assembly part number and returns the number of parts that make up the assembly, the total part cost, and a result set. The result set lists the part numbers, quantity, and unit cost of each part. Assume that the input parameter cannot contain a null value and that the procedure is to run in a WLM environment called PARTSA.

```
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
LANGUAGE COBOL
EXTERNAL NAME MYMODULE
PARAMETER STYLE GENERAL
WLM ENVIRONMENT PARTSA
DYNAMIC RESULT SETS 1;
```

*Example 2:* Create the definition for the stored procedure described in Example 1, except use the linkage convention that passes more information than the parameter specified on the CALL statement. Specify Language Environment runtime options HEAP, BELOW, ALL31, and STACK.

```
CREATE PROCEDURE SYSPROC.MYPROC(IN INT, OUT INT, OUT DECIMAL(7,2))
LANGUAGE COBOL
EXTERNAL NAME MYMODULE
PARAMETER STYLE SQL
WLM ENVIRONMENT PARTSA
DYNAMIC RESULT SETS 1
RUN OPTIONS 'HEAP(,,ANY),BELOW(4K,,),ALL31(ON),STACK(,,ANY,)';
```

*Example 3:* Create the procedure definition for a stored procedure, written in Java, that is passed a part number and returns the cost of the part and the quantity that is currently available.

```
CREATE PROCEDURE PARTS_ON_HAND(IN PARTNUM INT,
                               OUT COST DECIMAL(7,2),
                               OUT QUANTITY INT)
LANGUAGE JAVA
EXTERNAL NAME 'PARTS.ONHAND'
PARAMETER STYLE JAVA;
```

## CREATE PROCEDURE (SQL - external)

The CREATE PROCEDURE statement defines an external SQL procedure at the current server and specifies the source statements for the procedure. This is the only type of SQL procedure that is available for versions of DB2 prior to Version 9.

For information about the SQL control statements that are supported in external SQL procedures, refer to “SQL control statements for external SQL procedures” on page 1610.

### Invocation

This statement can only be dynamically prepared, but the DYNAMICRULES run behavior must be specified implicitly or explicitly. It is intended to be processed using one of the following methods:

- JCL
- The DB2 for z/OS SQL procedure processor (DSNTPSMP) (IBM Optim<sup>TM</sup> Development Studio uses this method.)

Issuing the CREATE PROCEDURE statement from another context will result in an incomplete procedure definition even though the statement processing returns without error. For more information on preparing SQL procedures for execution, see *DB2 Application Programming and SQL Guide*.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

The authorization ID that is used to create the stored procedure must have authority to create programs that are to be run in the specified WLM environment.

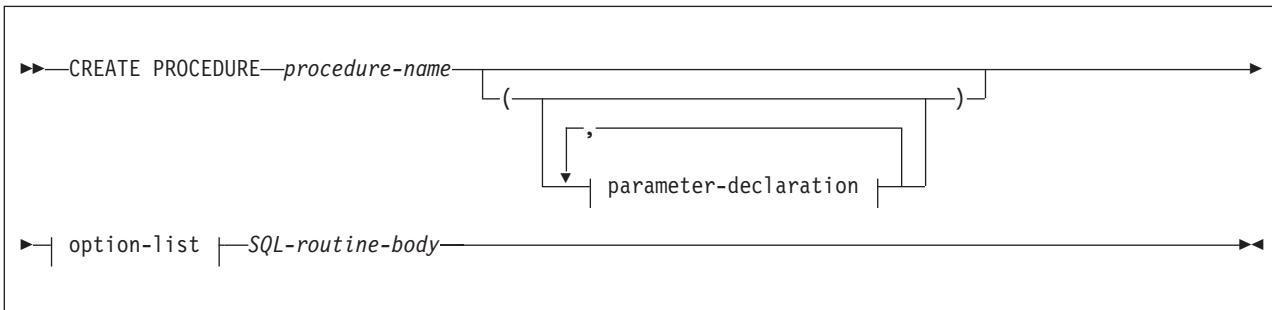

The owner of the procedure is determined by how the CREATE PROCEDURE statement is invoked:

- If the statement is embedded in a program, the owner is the authorization ID of the owner of the plan or package.

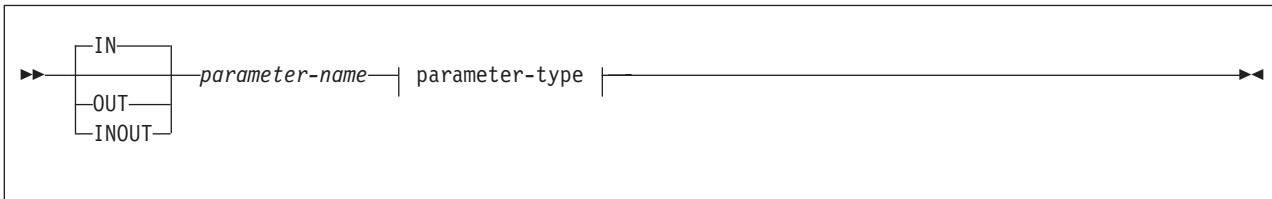

- If the statement is dynamically prepared, the owner is the SQL authorization ID in the CURRENT\_SQLID special register.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

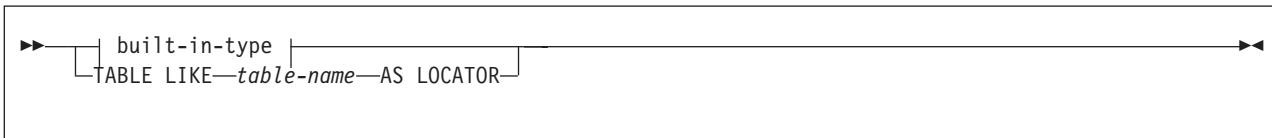

## Syntax

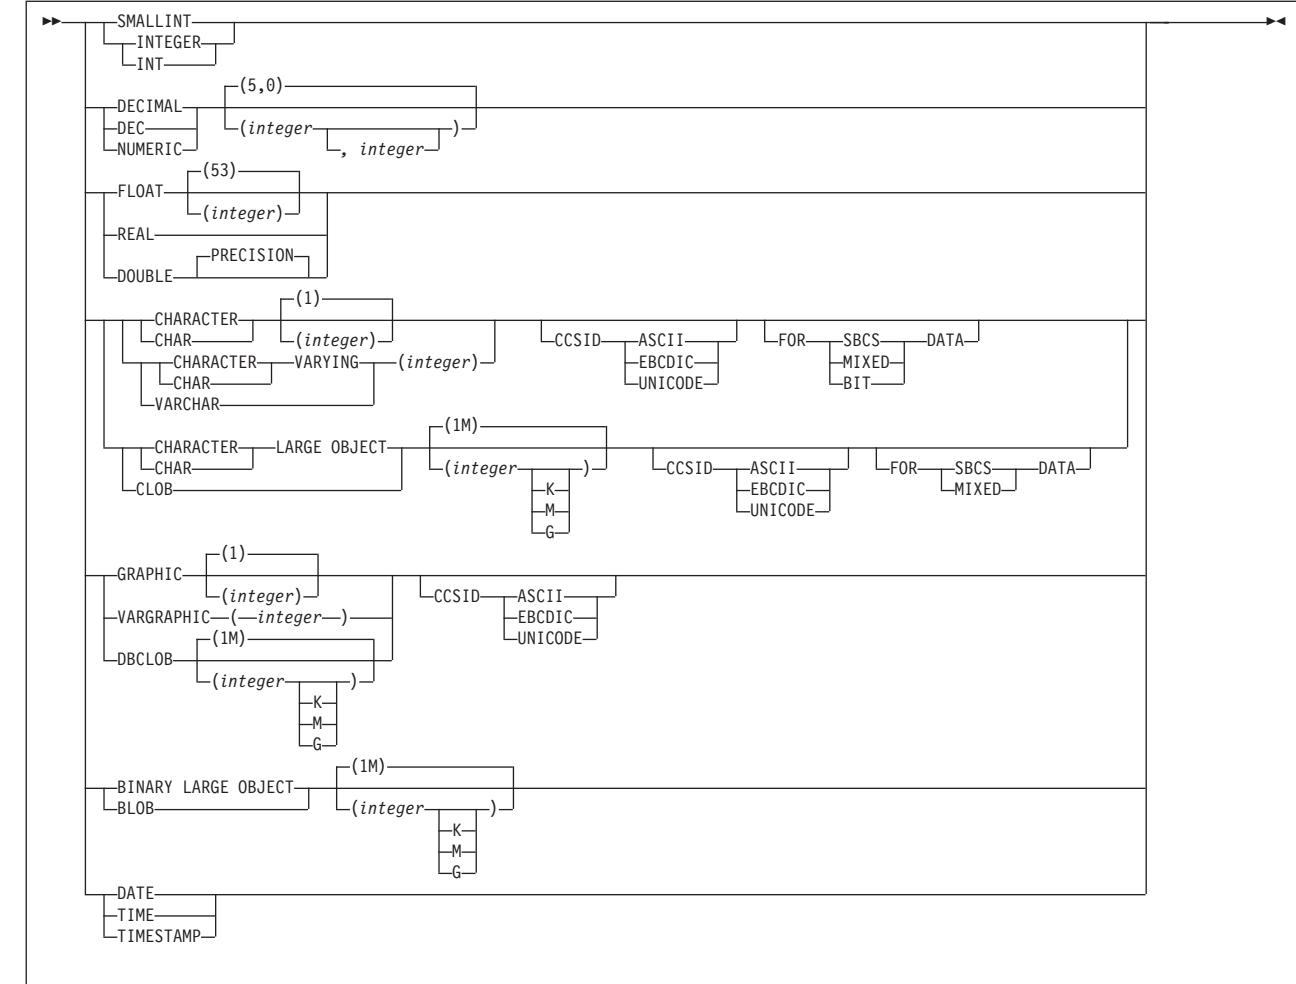

**parameter-declaration:**

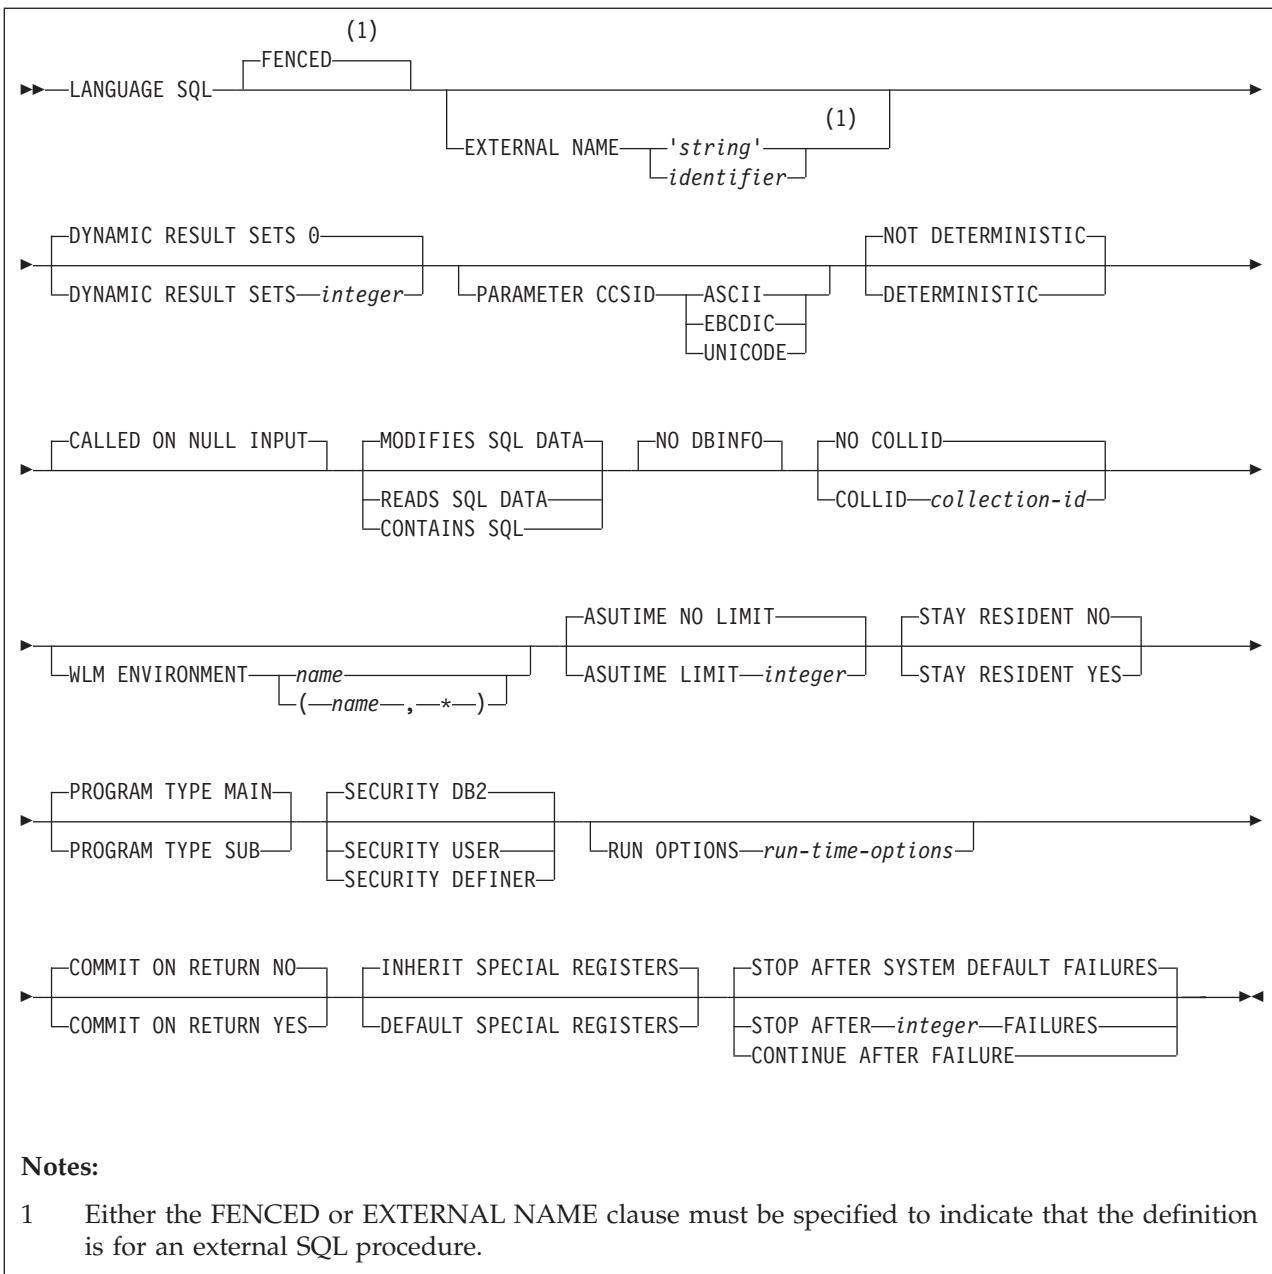

**parameter-type:**

**built-in-type:**

**option-list:** (The options can be specified in any order, but each option can be specified only one time)

## Description

*procedure-name*

Names the procedure. The name, including the implicit or explicit qualifier, must not identify an existing stored procedure at the current server.

*(parameter-declaration,...)*

Specifies the number of parameters of the procedure, the data type of each parameter, and the name of each parameter. A parameter for a procedure can be used only for input, only for output, or for both input and output. If an error is returned by the procedure, OUT parameters are undefined, and INOUT parameters are unchanged. All of the parameters are nullable.

**IN** Identifies the parameter as an input parameter to the procedure. The value

of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

**INOUT**

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

*parameter-name*

Names the parameter for use as an SQL variable. *parameter-name* is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. A parameter name cannot be the same as the name of any other parameter for this version of the procedure.

*parameter-type*

Specifies the data type of the parameter.

*built-in-type*

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see *built-in-type*. For external SQL procedures, the maximum limit for VARCHAR is 32767 and for VARGRAPHIC is 16382.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

A parameter with a datetime data type is passed to the SQL procedure as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is determined as follows:

- If there are one or more parameters with a character or graphic data type, the encoding scheme of the datetime type parameter is the same as the encoding scheme of the character or graphic parameters.
- Otherwise, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**TABLE LIKE *table-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the

procedure is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. A procedure with a table parameter can only be invoked from the triggered action of a trigger.

The transition table includes columns that are defined as implicitly hidden in the table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns.

For more information about the TABLE LIKE clause, see TABLE LIKE. For more information about using table locators, see *DB2 Application Programming and SQL Guide*.

#### **LANGUAGE**

Specifies the application programming language in which the procedure is written.

#### **SQL**

The procedure is written in DB2 SQL procedural language.

#### **FENCED**

Specifies that the procedure runs in an external address space. FENCED also specifies that the SQL procedure program is an MVS load module with an external name.

#### **DYNAMIC RESULT SETS *integer***

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that the procedure can return no result sets. The value of *integer* must be between 0 and 32767.

#### **PARAMETER CCSID**

Indicates whether the encoding scheme for character and graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character and graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that is to be used for system-generated parameters of the routine such as message tokens and DBINFO.

#### **EXTERNAL NAME '*string*' **or** *identifier***

Specifies the name of the MVS load module for the program that runs when the procedure name is specified in an SQL CALL statement. The value must conform to the naming conventions for MVS load modules: the value must be less than or equal to 8 bytes, and it must conform to the rules for an ordinary identifier with the exception that it must not contain an underscore.

EXTERNAL NAME *procedure-name* is the default. In some cases, the default name will not be valid. To avoid an invalid name, specify EXTERNAL NAME for a procedure that has a name that is greater than 8 bytes in length, contains an underscore, or does not conform to the rules for an ordinary identifier.

**NOT DETERMINISTIC or DETERMINISTIC**

Specifies whether the procedure returns the same results each time the procedure is called with the same IN and INOUT arguments.

**NOT DETERMINISTIC**

The procedure might not return the same result each time the procedure is called with the same IN and INOUT arguments, even when the referenced data in the database has not changed.

NOT DETERMINISTIC is the default.

**DETERMINISTIC**

The procedure always returns the same results each time the stored procedure is called with the same IN and INOUT arguments, if the referenced data in the database has not changed.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**CALLED ON NULL INPUT**

Specifies that the procedure is to be called even if any or all argument values are null, which means that the procedure must be coded to test for null argument values. The procedure can return null or non-null values.

CALLED ON NULL INPUT is the default.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements that the procedure can execute. For the data access classification of each statement, see Table 138 on page 1605. Statements that are not supported in any procedure return an error.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

**READS SQL DATA**

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**NO DBINFO**

Specifies that no additional status information that is known by DB2 is passed to the procedure when it is invoked.

**NO COLLID or COLLID *collection-id***

Identifies the package collection that is to be used when the procedure is executed. This is the package collection into which the DBRM that is associated with the procedure is bound.

**NO COLLID**

Specifies that the package collection for the procedure is the same as the package collection of the calling program. If the invoking program does not use a package, DB2 resolves the package by using the CURRENT PACKAGE PATH special register, the CURRENT PACKAGESET special register, or the PKLIST bind option (in this order). For details about how

DB2 uses these three items, see the information on package resolution in *DB2 Application Programming and SQL Guide*.

NO COLLID is the default.

**COLLID** *collection-id*

Specifies the package collection for the procedure.

**WLM ENVIRONMENT** *name or (name,\*)*

Identifies the WLM (workload manager) environment in which the stored procedure is to run when the DB2 stored procedure address space is WLM-established. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT, the procedure runs in the default WLM-established stored procedure address space that is specified at installation time.

**name**

The WLM environment in which the procedure must run. If another procedure or a user-defined function calls the procedure and that calling routine is running in an address space that is not associated with the specified WLM environment, DB2 routes the procedure request to a different address space.

**(name,\*)**

When an SQL application program directly calls a procedure, *name* specifies the WLM environment in which the procedure runs.

If another procedure or a user-defined function calls the stored procedure, the procedure runs in the same WLM environment that the calling routine uses.

To define a procedure that is to run in a specified WLM environment, you must have appropriate authority for the WLM environment. For an example of a RACF command that provides this authorization, see *Running stored procedures*.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a procedure can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a procedure, setting a limit can be helpful in case the procedure gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

There is no limit on the number of CPU service units that the procedure can run.

NO LIMIT is the default.

**LIMIT** *integer*

The limit on the number of CPU service units is a positive *integer* in the range of 1 to 2 147 483 647. If the procedure uses more service units than the specified value, DB2 cancels the procedure.

**STAY RESIDENT**

Specifies whether the load module for the procedure remains resident in memory when the procedure ends.

**NO** The load module is deleted from memory after the procedure ends.

NO is the default.

**YES**

The load module remains resident in memory after the procedure ends.

**PROGRAM TYPE**

Specifies whether the procedure runs as a main routine or a subroutine.

**MAIN**

The procedure runs as a main routine.

MAIN is the default.

**SUB**

The procedure runs as a subroutine.

**SECURITY**

Specifies how the procedure interacts with an external security product, such as RACF, to control access to non-SQL resources.

**DB2**

The procedure does not require a special external security environment. If the procedure accesses resources that an external security product protects, the access is performed using the authorization ID that is associated with the address space in which the procedure runs.

DB2 is the default.

**USER**

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the user who invoked the procedure.

**DEFINER**

An external security environment should be established for the procedure. If the procedure accesses resources that the external security product protects, the access is performed using the authorization ID of the owner of the procedure.

**RUN OPTIONS** *run-time-options*

Specifies the Language Environment runtime options that are to be used for the procedure. You must specify *run-time-options* as a character string that is no longer than 254 bytes. If you do not specify RUN OPTIONS or pass an empty string, DB2 does not pass any runtime options to Language Environment, and Language Environment uses its installation defaults.

For a description of the Language Environment runtime options, see *z/OS Language Environment Programming Reference*.

**COMMIT ON RETURN**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**NO** DB2 does not issue a commit when the procedure returns.

NO is the default.

**YES**

DB2 issues a commit when the procedure returns if the following statements are true:

- A positive SQLCODE is returned by the CALL statement.
- The procedure is not in a must abort state.

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

#### **INHERIT SPECIAL REGISTERS or DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

##### **INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a procedure in Table 37 on page 151.

INHERIT SPECIAL REGISTERS is the default.

##### **DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a procedure in Table 37 on page 151.

#### **STOP AFTER SYSTEM DEFAULT FAILURES, STOP AFTER *nn* FAILURES, or CONTINUE AFTER FAILURE**

Specifies the routine is stopped after failures.

##### **STOP AFTER SYSTEM DEFAULT FAILURES**

Specifies that this routine should be placed in a stopped state after the number of failures indicated by the value of field MAX ABEND COUNT on installation panel DSNTIPX.

STOP AFTER SYSTEM DEFAULT FAILURES is the default.

##### **STOP AFTER *nn* FAILURES**

Specifies that this routine should be placed in a stopped state after *nn* failures. The value *nn* can be an integer from 1 to 32767.

##### **CONTINUE AFTER FAILURE**

Specifies that this routine should not be placed in a stopped state after any failure.

#### *SQL-routine-body*

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in external SQL procedures, see “SQL control statements for external SQL procedures” on page 1610. For information on the SQL statements that are allowed in external SQL procedures, see “SQL statements allowed in SQL procedures” on page 1608.

## **Notes**

See “Notes” on page 1032 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Environments for running stored procedures
- Accessing result sets from nested stored procedures

**Error handling in SQL procedures:** You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception

SQLSTATE that is not handled within the procedure using a handler within a compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC

## Examples

*Example 1:* Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATESALARY
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY1'
MODIFIES SQL DATA
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

*Example 2:* Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The procedure runs in a WLM environment called PARTSA.
- The same input always produces the same output.
- SQL work is committed on return to the caller.
- The Language Environment runtime options to be used when the SQL procedure executes are 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'.

```
CREATE PROCEDURE UPDATESALARY
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
FENCED
EXTERNAL NAME 'USALARY2'
MODIFIES SQL DATA
WLM ENVIRONMENT PARTSA
DETERMINISTIC
RUN OPTIONS 'MSGFILE(OUTFILE),RPTSTG(ON),RPTOPTS(ON)'
COMMIT ON RETURN YES
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see “SQL control statements for external SQL procedures” on page 1610.

## CREATE PROCEDURE (SQL - native)

The CREATE PROCEDURE statement defines an SQL procedure at the current server and specifies the source statements for the procedure. You can define multiple versions of the procedure. CREATE PROCEDURE is used to define the initial version, and ALTER PROCEDURE is used to define subsequent versions.

For information about the SQL control statements that are supported in native SQL procedures, refer to Chapter 6, “SQL control statements for native SQL procedures,” on page 1541.

### Invocation

This statement can only be dynamically prepared, and the DYNAMICRULES run behavior must be specified implicitly or explicitly.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema and the required authorization to add a new package or a new version of an existing package depending on the value of the BIND NEW PACKAGE field on installation panel DSNTIPP
- SYSADM authority
- SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** The privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process and the owner is that role.

If the statement is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

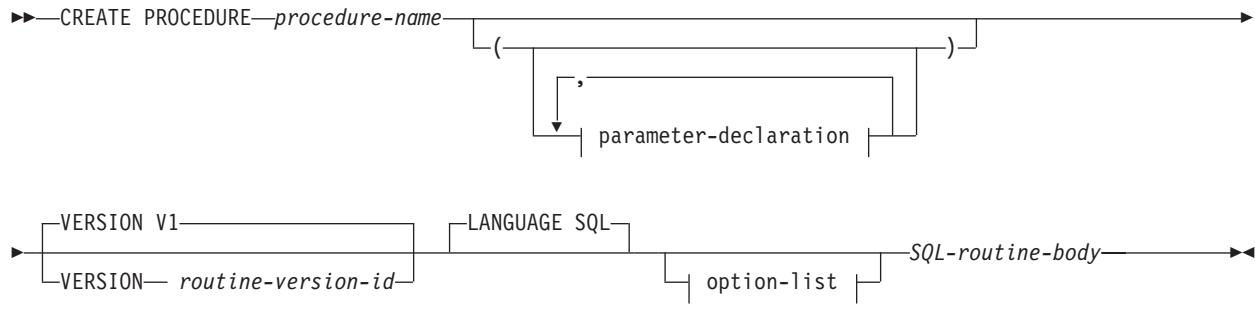

The privilege set must also include the privileges required to execute the statements in *SQL-routine-body*.

If the WLM ENVIRONMENT FOR DEBUG MODE clause is specified, the privilege set must have authority to define programs that run in the specified WLM environment.

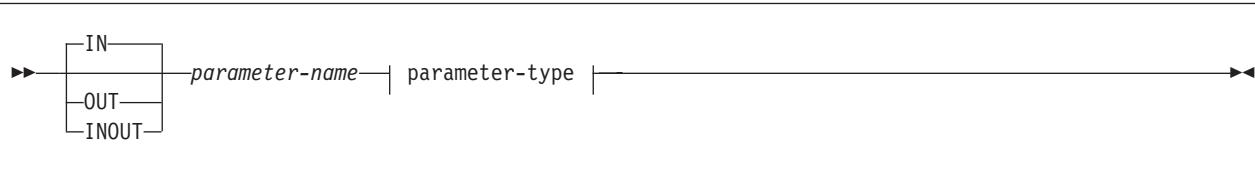

The owner of the procedure is the SQL authorization ID in the CURRENT SQLID special register unless the process is running within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the owner of the procedure is the role that is associated with the primary authorization ID of the process.

The owner is implicitly given the EXECUTE privilege with the GRANT option for the procedure.

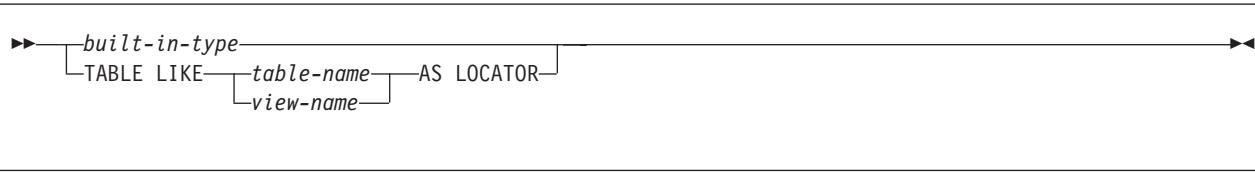

## Syntax

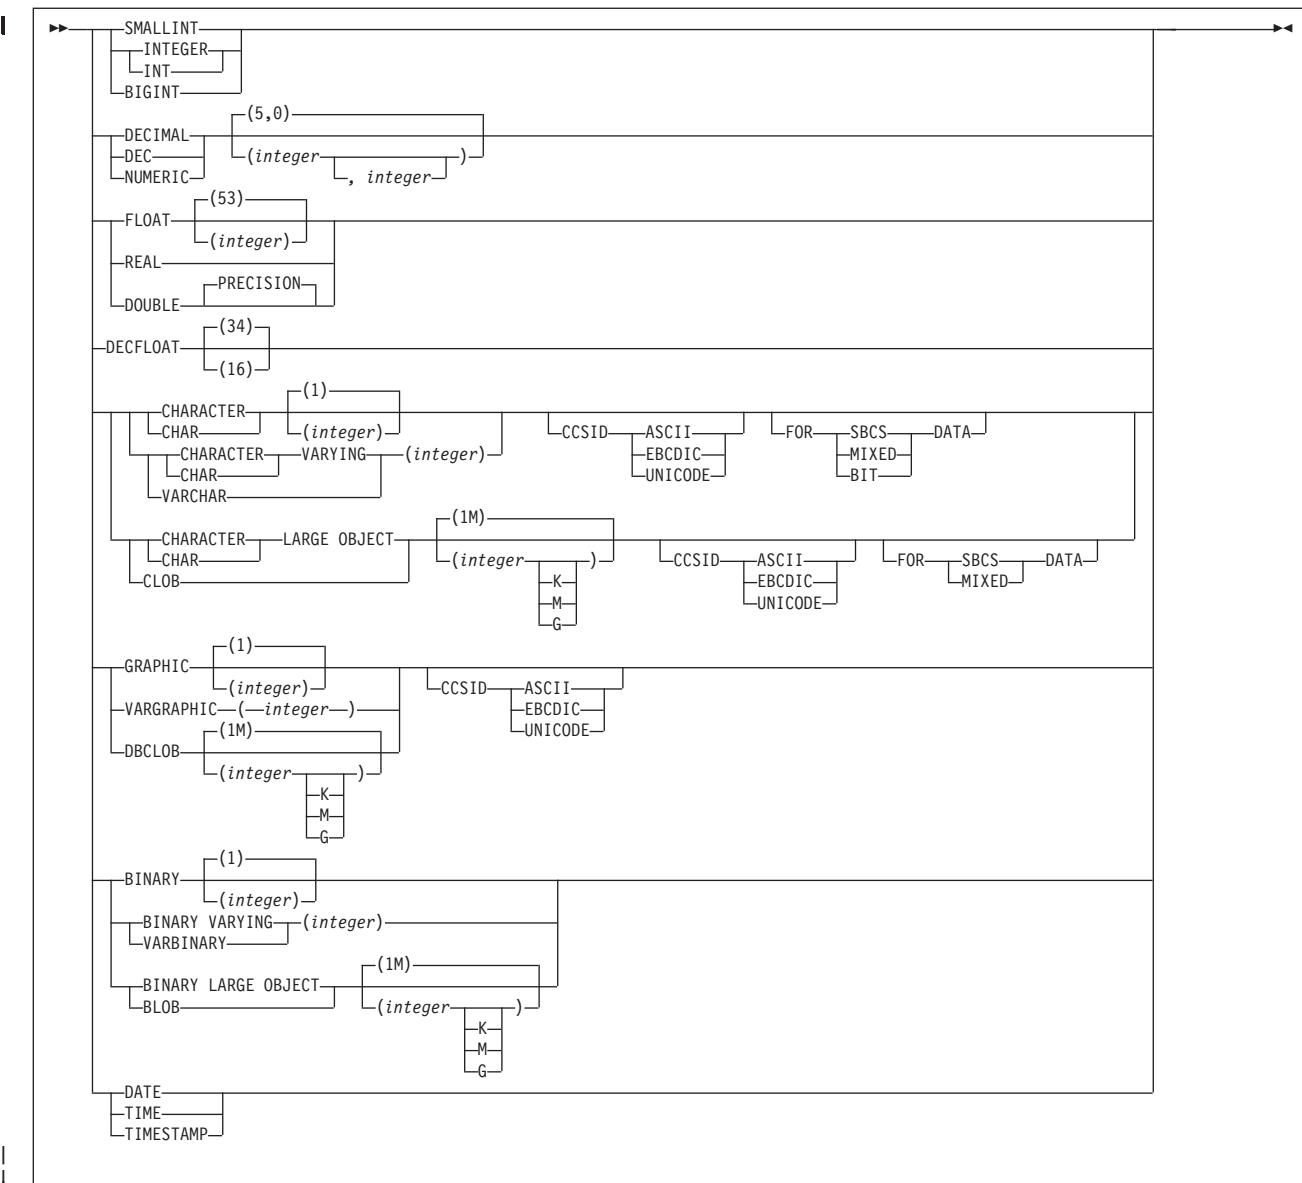

**parameter-declaration:**

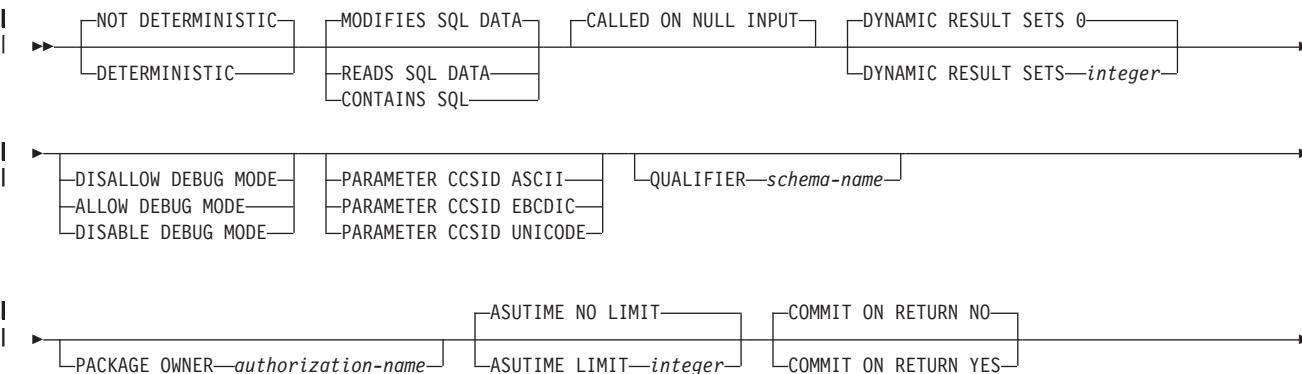

**parameter-type:**

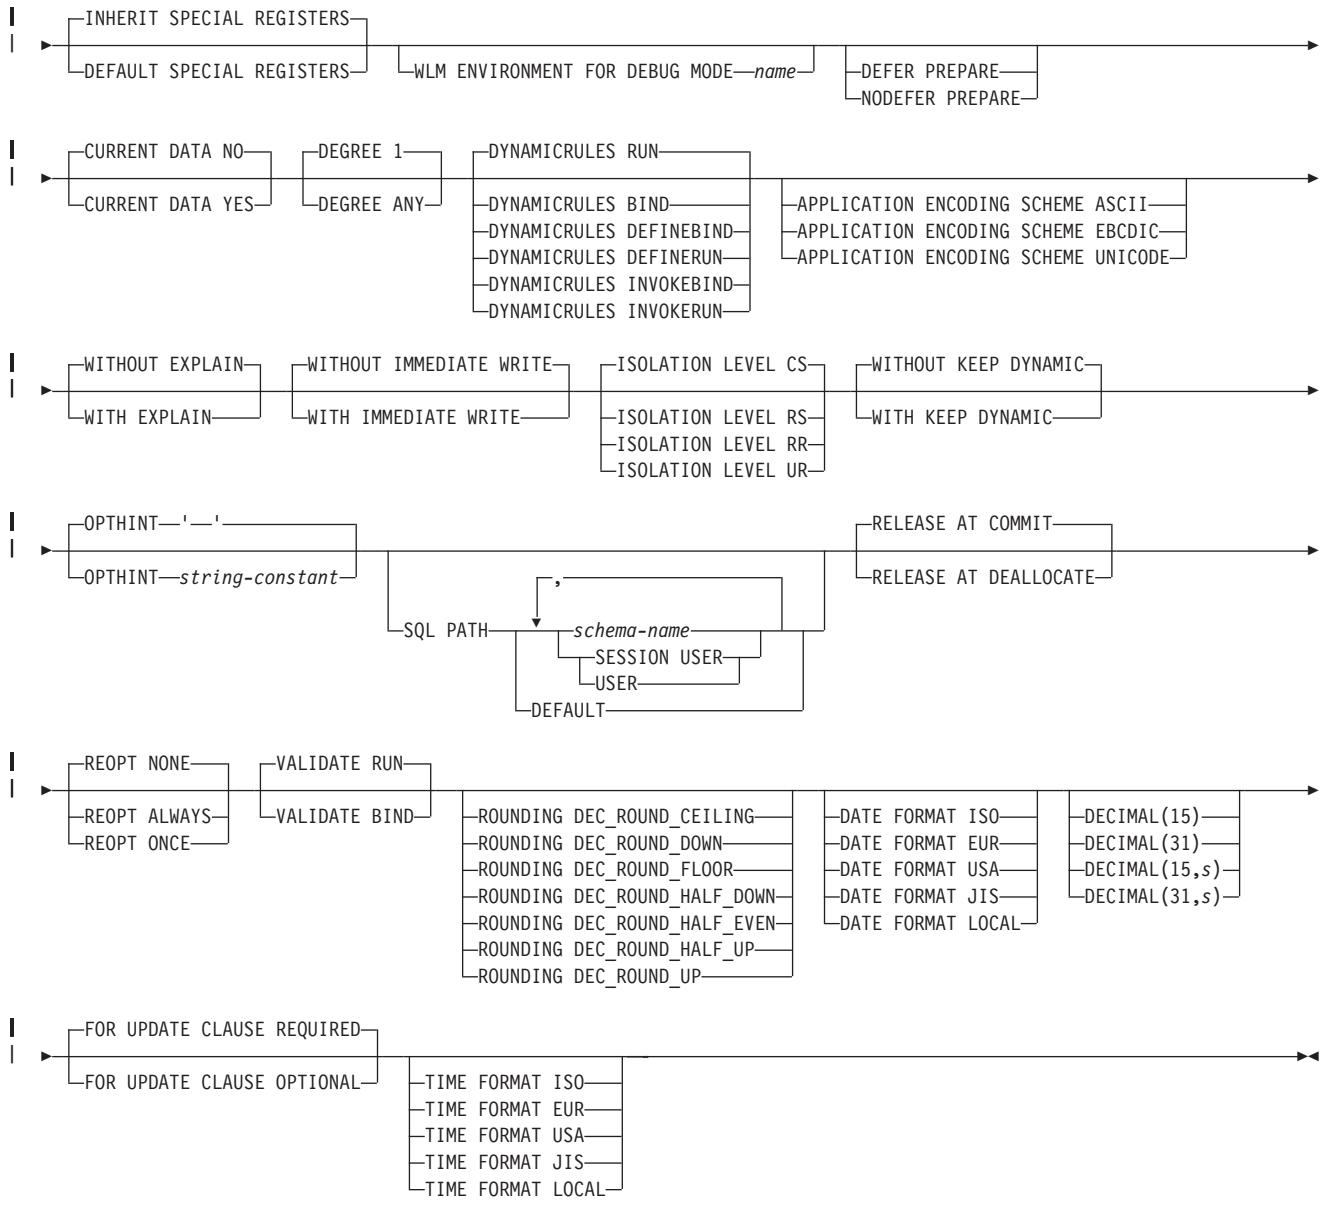

**built-in-type:**

**option-list:** (The options can be specified in any order, but each one can only be specified one time.)

## Description

*procedure-name*

NAMES the procedure. If *procedure-name* already exists, an error is returned even if VERSION is specified with a *version-id* that is different from any existing version identifier for the procedure that is specified in *procedure-name*.

*(parameter-declaration,...)*

Specifies the number of parameters of the procedure, the data type and usage of each parameter, and the name of each parameter for the version of the procedure that is being defined. The number of parameters and the specified data type and usage of each parameter must match the data types in the corresponding position of the parameter for all other versions of this procedure. Synonyms for data types are considered to be a match.

IN, OUT, and INOUT specify the usage of the parameter. The usage of the parameters must match the implicit or explicit usage of the parameters of other versions of the same procedure.

**IN** Identifies the parameter as an input parameter to the procedure. The value of the parameter on entry to the procedure is the value that is returned to the calling SQL application, even if changes are made to the parameter within the procedure.

IN is the default.

**OUT**

Identifies the parameter as an output parameter that is returned by the procedure. If the parameter is not set within the procedure, the null value is returned.

**INOUT**

Identifies the parameter as both an input and output parameter for the procedure. If the parameter is not set within the procedure, its input value is returned.

*parameter-name*

Names the parameter for use as an SQL variable. A parameter name cannot be the same as the name of any other parameter for this version of the procedure. The name of the parameter in this version of the procedure can be different than the name of the corresponding parameter for other versions of this procedure.

*built-in-type*

The data type of the parameter is a built-in data type.

For more information on the data types, including the subtype of character data types (the FOR *subtype* DATA clause), see *built-in-type*. However, the varying length string data types have different maximum lengths than for the CREATE TABLE statement. The maximum lengths for parameters (and SQL variables) are as follows: 32704 for VARCHAR or VARBINARY, and 16352 for VARGRAPHIC.

For parameters with a character or graphic data type, the PARAMETER CCSID clause or CCSID clause indicates the encoding scheme of the parameter. If you do not specify either of these clauses, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

Although an input parameter with a character data type has an implicitly or explicitly specified subtype (BIT, SBCS, or MIXED), the value that is actually passed in the input parameter can have any subtype. Therefore, conversion of the input data to the subtype of the parameter might occur when the procedure is called. With ASCII or EBCDIC, an error occurs if mixed data that actually contains DBCS characters is used as the value for an input parameter that is declared with an SBCS subtype.

A parameter with a datetime data type is passed to the SQL procedure as a character data type, and the data is passed in ISO format.

The encoding scheme for a datetime type parameter is determined as follows:

- If there are one or more parameters with a character or graphic data type, the encoding scheme of the datetime type parameter is the same as the encoding scheme of the character or graphic parameters.
- Otherwise, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

**TABLE LIKE *table-name* AS LOCATOR**

Specifies that the parameter is a transition table. However, when the procedure

is called, the actual values in the transition table are not passed to the procedure. A single value is passed instead. This single value is a locator to the table, which the procedure uses to access the columns of the transition table. The table that is identified can contain XML columns; however, the procedure cannot reference those XML columns. A procedure with a table parameter can only be invoked from the triggered action of a trigger. For additional information about using table locators, refer to *DB2 Application Programming and SQL Guide*.

**VERSION *routine-version-id***

Specifies the version identifier for the first version of the procedure that is to be generated. See “Naming conventions” on page 51 for information about specifying *routine-version-id*. You can use an ALTER PROCEDURE statement with the ADD VERSION clause or the BIND DEPLOY command to create additional versions of the procedure.

V1 is the default version identifier.

See Versions of a procedure for more information about the use of versions for procedures.

**LANGUAGE SQL**

Specifies that the procedure is written in the DB2 SQL procedural language.

**DETERMINISTIC or NOT DETERMINISTIC**

Specifies whether the procedure returns the same results each time it is called with the same IN and INOUT arguments.

**DETERMINISTIC**

The procedure always returns the same results each time it is called with the same IN and INOUT arguments if the data that is referenced in the database has not changed.

**NOT DETERMINISTIC**

The procedure might not return the same result each time it is called with the same IN and INOUT arguments, even when the data that is referenced in the database has not changed.

NOT DETERMINISTIC is the default.

DB2 does not verify that the procedure code is consistent with the specification of DETERMINISTIC or NOT DETERMINISTIC.

**MODIFIES SQL DATA, READS SQL DATA, or CONTAINS SQL**

Specifies the classification of SQL statements that the procedure can execute.

For the data access classification of each statement, see “SQL statements allowed in SQL procedures” on page 1608.

**MODIFIES SQL DATA**

Specifies that the procedure can execute any SQL statement except statements that are not supported in procedures.

MODIFIES SQL DATA is the default.

**READS SQL DATA**

Specifies that the procedure can execute statements with a data access indication of READS SQL DATA or CONTAINS SQL. The procedure cannot execute SQL statements that modify data.

**CONTAINS SQL**

Specifies that the procedure can execute only SQL statements with a data access indication of CONTAINS SQL. The procedure cannot execute statements that read or modify data.

**CALLED ON NULL INPUT**

Specifies that the procedure will be called if any, or even if all parameter values are null.

**DYNAMIC RESULT SETS *integer***

Specifies the maximum number of query result sets that the procedure can return. The default is DYNAMIC RESULT SETS 0, which indicates that there are no result sets. The value must be between 0 and 32767.

**ALLOW DEBUG MODE, DISALLOW DEBUG MODE, or DISABLE DEBUG MODE**

Specifies whether this version of the routine can be run in debugging mode. The default is determined using the value of the CURRENT DEBUG MODE special register.

**ALLOW DEBUG MODE**

Specifies that this version of the routine can be run in debugging mode. When this version of the routine is invoked and debugging is attempted, a WLM environment must be available.

**DISALLOW DEBUG MODE**

Specifies that this version of the routine cannot be run in debugging mode. You can use an ALTER statement to change this option to ALLOW DEBUG MODE for this initial version of the routine.

**DISABLE DEBUG MODE**

Specifies that this version of the routine can never be run in debugging mode.

This version of the routine cannot be changed to specify ALLOW DEBUG MODE or DISALLOW DEBUG MODE after this version of the routine has been created or altered to use DISABLE DEBUG MODE. To change this option, drop the routine and create it again using the desired option. An alternative to dropping and recreating the routine is to create a version of the routine that uses the desired option and make that version the active version.

When DISABLE DEBUG MODE is in effect, the WLM ENVIRONMENT FOR DEBUG MODE is ignored.

**PARAMETER CCSID**

Indicates whether the encoding scheme for character or graphic string parameters is ASCII, EBCDIC, or UNICODE. The default encoding scheme is the value that is specified in the CCSID clauses of the parameter list or in the field DEF ENCODING SCHEME on installation panel DSNTIPF.

This clause provides a convenient way to specify the encoding scheme for character or graphic string parameters. If individual CCSID clauses are specified for individual parameters in addition to this PARAMETER CCSID clause, the value that is specified in *all* of the CCSID clauses must be the same value that is specified in this clause.

This clause also specifies the encoding scheme that will be used for system-generated parameters of the routine.

**QUALIFIER *schema-name***

Specifies the implicit qualifier that is used for unqualified names of tables,

views, indexes, and aliases that are referenced in the routine body. The default value is the same as the default schema.

**PACKAGE OWNER** *authorization-name*

Specifies the owner of the package that is associated with the first version of the routine. The SQL authorization ID of the process is the default value.

The authorization ID must have the privileges that are required to execute the SQL statements that are contained in the routine body. The value of PACKAGE OWNER is subject to translation when it is sent to a remote system.

If the privilege set lacks SYSADM or SYSCTRL authority, *authorization-name* must be the same as one of the authorization IDs of the process or the authorization ID of the process. If the privilege set includes SYSADM or SYSCTRL authority, *authorization-name* can be any authorization ID.

**ASUTIME**

Specifies the total amount of processor time, in CPU service units, that a single invocation of a routine can run. The value is unrelated to the ASUTIME column of the resource limit specification table.

When you are debugging a routine, setting a limit can be helpful in case the routine gets caught in a loop. For information on service units, see *z/OS MVS Initialization and Tuning Guide*.

**NO LIMIT**

Specifies that there is no limit on the service units.

**NO LIMIT** is the default.

**LIMIT** *integer*

Specifies that the limit on the service units is a positive *integer* in the range of 1 to 2 147 483 647. If the routine uses more service units than the specified value, DB2 cancels the routine.

**COMMIT ON RETURN NO** or **COMMIT ON RETURN YES**

Indicates whether DB2 commits the transaction immediately on return from the procedure.

**COMMIT ON RETURN NO**

DB2 does not issue a commit when the procedure returns. NO is the default.

**COMMIT ON RETURN YES**,

DB2 issues a commit when the procedure returns if the following statements are true:

- The SQLCODE that is returned by the CALL statement is not negative.
- The procedure is not in a must-abort state.

The commit operation includes the work that is performed by the calling application process and by the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

**INHERIT SPECIAL REGISTERS** or **DEFAULT SPECIAL REGISTERS**

Specifies how special registers are set on entry to the routine.

**INHERIT SPECIAL REGISTERS**

Specifies that the values of special registers are inherited, according to the rules that are listed in the table for characteristics of special registers in a routine in Table 37 on page 151.

**INHERIT SPECIAL REGISTERS** is the default.

**DEFAULT SPECIAL REGISTERS**

Specifies that special registers are initialized to the default values, as indicated by the rules in the table for characteristics of special registers in a routine in Table 37 on page 151.

**WLM ENVIRONMENT FOR DEBUG MODE *name***

Specifies the WLM (workload manager) application environment that is used by DB2 when debugging the routine. The *name* of the WLM environment is an SQL identifier.

If you do not specify WLM ENVIRONMENT FOR DEBUG MODE, DB2 uses the default WLM-established stored procedure address space specified at installation time.

To define a routine that is to run in a specified WLM application environment, you must have the appropriate authority for the WLM application environment. For an example of a RACF command that provides this authorization, see Running stored procedures.

The WLM ENVIRONMENT FOR DEBUG MODE value is ignored when DISABLE DEBUG MODE is in effect.

**DEFER PREPARE or NODEFER PREPARE**

Specifies whether to defer preparation of dynamic SQL statements that refer to remote objects, or to prepare them immediately.

The default depends on the value in effect for the REOPT option. If REOPT NONE is in effect, the default is inherited from the plan at run time. Otherwise, the default is DEFER PREPARE.

**DEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will be deferred.

Refer to the DEFER(PREPARE) option in *DB2 Command Reference* for considerations with distributed processing.

**NODEFER PREPARE**

Specifies that the preparation of dynamic SQL statements that refer to remote objects will not be deferred.

**CURRENT DATA(YES) or CURRENT DATA(NO)**

Specifies whether to require data currency for read-only and ambiguous cursors when the isolation level of cursor stability is in effect. CURRENT DATA also determines whether block fetch can be used for distributed, ambiguous cursors.

**YES**

Specifies that data currency is required for read-only and ambiguous cursors. DB2 acquired page or row locks to ensure data currency. Block fetch is ignored for distributed, ambiguous cursors.

**NO**

Specifies that data currency is not required for read-only and ambiguous cursors. Block fetch is allowed for distributed, ambiguous cursors. Use of **CURRENT DATA(NO)** is not recommended if the routine attempts to dynamically prepare and execute a DELETE WHERE CURRENT OF statement against an ambiguous cursor after that cursor is opened. You receive a negative SQLCODE if your routine attempts to use a DELETE WHERE CURRENT OF statement for any of the following cursors:

- A cursor that is using block fetch

- A cursor that is using query parallelism
- A cursor that is positioned on a row that is modified by this or another application process

**NO** is the default.

#### **DEGREE**

Specifies whether to attempt to run a query using parallel processing to maximize performance.

**1** Specifies that parallel processing should not be used.

1 is the default.

#### **ANY**

Specifies that parallel processing can be used.

#### **DYNAMICRULES**

Specifies the values that apply, at run time, for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- The qualifier that is used for unqualified objects
- The source for application programming options that DB2 uses to parse and semantically verify dynamic SQL statements

DYNAMICRULES also specifies whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements.

In addition to the value of the DYNAMICRULES clause, the runtime environment of a routine controls how dynamic SQL statements behave at run time. The combination of the DYNAMICRULES value and the runtime environment determines the value for the dynamic SQL attributes. That set of attribute values is called the dynamic SQL statement behavior. The following values can be specified:

#### **RUN**

Specifies that dynamic SQL statements are to be processed using run behavior.

**RUN** is the default.

#### **BIND**

Specifies that dynamic SQL statements are to be processed using bind behavior.

#### **DEFINEBIND**

Specifies that dynamic SQL statements are to be processed using either define behavior or bind behavior.

#### **DEFINERUN**

Specifies that dynamic SQL statements are to be processed using either define behavior or run behavior.

#### **INVOKEBIND**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or bind behavior.

#### **INVOKERUN**

Specifies that dynamic SQL statements are to be processed using either invoke behavior or run behavior.

See “Authorization IDs and dynamic SQL” on page 64 for information on the effects of these options.

#### **APPLICATION ENCODING SCHEME**

Specifies the default encoding scheme for SQL variables in static SQL statements in the routine body. The value is used for defining an SQL variable in a compound statement if the CCSID clause is not specified as part of the data type, and the PARAMETER CCSID routine option is not specified.

##### **ASCII**

Specifies that the data is encoded using the ASCII CCSIDs of the server.

##### **EBCDIC**

Specifies that the data is encoded using the EBCDIC CCSIDs of the server.

##### **UNICODE**

Specifies that the data is encoded using the Unicode CCSIDs of the server.

See the ENCODING bind option in *DB2 Command Reference* for information about how the default for this option is determined.

#### **WITH EXPLAIN or WITHOUT EXPLAIN**

Specifies whether information will be provided about how SQL statements in the routine will execute.

##### **WITHOUT EXPLAIN**

Specifies that information will not be provided about how SQL statements in the routine will execute.

You can get EXPLAIN output for a statement that is embedded in a routine that is specified using WITHOUT EXPLAIN by embedding the SQL statement EXPLAIN in the routine body. Otherwise, the value of the EXPLAIN option applies to all explainable SQL statements in the routine body, and to the fullselect portion of any DECLARE CURSOR statements.

**WITHOUT EXPLAIN** is the default.

##### **WITH EXPLAIN**

Specifies that information will be provided about how SQL statements in the routine will execute. Information is inserted into the table *owner.PLAN\_TABLE*. *owner* is the authorization ID of the owner of the routine. Alternatively, the authorization ID of the owner of the routine can have an alias as *owner.PLAN\_TABLE* that points to the base table, *PLAN\_TABLE*. *owner* must also have the appropriate SELECT and INSERT privileges on that table. WITH EXPLAIN does not obtain information for statements that access remote objects. *PLAN\_TABLE* must have a base table and can have multiple aliases with the same table name, *PLAN\_TABLE*, but have different schema qualifiers. It cannot be a view or a synonym and should exist before the version is added or replaced. In all inserts to *owner.PLAN\_TABLE*, the value of QUERYNO is the statement number that is assigned by DB2.

The WITH EXPLAIN option also populates two optional tables if they exist: DSN\_STATEMNT\_TABLE and DSN\_FUNCTION\_TABLE.

DSN\_STATEMNT\_TABLE contains an estimate of the processing cost for an SQL statement. See *DB2 Application Programming and SQL Guide* for more information. DSN\_FUNCTION\_TABLE contains information about function resolution. See *DB2 Application Programming and SQL Guide* for more information.

For a description of the tables that are populated by the WITH EXPLAIN option, see "EXPLAIN" on page 1283.

#### **WITH IMMEDIATE WRITE or WITHOUT IMMEDIATE WRITE**

Specifies whether immediate writes are to be done for updates that are made to group buffer pool dependent page sets or partitions. This option is only applicable for data sharing environments. The IMMEDWRITE subsystem parameter has no affect of this option. *DB2 Command Reference* shows the implied hierarchy of the IMMEDWRITE bind option (which is similar to this routine option) as it affects run time.

#### **WITHOUT IMMEDIATE WRITE**

Specifies that normal write activity is performed. Updated pages that are group buffer pool dependent are written at or before phase one of commit or at the end of abort for transactions that have been rolled back.

**WITHOUT IMMEDIATE WRITE** is the default.

#### **WITH IMMEDIATE WRITE**

Specifies that updated pages that are group buffer pool dependent are immediately written as soon as the buffer update completes. Updated pages are written immediately even if the buffer is updated during forward progress or during the rollback of a transaction. **WITH IMMEDIATE WRITE** might impact performance.

#### **ISOLATION LEVEL RR, RS, CS, or UR**

Specifies how far to isolate the routine from the effects of other running applications. For information about isolation levels, see *DB2 Performance Monitoring and Tuning Guide*.

**RR** Specifies repeatable read.

**RS** Specifies read stability.

**CS** Specifies cursor stability. **CS** is the default.

**UR** Specifies uncommitted read.

#### **WITH KEEP DYNAMIC or WITHOUT KEEP DYNAMIC**

Specifies whether DB2 keeps dynamic SQL statements after commit points.

#### **WITHOUT KEEP DYNAMIC**

Specifies that DB2 does not keep dynamic SQL statements after commit points.

**WITHOUT KEEP DYNAMIC** is the default.

#### **WITH KEEP DYNAMIC**

Specifies that DB2 keeps dynamic SQL statements after commit points. If you specify **WITH KEEP DYNAMIC**, the application does not need to prepare an SQL statement after every commit point. DB2 keeps the dynamic SQL statement until one of the following occurs:

- The application process ends
- A rollback operations occurs
- The application executes an explicit PREPARE statement with the same statement identifier as the dynamic SQL statement

If you specify **WITH KEEP DYNAMIC**, and the prepared statement cache is active, the DB2 subsystem keeps a copy of the prepared statement in the cache. If the prepared statement cache is not active, the subsystem keeps

only the SQL statement string past a commit point. If the application executes an OPEN, EXECUTE, or DESCRIBE operation for that statement, the statement is implicitly prepared.

If you specify WITH KEEP DYNAMIC, DDF server threads that are used to execute procedures or packages that have this option in effect will remain active. Active DDF server threads are subject to idle thread timeouts, as described in *DB2 Installation Guide* for install panel DSNTIPR.

If you specify WITH KEEP DYNAMIC, you must not specify REOPT ALWAYS. WITH KEEP DYNAMIC and REOPT ALWAYS are mutually exclusive. However, you can specify WITH KEEP DYNAMIC and REOPT ONCE.

Use WITH KEEP DYNAMIC to improve performance if your DRDA client application uses a cursor that is defined as WITH HOLD. The DB2 subsystem automatically closes a held cursor when there are no more rows to retrieve, which eliminates an extra network message.

#### **OPTHINT** *string-constant*

Specifies whether query optimization hints are used for static SQL statements that are contained within the body of the routine.

*string-constant* is a character string of up to 128 bytes in length, which is used by the DB2 subsystem when searching the PLAN\_TABLE for rows to use as input. The default value is an empty string, which indicates that the DB2 subsystem does not use optimization hints for static SQL statements.

Optimization hints are only used if optimization hints are enabled for your system. See *DB2 Installation Guide* for information about enabling optimization hints.

#### **SQL PATH**

Specifies the SQL path that DB2 uses to resolve unqualified user-defined distinct type, function, and procedure names in the procedure body. The default value is "SYSIBM," "SYSFUN," "SYSPROC," and *procedure-schema*, where *procedure-schema* is the schema qualifier for the procedure that is the target of the statement.

Schemas SYSIBM, SYSFUN, and SYSPROC do not need to be explicitly specified. If any of these schemas is not explicitly specified, it is implicitly assumed at the beginning the SQL path. See "SQL path" on page 56 for information about how to specify the path so that the intended procedure is selected when it is invoked with an unqualified name.

DB2 calculates the length by taking each *schema-name* specified and removing any trailing blanks from it, adding two delimiters around it, and adding one comma after each schema name except for the last one. The length of the resulting string cannot exceed the length of the CURRENT SCHEMA special register. If you do not specify the SYSIBM, SYSFUN, and SYSPROC, schemas, they are not included in the length of the SQL path. If the total length of the SQL path exceeds the length of the CURRENT PATH special register, DB2 returns an error for the CREATE statement.

See "CURRENT SCHEMA" on page 147 for information about the length of the CURRENT SCHEMA special register and "CURRENT PATH" on page 142 for information about the length of the CURRENT PATH special register.

#### *schema-name*

Specifies a schema. DB2 does not validate that the specified schema actually exists when the CREATE statement is processed.

*schema-name-list*

Specifies a comma separated list of schema names. The same schema name should not appear more than once in the list of schema names. The number of schema names that you can specify is limited by the maximum length of the resulting SQL path.

**SESSION\_USER or USER**

Specifies the value of the SESSION\_USER or USER special register, which represents a maximum 8 byte (in EBCDIC) *schema-name*. At the time the CREATE statement is processed, this length is included in the total length of the list of schema names that is specified for the PATH bind option.

**DEFAULT**

Specifies that the SQL PATH should be set to "SYSIBM", "SYSFUN", "SYSPROC", *procedure-schema*. *procedure-schema* is the schema qualifier for the procedure that is being created.

If you specify DEFAULT, you do not need to explicitly specify the SYSIBM, SYSFUN, and SYSPROC schemas; these schemas are implicitly added to the beginning of the SQL path in the order listed.

**RELEASE AT**

Specifies when to release resources that the procedure uses: either at each commit point or when the procedure terminates.

**COMMIT**

Specifies that resources will be released at each commit point.

COMMIT is the default.

**DEALLOCATE**

Specifies that resources will be released only when the procedure terminates. DEALLOCATE has no effect on packages that run on a DB2 server through a DRDA connection with a client system. DEALLOCATE has no effect on dynamic SQL statements, which always use RELEASE AT COMMIT, with this exception: When you use the RELEASE AT DEALLOCATE clause and the WITH KEEP DYNAMIC clause, and the subsystem is installed with a value of YES for the field CACHE DYNAMIC SQL on installation panel DSNTIP8, the RELEASE AT DEALLOCATE option is honored for dynamic SELECT and data change statements.

Locks that are acquired for dynamic statements are held until one of the following events occurs:

- The application process ends.
- The application process issues a PREPARE statement with the same statement identifier. (Locks are released at the next commit point).
- The statement is removed from the prepared statement cache because the statement has not been used. (Locks are released at the next commit point).
- An object that the statement is dependent on is dropped or altered, or a privilege that the statement needs is revoked. (Locks are released at the next commit point).

RELEASE AT DEALLOCATE can increase the package or plan size because additional items become resident in the package or plan. For more information about how the RELEASE clause affects locking and concurrency, see *DB2 Performance Monitoring and Tuning Guide*.

**REOPT**

Specifies if DB2 will determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

**NONE**

Specifies that DB2 does not determine the access path at run time by using the values of SQL variables or SQL parameters, parameter markers, and special registers.

**NONE** is the default.

**ALWAYS**

Specifies that DB2 always determines the access path at run time each time an SQL statement is run. Do not specify REOPT ALWAYS with the WITH KEEP DYNAMIC or NODEFER PREPARE clauses.

**ONCE**

Specifies that DB2 determine the access path for any dynamic SQL statements only once, at the first time the statement is opened. This access path is used until the prepared statement is invalidated or removed from the dynamic statement cache and need to be prepared again.

**VALIDATE RUN or VALIDATE BIND**

Specifies whether to recheck, at run time, errors of the type "OBJECT NOT FOUND" and "NOT AUTHORIZED" that are found during bind or rebind. The option has no effect if all objects and needed privileges exist.

**VALIDATE RUN**

Specifies that if needed objects or privileges do not exist when the CREATE statement is processed, warning messages are returned, but the CREATE statement succeeds. The DB2 subsystem rechecks for the objects and privileges at run time for those SQL statements that failed the checks during processing of the CREATE statement. The authorization checks the use of the authorization ID of the owner of the routine.

**VALIDATE RUN** is the default.

**VALIDATE BIND**

Specifies that if needed objects or privileges do not exist at the time the CREATE statement is processed, an error is issued and the CREATE statement fails.

**ROUNDING**

Specifies the desired rounding mode for manipulation of DECFLOAT data. The default value is taken from the DEFAULT DECIMAL FLOATING POINT ROUNDING MODE in DECP.

**DEC\_ROUND\_CEILING**

Specifies numbers are rounded towards positive infinity.

**DEC\_ROUND\_DOWN**

Specifies numbers are rounded towards 0 (truncation).

**DEC\_ROUND\_FLOOR**

Specifies numbers are rounded towards negative infinity.

**DEC\_ROUND\_HALF\_DOWN**

Specifies numbers are rounded to nearest; if equidistant, round down.

**DEC\_ROUND\_HALF\_EVEN**

Specifies numbers are rounded to nearest; if equidistant, round so that the final digit is even.

**DEC\_ROUND\_HALF\_UP**

Specifies numbers are rounded to nearest; if equidistant, round up.

**DEC\_ROUND\_UP**

Specifies numbers are rounded away from 0.

**DATE FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the date format for result values that are string representations of date or time values. See “String representations of datetime values” on page 89 for more information.

The default format is specified in the DATE FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

**DECIMAL(15), DECIMAL(31), DECIMAL(15,s), or DECIMAL(31,s)**

Specifies the maximum precision that is to be used for decimal arithmetic operations. See “Arithmetic with two decimal operands” on page 183 for more information. The default format is specified in the DECIMAL ARITHMETIC field of installation panel DSNTIPF of the system where the routine is defined. If the form *pp.s* is specified, *s* must be a number between 1 and 9. *s* represents the minimum scale that is to be used for division.

**FOR UPDATE CLAUSE OPTIONAL or FOR UPDATE CLAUSE REQUIRED**

Specifies whether the FOR UPDATE clause is required for a DECLARE CURSOR statement if the cursor is to be used to perform positioned updates.

**FOR UPDATE CLAUSE REQUIRED**

Specifies that a FOR UPDATE clause must be specified as part of the cursor definition if the cursor will be used to make positioned updates.

**FOR UPDATE CLAUSE REQUIRED** is the default.

**FOR UPDATE CLAUSE OPTIONAL**

Specifies that the FOR UPDATE clause does not need to be specified in order for a cursor to be used for positioned updates. The routine body can include positioned UPDATE statements that update columns that the user is authorized to update.

The FOR UPDATE clause with no column list applies to static or dynamic SQL statements. Even if you do not use this clause, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are named in the FOR UPDATE clause and to specify the acquisition of update locks.

**TIME FORMAT ISO, EUR, USA, JIS, or LOCAL**

Specifies the time format for result values that are string representations of date or time values. See “String representations of datetime values” on page 89 for more information.

The default format is specified in the TIME FORMAT field of installation panel DSNTIP4 of the system where the routine is defined. You cannot use the LOCAL option unless you have a date exit routine.

***SQL-routine-body***

Specifies the statements that define the body of the SQL procedure. For information on the SQL control statements that are supported in native SQL procedures, see Chapter 6, “SQL control statements for native SQL procedures,” on page 1541. If an *SQL-procedure-statement* is the only statement in the procedure body, the statement must not end with a semicolon. For information on the SQL statements that are allowed in native SQL procedures, see “SQL statements allowed in SQL procedures” on page 1608.

## Notes

See "Notes" on page 1032 for information about:

- Owner privileges
- Choosing data types for parameters
- Specifying the encoding scheme for parameters
- Environments for running stored procedures
- Accessing result sets from nested stored procedures

**Versions of a procedure:** The CREATE PROCEDURE statement for an SQL procedure defines the initial version of the procedure. You can define additional versions using the ADD VERSION clause of the ALTER PROCEDURE statement. All versions of a procedure share the same procedure signature and the same specific name. However, the parameters names can differ between versions of a procedure. Only one version of the procedure can be considered to be the active version of the procedure.

**Characteristics of the package that is generated for a procedure:** The package that is associated with the first version of a procedure is named as follows:

- *location* is set to the value of the CURRENT SERVER special register
- *collection-id* (schema) for the package is the same as the schema qualifier of the procedure.
- *package-id* is the same as the specific name of the procedure
- *version-id* is the same as the version identifier for the initial version of the procedure.

If you want to change the *collection-id* for the name of the package, you need to make a copy of the package.

The package is generated using the bind options that correspond to the implicitly or explicitly specified procedure options. See "Implicit rebinding and regeneration that occurs because of an ALTER PROCEDURE statement" in Chapter 6, "SQL control statements for native SQL procedures," on page 1541 for more information. In addition to the corresponding bind options, the package is generated using the following bind options:

- DBPROTOCOL(DRDA)
- FLAG(1)
- SQLERROR(NOPACKAGE)
- ENABLE(\*)

See Table 83 on page 775 for additional information about the correspondence of procedure options to bind options.

**Identifier resolution:** See Chapter 6, "SQL control statements for native SQL procedures," on page 1541 for information on how names are resolved to columns, SQL variables, or SQL parameters within an SQL routine. Name resolution is unchanged for external SQL procedures.

If duplicate names are used for columns and SQL variables and parameters, qualify the duplicate names by using the table designator for columns, the procedure name for parameters, and the label name for SQL variables.

**Lines within the SQL procedure definition:** When a procedure is created, information is retained on lines in the CREATE statement. Lines are determined by the presence of the *new line control character*.

**Error handling in SQL procedures:** You should consider the possible exceptions that can occur for each SQL statement in the body of a procedure. Any exception SQLSTATE that is not handled within the procedure using a handler within a compound statement or a compound statement that is nested within that compound statement results in the exception SQLSTATE being returned to the caller of the procedure.

**Compatibilities:** For compatibility with previous versions of DB2, the following clauses can be specified, but they will be ignored and a warning will be issued:

- STAY RESIDENT
- PROGRAM TYPE
- RUN OPTIONS
- NO DBINFO
- COLLID or NOCOLLID
- SECURITY
- PARAMETER STYLE GENERAL WITH NULLS
- STOP AFTER SYSTEM DEFAULT FAILURES
- STOP AFTER *nn* FAILURES
- CONTINUE AFTER FAILURES

If the FENCED or EXTERNAL clause is specified, an external SQL procedure will be generated. See “CREATE PROCEDURE (SQL - external)” on page 1035 for more information.

If WLM ENVIRONMENT is specified without the FOR DEBUG MODE keywords, an error is returned. If WLM ENVIRONMENT is specified for a native SQL procedure, WLM ENVIRONMENT FOR DEBUG MODE must be specified.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RESULT SET and RESULT SETS as synonyms for DYNAMIC RESULT SETS
- VARIANT as a synonym for NOT DETERMINISTIC
- NOT VARIANT as a synonym for DETERMINISTIC
- NULL CALL as a synonym for CALLED ON NULL

## Examples

*Example 1:* Create the definition for an SQL procedure. The procedure accepts an employee number and a multiplier for a pay raise as input. The following tasks are performed in the procedure body:

- Calculate the employee's new salary.
- Update the employee table with the new salary value.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
UPDATE EMP
SET SALARY = SALARY * RATE
WHERE EMPNO = EMPLOYEE_NUMBER
```

*Example 2:* Create the definition for the SQL procedure described in example 1, but specify that the procedure has these characteristics:

- The same input always produces the same output.
- SQL work is committed on return to the caller.

```
CREATE PROCEDURE UPDATE_SALARY_1
  (IN EMPLOYEE_NUMBER CHAR(10),
   IN RATE DECIMAL(6,2))
LANGUAGE SQL
MODIFIES SQL DATA
DETERMINISTIC
COMMIT ON RETURN YES
UPDATE EMP
  SET SALARY = SALARY * RATE
  WHERE EMPNO = EMPLOYEE_NUMBER
```

For more examples of SQL procedures, see Chapter 6, “SQL control statements for native SQL procedures,” on page 1541.

## CREATE ROLE

The CREATE ROLE statement creates a role at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following authorities:

- SYSADM authority
- SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the set of privileges that are held by the owner of the plan or package.

If the statement is dynamically prepared, the privilege set is the set of privileges that are held by the SQL authorization ID of the process or by the role that is associated with the primary authorization ID, if the statement is run in a trusted context and the ROLE AS OBJECT OWNER clause is specified.

### Syntax

```
►►—CREATE ROLE—role-name————►►
```

### Description

*role-name*

Names the role. The name must not identify a role that exists at the current server. The name must not be 'PUBLIC'.

### Examples

The following statement creates a role named TELLER.

```
CREATE ROLE TELLER;
```

---

## CREATE SEQUENCE

The CREATE SEQUENCE statement creates a sequence at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

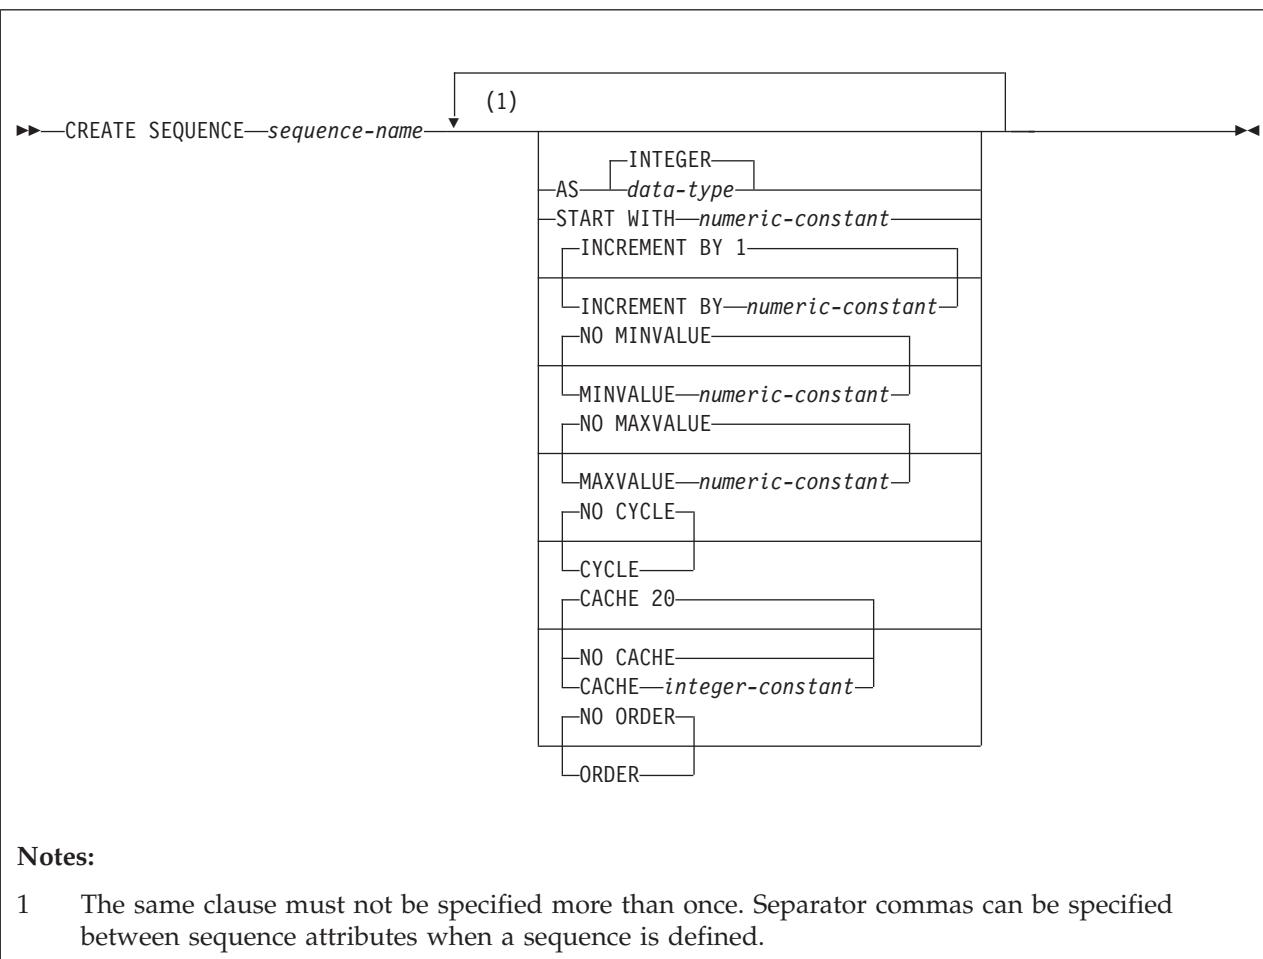

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

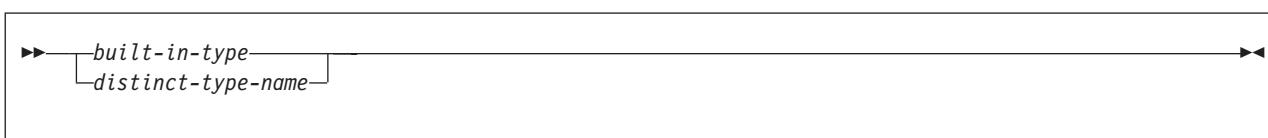

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

If the data type of the sequence is a distinct type, the privilege set must include the USAGE privilege on the distinct type.

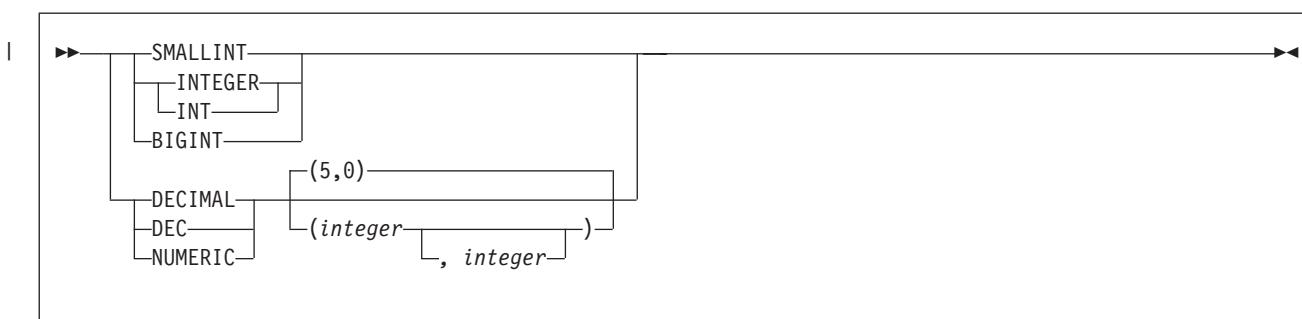

## Syntax

**data-type:**

**built-in-type:**

## Description

### *sequence-name*

Names the sequence. The name, including the implicit or explicit qualifiers, must not identify an existing sequence at the current server, including the sequence names that are generated by DB2.

The schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

### **AS** *data-type*

Specifies the data type to be used for the sequence value. The data type can be any exact numeric data type (SMALLINT, INTEGER, BIGINT, or DECIMAL with a scale of zero), or a user-defined distinct type for which the source type is an exact numeric data type with a scale of zero. The default, when AS is not specified, is INTEGER. If DECIMAL is specified, the default is DECIMAL(5,0).

### **START WITH** *numeric-constant*

Specifies the first value for the sequence. The value can be any positive or negative value that could be assigned to a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point.

If the START WITH clause is not explicitly specified with a value, the default is the MINVALUE for ascending sequences and MAXVALUE for descending sequences.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

### **INCREMENT BY** *numeric-constant*

Specifies the interval between consecutive values of the sequence. The value can be any positive or negative value (including 0) that could be assigned to a column of the data type that is associated with the sequence without any non-zero digits existing to the right of the decimal point. The default is 1.

If INCREMENT BY is positive, the sequence ascends. If INCREMENT BY is negative, the sequence descends. If INCREMENT is 0, the sequence is treated as an ascending sequence.

The absolute value of INCREMENT BY can be greater than the difference between MAXVALUE and MINVALUE.

### **MINVALUE or NO MINVALUE**

Specifies the minimum value at which a descending sequence either cycles or stops generating values or an ascending sequence cycles to after reaching the maximum value. The default is NO MINVALUE.

### **MINVALUE** *numeric-constant*

Specifies the minimum end of the range of values for the sequence. The last value that is generated for a cycle of a descending sequence will be equal to or greater than this value. MINVALUE is the value to which an ascending sequence cycles to after reaching the maximum value.

The value can be any positive or negative value that could be assigned to a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

For the effects of defining MINVALUE and MAXVALUE with the same value, see Defining a constant sequence.

#### **NO MINVALUE**

Specifies that the minimum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending sequence, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending sequence, the value is the minimum value of the data type that is associated with the sequence.

#### **MAXVALUE or NO MAXVALUE**

Specifies the maximum value at which an ascending sequence either cycles or stops generating values or an descending sequence cycles to after reaching the minimum value. The default is NO MAXVALUE.

##### **MAXVALUE *numeric-constant***

Specifies the maximum end of the range of values for the sequence. The last value that is generated for a cycle of an ascending sequence will be less than or equal to this value. MAXVALUE is the value to which a descending sequence cycles to after reaching the minimum value.

The value can be any positive or negative value that could be assigned to the a column of the data type that is associated with the sequence without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

If DECIMAL is specified in the AS clause, *numeric-constant* has a maximum value of 99 999.

For the effects of defining MAXVALUE and MINVALUE with the same value, see Defining a constant sequence.

#### **NO MAXVALUE**

Specifies the maximum end point of the range of values for the sequence has not been specified explicitly. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending sequence, the value is the maximum value of the data type that is associated with the sequence.
- For a descending sequence, the value is the START WITH value or -1 if START WITH is not specified.

#### **CYCLE or NO CYCLE**

Specifies whether or not the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition or by overshooting it. The default is NO CYCLE.

#### **CYCLE**

Specifies that the sequence continue to generate values after either the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence defined by the MINVALUE and MAXVALUE options determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by the sequence. When a sequence is defined with CYCLE, any application

conversion tools for converting applications from other vendor platforms to DB2 should also explicitly specify MINVALUE, MAXVALUE, and START WITH values.

#### **NO CYCLE**

Specifies that the sequence cannot generate more values once the maximum or minimum value for the sequence has been reached. The NO CYCLE option (the default) can be altered to CYCLE at any time during the life of the sequence.

When the next value is being generated for a sequence if the maximum value (for an ascending sequence) or the minimum value (for a descending sequence) of the logical range of the sequence is exceeded and the NO CYCLE option is in effect, an error occurs.

#### **CACHE or NO CACHE**

Specifies whether or not to keep some preallocated values in memory for faster access. This is a performance and tuning option.

##### **CACHE *integer-constant***

Specifies the maximum number of values of the sequence that DB2 can preallocate and keep in memory. Preallocating values in the cache reduces synchronous I/O when values are generated for the sequence. The actual number of values that DB2 caches is always the lesser of the number in effect for the CACHE option and the number of remaining values within the logical range. Thus, the CACHE value is essentially an upper limit for the size of the cache.

In the event the system is shut down (either normally or through a system failure), all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost when the system is shut down.

The minimum value is 2. The default is CACHE 20.

In a data sharing environment, you can use the CACHE and NO ORDER options to allow multiple DB2 members to cache sequence values simultaneously.

##### **NO CACHE**

Specifies that values of the sequence are not to be preallocated. This option ensures that there is not a loss of values in the case of a system failure.

When NO CACHE is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O.

#### **ORDER or NO ORDER**

Specifies whether the sequence numbers must be generated in order of request. The default is NO ORDER.

##### **ORDER**

Specifies that the sequence numbers are generated in order of request. Specifying ORDER might disable the caching of values. There is no guarantee that values are assigned in order across the entire server unless NO CACHE is also specified. ORDER applies only to a single-application process.

##### **NO ORDER**

Specifies that the sequence numbers do not need to be generated in order of request.

In a data sharing environment, if the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously, and the requests for next value assignments from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the same sequence, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested for next value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple DB2 members using the same sequence concurrently, specify the ORDER option.

## Notes

**Owner privileges:** The owner is authorized to change (ALTER privilege) or use (USAGE privilege) the sequence and grant others these privileges. See “GRANT (sequence privileges)” on page 1351. For more information about ownership of the object see “Authorization, privileges, and object ownership” on page 60.

**Relationship of MINVALUE and MAXVALUE:** MINVALUE must not be greater than MAXVALUE. Although MINVALUE is typically less than MAXVALUE, MINVALUE can equal MAXVALUE. If START WITH were the same value as MINVALUE and MAXVALUE, the sequence would be constant. The request for the next value in a constant sequence appears to have no effect because all of the values that are generated by the sequence are in fact the same value.

**Defining sequences that cycle:** When you define a sequence, you can choose to have it cycle automatically or not when the maximum or minimum value for the sequence has been reached.

- Implicitly or explicitly defining a sequence with NO CYCLE causes the sequence to not cycle automatically after the boundary is reached. However, you can use the ALTER SEQUENCE statement to cycle the sequence manually. ALTER SEQUENCE allows you to restart or extend the sequence, which causes sequence values to continue to be generated.
- Explicitly defining a sequence with CYCLE causes the sequence to cycle automatically after the boundary is reached. Sequence values continue to be generated after the sequence cycles.

When a sequence is defined to cycle automatically, the maximum or minimum value that is generated for a sequence might not be the actual MAXVALUE or MINVALUE value that is specified if the increment is a value other than 1 or -1. For example, the sequence defined with START WITH=1, INCREMENT=2, MAXVALUE=10 will generate a maximum value of 9, and will not generate the value 10.

When a sequence is defined with CYCLE, any application conversion tools (for converting applications from other vendor platforms to DB2) should also explicitly specify MINVALUE, MAXVALUE, and START WITH.

**Defining a constant sequence:** You can define a sequence such that it always returns the same (or a constant) value. To create a constant sequence, use either of these techniques when defining the sequence:

- Specify an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE.
- Specify the same value for START WITH, MINVALUE, and MAXVALUE, and specify CYCLE.

A constant sequence can be used as a numeric global variable. You can use ALTER SEQUENCE to adjust the values that are generated for a constant sequence.

**Consumed values of a sequence:** After DB2 generates a value for a sequence, that value can be said to be "consumed" regardless of whether or not that value is utilized by the application or not. The value is not reused within the current cycle. A consumed value might not be utilized when the statement that caused the value to be generated fails for some reason or is rolled back after the value was generated. Generated but unused values can constitute gaps in a sequence.

**Gaps in a sequence:** Consecutive values in a sequence differ by the constant INCREMENT BY value specified for the sequence. However, gaps can occur in the values that are assigned to a sequence object by DB2.

The following situations are some examples of how gaps can be introduced in the sequence values:

- A transaction has advanced the sequence and then rolls back.
- The SQL statement leading to the generation of the next value fails after the value was generated.
- The NEXT VALUE expression is used in the SELECT statement of a cursor in a DRDA environment where the client uses block-fetch and not all retrieved rows are fetched by the application.
- The sequence is altered and then the alteration is rolled back.
- The sequence (or an identity column table) is dropped and then the drop is rolled back.
- The SYSIBM.SYSSEQ table space is stopped or closed for any reason (including when DSMAX is reached)
- The DB2 subsystem is stopped or goes down

Values of such gaps are not available for the current cycle, unless the sequence is altered and restarted in a specific way to make them available.

A sequence is incremented independently of a transaction. Thus, a given transaction increments the sequence two times might see a gap in the two numbers that it receives if other transactions concurrently increment the same sequence. Most applications can tolerate these instances as these are not really gaps.

**Duplicate sequence values:** It is possible the duplicate values can be generated for a sequence. Duplicate values are most likely to occur when a sequence is defined with the CYCLE option, is defined as a constant sequence, or is altered. For example, the following situations could cause duplicate sequence values:

- A sequence is defined with the attributes START WITH=2, INCREMENT BY 2, MINVALUE=2, MAXVALUE=10, and CYCLE.
- The ALTER SEQUENCE statement is used to restart the sequence with a value that has already been generated.
- The ALTER SEQUENCE statement is used to reverse the ascending direction of a sequence by changing the INCREMENT BY value from a positive to a negative.

**Using sequences:** A sequence can be referenced using a *sequence-reference*. A sequence reference can appear in most places that an expression can appear. A sequence reference can specify whether the value to be returned is a newly generated value or the previously generated value. A NEXT VALUE sequence expression is used to generate a new value. A PREVIOUS VALUE sequence

expression is used to obtain the last assigned value of a sequence. For more information, see “Sequence reference” on page 217.

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- NOMINVALUE (single key word) as a synonym for NO MINVALUE
- NOMAXVALUE (single key word) as a synonym for NO MAXVALUE
- NOCYCLE (single key word) as a synonym for NO CYCLE
- NOCACHE (single key word) as a synonym for NO CACHE
- NOORDER (single key word) as a synonym for NO ORDER

## Examples

*Example 1:* Create a sequence names "org\_seq" that starts at 1 increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORDER_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 24;
```

INCREMENT 1, NO MAXVALUE, and NO CYCLE are defaults and do not need to be specified.

*Example 2:* The following example shows how to create and use a sequence named "order\_seq" in a table named "orders":

```
CREATE SEQUENCE ORDER_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 20;
INSERT INTO ORDERS (ORDERNO, CUSTNO)
  VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
```

or to update the orders:

```
UPDATE ORDERS
  SET ORDERNO = NEXT VALUE FOR ORDER_SEQ
  WHERE CUSTNO = 123456;
```

*Example 3:* The following example shows how to use the same sequence number as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row to generate the sequence value and with a PREVIOUS VALUE expression for the other rows to refer to the sequence value most recently generated.

```
INSERT INTO ORDERS (ORDERNO, CUSTNO)
  VALUES (NEXT VALUE FOR ORDER_SEQ, 123456);
INSERT INTO LINE_ITEMS (ORDERNO, PARTNO, QUANTITY)
  VALUES (PREVIOUS VALUE FOR ORDER_SEQ, 987654, 100);
```

If NEXT VALUE is invoked in the same statement as the PREVIOUS VALUE, then regardless of their order in the statement, PREVIOUS VALUE returns the previous (unincremented) value and NEXT VALUE returns the next value.

## CREATE STOGROUP

The CREATE STOGROUP statement creates a storage group at the current server. Storage from the identified volumes can later be allocated for table spaces and index spaces.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

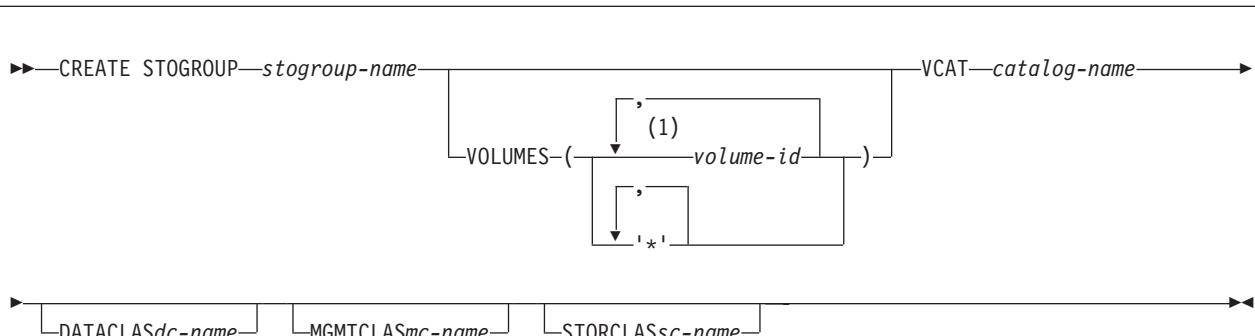

The privilege set that is defined below must include at least one of the following:

- The CREATESG privilege
- SYSADM or SYSCTRL authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

### Syntax

#### Notes:

- 1 The same *volume-id* must not be specified more than once.

### Description

#### *stogroup-name*

Names the storage group. The name must not identify a storage group that exists at the current server.

**VOLUMES(*volume-id*,...)** or **VOLUMES('\*','...')**

Defines the volumes of the storage group. Each *volume-id* is a volume serial number of a storage volume. The volume serial number can have a maximum of six characters and is specified as an identifier or a string constant.

If the data set that is associated with the storage group is not managed by Storage Management Subsystem (SMS), VOLUMES must be specified.

Asterisks are recognized only by SMS. SMS usage is recommended, rather than using DB2 to allocate data to specific volumes. Having DB2 select the volume requires non-SMS usage or assigning an SMS Storage Class with guaranteed space. However, because guaranteed space reduces the benefits of SMS allocation, it is not recommended. If one or more of the DATACLAS, MGMTCLAS, or STORCLAS clauses are specified, VOLUMES can be omitted. If the VOLUMES clause is omitted, the volume selection is controlled by SMS.

If you do choose to use specific volume assignments, additional manual space management must be performed. Free space must be managed for each individual volume to prevent failures during the initial allocation and extension. This process generally requires more time for space management and results in more space shortages. Guaranteed space should be used only where the space needs are relatively small and do not change.

**VCAT *catalog-name***

Identifies the integrated catalog facility catalog for the storage group. You must specify an alias<sup>30</sup> if the name of the integrated catalog facility catalog is longer than 8 characters.

The designated catalog is the one in which entries are placed for the data sets created by DB2 with the aid of the storage group. These are linear VSAM data sets for associated table or index spaces or for their partitions. For each such space or partition, association is made through a USING clause in a CREATE TABLESPACE, CREATE INDEX, ALTER TABLESPACE, or ALTER INDEX statement. For more on the association, see the descriptions of those statements in this chapter.

Conventions for data set names are given in *DB2 Administration Guide*. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

**DATACLAS *dc-name***

Identifies the name of the SMS data class to associate with the DB2 storage group. The SMS data class name must be from 1-8 characters in length. The SMS storage administrator defines the data class that can be used. DATACLAS must not be specified more than one time.

**MGMTCLAS *mc-name***

Identifies the name of the SMS management class to associate with the DB2 storage group. The SMS management class name must be from 1-8 characters in length. The SMS storage administrator defines the management class that can be used. MGMTCLAS must not be specified more than one time.

**STORCLAS *sc-name***

Identifies the name of the SMS storage class to associate with the DB2 storage group. The SMS storage class name must be from 1-8 characters in length. The

30. The alias of an integrated catalog facility catalog.

|  
| SMS storage administrator defines the storage class that can be used.  
| STORCLAS must not be specified more than one time.

## Notes

*Device types:* When the storage group is used at run time, an error can occur if the volumes in the storage group are of different device types, or if a volume is not available to z/OS for dynamic allocation of data sets.

When a storage group is used to extend a data set, all volumes in the storage group must be of the same device type as the volumes used when the data set was defined. Otherwise, an extend failure occurs if an attempt is made to extend the data set.

*Number of volumes:* There is no specific limit on the number of volumes that can be defined for a storage group. However, the maximum number of volumes that can be managed for a storage group is 133.

|  
| z/OS imposes a limit on the number of volumes that can be allocated per data set  
| (currently, 59 volumes). For the latest information on that restriction, see  
| *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

*Storage group owner:* If the statement is embedded in an application program, the owner of the plan or package is the owner of the storage group. If the statement is dynamically prepared, the SQL authorization ID of the process is the owner of the storage group. The owner has the privilege of altering and dropping the storage group.

*Specifying volume IDs:* A new storage group must have either specific volume IDs or non-specific volume IDs. You cannot create a storage group that contains a mixture of specific and non-specific volume IDs.

|  
| *Verifying the existence of volumes and classes:* When processing the VOLUMES,  
| DATACLAS, MGMTCLAS, or STORCLAS clauses, DB2 does not check the  
| existence of the volumes or classes or determine the types of devices that are  
| identified or if SMS is active. Later, when the storage group allocates data sets, the  
| list of volumes is passed in the specified order to Data Facilities (DFSMSdfp). See  
| *DB2 Administration Guide* for more information about creating DB2 storage groups.

## Example

Create storage group, DSN8G910, of volumes ABC005 and DEF008. DSNCAT is the integrated catalog facility catalog name.

```
CREATE STOGROUP DSN8G910
  VOLUMES (ABC005,DEF008)
  VCAT DSNCAT;
```

## CREATE SYNONYM

The CREATE SYNONYM statement defines a synonym for a table or view at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified. The statement cannot be processed in a trusted context that is defined with a role as the object owner.

### Authorization

None required.

### Syntax

```
►►CREATE SYNONYM—synonym—FOR—authorization-name.table-name  
                                                  |  
                                                  view-name►►
```

### Description

#### *synonym*

Names the synonym. The name must not identify a synonym, table, view, or alias that is owned by the owner of the synonym that is being created.

#### **FOR** *authorization-name.table-name* **or** *authorization-name.view-name*

Identifies the object to which the synonym applies. The name must consist of two parts and must identify a table, view, or alias that exists at the current server. If a table is identified, it must not be an auxiliary table or a declared temporary table. If an alias is identified, it must be an alias for a table or view at the current server and the synonym is defined for that table or view. The name must not identify a table that was implicitly created for an XML column.

### Notes

**Owner privileges:** There are no specific privileges on a synonym. For more information about ownership of an object, see “Authorization, privileges, and object ownership” on page 60.

In cases where the statement is dynamically prepared, users with SYSADM authority can create synonyms for other users. This is done by changing the value of the CURRENT SQLID special register before issuing the CREATE SYNONYM statement. See “SET CURRENT SQLID” on page 1500 for details on changing the value of the CURRENT SQLID special register.

### Example

Define DEPT as a synonym for the table DSN8910.DEPT.

```
CREATE SYNONYM DEPT  
      FOR DSN8910.DEPT;
```

This example does not work if the current SQL authorization ID is DSN8910.

## CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key and its table space.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETAB privilege for the database explicitly specified by the IN clause.  
If the IN clause is not specified, the CREATETAB privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCtrl authority

If the table space is created implicitly, the privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database explicitly specified by the IN clause.  
If the IN clause is not specified, the CREATETS privilege on database DSNDB04 is required.
- DBADM, DBCTRL, or DBMAINT authority for the database explicitly specified by the IN clause. If the IN clause is not specified, DBADM, DBCTRL, or DBMAINT authority for database DSNDB04 is required.
- SYSADM or SYSCtrl authority

The privilege set must also have the USE privilege for the default buffer pool and default storage group of the database if the database is specified in the IN clause.

For tables that are created in an implicit database, the database authority must be held on DSNDB04.

Additional privileges might be required in the following conditions:

- The clause IN, LIKE or FOREIGN KEY is specified.
- The data type of a column is a distinct type.
- The table space is implicitly created.
- A *fullselect* is specified.
- A column is defined as a security label column.

See the description of the appropriate clauses for details about these privileges.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified:

- A role is the owner of the table that is being created
- The privilege set is the set of privileges that are held by that role
- The schema qualifier (implicit or explicit) must be the same as the role, unless the role has the CREATEIN privilege on the schema, or SYSADM or SYSCTRL authority

Otherwise, an authorization ID is the owner of the plan or package, and the following rules apply:

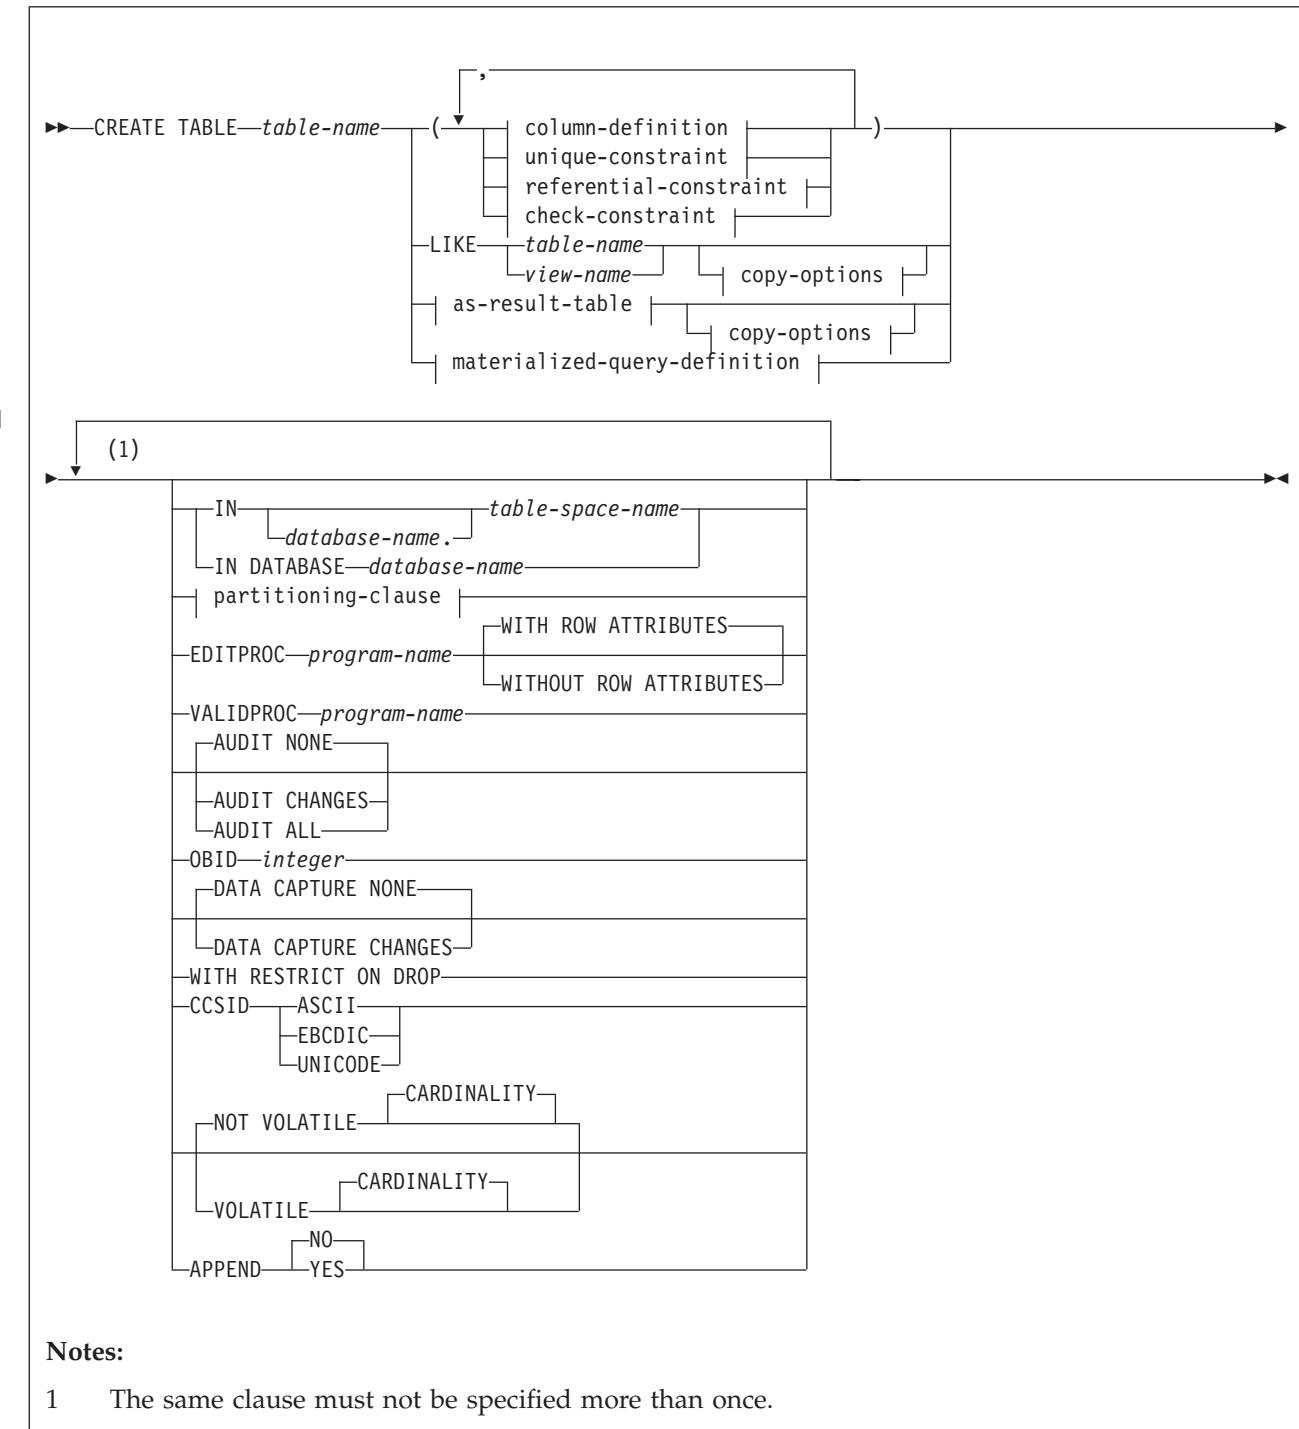

- If the privilege set lacks the CREATEIN privilege on the schema, or SYSADM or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as the authorization ID of the owner of the plan or package, and the owner of the table is that authorization ID.
- If the privilege set includes SYSADM or SYSCTRL authority, the schema qualifier (implicit or explicit) can be any schema name.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is in effect. When ROLE AS OBJECT OWNER is in effect, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process, and the owner of the table is that role. The schema qualifier (implicit or explicit) must be the same as that role, unless the role has CREATEIN privilege on the schema, or SYSADM or SYSCTRL authority.

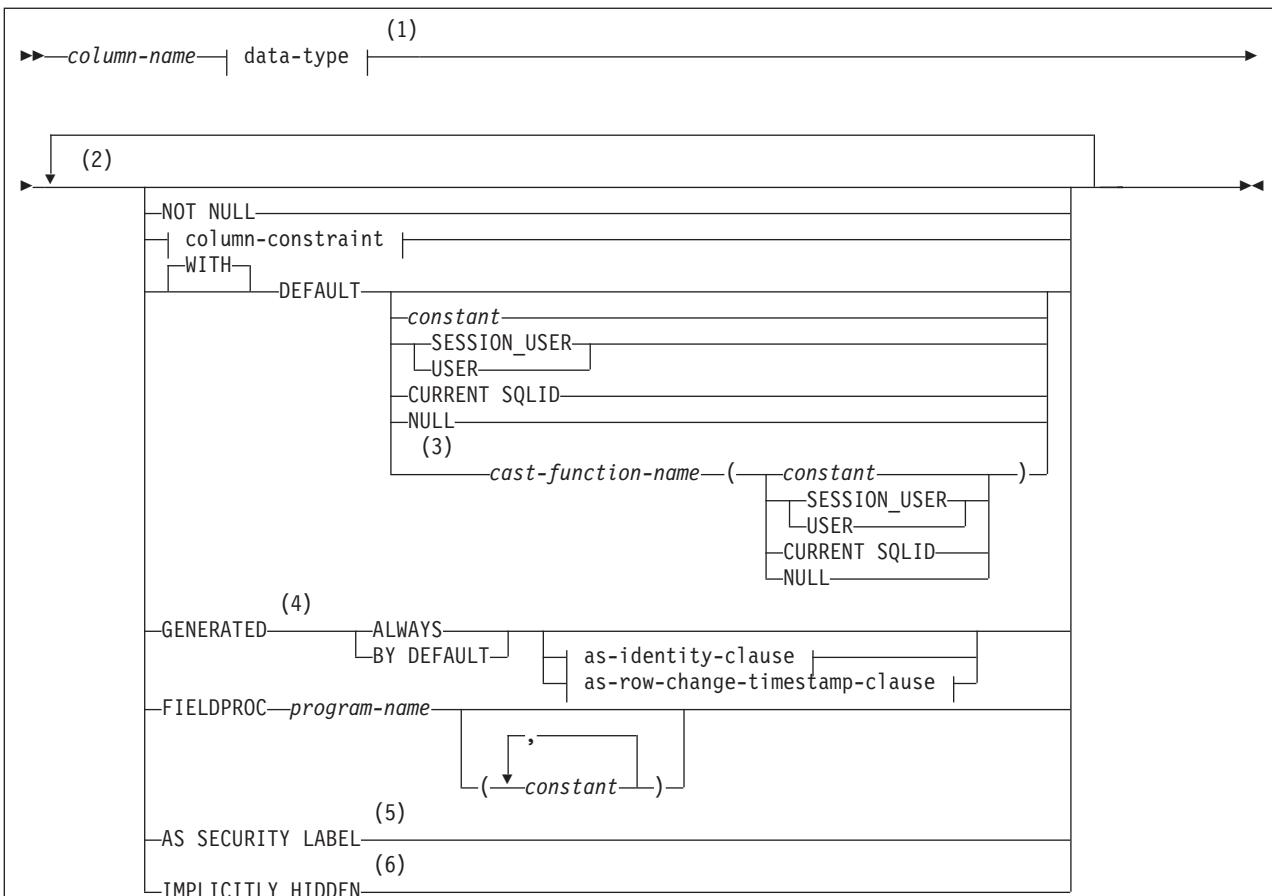

For the case where the SQL authorization ID of the process holds the privileges, the owner of the table is the schema if the schema is explicitly specified, otherwise the owner of the table is the SQL authorization ID of the process. Additionally:

- If the privilege set lacks CREATEIN privilege on the schema, or SYSADM or SYSCTRL authority, the schema qualifier must be the same as one of the authorization IDs of the process and the privilege set that is held by that authorization ID must include all privileges that are needed to create the table.
- If the privilege set includes SYSADM or SYSCTRL authority, the schema qualifier can be any schema name. The privilege set that is held by the SQL authorization ID of the process must include all privileges that are needed to create the table.

## Syntax

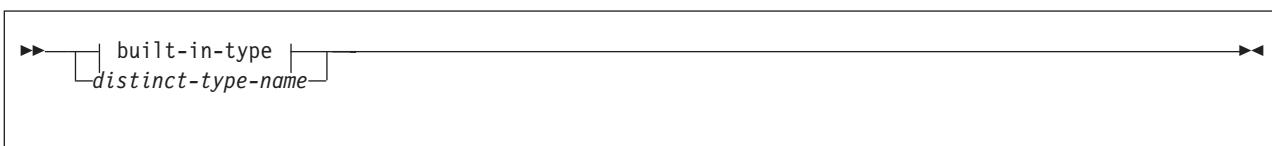

**column-definition:**

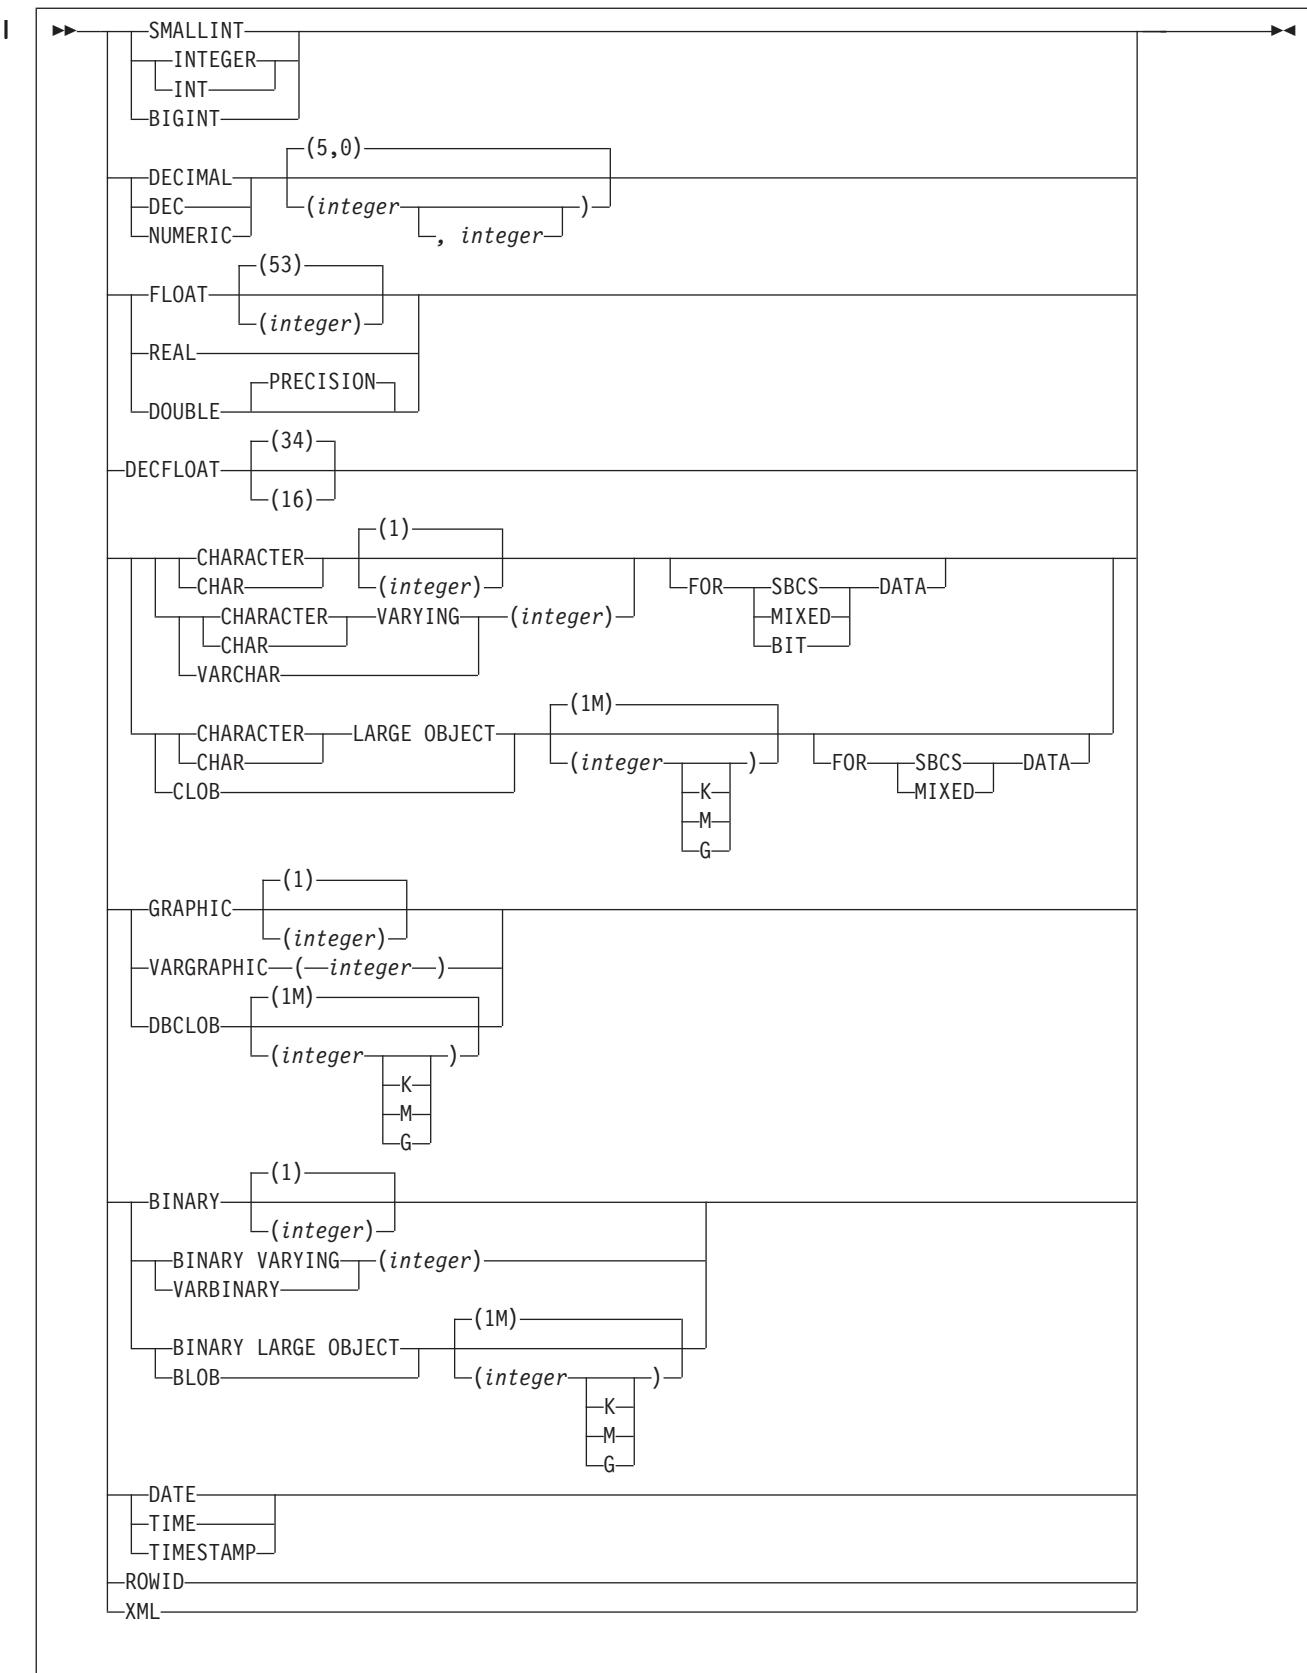

#### Notes:

- 1 Data type is optional if `as-row-change-timestamp-clause` is specified
- 2 The same clause must not be specified more than once.
- 3 This form of the `DEFAULT` value can only be used with columns that are defined as a distinct type.
- 4 A column that has a `ROWID` data type (or a distinct type that is based on a `ROWID` data type) defaults to `GENERATED ALWAYS`.
- 5 `AS SECURITY LABEL` can be specified only for a `CHAR(8)` data type and requires that the `NOT NULL` and `WITH DEFAULT` clauses be specified.
- 6 `IMPLICITLY HIDDEN` must not be specified for a column defined as a `ROWID`, or a distinct type that is based on a `ROWID`.

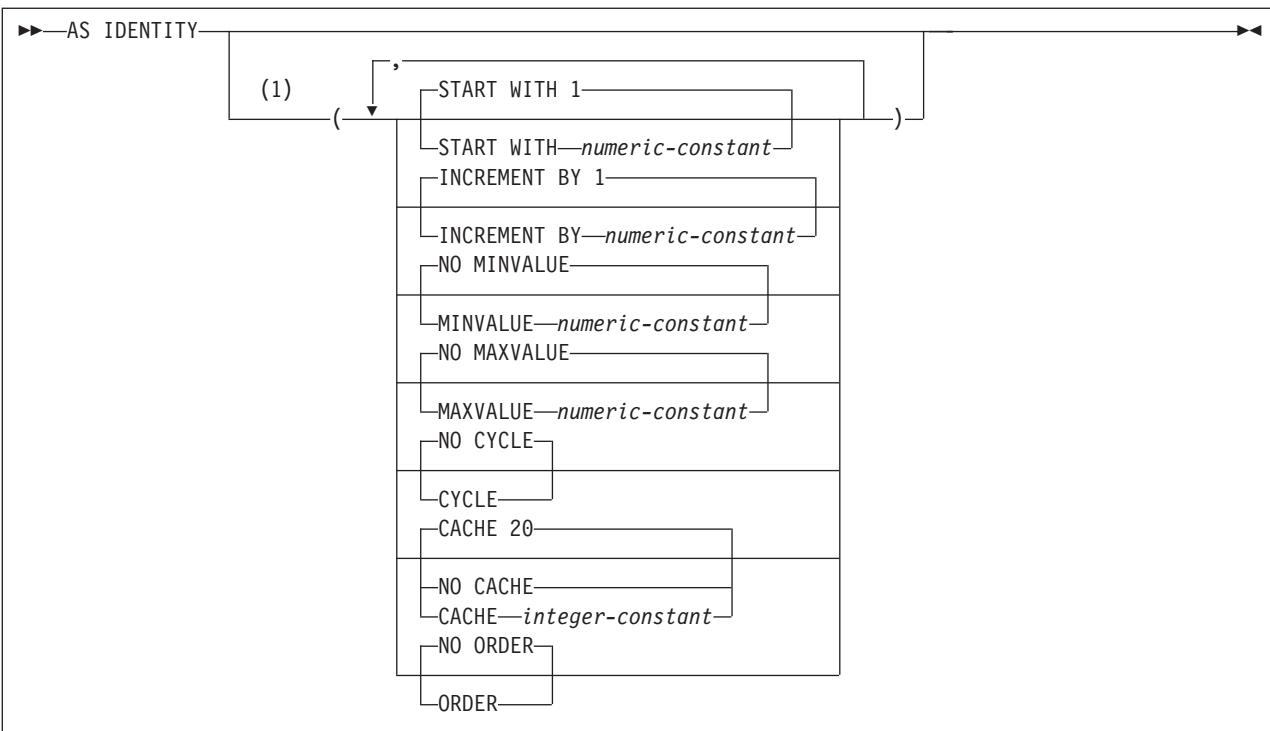

**data-type:**

**built-in-type:**

**as-identity-clause:**

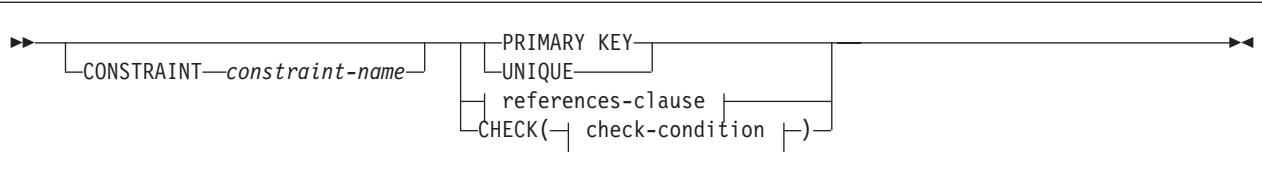

#### Notes:

- 1 Separator commas can be specified between attributes when an identity column is defined.

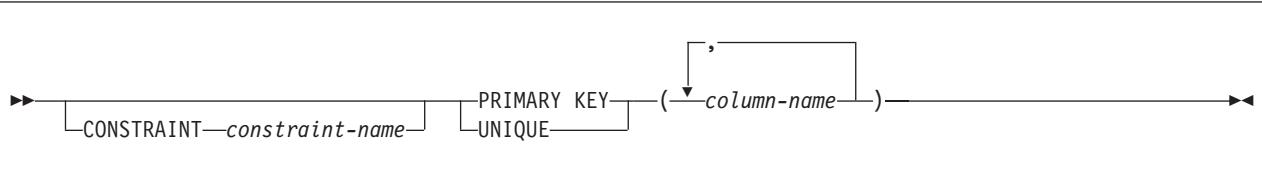

#### as-row-change-timestamp-clause:

```
>>> FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
```

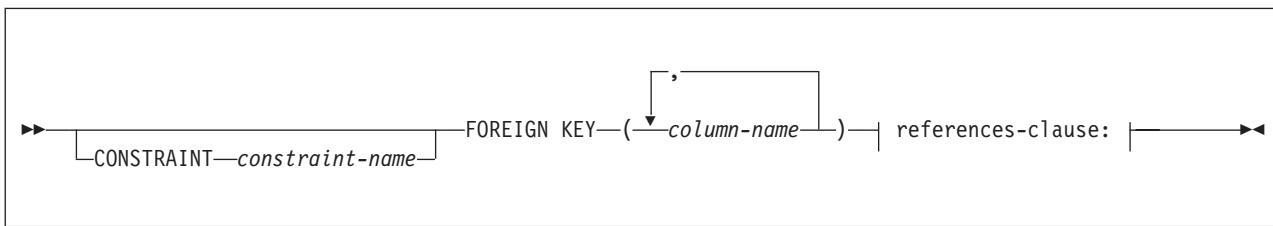

#### column-constraint:

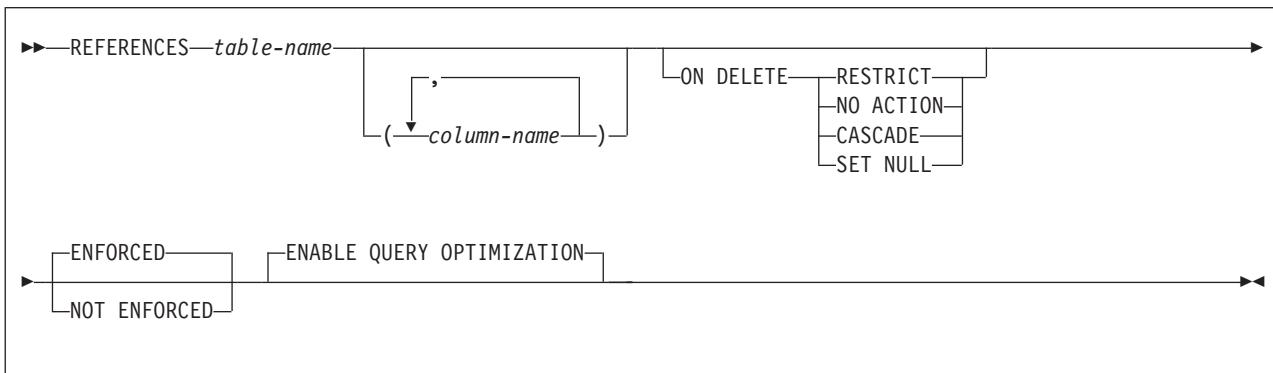

#### unique-constraint:

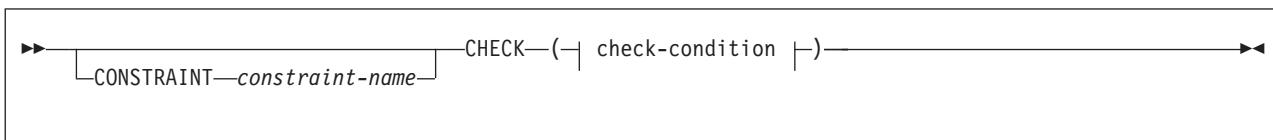

**referential-constraint:**

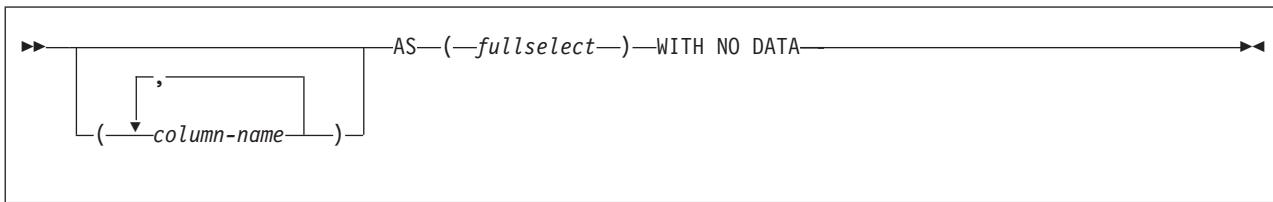

**references-clause:**

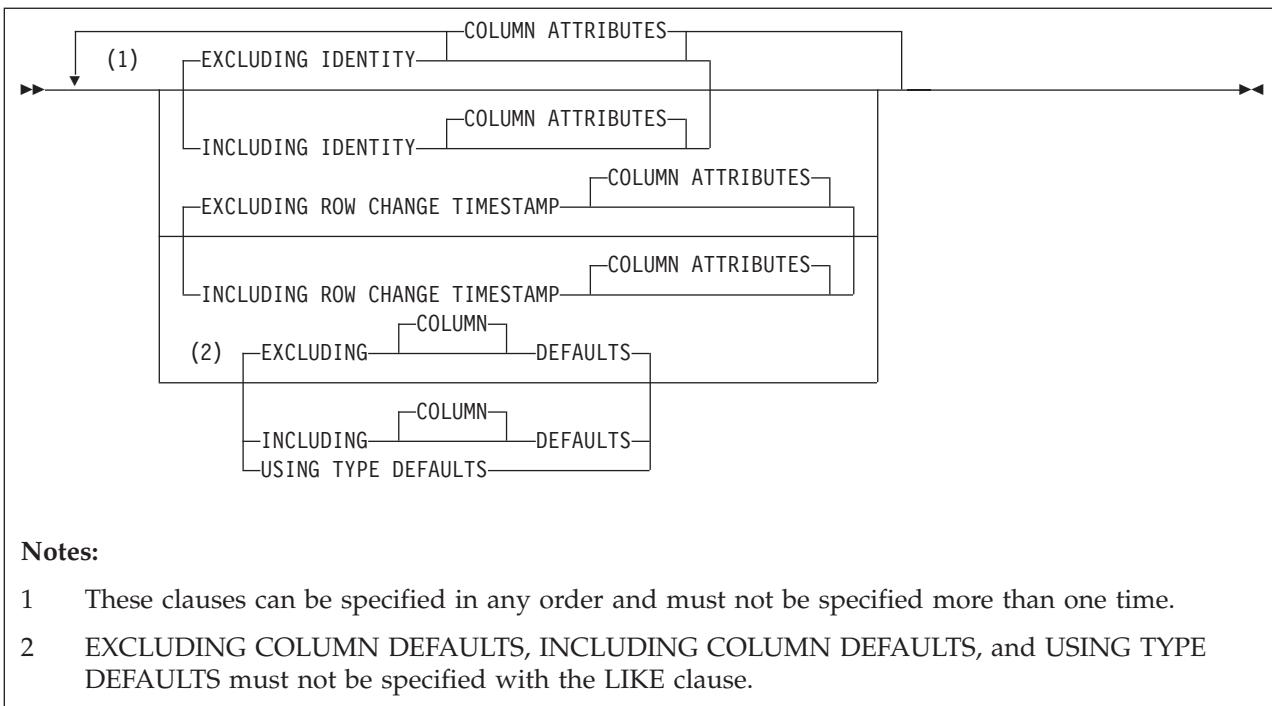

**check-constraint:**

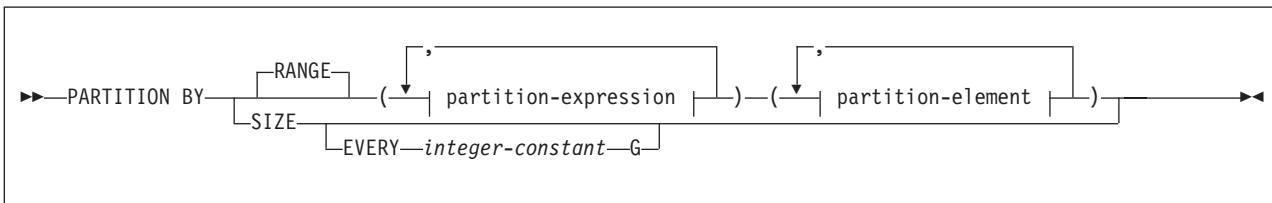

|  
| **as-result-table:**

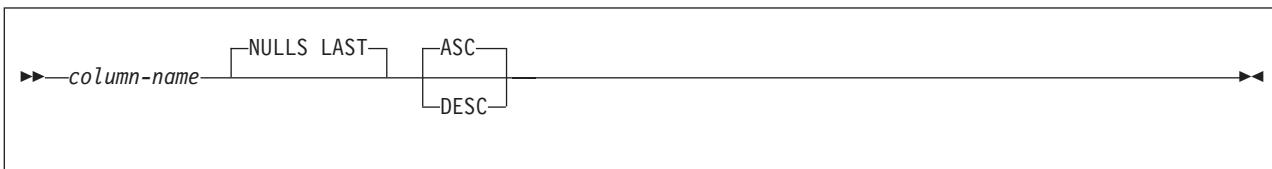

**copy-options:**

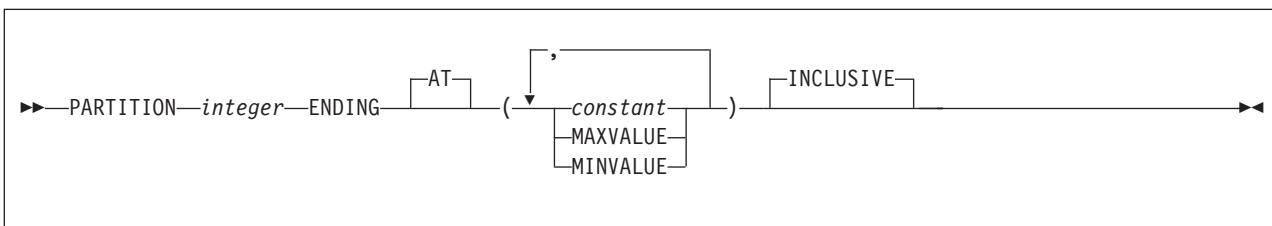

**partitioning-clause:**

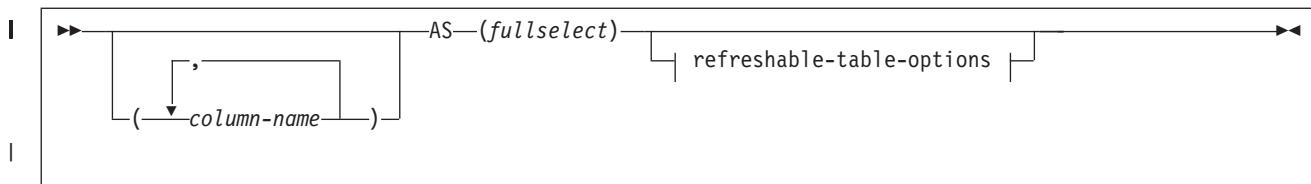

**partition-expression:**

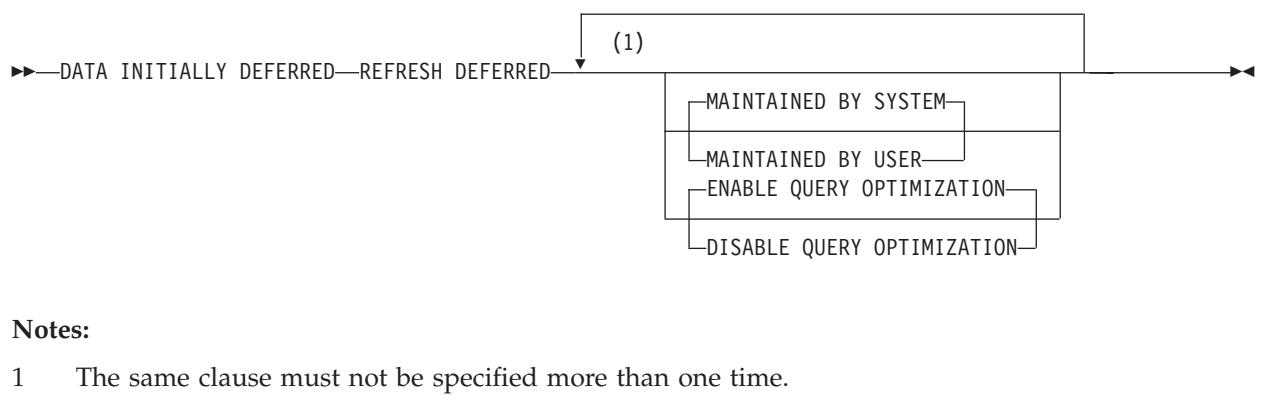

**partition-element:**

**materialized-query-definition**

**refreshable-table-options:**

#### Notes:

- 1 The same clause must not be specified more than one time.

## Description

### *table-name*

Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of field DB2 LOCATION NAME on installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

### *column-name*

Names a column of the table. For a dependent table, up to 749 columns can be named. For a table that is not a dependent, this number is 750. Do not qualify *column-name* and do not use the same name for more than one column of the table.

### *built-in-type*

Specifies the data type of the column as one of the following built-in data types, and for character string data types, specifies the subtype. For more information about defining a table with a LOB column (CLOB, BLOB, or DBCLOB), see Creating a table with LOB columns.

#### **SMALLINT**

For a small integer.

#### **INTEGER or INT**

For a large integer.

#### **BIGINT**

For a big integer.

#### **DECIMAL(*integer*, *integer*) or DEC(*integer*, *integer*)**

#### **DECIMAL(*integer*) or DEC(*integer*)**

**DECIMAL or DEC**

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(*p*) for DECIMAL(*p,0*) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

**DECFLOAT( *integer* )**

For a decimal floating-point number. The value of *integer* must be either 16 or 34 and represents the number of significant digits that can be stored. If *integer* is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

**FLOAT( *integer* )****FLOAT**

For a floating-point number. If *integer* is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

**REAL**

For single precision floating-point.

**DOUBLE or DOUBLE PRECISION**

For double precision floating-point

**CHARACTER( *integer* ) or CHAR( *integer* )****CHARACTER or CHAR**

For a fixed-length character string of length *integer*, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

**VARCHAR( *integer* ), CHAR VARYING( *integer* ), or CHARACTER VARYING( *integer* )**

For a varying-length character string of maximum length *integer*, which can range from 1 to the maximum record size minus 10 bytes. See Table 98 on page 1122 to determine the maximum record size.

**FOR *subtype* DATA**

Specifies a subtype for a character string column, which is a column with a data type of CHAR, VARCHAR, or CLOB. Do not use the FOR *subtype* DATA clause with columns of any other data type (including any distinct type). *subtype* can be one of the following:

**SBCS**

Column holds single-byte data.

**MIXED**

Column holds mixed data. Do not specify MIXED if the value of field MIXED DATA on installation panel DSNTIPF is NO unless the CCSID UNICODE clause is also specified, or the table is being created in a Unicode table space or database.

**BIT**

Column holds BIT data. Do not specify BIT for a CLOB column.

| Only character strings are valid when subtype is BIT.

If you do not specify the FOR clause, the column is defined with a default subtype. For ASCII or EBCDIC data:

- The default is SBCS when the value of field MIXED DATA on installation panel DSNTIPP is NO.
- The default is MIXED when the value is YES.

For Unicode data, the default subtype is MIXED.

A security label column is always considered SBCS data, regardless of the encoding scheme of the table.

**CLOB(*integer* [K|M|G]), CHAR LARGE OBJECT(*integer* [K|M|G]), or CHARACTER LARGE OBJECT(*integer* [K|M|G])**

**CLOB, CHAR LARGE OBJECT, or CHARACTER LARGE OBJECT**

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2 147 483 647.

A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see "Restrictions using LOBs" on page 86.

When *integer* is not specified, the default length is **1M**. The maximum value that can be specified for *integer* depends on whether a units indicator is also specified as shown in the following list.

*integer* **K** The maximum value for *integer* is 2 147 483 647. The maximum length of the string is *integer*.

*integer* **M** The maximum value for *integer* is 2 097 152. The maximum length is 1024 times *integer*.

*integer* **G** The maximum value for *integer* is 2048. The maximum length is 1 048 576 times *integer*.

If you specify a value that evaluates to 2 gigabytes (2 147 483 648), DB2 uses a value that is one byte less, or 2 147 483 647.

**GRAPHIC(*integer*)**

**GRAPHIC**

For a fixed-length graphic string of length *integer*, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

**VARGRAPHIC(*integer*)**

For a varying-length graphic string of maximum length *integer*, which must range from 1 to *n*/2, where *n* is the maximum row size minus 2 bytes.

**DBCLOB(*integer* [K|M|G])**

**DBCLOB**

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1 073 741 823. A DBCLOB column has a

varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 86.

When *integer* is not specified, the default length is **1M**. The meaning of *integer K|M|G* is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

#### **BINARY(*integer*)**

A fixed-length binary string of length *integer*. The *integer* can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

#### **BINARY VARYING(*integer*) or VARBINARY(*integer*)**

A varying-length binary string of maximum length *integer*, which can range from 1 through 32704. The length is limited by the page size of the table space.

#### **BLOB (*integer [K|M|G]*) or BINARY LARGE OBJECT(*integer [K|M|G]*)**

#### **BLOB or BINARY LARGE OBJECT**

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2 147 483 647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 86.

When *integer* is not specified, the default length is **1M**. The meaning of *integer K|M|G* is the same as for CLOB.

#### **DATE**

For a date.

#### **TIME**

For a time.

#### **TIMESTAMP**

For a timestamp.

#### **ROWID**

For a row ID type.

A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

#### **XML**

For an XML document. Only well-formed XML documents can be inserted into an XML column.

#### *distinct-type-name*

Specifies the data type of the column is a distinct type (a user-defined data type). The length, precision, and scale of the column are respectively the length, precision, and scale of the source type of the distinct type. The privilege set must implicitly or explicitly include the USAGE privilege on the distinct type.

The encoding scheme of the distinct type must be the same as the encoding scheme of the table. The subtype for the distinct type, if it has the attribute, is the subtype with which the distinct type was created.

If the column is to be used in the definition of the foreign key of a referential constraint, the data type of the corresponding column of the parent key must have the same distinct type.

**NOT NULL**

Prevents the column from containing null values. Omission of NOT NULL implies that the column can contain null values.

*column-constraint*

The *column-constraint* of a *column-definition* provides a shorthand method of defining a constraint composed of a single column. Thus, if a *column-constraint* is specified in the definition of column C, the effect is the same as if that constraint were specified as a *unique-constraint*, *referential-constraint*, or *check-constraint* in which C is the only identified column.

**CONSTRAINT constraint-name**

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If the name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**PRIMARY KEY**

Provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. PRIMARY KEY cannot be specified more than one time in a column definition, and must not be specified if the UNIQUE clause is specified in the definition or if the definition is for a LOB, ROWID, DECFLOAT (including a distinct type that is based on a LOB, ROWID, or DECFLOAT data type), XML column, or a row change timestamp column.

The table is marked as unavailable until its primary index is explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see *Implicitly created indexes*.)

**UNIQUE**

Provides a shorthand method of defining a unique key composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

The NOT NULL clause must be specified with this clause. UNIQUE cannot be specified more than one time in a column definition and must not be specified if the PRIMARY KEY clause is specified in the column definition or if the definition is for a LOB, ROWID, row change timestamp, XML, or DECFLOAT column (including a distinct type that is based on a LOB, ROWID, or DECFLOAT data type).

The table is marked as unavailable until all the required indexes are explicitly created unless the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created. In that case, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see *Implicitly created indexes*.)

### *references-clause*

The *references-clause* of a *column-definition* provides a shorthand method of defining a foreign key composed of a single column. Thus, if *references-clause* is specified in the definition of column C, the effect is the same as if the *references-clause* were specified as part of a FOREIGN KEY clause in which C is the only identified column.

|  
|  
| Do not specify *references-clause* in the definition of a LOB, ROWID, XML, DECFLOAT, security label, or row change timestamp column; a LOB, ROWID, XML, DECFLOAT, security label, or row change timestamp column cannot be a foreign key.

### **CHECK** (*check-condition*)

CHECK (*check-condition*) provides a shorthand method of defining a check constraint that applies to a single column. For conformance with the SQL standard, if CHECK is specified in the column definition of column C, no columns other than C should be referenced in the check condition of the check constraint. The effect is the same as if the check condition were specified as a separate clause.

### **DEFAULT**

Specifies the default value that is assigned to the column in the absence of a value specified on an insert or update operation or LOAD. DEFAULT must not be specified more than one time in the same *column-definition*. Do not specify DEFAULT for the following types of columns because DB2 generates default values:

- | • An identity column (a column that is defined AS IDENTITY)
- | • A ROWID column (or a distinct type that is based on a ROWID)
- | • A row change timestamp column
- | • An XML column

Do not specify a value after the DEFAULT keyword for a security label column. DB2 provides the default value for a security label column.

If a value is not specified after DEFAULT, the default value depends on the data type of the column, as follows:

#### **Data Type**

#### **Default Value**

##### **Numeric**

0

##### **Big integer**

0

##### **Fixed-length character string**

Blanks

##### **Fixed-length graphic string**

Blanks

##### **Fixed-length binary string**

Hexadecimal zeros

##### **Varying-length string**

A string of length 0

**Date** CURRENT DATE

**Time** CURRENT TIME

##### **Timestamp**

CURRENT TIMESTAMP

##### **Distinct type**

The default of the source data type

A default value other than the one that is listed above can be specified in one of the following forms, except for a LOB column. The only form that can be specified for a LOB column is DEFAULT NULL. Unlike other varying-length strings, a LOB column can have the default value of only a zero-length string or null. Specify:

- WITH DEFAULT for a default value of an empty string
- DEFAULT NULL for a default value of null

Omission of NOT NULL and DEFAULT from a *column-definition*, for a column other than an identity column, is an implicit specification of DEFAULT NULL. For an identity column, it is an implicit specification of NOT NULL, and DB2 generates default values.

*constant*

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column.

A character or graphic string constant must be short enough so that its UTF-8 representation requires no more than 1536. A hexadecimal graphic string constant (GX) cannot be specified.

**SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register at the time of an SQL data change statement or LOAD as the default value for the column. If SESSION\_USER is specified, the data type of the column must be a character string with a length attribute greater than or equal to 8 characters when the value is expressed in CCSID 37.

**CURRENT\_SQLID**

Specifies the value of the SQL authorization ID of the process at the time of an insert or update operation or LOAD as the default value for the column. If CURRENT\_SQLID is specified, the data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT\_SQLID special register.

**NULL**

Specifies null as the default value for the column. If NOT NULL is specified, DEFAULT NULL must not be specified with the same *column-definition*.

*cast-function-name*

The name of the cast function that matches the name of the distinct type for the column. A cast function can only be specified if the data type of the column is a distinct type.

The schema name of the cast function, whether it is explicitly specified or implicitly resolved through function resolution, must be the same as the explicitly or implicitly specified schema name of the distinct type.

*constant*

Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type.

**SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the SESSION\_USER special register.

**CURRENT\_SQLID**

Specifies the value of the CURRENT\_SQLID special register at the time a row is inserted as the default for the column. The source type of the distinct type of the column must be a CHAR or VARCHAR with a length attribute that is greater than or equal to the length attribute of the CURRENT\_SQLID special register.

**NULL**

Specifies the NULL value as the argument.

In a given column definition:

- DEFAULT and FIELDPROC cannot both be specified.
- NOT NULL and DEFAULT NULL cannot both be specified.

Table 96 summarizes the effect of specifying the various combinations of the NOT NULL and DEFAULT clauses on the CREATE TABLE statement *column-description* clause.

*Table 96. Effect of specifying combinations of the NOT NULL and DEFAULT clauses*

If NOT NULL is:	And DEFAULT is:	The effect is:
Specified <sup>1</sup>	Omitted	An error occurs if a value is not provided for the column on an insert or update operation or LOAD.
	Specified without an operand	The system defined nonnull default value is used.
	<i>constant</i>	The specified constant is used as the default value.
	SESSION_USER	The value of the SESSION_USER special register at the time of an insert or update operation or LOAD is used as the default value.
	CURRENT_SQLID	The SQL authorization ID of the process at the time of an insert or update operation or LOAD is used as the default value.
	NULL	An error occurs during the execution of CREATE TABLE.
Omitted	Omitted	Equivalent to an implicit specification of DEFAULT NULL.
	Specified without an operand	The system defined nonnull default value is used.
	<i>constant</i>	The specified constant is used as the default value.
	SESSION_USER	The value of the SESSION_USER special register at execution time is used as the default value.
	CURRENT_SQLID	The SQL authorization ID of the process is used as the default value.
	NULL	Null is used as the default value.

**Note:** The table does not apply to a column with a ROWID data type or to an identity column.

#### **GENERATED**

Specifies that DB2 generates values for the column. GENERATED must be specified if the column is to be considered one of the following types of columns:

- An identity column
- A row change timestamp column.
- A ROWID column

If the data type of the column is a ROWID (or a distinct type that is based on a ROWID), the default is GENERATED ALWAYS.

#### **ALWAYS**

Specifies that DB2 will always generate a value for the column when a row is inserted or updated and a default value must be generated. ALWAYS is the recommended value unless you are using data propagation.

#### **BY DEFAULT**

Specifies that DB2 will generate a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

For a ROWID column, DB2 uses a specified value only if it is a valid row ID value that was previously generated by DB2 and the column has a unique, single-column index. Until this index is created on the ROWID column, the SQL insert or update operation and the LOAD utility cannot be used to add rows to the table. If the table space is explicitly created and the value of the CURRENT RULES special register is 'STD' when the CREATE TABLE statement is processed, or if the table space is implicitly created, DB2 implicitly creates the index on the ROWID column. The name of this index is 'T' followed by the first ten characters of the column name followed by seven randomly generated characters. If the column name is less than ten characters, DB2 adds underscore characters to the end of the name until it has ten characters. The implicitly created index has the COPY NO attribute.

For an identity column, DB2 inserts a specified value but does not verify that it a unique value for the column unless the identity column has a unique, single-column index.

BY DEFAULT is the recommended value only when you are using data propagation.

#### **FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP**

Specifies that the column is a timestamp column for the table. DB2 generates a value for the column for each row as the row is inserted, and for any row in which any column is updated. The value that is generated for a row change timestamp column is a timestamp that corresponds to the insert or update time of the row. If multiple rows are inserted or updated with a single statement, the value for the row change timestamp column might be different for each row.

A table can only have one row change timestamp column.

If *data-type* is specified, it must be TIMESTAMP.

A row change timestamp column cannot have a DEFAULT clause. NOT NULL must be specified for a row change timestamp column.

#### **AS IDENTITY**

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the

|  
| data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero, or a distinct type based on one of these types).

| An identity column is implicitly NOT NULL. An identity column cannot have a WITH DEFAULT clause.

| Defining a column AS IDENTITY does not necessarily ensure the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the identity column.

#### **START WITH** *numeric-constant*

Specifies the first value that is generated for the identity column. The value can be any positive or negative value that could be assigned to the column without non-zero digits existing to the right of the decimal point.

If a value is not explicitly specified when the identity column is defined, the default is the MINVALUE for an ascending identity column and the MAXVALUE for a descending identity column. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

#### **INCREMENT BY** *numeric-constant*

Specifies the interval between consecutive values of the identity column. The value can be any positive or negative value (including 0) that does not exceed the value of a large integer constant, and could be assigned to the column without any non-zero digits existing to the right of the decimal point.

If this value is negative, the values for the identity column descend. If this value is 0 or positive, the values for the identity column ascend. The default is 1.

#### **MINVALUE or NO MINVALUE**

Specifies the minimum value at which a descending identity column either cycles or stops generating values or an ascending identity column cycles to after reaching the maximum value.

#### **NO MINVALUE**

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MINVALUE becomes one of the following:

- For an ascending identity column, the value is the START WITH value or 1 if START WITH is not specified.
- For a descending identity column, the value is the minimum value of the data type of the column.

The default is NO MINVALUE.

#### **MINVALUE** *numeric-constant*

Specifies the numeric constant that is the minimum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be less than or equal to the maximum value.

**MAXVALUE or NO MAXVALUE**

Specifies the maximum value at which an ascending identity column either cycles or stops generating values or a descending identity column cycles to after reaching the minimum value.

**NO MAXVALUE**

Specifies that the minimum end point of the range of values for the identity column has not be set. In such a case, the default value for MAXVALUE becomes one of the following:

- For an ascending identity column, the value is the maximum value of the data type associated with the column.
- For a descending identity column, the value is the START WITH value -1 if START WITH is not specified.

The default is NO MAXVALUE.

**MAXVALUE *numeric-constant***

Specifies the numeric constant that is the maximum value that is generated for this identity column. This value can be any positive or negative value that could be assigned to this column without non-zero digits existing to the right of the decimal point. The value must be greater than or equal to the minimum value.

**CYCLE or NO CYCLE**

Specifies whether this identity column should continue to generate values after reaching either its maximum or minimum value. The default is NO CYCLE.

**NO CYCLE**

Specifies that values will not be generated for the identity column after the maximum or minimum value has been reached.

**CYCLE**

Specifies that values continue to be generated for the identity column after the maximum or minimum value has been reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value. After a descending identity column reaches its minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated by DB2 for an identity column. However, if a unique index exists on the identity column and a non-unique value is generated for it, an error occurs.

**CACHE *integer-constant* or NO CACHE**

Specifies whether to keep some preallocated values in memory. Preallocating and storing values in the cache improves the performance of inserting rows into a table. The default is **CACHE 20**.

**NO CACHE**

Specifies that values for the identity column and sequences are not preallocated and stored in the cache, ensuring that values will not be lost in the case of a system failure. In this case, every request for a new value for the identity column or sequence results in synchronous I/O.

In a data sharing environment, use **NO CACHE** if you need to guarantee that the identity column and sequence values are generated in the order in which they are requested.

**CACHE** *integer-constant*

Specifies the maximum number of values of the identity column sequence that DB2 can preallocate and keep in memory.

During a DB2 shutdown, all cached identity column values and sequence values that are yet to be assigned will be lost and will not be used. Therefore, the value that is specified for **CACHE** also represents the maximum number of identity column values and sequence values that will be lost during a DB2 shutdown.

The minimum value is 2.

In a data sharing environment, you can use the **CACHE** and **NO ORDER** options to allow multiple DB2 members to cache sequence values simultaneously.

**ORDER or NO ORDER**

Specifies whether the identity column values must be generated in order of request. The default is **NO ORDER**.

**NO ORDER**

Specifies that the values do not need to be generated in order of request.

**ORDER**

Specifies that the values are generated in order of request. Specifying **ORDER** might disable the caching of values. **ORDER** applies only to a single-application process.

In a data sharing environment, if the **CACHE** and **NO ORDER** options are in effect, multiple caches can be active simultaneously, and the requests for identity values from different DB2 members might not result in the assignment of values in strict numeric order. For example, if members DB2A and DB2B are using the identity column, and DB2A gets the cache values 1 to 20 and DB2B gets the cache values 21 to 40, the actual order of values assigned would be 1,21,2 if DB2A requested a value first, then DB2B requested, and then DB2A again requested. Therefore, to guarantee that identity values are generated in strict numeric order among multiple DB2 members using the same identity column, specify the **ORDER** option.

**FIELDPROC** *program-name*

Designates *program-name* as the field procedure exit routine for the column. Writing a field procedure exit routine is described in *DB2 Administration Guide*. A field procedure can be specified only for a column with a length attribute that is not greater than 255 bytes. FIELDPROC can only be specified for columns that are a built-in character string or graphic string data type that is not a LOB. The column must not be one of the following:

- a security label column
- a row change timestamp column

For more information about string comparisons with field procedures, see “Character and graphic string comparisons” on page 116.

The field procedure encodes and decodes column values: before a value is inserted in the column, it is passed to the field procedure for encoding. Before

a value from the column is used by a program, it is passed to the field procedure for decoding. A field procedure could be used, for example, to alter the sorting sequence of values entered in the column.

The field procedure is also invoked during the processing of the CREATE TABLE statement. When so invoked, the procedure provides DB2 with the column's *field description*. The field description defines the data characteristics of the encoded values. By contrast, the information you supply for the column in the CREATE TABLE statement defines the data characteristics of the decoded values.

#### *constant*

Is a parameter that is passed to the field procedure when it is invoked. A parameter list is optional. The *n*th parameter specified in the FIELDPROC clause on CREATE TABLE corresponds to the *n*th parameter of the specified field procedure. The maximum length of the parameter list is 254 bytes, including commas but excluding insignificant blanks and the delimiting parentheses.

If you omit FIELDPROC, the column has no field procedure.

#### **AS SECURITY LABEL**

Specifies that the column will contain security label values. This also indicates that the table is defined with multilevel security with row level granularity. A table can have only one security label column. To define a table with a security label column, the primary authorization ID of the statement must have a valid security label, and the RACF SECLABEL class must be active. In addition, the following conditions are also required:

- The data type of the column must be CHAR(8).
- The subtype of the column must be SBCS.
- The column must be defined with the NOT NULL and WITH DEFAULT clauses.
- The WITH DEFAULT clause must not specify a default value (DB2 determines the default value)
- No field procedures, check constraints, or referential constraints are defined on the column.
- No edit procedure for the table can be defined with row attribute sensitivity.

For information about using multilevel security, see *DB2 Administration Guide*.

#### **IMPLICITLY HIDDEN**

Specifies that the column is not visible in the result for SQL statements unless you explicitly refer to the column by name. For example, assuming that the table T1 includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT \* would not include the implicitly hidden column. However, the result of a SELECT statement that explicitly refers to the name of the implicitly hidden column would include that column in the result table.

IMPLICITLY HIDDEN must not be specified for a column that is defined as a ROWID, or a distinct type that is based on a ROWID. IMPLICITLY HIDDEN must not be specified for all columns of a table.

#### **CONSTRAINT *constraint-name***

Names the constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**PRIMARY KEY(*column-name*,...)**

Defines a primary key composed of the identified columns. The clause must not be specified more than once and the identified columns must be defined as NOT NULL. Each *column-name* must be an unqualified name that identifies a column of the table except a LOB, a ROWID, a DECFLOAT (including a distinct type that is based on a LOB, ROWID, or DECFLOAT), an XML column, or a row change timestamp column and the same column must not be identified more than once. The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than  $2000 - 2m$ , where  $m$  is the number of varying-length columns in the key.

The table is marked as unavailable until its primary index is explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In that case, DB2 implicitly creates an index to enforce the uniqueness of the primary key and the table definition is considered complete. (For more information about implicitly created indexes, see *Implicitly created indexes*.)

**UNIQUE(*column-name*,...)**

Defines a unique key composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table except a LOB, a ROWID, a DECFLOAT column (including a distinct type that is based on a LOB, ROWID, or DECFLOAT), or a row change timestamp column and the same column must not be identified more than once. Each identified column must be defined as NOT NULL. The number of identified columns must not exceed 64. In addition, the sum of the length attributes of the columns must not be greater than  $2000 - 2m$ , where  $m$  is the number of varying-length columns in the key.

A unique key is a duplicate if it is the same as the primary key or a previously defined unique key. The specification of a duplicate unique key is ignored with a warning.

The table is marked as unavailable until all the required indexes are explicitly created unless the table space is explicitly created and the CREATE TABLE statement is processed by the schema processor, or the table space is implicitly created. In these cases, DB2 implicitly creates the indexes that are required for the unique keys and the table definition is considered complete. (For more information about implicitly created indexes, see *Implicitly created indexes*.)

**CONSTRAINT *constraint-name***

Names the referential constraint. If a constraint name is not specified, a unique constraint name is generated. If a name is specified, it must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

**FOREIGN KEY (*column-name*,...) REFERENCES-CLAUSE**

Each specification of the FOREIGN KEY clause defines a referential constraint.

The foreign key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of the table except a LOB, ROWID, XML, DECFLOAT, security label, or row change timestamp column, and the same column must not be identified more than one time. The number of identified columns must not exceed 64, and the sum of their length attributes must not exceed 255 minus the number of columns that allow null values. The referential constraint is a duplicate if the FOREIGN KEY and parent table are the same as the FOREIGN KEY and

parent table of a previously defined referential constraint. The specification of a duplicate referential constraint is ignored with a warning.

#### **REFERENCES** *table-name* (*column-name*,...)

The table name specified after REFERENCES must identify a table that exists at the current server<sup>31</sup>, but it must not identify a catalog table or a declared global temporary table. In the following discussion, let T2 denote an identified table and let T1 denote the table that you are creating (T1 and T2 cannot be the same table<sup>31</sup>).

T2 must have a unique index and the privilege set must include the ALTER or REFERENCES privilege on the parent table, or the REFERENCES privilege on the columns of the nominated parent key.

The parent key of the referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The identified column cannot be a LOB, ROWID, XML, DECFLOAT, security label, or a row change timestamp column. The same column must not be identified more than one time.

The list of column names in the parent key must be identical to the list of column names in a primary key or unique key in the parent table T2. The column names must be specified in the *same order* as in the primary key or unique key. If any of the referenced columns in T2 has a non-numeric data type, T2 and T1 must use the same encoding scheme.

If a list of column names is not specified, T2 must have a primary key. Omission of a list of column names is an implicit specification of the columns of the primary key for T2.

The specified foreign key must have the same number of columns as the parent key of T2 and, except for their names, default values, null attributes and check constraints, the description of the *n*th column of the foreign key must be identical to the description of the *n*th column of the nominated parent key. If the foreign key includes a column defined as a distinct type, the corresponding column of the nominated parent key must be the same distinct type. If a column of the foreign key has a field procedure, the corresponding column of the nominated parent key must have the same field procedure and an identical field description. A field description is a description of the encoded value as it is stored in the database for a column that has been defined to have an associated field procedure.

The referential constraint specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent. A description of the referential constraint is recorded in the catalog.

#### **ON DELETE**

The delete rule of the relationship is determined by the ON DELETE clause. For more on the concepts used here, see “Referential constraints” on page 20.

SET NULL must not be specified unless some column of the foreign key allows null values. The default value for the rule depends on the value of the CURRENT RULES special register when the CREATE TABLE statement is processed. If the value of the register is 'DB2', the delete rule defaults to RESTRICT; if the value is 'STD', the delete rule defaults to NO ACTION.

---

31. This restriction is relaxed when the statement is processed by the schema processor and the other table is created within the same CREATE SCHEMA.

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let  $p$  denote such a row of T2. Then:

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of  $p$  in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of  $p$  in T1 is set to null.

Let T3 denote a table identified in another FOREIGN KEY clause (if any) of the CREATE TABLE statement. The delete rules of the relationships involving T2 and T3 must be the same and must not be SET NULL if:

- T2 and T3 are the same table.
- T2 is a descendent of T3 and the deletion of rows from T3 cascades to T2.
- T2 and T3 are both descendants of the same table and the deletion of rows from that table cascades to both T2 and T3.

#### **ENFORCED or NOT ENFORCED**

Indicates whether or not the referential constraint is enforced by DB2 during normal operations, such as insert, update, or delete.

##### **ENFORCED**

Specifies that the referential constraint is enforced by the DB2 during normal operations (such as insert, update, or delete) and that it is guaranteed to be correct. This is the default.

##### **NOT ENFORCED**

Specifies that the referential constraint is not enforced by DB2 during normal operations, such as insert, update, or delete. This option should only be used when the data that is stored in the table is verified to conform to the constraint by some other method than relying on the database manager.

#### **ENABLE QUERY OPTIMIZATION**

Specifies that the constraint can be used for query optimization. DB2 uses the information in query optimization using materialized query tables with the assumption that the constraint is correct. This is the default.

#### **check-constraint**

##### **CONSTRAINT *constraint-name***

Names the check constraint. The constraint name must be different from the names of any referential, check, primary key, or unique key constraints previously specified on the table.

If *constraint-name* is not specified, a unique constraint name is derived from the name of the first column in the *check-condition* specified in the definition of the check constraint.

##### **CHECK (*check-condition*)**

Defines a check constraint. At any time, the *check-condition* must be true or unknown for every row of the table. A *check-condition* can evaluate to unknown if a column that is an operand of the predicate is null. A *check-condition* that evaluates to unknown does not violate the check constraint. A *check-condition* is a search condition, with the following restrictions:

- It can refer only to columns of table *table-name*; however, the columns cannot be LOB, ROWID, XML, DECFLOAT, or security label columns (including distinct types that are based on LOB, ROWID, and DECFLOAT data types).

- It can be up to 3800 bytes long, not including redundant blanks.
- It must not contain any of the following:
  - Subselects
  - Built-in or user-defined functions
  - CAST specifications
  - Cast functions other than those created when the distinct type was created
  - Host variables
  - Parameter markers
  - Special registers
  - Columns that include a field procedure
  - CASE expressions
  - ROW CHANGE expressions
  - Row expressions
  - DISTINCT predicates
  - GX constants (hexadecimal graphic string constants)
  - sequence references
  - OLAP specifications
- If a *check-condition* refers to a LOB column (including a distinct type that is based on a LOB), the reference must occur within a LIKE predicate.
- The AND and OR logical operators can be used between predicates. The NOT logical operator cannot be used.
- The first operand of every predicate must be the column name of a column in the table.
- The second operand in the *check-condition* must be either a constant or a column name of a column in the table.
  - If the second operand of a predicate is a constant, and if the constant is:
    - A floating-point number, then the column data type must be floating point.
    - A decimal number, then the column data type must be either floating point or decimal.
    - An integer number, then the column data type must not be a small integer.
    - A small integer number, then the column data type must be small integer.
    - A decimal constant, then its precision must not be larger than the precision of the column.
  - If the second operand of a predicate is a column, then both columns of the predicate must have:
    - The same data type.
    - Identical descriptions with the exception that the specification of the NOT NULL and DEFAULT clauses for the columns can be different, and that string columns with the same data type can have different length attributes.

**LIKE *table-name* or *view-name***

Specifies that the columns of the table have exactly the same name and description as the columns of the identified table or view. The name specified after LIKE must identify a table or view that exists at the current server or a

declared temporary table. The privilege set must implicitly or explicitly include the SELECT privilege on the identified table or view. If the identified table or view contains a column with a distinct type, the USAGE privilege on the distinct type is also needed. An identified table must not be an auxiliary table or a clone table. An identified view must not include a column that is an explicitly defined ROWID column (including a distinct type that is based on a ROWID), an identity column, or a row change timestamp column. (For more information, see “Notes” on page 1071.)

The LIKE clause must not be specified in a Common Criteria environment.

The use of LIKE is an implicit definition of  $n$  columns, where  $n$  is the number of columns in the identified table (including implicitly hidden columns) or view. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition includes all attributes of the  $n$  columns as they are described in SYSCOLUMNS with the following exceptions:

- When a table is identified in the LIKE clause and a column in the table has a field procedure, the corresponding column of the new table has the same field procedure and the field description. However, the field procedure is not invoked during the execution of the CREATE TABLE statement. When a view is identified in the LIKE clause, none of the columns of the new table will have a field procedure. This is true even in the case that a column of a base table underlying the view has a field procedure defined.
- When a table is identified in the LIKE clause and a column in the table is an identity column, the corresponding column of the new table inherits only the data type of the identity column; none of the identity attributes of the column are inherited unless the INCLUDING IDENTITY clause is specified.
- When a table is identified in the LIKE clause and a column in the table is a security label column, the corresponding column of the new table inherits only the data type of the security label column; none of the security label attributes of the column are inherited.
- When a table is identified in the LIKE clause and the table contains a ROWID column (explicitly-defined or implicitly hidden), the corresponding columns of the new table inherits the ROWID columns.
- When a table is identified in the LIKE clause and the table contains a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.
- When a view is identified in the LIKE clause, the default value that is associated with the corresponding column of the new table depends on the column of the underlying base table for the view. If the column of the base table does not have a default, the new column does not have a default. If the column of the base table has a default, the default of the new column is:
  - Null if the column of the underlying base table allows nulls.
  - The default for the data type of the underlying base table if the underlying base table does not allow nulls.

The above defaults are chosen regardless of the current default of the base table column. The existence of an INSTEAD OF trigger does not affect the inheritance of default values.

- When a table that uses table-controlled partitioning is identified in the LIKE clause, the new table does not inherit partitioning scheme of that table. If desired, these partition boundaries can be added by specifying ALTER TABLE with the ADD PARTITION BY RANGE clause.

- The CCSID of the column is determined by the implicit or explicit CCSID clause. For more information, see the CCSID clause.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

#### **AS (*fullselect*)**

Specifies that the table definition is based on the column definitions from the result of a query expression. The use of AS (*fullselect*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The AS (*fullselect*) clause must not be specified in a Common Criteria environment.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each column must not be 0. Other column attributes, such as DEFAULT and IDENTITY, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be mapped to a column of a base table or a view. The new table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the statement has a valid security label. If more than one table in the *fullselect* contains a security label column, an error occurs.

The implicit definition does not include any other attributes of the identified table or view. For example, the new table does not have a primary key or foreign key. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the tables of the fullselect reside

The rules for establishing the qualifiers for names used in the fullselect are the same as the rules used to establish the qualifiers for *table-name*.

The fullselect must not:

- Result in a column having a ROWID, BLOB, CLOB, DBCLOB, or XML data type or a distinct type based on these data types.
- Include multiple security label columns.
- Include a PREVIOUS VALUE or a NEXT VALUE expression.

- Refer to host variables or include parameter markers.
- Include an SQL data change statement in the FROM clause.
- Reference data that is encoded with different CCSID sets.
- Reference a remote object.

If the WITH NO DATA clause is not specified, the new table is considered a materialized query table.

#### **WITH NO DATA**

Specifies that the query is used only to define the attributes of the new table. The table is not populated using the results of the query and the REFRESH TABLE statement cannot be used.

#### *copy-options*

Specifies whether identity column attributes, row change timestamp attributes, and column defaults are inherited from the definition of the source of the result table.

#### **EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited from the definition of the source of the result table.

##### **EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that identity column attributes are not inherited from the definition of the source of the result table. This is the default.

##### **INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that, if available, identity column attributes (such as START WITH, INCREMENT BY, and CACHE values) are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table, view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table with the identity attribute. In other cases, the columns of the new temporary table do not inherit the identity attributes. The columns of the new table do not inherit the identity attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

#### **EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES or INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies whether row change timestamp column attributes are inherited from the definition of the source of the result table.

##### **EXCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies that row change timestamp column attributes are not inherited from the source result table definition. This is the default.

##### **INCLUDING ROW CHANGE TIMESTAMP COLUMN ATTRIBUTES**

Specifies that, if available, row change timestamp column attributes are inherited from the definition of the source table. These attributes can be inherited if the element of the corresponding column in the table,

view, or *fullselect* is the name of a column of a table or the name of a column of a view that directly or indirectly maps to the column name of a base table defined as a row change timestamp column. In other cases, the columns of the new temporary table do not inherit the row change timestamp column attributes. The columns of the new table do not inherit the row change timestamp attributes in the following cases:

- The select list of the *fullselect* includes multiple instances of a row change timestamp column name (that is, selecting the same column more than one time).
- The select list of the *fullselect* includes multiple row change timestamp column names (that is, it involves a join).
- The row change timestamp column is included in an expression in the select list.
- The *fullselect* includes a set operation (such as union).

#### **EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS**

Specifies whether column defaults are inherited from the source result table definition. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

##### **EXCLUDING COLUMN DEFAULTS**

Specifies that the column defaults are not inherited from the definition of the source table. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert or update operation, or LOAD for the new table.

##### **INCLUDING COLUMN DEFAULTS**

Specifies that column defaults for each updatable column of the definition of the source table are inherited. Columns that are not updatable do not have a default defined in the corresponding column of the created table. The existence of an INSTEAD OF trigger for a view does not affect the inheritance of default values.

##### **USING TYPE DEFAULTS**

Specifies that the default values for the table depend on data type of the columns that result from *fullselect*, as follows:

###### **Data type**

###### **Default value**

###### **Numeric**

0

###### **Fixed-length character string**

Blanks

###### **Fixed-length graphic string**

Blanks

###### **Fixed-length binary string**

Hexadecimal zeros

###### **Varying-length string**

A string of length 0

###### **Fixed-length char or fixed-length graphic**

A string of blanks

###### **Fixed-length binary**

Hexadecimal zeros

**Date** CURRENT DATE  
**Time** CURRENT TIME  
**Timestamp**  
CURRENT TIMESTAMP

**WITH RESTRICT ON DROP**

Indicates that the table can be dropped only by using REPAIR DBD DROP. In addition, the database and table space that contain the table can be dropped only by using REPAIR DBD DROP.

**IN *database-name.table-space-name* or IN DATABASE *database-name***

Identifies the database and table space in which the table is created. Both forms are optional.

If you specify both a database and a table space, the database must be described in the current server's catalog, and must not be DSNDB06 or a work file database. The table space must belong to the database that you specify and must not be an XML table space.

If you specify a database but not a table space, a table space is implicitly created in *database-name*. The name of the table space is derived from the name of the table. The qualifier of the table space is the same as the qualifier of the table. The buffer pool that is used is the default buffer pool for user data that is specified on installation panel DSNTIP1. If you specify a table space but not a database, the database that contains the table space is used.

If you specify neither a table space or a database, a database is implicitly created with the name DSNxxxx, where xxxx is a five digit number. A table space is also implicitly created.

If you specify a table space, it must not be one that was created implicitly, be a partitioned or a partition-by-growth table space that already contains a table, or be a LOB table space. If you specify a partitioned table space, you cannot load or use the table until its partitioned scheme is created.

You cannot specify the name of an implicitly created database. That is, you specify a database name that is eight characters, DSNxxxx, where xxxx is a five digit number.

To create a table space implicitly, the privilege set must have: SYSADM or SYSCTRL authority; DBADM, DBCTRL, or DBMAINT authority for the database; or the CREATETS privilege for the database. You must also have the USE privilege for the database's default buffer pool and default storage group.

If you specify a table space name, you must have SYSADM or SYSCTRL authority, DBADM authority for the database, or the USE privilege for the table space.

**PARTITION BY RANGE or PARTITION BY SIZE**

Specifies the partitioning scheme for the table.

**PARTITION BY RANGE**

Specifies the range partitioning scheme for the table (the columns that are used to partition the data). When this clause is specified, the table space is complete, and it is not necessary to create a partitioned index on the table. If this clause is used, the ENDING AT clause cannot be used on a subsequent CREATE INDEX statement for this table.

If this clause is specified, the IN *database-name.table-space-name* clause is required. This clause applies only to tables in a partitioned table space. PARTITION BY RANGE must not be specified for a table that is created in a partition-by-growth table space.

*partition-expression*

Specifies the key data over which the range is defined to determine the target data partition of the data.

*column-name*

Specifies the columns of the key. Each *column-name* must identify a column of the table. Do not specify more than 64 columns or the same column more than one time. The sum of length attributes of the columns must not be greater than  $255 - n$ , where  $n$  is the number of columns that can contain null values. Do not specify a qualified column name. Do not specify a column for *column-name* if the column is defined as follows:

- a LOB column (or a column with a distinct type that is based on a LOB data type)
- a BINARY column (or a column with a distinct type that is based on a BINARY data type)
- a VARBINARY column (or a column with a distinct type that is based on a VARBINARY data type)
- a DECFLOAT column (or a column with a distinct type that is based on a DECFLOAT data type)
- an XML column
- a row change timestamp column

**NULLS LAST**

Specifies that null values are treated as positive infinity for purposes of comparison.

**ASC**

Puts the entries in ascending order by the column. ASC is the default.

**DESC**

Puts the entries in descending order by the column.

*partition-element*

Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

**PARTITION** *integer*

*integer* is the physical number of a partition in the table space. A PARTITION clause must be specified for every partition of the table space. In this context, highest means highest in the sorting sequences of the columns. In a column defined as ascending (ASC), highest and lowest have their usual meanings. In a column defined as descending (DESC), the lowest actual value is highest in the sorting sequence.

**ENDING AT** (*constant*, MAXVALUE, or MINVALUE, ...)

Defines the limit key for a partition boundary. Specify at least one value (*constant*, MAXVALUE, or MINVALUE) after ENDING AT in each PARTITION clause. You can use as many values as there are columns in the key. The concatenation of all values is the highest value of the key for ascending and the lowest for descending.

*constant*

Specifies a constant value with a data type that must conform to the rules for assigning that value to the column. If a string constant is longer or shorter than required by the length

attribute of its column, the constant is either truncated or padded on the right to the required length. If the column is ascending, the padding character is X'FF'. If the column is descending, the padding character is X'00'. The precision and scale of a decimal constant must not be greater than the precision and scale of its corresponding column. A hexadecimal string constant (GX) cannot be specified.

#### **MAXVALUE**

Specifies a value greater than the maximum value for the limit key of a partition boundary (that is, all X'FF' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are ascending, a constant or the MINVALUE clause cannot be specified following MAXVALUE. After MAXVALUE is specified, all subsequent columns must be MAXVALUE.

#### **MINVALUE**

Specifies a value that is smaller than the minimum value for the limit key of a partition boundary (that is, all X'00' regardless of whether the column is ascending or descending). If all of the columns in the partitioning key are descending, a constant or the MAXVALUE clause cannot be specified following MINVALUE. After MINVALUE is specified, all subsequent columns must be MINVALUE.

The key values are subject to the following rules:

- The first value corresponds to the first column of the key, the second value to the second column, and so on. Using fewer values than there are columns in the key has the same effect as using the highest or lowest values for the omitted columns, depending on whether they are ascending or descending.
- The highest value of the key in any partition must be lower than the highest value of the key in the next partition for ascending cases.
- The values specified for the last partition are enforced. The value specified for the last partition is the highest value of the key that can be placed in the table. Any key values greater than the value specified for the last partition are out of range.
- The combination of the number of table space partitions and the corresponding limit key size cannot exceed the number of partitions \* (106 + limit key size in bytes) <65394.
- If the concatenation of all the values exceeds 255 bytes, only the first 255 bytes are considered.
- If a key includes a ROWID column or a column with a distinct type that is based on a ROWID data type, 17 bytes of the constant that is specified for the corresponding ROWID column are considered.
- If a null value is specified for the partitioning key and the key is ascending, an error is returned unless MAXVALUE is specified. If the key is descending, an error is returned unless MINVALUE is specified..

#### **INCLUSIVE**

Specifies that the specified range values are included in the data partition.

**PARTITION BY SIZE**

Specifies that the table is created in a partition-by-growth table space. If the IN clause is also specified, the IN clause must identify a partition-by-growth table space.

**EVERY *integer G***

Specifies that the table is to be partitioned by growth, every *integer G* bytes. *integer* must not be greater than 64. If the IN clause identifies a table space, *integer* must be the same as the DSSIZE value that is in effect for the table space that will contain the table.

**EDITPROC *program-name***

Identifies the user-written code that implements the edit procedure for the table. The edit procedure must exist at the current server. The procedure is invoked during the execution of an SQL data change statement or LOAD and all row retrieval operations on the table.

An edit routine receives an entire table row, and can transform that row in any way. Also, it receives a transformed row and must change the row back to its original form.

You must not specify an edit routine for a table with a LOB column. For information on writing an EDITPROC exit routine, see Edit procedures.

**WITH ROW ATTRIBUTES**

Specifies that the edit procedure parameter list contains an address for the description of a row. WITH ROW ATTRIBUTES must not be specified for a table with an identity, LOB, XML, ROWID, or SECURITY LABEL column.

WITH ROW ATTRIBUTES is the default. When WITH ROW ATTRIBUTES is specified, the column names in the table must not be longer than 18 EBCDIC SBCS characters in length.

**WITHOUT ROW ATTRIBUTES**

Specifies that the description of the row is not provided to the edit procedure. On entry to the edit procedure, the address for the row description in the parameter list contains a value of zero.

**VALIDPROC *program-name***

Designates *program-name* as the validation exit routine for the table. Writing a validation exit routine is described in *DB2 Administration Guide*.

The validation routine can inhibit a load, insert, update, or delete operation on any row of the table: before the operation takes place, the procedure is passed the row. The values that are represented by any LOB or XML columns in the table are not passed to the validation routine. On an insert or update operation, if the table has a security label column and the user does not have write-down privilege, the user's security label value is passed to the validation routine as the value of the column. After examining the row, the procedure returns a value that indicates whether the operation should proceed. A typical use is to impose restrictions on the values that can appear in various columns.

A table can have only one validation procedure at a time. In an ALTER TABLE statement, you can designate a replacement procedure or discontinue the use of a validation procedure.

If you omit VALIDPROC, the table has no validation routine.

**AUDIT**

Identifies the types of access to this table that causes auditing to be performed. For information about audit trace classes, see *DB2 Administration Guide*.

If a materialized query table is refreshed with the REFRESH TABLE statement, the auditing also occurs during the REFRESH TABLE operation. AUDIT works as usual for LOAD and SQL data change operations on a user-maintained materialized query table.

#### **NONE**

Specifies that no auditing is to be done when this table is accessed. This is the default.

#### **CHANGES**

Specifies that auditing is to be done when the table is accessed during the first insert, update, or delete operation. However, the auditing is done only if the appropriate audit trace class is active.

#### **ALL**

Specifies that auditing is to be done when the table is accessed during the first operation of any kind performed by a utility or application process. However, the auditing is done only if the appropriate audit trace class is active and the access is not performed with COPY, RECOVER, REPAIR, or any stand-alone utility.

If the table is subsequently altered with an ALTER TABLE statement, the ALTER TABLE statement is audited for successful and failed attempts in the following cases, if the appropriate audit trace class is active:

- AUDIT attribute is changed to NONE, CHANGES, or ALL on an audited or non-audited table.
- AUDIT CHANGES or AUDIT ALL is in effect.

#### **OBID integer**

Identifies the OBID to be used for this table. An OBID is the identifier for an object's internal descriptor. The integer must not identify an existing or previously used OBID of the database. If you omit OBID, DB2 generates a value.

The following statement retrieves the value of OBID:

```
SELECT OBID  
      FROM SYSIBM.SYSTABLES  
     WHERE CREATOR = 'ccc' AND NAME = 'nnn';
```

Here, *nnn* is the table name and *ccc* is the creator of the table.

#### **DATA CAPTURE**

Specifies whether the logging of the following actions on the table is augmented by additional information:

- SQL data change operations
- Adding columns (using the ADD COLUMN clause of the ALTER TABLE statement)
- Changing columns (using the ALTER COLUMN clause of the ALTER TABLE statement)

For guidance on intended uses of the expanded log records, see:

- The description of data propagation to IMS in *IMS DataPropagator: An Introduction*
- The instructions for using Remote Recovery Data Facility (RRDF) in *Remote Recovery Data Facility Program Description and Operations*
- The instructions for reading log records in *DB2 Administration Guide*

If a materialized query table is refreshed with the REFRESH TABLE statement, the logging of the augmented information occurs during the REFRESH TABLE

operation. DATA CAPTURE works as usual for insert, update, and delete operations on a user-maintained materialized query table.

#### **NONE**

Do not record additional information to the log. This is the default.

#### **CHANGES**

Write additional data about SQL updates to the log. Information about the values that are represented by any LOB or XML columns is not available. Do not specify DATA CAPTURE CHANGES for tables that reside in table spaces that specify NOT LOGGED.

#### **CCSID *encoding-scheme***

Specifies the encoding scheme for string data stored in the table. If the IN clause is specified with a table space, the value must agree with the encoding scheme that is already in use for the specified table space. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the table space or database specified in the IN clause. If the IN clause is not specified, the value specified is used for the table being created as well as for the table space that DB2 implicitly creates. The specific CCSIDs for SBCS, mixed, and graphic data are determined by the default CCSIDs for the server for the specified encoding scheme. The valid values are ASCII, EBCDIC, and UNICODE.

If the CCSID clause is not specified, the encoding scheme for the table depends on the IN clause:

- If the IN clause is specified, the encoding scheme already in use for the table space or database specified in the IN clause is used.
- If the IN clause is not specified, the encoding scheme of the new table is the same as the scheme for the table that is specified in the LIKE clause.

If the CCSID clause is specified for a materialized query table, the encoding scheme specified in the clause must be the same as the scheme for the result CCSID of the fullselect. The CCSID must also be the same as the CCSID of the table space for the table being created.

#### **VOLATILE or NOT VOLATILE**

Specifies how DB2 is to choose access to the table.

#### **VOLATILE**

Specifies that index access should be used on this table whenever possible for SQL operations. However, be aware that list prefetch and certain other optimization techniques are disabled when VOLATILE is used.

One instance in which use of VOLATILE might be desired is for a table whose size can vary greatly. If statistics are taken when the table is empty or has only a few rows, those statistics might not be appropriate when the table has many rows. Another instance in which use of VOLATILE might be desired is for a table that contains groups of rows, as defined by the primary key on the table. All but the last column of the primary key of such a table indicate the group to which a given row belongs. The last column of the primary key is the sequence number indicating the order in which the rows are to be read from the group. VOLATILE maximizes concurrency of operations on rows within each group, since rows are usually accessed in the same order for each operation.

#### **NOT VOLATILE**

Specifies that SQL access to this table should be based on the current statistics. NOT VOLATILE is the default.

## CARDINALITY

An optional keyword that currently has no effect, but that is provided for DB2 family compatibility.

### APPEND NO or APPEND YES

Specifies whether append processing is used for the table. The APPEND clause must not be specified for a table that is created in a work file table space.

**NO** Specifies that append processing is not used for the table. For insert and LOAD operations, DB2 will attempt to place data rows in a well clustered manner with respect to the value in the row's cluster key column.

NO is the default.

### YES

Specifies that data rows are to be placed into the table by disregarding the clustering during insert and LOAD operations.

### *materialized-query-definition*

Specifies that the column definitions of the materialized query table are based on the result of a fullselect. If *materialized-query-table-options* are specified, the REFRESH TABLE statement can be used to populate the table with the results of the fullselect.

### *column-name*

Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the fullselect.

A list of column names must be specified if the result table of the fullselect has duplicate column names or an unnamed column. An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

### AS (*fullselect*)

Specifies that the table definition is based on the column definitions from the result of a query expression. The use of AS (*fullselect*) is an implicit definition of *n* columns for the table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the *select-clause* to provide unique names.

The implicit definition includes the column name, data type, length, precision, scale, and nullability characteristic of each of the result columns of *fullselect*. The length of each result column must not be 0. Other column attributes, such as DEFAULT, IDENTITY, and unique constraints, are not inherited from the *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table. The generated column attributes are not inherited from the *fullselect*. That is, the new column of the materialized query table is not considered as a generated column. A FIELDPROC is inherited for a column if the corresponding select item of the *fullselect* is a column that can be directly mapped to a column of a base table or a view in the FROM clause of the *fullselect*. The materialized query table contains a security label column if only one table in the *fullselect* contains a security label column and the primary authorization ID of the

statement has a valid security label. If more than one table in the *fullselect* contains a security label column, an error occurs.

The owner of the table being created must have the SELECT privilege on the tables or views referenced in the fullselect, or the privilege set must include SYSADM or DBADM authority for the database in which the tables of the fullselect reside. Having SELECT privilege means that the owner has at least one of the following authorizations:

- Ownership of the tables or views referenced in the fullselect
- The SELECT privilege on the tables and views referenced in the fullselect
- SYSADM authority
- DBADM authority for the database in which the tables of the fullselect reside

The rules for establishing the qualifiers for names used in the fullselect are the same as the rules used to establish the qualifiers for *table-name*.

The following restrictions apply when creating materialized query tables. When *fullselect* does not satisfy the restrictions, an error occurs:

- The fullselect must not refer to host variables or include parameter markers.
- When **DISABLE QUERY OPTIMIZATION** is specified, the following additional restrictions apply:
  - The fullselect cannot contain a reference to a created global temporary table or a declared global temporary table.
  - The fullselect cannot reference another materialized query table.
- When **ENABLE QUERY OPTIMIZATION** is specified, the following additional restrictions apply:
  - The fullselect must be a subselect.
  - The outermost SELECT list of the subselect must not reference data that is encoded with different CCSID sets.
  - If the subselect references a view, the fullselect in the view definition must satisfy the restrictions for using a fullselect when the **ENABLE QUERY OPTIMIZATION** clause is specified.
  - The subselect cannot contain:
    - A FETCH FIRST clause
    - A nested table expression or view that requires temporary materialization
    - A join using the INNER JOIN syntax
    - An outer join
    - A special register
    - A scalar fullselect
    - A row change timestamp column
    - Any predicates that include a subquery
    - A row expression predicate
    - A function or expression that is not deterministic or that has external actions
    - A ROW CHANGE expression
    - lateral correlation

#### *refreshable-table-options*

Specifies the options for a refreshable materialized query table. The

ORDER BY clause is allowed, but it is used only by REFRESH. The ORDER BY clause can improve the locality of reference of data in the materialized query table.

#### **DATA INITIALLY DEFERRED**

Specifies that the data is not inserted into the materialized query table when it is created. Use the REFRESH TABLE statement to populate the materialized query table, or use the INSERT statement to insert data into a user-maintained materialized query table.

#### **REFRESH DEFERRED**

Specifies that the data in the table can be refreshed at any time using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time when the REFRESH TABLE statement is processed or when it was last updated for a user-maintained materialized query table.

#### **MAINTAINED BY SYSTEM or MAINTAINED BY USER**

Specifies how the data in the materialized query table is maintained.

##### **MAINTAINED BY SYSTEM**

Specifies that the materialized query table is maintained by the system. Only the REFRESH statement is allowed on the table. This is the default.

##### **MAINTAINED BY USER**

Specifies that the materialized query table is maintained by the user, who can use the LOAD utility, an SQL data change statement, a SELECT from data change statement, or REFRESH TABLE SQL statements on the table.

#### **ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION**

Specifies whether this materialized query table can be used for optimization.

##### **ENABLE QUERY OPTIMIZATION**

Specifies that the materialized query table can be used for query optimization. If the fullselect specified does not satisfy the restrictions for query optimization, an error occurs.

ENABLE QUERY OPTIMIZATION is the default.

##### **DISABLE QUERY OPTIMIZATION**

Specifies that the materialized query table cannot be used for query optimization. The table can still be queried directly.

## **Notes®**

**Owner privileges:** The owner of the table has all table privileges (see “GRANT (table or view privileges)” on page 1355) with the ability to grant these privileges to others. For more information about ownership of the object, see “Authorization, privileges, and object ownership” on page 60.

**Table design:** Designing tables is part of the process of database design. For information on design, see *Introduction to DB2 for z/OS*.

**Creating a table in a segmented table space:** A table cannot be created in a segmented table space if:

- The available space in the data set is less than the segment size specified for the table space, and

- The data set cannot be extended.

**Creating a table with graphic and mixed data columns:** You cannot create an ASCII or EBCDIC table with a GRAPHIC, VARGRAPHIC, or DBCLOB column or a CHAR, VARCHAR, or CLOB column defined as FOR MIXED DATA when the setting for installation option MIXED DATA is NO.

**Creating a table with distinct type columns based on LOB, ROWID, and DECFLOAT columns:** Because a distinct type is subject to the same restrictions as its source type, all the syntactic rules that apply to LOB columns (CLOB, DBCLOB, and BLOB), ROWID columns, and DECFLOAT columns apply to distinct type columns that are based on LOBs, row IDs, and DECFLOATs. For example, a table cannot have both an explicitly defined ROWID column and a column with a distinct type that is based on a row ID.

**Creating a table with LOB columns:** A table with a LOB column (CLOB, DBCLOB, or BLOB) must also have a ROWID column and one or more auxiliary tables. When you create the table, DB2 implicitly generates a ROWID column for you. This is called an *implicitly hidden ROWID column*, and DB2:

- Creates the column with a name of DB2\_GENERATED\_ROWID\_FOR\_LOBS $nn$ . DB2 appends  $nn$  only if the column name already exists in the table, replacing  $nn$  with 00 and incrementing by 1 until the name is unique within the row.
- Defines the column as GENERATED ALWAYS.
- Appends the implicitly hidden ROWID column to the end of the row after all the other explicitly defined columns.

For example, assume that DB2 generated an implicitly hidden ROWID column named DB2\_GENERATED\_ROWID\_FOR\_LOBS for table MYTABLE. The result table for a SELECT \* statement for table MYTABLE would not contain that ROWID column. However, the result table for SELECT COL1, DB2\_GENERATED\_ROWID\_FOR\_LOBS would include the implicitly hidden ROWID column.

The definition of the table is marked incomplete until an auxiliary table is created in a LOB table space for each LOB column in the base table and index is created on each auxiliary table. The auxiliary table stores the actual values of a LOB column. If you create a table with a LOB column in a partitioned table space, there must be one auxiliary table defined for each partition of the base table space.

Unless DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table, you need to create these objects using the CREATE TABLESPACE, CREATE AUXILIARY TABLE, and CREATE INDEX statements.

If the table space that contains the table is explicitly created and the value of the CURRENT RULES special register is 'STD' when the CREATE TABLE statement is processed, or the table space that contains the table is implicitly created, DB2 implicitly creates the LOB table space, auxiliary table, and index on the auxiliary table for each LOB column in the base table.

The privilege set must include the following privileges:

- The USE privilege on the buffer pool and the storage group that is used by the XML objects

- If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

DB2 chooses the names of implicitly created objects using these conventions:

#### **LOB table space**

Name is 8 characters long, consisting of an 'L' followed by 7 random characters.

#### **auxiliary table**

Name is 18 characters long. The first five characters of the name are the first five characters of the name of the base table. The second five characters are the first five characters of the name of the LOB column. The last eight characters are randomly generated. If a base table name or a LOB column name is less than five characters, DB2 adds underscore characters to the name to pad it to a length of five characters.

#### **index on the auxiliary table**

Name is 18 characters long. The first character of the name is an 'T'. The next ten characters are the first ten characters of the name of the auxiliary table. The last seven characters are randomly generated. The index has the COPY NO attribute.

The other attributes of these implicitly created objects are those that would have been created by their respective CREATE statements with all optional clauses omitted, with the following exceptions:

- The database name is the database name of the base table.
- If the LOB table space is implicitly created, the buffer pool is determined by the DEFAULT BUFFER POOL FOR USER LOB DATA fields of install panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

Utility REPORT TABLESPACESET identifies the LOB table spaces that DB2 implicitly created.

***Creating a table with an XML column:*** When a table is created with an XML column, an XML table space, XML table, and a node ID index and document ID index are implicitly created.

The privilege set must include the following privileges:

- The USE privilege on the buffer pool and the storage group that is used by the XML objects
- If the base table space is explicitly created, CREATETS is also required on the database that contains the table (DSNDB04 if the database is implicitly created)

The buffer pool for the XML table space is determined by the DEFAULT BUFFER POOL FOR USER XML DATA fields of install panel DSNTIP1. The appropriate USE privilege is required on that buffer pool.

The XML table space will have a larger DSSIZE than the base table space if the base table space is partitioned by range. If the base table space is partitioned by growth, the default DSSIZE of 4GB will be used for the XML table space. The DSSIZE for an XML table space that is associated with a partitioned by range base table space is determined as follows.

*Table 97. Default DSSIZE for XML table spaces, given base table space DSSIZE and page size*

Base table space DSSIZE	4KB base page size	8KB base page size	16KB base page size	32KB base page size
1GB - 4GB	4GB	4GB	4GB	4GB
8GB	32GB	16GB	16GB	16GB
16GB	64GB	32GB	16GB	16GB
32GB	64GB	64GB	32GB	16GB
64GB	64GB	64GB	64GB	32GB

For example: for a base table space that has a DSSIZE of 8GB and a page size of 8KB, the XML table space will have a DSSIZE of 16GB.

**Naming convention for implicitly created XML objects:** Implicitly created XML table spaces names will be *Xyyy**nnnn*, where *yyy* is the first three UTF-8 bytes of the base table name (if the name is shorter than 3, *yyy* is padded with #). *nnnn* is a numeric string that will start at 0000 and be incremented by 1 until a unique number is found.

Implicitly created XML table names will be *Xyyyyyyyyyyyyyyyyyyyyy**nnnn*, where *yyyyyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or of the entire name if it is less than 18. *nnnn* will only be appended if the name already exists in the table. If the name already exists, *nnnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created document ID index names will be *I\_DOCID**yyyyyyyyyyyyyyyyy**nnnn*, where *yyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the base table name or the entire name if it is less than 18. *nnnn* will only be appended if the index already exists in the table. If the index already exists, *nnnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

Implicitly created node ID index names will be *I\_NODEID**yyyyyyyyyyyyyyyyy**nnnn*, where *yyyyyyyyyyyyyyyyy* is the first 18 UTF-8 bytes of the XML table name or the entire name if it is less than 18. *nnnn* will only be appended if the index already exists in the table. If the index already exists, *nnnn* will be replaced with 000 and will be incremented by 1 until the name is unique.

**Creating a table with an identity column:** When a table has an identity column, DB2 can automatically generate sequential numeric values for the column as rows are inserted into the table. Thus, identity columns are ideal for primary keys. Identity columns and ROWID columns are similar in that both types of columns contain values that DB2 generates. ROWID columns are used in large object (LOB) table spaces and can be useful in direct-row access. ROWID columns contain values of the ROWID data type, which returns a 40 byte VARCHAR value that is not regularly ascending or descending. ROWID data values are therefore not well suited to many application uses, such as generating employee numbers or product numbers. For data that is not LOB data and that does not require direct-row access, identity columns are usually a better approach, because identity columns contain existing numeric data types and can be used in a wide variety of uses for which ROWID values would not be suitable.

When a table is recovered to a point-in-time, it is possible that a large gap in the generated values for the identity column might result. For example, assume a table

has an identity column that has an incremental value of 1 and that the last generated value at time T1 was 100 and DB2 subsequently generates values up to 1000. Now, assume that the table space is recovered back to time T1. The generated value of the identity column for the next row that is inserted after the recovery completes will be 1001, leaving a gap from 100 to 1001 in the values of the identity column.

If you want to ensure that an identity column has unique values, create a unique index on the column.

***Creating a table with a LONG VARCHAR or LONG VARGRAPHIC column:***

Although the syntax LONG VARCHAR and LONG VARGRAPHIC is allowed for compatibility with previous releases of DB2, its use is not encouraged. VARCHAR(*integer*) and VARGRAPHIC(*integer*) is the recommended syntax, because after the CREATE TABLE statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

When a column is defined using the LONG VARCHAR or LONG VARGRAPHIC syntax, DB2 determines the length attribute of the column. You can use the following information, which is provided for existing applications that require the use of the LONG VARCHAR or LONGVARGRAPHIC syntax, to calculate the byte count and the character count of the column.

To calculate the byte count, use this formula:

$$2 * (\text{INTEGER}((\text{INTEGER}((m-i-k)/j))/2))$$

Where:

- m* Is the maximum row size (8 less than the maximum record size)
- i* Is the sum of the byte counts of all columns in the table that are not LONG VARCHAR or LONG VARGRAPHIC
- j* is the number of LONG VARCHAR and LONG VARGRAPHIC columns in the table
- k* *k* is the number of LONG VARCHAR and LONG VARGRAPHIC columns that allow nulls

To find the character count:

1. Find the byte count.
2. Subtract 2.
3. If the data type is LONG VARGRAPHIC, divide the result by 2. If the result is not an integer, drop the fractional part.

***If the IN DATABASE clause is specified:*** If you specify IN DATABASE (either explicitly or by default), but do not specify a table space, a table space is implicitly created in *database-name*. The name of the table space is derived from the table name. The qualifier of the table space is the same as the qualifier of the table.

If range-partitioning is not specified, the implicitly created table space is a partition-by-growth table space with MAXPARTITIONS 256, SEGSIZE 4, and DSSIZE 4G.

If range-partitioning is specified, the table space will be segmented with a SEGSIZE of 4, LOCKSIZE ROW, and LOCKMAX SYSTEM.

*If the IN clause is not specified:* If you do not specify the IN clause, DB2 will implicitly create a table space as described previously, but DB2 will also choose a database as follows:

- DB2 chooses a name of the form DSNnnnnn, where nnnnn is between 00001 and 10000, inclusive.
  - If DSNnnnnn already exists and is an implicitly created database, DB2 creates the table in that database.
  - If DSNnnnnn does not exist, DB2 creates a database with the name DSNnnnnn.

If DSNnnnnn cannot be created because of a deadlock, timeout, or resource unavailable condition, DB2 increments nnnnn by one and tries the resultant database name. If DB2 reaches 10000, and DSN10000 is not available, DB2 sets nnnnn to 00001 and tries the resultant database name. If DB2 tries 10000 database names without success, an error occurs.

*Implicitly created table spaces:* If the table space is implicitly created, all of the following required system objects will also be implicitly created:

- The enforcing primary key index
- The enforcing unique key index
- Any necessary LOB table spaces, auxiliary table spaces, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

*Implicitly created indexes:* When the PRIMARY KEY or UNIQUE clause is used in the CREATE TABLE statement and the CREATE TABLE statement is processed by the schema processor or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the primary or unique keys.

When a ROWID column is defined as GENERATED BY DEFAULT in the CREATE TABLE statement, and the CREATE TABLE statement is processed by SET CURRENT RULES = 'STD' or the table space that contains the table is implicitly created, DB2 implicitly creates the unique indexes used to enforce the uniqueness of the ROWID column.

The privilege set must include the USE privilege of the buffer pool.

Each index is created as if the following CREATE INDEX statement were issued:  
CREATE UNIQUE INDEX xxx ON *table-name* (*column1*,...)

Where:

- *xxx* is the name of the index that DB2 generates.
- *table-name* is the name of the table specified in the CREATE TABLE statement.
- (*column1*,...) is the list of column names that were specified in the UNIQUE or PRIMARY KEY clause of the CREATE TABLE statement, or the column is a ROWID column that is defined as GENERATED BY DEFAULT.

For more information about the schema processor, see *DB2 Administration Guide*.

In addition, if the table space that contains the table is implicitly created, DB2 will check the DEFINE DATA SET subsystem parameter to determine whether to define the underlying data set for the index space of the implicitly created index on the base table.

If DEFINE DATA SET is NO, the index is created as if the following CREATE INDEX statement is issued:

```
CREATE UNIQUE INDEX xxx ON table-name (column1,...) DEFINE NO
```

**Maximum record size:** The maximum record size of a table depends on the page size of the table space and whether the EDITPROC clause is specified, as shown in Table 98. The initial page size of the table space is the size of its buffer, which is determined by the BUFFERPOOL clause that was explicitly or implicitly specified when the table space was created. When the record size reaches 90 percent of the maximum record size for the page size of the table space, the next largest page size is automatically used.

Table 98. Maximum record size, in bytes

EDITPROC	Page Size = 4KB	Page Size = 8KB	Page Size = 16KB	Page Size = 32KB
NO	4056	8138	16330	32714
YES	4046	8128	16320	32704

The maximum record size corresponds to the maximum length of a VARCHAR column if that column is the only column in the table.

If the table space that contains the table is implicitly created, the proper buffer pool size is chosen according to the actual record size. If the record size reaches 90% of the maximum record size for the page size of the table space, the next largest page size will be used. Table 99 shows what 90% of the maximum record size:

Table 99. 90% of Maximum record size, in bytes

Page Size = 4KB	Page Size = 8KB	Page Size = 16KB	Page Size = 32KB
3640	7310	14680	29432

**Byte counts:** The sum of the byte counts of the columns must not exceed the maximum row size of the table. The maximum row size is eight less than the maximum record size.

For columns that do not allow null values, Table 100 gives the byte counts of columns by data type. For columns that allow null values, the byte count is one more than shown in the table.

Table 100. Byte counts of columns by data type

Data Type	Byte Count
INTEGER	4
SMALLINT	2
BIGINT	8

*Table 100. Byte counts of columns by data type (continued)*

Data Type	Byte Count
FLOAT( <i>n</i> )	If <i>n</i> is between 1 and 21, the byte count is 4. If <i>n</i> is between 22 and 53, the byte count is 8.
DECIMAL	INTEGER( <i>p</i> /2)+1, where <i>p</i> is the precision
DECFLOAT(16)	9
DECFLOAT(34)	17
CHAR( <i>n</i> )	<i>n</i>
VARCHAR( <i>n</i> )	<i>n</i> +2
CLOB	6
GRAPHIC( <i>n</i> )	2 <i>n</i>
VARGRAPHIC( <i>n</i> )	2 <i>n</i> +2
DBCLOB	6
BINARY( <i>n</i> )	<i>n</i>
VARBINARY( <i>n</i> )	<i>n</i> +2
BLOB	6
DATE	4
TIME	3
TIMESTAMP	10
ROWID	19
distinct type	The length of the source data type upon which the distinct type was based

***Creating a materialized query table:*** If the fullselect in the CREATE TABLE statement contains a SELECT \*, the select list of the subselect is determined at the time the materialized query table is created. In addition, any references to user-defined functions are resolved at the same time. The isolation level at the time when the CREATE TABLE statement is executed is the isolation level for the materialized query table. After a materialized query table is created, the REFRESH\_TIME column of the row for the table in the SYSIBM.SYSVIEWS catalog table contains the default timestamp.

The owner of a materialized query table has all the table privileges with the grant option on the table irrespective of whether the owner has the necessary privileges on the base tables, views, functions, and sequences.

No unique constraints or unique indexes can be created for materialized query tables. Thus, a materialized query table cannot be a parent table in a referential constraint.

When you are creating user-maintained materialized query tables, you should create the materialized query table with query optimization disabled and then enable the table for query optimization after it is populated. Otherwise, DB2 might rewrite queries to use the empty materialized query table, and you will not get accurate results.

***Considerations for implicitly hidden columns:*** A column that is defined as implicitly hidden is not part of the result table of a query that specifies \* in a SELECT list. However, an implicitly hidden column can be explicitly referenced in

a query. For example, an implicitly hidden column can be referenced in the SELECT list or in a predicate in a query. Additionally, an implicitly hidden column can be explicitly referenced in a COMMENT, CREATE INDEX statement, ALTER TABLE statement, INSERT statement, MERGE statement, UPDATE statement, or RENAME statement. An implicitly hidden column can be referenced in a referential constraint. A REFERENCES clause that does not contain a column list refers implicitly to the primary key of the parent table. It is possible that the primary key of the parent table includes a column defined as implicitly hidden. Such a referential constraint is allowed.

If the SELECT list of the fullselect of a materialized query definition explicitly refers to an implicitly hidden column, that column will be part of the materialized query table.

If the SELECT list of the full select of a view definition (CREATE VIEW statement) explicitly refers to an implicitly hidden column, that column will be part of the view, however the view column is not considered 'hidden'.

**Restrictions on field procedures, edit procedures, and validation exit procedures:** Field procedures, edit procedures, and validation exit procedures cannot be used on tables that have column names that are larger than 18 EBCDIC bytes. If you have tables that have field procedures or validation exit procedures and you add a column where the column name is larger than 18 bytes, the field procedures and validation exit procedures for the table will be invalidated.

Consider using triggers to replace the functionality on field procedures, edit procedures, and validation exit procedures on tables where the column names are larger than 18 EBCDIC bytes.

**Restrictions on SQL data change statements in the same unit of work as CREATE TABLE:** SQL data change statements cannot follow, in the same unit of work, CREATE TABLE statements that specify the PARTITION BY clause.

**Creating a table while a utility runs:** You cannot use CREATE TABLE while a DB2 utility has control of the table space implicitly or explicitly specified by the IN clause.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- NOCACHE (single clause) as a synonym for NO CACHE
- NOCYCLE (single clause) as a synonym for NO CYCLE
- NOMINVALUE (single clause) as a synonym for NO MINVALUE
- NOMAXVALUE (single clause) as a synonym for NO MAXVALUE
- NOORDER (single clause) as a synonym for NO ORDER
- PART *integer* VALUES can be specified as an alternative to PARTITION *integer* ENDING AT.
- VALUES as a synonym for ENDING AT
- DEFINITION ONLY as a synonym for WITH NO DATA
- SUMMARY between CREATE and TABLE

## Examples

*Example 1:* Create a table named DSN8910.DEPT in the table space DSN8S91D of the database DSN8D91A. Name the five columns DEPTNO, DEPTNAME,

MGRNO, ADMRDEPT, and LOCATION, allowing only MGRNO and LOCATION to contain nulls, and designating DEPTNO as the only column in the primary key. All five columns hold character string data. Assuming a value of NO for the field MIXED DATA on installation panel DSNTIPF, all five columns have the subtype SBCS.

```
CREATE TABLE DSN8910.DEPT
  (DEPTNO  CHAR(3)      NOT NULL,
   DEPTNAME VARCHAR(36) NOT NULL,
   MGRNO    CHAR(6)      ,
   ADMRDEPT CHAR(3)      NOT NULL,
   LOCATION CHAR(16)    ,
   PRIMARY KEY(DEPTNO)      )
IN DSN8D91A.DSN8S91D;
```

*Example 2:* Create a table named DSN8910.PROJ in an implicitly created table space of the database DSN8D91A. Assign the table a validation procedure named DSN8EAPR.

```
CREATE TABLE DSN8910.PROJ
  (PROJNO  CHAR(6)      NOT NULL,
   PROJNAME VARCHAR(24) NOT NULL,
   DEPTNO   CHAR(3)      NOT NULL,
   RESPEMP  CHAR(6)      NOT NULL,
   PRSTAFF  DECIMAL(5,2) ,
   PRSTDATE DATE        ,
   PRENDATE DATE        ,
   MAJPROJ  CHAR(6)      NOT NULL)
IN DATABASE DSN8D91A
VALIDPROC DSN8EAPR;
```

*Example 3:* Assume that table PROJECT has a non-primary unique key that consists of columns DEPTNO and RESPEMP (the department number and employee responsible for a project). Create a project activity table named ACTIVITY with a foreign key on that unique key.

```
CREATE TABLE ACTIVITY
  (PROJNO  CHAR(6)      NOT NULL,
   ACTNO   SMALLINT     NOT NULL,
   ACTDEPT CHAR(3)      NOT NULL,
   ACTOWNER CHAR(6)     NOT NULL,
   ACSTAFF  DECIMAL(5,2) ,
   ACSTDATE DATE        NOT NULL,
   ACENDATE DATE        ,
   FOREIGN KEY (ACTDEPT,ACTOWNER)
   REFERENCES PROJECT (DEPTNO,RESPEMP) ON DELETE RESTRICT)
IN DSN8D91A.DSN8S91D;
```

*Example 4:* Create an employee photo and resume table EMP\_PHOTO\_RESUME that complements the sample employee table. The table contains a photo and resume for each employee. Put the table in table space DSN8D91A.DSN8S91E. Let DB2 always generate the values for the ROWID column.

```
CREATE TABLE DSN8910.EMP_PHOTO_RESUME
  (EMPNO    CHAR(6)      NOT NULL,
   EMP_ROWID ROWID NOT NULL GENERATED ALWAYS,
   EMP_PHOTO BLOB(110K),
   RESUME    CLOB(5K),
   PRIMARY KEY (EMPNO))
IN DSN8D91A.DSN8S91E
CCSID EBCDIC;
```

*Example 5:* Create an EMPLOYEE table with an identity column named EMPNO. Define the identity column so that DB2 will always generate the values for the

column. Use the default value, which is 1, for the first value that should be assigned and for the incremental difference between the subsequently generated consecutive numbers.

```
CREATE TABLE EMPLOYEE
  (EMPNO      INTEGER GENERATED ALWAYS AS IDENTITY,
   ID         SMALLINT,
   NAME       CHAR(30),
   SALARY     DECIMAL(5,2),
   DEPTNO    SMALLINT)
IN DSN8D91A.DSN8S91D;
```

*Example 6:* Assume a very large transaction table named TRANS contains one row for each transaction processed by a company. The table is defined with many columns. Create a materialized query table for the TRANS table that contain daily summary data for the date and amount of a transaction.

```
CREATE TABLE STRANS AS
  (SELECT YEAR AS SYEAR, MONTH AS SMONTH, DAY AS SDAY, SUM(AMOUNT) AS SSUM
   FROM TRANS
   GROUP BY YEAR, MONTH, DAY)
  DATA INITIALLY DEFERRED REFRESH DEFERRED;
```

*Example 7:* The following example creates a table in a partition-by-growth table space and includes the APPEND option:

```
CREATE TABLE TS01TB
  (C1 SMALLINT,
   C2 DECIMAL(9,2),
   C3 CHAR(4))
  APPEND YES
  IN TS01DB.TS01TS;
```

*Example 8:* The following example creates a table in a partition-by-growth table space where the table space is implicitly created:

```
CREATE TABLE TS02TB
  (C1 SMALLINT,
   C2 DECIMAL(9,2),
   C3 CHAR(4))
  PARTITION BY SIZE EVERY 4G
  IN DATABASE DSNDB04;
```

*Example 9:* Create a table, EMP\_INFO, that contains a phone number and address for each employee. Include a row change timestamp column in the table to track the modification of employee information:

```
CREATE TABLE EMP_INFO
  (EMPNO CHAR(6) NOT NULL,
   EMP_INFOCHANGE NOT NULL
     GENERATED ALWAYS FOR EACH ROW ON UPDATE
     AS ROW CHANGE TIMESTAMP,
   EMP_ADDRESS VARCHAR(300),
   EMP_PHONENO CHAR(4),
   PRIMARY KEY (EMPNO));
```

*Example 10:* Create a table, TB01, that uses a range partitioning scheme with a segment size of 4 and 4 partitions.

```
CREATE TABLE TB01 (
  ACCT_NUM      INTEGER,
  CUST_LAST_NM  CHAR(15),
  LAST_ACTIVITY_DT VARCHAR(25),
  COL2          CHAR(10),
  COL3          CHAR(25),
  COL4          CHAR(25),
  COL5          CHAR(25),
```

```
|           COL6          CHAR(55),  
|           STATE         CHAR(55))  
|           IN DBB.TS01  
  
|           PARTITION BY (ACCT_NUM)  
|           (PARTITION 1 ENDING AT (199),  
|            PARTITION 2 ENDING AT (299),  
|            PARTITION 3 ENDING AT (399),  
|            PARTITION 4 ENDING AT (MAXVALUE));
```

## CREATE TABLESPACE

The CREATE TABLESPACE statement defines a segmented, partitioned, or universal table space at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATETS privilege for the database
- DBADM, DBCTRL, or DBMAINT authority for the database
- SYSADM or SYSCTRL authority

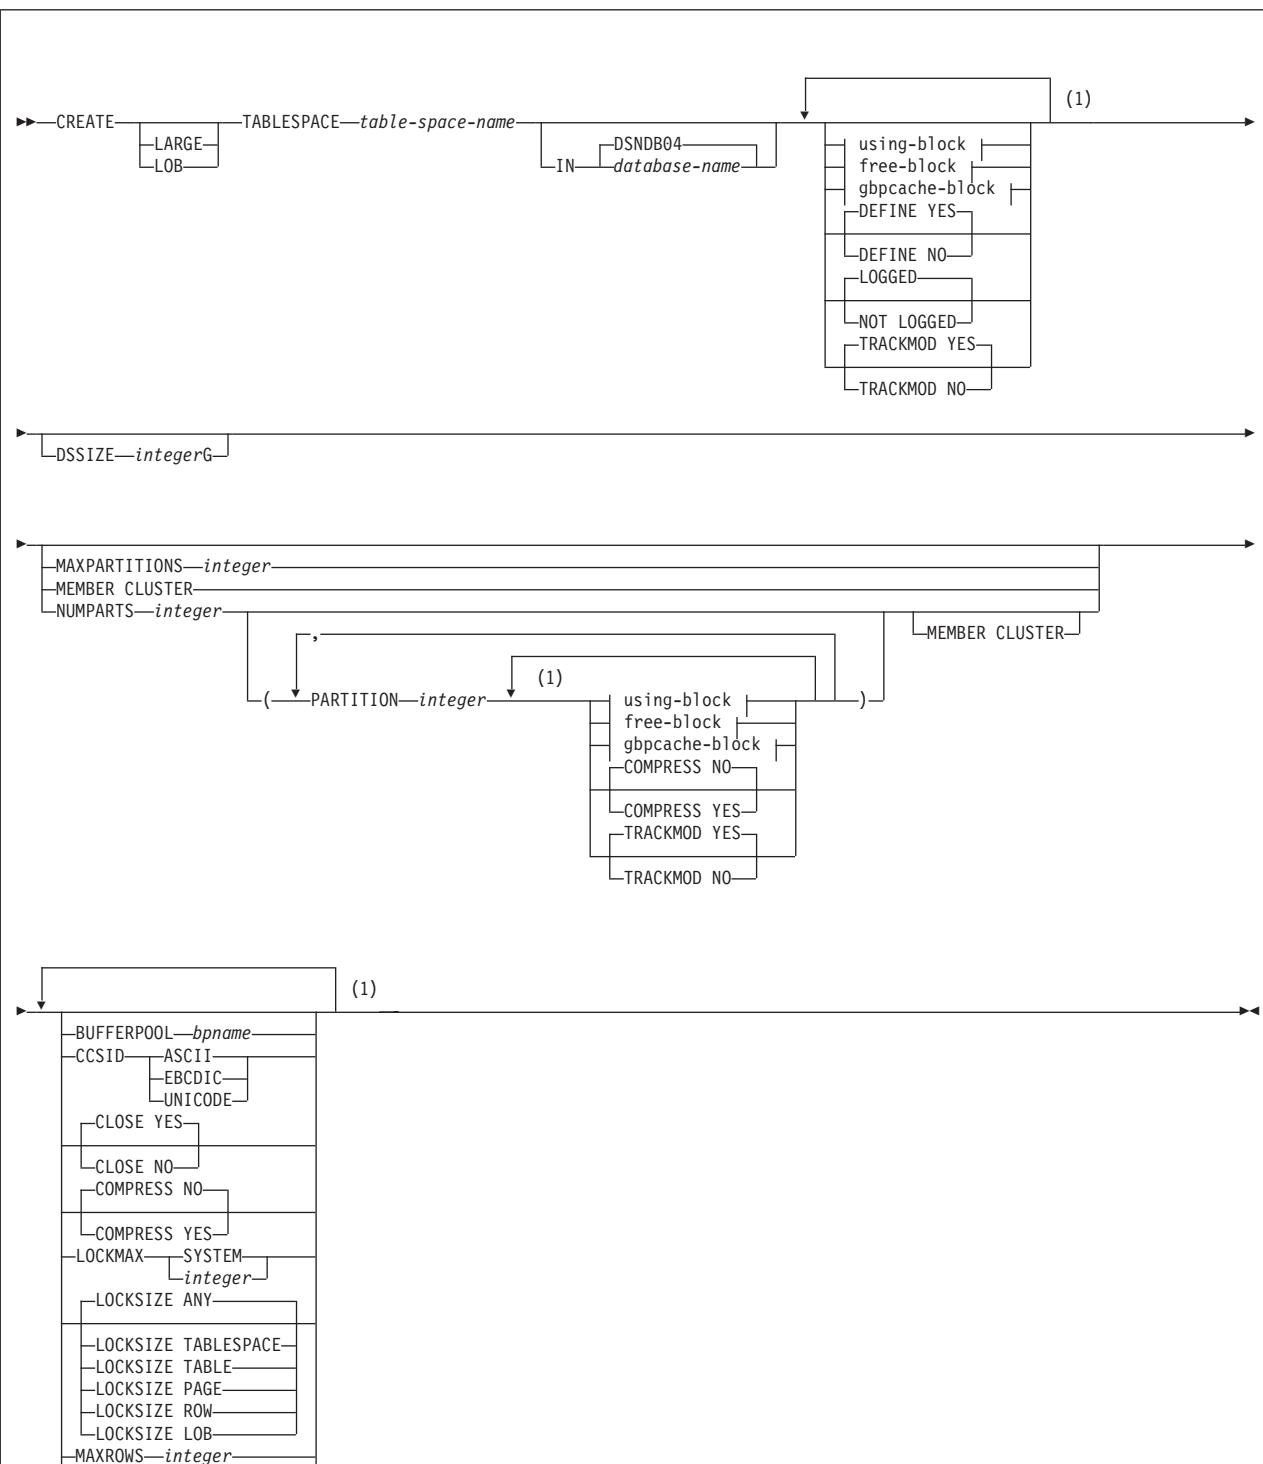

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additional privileges might be required, as explained in the description of the BUFFERPOOL and USING STOGROUP clauses.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privileges set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

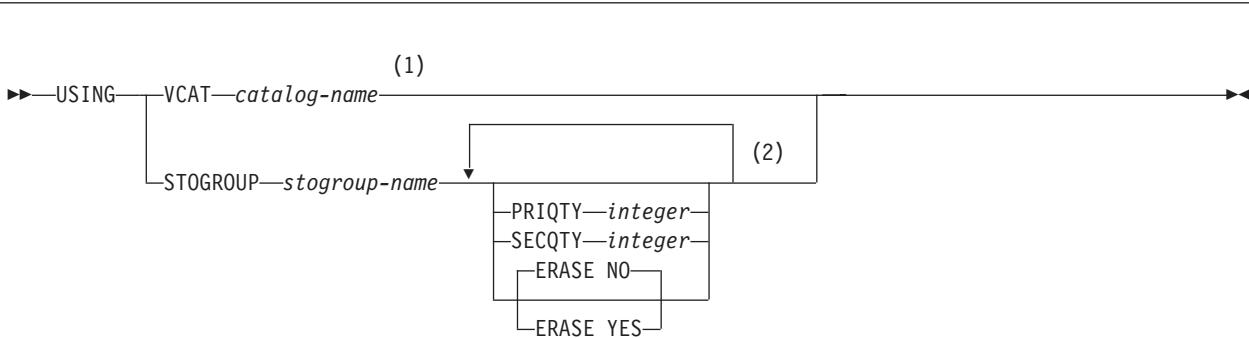

## Syntax

### Notes:

- 1 The same clause must not be specified more than once.

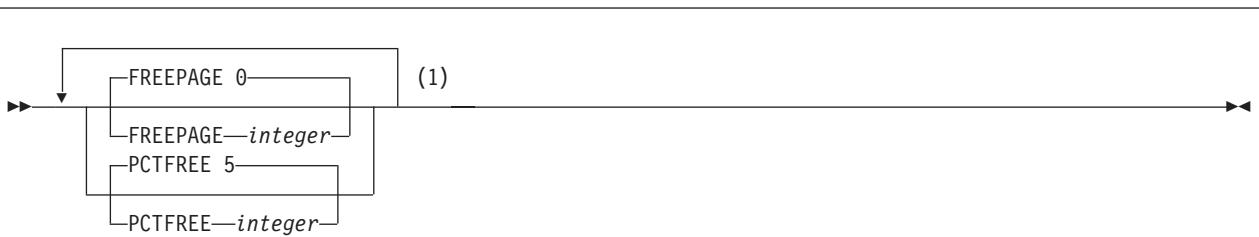

### **using-block:**

#### **Notes:**

- 1 USING VCAT must not be specified if MAXPARTITIONS is also specified.
- 2 The same clause must not be specified more than once.

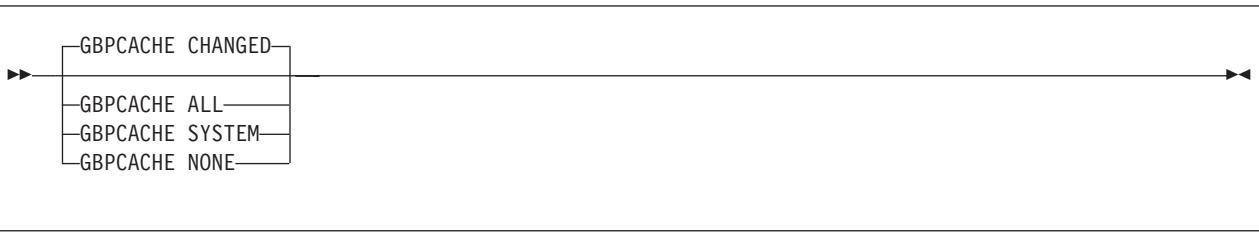

### **free-block:**

#### **Notes:**

- 1 The same clause must not be specified more than once.

### **gbpcache-block:**

### **Description**

#### **LARGE**

Identifies that each partition of a partitioned table space has a maximum partition size of 4 GB, which enables the table space to contain more than 64 GB of data. The preferred method to specify a maximum partition size of 4 GB and larger is the DSSIZE clause. The LARGE clause is for compatibility of releases of DB2 for z/OS prior to Version 6. Do not specify LARGE if LOB or DSSIZE is specified. Do not specify LARGE for a table space in a work file database.

**LOB**

Identifies the table space as LOB table space. A LOB table space is used to hold LOB values.

The LOB table space must be in the same database as its associated base table space. Do not specify LOB for a table space in a work file database.

***table-space-name***

NAMES the table space. The name, qualified with the *database-name* implicitly or explicitly specified by the IN clause, must not identify a table space, index space, or LOB table space that exists at the current server.

A table space that is for declared temporary tables must be in the work file database. PUBLIC implicitly receives the USE privilege (without GRANT authority) on any table space created in the work file database. This implicit privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**IN *database-name***

SPECIFIES the database in which the table space is created. *database-name* must identify a database that exists at the current server and must not specify the following:

- DSNDB06 for any type of table space
- A work file database for a LOB table space
- A TEMP database
- An implicitly created database

If the table space is for declared temporary tables or static scrollable cursors, the name of the work file database must be specified.

DSNDB04 is the default.

**The components of the USING clause are discussed below, first for nonpartitioned table spaces and then for partitioned table spaces. If you omit USING, the default storage group of the database must exist.**

**USING clause for nonpartitioned table spaces:**

For nonpartitioned table spaces, the USING clause indicates whether the data set for the table space is defined by you or by DB2. If DB2 is to define the data set, the clause also gives space allocation parameters and an erase rule.

If you omit USING, DB2 defines the data sets using the default storage group of the database and the defaults for PRIQTY, SECQTY, and ERASE.

**VCAT *catalog-name***

SPECIFIES that the first data set for the table space is managed by the user, and following data sets, if needed, are also managed by the user.

The data sets defined for the table space are linear VSAM data sets cataloged in an integrated catalog facility catalog identified by *catalog-name*. An alias<sup>32</sup> must be used if the catalog name is longer than eight characters.

Conventions for table space data set names are given in *DB2 Administration Guide*. *catalog-name* is the first qualifier for each data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

32. The alias of an integrated catalog facility catalog.

| VCAT must not be specified if MAXPARTITIONS is also specified.

**STOGROUP** *stogroup-name*

Specifies that DB2 will define and manage the data sets for the table space. Each data set will be defined on a volume of the identified storage group. The values specified (or the defaults) for PRIQTY and SECQTY determine the primary and secondary allocations for the data set. The storage group supplies the name of a volume for the data set and the first-level qualifier for the data set name. The first-level qualifier is also the name of, or an alias<sup>32</sup> for, the integrated catalog facility catalog on which the data set is to be cataloged. The naming conventions for the data set are the same as if the data set is managed by the user. As was mentioned above for VCAT, the first-level qualifier could cause naming conflicts if the local DB2 can share integrated catalog facility catalogs with other DB2 subsystems.

*stogroup-name* must identify a storage group that exists at the current server. SYSADM or SYSCTRL authority, or the USE privilege on the storage group, is required.

The description of the storage group must include at least one volume serial number, or it must indicate that the choice of volumes is left to Storage Management Subsystem (SMS). If volume serial numbers appear in the description, each must identify a volume that is accessible to z/OS for dynamic allocation of the data set, and all identified volumes must be of the same device type.

The integrated catalog facility catalog used for the storage group must *not* contain an entry for the first data set of the table space. If the integrated catalog facility catalog is password protected, the description of the storage group must include a valid password.

**PRIQTY** *integer*

Specifies the minimum primary space allocation for a DB2-managed data set. When you specify PRIQTY with a value other than -1, the primary space allocation is at least *n* kilobytes, where *n* is the value of *integer* with the following exceptions:

- For 4KB page sizes, if *integer* is less than 12, *n* is 12.
- For 8KB page sizes, if *integer* is less than 24, *n* is 24.
- For 16KB page sizes, if *integer* is less than 48, *n* is 48.
- For 32KB page sizes, if *integer* is less than 96, *n* is 96.
- For any page size, if *integer* is greater than 4194304, *n* is 4194304.

For LOB table spaces, the exceptions are:

- For 4KB page sizes, if *integer* is less than 200, *n* is 200.
- For 8KB page sizes, if *integer* is less than 400, *n* is 400.
- For 16KB page sizes, if *integer* is less than 800, *n* is 800.
- For 32KB page sizes, if *integer* is less than 1600, *n* is 1600.
- For any page size, if *integer* is greater than 4194304, *n* is 4194304.

If the DB2 subsystem is under DFP 1.5, the maximum value allowed for PRIQTY is 64GB (67108864 kilobytes). Otherwise, the existing maximum value of 4GB (4194304 kilobytes) applies.

If you do not specify PRIQTY or specify PRIQTY -1, DB2 uses a default value for the primary space allocation; for information on how DB2 determines the default value, see Rules for primary and secondary space allocation.

If you specify PRIQTY and do not specify a value of -1, DB2 specifies the primary space allocation to access method services using the smallest multiple of  $p$  KB not less than  $n$ , where  $p$  is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. The amount of storage space requested must be available on some volume in the storage group based on VSAM space allocation restrictions. Otherwise, the primary space allocation will fail. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command in *DFSMS/MVS: Access Method Services for the Integrated Catalog*.

Executing this statement causes only one data set to be created. However, you might have more data than this one data set can hold. DB2 automatically defines more data sets when they are needed. Regardless of the value in PRIQTY, when a data set reaches its maximum size, DB2 creates a new one. To enable a data set to reach its maximum size without running out of extents, it is recommended that you allow DB2 to automatically choose the value of the secondary space allocations for extents.

If you do choose to explicitly specify SECQTY, to avoid wasting space, use the following formula to make sure that PRIQTY and its associated secondary extent values do not exceed the maximum size of the data set:

PRIQTY + (number of extents \* SECQTY) <= DSSIZE (implicit or explicit)

**SECQTY integer**

Specifies the minimum secondary space allocation for a DB2-managed data set. If you do not specify SECQTY, DB2 uses a formula to determine a value. For information on the actual value that is used for secondary space allocation, whether you specify a value or not, see Rules for primary and secondary space allocation.

If you specify SECQTY and do not specify a value of -1, DB2 specifies the secondary space allocation to access method services using the smallest multiple of  $p$  KB not less than  $n$ , where  $p$  is the page size of the table space. The allocated space can be greater than the amount of space requested by DB2. For example, it could be the smallest number of tracks that will accommodate the request. To more closely estimate the actual amount of storage, see the description of the DEFINE CLUSTER command in .

**ERASE**

Indicates whether the DB2-managed data sets for the table space or partition are to be erased when they are deleted during the execution of a utility or an SQL statement that drops the table space.

**NO** Does not erase the data sets. Operations involving data set deletion will perform better than ERASE YES. However, the data is still accessible, though not through DB2. This is the default.

**YES**

Erases the data sets. As a security measure, DB2 overwrites all data in the data sets with zeros before they are deleted.

**USING clause for partitioned table spaces:**

If the table space is partitioned, there is a USING clause for each partition;

either one you give explicitly or one provided by default. Except as explained below, the meaning of the clause and the rules that apply to it are the same as for a nonpartitioned table space.

The USING clause for a particular partition is the first of these choices that can be found:

- A USING clause in the PARTITION clause for the partition
- A USING clause that is not in any PARTITION clause
- An implicit USING STOGROUP clause that identifies the default storage group of the database and accepts the defaults for PRIQTY, SECQTY, and ERASE

**VCAT** *catalog-name*

Indicates that the data set for the partition is managed by the user using the naming conventions set forth in *DB2 Administration Guide*. As was true for the nonpartitioned case, *catalog-name* identifies the catalog for the data set and supplies the first-level qualifier for the data set name.

One or more DB2 subsystems could share integrated catalog facility catalogs with the current server. To avoid the chance of having one of those subsystems attempt to assign the same name to different data sets, select a value for *catalog-name* that is not used by the other DB2 subsystems.

DB2 assumes one and only one data set for each partition.

**STOGROUP** *stogroup-name*

Indicates that DB2 will create a data set for the partition with the aid of a storage group named *stogroup-name*. The data set is defined during the execution of this statement. DB2 assumes one and only one data set for each partition.

The *stogroup-name* must identify a storage group that exists at the current server and the privilege set must include SYSADM authority, SYSCTRL authority, or the USE privilege for the storage group. The integrated catalog facility catalog used for the storage group must *not* contain an entry for that data set.

When USING STOGROUP is specified for a partition, the defaults for PRIQTY, SECQTY, and ERASE are the values specified in the USING STOGROUP clause that is not in any PARTITION clause. If that USING STOGROUP clause is not specified, the defaults are those specified in the description of PRIQTY, SECQTY, and ERASE.

**FREEPAGE** *integer*

Specifies how often to leave a page of free space when the table space or partition is loaded or reorganized. You must specify an integer in the range 0 to 255. If you specify 0, no pages are left as free space. Otherwise, one free page is left after every *n* pages, where *n* is the specified integer. However, if the table space is segmented and the integer you specify is not less than the segment size, *n* is one less than the segment size.

If the table space is segmented, the number of pages left free must be less than the SEGSIZE value. If the number of pages to be left free is greater than or equal to the SEGSIZE value, then the number of pages is adjusted downward to one less than the SEGSIZE value.

The default is FREEPAGE 0, leaving no free pages. Do not specify FREEPAGE for a LOB table space or a table space in a work file database.

| For XML table spaces, this change has no effect until data in the table space is  
| reorganized.

**PCTFREE integer**

Indicates what percentage of each page to leave as free space when the table is loaded or reorganized. *integer* can range from 0 to 99. The first record on each page is loaded without restriction. When additional records are loaded, at least *integer* percent of free space is left on each page.

| The default is PCTFREE 5. Do not specify PCTFREE for a LOB table space or a  
| table space in a work file database.

| For XML table spaces, this change has no effect until data in the table space is  
| reorganized.

If the table space is partitioned, the values of FREEPAGE and PCTFREE for a particular partition are given by the first of these choices that apply:

- The values of FREEPAGE and PCTFREE given in the PARTITION clause for that partition
- The values given in a *free-block* that is not in any PARTITION clause
- The default values are FREEPAGE 0 and PCTFREE 5.

**GBPCACHE**

In a data sharing environment, specifies what pages of the table space or partition are written to the group buffer pool in a data sharing environment. In a non-data-sharing environment, you can specify GBPCACHE for a table space other than one in a work file database, but it is ignored. Do not specify GBPCACHE for a table space in a work file database in either environment (data sharing or non-data-sharing).

**CHANGED**

When there is inter-DB2 R/W interest on the table space or partition, updated pages are written to the group buffer pool. When there is no inter-DB2 R/W interest, the group buffer pool is not used. Inter-DB2 R/W interest exists when more than one member in the data sharing group has the table space or partition open, and at least one member has it open for update. GBPCACHE CHANGED is the default.

If the table space is in a group buffer pool that is defined to be used only for cross-validation (GBPCACHE NO), CHANGED is ignored and no pages are cached to the group buffer pool.

**ALL**

Indicates that pages are to be cached in the group buffer pool as they are read in from DASD.

**Exception:** In the case of a single updating DB2 when no other DB2s have any interest in the page set, no pages are cached in the group buffer pool.

If the table space is in a group buffer pool that is defined to be used only for cross-validation (GBPCACHE NO), ALL is ignored and no pages are cached to the group buffer pool.

**SYSTEM**

Indicates that only changed system pages within the LOB table space are to be cached to the group buffer pool. A system page is a space map page or any other page that does not contain actual data values.

This is the default for LOB table spaces. You can use SYSTEM only for a LOB table space.

**NONE**

Indicates that no pages are to be cached to the group buffer pool. DB2 uses the group buffer pool only for cross-validation.

If you specify NONE, the table space or partition must not be in recover pending status and must be in the stopped state when the CREATE TABLESPACE statement is executed.

If the table space is partitioned, the value of GBPCACHE for a particular partition is given by the first of these choices that applies:

1. The value of GBPCACHE given in the PARTITION clause for that partition. Do not use more than one *gbpcache-block* in any PARTITION clause.
2. The value given in a *gbpcache-block* that is not in any PARTITION clause.
3. The default value CHANGED.

**DEFINE**

Specifies when the underlying data sets for the table space are physically created.

**YES**

The data sets are created when the table space is created (the CREATE TABLESPACE statement is executed). YES is the default.

If MAXPARTITIONS is also specified, only the first partition is created when the table space is created. Additional partitions are created as needed.

**NO** The data sets are not created until data is inserted into the table space. DEFINE NO is applicable only for DB2-managed data sets (USING STOGROUP is specified). DEFINE NO is ignored for user-managed data sets (USING VCAT is specified). DB2 uses the SPACE column in catalog table SYSTABLEPART to record the status of the data sets (undefined or allocated). DEFINE NO is also ignored for a LOB table space.

Do not specify DEFINE NO for a table space in a work file database. DEFINE NO is not recommended if you intend to use any tools outside of DB2 to manipulate data, such as to load data, because data sets might then exist when DB2 does not expect them to exist. When DB2 encounters this inconsistent state, applications will receive an error.

**LOGGED or NOT LOGGED**

Specifies whether changes that are made to the data in the specified table space are recorded in the log.

**LOGGED**

Specifies that changes that are made to the data in the specified table space are recorded in the log. This applies to all tables that are created in the specified table space and to all indexes of those tables. XML table spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes also inherit the logging attribute from the associated base table space.

LOGGED cannot be specified for table spaces in DSNDB06 (the DB2 catalog) or in a work file database.

LOGGED is the default.

**NOT LOGGED**

Specifies that changes that are made to data in the specified table space are not recorded in the log. This parameter applies to all tables that are created in the specified table space and to all indexes of those tables. XML table

spaces and their indexes inherit the logging attribute from the associated base table space. Auxiliary indexes inherit the logging attribute from the associated base table space.

NOT LOGGED prevents undo and redo information from being recorded in the log; however, control information for the specified table space will continue to be recorded in the log.

NOT LOGGED cannot be specified for table spaces in the following databases:

- DSNDB06 (the DB2 catalog)
- a work file database

#### **TRACKMOD**

Specifies whether DB2 tracks modified pages in the space map pages of the table space or partition. Do not specify TRACKMOD for a LOB table space. Do not specify TRACKMOD for a table space in a work file database.

##### **YES**

DB2 tracks changed pages in the space map pages to improve the performance of incremental image copy.

**NO** DB2 does not track changed pages in the space map pages. It uses the LRSN value in each page to determine whether a page has been changed.

If the table space is partitioned, the value of TRACKMOD for a particular partition is given by the first of these choices that applies:

1. The value of TRACKMOD given in the PARTITION clause for that partition.
2. The value given in a *trackmod-block* that is not in any PARTITION clause.
3. The default value YES.

#### **DSSIZE integerG**

Specifies the maximum size for each partition, or for LOB table spaces, each data set. If you specify DSSIZE, you must also specify the NUMPARTS, MAXPARTITIONS, or LOB clause.

The following values are valid:

- |            |              |
|------------|--------------|
| <b>1G</b>  | 1 gigabyte   |
| <b>2G</b>  | 2 gigabytes  |
| <b>4G</b>  | 4 gigabytes  |
| <b>8G</b>  | 8 gigabytes  |
| <b>16G</b> | 16 gigabytes |
| <b>32G</b> | 32 gigabytes |
| <b>64G</b> | 64 gigabytes |

To specify a value greater than 4G, the following conditions must be true:

- DB2 is running with DFSMS Version 1 Release 5.
- The data sets for the table space are associated with a DFSMS data class that has been specified with extended format and extended addressability.

If NUMPARTS is also specified, the maximum size of each partition depends on the value of NUMPARTS, as shown in the following table. Otherwise, the maximum size of each partition is 4G.

*Table 101. Maximum partition size depending on value of NUMPARTS (assuming that LARGE is not specified)*

Value of NUMPARTS	Maximum partition size (default for DSSIZE)
1 to 16	4GB (4G)
17 to 32	2GB (2G)
33 to 64	1GB (1G)
65 to 256	4GB (4G)

If NUMPARTS is greater than 256, the maximum partition size (and the default for DSSIZE) depends on the page size of the table space, as shown in the following table. If DSSIZE is explicitly specified, the maximum partition size can be 64GB when NUMPARTS 34 is specified (i.e. if DSSIZE 64GB is specified, the maximum NUMPARTS can be 256 for a 4K page size partitioned table). For a 8K page size table, the maximum number of NUMPARTS can be 512 if DSSIZE is set to 64GB.

*Table 102. Maximum partition size depending on page size (assuming that LARGE is not specified)*

Page size	Maximum partition size (default for DSSIZE)
4K	4GB (4G)
8K	8GB (8G)
16K	16GB (16G)
32K	32GB (32G)

The partition size shown is not necessarily the actual number of bytes used or allocated for any one partition; it is the largest number that can be logically addressed. Each partition occupies one data set.

For LOB table spaces, if DSSIZE is not specified, the default for the maximum size of each data set is 4GB. The maximum number of data sets is 254.

#### **MAXPARTITIONS integer**

Specifies that the table space is a partition-by-growth table space. The data set for the first partition is allocated unless the DEFINE NO clause is specified for the partition. The data sets for additional partitions are not allocated until they are needed.

*integer* specifies the maximum number of partitions to which the table space can grow. *integer* must be in the range of 1 to 4096, depending on the corresponding value of the DSSIZE clause. The following table shows the maximum value for MAXPARTITIONS in relation to the page size or DSSIZE value for the table space.

*Table 103. Maximum value for MAXPARTITIONS given the page size or DSSIZE value for the table space*

DSSIZE value	4K page size	8K page size	16K page size	32K page size
1G - 4G (1 GB to 4 GB)	4096	4096	4096	4096
8G (8 GB)	2048	4096	4096	4096
16G (16 GB)	1024	2048	4096	4096

*Table 103. Maximum value for MAXPARTITIONS given the page size or DSSIZE value for the table space (continued)*

DSSIZE value	4K page size	8K page size	16K page size	32K page size
32G (32 GB)	512	1024	2048	4096
64G (64 GB)	256	512	1024	2048

MAXPARTITIONS should not be specified for a table space that is in a work file database.

#### **MEMBER CLUSTER**

Specifies that data inserted by an insert operation is not clustered by the implicit clustering index (the first index) or the explicit clustering index. Instead, DB2 chooses where to locate the data in the table space based on available space.

Do not specify MEMBER CLUSTER for segmented table spaces.

Do not specify MEMBER CLUSTER for a LOB table space, a universal table space, or a table space in a work file database.

#### **NUMPARTS integer**

Indicates that the table space is partitioned. If SEGSIZE is also specified, the table space is a range-partitioned universal table space.

*integer* is the number of partitions, and can range from 1 to 4096 inclusive. NUMPARTS must be specified if DSSIZE is specified and LOB is omitted, or if LARGE is specified.

The maximum size of each partition depends on the value that is specified for DSSIZE or LARGE. If DSSIZE or LARGE is not specified, the number of partitions that are specified determines the maximum size of each partition. For a summary of the values for the maximum size of each partition, see Table 101 on page 1138 and Table 102 on page 1138.

The maximum number of partitions that a table space can have depends on the page size and DSSIZE. The total table space size depends on how many partitions it has and DSSIZE. Page size affects table size because it affects how many partitions a table space can have. The following table shows the maximum number of partitions for DSSIZE and page size and total table space size for both EA-enabled (extended addressability) and non-EA-enabled data sets. (Specifying a DSSIZE greater than 4GB requires EA-enabled data sets.)

*Table 104. Table space size given page size and partitions*

Type of RID	Page size	DSSIZE	Maximum number of partitions	Total table space size
5-byte EA	4KB	1GB	4096	4TB
5-byte EA	4KB	2GB	4096	8TB
5-byte EA	4KB	4GB	4096	16TB
5-byte EA	4KB	8GB	2048	16TB
5-byte EA	4KB	16GB	1024	16TB
5-byte EA	4KB	32GB	512	16TB
5-byte EA	4KB	64GB	256	16TB
5-byte EA	8KB	1GB	4096	4TB
5-byte EA	8KB	2GB	4096	8TB

Table 104. Table space size given page size and partitions (continued)

Type of RID	Page size	DSSIZE	Maximum number of partitions	Total table space size
5-byte EA	8KB	4GB	4096	16TB
5-byte EA	8KB	8GB	4096	32TB
5-byte EA	8KB	16GB	2048	32TB
5-byte EA	8KB	32GB	1024	32TB
5-byte EA	8KB	64GB	512	32TB
5-byte EA	16KB	1GB	4096	4TB
5-byte EA	16KB	2GB	4096	8TB
5-byte EA	16KB	4GB	4096	16TB
5-byte EA	16KB	8GB	4096	32TB
5-byte EA	16KB	16GB	4096	64TB
5-byte EA	16KB	32GB	2048	64TB
5-byte EA	16KB	64GB	1024	64TB
5-byte EA	32KB	1GB	4096	4TB
5-byte EA	32KB	2GB	4096	8TB
5-byte EA	32KB	4GB	4096	16TB
5-byte EA	32KB	8GB	4096	32TB
5-byte EA	32KB	16GB	4096	64TB
5-byte EA	32KB	32GB	4096	128TB
5-byte EA	32KB	64GB	2048	128TB
5-byte (non-EA) LARGE	4KB	(4GB)	4096	16TB

If you omit NUMPARTS, the table space is segmented with a SEGSIZE of 4, LOCKSIZE ANY (unless it is explicitly specified), is not partitioned, and initially occupies one data set.

Do not specify NUMPARTS for a LOB table space, a table space in a work file database, or a partition-by-growth table space.

#### PARTITION *integer*

Specifies to which partition the following *using-block* or *free-block* applies. *integer* can range from 1 to the number of partitions given by NUMPARTS.

You can code the PARTITION clause (and any *using-block* or *free-block* that follows it) as many times as needed. If you use the same partition number more than once, only the last specification for that partition is used.

#### BUFFERPOOL *bpname*

Identifies the buffer pool to be used for the table space and determines the page size of the table space. For 4KB, 8KB, 16KB and 32KB page buffer pools, the page sizes are 4 KB, 8 KB, 16 KB, and 32 KB, respectively. The *bpname* must identify an activated buffer pool, and the privilege set must include SYSADM or SYSCTRL authority, or the USE privilege on the buffer pool. If the table space is to be created in a work file database, you cannot specify 8KB and 16KB buffer pools.

If you do not specify the BUFFERPOOL clause, the default buffer pool of the database is used unless the table space that is being created is a LOB table space. If you do not specify the BUFFERPOOL clause and the table space that is being created is a LOB table space, the default buffer pool is the buffer pool that is specified in the DEFAULT BUFFER POOL FOR USER LOB DATA field on installation panel DSNTIP1.

See “Naming conventions” on page 51 for more details about *bpname*. See *DB2 Command Reference* for a description of active and inactive buffer pools.

#### **LOCKSIZE**

Specifies the size of locks used within the table space and, in some cases, also the threshold at which lock escalation occurs. Do not use this clause for a table space in a work file database.

##### **ANY**

Specifies that DB2 can use any lock size.

In most cases, DB2 uses LOCKSIZE PAGE LOCKMAX SYSTEM for non-LOB table spaces and LOCKSIZE LOB LOCKMAX SYSTEM for LOB table spaces. However, when the number of locks acquired for the table space exceeds the maximum number of locks allowed for a table space (an installation parameter), the page or LOB locks are released and locking is set at the next higher level. If the table space is segmented, the next higher level is the table. If the table space is nonsegmented, the next higher level is the table space.

If the table space is implicitly created, DB2 uses LOCKSIZE ROW.

#### **TABLESPACE**

Specifies table space locks.

#### **TABLE**

Specifies table locks. Use TABLE only for a segmented table space. Do not use TABLE for a universal table space.

#### **PAGE**

Specifies page locks. Do not use PAGE for a LOB table space.

#### **ROW**

Specifies row locks. Do not use ROW for a LOB table space.

#### **LOB**

Specifies LOB locks. Use LOB only for a LOB table space.

#### **LOCKMAX**

Specifies the maximum number of page, row, or LOB locks an application process can hold simultaneously in the table space. If a program requests more than that number, locks are escalated. The page, row, or LOB locks are released and the intent lock on the table space or segmented table is promoted to S or X mode. If you specify LOCKMAX for a table space in a work file database, DB2 ignores the value because these types of locks are not used.

##### *integer*

Specifies the number of locks allowed before escalating, in the range 0 to 2 147 483 647.

Zero (0) indicates that the number of locks on the table or table space are not counted and escalation does not occur.

#### **SYSTEM**

Indicates that the value of LOCKS PER TABLE(SPACE), on installation

panel DSNTIPJ, specifies the maximum number of page, row, or LOB locks a program can hold simultaneously in the table or table space.

The following table summarizes the results of specifying a LOCKSIZE value while omitting LOCKMAX.

LOCKSIZE	Resultant LOCKMAX
ANY	SYSTEM
TABLESPACE, TABLE, PAGE, ROW, or LOB	

If the lock size is TABLESPACE or TABLE, LOCKMAX must be omitted, or its operand must be 0.

For an application that uses Sysplex query parallelism, a lock count is maintained on each member.

#### CLOSE

When the limit on the number of open data sets is reached, specifies the priority in which data sets are closed.

##### YES

Eligible for closing before CLOSE NO data sets. This is the default unless the table space is in a work file database.

**NO** Eligible for closing after all eligible CLOSE YES data sets are closed.

For a table space in a work file database, DB2 uses CLOSE NO regardless of the value specified.

#### COMPRESS

Specifies whether data compression applies to the rows of the table space or partition. Do not specify COMPRESS for a LOB table space or a table space in a work file database.

For partitioned table spaces, the COMPRESS attribute for each partition is the value from the first of the following conditions that apply:

- The value specified in the COMPRESS clause in the PARTITION clause for the partition
- The value specified in the COMPRESS clause that is not in any PARTITION clause
- An implicit COMPRESS NO by default.

See *DB2 Performance Monitoring and Tuning Guide* for more information about data compression.

##### YES

Specifies data compression. The rows are not compressed until the LOAD or REORG utility is run on the table in the table space or partition. If COMPRESS YES is specified, the table space is created with basic row format.

**NO** Specifies no data compression for the table space or partition.

#### CCSID *encoding-scheme*

Specifies the encoding scheme for tables stored in the table space.

If you do not specify a CCSID when it is allowed, the default is the encoding scheme of the database in which the table space resides, except for table spaces

in database DSNDB04; for table spaces in DSNDB04, the default is the value of field DEF ENCODING SCHEME on installation panel DSNTIPE.

**ASCII** Specifies that the data is to be encoded using ASCII CCSIDs. If the database in which the table space is to reside is already defined as ASCII, the ASCII CCSIDs associated with that database are used. Otherwise, the default ASCII CCSIDs of the server are used.

**EBCDIC**

Specifies that the data is to be encoded using EBCDIC CCSIDs.

**UNICODE**

Specifies that the data is to be encoded using the UNICODE CCSIDs of the server.

Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or Unicode data is used.

All data stored within a table space must use the same encoding scheme unless the table space is in a work file database.

Do not specify CCSID for a LOB table space or a table space in a work file database. The encoding scheme for a LOB table space is inherited from the base table space. A table space in a work file database does not have an associated encoding scheme because the table space can contain created and declared temporary tables with a mixture of encoding schemes.

**MAXROWS *integer***

Specifies the maximum number of rows that DB2 will consider placing on each data page. The integer can range from 1 through 255. This value is considered for insert operations, LOAD, and REORG. For LOAD and REORG (which do not apply for a table space in the work file database), the PCTFREE specification is considered before MAXROWS; therefore, fewer rows might be stored than the value you specify for MAXROWS.

If you do not specify MAXROWS, the default number of rows is 255.

Do not use MAXROWS for a LOB table space or a table space in a work file database.

**SEGSIZE *integer***

Specifies that the table space will be a segmented or a universal table space depending on the specification of the MAXPARTITIONS or NUMPARTS clauses. *integer* specifies the number of pages that are to be assigned to each segment of the table space. *integer* must be a multiple of 4 between 4 and 64 (inclusive). Do not specify SEGSIZE for a LOB table space. The type of table space is determined by the SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses as shown in the following table:

*Table 105. Type of table space depending on value of SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses*

SEGSIZE clause	MAXPARTITIONS clause	NUMPARTS clause	Type of table space
specified	specified	not specified	partition-by-growth table space
specified	not specified	not specified	segmented table space
specified	not specified	specified	range-partitioned universal table space

*Table 105. Type of table space depending on value of SEGSIZE, MAXPARTITIONS, and NUMPARTS clauses (continued)*

SEGSIZE clause	MAXPARTITIONS clause	NUMPARTS clause	Type of table space
not specified	specified	not specified	partition-by-growth table space with an implicit specification of SEGSIZE 4
not specified	not specified	not specified	segmented table space with an implicit specification of SEGSIZE 4
not specified	not specified	specified	partitioned table space

If you specify SEGSIZE with NUMPARTS, the table space will be created as a range-partitioned universal table space. If SEGSIZE is specified with MAXPARTITIONS, the table space will be created as a partition-by-growth universal table space. See *DB2 Administration Guide* for information about universal table spaces.

## Notes

**Segmented table spaces:** If neither LOB, NUMPARTS, nor SEGSIZE are specified, the table space that is created is a segmented table space. See *DB2 Administration Guide* for a discussion of types of table spaces.

**Universal table spaces:** If NUMPARTS and SEGSIZE are specified, the table space that is created is a range-partitioned universal table space. If MAXPARTITIONS or MAXPARTITIONS and SEGSIZE are specified, the table space that is created is a partition-by-growth universal table space. See *DB2 Administration Guide* for information about universal table spaces. If a range-partitioned universal table space contains an XML column, the corresponding XML table space will be range-partitioned universal as well.

**Table spaces in a work file database:** The following restrictions apply to table spaces created in a work file database:

- They can be created for another member only if both the executing DB2 subsystem and the other member can access the work file data sets. That is required whether the data sets are user-managed or in a DB2 storage group.
- They cannot use 8 KB or 16 KB page sizes. (The buffer pool in which you define the table space determines the page size. For example, a table space that is defined in a 4 KB buffer pool has 4 KB page sizes.)
- When you create a table space in a work file database, the following clauses are not allowed:

CCSID	LARGE	MAXPARTITIONS
COMPRESS	LOB	MEMBER CLUSTER
DEFINE NO	LOCKPART	NOT LOGGED
FREEPAGE	LOCKSIZE	NUMPARTS
GBPCACHE	LOGGED	PCTFREE
	MAXROWS	TRACKMOD

**Table spaces for declared temporary tables:** Declared temporary tables and sensitive static scrollable cursors must reside in segmented table spaces in the work file database. At least one table space with a 32KB page size must exist in the work file database before a declared temporary table can be defined and used or before sensitive static scrollable cursors are opened.

Table spaces in the work file database are shared by work files, created and declared global temporary tables and sensitive static scrollable cursor result tables. You cannot specify which table space is to be used for any specific object.

When you create table spaces in the work file database, it is recommended that you give each table space the same segment size, with the same minimum primary and secondary space allocation values for the data sets, to maximize the use of all the table spaces for all objects in all application processes.

**Creating LOB table spaces:** When you create a LOB table space, the following clauses are not allowed:

CCSID	LOCKSIZE PAGE	PCTFREE
COMPRESS	LOCKSIZE ROW	SEGSIZE
FREEPAGE	MAXPARTITIONS	TRACKMOD
LOCKSIZE TABLE	NUMPARTS	

**Recommended GBPCACHE setting for LOB table spaces:** For LOB table spaces, use the GBPCACHE CHANGED option instead of the GBPCACHE SYSTEM option. Due to the usage patterns of LOBs, the use of GBPCACHE CHANGED can help avoid excessive and synchronous writes to disk and the group buffer pool.

**Altering the logging attribute of a table space:** See “Notes” on page 852 of “ALTER TABLESPACE” on page 841 for information about altering the logging attributes of a table space.

**Table space row formats:** Depending on the value of the SPRMRRF subsystem parameter, newly created table spaces will be in either re-ordered row format or basic row format. When the value of the SPRMRRF parameter is ENABLE, table spaces will be created in re-ordered row format. When the value of the SPRMRRF parameter is DISABLE, newly created table spaces will be created in basic row format. This includes universal table spaces, except for XML table spaces, which are always created in re-ordered row format, regardless of the value of the SPRMRRF parameter.

**Making a partitioned table space larger:** Depending on the needs of your application, you might need to increase the size of a partitioned table space to hold more data by either adding more partitions or by increasing the size of the existing partitions:

- To add more partitions, use the ALTER TABLE statement with the ADD PARTITION clause.
- To increase the size of the partitions, use the following steps:
  1. Unload the data rows from the table space, if necessary.
  2. Drop the table space. The table and any indexes, views, or synonyms dependent on the table are dropped, and authorizations for the table and views are revoked.

3. Recreate the table space (specifying an appropriate value for the DSSIZE clause), the table (create the partitioning scheme for the table using either table-controlled or index-controlled partitioning), and the necessary indexes.
4. Recreate views and synonyms. Reestablish appropriate authorizations.
5. Load data into the new table.
6. Rebind any plans and packages that have changed.

**Redistributing data between existing partitions:** If you need to redistribute the data between the existing partitions to make better use of the space within the existing table, you can use either of these two methods:

- Use the ALTER TABLE statement with the ALTER PARTITION clause. You can alter the partitions to specify new partition boundaries to explicitly specify how to redistribute the data. Any affected partitions are set to REORG-pending status.
- Use the REORG utility with the REBALANCE keyword. REBALANCE specifies that the data is evenly redistributed across the partitions that are reorganized. See *DB2 Utility Guide and Reference* for information about using the REORG utility.

**Rules for primary and secondary space allocation:** You can specify the primary and secondary space allocation for table spaces and indexes or allow DB2 to choose them. Having DB2 choose the values, especially the secondary space quantity, increases the possibility of reaching the maximum data set size before running out of extents.

In the following rules that describe how allocation works, these terms are used:

#### PRIQTY, SECQTY

The keywords for CREATE TABLESPACE, ALTER TABLESPACE, CREATE INDEX, and ALTER INDEX.

##### *specified-priqty*

The user-specified value for PRIQTY.

##### *specified-secqty*

The user-specified value for SECQTY.

##### *actual-priqty*

The actual primary space allocation, in kilobytes.

##### *actual-priqty-cylinders*

The actual primary space allocation, in cylinders.

##### *actual-secqty*

The actual secondary space allocation, in kilobytes.

##### *actual-secqty-cylinders*

The actual secondary space allocation, in cylinders.

##### *calculated-extent-cylinders*

A value that is calculated by DB2 using a *sliding scale*. A sliding scale means that the first secondary extent allocations are smaller than later secondary allocations. For example, Figure 19 on page 1147 shows the sliding scale of secondary extent allocations that DB2 uses for a 64-GB data set. The size of each secondary extent is larger for each secondary extent that is allocated up to the 127th extent. For the 127th secondary extent and any subsequent extents, the secondary size allocation is 559 cylinders.

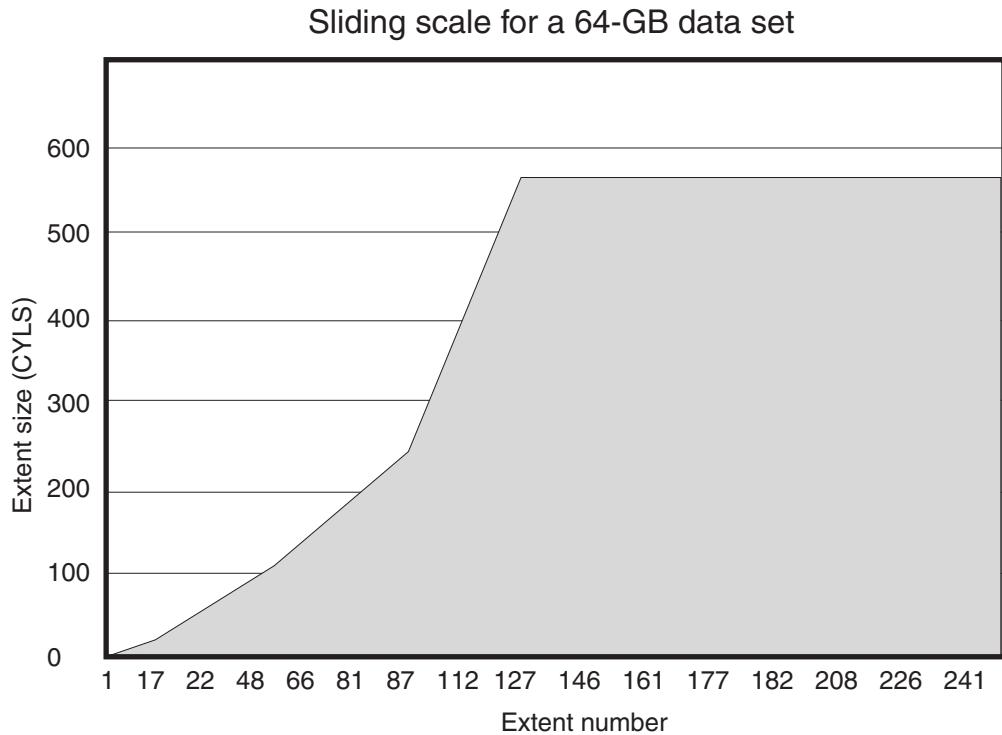

Figure 19. Sliding scale allocation of secondary extents for a 64 GB data set

The rules are:

- **Rule 1 (for primary space allocation)**

If PRIQTY is specified and *specified-priqty* is not equal to -1, *actual-priqty* is at least *specified-priqty* KB.

If PRIQTY is not specified or *specified-priqty* is equal to -1, *actual-priqty* is determined as follows:

- For a table space, if the TSQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of TSQTY.  
If the TSQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder for a non-LOB table space. *actual-priqty* is 10 cylinders for a LOB table space.
- For an index, if the IXQTY subsystem parameter value is specified and is greater than 0, *actual-priqty* is at least the value of IXQTY.  
If the IXQTY subsystem parameter is not specified or is 0, *actual-priqty* is one cylinder.

- **Rule 2 (for secondary space allocation)**

If SECQTY is not specified, the following formulas determine *actual-secqty*:

- If the maximum size of a data set in the table space or index is less than 32 GB, the formula is:  

$$\text{actual-secqty-cylinders} = \text{MAX}(0.1 * \text{actual-priqty-cylinders}, \text{MIN}(\text{calculated-extent-cylinders}, 127))$$
- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:  

$$\text{actual-secqty-cylinders} = \text{MAX}(0.1 * \text{actual-priqty-cylinders}, \text{MIN}(\text{calculated-extent-cylinders}, 559))$$

- **Rule 3 (for secondary space allocation)**

If SECQTY is 0, *actual-secqty* is 0.

- **Rule 4 (for secondary space allocation)**

This is the only rule that depends on the value of subsystem parameter MGEXTSZ (field OPTIMIZE EXTENT on installation panel DSNTIP7).

If MGEXTSZ is YES:

- If SECQTY is specified and *specified-secqty* is not equal to -1 or 0, the following formulas determine *actual-secqty*:

- If the maximum size of a data set in the table space or index is less 32 GB, the formula is:

$$\text{actual-secqty-cylinders} = \text{MAX}(\text{MIN}(\text{calculated-extent-cylinders}, 127), \text{specified-secqty-cylinders})$$

- If the maximum size of a data set in the table space or index is 32 GB or greater, the formula is:

$$\text{actual-secqty-cylinders} = \text{MAX}(\text{MIN}(\text{calculated-extent-cylinders}, 559), \text{specified-secqty-cylinders})$$

If MGEXTSZ is NO:

- For a table space, if SECQTY is *n*, the secondary space allocation is at least *n* kilobytes, with the following exceptions:

- If SECQTY is greater than 4194304, *n* is 4194304 kilobytes.

- For LOB table spaces:

- For 4KB page sizes, if *integer* is greater than 0 and less than 200, *n* is 200.

- For 8KB page sizes, if *integer* is greater than 0 and less than 400, *n* is 400.

- For 16KB page sizes, if *integer* is greater than 0 and less than 800, *n* is 800.

- For 32KB page sizes, if *integer* is greater than 0 and less than 1600, *n* is 1600.

- For any page size, if *integer* is greater than 4194304, *n* is 4194304.

- For an index, if SECQTY is *integer*, the secondary space allocation is at least *n* kilobytes, where *n* is:

**12**      If SECQTY and PRIQTY are omitted

**4194304**

    If *integer* is greater than 4194304

*integer*    If *integer* is not greater than 4194304

**Alternative syntax and synonyms:** For compatibility with previous releases of DB2, the following keywords are supported:

- You can specify the LOCKPART clause, but it has no effect. Starting with Version 8, DB2 treats all table spaces as if they were defined as LOCKPART YES. LOCKPART YES specifies the use of selective partition locking. When all the conditions for selective partition locking are met, DB2 locks only the partitions that are accessed. When the conditions for selective partition locking are not met, DB2 locks every partition of the table space.

If you specify LOCKSIZE TABLESPACE, the table space must be defined with LOCKPART NO. LOCKSIZE TABLESPACE and LOCKPART YES are mutually exclusive.

- When creating a partitioned table space, you can specify PART as a synonym for PARTITION.
- When specifying the logging attributes for a table space, you can specify LOG YES as a synonym for LOGGED, and you can specify LOG NO as a synonym for NOT LOGGED.

Although these keywords are supported as alternatives, they are not the preferred syntax.

## Examples

*Example 1:* Create table space DSN8S91D in database DSN8D91A. Let DB2 define the data sets, using storage group DSN8G910. The primary space allocation is 52 kilobytes; the secondary, 20 kilobytes. The data sets need not be erased before they are deleted.

Locking on tables in the space is to take place at the page level. Associate the table space with buffer pool BP1. The data sets can be closed when no one is using the table space.

```
CREATE TABLESPACE DSN8S91D
  IN DSN8D91A
  USING STOGROUP DSN8G910
    PRIQTY 52
    SECQTY 20
    ERASE NO
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE YES;
```

For the above example, the underlying data sets for the table space will be created immediately, which is the default (DEFINE YES). If you want to defer the creation of the data sets until data is first inserted into the table space, you would specify DEFINE NO instead of accepting the default behavior.

*Example 2:* Assume that a large query database application uses a table space to record historical sales data for marketing statistics. Create large table space SALESHX in database DSN8D91A for the application. Create it with 82 partitions, specifying that the data in partitions 80 through 82 is to be compressed.

Let DB2 define the data sets for all the partitions in the table space, using storage group DSN8G910. For each data set, the primary space allocation is 4000 kilobytes, and the secondary space allocation is 130 kilobytes. Except for the data set for partition 82, the data sets do not need to be erased before they are deleted.

Locking on the table is to take place at the page level. There can only be one table in a partitioned table space. Associate the table space with buffer pool BP1. The data sets cannot be closed when no one is using the table space. If there are no CLOSE YES data sets to close, DB2 might close the CLOSE NO data sets when the DSMAX is reached.

```
CREATE TABLESPACE SALESHX
  IN DSN8D91A
  USING STOGROUP DSN8G910
    PRIQTY 4000
    SECQTY 130
    ERASE NO
  NUMPARTS 82
  (PARTITION 80
    COMPRESS YES,
    PARTITION 81
    COMPRESS YES,
    PARTITION 82
    COMPRESS YES
    ERASE YES)
  LOCKSIZE PAGE
  BUFFERPOOL BP1
  CLOSE NO;
```

*Example 3:* Assume that a column named EMP\_PHOTO with a data type of BLOB(110K) has been added to the sample employee table for each employee's photo. Create LOB table space PHOTOLTS in database DSN8D91A for the auxiliary table that will hold the BLOB data.

Let DB2 define the data sets for the table space, using storage group DSN8G910. For each data set, the primary space allocation is 3200 kilobytes, and the secondary space allocation is 1600 kilobytes. The data sets do not need to be erased before they are deleted. (Because ERASE NO is the default, the clause does not have to be explicitly specified to get the desired behavior.)

```
CREATE LOB TABLESPACE PHOTOLTS
  IN DSN8D91A
  USING STOGROUP DSN8G910
    PRIQTY 3200
    SECQTY 1600
  LOCKSIZE LOB
  BUFFERPOOL BP16K0
  GBPCACHE SYSTEM
  NOT LOGGED
  CLOSE NO;
```

*Example 4:* The following example creates a range-partitioned universal table space, TS1, in database DSN8D91A using storage group DSN8G910. The table space has 16 pages per segment and has 55 partitions. It specifies LOCKSIZE ANY.

```
CREATE TABLESPACE TS1
  IN DSN8D91A
  USING STOGROUP DSN8G910
  NUMPARTS 55
  SEGSIZE 16
  LOCKSIZE ANY;
```

*Example 5:* The following example creates a range-partitioned universal table space, TS2, in database DSN8D91A using storage group DSN8G910. The table space has 64 pages per segment and has seven defer-defined partitions, where every other partition is compressed.

```
CREATE TABLESPACE TS2
  IN DSN8D91A
  USING STOGROUP DSN8G910
  NUMPARTS 7
  (
    PARTITION 1 COMPRESS YES,
    PARTITION 3 COMPRESS YES,
    PARTITION 5 COMPRESS YES,
    PARTITION 7 COMPRESS YES
  )
  SEGSIZE 64
  DEFINE NO;
```

*Example 6:* The following example creates a partition-by-growth table space that has a maximum size of 2 GB for each partition, four pages per segment with a maximum of 24 partitions for the table space.

```
CREATE TABLESPACE TS01TS IN TS01DB USING STOGROUP SG1
  DSSIZE 2G
  MAXPARTITIONS 24
  LOCKSIZE ANY
  SEGSIZE 4;
```

## CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger in a schema and builds a trigger package at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

In defining a trigger on a table, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on the table on which the trigger is defined if any transition variables or transition tables are specified
- The SELECT privilege on any table or view to which the search condition of triggered action refers
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the table, which must include at least one of the following:
  - The TRIGGER privilege on the table on which the trigger is defined
  - The ALTER privilege on the table on which the trigger is defined
  - DBADM authority on the database that contains the table
  - SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

In defining a trigger on a view, the privilege set that is defined below must include SYSADM authority or each of the following:

- The SELECT privilege on any table or view to which the search condition of triggered action refers
- The necessary privileges to invoke the triggered SQL statements in the triggered action
- The authorization to define a trigger on the view, which must include at least one of the following:
  - Ownership of the view on which the trigger is defined
  - SYSCTRL authority

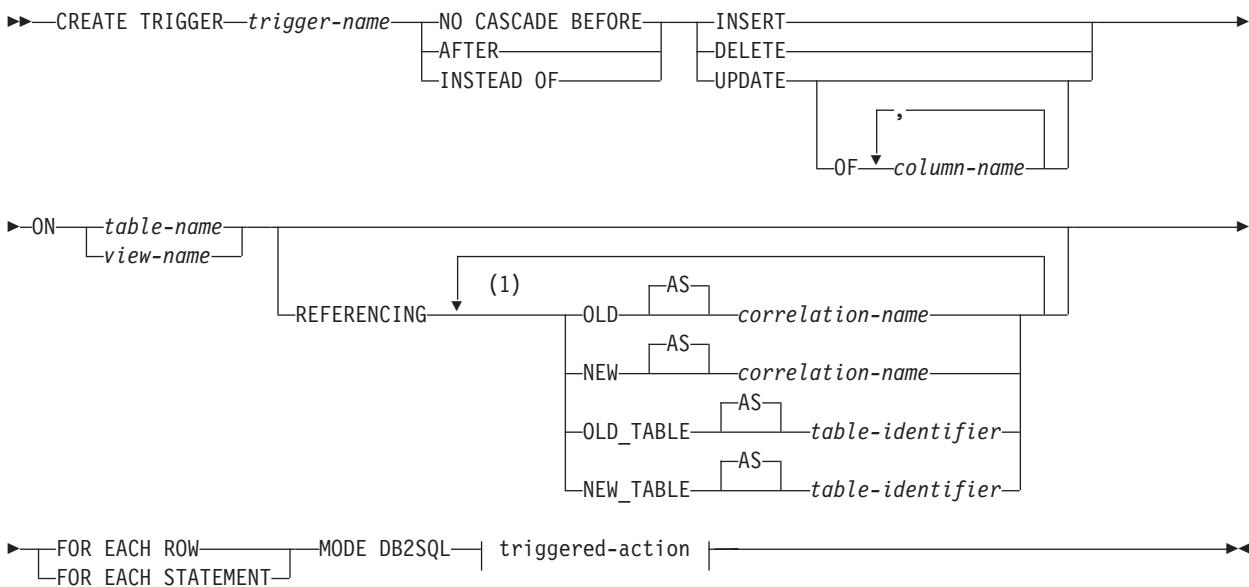

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the

set of privileges that are held by the SQL authorization ID of the process. The specified trigger name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

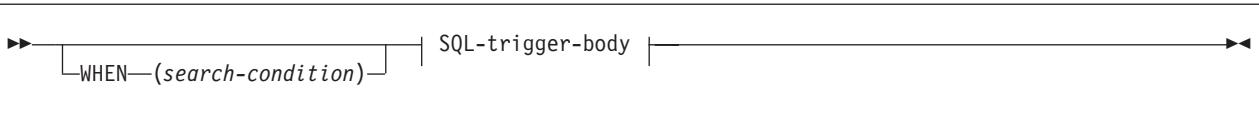

## Syntax

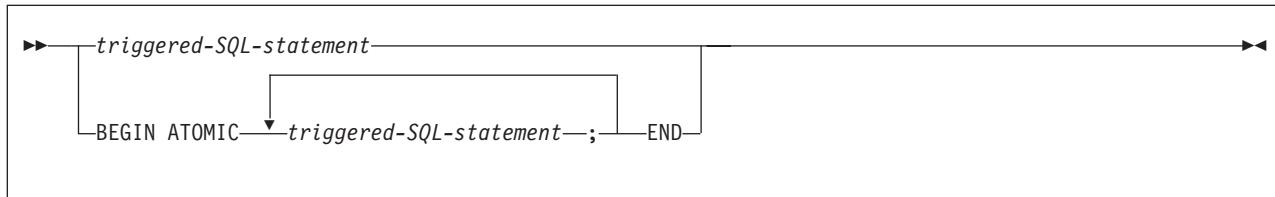

### Notes:

- 1 The same clause must not be specified more than one time.

### triggered-action

### SQL-trigger-body

## Description

*trigger-name*

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger that exists at the current server.

The name is also used to create the trigger package; therefore, the name must also not identify a package that is already described in the catalog. The schema name becomes the collection-id of the trigger package. Although *trigger-name* can be specified as an ordinary or delimited identifier, the name should conform to the rules for an ordinary identifier. Refer to The implicitly created trigger package for additional information.

The schema name must not begin with 'SYS' unless the name is 'SYSADM', or the schema name is 'SYSTOOLS' and the user who executes the CREATE statement has SYSADM or SYSCTRL privilege.

### **NO CASCADE BEFORE**

Specifies that the trigger is a before trigger. DB2 executes the triggered action before it applies any changes caused by an insert, delete, or update operation on the subject table. It also specifies that the triggered action does not activate other triggers because the triggered action of a before trigger cannot contain any updates.

NO CASCADE BEFORE must not be specified when *view-name* is also specified. FOR EACH ROW must be specified for a BEFORE trigger.

### **AFTER**

Specifies that the trigger is an after trigger. DB2 executes the triggered action after it applies any changes caused by an insert, delete, or update operation on the subject table. AFTER must not be specified if *view-name* is also specified.

### **INSTEAD OF**

Specifies that the trigger is an instead of trigger. The associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each type of operation on a given subject view. DB2 executes the triggered-action instead of the insert, update, or delete operation on the subject view.

INSTEAD OF must not be specified when *table-name* is also specified. The WHEN clause can not be specified for an INSTEAD OF trigger. FOR EACH STATEMENT must not be specified for an INSTEAD OF trigger.

### **INSERT**

Specifies that the trigger is an insert trigger. DB2 executes the triggered action whenever there is an insert operation on the subject table. However, if the insert trigger is defined on any explain table, and the insert operation was caused by DB2 adding a row to the table, the triggered action is not to be executed.

### **DELETE**

Specifies that the trigger is a delete trigger. DB2 executes the triggered action whenever there is a delete operation on the subject table.

### **UPDATE**

Specifies that the trigger is an update trigger. DB2 executes the triggered action whenever there is an update operation on the subject table.

If you do not specify a list of column names, an update operation on any column of the subject table, including columns that are subsequently added with the ALTER TABLE statement, activates the triggered action.

**OF** *column-name*,...

Each *column-name* that you specify must be a column of the subject table and must appear in the list only once. An update operation on any of the listed columns activates the triggered action.

UPDATE OF *column-name* cannot be specified for an INSTEAD OF trigger.

**ON** *table-name*

Identifies the subject table of the BEFORE or AFTER trigger definition. The name must identify a base table that exists at the current server. It must not identify a materialized query table, a clone table, a temporary table, an auxiliary table, an alias, a synonym, a real-time statistics table, or a catalog table.

**ON** *view-name*

Identifies the subject view of the INSTEAD OF trigger definition. The name must identify a view that exists at the current server.

*view-name* must not specify a view where any of the following conditions are true:

- The view is defined with the WITH CASCADED CHECK option (a symmetric view)
- The view on which a symmetric view has been defined
- The view references data that is encoded with different encoding schemes or CCSID values
- The view has a column that is a rowid, LOB, or XML (or a distinct type that is defined as one of these types)
- The view has a column that is based on an underlying column that is defined as an identity column, security label column, or a row change timestamp column
- The view has a column that is defined (directly or indirectly) as an expression
- The view has a column that is based on a column of a result table that involves a set operator
- The view has columns that have field procedures
- All of the underlying tables of the view are catalog tables or created global temporary tables
- The view has other views that are dependent on it

**REFERENCING**

Specifies the correlation names for the transition variables and the table names for the transition tables. For the rows in the subject table that are modified by the triggering SQL operation (insert, delete, or update), a correlation name identifies the columns of a specific row. *table-identifiers* identify the complete set of affected rows. Transition variables with XML types cannot be referenced inside of a trigger. If the column of a transition table is referenced, the data type of the column cannot be XML.

Each row that is affected by the triggering SQL operation is available to the triggered action by qualifying column names with *correlation-names* that are specified as follows:

**OLD AS** *correlation-name*

Specifies the correlation name that identifies the values in the row prior to the triggering SQL operation.

**NEW AS** *correlation-name*

Specifies the correlation name that identifies the values in the row as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

The complete set of rows that are affected by the triggering operation is available to the triggered action by using *table-identifiers* that are specified as follows:

**OLD\_TABLE AS** *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows that are modified rows by the triggering SQL operation prior to any actual changes.

**NEW\_TABLE AS** *table-identifier*

Specifies the name of a temporary table that identifies the values in the complete set of rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed.

Only one OLD and one NEW *correlation-name* can be specified for a trigger. Only one OLD\_TABLE and one NEW\_TABLE *table-identifier* can be specified for a trigger. All of the *correlation-names* and *table-identifiers* must be unique from one another.

Table 106 on page 1156 summarizes the allowable combinations of transition variables and transition tables that you can specify for the various trigger types. The OLD *correlation-name* and the OLD\_TABLE *table-identifier* are valid only if the triggering event is either a delete operation or an update operation. For a delete operation, the OLD *correlation-name* captures the values of the columns in the deleted row, and the OLD\_TABLE *table-identifier* captures the values in the set of deleted rows. For an update operation, the OLD *correlation-name* captures the values of the columns of a row before the update operation, and the OLD\_TABLE *table-identifier* captures the values in the set of updated rows.

The NEW *correlation-name* and the NEW\_TABLE *table-identifier* are valid only if the triggering event is either an insert operation or an update operation. For both operations, the NEW *correlation-name* captures the values of the columns in the inserted or updated row and the NEW\_TABLE *table-identifier* captures the values in the set of inserted or updated rows. For BEFORE triggers, the values of the updated rows include the changes from any SET statements in the triggered action of BEFORE triggers.

The OLD and NEW *correlation-name* variables cannot be modified in an AFTER or INSTEAD OF trigger.

Table 106. Allowable combinations of attributes in a trigger definition

Granularity	Activation time	Triggering SQL operation	Transition variables allowed1	Transition tables allowed1
FOR EACH ROW	BEFORE	DELETE	OLD	None
		INSERT	NEW	None
		UPDATE	OLD, NEW	None
	AFTER	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
	INSTEAD OF	DELETE	OLD	OLD_TABLE
		INSERT	NEW	NEW_TABLE
		UPDATE	OLD, NEW	OLD_TABLE, NEW_TABLE
FOR EACH STATEMENT	AFTER	DELETE	None	OLD_TABLE
		INSERT	None	NEW_TABLE
		UPDATE	None	OLD_TABLE, NEW_TABLE

**Note:**

1. If a transition table or variable is referenced where it is not allowed, an error is returned.

A transition variable that has a character data type inherits the subtype and CCSID of the column of the subject table. During the execution of the triggered action, the transition variables are treated like host variables. Therefore, character conversion might occur. However, unlike a host variable, a transition variable can have the bit data attribute, and character conversion never occurs for bit data. A transition variable is considered to be bit data if the column of the table to which it corresponds is bit data.

You cannot modify a transition table; transition tables are read-only. Although a transition table does not inherit any edit or validation procedures from the subject table, it does inherit the encoding scheme and field procedures of the subject table.

The scope of each *correlation-name* and each *table-identifier* is the entire trigger definition.

**FOR EACH ROW or FOR EACH STATEMENT**

Specifies the conditions for which DB2 executes the triggered action.

**FOR EACH ROW**

Specifies that DB2 executes the triggered action for each row of the subject table that the triggering SQL operation modifies. If the triggering SQL operation does not modify any rows, the triggered action is not executed.

**FOR EACH STATEMENT**

Specifies that DB2 executes the triggered action only one time for the triggering operation. Even if the triggering operation does not modify or delete any rows, the triggered action is executed one time.

FOR EACH STATEMENT must not be specified for a BEFORE or INSTEAD OF trigger.

**MODE DB2SQL**

Specifies the mode of the trigger. MODE DB2SQL triggers are activated after all of the row operations have occurred.

*triggered-action*

Specifies the action to be performed when the trigger is activated. The *triggered-action* is composed of one or more SQL statements and an optional condition that controls whether the statements are executed.

**WHEN (*search-condition*)**

Specifies a condition that evaluates to true, false, or unknown. The triggered SQL statements are executed only if the *search-condition* evaluates to true. If the WHEN clause is omitted, the associated SQL statements are always executed. The condition for a before trigger must not include a subselect that references the subject table.

The WHEN clause must not be specified for an INSTEAD OF trigger.

*SQL-trigger-body*

Specifies the SQL statements that are to be executed for the triggered action.

*triggered-SQL-statement*

Specifies a single SQL statement that is to be executed for the triggered action.

**BEGIN ATOMIC *triggered-SQL-statement*,... END**

Specifies a list of SQL statements that are to be executed for the triggered action. The statements are executed in the order in which they are specified.

SQL processor programs, such as SPUFI, the command line processor, and DSNTEP2, might not correctly parse SQL statements in the triggered action that are ended with semicolons. These processor programs accept multiple SQL statements, each separated with a terminator character, as input. Processor programs that use a semicolon as the SQL statement terminator can truncate a CREATE TRIGGER statement with embedded semicolons and pass only a portion of it to DB2. Therefore, you might need to change the SQL terminator character for these processor programs. For information on changing the terminator character for SPUFI and DSNTEP2, see *DB2 Application Programming and SQL Guide*.

Only certain SQL statements can be specified in the *SQL-trigger-body*. Table 107 shows the list of allowable SQL statements, which differs depending on whether the trigger is being defined as BEFORE, AFTER, or INSTEAD OF. An 'X' in the table indicates that the statement is valid.

Table 107. Allowable SQL statements

SQL statement	Trigger activation time		
	BEFORE	AFTER	INSTEAD OF
CALL	X	X	X
DELETE (searched)		X	X
fullselect	X	X	X
INSERT		X	X
MERGE		X	X
REFRESH TABLE		X	X

Table 107. Allowable SQL statements (continued)

SQL statement	Trigger activation time		
	BEFORE	AFTER	INSTEAD OF
SET transition variable	X		
SIGNAL	X	X	X
UPDATE (searched)		X	X
VALUES	X	X	X

The statements in the triggered action have these restrictions:

- They must not refer to host variables, parameter markers, undefined transition variables, or declared temporary tables.
- They must only refer to a table or view that is at the current server.
- They must only invoke a stored procedure or user-defined function that is at the current server. An invoked routine can, however, access a server other than the current server.
- They must not contain a fullselect that refers to the subject table if the trigger is defined as BEFORE.

The triggered action can refer to the values in the set of affected rows. This action is supported through the use of transition variables and transition tables.

Transition variables use the names of the columns in the subject table qualified by a specified name that identifies whether the reference is to the old value (before the update) or the new value (after the update). A transition variable can be referenced in *search-condition* or *triggered-SQL-statement* of the triggered action wherever a host variable is allowed in the statement if it were issued outside the body of a trigger.

Transition tables can be referenced in the triggered action of an after trigger. Transition tables are read-only. Transition tables also use the name of the columns of the subject table but have a name specified that allows the complete set of affected rows to be treated as a table. The name of the transition table can be referenced in *triggered-SQL-statement* of the triggered action whenever a table name is allowed in the statement if it were issued outside the body of a trigger. The name of the transition table can be specified in *search-condition* or *triggered-SQL-statement* of the triggered action whenever a column name is allowed in the statement if it were issued outside the body of a trigger.

In addition, a transition table can be passed as a parameter to a user-defined function or procedure specifying the TABLE keyword before the name of the transition table. When the function or procedure is invoked, a table locator is passed for the transition table.

A transition variable or transition table is not affected after being returned from a procedure invoked from within a triggered action regardless of whether the corresponding parameter was defined in the CREATE PROCEDURE statement as IN, INOUT, or OUT.

## Notes

### Owner privileges:

When an INSTEAD OF trigger is defined, the associated privilege (INSERT, UPDATE, or DELETE on the view) is given to the owner of the view. The

| owner is granted the privilege with the ability to grant that privilege to others. For more information about ownership of an object, see “Authorization, privileges, and object ownership” on page 60.

**Execution authorization:**

The user executing the triggering SQL operation does not need authority to execute a triggered-SQL-statement. A triggered-SQL-statement will execute using the authority of the owner of the trigger.

**Activating a trigger:**

Only insert, delete, or update operations can activate a trigger. The activation of a trigger might cause trigger cascading. *Trigger cascading* is the result of the activation of one trigger that executes SQL statements that cause the activation of other triggers or even the same trigger again. The triggered actions might also cause updates as a result of the original modification, which can result in the activation of additional triggers. With trigger cascading, a significant chain of triggers might be activated, causing a significant change to the database as a result of a single insert, delete, or update operation.

Loading a table with the LOAD utility does not activate any triggers that are defined for the table if SHRLEVEL NONE is specified as part of the LOAD utility or if the default SHRLEVEL option for LOAD is taken. If SHRLEVEL CHANGE is specified as part of the LOAD utility, triggers are activated when loading a table with the LOAD utility.

**Adding triggers to enforce constraints:**

Adding a trigger on a table that already has rows in it will not cause the triggered action to be executed. Thus, if the trigger is designed to enforce constraints on the data in the table, the data in the existing rows might not satisfy those constraints.

**Multiple triggers:**

Multiple triggers that have the same triggering SQL operation and activation time can be defined on a table. The triggers are activated in the order in which they were created. For example, the trigger that was created first is executed first; the trigger that was created second is executed second.

**Read-only views:**

The addition of an INSTEAD OF trigger for a view affects the read only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

The creation of an INSTEAD OF trigger causes dependent packages, plans, and statements in the dynamic statement cache to be marked invalid if the view definition is not read-only.

**Invalidation of plans and packages:**

A trigger package becomes invalid if an object or privilege on which it depends is dropped or revoked. The next time the trigger is activated, DB2 attempts to rebind the invalid trigger package. If the automatic rebind is unsuccessful, the trigger package remains invalid.

You cannot create another package from the trigger package, such as with the BIND COPY command. The only way to drop a trigger package is to

drop the trigger or the subject table. Dropping the trigger drops the trigger package; dropping the subject table drops the trigger and the trigger package.

DB2 creates the trigger package with the following initial attributes (some of these attributes can be modified using the REBIND TRIGGER PACKAGE command):

- ACTION(ADD)
- CURRENTDATA(NO)
- DBPROTOCOL(DRDA)
- DEGREE(1)
- DYNAMICRULES(BIND)
- ENABLE(\*)
- ENCODING(0)
- EXPLAIN(NO)
- FLAG(I)
- ISOLATION(CS)
- REOPT(NONE) and NODEFER(PREPARE)
- OWNER(authorization ID) or ROLE of appropriate
- QUERYOPT(1)
- PATH(path)
- RELEASE(COMMIT)
- ROUNDING(value from the CURRENT DECFLOAT ROUNDING MODE special register)
- SQLERROR(NOPACKAGE)
- QUALIFIER(authorization ID)
- VALIDATE(BIND)

The values of OWNER, QUALIFIER, and PATH are set depending on whether the CREATE TRIGGER statement is embedded in a program or issued interactively. If the statement is embedded in a program, OWNER and QUALIFIER are the owner and qualifier of the package or plan. PATH is the value from the PATH bind option. If the statement is issued interactively, both OWNER and QUALIFIER are the SQL authorization ID. PATH is the value in the CURRENT PATH special register.

#### Transition variable values and INSTEAD OF triggers:

The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:

- If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
- If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value

The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:

- If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value
- If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:
  - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
  - otherwise, the null value
- Otherwise, the corresponding new transition variable is the existing value of the column in the row.

#### **Considerations for a MERGE statement:**

The MERGE statement can execute insert and update operations. The applicable INSERT or UPDATE triggers are activated for the MERGE statement when an insert or update operation is executed.

#### **Considerations for implicitly hidden columns:**

In the body of a trigger, a trigger transition variable that corresponds to an implicitly hidden column can be referenced. A trigger transition table, that corresponds to a table with an implicitly hidden column, includes that column as part of the transition table. Likewise, a trigger transition variable will exist for the column that is defined as implicitly hidden. A trigger transition variable that corresponds to an implicitly hidden column can be referenced in the body of a trigger.

#### **Considerations for the special plan, statement, and function tables for EXPLAIN:**

You can create a trigger on PLAN\_TABLE, DSN\_STATEMENT\_TABLE, or DSN\_FUNCTION\_TABLE. However, insert triggers that are defined on these tables are not activated when DB2 adds rows to the tables.

#### **Adding columns to a subject table or a table referenced in the triggered action:**

If a column is added to the subject table after triggers have been defined, the following rules apply:

- If the trigger is an update trigger that was defined without an explicit list of column names, an update to the new column activates the trigger.
- If the subject table is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.
- The OLD\_TABLE and the NEW\_TABLE transition tables contain the new column, but the column cannot be referenced unless the trigger is recreated. If the transition tables are passed to a user-defined function or a stored procedure, the user-defined function or stored procedure must be recreated with the new definition of the table (that is, the function or procedure must be dropped and recreated), and the package for the user-defined function or stored procedure must be rebound.

If a column is added to any table that is referenced in the *triggered-action*, the new column is not accessible to the SQL statements until the trigger package is rebound.

#### **Altering the attributes of a column that the triggered action references:**

If a column is altered in the table on which the trigger is defined (the subject table), the alter is processed, and the dependent trigger packages are invalidated.

#### **Renaming the table for which the trigger is defined, or tables referenced in the triggered action:**

You cannot rename a table for which a trigger is defined (the subject table).

Except for the subject table, you can rename any table to which the SQL statements in the triggered action refer. After renaming such a table, drop the trigger and then re-create the trigger so that it refers to the renamed table.

#### Dependencies when dropping objects and revoking privileges:

The following dependencies apply to a trigger:

- Dropping the subject table (the table on which the trigger is defined) causes the trigger and its package to also be dropped.
- Dropping any table, view, alias, or index that is referenced or used within the SQL statements in the triggered action causes the trigger and its package to be invalidated. Dropping a referenced synonym has no effect.
- Dropping a user-defined function that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Dropping a sequence that is referenced by the SQL statements in the triggered action is not allowed. An error occurs.
- Revoking a privilege on which the trigger depends causes the trigger and its package to be invalidated.

#### Errors executing triggers:

Severe errors that occur during the execution of triggered SQL statements are returned with SQLCODE -901, -906, -911, and -913 and the corresponding SQLSTATE. Non-severe errors raised by a triggered SQL statement that is a SIGNAL statement or that contains a RAISE\_ERROR function are returned with SQLCODE -438 and the SQLSTATE that is specified in the SIGNAL statement or the RAISE\_ERROR condition. Other non-severe errors are returned with SQLCODE -723 and SQLSTATE 09000. Warnings are not returned.

#### Special registers:

The values of the special registers are saved before a trigger is activated and are restored on return from the trigger.

The following table describes how special registers are set on entry to the trigger body. Some of the special registers are applicable only to dynamic SQL. Although dynamic SQL statements are not allowed directly in the triggered SQL statements, they are allowed in a user-defined function or stored procedure that is invoked by the triggered SQL statements.

*Table 108. Rules for the values of special registers in triggers*

Special register	The value is ....
CURRENT DATE	Inherited from the triggering SQL operation (delete, insert, update). All triggered SQL statements, including the SQL statements in a user-defined function or a stored procedure invoked by the trigger, inherit these values.
CURRENT TIME	
CURRENT TIMESTAMP	
CURRENT PACKAGESET	Set to the schema name of the trigger
CURRENT TIMEZONE	Set to the TIMEZONE parameter

*Table 108. Rules for the values of special registers in triggers (continued)*

Special register	The value is ....
• CURRENT CLIENT_ACCTNG	Inherited from the triggering SQL operation
• CURRENT CLIENT_APPLNAME	(delete, insert, update)
• CURRENT CLIENT_USERID	
• CURRENT CLIENT_WRKSTNNNAME	
•	
CURRENT APPLICATION ENCODING SCHEME	
•	
CURRENT DECFLOAT ROUNDING MODE	
• CURRENT DEBUG MODE	
• CURRENT DEGREE	
• CURRENT LC_CTYPE	
•	
CURRENT MAINTAINED TABLE TYPES	
• CURRENT MEMBER	
• CURRENT OPTIMIZATION HINT	
• CURRENT PATH	
• CURRENT PACKAGE PATH	
• CURRENT PRECISION	
• CURRENT REFRESH AGE	
• CURRENT RULES	
• CURRENT SERVER	
• CURRENT SQLID	
• SESSION_USER	

**Result sets for stored procedures:**

If a trigger invokes a stored procedure that returns result sets, the application that activated the trigger cannot access those result sets.

**Transaction isolation:**

All of the statements in the *SQL-trigger-body* run under the isolation level in effect for the trigger.

**Limiting processor time:**

The DB2 resource limit facility allows you to specify the maximum amount of processor time for a dynamic, manipulative SQL statement such as SELECT or SQL data change statements. The execution of a trigger is counted as part of the triggering SQL statement.

**The implicitly created trigger package:**

When you create a trigger, DB2 automatically creates a trigger package with the same name as the trigger name. The collection name of the trigger package is the schema name of the trigger, and the version identifier is the empty string. Multiple versions of a trigger package are not allowed.

Use the REBIND command to explicitly rebind the trigger package. To specify the name of a trigger package for the bind commands, the name must conform to the rules for an ordinary identifier.

**Defining triggers on tables that contain XML columns:**

Although a trigger can be defined on a table that contains an XML column,

an XML column cannot be referenced with a trigger transition variable in the trigger body. An *SQL-procedure-statement* cannot reference a transition variable that is an XML data type.

#### Errors binding triggers:

When a CREATE TRIGGER statement is bound, the SQL statements within the triggered action might not be fully parsed. Syntax errors in those statements might not be caught until the CREATE TRIGGER statement is executed.

#### Alternative syntax and synonyms:

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- OLD TABLE as a synonym for OLD\_TABLE
- NEW TABLE as a synonym for NEW\_TABLE

## Examples

*Example 1:* Create two triggers that track the number of employees that a company manages. The subject table is the EMPLOYEE table, and the triggers increment and decrement a column with the total number of employees in the COMPANY\_STATS table. The tables have these columns:

EMPLOYEE table: ID, NAME, ADDRESS, and POSITION  
COMPANY\_STATS table: NBEMP, NBPRODUCT, and REVENUE

This example shows the use of transition variables in a row trigger to maintain summary data in another table.

Create the first trigger, NEW\_HIRE, so that it increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table, increase the value of column NBEMP in table COMPANY\_STATS by 1.

```
CREATE TRIGGER NEW_HIRE
  AFTER INSERT ON EMPLOYEE
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
    UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
  END
```

Create the second trigger, FORM\_EMP, so that it decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE, decrease the value of column NBEMP in table COMPANY\_STATS by 1.

```
CREATE TRIGGER FORM_EMP
  AFTER DELETE ON EMPLOYEE
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
    UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
  END
```

*Example 2:* Create a trigger, REORDER, that invokes user-defined function ISSUE\_SHIP\_REQUEST to issue a shipping request whenever a parts record is updated and the on-hand quantity for the affected part is less than 10% of its maximum stocked quantity. User-defined function ISSUE\_SHIP\_REQUEST orders a quantity of the part that is equal to the part's maximum stocked quantity minus its on-hand quantity; the function also ensures that the request is sent to the appropriate supplier.

The parts records are in the PARTS table. Although the table has more columns, the trigger is activated only when columns ON\_HAND and MAX\_STOCKED are updated.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW AS NROW
  FOR EACH ROW MODE DB2SQL
  WHEN (NROW.ON_HAND < 0.10 * NROW.MAX_STOCKED)
  BEGIN ATOMIC
    VALUES(ISSUE_SHIP_REQUEST(NROW.MAX_STOCKED - NROW.ON_HAND, NROW.PARTNO));
  END
```

*Example 3:* Repeat the scenario in *Example 2* except use a fullselect instead of a VALUES statement to invoke the user-defined function. This example also shows how to define the trigger as a statement trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW_TABLE AS NTABLE
  FOR EACH STATEMENT MODE DB2SQL
  BEGIN ATOMIC
    SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
      FROM NTABLE
     WHERE (ON_HAND < 0.10 * MAX_STOCKED);
  END
```

*Example 4:* Assume that table EMPLOYEE contains column SALARY. Create a trigger, SAL\_ADJ, that prevents an update to an employee's salary that exceeds 20% and signals such an error. Have the error that is returned with an SQLSTATE of '75001' and a description. This example shows that the SIGNAL statement is useful for restricting changes that violate business rules.

```
CREATE TRIGGER SAL_ADJ
  AFTER UPDATE OF SALARY ON EMPLOYEE
  REFERENCING OLD AS OLD_EMP
           NEW AS NEW_EMP
  FOR EACH ROW MODE DB2SQL
  WHEN (NEW_EMP.SALARY > (OLD_EMP.SALARY * 1.20))
  BEGIN ATOMIC
    SIGNAL SQLSTATE '75001' ('Invalid Salary Increase - Exceeds 20')
  END
```

*Example 5:* Assume that the following statements create a table, WEATHER (which stores temperature values in Fahrenheit), and a view, CELSIUS\_WEATHER for users who prefer to work in Celsius instead of Fahrenheit:

```
CREATE TABLE WEATHER
  (CITY VARCHAR(25),
   TEMPF DECIMAL(5,2));
CREATE VIEW CELSIUS_WEATHER (CITY, TEMPC) AS
  SELECT CITY, (TEMPF-32)/1.8
    FROM WEATHER;
```

The following INSTEAD OF trigger is used on the CELSIUS\_WEATHER view to convert Celsius values to Fahrenheit values and then insert the Fahrenheit value into the WEATHER table:

```
CREATE TRIGGER CW_INSERT INSTEAD OF INSERT
  ON CELSIUS_WEATHER
  REFERENCING NEW AS NEWCW
  FOR EACH ROW MODE DB2SQL
  BEGIN ATOMIC
```

```
|           INSERT INTO WEATHER VALUES  
|           (NEWCW.CITY,  
|           1.8*NEWCW.TEMPC+32)  
|           END;  
  
|
```

---

## CREATE TRUSTED CONTEXT

The CREATE TRUSTED CONTEXT statement defines a trusted context at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

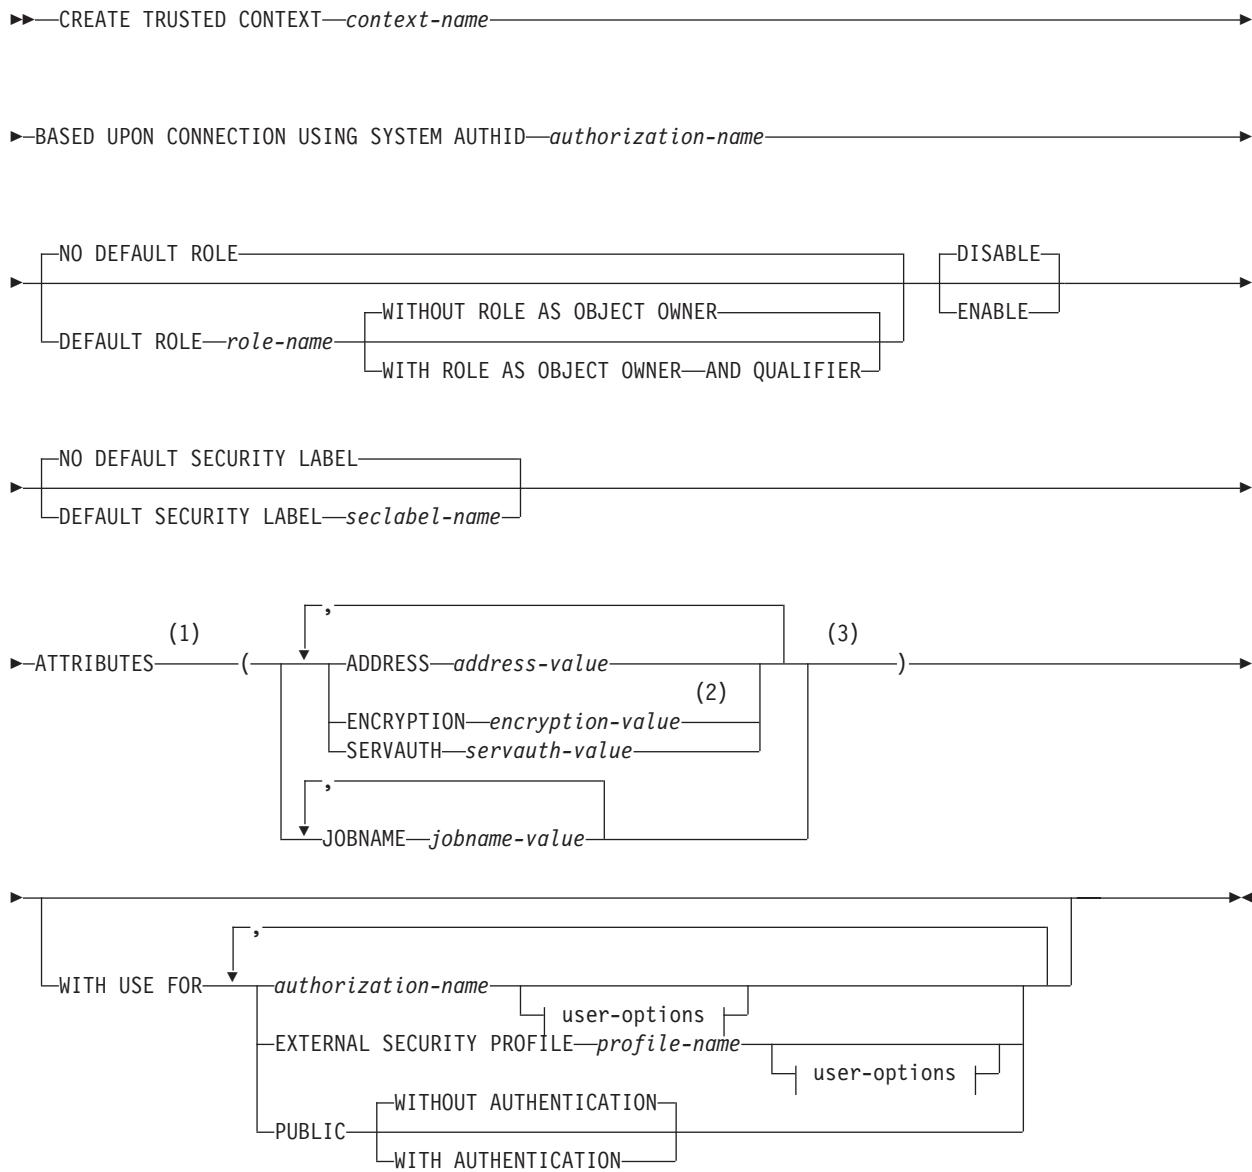

### Authorization

The privilege set that is defined below must include SYSADM authority.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process unless the process is within a trusted context and the ROLE AS OBJECT OWNER clause is specified. In that case, the privilege set is the privileges that are held by the role that is associated with the primary authorization ID of the process.

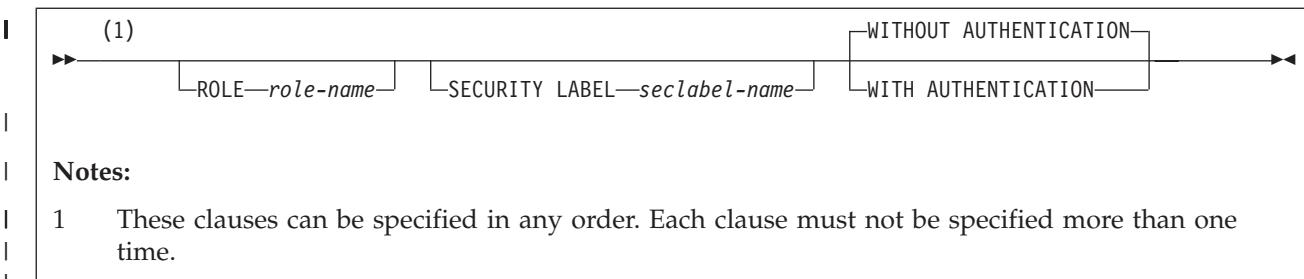

## Syntax

### Notes:

- 1 This clause and the clauses that follow can be specified in any order. Each clause must not be specified more than one time.
- 2 ENCRYPTION must not be specified more than one time.
- 3 Each pair of attribute name and corresponding value must be unique.

**user-options:**

## Description

### *context-name*

Names the trusted context. The name must not identify a trusted context that exists at the current server.

### **BASED UPON CONNECTION USING SYSTEM AUTHID *authorization-name***

Specifies that the context is a connection that is established by the authorization ID that is specified by *authorization-name*. The system authorization ID is the primary authorization ID. For a remote connection, it is derived from the system user ID that is provided by an external entity, such as a middleware server. For a local connection, the system authorization ID is derived depending on the sources, as specified in Table 109.

*Table 109. System authorization ID for a local connection*

Source of local connection	System authorization ID
Started task (RRSAF)	USER parameter on JOB statement or RACF USER.
TSO	TSO logon ID
BATCH	USER parameter on JOB statement

*authorization-name* must not be associated with an existing trusted context.

### **NO DEFAULT ROLE or DEFAULT ROLE *role-name***

Specifies whether a default role is associated with a trusted connection that is based on the specified trusted context.

#### **NO DEFAULT ROLE**

Specifies that the trusted context does not have a default role. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create that object.

NO DEFAULT ROLE is the default.

#### **DEFAULT ROLE *role-name***

Specifies that *role-name* is the role for the trusted context. *role-name* must identify a role that exists at the current server. This role is used with the user in a trusted connection that is based on the specified trusted context when the user does not have a user-specified role that is defined as part of the definition of this trusted context.

### **WITHOUT ROLE AS OBJECT OWNER or WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies whether a role is used as the owner of objects that are created using a trusted connection that is based on the specified trusted context.

#### **WITHOUT ROLE AS OBJECT OWNER**

Specifies that a role is not used as the owner of the objects that are created

using a trusted connection that is based on the specified trusted context. The authorization ID of the process is the owner of any object that is created using a trusted connection that is based on this trusted context. That authorization ID must possess all of the privileges that are necessary to create the object.

WITHOUT ROLE AS OBJECT OWNER is the default.

#### **WITH ROLE AS OBJECT OWNER AND QUALIFIER**

Specifies that the context assigned role is the owner of the objects that are created using a trusted connection that is based on this trusted context and that role must possess all of the privileges that are necessary to create the object. The context assigned role is the role that is defined for the user within this trusted context, if one is defined. Otherwise, the role is the default role that is associated with the trusted context. The role is also used as the grantor for any GRANT statements that are issued, and the revoker for any REVOKE statement that are issued using a trusted connection that is based on this trusted context.

#### **AND QUALIFIER**

Specifies that *role-name* will be used as the default for the CURRENT SCHEMA special register. The *role-name* will also be included in the SQL PATH (in place of CURRENT SQLID).

When **WITH ROLE AS OBJECT OWNER AND QUALIFIER** is not specified, there is no change to the default for the CURRENT SCHEMA special register and the SQL PATH.

#### **DISABLE or ENABLE**

Specifies whether the trusted context is created in the enabled or disabled state.

##### **DISABLE**

Specifies that the trusted context is disabled when it is created. A trusted context that is disabled is not considered when a trusted connection is established. DISABLE is the default.

##### **ENABLE**

Specifies that the trusted context is enabled when it is created.

#### **NO DEFAULT SECURITY LABEL or DEFAULT SECURITY LABEL *seclabel-name***

Specifies whether the trusted connection has a default security label.

##### **NO DEFAULT SECURITY LABEL**

Specifies that the trusted context does not have a default security label.

##### **DEFAULT SECURITY LABEL *seclabel-name***

Specifies that *seclabel-name* is the default security label for the trusted context and is the security label that is used for multilevel security verification. *seclabel-name* must identify one of the RACF SECLABEL values that is defined for the SYSTEM AUTHID. This security label is used for a trusted connection that is based on the specified trusted context when the user does not have a specific security label defined as part of the definition of this trusted context. In this case, *seclabel-name* must also identify one of the RACF SECLABEL values that is defined for the user.

#### **ATTRIBUTES**

Specifies a list of one or more connection trust attributes that are used to define the trusted context.

#### **ADDRESS *address-value***

Specifies the actual communication address that is used by the connection

to communicate with the database manager. The protocol supported is only for TCP/IP. The ADDRESS attribute can be specified multiple times, but each *address-value* must be unique.

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute for a trusted context, a candidate connection is considered to match this attribute if the address that is used by a connection matches any of the defined values for the ADDRESS attribute of the trusted context.

*address-value* specifies a string constant that contains the value that is associated with the ADDRESS trust attribute. *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name with a length no greater than 254 bytes. No validation of *address-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed. *address-value* must be left justified within the string constant.

- An IPv4 address is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111
- An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. This address can also be expressed in a compressed form as 2001:DB8::8:800:200C:417A.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is www.ibm.com. The gethostbyname socket call is used to resolve the domain name.

#### **ENCRYPTION** *encryption-value*

Specifies the minimum level of encryption of the data stream (network encryption).

*encryption-value* specifies a string constant that contains the value that is associated with the ENCRYPTION trust attribute. *encryption-value* must be left justified within the string constant. ENCRYPTION must not be specified more than one time in the statement. *encryption-value* must be one of the following:

- NONE, which specifies that no specific level of encryption is required.
- LOW, which specifies that a minimum of light encryption is required. LOW corresponds to 64-bit DRDA encryption.
- HIGH, which specifies that strong encryption is required. HIGH corresponds to SSL encryption.

The following table summarizes when a trusted context can be used depending on the encryption that is used by the existing connection. If the trusted context cannot be used for the connection, a warning is returned.

*Table 110. Summary of when trusted context can be used by an existing connection*

Encryption that is used by the existing connection	Value of the ENCRYPTION clause for the trusted context	Can the trusted context be used for the connection?
No encryption	NONE	Yes
No encryption	LOW	No
No encryption	HIGH	No
Low encryption (64-bit)	NONE	Yes
Low encryption (64-bit)	LOW	Yes
Low encryption (64-bit)	HIGH	No

*Table 110. Summary of when trusted context can be used by an existing connection (continued)*

Encryption that is used by the existing connection	Value of the ENCRYPTION clause for the trusted context	Can the trusted context be used for the connection?
High encryption (128-bit)	NONE	Yes
High encryption (128-bit)	LOW	Yes
High encryption (128-bit)	HIGH	Yes

**JOBNAME** *jobname-value*

Specifies the z/OS job name or started task name (depending on the source of the address space) for local applications. The JOBNAME attribute can be specified multiple times, but each *jobname-value* must be unique.

*jobname-value* specifies a string constant that contains the value that is associated with the JOBNAME trust attribute. *jobname-value* is an EBCDIC 8 byte value that specifies the job name or the started task name. The value must be left justified within the string constant. The last character in the name can be a wildcard character (\*) if the first character is an alphabetic character. If the job name ends with a wildcard, any job names that begin with the specified characters are considered for establishing the trusted connection.

The following table lists possible values for the job name depending on the source of the address space.

*Table 111. Job name for local connection*

Source of the address space	Job name
RRSAF	Job name or started task name
TSO	TSO logon ID
BATCH	Job name on JOB statement

**SERVAUTH** *servauth-value*

Specifies the name of a resource in the RACF SERVAUTH class. This resource is the network access security zone name that contains the IP address of the connection that is used to communicate with DB2. The SERVAUTH attribute can be specified multiple times but each *servauth-value* must be unique.

*servauth-value* specifies a string constant that contains the value that is associated with the SERVAUTH trust attribute. *servauth-value* is an EBCDIC 64 byte RACF SERVAUTH CLASS resource name. *servauth-value* must be left justified in the string constant. No validation of *servauth-value* is done at the time the CREATE TRUSTED CONTEXT statement is processed.

**WITH USE FOR**

Specifies who can use a trusted connection that is based on the specified trusted context.

*authorization-name*

Specifies that the trusted connection can be used by the specified *authorization-name*. This is the DB2 primary authorization ID. The *authorization-name* must not be specified more than one time in the WITH USE FOR clause.

**ROLE** *role-name*

Specifies that *role-name* is the role that is used when a trusted

connection is used by the specified *authorization-name*. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the user overrides any default role that is associated with the trusted context.

**SECURITY LABEL *seclabel-name***

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by the specified *authorization-name*. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the user overrides any default security label that is associated with the trusted context.

**WITHOUT AUTHENTICATION or WITH AUTHENTICATION**

Specifies whether use of the trusted connection requires authentication of the user.

**WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

**WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

**EXTERNAL SECURITY PROFILE *profile-name***

Specifies that the trusted connection can be used by the DB2 primary authorization IDs that are permitted to use the specified *profile-name* in RACF. The *profile-name* must not be specified more than one time in the WITH USE FOR clause.

**ROLE *role-name***

Specifies that *role-name* is the role that is used when a trusted connection is used by any authorization ID permitted to use the specified *profile-name* in RACF. The *role-name* must identify a role that exists at the current server. The role that is explicitly specified for the profile overrides any default role that is associated with the trusted context.

**SECURITY LABEL *seclabel-name***

Specifies that *seclabel-name* is the security label to use for multilevel security verification when the trusted connection is used by any authorization ID that is permitted to use the specified *profile-name* in RACF. The *seclabel-name* must be one of the RACF SECLABEL values that is defined for the user. The security label that is explicitly specified for the profile overrides any default security label that is associated with the trusted context.

**WITHOUT AUTHENTICATION or WITH AUTHENTICATION**

Specifies whether use of the trusted connection requires authentication of the user.

**WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

**WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

**PUBLIC**

Specifies that a trusted connection that is based on the specified trusted context can be used by any user. All users that are using a trusted connection that is defined with PUBLIC use the privileges that are associated with the default role for the associated trusted context. If the default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection that is based on the specified trusted context.

If the default security label for the trusted context is defined, all users that are using the trusted context must have the security label defined as one of the RACF SECLABEL values for the user. The default security label is used for multilevel security verification with all users that are using the trusted context.

**WITHOUT AUTHENTICATION or WITH AUTHENTICATION**

Specifies whether use of the trusted connection requires authentication of the user.

**WITHOUT AUTHENTICATION**

Specifies that use of a trusted connection by the user does not require authentication. WITHOUT AUTHENTICATION is the default.

**WITH AUTHENTICATION**

Specifies that use of a trusted connection requires the authentication token with the authorization ID to authenticate the user. If a trusted connection is established locally, the authentication token is the password that is provided by the CONNECT statement with the USER and USING clauses. If the trusted connection is established from a remote client, the authentication token can be one of the following tokens:

- password
- RACF Passticket
- Kerberos token

## Notes

*Owner privileges:* There are no specific privileges on a trusted context.

*Order of precedence for users of a trusted connection:* The specifications for a user are determined in the following order of precedence:

- *authorization-name*
- **EXTERNAL SECURITY PROFILE** *profile-name*
- **PUBLIC**

For example, assume that a trusted context is defined with use for JOE WITH AUTHENTICATION, EXTERNAL SECURITY PROFILE SPROFILE WITHOUT AUTHENTICATION, and PUBLIC WITH AUTHENTICATION. Users JOE and SAM are permitted to use the RACF PROFILE SPROFILE. If the trusted connection is used by JOE, authentication is required. If the trusted connection is used by SAM, authentication is not required. However, if user SALLY uses the trusted connection, authentication is required.

*User-clause SYSTEM AUTHID considerations:* If the *authorization-name* that is specified in the SYSTEM AUTHID clause is the same as the *authorization-name* that is specified in the user-clause *authorization-name*, the role or the security label that is specified for *authorization-name* takes precedence over the default value. The value that is specified for the *profile-name*, is permitted to use the profile. If the authorization name that is specified in the SYSTEM AUTHID clause is permitted to use one of the profile names and is not defined in *authorization-name*, the role or the security label that is specified for that *profile-name* takes precedence over the default value.

If authentication is required for SYSTEM AUTHID, either by specification of the AUTHENTICATION clause in the *user-clause* or by setting the value of the TCP/IP Already Verified subsystem parameter to NO, the authentication requirement takes precedence when establishing a remote trusted connection. For example, if *authorization-name* is the same as the authorization name that is specified for SYSTEM AUTHID and the WITHOUT AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to NO, an authentication token is required for SYSTEM AUTHID when the remote trusted connection is established. If *authorization-name* is the SYSTEM AUTHID and the WITH AUTHENTICATION clause is specified, but the TCP/IP Already Verified subsystem parameter is set to YES, an authentication token is still required for SYSTEM AUTHID.

*Specifying a role in the definition of a trusted context:* The definition of a trusted context can designate a role for a specific authorization ID, and a default role for use for an authorization ID for which a specific role has not been specified in the definition of the trusted context. This role can be used with a trusted connection that is based on the trusted context, but it does not make the role available outside of a trusted connection that is based on the trusted context. When an SQL statement that is not a CREATE, GRANT, or REVOKE statement is issued using a trusted connection, the privileges that are held by a role that is in effect for the authorization ID within the definition of the associated trusted context are considered in addition to other privileges that are directly held by the authorization ID of the statement. The CREATE, GRANT, and REVOKE statements only consider the privileges of the role that is in effect for the trusted connection, or the authorization ID of the statement if a role is not in effect for the trusted connection. If ROLE AS OBJECT OWNER is in effect for a trusted connection, the

role that is in effect for the authorization ID for the trusted connection becomes the owner of any object that is created while using the trusted connection.

***When a newly created trusted context takes effect:*** The newly created trusted context takes effect after the CREATE TRUSTED CONTEXT statement is committed. If the CREATE TRUSTED CONTEXT statement results in an error or is rolled back, no trusted context is created.

## Examples

***Example 1:*** The following statement creates a trusted context called CTX1, which is based on a connection and can only be used by users JOE and SAM.

Authentication information is required for JOE to use the trusted connection. The trusted context specifies a default role called CTXROLE. However, when JOE uses the trusted connection, the default role is overridden by the user role, ROLE1. When SAM uses the trusted connection, SAM uses the default role. CTX1 is enabled when it is created.

```
CREATE TRUSTED CONTEXT CTX1
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF001
  ATTRIBUTES (ADDRESS '9.30.131.203',
               ENCRYPTION 'LOW')
  DEFAULT ROLE CTXROLE
  ENABLE
  WITH USE FOR SAM, JOE ROLE ROLE1 WITH AUTHENTICATION;
```

***Example 2:*** The following statement creates a trusted context, CTX2, for a started task, WASPROD. CTX2 is based on a connection, can be used by user SALLY, specifies a default role CTXROLE, and is enabled when it is created. SALLY uses the default role that is associated with the trusted context.

```
CREATE TRUSTED CONTEXT CTX2
  BASED UPON CONNECTION USING SYSTEM AUTHID ADMF002
  ATTRIBUTES (JOBNAME 'WASPROD')
  DEFAULT ROLE CTXROLE WITH ROLE AS OBJECT OWNER AND QUALIFIER
  ENABLE
  WITH USE FOR SALLY;
```

## CREATE TYPE

The CREATE TYPE statement defines a distinct type, which is a data type that a user defines. A distinct type must be based on one of the built-in data types.

Successful execution of the statement also generates:

- A function to cast between the distinct type and its source type
- A function to cast between the source type and its distinct type
- As appropriate, support for the use of comparison operators with the distinct type

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The CREATEIN privilege on the schema
- SYSADM or SYSCTRL authority

The authorization ID that matches the schema name implicitly has the CREATEIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the owner is a role, the implicit schema match does not apply and this role needs to include one of the previously listed conditions.

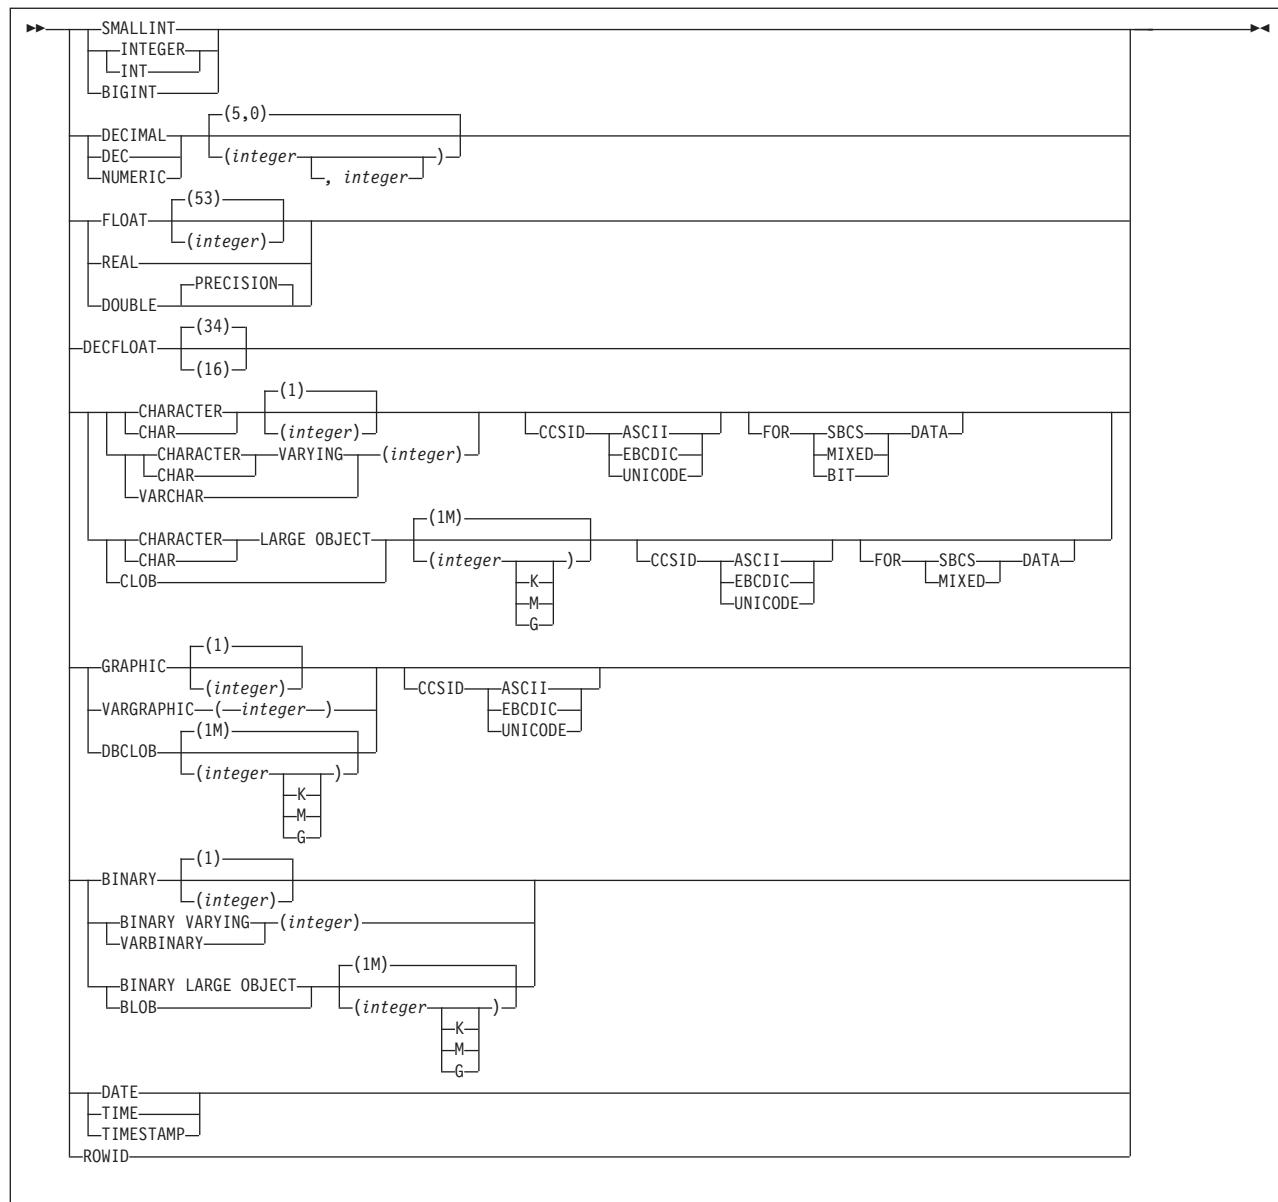

If the statement is dynamically prepared and is not running in a trusted context for which the ROLE AS OBJECT OWNER clause is specified, the privilege set is the set of privileges that are held by the SQL authorization ID of the process. The specified distinct type name can include a schema name (a qualifier). If the schema name is not the same as the SQL authorization ID of the process, one of the following conditions must be met:

- The privilege set includes SYSADM or SYSCTRL authority.
- The SQL authorization ID of the process has the CREATEIN privilege on the schema.

### Syntax

```
►►—CREATE—TYPE—distinct-type-name—AS—| source-data-type |————►►
```

**source-data-type**

## Description

*distinct-type-name*

Names the distinct type. The name, including the implicit or explicit qualifier, must not identify a distinct type that exists at the current server.

- The unqualified form of *distinct-type-name* must not be the name of a built-in data type, BOOLEAN, or any of following system-reserved keywords even if you specify them as delimited identifiers:

ALL	LIKE	UNIQUE
AND	MATCH	UNKNOWN
ANY	NOT	=
BETWEEN	NULL	~=
DISTINCT	ONLY	<
EXCEPT	OR	≤
EXISTS	OVERLAPS	⊓
FALSE	SIMILAR	>

FOR	SOME	>=
FROM	TABLE	->
IN	TRUE	<>
IS	TYPE	

- The qualified form of *distinct-type-name* is an SQL identifier (the schema name) followed by a period and an SQL identifier.

The schema name can be 'SYSTOOLS' if the user who executes the CREATE statement has SYSADM or SYSCTRL privilege. Otherwise, the schema name must not begin with 'SYS' unless the schema name is 'SYSADM'.

#### *source-data-type*

Specifies the data type that is used as the basis for the internal representation of the distinct type. The data type must be a built-in data type. For more information on built-in data types, see *built-in-type*.

If the distinct type is based on a character or graphic string data type, the FOR clause indicates the subtype. If you do not specify the FOR clause, the distinct type is defined with the default subtype. For ASCII or EBCDIC data, the default is SBCS when the value of field MIXED DATA on installation panel DSNTIPF is NO. The default is MIXED when the value is YES. For UNICODE character data, the default subtype is mixed.

If the distinct type is based on a string data type, the CCSID clause indicates whether the encoding scheme of the data is ASCII, EBCDIC or UNICODE. If you do not specify CCSID ASCII, CCSID EBCDIC, or UNICODE, the encoding scheme is the value of field DEF ENCODING SCHEME on installation panel DSNTIPF.

## Notes

**Owner privileges:** The owner of the distinct type is authorized to define columns, parameters, or variables with the distinct type (USAGE privilege) with the ability to grant these privileges to others. See "GRANT (type or JAR file privileges)" on page 1359. The owner is also authorized to invoke the generated cast function (EXECUTE privilege; see "GRANT (function or procedure privileges)" on page 1340). The owner is given the USAGE and EXECUTE privileges with the GRANT option. For more information about ownership of the object, see "Authorization, privileges, and object ownership" on page 60.

**Source data types with DBCS or mixed data:** When the implicit or explicit encoding scheme is ASCII or EBCDIC and the source data type is graphic or a character type is MIXED DATA, then the value of field FOR MIXED DATA on installation panel DSNTIPF must be YES; otherwise, an error occurs.

**Generated cast functions:** The successful execution of the CREATE TYPE statement causes DB2 to generate the following cast functions:

- A function to convert from the distinct type to its source data type
- A function to convert from the source data type to the distinct type
- A function to cast from a data type *A* to distinct type *DT*, where *A* is promotable to the source data type *S* of distinct type *DT*

For some source data types, DB2 supports an additional function to convert from:

- INTEGER to the distinct type if the source type is SMALLINT
- VARCHAR to the distinct type if the source type is CHAR
- VARGRAPHIC to the distinct type if the source type is GRAPHIC

- VARBINARY to the distinct type if the source type is BINARY
- DOUBLE to the distinct type if the source type is REAL

The cast functions are created as if the following statements were executed:

```
CREATE FUNCTION source-type-name (distinct-type-name)
    RETURNS source-type-name ...
CREATE FUNCTION distinct-type-name (source-type-name)
    RETURNS distinct-type-name ...
```

Even if you specified a length, precision, or scale for the source data type in the CREATE TYPE statement, the name of the cast function that converts from the distinct type to the source type is simply the name of the source data type. The data type of the value that the cast function returns includes any length, precision, or scale values that you specified for the source data type. (See Table 112 on page 1181 for details.)

The name of the cast function that converts from the source type to the distinct type is the name of the distinct type. The input parameter of the cast function has the same data type as the source data type, including the length, precision, and scale.

For example, assume that a distinct type named T\_SHOESIZE is created with the following statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS VARCHAR(2)
```

When the statement is executed, DB2 also generates the following cast functions. VARCHAR converts from the distinct type to the source type, and T\_SHOESIZE converts from the source type to the distinct type.

```
FUNCTION CLAIRE.VARCHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.VARCHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that function VARCHAR returns a value with a data type of VARCHAR(2) and that function T\_SHOESIZE has an input parameter with a data type of VARCHAR(2).

The schema of the generated cast functions is the same as the schema of the distinct type. No other function with the same name and function signature must already exist in the database.

In the preceding example, if T\_SHOESIZE had been sourced on a SMALLINT, CHAR, or GRAPHIC data type instead of a VARCHAR data type, another cast function would have been generated in addition to the two functions to cast between the distinct type and the source data type. For example, assume that T\_SHOESIZE is created with this statement:

```
CREATE TYPE CLAIRE.T_SHOESIZE AS CHAR(2)
```

When the statement is executed, DB2 generates these cast functions:

```
FUNCTION CLAIRE.CHAR (CLAIRE.T_SHOESIZE) RETURNS SYSIBM.CHAR (2)
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.CHAR (2)) RETURNS CLAIRE.T_SHOESIZE
FUNCTION CLAIRE.T_SHOESIZE (SYSIBM.VARCHAR (2)) RETURNS CLAIRE.T_SHOESIZE
```

Notice that the third function enables the casting of a VARCHAR(2) to T\_SHOESIZE. This additional function is created to enable casting a constant, such as 'AB', directly to the distinct type. Without the additional function, you would have to first cast 'AB', which has a data type of VARCHAR, to a data type of CHAR and then cast it to the distinct type.

You cannot explicitly drop a generated cast function. The cast functions that are generated for a distinct type are implicitly dropped when the distinct type is dropped with the DROP statement.

For each built-in data type that can be the source data type for a distinct type, Table 112 gives the names of the generated cast functions, the data types of the input parameters, and the data types of the values that the functions returns.

*Table 112. CAST functions on distinct types*

Source type name	Function name	Parameter-type	Return-type
SMALLINT	<i>distinct-type-name</i>	SMALLINT	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	INTEGER	<i>distinct-type-name</i>
	SMALLINT	<i>distinct-type-name</i>	SMALLINT
INTEGER	<i>distinct-type-name</i>	INTEGER	<i>distinct-type-name</i>
	INTEGER	<i>distinct-type-name</i>	INTEGER
BIGINT	<i>distinct-type-name</i>	BIGINT	<i>distinct-type-name</i>
	BIGINT	<i>distinct-type-name</i>	BIGINT
DECIMAL	<i>distinct-type-name</i>	DECIMAL (p,s)	<i>distinct-type-name</i>
	DECIMAL	<i>distinct-type-name</i>	DECIMAL (p,s)
NUMERIC	<i>distinct-type-name</i>	DECIMAL (p,s)	<i>distinct-type-name</i>
	DECIMAL	<i>distinct-type-name</i>	DECIMAL (p,s)
REAL	<i>distinct-type-name</i>	REAL	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	REAL	<i>distinct-type-name</i>	REAL
DECFLOAT	<i>distinct-type-name</i>	DECFLOAT(n)	DECFLOAT(n)
	DECFLOAT	<i>distinct-type-name</i>	DECFLOAT(n)
FLOAT( <i>n</i> ) where <i>n</i> <=21	<i>distinct-type-name</i>	REAL	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	REAL	<i>distinct-type-name</i>	REAL
FLOAT( <i>n</i> ) where <i>n</i> >21	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	DOUBLE	<i>distinct-type-name</i>	DOUBLE
FLOAT	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	DOUBLE	<i>distinct-type-name</i>	DOUBLE
DOUBLE	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	DOUBLE	<i>distinct-type-name</i>	DOUBLE
DOUBLE PRECISION	<i>distinct-type-name</i>	DOUBLE	<i>distinct-type-name</i>
	<i>distinct-type-name</i>	CHAR (n)	<i>distinct-type-name</i>
	CHAR	<i>distinct-type-name</i>	CHAR (n)
	<i>distinct-type-name</i>	VARCHAR (n)	<i>distinct-type-name</i>
	DOUBLE	<i>distinct-type-name</i>	DOUBLE
CHAR CHARACTER	<i>distinct-type-name</i>	CHAR (n)	<i>distinct-type-name</i>
	CHAR	<i>distinct-type-name</i>	CHAR (n)
	<i>distinct-type-name</i>	VARCHAR (n)	<i>distinct-type-name</i>

Table 112. CAST functions on distinct types (continued)

Source type name	Function name	Parameter-type	Return-type
VARCHAR CHARACTER VARYING CHAR VARYING	<i>distinct-type-name</i>	VARCHAR (n)	<i>distinct-type-name</i>
	VARCHAR	<i>distinct-type-name</i>	VARCHAR (n)
CLOB	<i>distinct-type-name</i>	CLOB (n)	<i>distinct-type-name</i>
	CLOB	<i>distinct-type-name</i>	CLOB (n)
GRAPHIC	<i>distinct-type-name</i>	GRAPHIC (n)	<i>distinct-type-name</i>
	GRAPHIC	<i>distinct-type-name</i>	GRAPHIC (n)
VARGRAPHIC	<i>distinct-type-name</i>	VARGRAPHIC (n)	<i>distinct-type-name</i>
	VARGRAPHIC	<i>distinct-type-name</i>	VARGRAPHIC (n)
DBCLOB	<i>distinct-type-name</i>	DBCLOB (n)	<i>distinct-type-name</i>
	DBCLOB	<i>distinct-type-name</i>	DBCLOB (n)
BINARY	<i>distinct-type-name</i>	BINARY(n)	<i>distinct-type-name</i>
	BINARY	<i>distinct-type-name</i>	BINARY(n)
VARBINARY	<i>distinct-type-name</i>	VARBINARY(n)	<i>distinct-type-name</i>
	VARBINARY	<i>distinct-type-name</i>	VARBINARY(n)
BLOB	<i>distinct-type-name</i>	BLOB (n)	<i>distinct-type-name</i>
	BLOB	<i>distinct-type-name</i>	BLOB (n)
DATE	<i>distinct-type-name</i>	DATE	<i>distinct-type-name</i>
	DATE	<i>distinct-type-name</i>	DATE
TIME	<i>distinct-type-name</i>	TIME	<i>distinct-type-name</i>
	TIME	<i>distinct-type-name</i>	TIME
TIMESTAMP	<i>distinct-type-name</i>	TIMESTAMP	<i>distinct-type-name</i>
	TIMESTAMP	<i>distinct-type-name</i>	TIMESTAMP
ROWID	<i>distinct-type-name</i>	ROWID	<i>distinct-type-name</i>
	ROWID	<i>distinct-type-name</i>	ROWID

**Notes:** NUMERIC and FLOAT are not recommended when creating a distinct type for a portable application. Use DECIMAL and DOUBLE (or REAL) instead.

**Built-in functions:** When a distinct type is defined, the built-in functions (such as AVG, MAX, and LENGTH) are not automatically supported for the distinct type. You can use a built-in function on a distinct type only after a sourced user-defined function, which is based on the built-in function, has been created for the distinct type. For information on defining sourced user-defined functions, see “CREATE FUNCTION (sourced)” on page 958.

**Syntax alternatives:** The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement. Use WITH COMPARISONS only if it is required for compatibility with other

products in the DB2 family. If the source data type is either BLOB, CLOB, or DBCLOB and WITH COMPARISONS is specified, a warning occurs as in previous releases.

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following clauses:

- DISTINCT TYPE as a synonym for TYPE

## Examples

*Example 1:* Create a distinct type named SHOESIZE that is based on an INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER;
```

The successful execution of this statement also generates two cast functions. Function INTEGER(SHOESIZE) returns a value with data type INTEGER, and function SHOESIZE(INTEGER) returns a value with distinct type SHOESIZE.

*Example 2:* Create a distinct type named MILES that is based on a DOUBLE data type.

```
CREATE TYPE MILES AS DOUBLE;
```

The successful execution of this statement also generates two cast functions. Function DOUBLE(MILES) returns a value with data type DOUBLE, and function MILES(DOUBLE) returns a value with distinct type MILES.

## CREATE VIEW

The CREATE VIEW statement creates a view on tables or views at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

For every table or view identified in the *fullselect*, the privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Authority requirements depend in part on the choice of the owner of the view. For information on how to choose the owner, see the description of *view-name* in “Description” on page 867.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the application is bound in a trusted context with the ROLE AS OBJECT OWNER clause specified, a role is the owner. Otherwise, an authorization ID is the owner.

- If this privilege set includes SYSADM authority, the owner of the view can be any authorization ID. If that set includes SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.

- If the privilege set lacks SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be any authorization ID if all of the following conditions are true:
  - The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
  - The view is not based only on views.

**Note:** The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

- If the privilege set lacks SYSADM, SYSCTRL, and DBADM authority, or if the authorization ID of the application plan or package fails to meet any of the previous conditions, the owner of the view must be the owner of the application plan or package.

If ROLE AS OBJECT OWNER is in effect, the schema qualifier must be the same as the role, unless the role has the CREATEIN privilege on the schema, SYSADM authority, or SYSCTRL authority.

If ROLE AS OBJECT OWNER is not in effect, one of the following rules applies:

- If the privilege set lacks the CREATIN privilege on the schema, SYSADM authority, or SYSCTRL authority, the schema qualifier (implicit or explicit) must be the same as one of the authorization ids of the process.
- If the privilege set includes SYSADM authority or SYSCTRL authority, the schema qualifier can be any valid schema name.

If the statement is dynamically prepared, the following rules apply:

- If the SQL authorization ID of the process has SYSADM authority, the owner of the view can be any authorization ID. If that authorization ID has SYSCTRL but not SYSADM authority, the following is true: the owner of the view can be any authorization ID, provided the view does not refer to user tables or views in the first FROM clause of its defining fullselect. (It could refer instead, for example, to catalog tables or views thereof.)

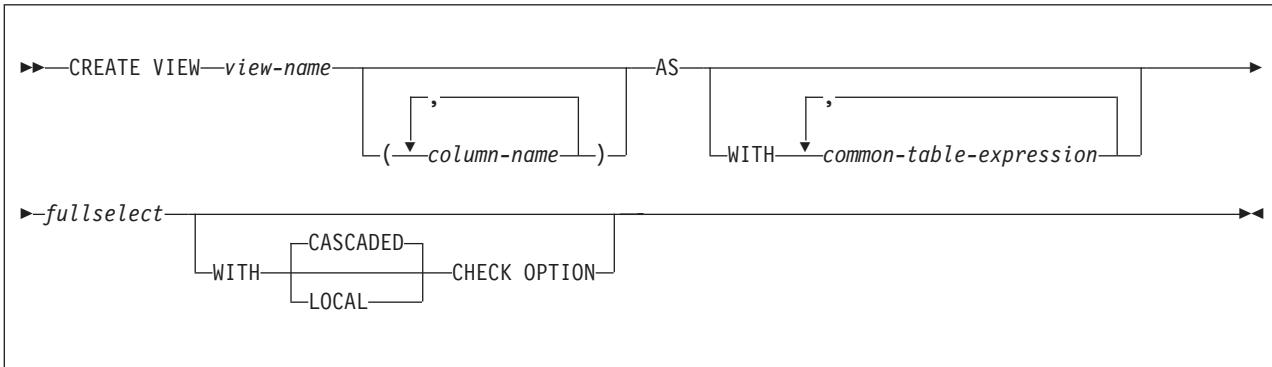

If the view satisfies the rules in the preceding paragraph, and if no errors are present in the CREATE statement, the view is created, even if the owner has no privileges at all on the tables and views identified in the fullselect of the view definition.

- If SQL authorization ID of the process lacks SYSADM and SYSCTRL but includes DBADM authority on at least one of the databases that contains a table from which the view is created, the owner of the view can be different from the SQL authorization ID if all of the following conditions are true:
  - The value of field DBADM CREATE AUTH was set to YES on panel DSNTIPP during DB2 installation.
  - The view is not based only on views.

**Note:** The owner of the view must have the SELECT privilege on all tables and views in the CREATE VIEW statement, or, if the owner does not have the SELECT privilege on a table, the creator must have DBADM authority on the database that contains that table.

- If the SQL authorization ID of the process lacks SYSADM, SYSCTRL, or DBADM authority, or if the SQL authorization ID of the process fails to meet any of the previous conditions, only the authorization IDs of the process can own the view. In this case, the privilege set is the privileges that are held by the authorization ID selected for ownership.

## Syntax

## Description

### *view-name*

Names the view. The name, including the implicit or explicit qualifier, must not identify a table, view, alias, or synonym that exists at the current server.

If the name is qualified, the name can be a two-part or three-part name. If a three-part name is used, the first part must match the value of the field DB2 LOCATION NAME of installation panel DSNTIPR at the current server. (If the current server is not the local DB2, this name is not necessarily the name in the CURRENT SERVER special register.)

### *column-name*,...

Names the columns in the view. If you specify a list of column names, it must consist of as many names as there are columns in the result table of the fullselect. Each name must be unique and unqualified. If you do not specify a list of column names, the columns of the view inherit the names of the columns of the result table of the fullselect.

You must specify a list of column names if the result table of the fullselect has duplicate column names or an unnamed column (a column derived from a constant, function, or expression that was not given a name by the AS clause). For more details about unnamed columns, see the information about names of result columns under "select-clause" on page 633.

**AS** Identifies the view definition.

### **WITH** *common-table-expression*

Defines a common table expression for use with the fullselect that follows. For an explanation of common table expression, see "common-table-expression" on page 670.

### *fullselect*

Defines the view. At any time, the view consists of the rows that would result if the fullselect were executed.

*fullselect* must not refer to any declared temporary tables, host variables, or parameter markers (question marks). In addition, the FROM clause of the *fullselect* must not include a *data-change-table-reference* or a view for which an INSTEAD OF trigger is defined. For an explanation of *fullselect*, see "fullselect" on page 662.

### **WITH CASCDED CHECK OPTION or WITH LOCAL CHECK OPTIONS**

Specifies that every row that is inserted or updated through the view must

conform to the definition of the view. A row that does not conform to the definition of the view is a row that cannot be retrieved using that view.

The CHECK OPTION clause must not be specified if the view is read-only, includes a subquery, references a function that is not deterministic or has an external action, or if the fullselect of the view refers to a created temporary table. If the CHECK OPTION clause is specified for an updatable view that does not allow inserts, it applies to updates only.

If the CHECK OPTION clause is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes the CHECK OPTION clause. Because the definition of the view is not used, rows might be inserted or updated through the view that do not conform to the definition of the view.

The difference between the two forms of the check option, CASCDED and LOCAL, is meaningful only when a view is dependent on another view. The default is CASCDED. The view on which another view is directly or indirectly defined is an *underlying view*.

#### CASCDED

Update and insert operations on view V must satisfy the search conditions of view V and all underlying views, regardless of whether the underlying views were defined with a check option. Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V) as a constraint on insert or update operations. WITH CASCDED CHECK OPTION must not be specified if a view on which the specified view definition is dependent has an INSTEAD OF trigger defined.

#### LOCAL

Update and insert operations on view V must satisfy the search conditions of view V and underlying views that are defined with a check option (either WITH CASCDED CHECK OPTION or WITH LOCAL CHECK OPTION). Furthermore, every updatable view that is directly or indirectly defined on view V inherits those search conditions (the search conditions of view V and all underlying views of V that are defined with a check option) as a constraint on insert or update operations.

The LOCAL form of the CHECK option lets you update or insert rows that do not conform to the search condition of view V. You can perform these operations if the view is directly or indirectly defined on a view that was defined without a check option.

Table 113 on page 1188 illustrates the effect of using the default check option, CASCDED. The information in Table 113 on page 1188 is based on the following views:

- CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10
- CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CASCDED CHECK OPTION
- CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100

Table 113. Examples using default check option, CASCDED

SQL statement	Description of result
INSERT INTO V1 VALUES(5)	Succeeds because V1 does not have a check option and it is not dependent on any other view that has a check option.
INSERT INTO V2 VALUES(5)	Results in an error because the inserted row does not conform to the search condition of V1 which is implicitly part of the definition of V2.
INSERT INTO V3 VALUES(5)	Results in an error because the inserted row does not conform to the search condition of V1.
INSERT INTO V3 VALUES(200)	Succeeds even though it does not conform to the definition of V3 (V3 does not have the view check option specified); it does conform to the definition of V2 (which does have the view check option specified).

The difference between CASCDED and LOCAL is shown best by example. Consider the following updatable views, where x and y represent either LOCAL or CASCDED:

- V1 is defined on Table T0.
- V2 is defined on V1 WITH x CHECK OPTION.
- V3 is defined on V2.
- V4 is defined on V3 WITH y CHECK OPTION.
- V5 is defined on V4.

This example shows V1 as an *underlying view* for V2 and V2 as *dependent* on V1.

Table 114 shows the views in which search conditions are checked during an insert or update operation:

Table 114. Views in which search conditions are checked during insert and update operations

View used in INSERT or UPDATE operation	x = LOCAL y = LOCAL	x = CASCDED y = CASCDED	x = LOCAL y = CASCDED	x = CASCDED y = LOCAL
V1	None	None	None	None
V2	V2	V2, V1	V2	V2, V1
V3	V2	V2, V1	V2	V2, V1
V4	V4, V2	V4, V3, V2, V1	V4, V3, V2, V1	V4, V2, V1
V5	V4, V2	V4, V3, V2, V1	V4, V3, V2, V1	V4, V2, V1

## Notes

**Owner privileges:** The owner of a view always acquires the SELECT privilege on the view and the authority to drop the view. If all of the privileges that are required to create the view are held with the GRANT option before the view is created, the owner of the view receives the SELECT privilege with the GRANT option. Otherwise, the owner receives the SELECT privilege without the GRANT option. For example, assume that a view definition also refers to a user-defined function. If the owner's EXECUTE privilege on the user-defined function is held without the GRANT option, the owner acquires the SELECT privilege on the view without the GRANT option.

The owner can also acquire INSERT, UPDATE, and DELETE privileges on the view. Acquiring these privileges is possible if the view is not "read-only", which means a single table or view is identified in the first FROM clause of the fullselect. For each privilege that the owner has on the identified table or view (INSERT, UPDATE, and DELETE) before the new view is created, the owner acquires that privilege on the view. The owner receives the privilege with the GRANT option if the privilege is held on the table or view with the GRANT option. Otherwise, the owner receives the privileges without the GRANT option.

With appropriate DB2 authority, a process can create views for those who have no authority to create the views themselves. The owner of such a view has the SELECT privilege on the view, without the GRANT option, and can drop the view.

For more information on the ownership of an object, see "Authorization, privileges, and object ownership" on page 60.

**Authorization for views created for other users:** When a process with appropriate authority creates a view for another user that does not have authorization for the underlying table or view, the SELECT privilege for the created view is implicitly granted to the user.

**Read-only views:** A view is *read-only* if one or more of the following statements is true of its definition:

- The first FROM clause identifies more than one table or view, or identifies a table function, a nested table expression, or a common table expression.
- The first SELECT clause specifies the keyword DISTINCT.
- The outer fullselect contains a GROUP BY clause.
- The outer fullselect contains a HAVING clause.
- The first SELECT clause contains an aggregate function.
- It contains a subquery such that the base object of the outer fullselect, and of the subquery, is the same table.
- The first FROM clause identifies a read-only view.
- The first FROM clause identifies a system-maintained materialized query table.
- The outer fullselect is not a subselect (contains a set operator).

A read-only view cannot be the object of an SQL data change statement or a TRUNCATE statement. A view that includes GROUP BY or HAVING cannot be referred to in a subquery of a basic predicate.

**Insertable views:** A view is insertable if an INSTEAD OF trigger for the insert operation has been defined for the view, or if at least one column of the view is updatable (independent of an INSTEAD OF trigger for update).

**Considerations for implicitly hidden columns:** It is possible that the result table of the fullselect will include a column of a base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.

**Testing a view definition:** You can test the semantics of your view definition by executing `SELECT * FROM view-name`.

**The two forms of a view definition:** Both the source and the operational form of a view definition are stored in the DB2 catalog. Those two forms are not necessarily equivalent because the operational form reflects the state that exists when the view is created. For example, consider the following statement:

```
CREATE VIEW V AS SELECT * FROM S;
```

In this example, S is a synonym or alias for A.T, which is a table with columns C1, C2, and C3. The operational form of the view definition is equivalent to:

```
SELECT C1, C2, C3 FROM A.T;
```

Adding columns to A.T using ALTER TABLE and dropping S does not affect the operational form of the view definition. Thus, if columns are added to A.T or if S is redefined, the source form of the view definition can be misleading.

**View restrictions:** A view definition cannot contain references to remote objects. A view definition cannot map to more than 15 base table instances. A view definition cannot reference a declared global temporary table.

## Examples

*Example 1:* Create the view DSN8910.VPROJRE1. PROJNO, PROJNAME, PROJDEP, RESPEMP, FIRSTNME, MIDINIT, and LASTNAME are column names. The view is a join of tables and is therefore read-only.

```
CREATE VIEW DSN8910.VPROJRE1
  (PROJNO,PROJNAME,PROJDEP,RESPEMP,
   FIRSTNME,MIDINIT,LASTNAME)
AS SELECT ALL
  PROJNO,PROJNAME,DEPTNO,EMPNO,
  FIRSTNME,MIDINIT,LASTNAME
  FROM DSN8910.PROJ, DSN8910.EMP
  WHERE RESPEMP = EMPNO;
```

In the example, the WHERE clause refers to the column EMPNO, which is contained in one of the base tables but is not part of the view. In general, a column named in the WHERE, GROUP BY, or HAVING clause need not be part of the view.

*Example 2:* Create the view DSN8910.FIRSTQTR that is the UNION ALL of three fullselects, one for each month of the first quarter of 2000. The common names are SNO, CHARGES, and DATE.

```
CREATE VIEW DSN8910.FIRSTQTR (SNO, CHARGES, DATE) AS
  SELECT SNO, CHARGES, DATE
    FROM MONTH1
   WHERE DATE BETWEEN '01/01/2000' and '01/31/2000'
     UNION ALL
  SELECT SNO, CHARGES, DATE
    FROM MONTH2
   WHERE DATE BETWEEN '02/01/2000' and '02/29/2000'
     UNION ALL
  SELECT SNO, CHARGES, DATE
    FROM MONTH3
   WHERE DATE BETWEEN '03/01/2000' and '03/31/2000';
```

---

## DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

### Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java.

### Authorization

For each table or view identified in the SELECT statement of the cursor, the privilege set must include at least one of the following:

- The SELECT privilege
- Ownership of the object
- DBADM authority for the corresponding database (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)

If the *select-statement* contains an SQL data change statement, the authorization requirements of that statement also apply to the DECLARE CURSOR statement.

The SELECT statement of the cursor is one of the following:

- The prepared select statement identified by *statement-name*
- The specified *select-statement*

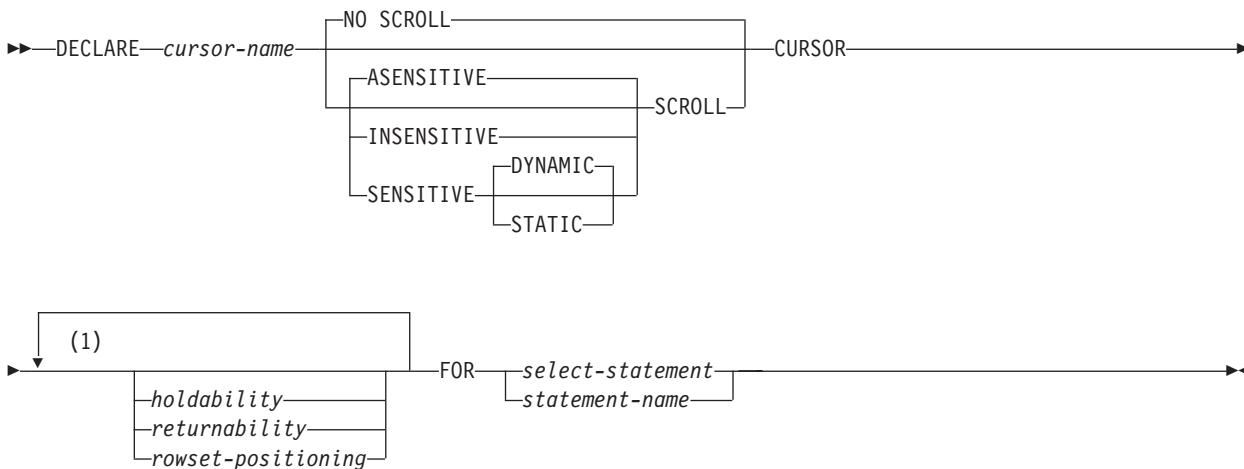

#### If **statement-name** is specified:

- The privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)
- The authorization check is performed when the SELECT statement is prepared.
- The cursor cannot be opened unless the SELECT statement is successfully prepared.

#### If **select-statement** is specified:

- The privilege set consists of the privileges that are held by the authorization ID of the owner of the plan or package.
- If the plan or package is bound with VALIDATE(BIND), the authorization check is performed at bind time, and the bind is unsuccessful if any required privilege does not exist.
- If the plan or package is bound with VALIDATE(RUN), an authorization check is performed at bind time, but all required privileges need not exist at that time. If all privileges exist at bind time, no authorization checking is performed when the cursor is opened. If any privilege does not exist at bind time, an authorization check is performed the first time the cursor is opened within a unit of work. The OPEN is unsuccessful if any required privilege does not exist.

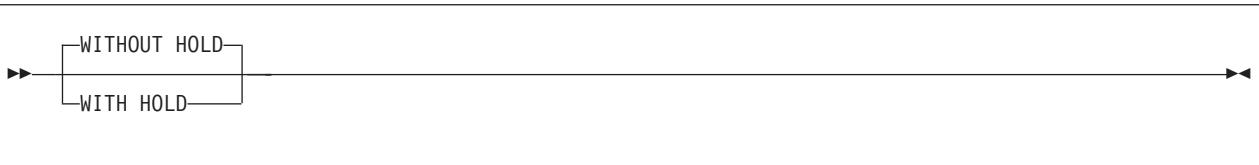

## Syntax

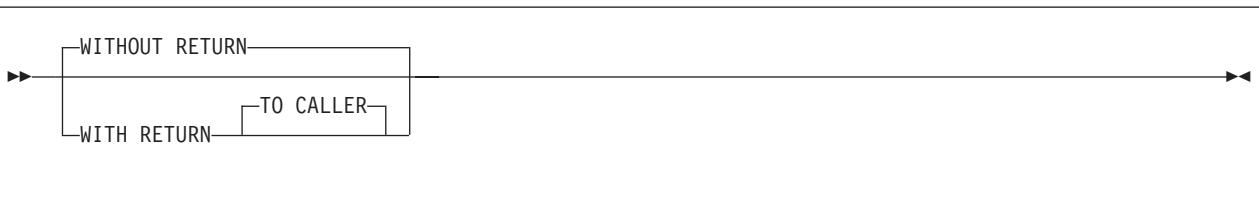

### Notes:

- 1 The same clause must not be specified more than once.

### holdability:

### returnability:

### rowset-positioning:

## Description

### *cursor-name*

Names the cursor. The name must not identify a cursor that has already been

declared in the source program. The name is usually VARCHAR(128); however, if the cursor is defined WITH RETURN, the name is limited to VARCHAR(30).

#### **NO SCROLL or SCROLL**

Specifies whether the cursor is scrollable or not scrollable.

#### **NO SCROLL**

Specifies that the cursor is not scrollable. This is the default.

#### **SCROLL**

Specifies that the cursor is scrollable. For a scrollable cursor, whether the cursor has sensitivity to inserts, updates, or deletes depends on the cursor sensitivity option in effect for the cursor. If a sensitivity option is not specified, ASENSITIVE is the default.

#### **ASENSITIVE**

Specifies that the cursor should be as sensitive as possible. This is the default.

A cursor that defined as ASESENTIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 1400.

#### **INSENSITIVE**

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

#### **SENSITIVE**

Specifies that the cursor has sensitivity to changes that are made to the database after the result table is materialized. The cursor is always sensitive to updates and deletes that are made using the cursor (that is, positioned updates and deletes using the same cursor). When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

If DB2 cannot make changes visible to the cursor, then an error is issued at bind time for OPEN CURSOR. DB2 cannot make changes visible to the cursor when the cursor implicitly becomes read-only. For example, when the result table must be materialized, as when the FROM clause of the SELECT statement contains more than one table or view. The current list of conditions that result in an implicit read-only cursor can be found in Read-only cursors.

The default is DYNAMIC.

#### **DYNAMIC**

Specifies that the result table of the cursor is dynamic, meaning that the size of the result table might change after the cursor is opened as rows are inserted into or deleted from the underlying table, and the order of the rows might change. Rows that are inserted, deleted, or updated by statements that are executed by the same application process as the cursor are visible to the cursor.

immediately. Rows that are inserted, deleted, or updated by statements that are executed by other application processes are visible only after the statements are committed. If a column for an ORDER BY clause is updated via a cursor or any means outside the process, the next FETCH statement behaves as if the updated row was deleted and re-inserted into the result table at its correct location. At the time of a positioned update, the cursor is positioned before the next row of the original location and there is no current row, making the row appear to have moved.

If a SENSITIVE DYNAMIC cursor is not possible, an error is returned. For example, if a temporary table is needed (such as for processing a FETCH FIRST n ROWS ONLY clause), an error is returned. The SELECT statement of a cursor that is defined as SENSITIVE DYNAMIC cannot contain an SQL data change statement.

#### **STATIC**

Specifies that the size of the result table and the order of the rows do not change after the cursor is opened. Rows inserted into the underlying table are not added to the result table regardless of how the rows are inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized. Positioned updates and deletes are allowed if the result table is updatable. The SELECT statement of a cursor that is defined as SENSITIVE STATIC cannot contain an SQL data change statement.

A STATIC cursor has visibility to changes made by *this* cursor using positioned updates or deletes. Committed changes made outside this cursor are visible with the SENSITIVE option of the FETCH statement. A FETCH SENSITIVE can result in a *hole* in the result table (that is, a difference between the result table and its underlying base table). If an updated row in the base table of a cursor no longer satisfies the predicate of its SELECT statement, an update hole occurs in the result table. If a row of a cursor was deleted in the base table, a delete hole occurs in the result table. When a FETCH SENSITIVE detects an update hole, no data is returned (a warning is issued), and the cursor is left positioned on the update hole. When a FETCH SENSITIVE detects a delete hole, no data is returned (a warning is issued), and the cursor is left positioned on the delete hole.

Updates through a cursor result in an automatic re-fetch of the row. This re-fetch means that updates can create a hole themselves. The re-fetched row also reflects changes as a result of triggers updating the same row. It is important to reflect these changes to maintain the consistency of data in the row.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of the *select-statement* or *statement-name* of a SENSITIVE STATIC cursor can cause misleading results. This situation occurs because DB2 constructs a temporary result table and retrieves rows from this table for FETCH INSENSITIVE statements. When DB2 processes a FETCH SENSITIVE statement, rows are fetched from the underlying table and predicates are re-evaluated. Using a function that is not deterministic can yield a

different result on each FETCH SENSITIVE of the same row, which could also result in the row no longer being considered a match.

A FETCH INSENSITIVE on a SENSITIVE STATIC SCROLL cursor is not sensitive to changes made outside the cursor, unless a previous FETCH SENSITIVE has already refreshed that row; however, positioned updates and delete changes with the cursor are visible.

STATIC cursors are insensitive to insertions.

#### **WITHOUT HOLD or WITH HOLD**

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

##### **WITHOUT HOLD**

Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

##### **WITH HOLD**

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared with WITH HOLD is closed at commit time if one of the following is true:

- The connection associated with the cursor is in the release pending status.
- The bind option DISCONNECT(AUTOMATIC) is in effect.
- The environment is one in which the option WITH HOLD is ignored.

When WITH HOLD is specified, a commit operation commits all of the changes in the current unit of work. For example, with a non-scrollable cursor, an initial FETCH statement is needed after a COMMIT statement to position the cursor on the row that follows the row that the cursor was positioned on before the commit operation.

WITH HOLD has no effect on an SQL data change statement within a SELECT statement. When a COMMIT is issued, the changes caused by the SQL data change statement are committed, regardless of whether or not the cursor is declared WITH HOLD.

All cursors are implicitly closed by a connect (Type 1) or rollback operation. A cursor is also implicitly closed by a commit operation if WITH HOLD is ignored or not specified.

Cursors that are declared with WITH HOLD in CICS or in IMS non-message-driven programs will not be closed by a rollback operation if the cursor was opened in a previous unit of work and no changes have been made to the database in the current unit of work. The cursor cannot be closed because CICS and IMS do not broadcast the rollback request to DB2 for a null unit of work.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the option WITH HOLD.

WITH HOLD is ignored in IMS message driven programs (MPP, IFP, and message-driven BMP). WITH HOLD maintains the cursor position in a CICS pseudo-conversational program until the end-of-task (EOT).

For details on restrictions that apply to declaring cursors with WITH HOLD, see *DB2 Application Programming and SQL Guide*.

**WITHOUT RETURN or WITH RETURN TO CALLER**

Specifies the intended use of the result table of the cursor. The default is WITHOUT RETURN, except in Java procedures, where the default is WITH RETURN TO CALLER.

**WITHOUT RETURN**

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from the program or procedure.

**WITH RETURN TO CALLER**

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from the program or procedure to the caller. Specifying TO CALLER is optional.

WITH RETURN TO CALLER is relevant when the SQL CALL statement is used to invoke a procedure that either contains the DECLARE CURSOR statement, or directly or indirectly invokes a program or procedure that contains the DECLARE CURSOR statement. In other cases, the precompiler might accept the clause, but the clause has no effect.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or procedure, that cursor defines a result set from the program or procedure. Use the CLOSE statement to close cursors that are not intended to be a result set from the program or procedure. Although DB2 will automatically close any cursors that are not declared using WITH RETURN TO CALLER, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

The caller is the program or procedure that executed the SQL CALL statement that either invokes the procedure that contains the DECLARE CURSOR statement, or directly or indirectly invokes the program that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

***rowset-positioning***

Specifies whether multiple rows of data can be accessed as a rowset on a single FETCH statement for the cursor. The default is WITHOUT ROWSET POSITIONING.

**WITHOUT ROWSET POSITIONING**

Specifies that the cursor can be used only with row-positioned FETCH statements. The cursor is to return a single row for each FETCH statement and the FOR *n* ROWS clause cannot be specified on a FETCH statement for this cursor. WITHOUT ROWSET POSITIONING or single row access refers to how data is fetched from the database engine. For remote access, data might be blocked and returned to the client in blocks.

**WITH ROWSET POSITIONING**

Specifies that the cursor can be used with either row-positioned or rowset-positioned FETCH statements. This cursor can be used to return either a single row or multiple rows, as a rowset, with a single FETCH statement. ROWSET POSITIONING refers to how data is fetched from the database engine. For remote access, if any row qualifies, at least 1 row is returned as a rowset. The size of the rowset depends on the number of

rows specified on the FETCH statement and on the number of rows that qualify. Data might be blocked and returned to the client in blocks.

#### *select-statement*

Specifies the result table of the cursor. See “*select-statement*” on page 669 for an explanation of *select-statement*.

The *select-statement* must not include parameter markers (except for REXX), but can include references to host variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of host variables and the statement must be prepared.

The USING clause of the OPEN statement can be used to specify host variables that will override the values of the host variables or parameter markers that are specified as part of the statement in the DECLARE CURSOR statement.

The *select-statement* of the cursor must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

#### *statement-name*

Identifies the prepared *select-statement* that specifies the result table of the cursor whenever the cursor is opened. The *statement-name* must not be identical to a statement name specified in another DECLARE CURSOR statement of the source program. For an explanation of prepared SELECT statements, see “PREPARE” on page 1405.

The prepared *select-statement* of the cursor must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

## Notes

A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

**Read-only cursors:** If the result table is *read-only*, the cursor is *read-only*. The cursor that references a view with instead of triggers are read-only since positioned UPDATE and positioned DELETE statements are not allowed using those cursors. The result table is *read-only* if one or more of the following statements is true about the SELECT statement of the cursor:

- The first FROM clause identifies or contains any of the following:
  - More than one table or view
  - A catalog table with no updatable columns
  - A read-only view
  - A nested table expression
  - A table function
  - A system-maintained materialized query table
- The first SELECT clause specifies the keyword DISTINCT, contains an aggregate function, or uses both
- It contains an SQL data change statement
- The outer subselect contains a GROUP BY clause, a HAVING clause, or both clauses

- It contains a subquery such that the base object of the outer subselect, and of the subquery, is the same table
- Any of the following operators or clauses are specified:
  - A set operator
  - An ORDER BY clause (except when the cursor is declared as SENSITIVE STATIC scrollable)
  - A FOR READ ONLY clause
- It is executed with isolation level UR and a FOR UPDATE clause is not specified.

If the result table is not *read-only*, the cursor can be used to update or delete the underlying rows of the result table.

**Work file database requirement for static scrollable cursors:** To use a static scrollable cursor, you must first create a work file database and at least one table space with a 32KB page size in this database because a static scrollable cursor requires a temporary table for its result table while the cursor is open. DB2 chooses a table space to use for the temporary result table. Dynamic scrollable cursors do not require a declared temporary table.

**Cursors in COBOL and Fortran programs:** In COBOL and Fortran source programs, the DECLARE CURSOR statement must precede all statements that explicitly refer to the cursor by name. This rule does not necessarily apply to the other host languages because the precompiler provides a two-pass option for these languages. This rule applies to other host languages if the two-pass option is not used.

**Cursors in REXX:** If host variables are used in a DECLARE CURSOR statement within a REXX procedure, the DECLARE CURSOR statement must be the object of a PREPARE and EXECUTE.

**Scope of a cursor:** The scope of *cursor-name* is the source program in which it is defined; that is, the application program submitted to the precompiler. Thus, you can only refer to a cursor by statements that are precompiled with the cursor declaration. For example, a COBOL program called from another program cannot use a cursor that was opened by the calling program. Furthermore, a cursor defined in a Fortran subprogram can only be referred to in that subprogram. Cursors that specify WITH RETURN in a procedure and are left open are returned as result sets.

Although the scope of a cursor is the program in which it is declared, each package (or DBRM of a plan) created from the program includes a separate instance of the cursor, and more than one instance of the cursor can be used in the same execution of the program. For example, assume a program is precompiled with the CONNECT(2) option and its DBRM is used to create a package at location X and a package at location Y. The program contains the following SQL statements:

```
DECLARE C CURSOR FOR ...
CONNECT TO X
OPEN C
FETCH C INTO ...
CONNECT TO Y
OPEN C
FETCH C INTO ...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C. The same notion applies to a single location if the packages are in different collections.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results can be different. If the SELECT statement of the cursor contains CURRENT DATE, CURRENT TIME or CURRENT TIMESTAMP, all references to these special registers yields the same respective datetime value on each FETCH operation. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

**Blocking of data:** To process data more efficiently, DB2 might block data for read-only cursors. If a cursor is not going to be used in a positioned UPDATE or positioned DELETE statement, define the cursor as FOR READ ONLY.

**Positioned deletes and isolation level UR:** Specify FOR UPDATE if you want to use the cursor for a positioned DELETE and the isolation level is UR because of a BIND option. In this case, the isolation level is CS.

**Returning a result set from a stored procedure:** A cursor that is declared in a stored procedure returns a result set when all of the following conditions are true:

- The cursor is declared with the WITH RETURN option. In a distributed environment, blocks of each result set of the cursor's data are returned with the CALL statement reply.
- The cursor is left open after exiting from the stored procedure. A cursor declared with the SCROLL option must be left positioned *before* the first row before exiting from the stored procedure.
- The cursor is declared with the WITH HOLD option if the stored procedure is defined to commit on return.

The result set is the set of all rows after the current position of the cursor after exiting the stored procedure. The result set is assumed to be read-only. If that same procedure is reinvoked, open result set cursors for a stored procedure at a given site are automatically closed by the database management system.

**Scrollable cursors specified with user-defined functions:** A row can be fetched more than once with a scrollable cursor. Therefore, if a scrollable cursor is defined with a function that is not deterministic in the select list of the cursor, a row can be fetched multiple times with different results for each fetch. (However, the value of a function that is not deterministic in the WHERE clause of a scrollable cursor is captured when the cursor is opened and remains unchanged until the cursor is closed.) Similarly, if a scrollable cursor is defined with a user-defined function with external action, the action is executed with every fetch.

## Examples

The statements in the following examples are assumed to be in PL/I programs.

*Example 1:* Declare C1 as the cursor of a query to retrieve data from the table DSN8910.DEPT. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
      SELECT DEPTNO, DEPTNAME, MGRNO
      FROM DSN8910.DEPT
      WHERE ADMRDEPT = 'A00';
```

*Example 2:* Declare C1 as the cursor of a query to retrieve data from the table DSN8810.DEPT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8910.DEPT
  WHERE ADMRDEPT = 'A00'
  FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

*Example 3:* Declare C2 as the cursor for a statement named STMT2.

```
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

*Example 4:* Declare C3 as the cursor for a query to be used in positioned updates of the table DSN8910.EMP. Allow the completed updates to be committed from time to time without closing the cursor.

```
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
  SELECT * FROM DSN8910.EMP
  FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of specifying which columns should be updated, you could use a FOR UPDATE clause without the names of the columns to indicate that all updatable columns are updated.

*Example 5:* In stored procedure SP1, declare C4 as the cursor for a query of the table DSN8910.PROJ. Enable the cursor to return a result set to the caller of SP1, which performs a commit on return.

```
EXEC SQL DECLARE C4 CURSOR WITH HOLD WITH RETURN FOR
  SELECT PROJNO, PROJNAME
  FROM DSN8910.PROJ
  WHERE DEPTNO = 'A01';
```

*Example 6:* In the following example, the DECLARE CURSOR statement associates the cursor name C5 with the results of the SELECT and specifies that the cursor is scrollable. C5 allows positioned updates and deletes because the result table can be updated.

```
EXEC SQL DECLARE C5 SENSITIVE STATIC SCROLL CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8910.DEPT
  WHERE ADMRDEPT = 'A00';
```

*Example 7:* In the following example, the DECLARE CURSOR statement associates the cursor name C6 with the results of the SELECT and specifies that the cursor is scrollable.

```
EXEC SQL DECLARE C6 INSENSITIVE SCROLL CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DSN8910.DEPT
  WHERE DEPTNO;
```

*Example 8:* The following example illustrates how an application program might use dynamic scrollable cursors. First create and populate a table.

```
CREATE TABLE ORDER
  (ORDERNUM INTEGER,
  CUSTNUM INTEGER,
  CUSTNAME VARCHAR(20),
  ORDERDATE CHAR(8),
  ORDERAMT DECIMAL(8,3),
  COMMENTS VARCHAR(20));
```

Populate the table by inserting or loading about 500 rows.

```
EXEC SQL DECLARE CURSOR ORDERSROLL  
    SENSITIVE DYNAMIC SCROLL FOR  
        SELECT ORDERNUM, CUSTNAME, ORDERAMT, ORDERDATE FROM ORDER  
        WHERE ORDERAMT > 1000  
        FOR UPDATE OF COMMENTS;
```

Open the scrollable cursor.

```
OPEN CURSOR ORDERSROLL;
```

Fetch forward from the scrollable cursor.

```
-- Loop-to-fill-screen  
-- do 10 times  
    FETCH FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;  
-- end
```

Fetch RELATIVE from the scrollable cursor.

```
-- Skip-forward-100-rows  
    FETCH RELATIVE +100  
        FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;  
-- Skip-backward-50-rows  
    FETCH RELATIVE -50  
        FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch ABSOLUTE from the scrollable cursor.

```
-- Re-read-the-third-row  
    FETCH ABSOLUTE +3  
        FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch RELATIVE from scrollable cursor.

```
-- Read-the-third-row-from current position  
    FETCH SENSITIVE RELATIVE +3  
        FROM ORDERSROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Do a positioned update through the scrollable cursor.

```
-- Update-the-current-row  
    UPDATE ORDER SET COMMENTS = "Expedite"  
        WHERE CURRENT OF ORDERSROLL;
```

Close the scrollable cursor.

```
CLOSE CURSOR ORDERSROLL;
```

*Example 9:* Declare C1 as the cursor of a query to retrieve a rowset from the table DEPT. The prepared statement is MYCURSOR.

```
EXEC SQL DECLARE C1 CURSOR  
    WITH ROWSET POSITIONING FOR MYCURSOR;
```

---

## DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table resides in the work file database and its description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description and instance of the temporary table. When the application process terminates, the temporary table is dropped.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

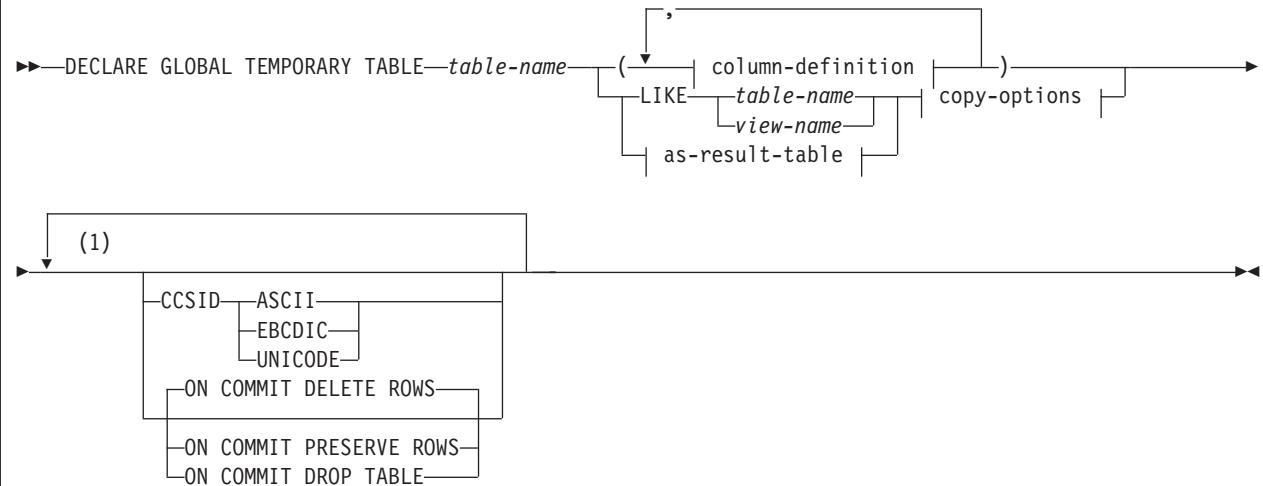

None are required, unless the LIKE clause is specified when additional privileges might be required.

PUBLIC implicitly has the following privileges without GRANT authority for declared temporary tables:

- The CREATETAB privilege to define a declared temporary table in the database that is defined AS WORKFILE, which is the database for declared temporary tables.
- The USE privilege to use the table spaces in the database that is defined as WORKFILE.
- All table privileges on the table and authority to drop the table. (Table privileges for a declared temporary table cannot be granted or revoked.)

These implicit privileges are not recorded in the DB2 catalog and cannot be revoked.

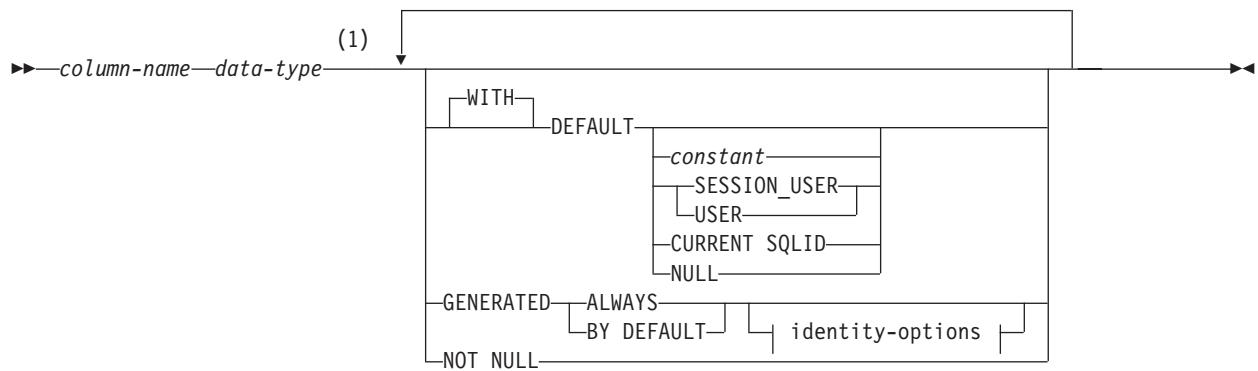

## Syntax

### Notes:

- 1 The same clause must not be specified more than one time.

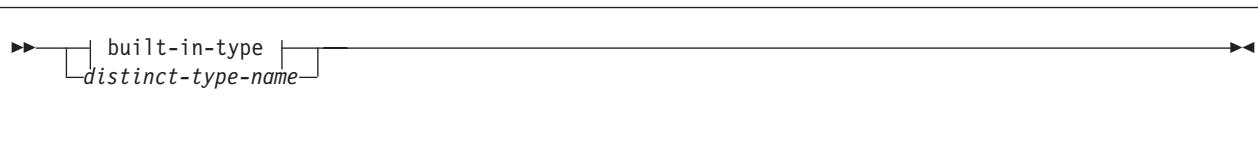

### column-definition:

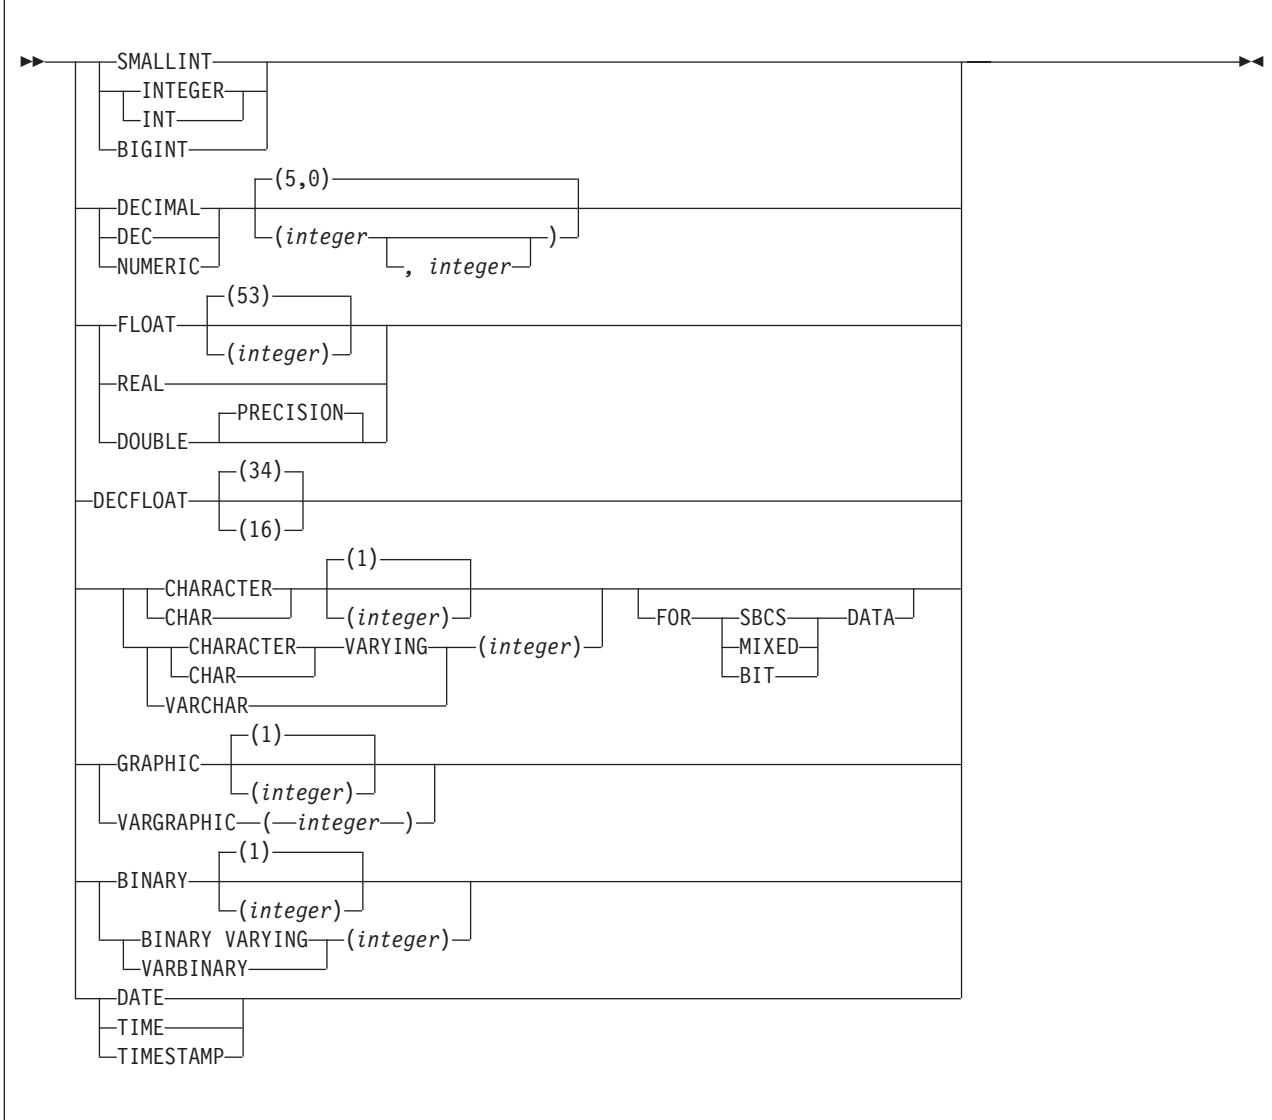

### Notes:

- 1 The same clause must not be specified more than once.

### data-type:

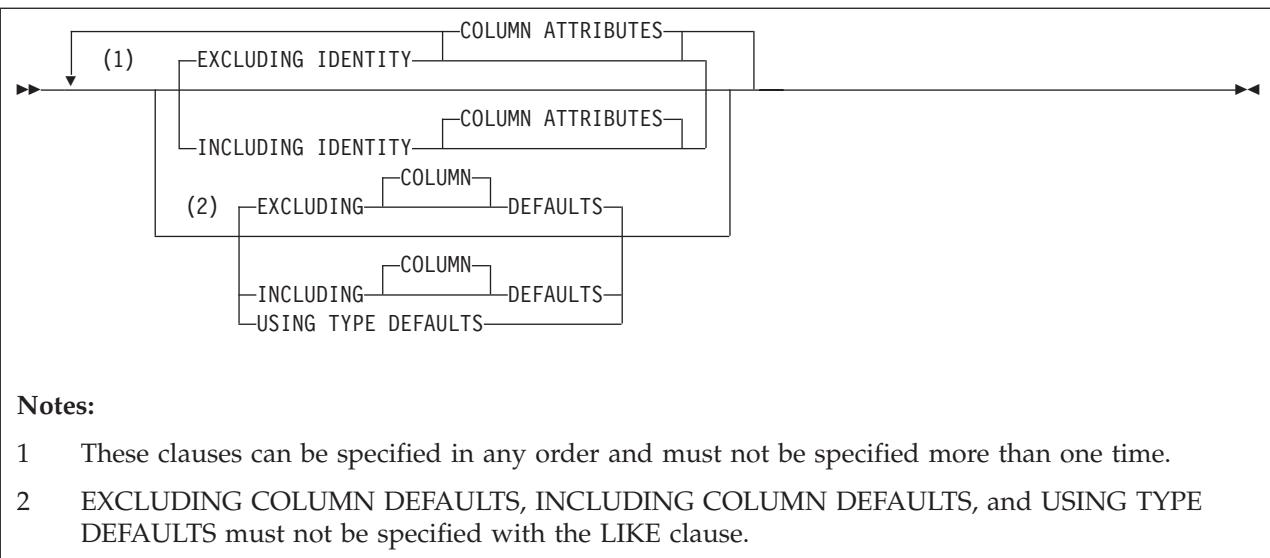

### built-in-type:

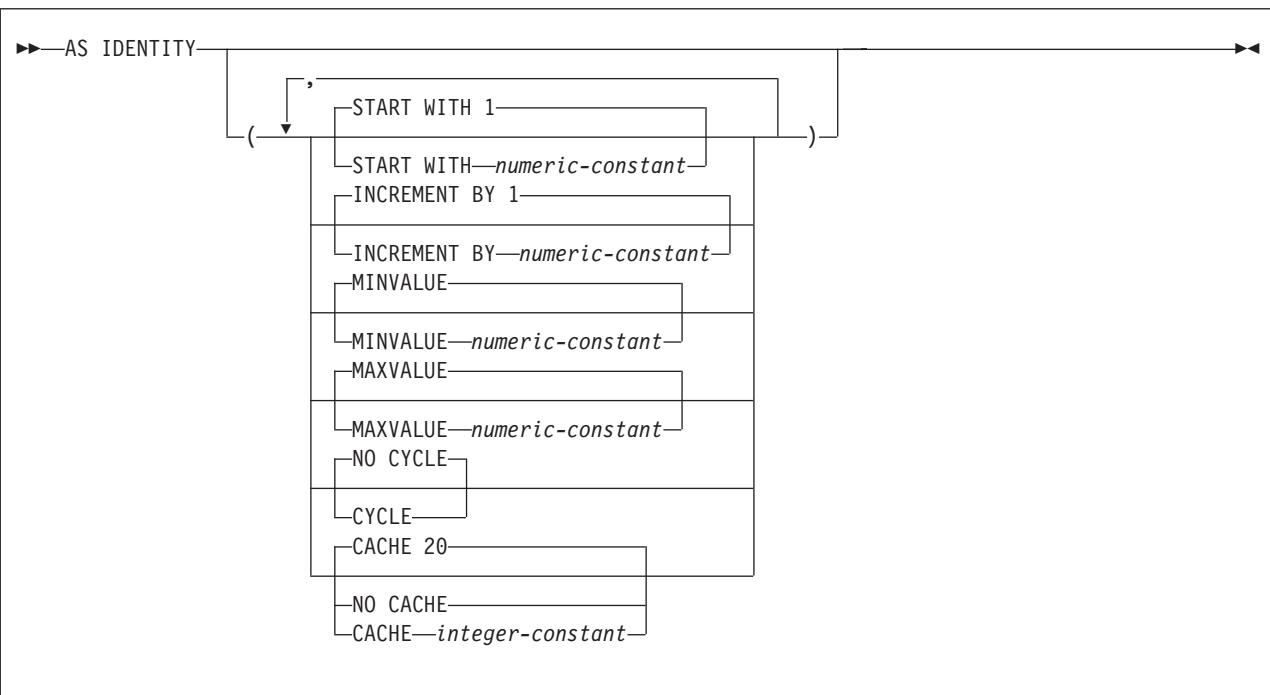

**as-result-table:**

►►AS—(*fullselect*)—WITH NO DATA►►

**copy-options:**

#### identity-options:

## Description

*table-name*

Names the temporary table. The qualifier, if specified explicitly, must be SESSION. If the qualifier is not specified, it is implicitly defined to be SESSION.

If a table, view, synonym, or alias already exists with the same name and an implicit or explicit qualifier of SESSION:

- The declared temporary table is still defined with SESSION.*table-name*. An error is not issued because the resolution of a declared temporary table name does not include the persistent and shared names in the DB2 catalog tables.
- Any references to SESSION.*table-name* will resolve to the declared temporary table rather than to any existing SESSION.*table-name* whose definition is persistent and is in the DB2 catalog tables.

*column-definition*

Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32683 bytes. The maximum row size must not exceed 32675 bytes (8 bytes less than the maximum record size).

*column-name*

Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

*data-type*

Specifies the data type of the column. The data type can be any built-in data type that can be specified for the CREATE TABLE statement except for a LOB (BLOB, CLOB, and DBCLOB), ROWID, or XML type. The FOR *subtype* DATA clause can be specified as part of *data-type*. For more information on the data types and the rules that apply to them, see built-in-type.

**DEFAULT**

Specifies a default value for the column. This clause must not be specified more than once in the same *column-definition*.

Omission of NOT NULL and DEFAULT from a *column-definition* is an implicit specification of DEFAULT NULL.

If DEFAULT is specified without a value after it, the default value of the column depends on the data type of the column, as follows:

**Data type**

**Default value**

**Numeric**

0

**Fixed-length character string**

A string of blanks

**Fixed-length graphic string**

A string of blanks

**Fixed-length binary string**

Hexadecimal zeros

**Varying-length string**

A string of length 0

**Date** CURRENT DATE

**Time** CURRENT TIME

**Timestamp**

CURRENT TIMESTAMP

A default value other than the one that is listed above can be specified in one of the following forms:

*constant*

Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column. A hexadecimal graphic string constant (GX) cannot be specified.

**SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register at the time of an insert or update operation or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the SESSION\_USER special register.

**CURRENT\_SQLID**

Specifies the value of the SQL authorization ID of the process at the time of an SQL data change statement or LOAD as the default value for the column. The data type of the column must be a character string with a length attribute greater than or equal to the length attribute of the CURRENT\_SQLID special register.

**NULL**

Specifies null as the default value for the column. If NOT NULL was specified, DEFAULT NULL must not be specified within the same *column-definition*.

**GENERATED**

Specifies that DB2 generates values for the column. GENERATED must be specified if the column is to be considered an IDENTITY column. If DEFAULT is specified for the column for an update operation, DB2 generates a value for both GENERATED ALWAYS and GENERATED BY DEFAULT.

**ALWAYS**

Specifies that DB2 always generates a value for the column when a row is inserted into the table.

**BY DEFAULT**

Specifies that DB2 generates a value for the column when a row is inserted into the table unless a value is specified. BY DEFAULT is the recommended value only when you are using data propagation.

Defining a column as GENERATED BY DEFAULT does not necessarily guarantee the uniqueness of the values. To ensure uniqueness of the values, define a unique, single-column index on the column.

**AS IDENTITY**

Specifies that the column is an identity column for the table. A table can have only one identity column. AS IDENTITY can be specified only if the data type for the column is an exact numeric type with a scale of zero (SMALLINT, INTEGER, BIGINT, DECIMAL with a scale of zero).

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause. For the descriptions of the identity attributes, see the description of the AS IDENTITY clause in “CREATE TABLE” on page 1079.

**NOT NULL**

Specifies that the column cannot contain nulls. Omission of NOT NULL indicates that the column can contain nulls.

**LIKE *table-name* or *view-name***

Specifies that the columns of the table have the same name, data type, and nullability attributes as the columns of the identified table or view. If a table is identified, the column default attributes are also defined by that table. The name specified must identify a table, view, synonym, or alias that exists at the current server. The identified table must not be an auxiliary table.

The LIKE clause must not be specified in a Common Criteria environment.

The privilege set must include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If LIKE results in a column having a LOB data type, a ROWID data type, or distinct type, the DECLARE GLOBAL TEMPORARY TABLE statement fails.
- In addition to these data type restrictions, if any column has any other attribute value that is not allowed in a declared temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.

When the identified object is a table, the column name, data type, nullability, and default attributes are determined from the columns of the specified table; any identity column attributes are inherited only if the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified.

#### *as-result-table*

Specifies that the table definition is based on the column definitions from the result of a query expression.

The behavior of these column attributes is controlled with the INCLUDING or USING TYPE DEFAULTS clauses, which are defined below.

#### **AS (*fullselect*)**

Specifies an implicit definition of *n* columns for the declared global temporary table, where *n* is the number of columns that would result from the *fullselect*. The columns of the new table are defined by the columns that result from the *fullselect*. Every select list element must have a unique name. The AS clause can be used in the select-clause to provide unique names. The implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of *fullselect*. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the *fullselect* is not considered hidden in the new table.

The AS (*fullselect*) clause must not be specified in a Common Criteria environment.

The result table of the *fullselect* must not contain a column that has a LOB data type, a ROWID data type, an XML data type or a distinct type.

If *fullselect* results in other column attributes that are not applicable for a declared temporary table, those attributes are ignored in the implicit definition for the declared temporary table.

If *fullselect* results in a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.

The *fullselect* must not refer to host variables or include parameter markers (question marks). The outermost SELECT list of the *fullselect* must not reference data that is encoded with different CCSID sets.

#### **WITH NO DATA**

Specifies that the *fullselect* is not executed. You can use the INSERT INTO statement with the same *fullselect* specified in the AS clause to populate the declared temporary table with the set of rows from the result table of the *fullselect*.

*copy-options*

Specifies whether identity column attributes and column defaults are inherited from the definition of the source of the result table.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies whether identity column attributes are inherited from the columns resulting from the *fullselect*, *table-name*, or *view-name*.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that the table does not inherit the identity attributes of the columns resulting from the *fullselect*, *table-name*, or *view-name*.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**

Specifies that the table inherits the identity attributes, if any, of the columns resulting from the *fullselect* or *table-name*. In general, the identity attributes are copied if the element of the corresponding column in the table or *fullselect* is the name of a table column that directly or indirectly maps to the name of a base table column that is an identity column.

If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS *fullselect* clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the *fullselect* includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the *fullselect* includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The *fullselect* includes a set operation.

If INCLUDING IDENTITY COLUMN ATTRIBUTES is not specified, the new table will not have an identity column.

If the LIKE clause identifies a view, INCLUDING IDENTITY COLUMN ATTRIBUTES must not be specified.

**EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS**

Specifies whether the table inherits the default values of the columns of the *fullselect*. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

**EXCLUDING COLUMN DEFAULTS**

Specifies that the table does not inherit the default values of the columns of the *fullselect*. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert operation for the new table.

**INCLUDING COLUMN DEFAULTS**

Specifies that the table inherits the default values of the columns of the *fullselect*. A default value is the value that is assigned to the column when a value is not specified on an insert operation or LOAD.

Columns resulting from the fullselect that are not updatable will not have a default defined in the corresponding column of the created table.

#### **USING TYPE DEFAULTS**

Specifies that the default values for the declared temporary table depend on the data type of the columns that result from *fullselect*, as follows:

<b>Data type</b>	<b>Default value</b>
<b>Numeric</b>	0
<b>Fixed-length character string</b>	Blanks
<b>Fixed-length graphic string</b>	Blanks
<b>Fixed-length binary string</b>	Hexadecimal zeros
<b>Varying-length string</b>	A string of length 0
<b>Date</b>	CURRENT DATE
<b>Time</b>	CURRENT TIME
<b>Timestamp</b>	CURRENT TIMESTAMP

#### **CCSID encoding-scheme**

Specifies the encoding scheme for string data that is stored in the table. For declared temporary tables, the encoding scheme for the data cannot be specified for the table space or database, and all data in one table space or the database need not use the same encoding scheme. Because there can be only one work file database for all declared temporary tables for each DB2 member, there can be a mixture of encoding schemes in both the database and each table space.

For the creation of temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause or as the scheme for the table identified by the AS (fullselect) clause.

**ASCII** Specifies that the data is encoded by using the ASCII CCSIDs of the server.

#### **EBCDIC**

Specifies that the data is encoded by using the EBCDIC CCSIDs of the server.

#### **UNICODE**

Specifies that the data is encoded by using the UNICODE CCSIDs of the server.

An error occurs if the CCSIDs for the encoding scheme have not been defined. Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.

#### **ON COMMIT**

Specifies what happens to the table for a commit operation. The default is ON COMMIT DELETE ROWS.

#### **DELETE ROWS**

Specifies that all of the rows of the table are deleted if there is no open cursor that is defined as WITH HOLD that references the table.

#### **PRESERVE ROWS**

Specifies that all of the rows of the table are preserved. Thread reuse capability is not available to any application process or thread that contains, at its most recent commit, an active declared temporary table that was defined with the ON COMMIT PRESERVE ROWS clause.

#### **DROP TABLE**

Specifies that the table is implicitly dropped at commit if there is no open cursor that is defined as WITH HOLD that references the table. If there is an open cursor defined as WITH HOLD on the table at commit, the rows are preserved.

## **Notes**

*Instantiation, scope, and termination:* For the following explanations, P denotes an application process, and T is a declared temporary table executed in P:

- An empty instance of T is created when a DECLARE GLOBAL TEMPORARY TABLE statement is executed in P.
- Any SQL statement in P can reference T, and any of those references to T in P is a reference to that same instance of T. ()

If a DECLARE GLOBAL TEMPORARY statement is specified within an SQL PL compound statement, the scope of the declared temporary table is the application process and not just the compound statement. A declared temporary table cannot be defined multiple times by the same name in other compound statements in that application process, unless the table has been dropped explicitly.

- If T was declared at a remote server, the reference to T must use the same DB2 connection that was used to declare T and that connection must not have been terminated after T was declared. When the connection to the database server at which T was declared terminates, T is dropped.
- If T was defined with the ON COMMIT DELETE ROWS clause specified implicitly or explicitly, when a commit operation terminates a unit of work in P and there is no open WITH HOLD cursor in P that is dependent on T, the commit deletes all rows from T.
- If T is defined with the ON COMMIT DROP TABLE clause, when a commit operation terminates a unit of work in P and no program in P has a WITH HOLD cursor open that is dependent on T, the commit includes the operation DROP TABLE T.
- When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the changes to table T are undone.

When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback drops table T.

When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the drop of the declaration of declared temporary table SESSION.T, the rollback undoes the drop of table T.

- When the application process that declared T terminates, T is dropped.

**Privileges:** When a declared temporary table is defined, PUBLIC is implicitly granted all table privileges on the table and authority to drop the table. These implicit privileges are not recorded in the DB2 catalog and cannot be revoked. This enables any SQL statement in the application process to reference a declared temporary table that has already been defined in that application process.

**Referring to a declared temporary table in other SQL statements:** Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, you must qualify the table name with SESSION. You can either specify SESSION explicitly in the table name or use the QUALIFIER bind option to specify SESSION as the qualifier for all SQL statements in the plan or package.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, DB2 assumes that you are not referring to a declared temporary table. DB2 resolves such table references to a table whose definition is persistent and appears in the DB2 catalog tables.

With the exception of the DECLARE GLOBAL TEMPORARY TABLE statement, any static SQL statement that references a declared temporary table is incrementally bound at run time. This is because the definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY statement is executed in the application process that contains those SQL statements and the definition does not persist when the application process finishes running.

When a plan or package is bound, any static SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) that references a *table-name* that is qualified by SESSION, regardless of whether the reference is for a declared temporary table, is not completely bound. However, the bind of the plan or package succeeds if there are no other errors. These static SQL statements are then incrementally bound at run time when the static SQL statement is issued. Object dependencies are not recorded in SYSIBM.SYSPLANDEP or SYSIBM.SYSPACKDEP tables. These incremental binds are necessary because:

- The definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY TABLE statement for the table is executed in the same application process that contains those SQL statements. Therefore, DB2 must wait until the plan or package is run to determine if SESSION.*table-name* refers to a base table or a declared temporary table.
- The definition of a declared temporary table does not persist after the table it is explicitly dropped (DROP statement), implicitly dropped (ON COMMIT DROP TABLE), or the application process that defined it finishes running. When the application process terminates or is re-used as a reusable application thread, the instantiated rows of the table are deleted and the definition of the declared temporary table is dropped if it has not already been explicitly or implicitly dropped.

After the plan or package is bound, any static SQL statement that refers to a *table-name* that is qualified by SESSION has a new statement status of M in the DB2 catalog table (STATUS column of SYSIBM.SYSSTMT or SYSIBM.SYSPACKSTMT).

**Thread reuse:** If a declared temporary table is defined in an application process that is running as a local thread, the application process or local thread that declared the table qualifies for explicit thread reuse if:

- The table was defined with the ON COMMIT DELETE ROWS attribute, which is the default.
- The table was defined with the ON COMMIT PRESERVE ROWS attribute and the table was explicitly dropped with the DROP TABLE statement before the thread's commit operation.
- The table was defined with the ON COMMIT DROP TABLE attribute. When a declared temporary table is defined with the ON COMMIT DROP TABLE and a commit occurs, the table is implicitly dropped if there are no open cursors defined with the WITH HOLD option.

When the thread is reused, the declared temporary table is dropped and its rows are destroyed. However, if you do not explicitly or implicitly drop all declared temporary tables before or when your thread performs a commit and the thread becomes idle waiting to be reused, as with all thread reuse situations, the idle thread holds resources and locks. This includes some declared temporary table resources and locks on the table spaces and the database descriptor (DBD) for the work file database. So, instead of using the implicit drop feature of thread reuse to drop your declared temporary tables, it is recommended that you:

- Use the DROP TABLE statement to explicitly drop your declared temporary tables before the thread performs a commit and becomes idle.
- Define the declared temporary tables with ON COMMIT DROP TABLE clause so that the tables are implicitly dropped when a commit occurs.

Explicitly dropping the tables before a commit occurs or having them implicitly dropped when the commit occurs enables you to maximize the use of declared temporary table resources and release locks when multiple threads are using declared temporary table.

Remote threads qualify for thread reuse differently than local threads. If a declared temporary table is defined (with or without ON COMMIT DELETE ROWS) in an application process that is running as a remote or DDF thread (also known as Database Access Thread or DBAT), the remote thread qualifies for thread reuse only when the declared temporary table is explicitly dropped before the thread performs a commit operation. Dropping the declared temporary table enables the remote thread to qualify for the implicit thread reuse that is supported for DDF threads via connection pooling and to become an inactive DBAT (type 1 inactive thread) or an inactive connection (type 2 inactive thread).

**Parallelism support:** Only I/O and CP parallelism are supported. Any query that involves a declared temporary table is limited to parallel tasks on a single CPC.

**Restrictions on the use of declared temporary tables:** Declared temporary tables cannot:

- Be specified in referential constraints.
- Be referenced in any SQL statements that are defined in a trigger body (CREATE TRIGGER statement). If you refer a table name that is qualified with SESSION in a trigger body, DB2 assumes that you are referring to a base table.
- Be referenced in a CREATE INDEX statement unless the schema name of the index is SESSION.

In addition, do not refer to a declared temporary table in any of the following statements.

ALTER INDEX	CREATE VIEW
ALTER TABLE	GRANT (table or view privileges)
COMMENT	LABEL
CREATE ALIAS	LOCK TABLE
CREATE FUNCTION (TABLE LIKE clause)	REFRESH TABLE
CREATE PROCEDURE (TABLE LIKE clause)	RENAME
CREATE TRIGGER	REVOKE (table or view privileges)

**Declared global temporary tables and dynamic statement caching:** The DB2 dynamic statement cache feature does not support dynamic SQL statements that reference declared temporary tables, even if the SQL statement also includes references to base or persistent tables. DB2 will not insert such statements into the dynamic statement cache. Instead, these dynamic statements are processed as if statement caching is not in effect. Declared temporary tables are unique and specific to an application process or DB2 thread, cannot be shared across threads, are not described in the DB2 catalog, and do not persist beyond termination of the DB2 thread or application process. These attributes prevent the use of the dynamic statement cache feature where tables and SQL statements are shared across threads or application processes.

**Table space requirements in the work file database:** DB2 stores all declared temporary tables in the work file database. You cannot define a declared temporary table unless a table space with at least an 32KB page size exists in the work file database.

**Alternative syntax and synonyms:** To provide compatibility with previous releases, DB2 allows you to specify:

- LONG VARCHAR as a synonym for VARCHAR(*integer*) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(*integer*) when defining the data type of a column.  
However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.
- DEFINITION ONLY as a synonym for WITH NO DATA.

## Examples

*Example 1:* Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.

```
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
  (EMPNO    CHAR(6)  NOT NULL,
   SALARY    DECIMAL(9, 2),
   BONUS    DECIMAL(9, 2),
   COMM     DECIMAL(9, 2))
   CCSID EBCDIC
   ON COMMIT PRESERVE ROWS;
```

*Example 2:* Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
  LIKE USER1.EMPTAB
  INCLUDING IDENTITY
  ON COMMIT PRESERVE ROWS;
```

In the above example, DB2 uses SESSION as the implicit qualifier for TEMPTAB1.

## DECLARE STATEMENT

The DECLARE STATEMENT statement is used for application program documentation. It declares names that are used to identify prepared SQL statements.

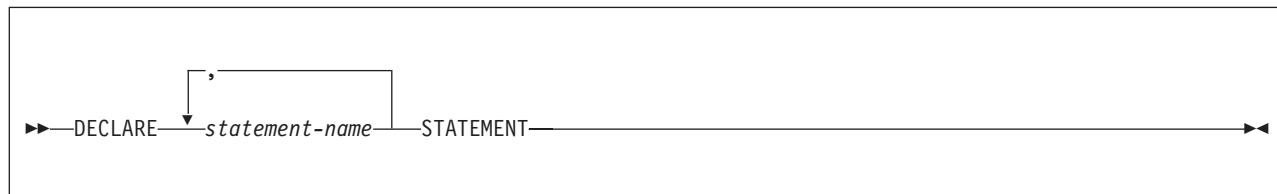

### Invocation

This statement can only be embedded in an application program. It is not an executable statement.

### Authorization

None required.

### Syntax

### Description

#### *statement-name* STATEMENT

Lists one or more names that are used in your application program to identify prepared SQL statements.

### Example

This example shows the use of the DECLARE STATEMENT statement in a PL/I program.

```
EXEC SQL DECLARE OBJECT_STATEMENT STATEMENT;  
  
EXEC SQL INCLUDE SQLDA;  
EXEC SQL DECLARE C1 CURSOR FOR OBJECT_STATEMENT;  
  
( SOURCE_STATEMENT IS "SELECT DEPTNO, DEPTNAME,  
      MGRNO FROM DSN8910.DEPT WHERE ADMRDEPT = 'A00'" )  
  
EXEC SQL PREPARE OBJECT_STATEMENT FROM SOURCE_STATEMENT;  
EXEC SQL DESCRIBE OBJECT_STATEMENT INTO SQLDA;  
  
/* Examine SQLDA */  
  
EXEC SQL OPEN C1;  
  
DO WHILE (SQLCODE = 0);  
  EXEC SQL FETCH C1 USING DESCRIPTOR SQLDA;  
  
/* Print results */  
  
END;  
  
EXEC SQL CLOSE C1;
```

## DECLARE TABLE

The DECLARE TABLE statement is used for application program documentation. It also provides the precompiler with information used to check your embedded SQL statements. (The DCLGEN subcommand can be used to generate declarations for tables and views described in any accessible DB2 catalog.)

For more on DCLGEN, see *DB2 Application Programming and SQL Guide* and *DB2 Command Reference*.)

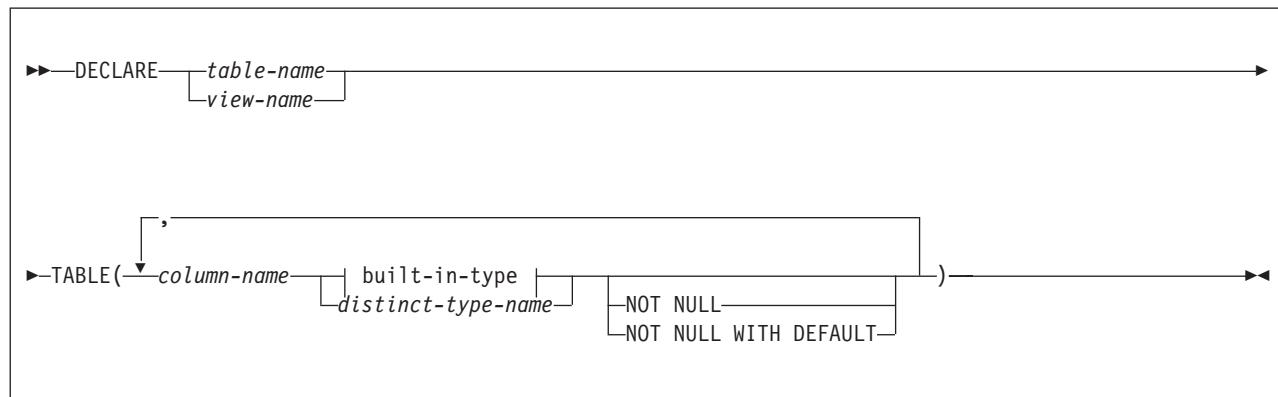

### Invocation

This statement can only be embedded in an application program. It is not an executable statement.

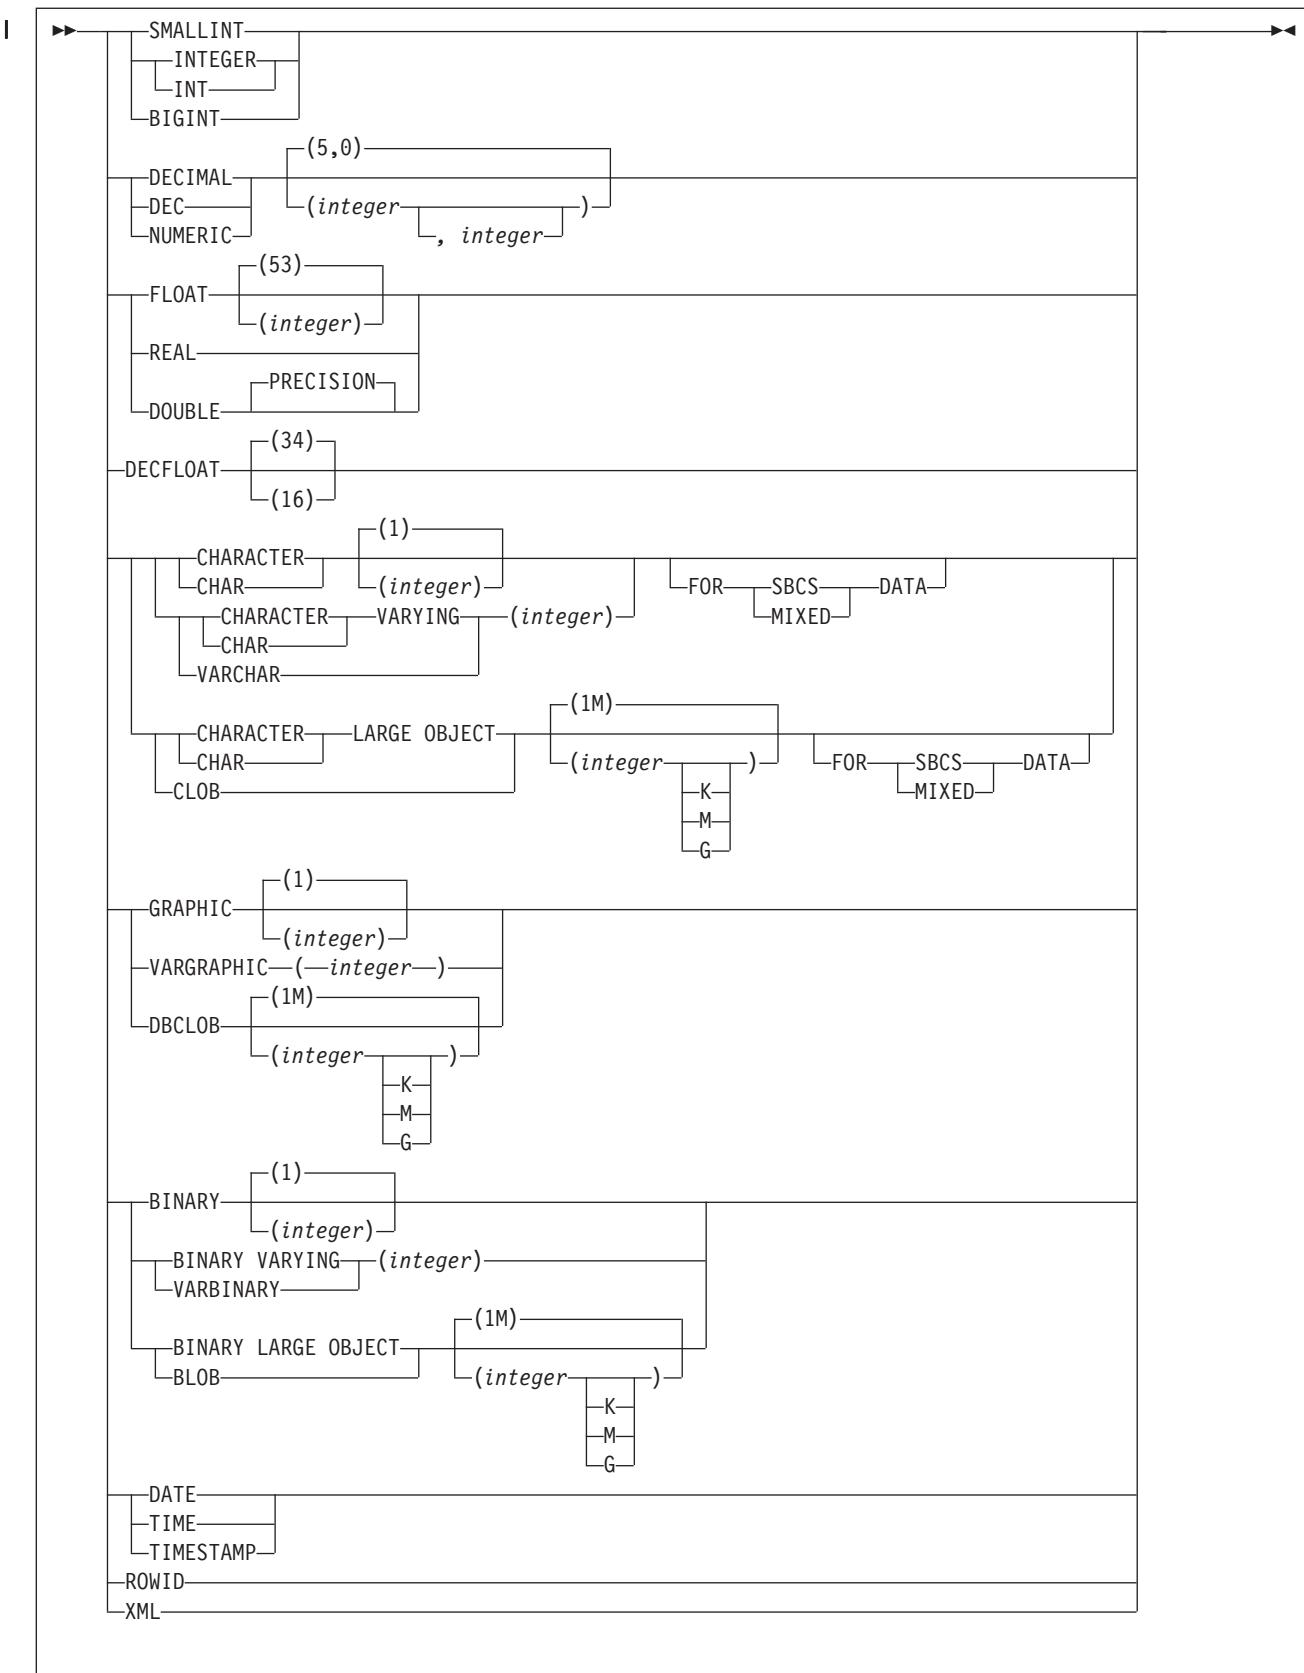

### Authorization

None required.

### Syntax

**built-in-type:**

## Description

*table-name or view-name*

Specifies the name of the table or view to document. If the table is defined in your application program, the description of the table in the SQL statement in which it is defined (for example, CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement) and the DECLARE TABLE statement must be identical.

*column-name*

Specifies the name of a column of the table or view.

The precompiler uses these names to check for consistency of names within your SQL statements. It also uses the data type to check for consistency of names and data types within your SQL statements.

*built-in-type*

Specifies the built-in data type of the column. Use one of the built-in data types. For more information on the data types, see *built-in-type*.

*distinct-type-name*

Specifies the distinct type (user-defined data type) of the column. An implicit or explicit schema name qualifies the name.

**NOT NULL**

Specifies that the column does not allow null values and does not provide a default value.

**NOT NULL WITH DEFAULT**

Specifies that the column does not allow null values but provides a default value.

## Notes

**Error handling during processing:** If an error occurs during the processing of the DECLARE TABLE statement, a warning message is issued, and the precompiler continues processing your source program.

**Documenting a distinct type column:** Although you can specify the name of a distinct type as the data type of a column in the DECLARE TABLE statement, use the built-in data type on which the distinct type is based instead. Using the base type enables the precompiler to check the embedded SQL statements for errors; otherwise, error checking is deferred until bind time.

To determine the source data type of the distinct type, check the value of column SOURCETYPE in catalog table SYSDATATYPES.

## Examples

*Example 1:* Declare the sample employee table, DSN8910.EMP.

```
EXEC SQL DECLARE DSN8910.EMP TABLE
  (EMPNO  CHAR(6)    NOT NULL,
   FIRSTNME VARCHAR(12) NOT NULL,
   MIDINIT  CHAR(1)    NOT NULL,
   LASTNAME VARCHAR(15) NOT NULL,
   WORKDEPT CHAR(3)      ,
   PHONENO  CHAR(4)      ,
   HIREDATE  DATE       ,
   JOB      CHAR(8)      ,
   EDLEVEL  SMALLINT    ,
   SEX      CHAR(1)      ,
```

```
BIRTHDATE DATE      ,
SALARY    DECIMAL(9,2)  ,
BONUS    DECIMAL(9,2)  ,
COMM     DECIMAL(9,2)  );
```

*Example 2:* Assume that table CANADIAN\_SALES keeps information for your company's sales in Canada. The table was created with the following definition:

```
CREATE TABLE CANADIAN_SALES
  (PRODUCT_ITEM  INTEGER,
   MONTH        INTEGER,
   YEAR         INTEGER,
   TOTAL        CANADIAN_DOLLAR);
```

CANADIAN\_DOLLAR is a distinct type that was created with the following statement:

```
CREATE TYPE CANADIAN_DOLLAR AS DECIMAL(9,2);
```

Declare the CANADIAN\_SALES table, using the source type for CANADIAN\_DOLLAR instead of the distinct type name.

```
DECLARE TABLE CANADIAN_SALES
  (PRODUCT_ITEM  INTEGER,
   MONTH        INTEGER,
   YEAR         INTEGER,
   TOTAL        DECIMAL(9,2);
```

## DECLARE VARIABLE

The DECLARE VARIABLE statement defines a CCSID for a host variable and the subtype of the variable. When it appears in an application program, the DECLARE VARIABLE statement causes the DB2 precompiler to tag a host variable with a specific CCSID. When the host variable appears in an SQL statement, the DB2 precompiler places this CCSID into the structures that it generates for the SQL statement.

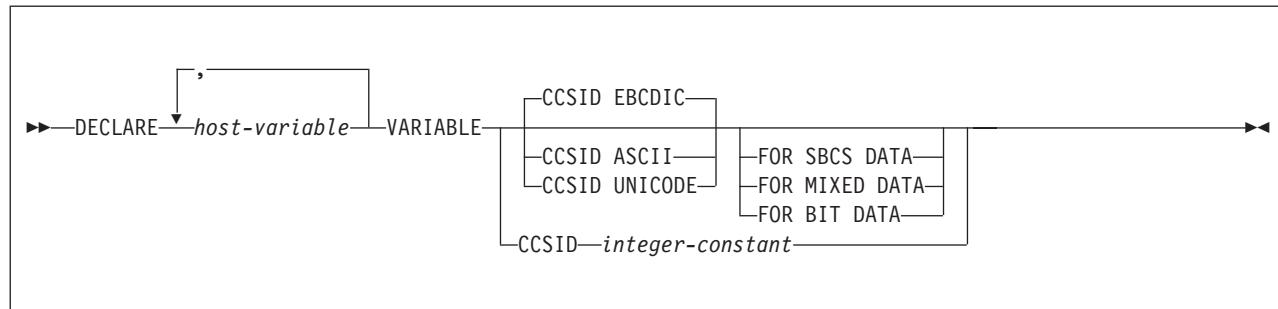

### Invocation

This statement can only be embedded in an application program. It is not an executable statement.

### Authorization

None required.

### Syntax

### Description

#### *host-variable*

Identifies a character or graphic string host variable defined in the program. An indicator variable cannot be specified for the host-variable.

#### **CCSID ASCII, EBCDIC, or UNICODE**

Specifies that the appropriate default CCSID for the specified encoding scheme of the server should be used. If this clause is not specified, the CCSID of the variable is the appropriate default EBCDIC CCSID of the server.

#### **CCSID ASCII**

Specifies that the default ASCII CCSID for the type of the variable at the server should be used.

#### **CCSID EBCDIC**

Specifies that the default EBCDIC CCSID for the type of the variable at the server should be used. CCSID EBCDIC is the default if this option is not specified.

#### **CCSID UNICODE**

Specifies that the default UNICODE CCSID for the type of the variable at the server should be used.

#### **FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA**

Specifies the type of data contained in the variable *host-variable*. The FOR clause cannot be specified when declaring a graphic host variable.

For ASCII or EBCDIC data, if this clause is not specified when declaring a character host variable, the default is FOR SBCS DATA if MIXED DATA = NO on the install panel DSNTIPF. The default is FOR MIXED DATA if MIXED DATA = YES on the install panel DSNTIPF.

For UNICODE data, the default is always FOR MIXED DATA, regardless of the setting of MIXED DATA on the install panel DSNTIPF.

#### **FOR SBCS DATA**

Specifies that the values of the host variable can contain only SBCS (single-byte character set) data.

#### **FOR MIXED DATA**

Specifies that the values of the host variable can contain both SBCS data and DBCS data.

#### **FOR BIT DATA**

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535.

#### **CCSID integer-constant**

Specifies that the values of the host variable contain data that is encoded using CCSID *integer-constant*. If the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a mixed data CCSID, the host variable is mixed data. For character host variables, the CCSID specified must be an SBCS, mixed CCSID, or UNICODE (UTF-8) CCSID. For graphic host variables, the CCSID specified must be a DBCS or UNICODE (UTF-16) CCSID. The valid range of values for the integer is 1 - 65533.

## **Notes**

**Placement of statement:** The DECLARE VARIABLE statement can be specified anywhere in an application program that SQL statements are valid with the following exception. The DECLARE VARIABLE statement must occur before an SQL statement that refers to a host variable specified in the DECLARE VARIABLE statement.

**CCSID exceptions for EXECUTE IMMEDIATE or PREPARE:** When the host variable appears in an SQL statement, the DB2 precompiler places the appropriate numeric CCSID into the structures it generates for the SQL statement. This placement of the CCSID occurs for any SQL statement other than the EXECUTE IMMEDIATE or PREPARE statements. The placement of the CCSID also occurs for a *host-variable* in an EXECUTE IMMEDIATE or PREPARE statement, but it does not occur for a variable in a *string-expression* in an EXECUTE IMMEDIATE or PREPARE statement.

If a PL/1 application program contains at least one DECLARE VARIABLE statement, a *string-expression* in any EXECUTE IMMEDIATE or PREPARE statement cannot be preceded by a colon. An expression that consists of just a variable name preceded by a colon is interpreted as a *host-variable*.

**Specific host languages:** If a DECLARE VARIABLE statement is used in an assembler source program, the ONEPASS precompiler option must not be used. If a DECLARE VARIABLE statement is used in a C, C++, or PL/I source program, the TWOPASS precompiler option must be used. For those languages, or COBOL, the host-variable definition can either precede or follow a DECLARE VARIABLE statement that refers to that variable. If a DECLARE VARIABLE statement is used

in a FORTRAN source program, then the host-variable definition must precede the DECLARE VARIABLE statement.

## Example

*Example:* Define the following host variables using PL/I data types: FRED as fixed length bit data, JEAN as fixed length UTF-8 (mixed) data, DAVE as varying length UTF-8 (mixed) data, PETE as fixed length graphic UTF-16 data, and AMBER as varying length graphic UTF-16 data.

Use the DECLARE VARIABLE statement to specify a data subtype or CCSID for these host variables: FRED as CCSID EBCDIC, JEAN as CCSID 1208 or CCSID UNICODE, DAVE as CCSID 1208 or CCSID UNICODE, PETE as CCSID 1200 or CCSID UNICODE, and AMBER as CCSID 1200 or CCSID UNICODE.

```
EXEC SQL BEGIN DECLARE SECTION;
  DCL FRED CHAR(10);
  EXEC SQL DECLARE :FRED VARIABLE CCSID EBCDIC FOR BIT DATA;
  DCL JEAN CHAR(30);
  EXEC SQL DECLARE :JEAN VARIABLE CCSID 1208;
  DCL DAVE CHAR(9) VARYING;
  EXEC SQL DECLARE :DAVE VARIABLE CCSID UNICODE;
  DCL PETE GRAPHIC(10);
  EXEC SQL DECLARE :PETE VARIABLE CCSID 1200;
  DCL AMBER VARGRAPHIC(20);
  EXEC SQL DECLARE :AMBER VARIABLE CCSID UNICODE;
EXEC SQL END DECLARE SECTION;
```

## DELETE

The DELETE statement deletes rows from a table or view or activates an instead of delete trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Deleting a row from a view deletes the row from the table on which the view is based if no instead of trigger is defined for the delete operation on this view. If such a trigger is defined, the trigger is activated instead of the delete operation.

There are two forms of this statement:

- The *searched* DELETE form is used to delete one or more rows, optionally determined by a search condition.
- The *positioned* DELETE form specifies that one or more rows corresponding to the current cursor position are to be deleted.

### Invocation

This statement can be embedded in an application program or issued interactively. A positioned DELETE is embedded in an application program. Both the embedded and interactive forms are executable statements that can be dynamically prepared.

### Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table, or a view, and whether the statement is a searched DELETE and SQL standard rules are in effect:

*When a table other than a catalog table is identified:* The privilege set must include at least one of the following:

- The DELETE privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

*When a catalog table is identified:* The privilege set must include at least one of the following:

- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

*When a view is identified:* The privilege set must include at least one of the following:

- The DELETE privilege on the view
- SYSADM authority

In a searched delete, the SELECT privilege is required in addition to the DELETE privilege when the option for the SQL standard is set as follows:

**Searched DELETE and SQL standard rules:** If SQL standard rules are in effect and the search-condition in a searched DELETE contains a reference to a column of the table or view, the privilege set must include at least one of the following:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table is not a catalog table
- SYSADM authority

SQL standard rules are in effect as follows:

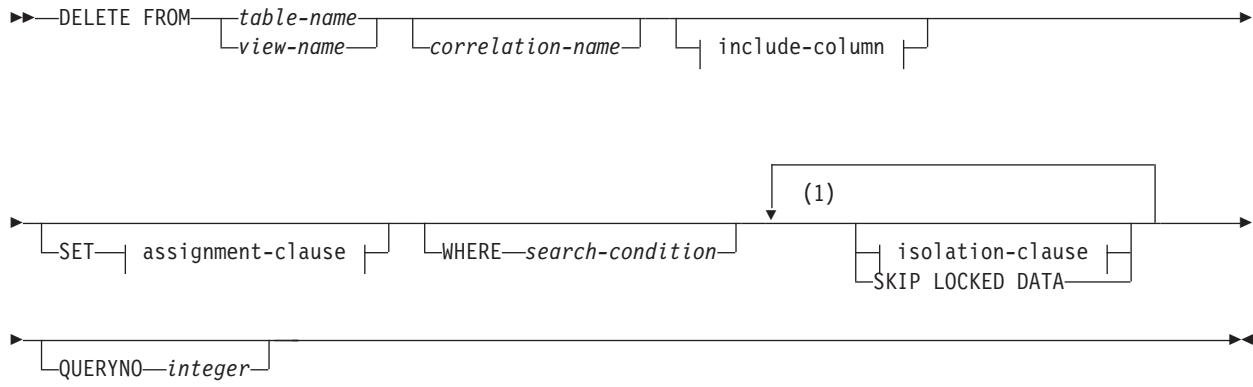

- For static SQL statements, if the SQLRULES(STD) bind option was specified
- For dynamic SQL statements, if the CURRENT RULES special register is set to 'STD'

The owner of a view, unlike the owner of a table, might not have DELETE authority on the view (or might have DELETE authority without being able to grant it to others). The nature of the view itself can preclude its use for DELETE. For more information, see the description of authority in "CREATE VIEW" on page 1184.

If a subselect is specified, the privilege set must include authority to execute the subselect. For more information about the subselect authorization rules, see "Authorization" on page 630.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 64.)

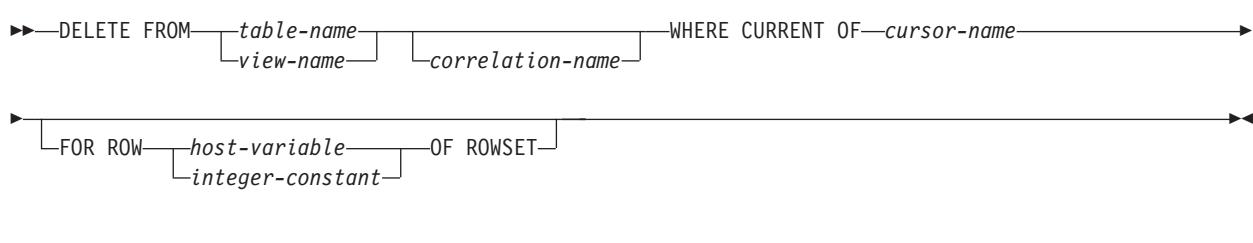

**searched delete:**

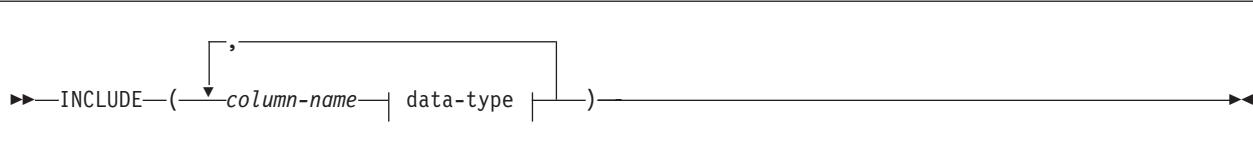

#### Notes:

- 1 The same clause must not be specified more than once.

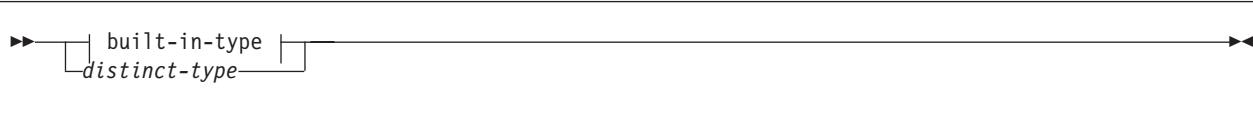

**positioned delete:**

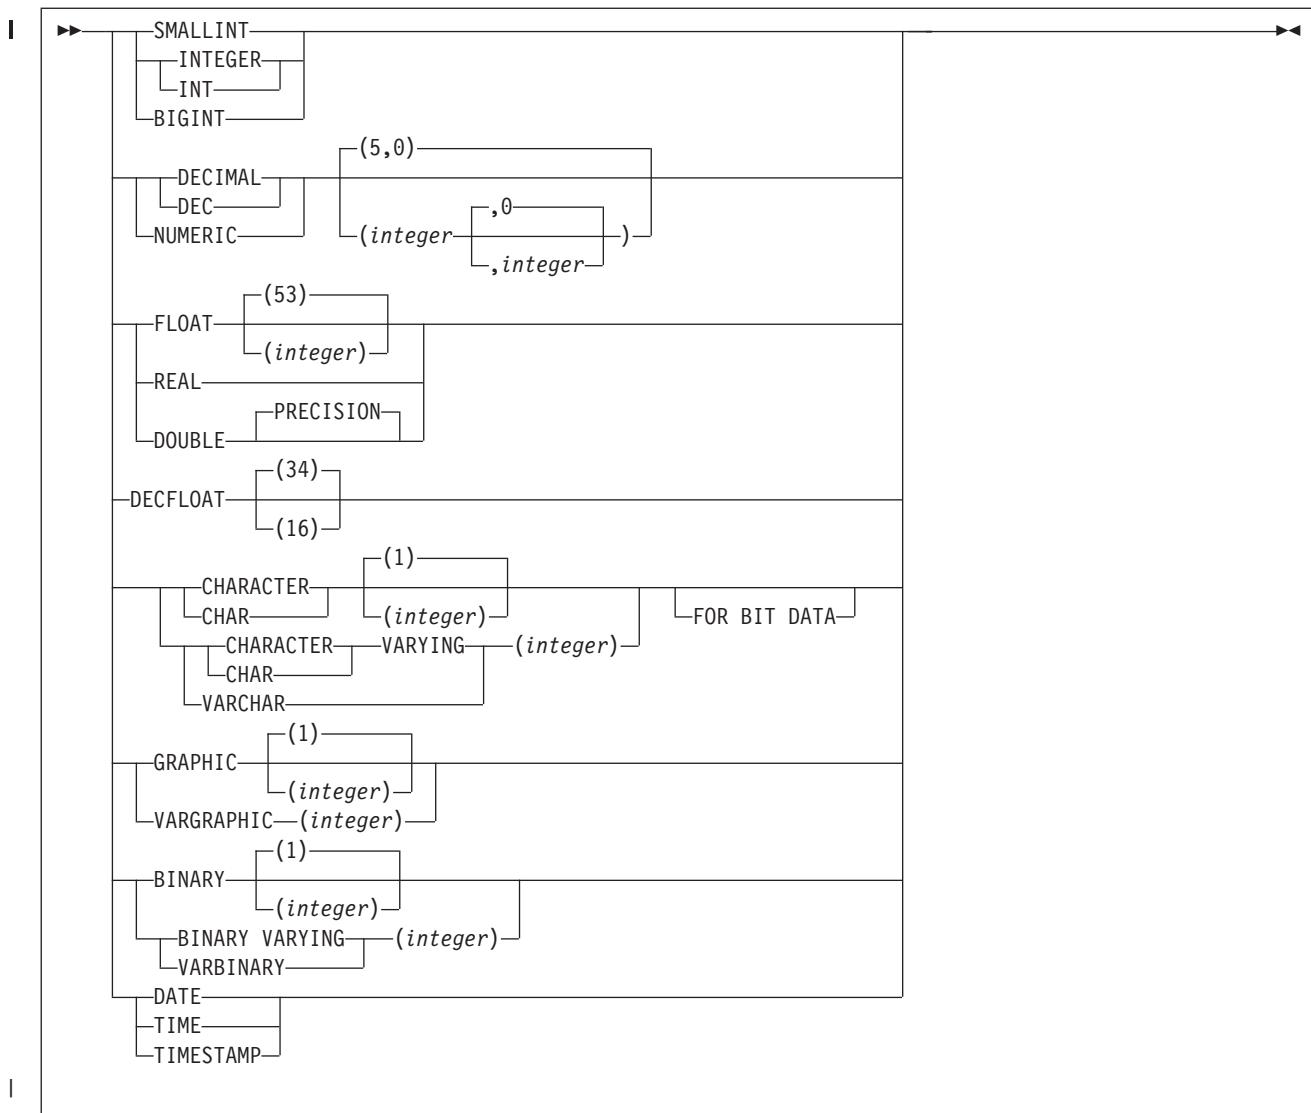

**include-column:**

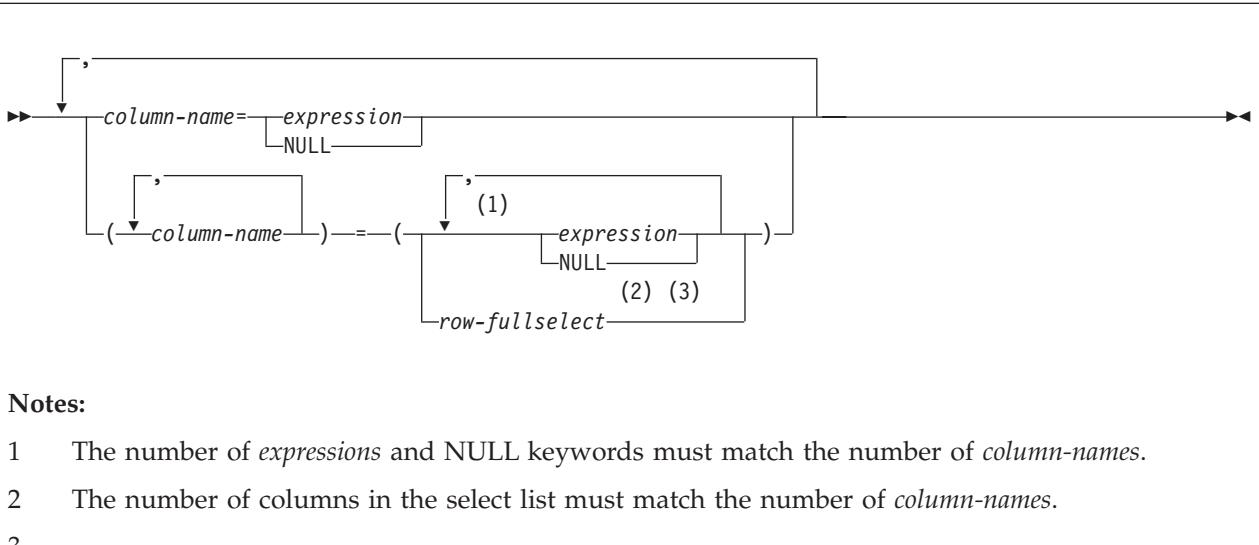

**data-type:**

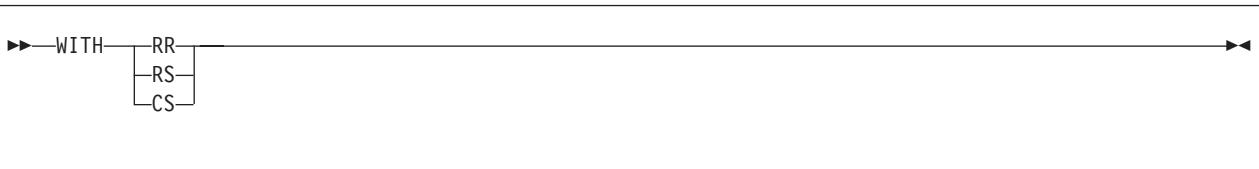

**built-in-type:**

| assignment clause:

**isolation-clause:**

## Description

**FROM table-name or view-name**

Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the DB2 subsystem identified by the implicitly or explicitly specified location name. The name must not identify:

- An auxiliary table
- A catalog table for which deletes are not allowed
- A view of such a catalog table
- A read-only view (For a description of a read-only view, see “CREATE VIEW” on page 1184.)
- A system-maintained materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

**correlation-name**

Specifies an alternate name that can be used within the *search-condition* to designate the table or view. (For an explanation of correlation names, see “Correlation names” on page 154.)

**include-column**

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the DELETE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*. If no value is assigned to a column that is specified by an *include-column*, a NULL value is returned for that column.

**INCLUDE**

Introduces a list of columns that are to be included in the result table of the DELETE statement. The included columns are only available if the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

*column-name*

Specifies the name for a column of the result table of the DELETE statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

**data-type**

Specifies the data type of the included column. The included columns are nullable.

**built-in-type**

Specifies a built-in data type. See “CREATE TABLE” on page 1079 for a description of each built-in type.

**distinct-type**

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**SET**

Introduces the assignment of values to columns.

*assignment-clause*

The assignment-clause introduces a list of one or more *column-names* and the values that are to be assigned to the columns. The *column-names* are the only columns that can be set using the *assignment-clause*.

*column-name*

Identifies an INCLUDE column.

Assignments to included columns are only processed when the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. The columns that are named in the INCLUDE clause are the only columns that can be set using the SET clause. The null value is returned for an included column that is not set by using an explicit SET clause.

*expression*

Indicates the new value of the column. The *expression* is any expression of the type described in “Expressions” on page 180. It must not include an aggregate function.

A *column-name* in an expression must identify a column of the table or view. For each row that is deleted, the value of the column in the expression is the value of the column in the row before the row is deleted.

**NULL**

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

*row-fullselect*

Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding *column-names*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column that is to be deleted is not nullable. An error also occurs if there is more than one row in the result.

If the fullselect refers to columns that are to be deleted, the value of such a column in the fullselect is the value of the column in the row before the row is deleted.

#### WHERE

Specifies the rows to be deleted. You can omit the clause, give a search condition, or specify a cursor. For a created temporary table or a view of a created temporary table, you must omit the clause. When the clause is omitted, all the rows of the table or view are deleted.

##### *search-condition*

Is any search condition as described in Chapter 2, “Language elements,” on page 47. Each *column-name* in the search condition, other than in a subquery, must identify a column of the table or view.

The search condition is applied to each row of the table or view and the deleted rows are those for which the result of the search condition is true.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

Let T2 denote the object table of a DELETE statement and let T1 denote a table that is referred to in the FROM clause of a subquery of that statement. T1 must not be a table that can be affected by the DELETE on T2. Thus, the following rules apply:

- T1 must not be a dependent of T2 in a relationship with a delete rule of CASCADE or SET NULL, unless the result of the subquery is materialized before the DELETE action is executed.
- T1 must not be a dependent of T3 in a relationship with a delete rule of CASCADE or SET NULL if deletes of T2 cascade to T3.

#### WHERE CURRENT OF *cursor-name*

Identifies the cursor to be used in the delete operation. *cursor-name* must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in “DECLARE CURSOR” on page 1191. If the DELETE statement is embedded in a program, the DECLARE CURSOR statement must include *select-statement* rather than *statement-name*.

The table or view named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must be capable of being deleted. For an explanation of read-only result tables, see Read-only cursors. Note that the object of the DELETE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

If the cursor is ambiguous and the plan or package was bound with CURRENTDATA(NO), DB2 might return an error to the application if DELETE WHERE CURRENT OF is attempted for any of the following:

- A cursor that is using block fetching
- A cursor that is using query parallelism
- A cursor that is positioned on a row that has been modified by this or another application process

When the DELETE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

- If the cursor is positioned on a single row, that row is the one deleted, and after the deletion the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted, and after the deletion the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

A positioned DELETE must not be specified for a cursor that references a view on which an instead of delete trigger is defined, even if the view is an updatable view.

#### **FOR ROW n OF ROWSET**

Specifies which row of the current rowset is to be deleted. The corresponding row of the rowset is deleted, and the cursor remains positioned on the current rowset. If the rowset consists of a single row, or all other rows in the rowset have already been deleted, then the cursor is positioned before the next rowset of the result table. If there is no next rowset, the cursor is positioned after the last rowset.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range of 1 to 32767. The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor.

If the specified row cannot be deleted, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as a delete hole (that is, a row in the result table whose corresponding row has deleted from the base table), an error is returned.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies a predicate of the SELECT statement), an error is returned.

It is possible for another application process to delete a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to delete such a row results in an error.

If the FOR ROW n OF ROWSET clause is not specified, the current position of cursor determines the rows that are affected by the statement:

- If the cursor is positioned on a single row, that row is the one deleted. After the row is deleted, the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted. After the rows are deleted, the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

#### *isolation-clause*

Specifies the isolation level used when locating the rows to be deleted by the statement.

## **WITH**

Introduces the isolation level, which may be one of the following:

- RR**    Repeatable read
- RS**    Read stability
- CS**    Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

## **SKIP LOCKED DATA**

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

For DELETE statements, SKIP LOCKED DATA can be specified only in the searched form of the DELETE statement. SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

## **QUERYNO integer**

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

## **Notes**

**Delete operation errors:** If an error occurs during the execution of any delete operation, no changes are made. If an error occurs during the execution of a positioned delete, the position of the cursor is unchanged. However, it is possible for an error to make the position of the cursor invalid, in which case the cursor is closed. It is also possible for a delete operation to cause a rollback, in which case the cursor is closed.

**Position of cursor:** If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of the

result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a searched DELETE). In the presence of an SQL data change statements that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.

**Locking:** Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful delete operation. Until the locks are released by a commit or rollback operation, the effect of the delete operation can only be perceived by the application process that performed the deletion and the locks can prevent other application processes from performing operations on the table. Locks are not acquired when rows are deleted from a declared temporary table unless all the rows are deleted (DELETE FROM T). When all the rows are deleted from a declared temporary table, a segmented table lock is acquired on the pages for the table and no other table in the table space is affected.

| **Triggers:** Delete operations can cause triggers to be activated. A trigger might cause other statements to be executed or might raise error conditions that are based on the deleted rows. If a DELETE statement on a view causes an INSTEAD OF trigger to be activated, referential integrity is checked against the updates that are performed in the trigger and not against the underlying tables of the view that cause the trigger to be activated.

**Referential integrity:** If the identified table or the base table of the identified view is a parent, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION. In addition, the delete operation must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted and any rows that are dependents of the selected rows are also deleted.

- The nullable columns of foreign keys in any rows that are their dependents in a relationship governed by a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship governed by a delete rule of CASCADE are also deleted, and these rules apply, in turn, to those rows.

The only difference between NO ACTION and RESTRICT is when the referential constraint is enforced. RESTRICT (IBM SQL rules) enforces the rule immediately, and NO ACTION (SQL standard rules) enforces the rule at the end of the statement. This difference matters only in the case of a searched DELETE involving a self-referencing constraint that deletes more than one row. NO ACTION might allow the DELETE to be successful where RESTRICT (if it were allowed) would prevent it.

**Check constraint:** A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL. If deleting a row in the parent table would cause a column in a dependent table to be set to null and there is a check constraint that specifies that the column must not be null, the row is not deleted.

**Nesting user-defined functions or stored procedures:** A DELETE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is

known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the DELETE must not access the table from which you are deleting rows.

**Indexes with VARBINARY columns:** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

**Number of rows deleted:** Except as noted below, a delete operation sets SQLERRD(3) in the SQLCA to the number of deleted rows. This number does not include any rows that were deleted as a result of a CASCADE delete rule or a trigger.

*DELETE FROM T without a WHERE clause deletes all rows of T.* If a table T is contained in a segmented table space and is not a parent table, this deletion will be performed without accessing T. The SQLERRD(3) field is set to -1. (For a complete description of the SQLCA, including exceptions to the above, see "SQL communication area (SQLCA)" on page 1646.)

**Rules for positioned DELETE with SENSITIVE STATIC scrollable cursor:** When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- *Delete attempt of delete holes or update holes.* If, with a positioned delete against a SENSITIVE STATIC scrollable cursor, an attempt is made to delete a row that has been identified as a delete hole (that is, a row in the result table whose corresponding row has been deleted from the base table), an error occurs. If an attempt is made to delete a row that has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies the predicate of the SELECT statement), an error occurs.
- *Delete operations.* Positioned delete operations with SENSITIVE STATIC scrollable cursors perform as follows:
  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, the delete operation is rejected and an error occurs. The operation can be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT list have not changed, the delete operation is allowed to proceed. Otherwise, an error occurs, the delete operation is rejected, and an update hole appears in the cursor.
  3. After the base table row is successfully deleted, the temporary result table is updated and the row is marked as a delete hole.
- *Rollback of delete holes.* Delete holes are usually permanent. Once a delete hole is identified, it remains a delete hole until the cursor is closed. However, if a positioned delete using *this* cursor actually caused the creation of the hole (that is, this cursor was used to make the changes that resulted in the hole) and the delete was subsequently rolled back, then the row is no longer considered a delete hole.

- *Result table.* Any deletes, either positioned or searched, to rows of the base table on which a SENSITIVE STATIC scrollable cursor is defined are reflected in the result table if a positioned update or positioned delete is attempted with the scrollable cursor. A SENSITIVE STATIC scrollable cursor sees these deletes when a FETCH SENSITIVE is attempted.

If the FOR ROW *n* OF ROWSET clause is not specified, the entire rowset fetched by the most recent FETCH statement that returned data for the specified cursor is deleted.

**Deleting rows from a table with multilevel security:** When you delete rows from a table with multilevel security, DB2 compares the security label of the user (the primary authorization ID) to the security label of the row. The delete proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is deleted.
- If the security label of the user dominates the security label of the row, the user's write-down privilege determines the security the result of the DELETE statement:
  - If the user has write-down privilege or write-down control is not enabled, the row is deleted.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not deleted.
- If the security label of the row dominates the security label of the user, the row is not deleted.

**Other SQL statements in the same unit of work:** The following statements cannot follow a DELETE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)

## Examples

Assume that the statements in the examples are embedded in PL/I programs.

*Example 1:* From the table DSN8910.EMP delete the row on which the cursor C1 is currently positioned.

```
EXEC SQL DELETE FROM DSN8910.EMP WHERE CURRENT OF C1;
```

*Example 2:* From the table DSN8910.EMP, delete all rows for departments E11 and D21.

```
EXEC SQL DELETE FROM DSN8910.EMP
  WHERE WORKDEPT = 'E11' OR WORKDEPT = 'D21';
```

*Example 3:* From employee table X, delete the employee who has the most absences.

```
EXEC SQL DELETE FROM EMP X
  WHERE ABSENT = (SELECT MAX(ABSENT) FROM EMP Y
    WHERE X.WORKDEPT = Y.WORKDEPT);
```

*Example 4:* Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete all 10 rows in the rowset.

```
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1;
```

*Example 5:* Assuming cursor CS1 is positioned on a rowset consisting of 10 rows of table T1, delete the fourth row of the rowset.

```
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1 FOR ROW 4 OF ROWSET;
```

---

## DESCRIBE

The DESCRIBE statement obtains information about an object. You can obtain the following types of information with this statement, each of which is described separately.

- Cursors

Gets information about the result set that is associated with the cursor. This information, such as column information, is put into a descriptor. See “DESCRIBE CURSOR” on page 1238.

- Input parameter markers of a prepared statement.

Gets information about the input parameter markers in a prepared statement. This information is put into a descriptor. See “DESCRIBE INPUT” on page 1240.

- The output of a prepared statement

Gets information about a prepared statement or information about the select list columns in a prepared SELECT statement. This information is put into a descriptor. See “DESCRIBE OUTPUT” on page 1243.

- Procedures

Gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor. See “DESCRIBE PROCEDURE” on page 1250.

- Tables

Gets information about a table or view. This information is put into a descriptor. See “DESCRIBE TABLE” on page 1253.

## DESCRIBE CURSOR

The DESCRIBE CURSOR statement gets information about the result set that is associated with the cursor. The information, such as column information, is put into a descriptor. Use DESCRIBE CURSOR for result set cursors from stored procedures. The cursor must be defined with the ALLOCATE CURSOR statement.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►—DESCRIBE CURSOR—cursor-name—INTO—descriptor-name—  
                  [host-variable]
```

### Description

#### *cursor-name* or *host-variable*

Identifies a cursor by the specified *cursor-name* or the cursor name contained in *host-variable*. The name must identify a cursor that has already been allocated in the source program.

If *host-variable* is used:

- It must be a character string variable that has a maximum length of 18 bytes.
- It must not be followed by an indicator variable.
- The cursor name must be left justified within the host variable and must not contain embedded blanks.
- If the length of the cursor name is less than the length of the host variable, it must be padded on the right with blanks.

#### INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the columns in the result set associated with the named cursor.

The considerations for allocating and initializing the SQLDA are similar to those of a varying-list SELECT statement. For more information, see *DB2 Application Programming and SQL Guide*.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE CURSOR statement is executed, the contents of the SQLDA are the same as after a DESCRIBE for a SELECT statement, with the following exceptions:

- The first 5 bytes of the SQLDAID field are set to 'SQLRS'.
- Bytes 6 to 8 of the SQLDAID field are reserved. If the cursor is declared WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set to 1.

These exceptions do not apply to a REXX SQLDA, which does not include the SQLDAID field.

## Notes

**Using cursors for result sets:** Column names are included in the information that DESCRIBE CURSOR obtains when the statement that generates the result set is either:

- Dynamic
- Static and the value of field DESCRIBE FOR STATIC on installation panel DSNTIP4 was YES when the package or stored procedure was bound. If the value of the field was NO, the returned information includes only the data type and length of the columns.

**Using host variables:** If the DESCRIBE CURSOR statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Examples

The statements in the following examples are assumed to be in PL/I programs.

*Example 1:* Place information about the result set associated with cursor C1 into the descriptor named by :sqlda1.

```
EXEC SQL DESCRIBE CURSOR C1 INTO :sqlda1
```

*Example 2:* Place information about the result set associated with the cursor named by :hv1 into the descriptor named by :sqlda2.

```
EXEC SQL DESCRIBE CURSOR :hv1 INTO :sqlda2
```

## DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the input parameter markers of a prepared statement.

For an explanation of prepared statements, see “PREPARE” on page 1405 and “DESCRIBE PROCEDURE” on page 1250.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required if the statement is used for a prepared statement.

### Syntax

```
►►DESCRIBE INPUT—statement-name—INTO—descriptor-name—►►
```

### Description

#### *statement-name*

Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

#### **INTO** *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in “SQL descriptor area (SQLDA)” on page 1656. See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C. The information returned in the SQLDA describes the parameter markers.

Before the DESCRIBE INPUT statement is executed, the user must set the SQLN field in the SQLDA and the SQLDA must be allocated. Considerations for initializing and allocating the SQLDA are similar to those for the DESCRIBE statement (see “DESCRIBE” on page 1237). An occurrence of an extended SQLVAR is needed for each parameter in addition to the required base SQLVAR only if the input data contains LOBs.

*For REXX:* The SQLDA is not allocated before it is used.

After the DESCRIBE INPUT statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. The SQLDA contents are similar to the contents returned for the DESCRIBE statement (see page The SQLDA contents returned after DESCRIBE) with these exceptions:

- In the SQLDAID, DB2 sets the value of the seventh byte only to the space character or '2'. A value of '3' is never used. The value '2' indicates that two SQLVAR entries (an occurrence of both a base SQLVAR and an extended SQLVAR) are required for each parameter because the input data contains LOBs. The seventh byte is a space character when either of the following conditions is true:

- The input data does not contain LOBs. Only a base SQLVAR occurrence is needed for each parameter.
- Only a base SQLVAR occurrence is needed for each column of the result, and the SQLDA is not large enough to contain the returned information.
- The SQLD field is set to the number of parameter markers being described. The value is 0 if the statement being described does not have input parameter markers.
- The SQLNAME field is not used.
- The SQLDATATYPE is set to a nullable, regardless of the usage of the parameter markers in the prepared statement.
- The SQLDATATYPE-NAME is not used if an extended SQLVAR entry is present. DESCRIBE INPUT does not return information about distinct types.

For complete information on the contents of the fields, see “SQL descriptor area (SQLDA)” on page 1656.

## Notes

*Preparing the SQLDA for OPEN or EXECUTE:* This note is relevant if you are applying DESCRIBE INPUT to a prepared statement and you intend to use the SQLDA in an OPEN or EXECUTE statement. To prepare the SQLDA for that purpose:

- Set SQLDATA to a valid address.
- If SQLTYPE is odd, set SQLIND to a valid address.

For the meaning of those fields in that context, see “SQL descriptor area (SQLDA)” on page 1656.

*Support for extended dynamic SQL in a distributed environment:* Unlike the DESCRIBE statement, which can be used in a distributed environment to describe static SQL statements generated by extended dynamic SQL, you cannot describe host variables in static SQL statements that are generated by extended dynamic SQL. A DESCRIBE INPUT statement issued against such static SQL statements always fails.

For information on how the DESCRIBE statement supports extended dynamic SQL, see Support for extended dynamic SQL in a distributed environment.

*Using host variables:* If the DESCRIBE INPUT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Example

Execute a DESCRIBE INPUT statement with an SQLDA that has enough SQLVAR occurrences to describe any number of input parameters a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

```
/* STMT1_STR contains INSERT statement with VALUES clause */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
... /* code to set SQLN to 5 and to allocate the SQLDA */ */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;
.
.
.
```

This example uses the first technique described in Allocating the SQLDA to allocate the SQLDA.

# DESCRIBE OUTPUT

The DESCRIBE OUTPUT statement obtains information about a prepared statement.

For an explanation of prepared statements, see “PREPARE” on page 1405 and “DESCRIBE PROCEDURE” on page 1250.

# Invocation

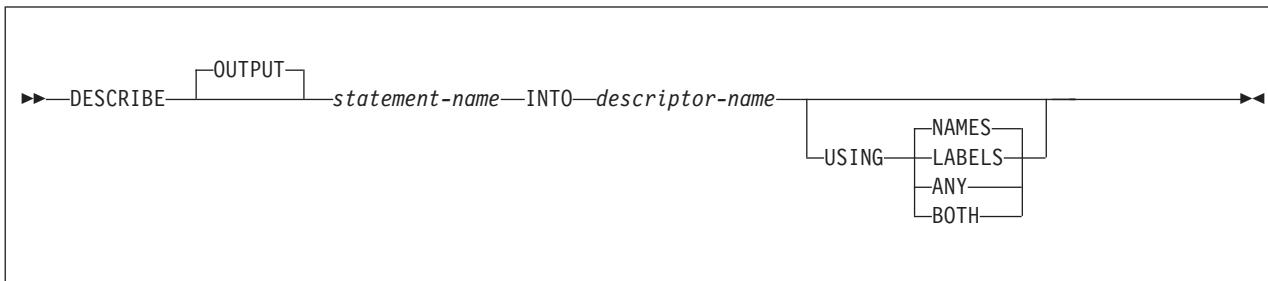

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

## Authorization

None required.

See “PREPARE” on page 1405 for the authorization required to create a prepared statement.

## Syntax

## Description

## OUTPUT

When a *statement-name* is specified, optional keyword to indicate that the describe will return information about the select list columns in a the prepared SELECT statement.

*statement-name*

Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

**INTO** *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in “SQL descriptor area (SQLDA)” on page 1656. See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

*For languages other than REXX:* Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

**SQLN** Indicates the number of SQLVAR occurrences provided in the SQLDA. DB2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.

*For REXX:* The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable *stem.SQLD*, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with *stem.n*.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

#### **USING**

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

#### **NAMES**

Assigns the name of the column. This is the default.

#### **LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

#### **ANY**

Assigns the column label, and if the column has no label, the column name.

#### **BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to  $2 \times n$  or  $3 \times n$ , where  $n$  is the number of columns in the object being described. For each of the columns, the first  $n$  occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third  $n$  occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

### **Notes**

*Using PREPARE INTO clause:* Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.

*Allocating the SQLDA:* Before the DESCRIBE or PREPARE INTO statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Also, enough storage must be allocated to contain the number of occurrences that SQLN specifies. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must be at least equal to the number of columns. Furthermore, if USING BOTH is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two or three times the number of columns. See "Determining how many SQLVAR occurrences are needed" on page 1661 for more information.

*First technique:* Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal three times the maximum number of columns allowed in a result table. After the SQLDA is allocated, the application can use the SQLDA repeatedly.

This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

*Second technique:* Repeat the following two steps for every processed select list:

1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero.
2. Allocate a new SQLDA with enough occurrences of SQLVAR. Use the values that are returned in SQLD and SQLCODE to determine the number of SQLVAR entries that are needed. The value of SQLD is the number of columns in the result table, which is either the required number of occurrences of SQLVAR or a fraction of the required number (see “Determining how many SQLVAR occurrences are needed” on page 1661 for details). If the SQLCODE is +236, +237, +238, or +239, the number of SQLVAR entries that is needed is two or three times the value in SQLD, depending on whether USING BOTH was specified. Set SQLN to reflect the number of SQLVAR entries that have been allocated.
3. Execute the DESCRIBE statement again, using the new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

*Third technique:* Allocate an SQLDA that is large enough to handle most (hopefully, all) select lists but is also reasonably small. If an execution of DESCRIBE fails because SQLDA is too small, allocate a larger SQLDA and execute the DESCRIBE statement again.

For the new larger SQLDA, use the values that are returned in SQLD and SQLCODE from the failing DESCRIBE statement to calculate the number of occurrences of SQLVAR that are needed, as described in technique two. Remember to check for SQLCODEs +236, +237, +238, and +239, which indicate whether *extended* SQLVAR entries are needed because the data includes LOBs or distinct types.

This third technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

**The SQLDA contents returned on DESCRIBE:** After a DESCRIBE statement is executed, the following list describes the contents of the SQLDA fields as they are set by DB2 or ignored. These descriptions do not necessarily apply to the uses of an SQLDA in other SQL statements (EXECUTE, OPEN, FETCH). For more on the other uses, see “SQL descriptor area (SQLDA)” on page 1656.

#### **SQLDAID**

DB2 sets the first 6 bytes to 'SQLDA ' (5 letters followed by the space character) and the eighth byte to a space character. The seventh byte is set to indicate the number of SQLVAR entries that are needed to describe each column of the result table as follows:

**space** The value of space occurs when:

- USING BOTH was not specified and the columns being described do not include LOBs or distinct types. Each column only needs one SQLVAR entry. If the SQL standard option is yes, DB2 sets SQLCODE to warning code +236. Otherwise, SQLCODE is zero.
- USING BOTH was specified and the columns being described do not include LOBs or distinct types. Each column needs two

SQLVAR entries. DB2 sets SQLD to two times the number of columns of the result table. The second set of SQLVARs is used for the labels.

- 2 Each column needs two SQLVAR entries. Two entries per column are required when:
  - USING BOTH was not specified and the columns being described include LOBs or distinct types or both. DB2 sets the second set of SQLVAR entries with information for the LOBs or distinct types being described.
  - USING BOTH was specified and the columns include LOBs but not distinct types. DB2 sets the second set of SQLVAR entries with information for the LOBs and labels for the columns being described.
- 3 Each column needs three SQLVAR entries. Three entries are required only when USING BOTH is specified and the columns being described include distinct types. The presence of LOB data does not matter. It is the distinct types and not the LOBs that cause the need for three SQLVAR entries per column when labels are also requested. DB2 sets the second set of SQLVAR entries with information for the distinct types (and LOBs, if any) and the third set of SQLVAR entries with the labels of the columns being described.

A REXX SQLDA does not contain this field.

#### **SQLDABC**

The length of the SQLDA in bytes. DB2 sets the value to  $SQLN \times 44 + 16$ .

A REXX SQLDA does not contain this field.

- SQLD** If the prepared statement is a query, DB2 sets the value to the number of columns in the object being described (the value is actually twice the number of columns in the case where USING BOTH was specified and the result table does not include LOBs or distinct types). Otherwise, if the statement is not a query, DB2 sets the value to 0.

#### **SQLVAR**

An array of field description information for the column being described. There are two types of SQLVAR entries—the base SQLVAR and the extended SQLVAR.

If the value of SQLD is 0, or is greater than the value of SQLN, no values are assigned to any occurrences of SQLVAR. If the value of SQLN was set so that there are enough SQLVAR occurrences to describe the specified columns (columns with LOBs or distinct types and a request for labels increase the number of SQLVAR entries that are needed), the values are assigned to the first  $n$  occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column, the second occurrence of SQLVAR contains a description of the second column, and so on. This first set of SQLVAR entries are referred to as *base SQLVAR* entries. Each column always has a base SQLVAR entry.

If the DESCRIBE statement included the USING BOTH clause, or the columns being described include LOBs or distinct types, additional SQLVAR entries are needed. These additional SQLVAR entries are referred to as the *extended SQLVAR* entries. There can be up to two sets of extended SQLVAR entries for each column.

For REXX, the SQLVAR is a set of stem variables that begin with *stem.n*, instead of a structure. The REXX SQLDA uses only a base SQLVAR. The way in which DB2 assigns values to the SQLVAR variables is the same as for other languages. That is, the *stem.1* variables describe the first column in the result table, the *stem.2* variables describe the second column in the result table, and so on. If USING BOTH is specified, the *stem.n+1* variables also describe the first column in the result table, the *stem.n+2* variables also describe the second column in the result table, and so on.

*The base SQLVAR:*

#### **SQLTYPE**

A code that indicates the data type of the column and whether the column can contain null values. For the possible values of SQLTYPE, see Table 146 on page 1666.

#### **SQLLEN**

A length value depending on the data type of the result columns. SQLLEN is 0 for LOB and XML data types. For the other possible values of SQLLEN, see Table 146 on page 1666.

In a REXX SQLDA, for DECIMAL or NUMERIC columns, DB2 sets the SQLPRECISION and SQLSCALE fields instead of the SQLLEN field.

#### **SQLDATA**

The CCSID of a string column. For possible values, see Table 147 on page 1668.

In a REXX SQLDA, DB2 sets the SQLCCSID field instead of the SQLDATA field.

#### **SQLIND**

Reserved.

#### **SQLNAME**

The unqualified name or label of the column, depending on the value of USING (NAMES, LABELS, ANY, or BOTH). The field is a string of length 0 if the column does not have a name or label. For more details on unnamed columns, see the discussion of the names of result columns under “select-clause” on page 633. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains the statement.

*The extended SQLVAR:*

#### **SQLLONGLEN**

The length attribute of a BLOB, CLOB, or DBCLOB column.

\* Reserved.

#### **SQLDATALEN**

Not Used.

#### **SQLDATATYPE-NAME**

For a distinct type, the fully qualified distinct type name. Otherwise, the value is the fully qualified name of the built-in data type.

For a label, the label for the column.

This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

The REXX SQLDA does not use the extended SQLVAR.

**Performance considerations:** Although DB2 does not change the value of SQLN, you might want to reset this value after the DESCRIBE statement is executed. If the contents of SQLDA from the DESCRIBE statement is used in a later FETCH statement, set SQLN to  $n$  (where  $n$  is the number of columns of the result table) before executing the FETCH statement. For details, see Preparing the SQLDA for data retrieval.

**Preparing the SQLDA for data retrievals:** This note is relevant if you are applying DESCRIBE to a prepared query and you intend to use the SQLDA in the FETCH statements you employ to retrieve the result table rows. To prepare the SQLDA for that task, you must set the SQLDATA field of SQLVAR. SQLIND must be set if SQLTYPE is odd, and SQLNAME must be set when overriding the CCSID. For the meaning of those fields in that context, see “SQL descriptor area (SQLDA)” on page 1656.

Also, SQLN and SQLDABC should be reset (if necessary) to  $n$  and  $n \times 44 + 16$ , where  $n$  is the number of columns in the result table. Doing so can improve performance when the rows of the result table are fetched.

**Support for extended dynamic SQL in a distributed environment:** In a distributed environment where DB2 for z/OS is the server and the requester supports extended dynamic SQL, such as DB2 Server for VSE & VM, a DESCRIBE statement that is executed against an SQL statement in the extended dynamic package appears to DB2 as a DESCRIBE statement against a static SQL statement in the DB2 package. A DESCRIBE statement cannot normally be issued against a static SQL statement. However, a DESCRIBE against a static SQL statement that is generated by extended dynamic SQL executes without error if the package has been rebound after field DESCRIBE FOR STATIC on installation panel DSNTIP4 has been set to YES.

YES indicates that DB2 generates an SQLDA for the DESCRIBE at bind time so that DESCRIBE requests for static SQL statements can be satisfied at execution time. For more information, see *DB2 Installation Guide*.

**Avoiding double preparation when using REOPT(ALWAYS) or REOPT(ONCE):** If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, DESCRIBE causes the statement to be prepared if it is not already prepared. If issued before an OPEN or an EXECUTE, the DESCRIBE causes the statement to be prepared without input variables. If the statement has input variables, the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid preparing statements twice, issue the DESCRIBE after the OPEN. For non-cursor statements, open and fetch processing are performed on the EXECUTE. So, if a DESCRIBE must be issued, the statement will be prepared twice.

The use of a prepared statement for an EXPLAIN statement can cause duplicate entries in the explain tables when the prepared statement specifies the REOPT(ALWAYS) bind option and is executed using the jcc driver.

**Errors occurring on DESCRIBE:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on DESCRIBE.

**Considerations for implicitly hidden columns:** A DESCRIBED OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

**Using host variables:** If the DESCRIBE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Example

In a PL/I program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA. This is the second technique described in Allocating the SQLDA.

```
EXEC SQL BEGIN DECLARE SECTION;
      DCL STMT1_STR CHAR(200) VARYING;
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
... /* code to prompt user for a query, then to generate */
     /* a select-statement in the STMT1_STR               */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
... /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
... /* code to check that SQLD is greater than zero, to set */
     /* SQLN to SQLD, then to re-allocate the SQLDA          */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
... /* code to prepare for the use of the SQLDA            */
EXEC SQL OPEN DYN_CURSOR;
... /* loop to fetch rows from result table              */
EXEC SQL FETCH DYN_CURSOR USING DESCRIPTOR :SQLDA;
.
.
```

## DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required.

### Syntax

```
►—DESCRIBE PROCEDURE—procedure-name—INTO—descriptor-name—  
                          └host-variable┘—————►
```

### Description

#### *procedure-name or host-variable*

Identifies the stored procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one, two, or three-part name. The procedure name in the DESCRIBE PROCEDURE statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the DESCRIBE PROCEDURE statement.

If a host variable is used:

- It must be a character string variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the database server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

#### **INTO** *descriptor-name*

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the result sets returned by the stored procedure.

Considerations for allocating and initializing the SQLDA are similar to those for DESCRIBE TABLE.

The contents of the SQLDA after executing a DESCRIBE PROCEDURE statement are:

- The first 5 bytes of the SQLDAID field are set to 'SQLPR'.  
A REXX SQLDA does not contain SQLDAID.
- Bytes 6 to 8 of the SQLDAID field are reserved.
- The SQLD field is set to the total number of result sets. A value of 0 in the field indicates there are no result sets.
- There is one SQLVAR entry for each result set.
- The SQLDATA field of each SQLVAR entry is set to the result set locator value associated with the result set.  
For a REXX SQLDA, SQLLOCATOR is set to the result set locator value.
- The SQLIND field of each SQLVAR entry is set to the estimated number of rows in the result set
- The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

## Notes

**SQLDA information:** A value of -1 in the SQLIND field indicates that an estimated number of rows in the result set is not provided. DB2 for z/OS always sets SQLIND to -1.

DESCRIBE PROCEDURE does not return information about the parameters expected by the stored procedure.

**Assignment of locator values:** Locator values are assigned to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

**Using host variables:** If the DESCRIBE PROCEDURE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Examples

The statements in the following examples are assumed to be in PL/I programs.

*Example 1:* Place information about the result sets returned by stored procedure P1 into the descriptor named by SQLDA1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL P1;
EXEC SQL DESCRIBE PROCEDURE P1 INTO :SQLDA1;
```

*Example 2:* Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSCHHEMA is used.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL MYSCHHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE MYSCHHEMA.P1 INTO :SQLDA1;
```

*Example 3:* Place information about the result sets returned by the stored procedure identified by host variable HV1 into the descriptor named by SQLDA2. Assume that host variable HV1 contains the value SITE2.MYSCHHEMA.P1 and the stored procedure is called with a three-part name.

```
EXEC SQL CALL SITE2.MYSCHHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE :HV1 INTO :SQLDA2;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSCHHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the DESCRIBE PROCEDURES statement.

```
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL SITE2.MYSCHHEMA.P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2)
    WITH PROCEDURE :HV1;
```

## DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a designated table or view.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

### Authorization

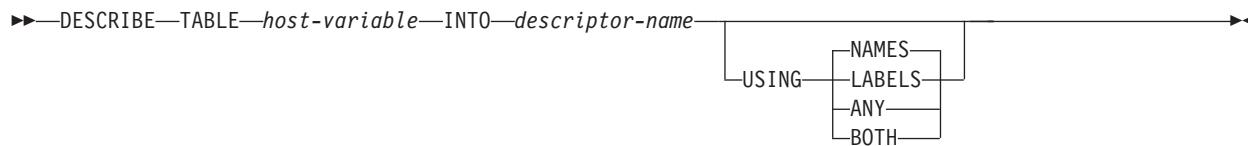

The privileges that are held by the authorization ID that owns the plan or package must include at least one of the following (if there is a plan, authorization checking is done only against the plan owner):

- Ownership of the table or view
- The SELECT, INSERT, UPDATE, DELETE, or REFERENCES privilege on the object
- The ALTER or INDEX privilege on the object (tables only)
- DBADM authority over the database that contains the object (tables only)
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

For an RRSASF application that does not have a plan and in which the requester and the server are DB2 for z/OS systems, authorization to execute the package is performed against the primary or secondary authorization ID of the process.

### Syntax

### Description

#### TABLE *host-variable*

Identifies the table or view. The name must not identify an auxiliary table.

When the DESCRIBE statement is executed, the host variable must contain a name which identifies a table or view that exists at the current server. This variable must be a fixed-length or varying-length character string with a length attribute less than 256. The name must be followed by one or more blanks if the length of the name is less than the length of the variable. It cannot contain a period as the first character and it cannot contain embedded blanks. In addition, the quotation mark is the escape character regardless of the value of the string delimiter option. An indicator variable must not be specified for the host variable.

**INTO** *descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in “SQL descriptor area (SQLDA)” on page 1656. See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

*For languages other than REXX:* Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

**SQLN** Indicates the number of SQLVAR occurrences provided in the SQLDA. DB2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.

*For REXX:* The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable *stem.SQLD*, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with *stem.n*.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

**USING**

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

**NAMES**

Assigns the name of the column. This is the default.

**LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

**ANY**

Assigns the column label, and if the column has no label, the column name.

**BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to  $2 \times n$  or  $3 \times n$ , where  $n$  is the number of columns in the object being described. For each of the columns, the first  $n$  occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third  $n$  occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

For a declared temporary table, the name of the column is assigned regardless of the value specified in the USING clause because declared temporary tables cannot have labels.

## Notes

See “DESCRIBE OUTPUT” on page 1243 for information about the following topics:

- Allocating the SQLDA
- The SQLDA contents that are returned on DESCRIBE

- Performance considerations for DESCRIBE
- Using host variables in DESCRIBE statements

| *Considerations for implicitly hidden columns:* A DESCRIBE TABLE statement does  
| return information about implicitly hidden columns in tables.

---

## DROP

The DROP statement removes an object at the current server. Except for storage groups, any objects that are directly or indirectly dependent on that object are deleted. Whenever an object is deleted, its description is deleted from the catalog at the current server, and any plans or packages that refer to the object are invalidated.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

To drop a table, table space, or index, the privilege set that is defined below must include at least one of the following:

- Ownership of the object (for an index, the owner is the owner of the table or index)
- DBADM authority
- SYSADM or SYSCTRL authority

If the table space is in a database that is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

To drop an alias, storage group, or view, the privilege set that is defined below must include at least one of the following:

- Ownership of the object
- SYSADM or SYSCTRL authority

To drop a role or a trusted context, the privilege set that is defined below must include at least one of the following:

- Ownership of the object
- SYSADM or SYSCTRL authority

To drop a database, the privilege set that is defined below must include at least one of the following:

- The DROP privilege on the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

To drop a package, the privilege set that is defined below must include at least one of the following:

- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

To drop a synonym, the privilege set that is defined below must include ownership of the synonym.

To drop a distinct type, stored procedure, trigger, user-defined function, or sequence, the privilege set that is defined below must include at least one of the following:

- Ownership of the object <sup>33</sup>
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority

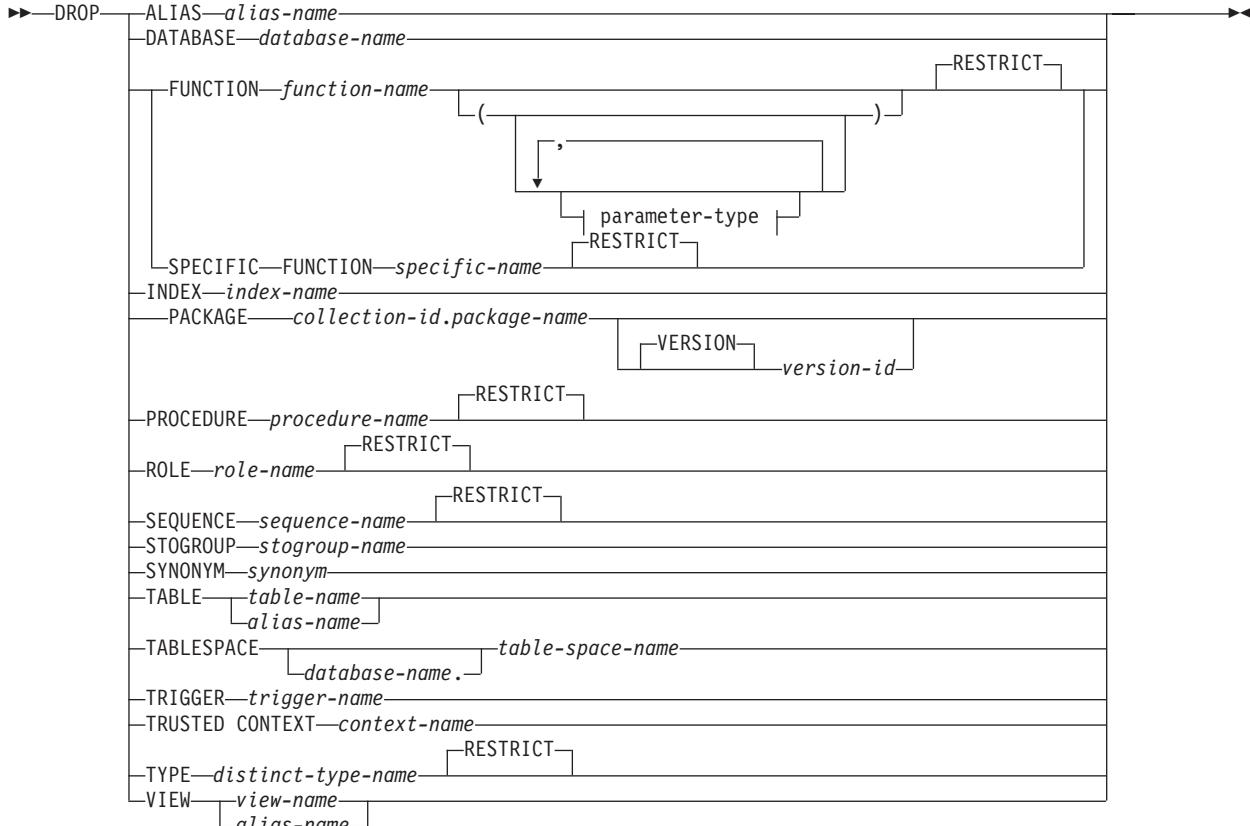

The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process. If running in a trusted context with a role, the privilege set also includes those privileges that are held by the role that is associated with the primary authorization ID. However, the implicit schema match does not apply to the role when determining if DROPIN schema privilege is held.

---

33. Not applicable for stored procedures defined in releases of DB2 for z/OS prior to Version 6.

## Syntax

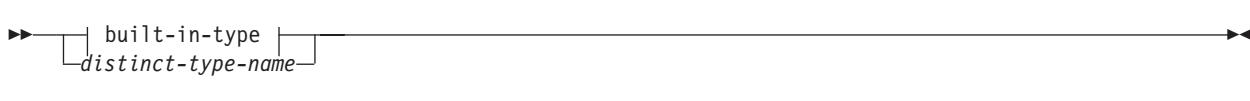

**parameter type:**

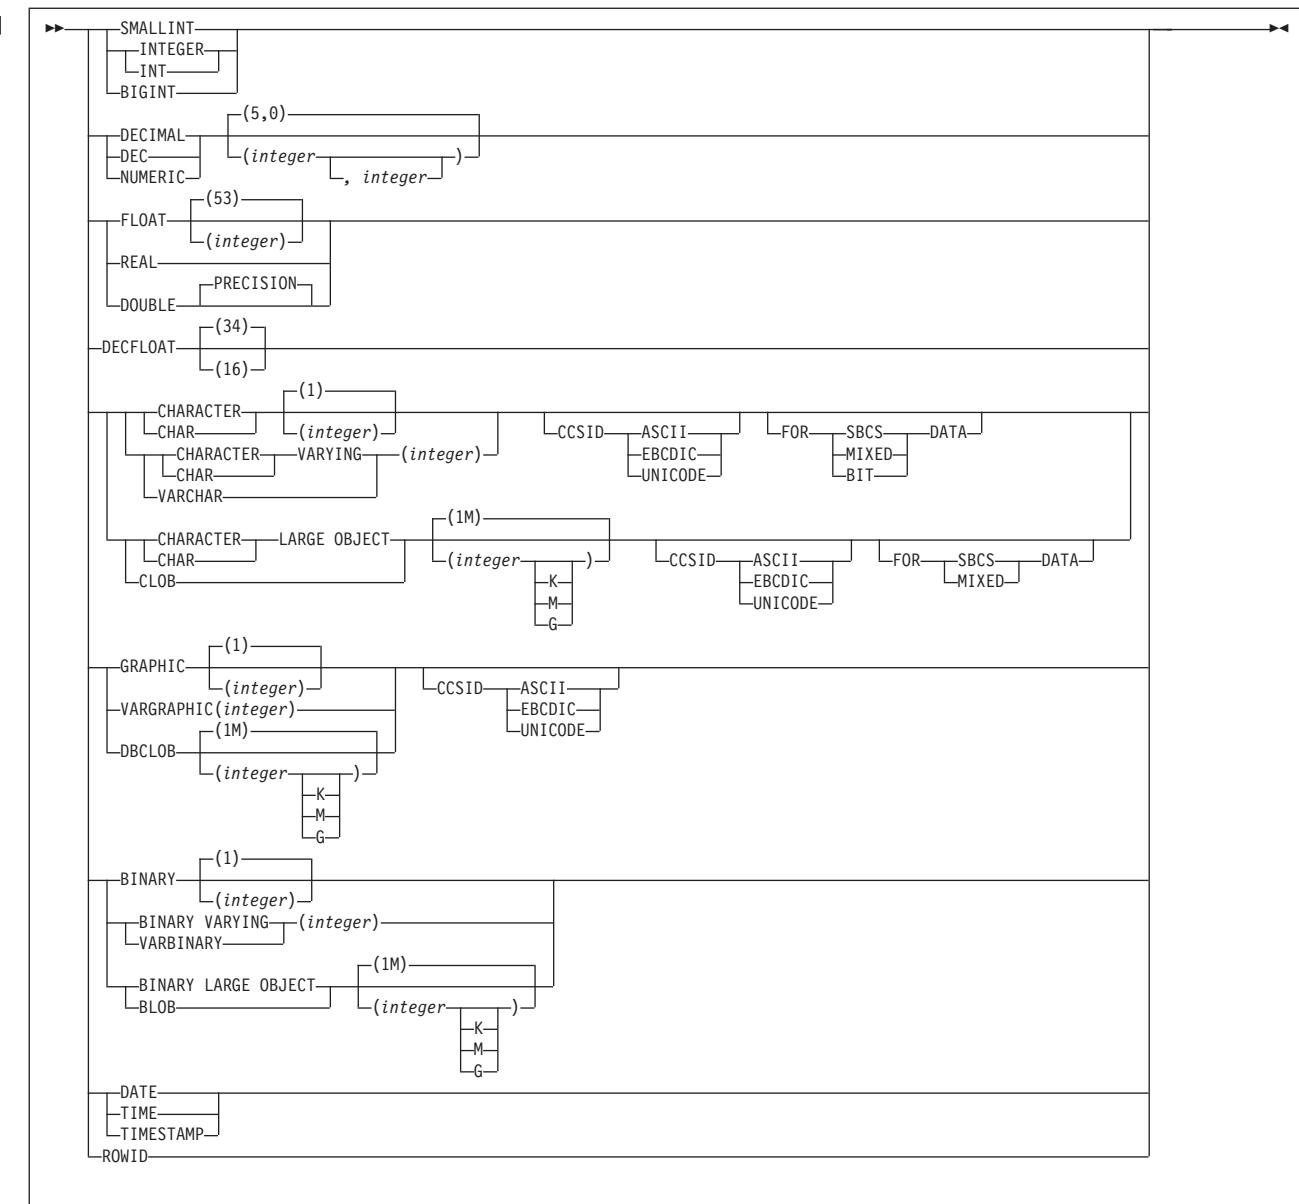

**Notes:**

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

**data type:**

**built-in-type:**

## Description

### **ALIAS** *alias-name*

Identifies the alias to drop. The name must identify an alias that exists at the current server. Dropping an alias has no effect on any view, materialized query table, or synonym that was defined using the alias.

### **DATABASE** *database-name*

Identifies the database to drop. The name must identify a database that exists at the current server. DSNDB04 or DSNDB06 must not be specified. The privilege set must include SYSADM authority.

Whenever a database is dropped, all of its table spaces, tables, index spaces, and indexes are also dropped.

### **FUNCTION or SPECIFIC FUNCTION**

Identifies the function to drop. The function must exist at the current server,

and it must have been defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name.

Functions that are implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

As indicated by the default keyword RESTRICT, the function is not dropped if any of the following dependencies exist:

- Another function is sourced on the function.
- A view uses the function.
- A trigger package uses the function.
- The definition of a materialized query table uses the function.

When a function is dropped, all privileges on the function are also dropped. Any plans or packages that are dependent on the function dropped are made inoperative.

**FUNCTION** *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

**FUNCTION** *function-name (parameter-type, ...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

*function-name*

Identifies the name of the function.

*(parameter-type, ...)*

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly

| DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional.

Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

**SPECIFIC FUNCTION *specific-name***

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

**INDEX *index-name***

Identifies the index to drop. The name must identify a user-defined index that exists at the current server but must not identify a populated index on an auxiliary table or an index that was implicitly created for a table that contains an XML column. (For details on dropping user-defined indexes on catalog tables, see “SQL statements allowed on the catalog” on page 1689.) A populated index on an auxiliary table can only be dropped by dropping the base table. The name must not identify an auxiliary table for an object that is involved in a clone relationship.

If the index that is dropped was created by specifying the ENDING AT clause to define partition boundaries, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

Whenever an index is directly or indirectly dropped, its index space is also dropped. The name of a dropped index space cannot be reused until a commit operation is performed.

If the index is a unique index used to enforce a unique constraint (primary or unique key), the unique constraint must be dropped before the index can be dropped. In addition, if a unique constraint supports a referential constraint, the index cannot be dropped unless the referential constraint is dropped.

However, a unique index (for a unique key only) can be dropped without first dropping the unique key constraint if the unique key was created in a release

of DB2 before Version 7 and if the unique key constraint has no associated referential constraints. For information about dropping constraints, see “ALTER TABLE” on page 789.

If the table space is explicitly created and a unique index is dropped and that index was defined on a ROWID column that is defined as GENERATED BY DEFAULT, the table can still be used, but rows cannot be inserted into that table.

If the table space is implicitly created, the index cannot be dropped if it is defined on a ROWID column that is defined as GENERATED BY DEFAULT.

If an empty index on an auxiliary table is dropped, the base table is marked incomplete. If the base table space is implicitly created, the index on an auxiliary table cannot be dropped.

Drop index will result in the deletion of rows in the SYSCOLDIST and SYSCOLDISTATS catalog tables if no other indexes on the table have the same column group in their key sequence prefix.

**PACKAGE** *collection-id.package-name*

Identifies the package version to drop. The name plus the implicitly or explicitly specified *version-id* must identify a package version that exists at the current server. Omission of the *version-id* is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. A trigger package can only be dropped by dropping the associated trigger or subject table. A package that is associated with a native SQL procedure can only be dropped with an ALTER PROCEDURE statement with a DROP VERSION clause that specifies the particular version that is to be dropped, or with a DROP PROCEDURE statement if it is the only version that is defined for the procedure.

Specify this clause to drop a package that is created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

If a package has current, previous, and original copies, the DROP statement will drop all copies.

**VERSION** *version-id*

*version-id* is the version identifier that was assigned to the package's DBRM when the DBRM was created. If *version-id* is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in *DB2 Application Programming and SQL Guide*.

**PROCEDURE** *procedure-name*

Identifies the stored procedure to drop. The name must identify a stored procedure that has been defined with the CREATE PROCEDURE statement at the current server.

All versions of the native SQL procedure are dropped; all privileges on the procedure are also dropped. In addition, any plans or packages that are dependent on the procedure are marked invalid.

If the procedure is a native SQL procedure, use an ALTER PROCEDURE statement with the DROP VERSION clause to drop a specific version of a procedure. Use a DROP PACKAGE statement to drop a package for a version of the procedure that is created using the BIND COPY command.

**ROLE** *role-name*

Identifies the role to drop. *role-name* must identify a role that exists at the current server.

When a role is dropped, all privileges and authorities that have been previously granted to that role are revoked. If the role that is dropped is the owner of statements in the dynamic statement cache, the cached statements are invalidated.

The role is not dropped if any REVOKE restrictions are encountered. REVOKE restrictions include those that are encountered during the cascading of the revocation of a role's privileges. If RESTRICT is specified, the role is not dropped if any of the following dependencies exist:

- The role is associated with any trusted context or any user in a trusted context.
- The role is associated with a currently running thread.
- The role is the owner of any of the following objects:

---

Alias	Sequence
Database	Storage group
Distinct type	Stored procedure
Index	Table
a JAR file	Table space
Materialized query table	Trigger
Plans	Trusted context
Packages	User-defined function
Role	View

---

**SEQUENCE** *sequence-name*

Identifies the sequence to drop. The name must identify an existing sequence at the current server.

*sequence-name* must not be the name of an internal sequence object that is used by DB2 (including an implicitly generated sequence for a DB2\_GENERATED\_DOCID\_FOR\_XML column). Sequences that are generated by the system for identity columns or implicitly created databases cannot be dropped by using the DROP SEQUENCE statement. A sequence object for an identity column is implicitly dropped when the table that contains the identity column is dropped.

The default keyword RESTRICT indicates that the sequence is not dropped if any of the following dependencies exist:

- A trigger that uses the sequence in a NEXT VALUE or PREVIOUS VALUE expression exists.
- An inline SQL function that uses the sequences in a NEXT VALUE or PREVIOUS VALUE expression exists.

Whenever a sequence is dropped, all privileges on the sequence are also dropped, and the plans and packages that refer to the sequence are invalidated. Dropping a sequence, even if the drop process is rolled back, results in the loss of the still-unassigned cache values for the sequence.

**STOGROUP** *stogroup-name*

Identifies the storage group to drop. The name must identify a storage group that exists at the current server but not a storage group that is used by any table space or index space.

For information on the effect of dropping the default storage group of a database, see Dropping a default storage group.

**SYNONYM** *synonym*

Identifies the synonym to drop. In a static DROP SYNONYM statement, the name must identify a synonym that is owned by the owner of the plan or package. In a dynamic DROP SYNONYM statement, the name must identify a synonym that is owned by the SQL authorization ID. Thus, using interactive SQL, a user with SYSADM authority can drop any synonym by first setting CURRENT SQLID to the owner of the synonym.

Dropping a synonym has no effect on any view, materialized query table, or alias that was defined using the synonym, nor does it invalidate any plans or packages that use such views, materialized query tables, or aliases.

**TABLE** *table-name or alias-name*

Identifies the table to drop. The name must identify a table that exists at the current server but must not identify a catalog table, a table in a partitioned table space, a table that is implicitly created for an XML column, or a populated auxiliary table. A table in a partitioned table space can only be dropped by dropping the table space. A populated auxiliary table or a table that is implicitly created for an XML column can only be dropped by dropping the associated base table.

If *alias-name* is specified, the actual table will be dropped as if *table-name* were specified. However, the alias is not dropped and can be dropped using the DROP ALIAS statement.

Whenever a table is directly or indirectly dropped, all privileges on the table, all referential constraints in which the table is a parent or dependent, and all synonyms, views, and indexes defined on the table are also dropped. If the table space for the table was implicitly created, it is also dropped.

Whenever a table is directly or indirectly dropped, all materialized query tables defined on the table are also dropped. Whenever a materialized query table is directly or indirectly dropped, all privileges on the materialized query table and all synonyms, views, and indexes that are defined on the materialized query table are also dropped. Any alias defined on the materialized query table is not dropped. Any plans or packages that are dependent on the dropped materialized query table are marked invalid.

You cannot use DROP TABLE to drop a clone table. You must use the ALTER TABLE statement with the DROP CLONE clause to drop a clone table. If a base table that is involved in a clone relationship is dropped, the associated clone table is also dropped. You cannot drop an auxiliary table for an object that is involved in a clone relationship.

If a table with LOB columns is dropped, the auxiliary tables associated with the table and the indexes on the auxiliary tables are also dropped. Any LOB table spaces that were implicitly created for the auxiliary tables are also dropped.

If a table with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

If an empty auxiliary table is dropped, the definition of the base table is marked incomplete. If the base table space is implicitly created, the auxiliary table cannot be dropped.

If the table has a security label column, the primary authorization ID of the DROP statement must have a valid security label, and the RACF SECLABEL class must be active.

**TABLESPACE** *database-name.table-space-name*

Identifies the table space to drop. The name must identify a table space that exists at the current server. The database name must not be DSNDB06.

Omission of the database name is an implicit specification of DSNDB04.

*table-space-name* must not identify a table space that is implicitly created for an XML column.

Whenever a table space is directly or indirectly dropped, all the tables in the table space are also dropped. The name of a dropped table space cannot be reused until a commit operation is performed.

A LOB table space can be dropped only if it does not contain an auxiliary table. If the LOB table space is implicitly created, it cannot be dropped.

Whenever a base table space that contains tables with LOB columns is dropped, all the auxiliary tables and indexes on those auxiliary tables that are associated with the base table space are also dropped.

Whenever a base table space that contains tables with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

**TRIGGER** *trigger-name*

Identifies the trigger to drop. The name must identify a trigger that exists at the current server.

Whenever a trigger is directly or indirectly dropped, all privileges on the trigger are also dropped and the associated trigger package is freed. The name of that trigger package is the same as the trigger name and the collection ID is the schema name.

When an INSTEAD OF trigger is dropped, the associated privilege is revoked from anyone that possesses the privilege as a result of an implicit grant that occurred when the trigger is created.

Dropping triggers causes certain packages to be marked invalid. For example, if *trigger-name* specifies an INSTEAD OF trigger on a view V, another trigger might depend on *trigger-name* through an update to the view V, and that trigger package is invalidated.

If a trigger has current, previous, and original copies, the DROP statement will drop all copies.

**TRUSTED CONTEXT** *context-name*

Identifies the trusted context to drop. The *context-name* must identify a trusted context that exists at the current server. When a trusted context is dropped, all associations to attributes (IP addresses, job names) and associations to users of the trusted context are dropped. If the trusted context is dropped while trusted connections for the context are active, the connections remain active until they terminate or the next attempt at reuse is made.

**TYPE** *distinct-type-name*

Identifies the distinct type to drop. The name must identify a distinct type that exists at the current server. The default keyword RESTRICT indicates that the distinct type is not dropped if any of the following dependencies exist:

- The definition of a column of a table uses the distinct type.
- The definition of an input or result parameter of a user-defined function uses the distinct type.
- The definition of a parameter of a stored procedure uses the distinct type.
- The definition of an extended index uses a cast function that is implicitly generated for the distinct type.
- A sequence exists for which the data type of the sequence is the distinct type.
- One of the following dependencies exists on one of the cast functions that are generated for the distinct type:
  - Another function is sourced from one of the cast functions
  - A view uses one of the cast functions
  - A trigger package uses one of the cast functions
  - The definition of a materialized query table uses one of the cast functions

Whenever a distinct type is dropped, all privileges on the distinct type are also dropped. In addition, the cast functions that were generated when the distinct type was created and the privileges on those cast functions are also dropped.

#### **VIEW *view-name* or *alias-name***

Identifies the view to drop. The name must identify a view that exists at the current server.

Whenever a view is directly or indirectly dropped, all privileges on the view and all synonyms and views that are defined on the view are also dropped. Whenever a view is directly or indirectly dropped, all materialized query tables defined on the view are also dropped.

If *alias-name* is specified, the actual view will be dropped as if *view-name* were specified. However, the alias is not dropped and can be dropped using the DROP ALIAS statement.

## **Notes**

**Restrictions on DROP:** DROP is subject to these restrictions:

- DROP DATABASE cannot be performed while a DB2 utility has control of any part of the database.
- DROP INDEX cannot be performed while a DB2 utility has control of the index or its associated table space.
- DROP TABLE cannot be performed while a DB2 utility has control of the table space that contains the table.
- DROP TABLESPACE cannot be performed while a DB2 utility has control of the table space.

In a data sharing environment, the following restrictions also apply:

- If any member has an active resource limit specification table (RLST) you cannot drop the database or table space that contains the table, the table itself, or any index on the table.
- If the member executing the drop cannot access the DB2-managed data sets, only the catalog and directory entries for those data sets are removed.

Objects that have certain dependencies cannot be dropped. For information on these restrictions, see Table 117 on page 1270.

**Recreating objects:** After an index or table space is dropped, a commit must be performed before the object can be recreated with the same name. If a table that was created without an IN clause (thereby causing a table space to be implicitly created) is dropped, a table cannot be recreated with the same name until a commit is performed.

**Dropping a parent table:** DROP is not DELETE and therefore does not involve delete rules.

**Dropping a default storage group:** If you drop the default storage group of a database, the database no longer has a legitimate default. You must then specify USING in any statement that creates a table space or index in the database. You must do this until you either:

- Create another storage group with the same name using the CREATE STOGROUP statement, or
- Designate another default storage group for the database using the ALTER DATABASE statement.

**Dropping a table space or index:** To drop a table space or index, the size of the buffer pool associated with the table space or index must not be zero.

**Dropping a LOB table space:** If the base table space is explicitly created, both explicitly created LOB table spaces and implicitly created LOB table spaces can be dropped if it does not contain any auxiliary tables. If the LOB table space is implicitly created, it will be dropped automatically when the auxiliary table is dropped. If the LOB table space is explicitly created, it is not dropped when the auxiliary table is dropped, and can be explicitly dropped later.

If the base table space is implicitly created, the LOB table space cannot be dropped. If the LOB table space is explicitly created, it can be dropped when the auxiliary table is dropped. The following table shows the relationship between the base table space, the LOB table space, and the use of DROP for the LOB table space and base table space:

Table 115. Use of DROP for LOB table space

How base table was created	How LOB table space was created	Whether DROP can be used on LOB table space	State of LOB table space if base table space is dropped
Explicitly	Explicitly	Yes	LOB table space remains
Explicitly	Implicitly	Yes	LOB table space is dropped
Implicitly	Explicitly	Yes	LOB table space remains
Implicitly	Implicitly	No	N/A

**Dropping a database when data sets for DB2 objects have already been deleted:** When some of the data sets for DB2 objects that associated with the database have already been deleted, DROP DATABASE will perform in the following manner:

**For DB2-managed objects:**

The DROP DATABASE statement will delete the underlying data sets if they exist. If the data sets do not exist, DROP DATABASE will delete only the catalog entries for those data sets.

|

| **For user-managed objects:**

|

The DROP DATABASE statement will delete only the catalog entries for the data sets. The underlying data sets will need to be manually deleted after the DROP DATABASE statement is complete.

*Dropping a table space in a work file database:* If one member of a data sharing group drops a table space in a work file database, or an entire work file database, that belongs to another member, DB2-managed data sets that the executing member cannot access are not dropped. However, the catalog and directory entries for those data sets are removed.

*Dropping resource limit facility (governor) indexes, tables, and table spaces:* While the RLST is active, you cannot issue a DROP DATABASE, DROP INDEX, DROP TABLE, or DROP TABLESPACE statement for an object associated with an RLST that is active on any member of a data sharing group. See *DB2 Performance Monitoring and Tuning Guide* for details.

*Dropping a temporary table:* To drop a created temporary table or a declared temporary table, use the DROP TABLE statement.

*Dropping a materialized query table:* To drop a materialized query table, use the DROP TABLE statement.

*Dropping an alias:* Dropping a table or view does not drop its aliases. However, if you use the DROP TABLE statement and specify an alias for a table or view, the table or view will be dropped. To drop an alias, use the DROP ALIAS statement.

|

| *Dropping a table from an implicitly created table space:* If you drop a table from an implicitly created table space, the following related objects are also dropped:

|

- The enforcing primary and unique key indexes
- Any LOB table spaces, auxiliary tables, and auxiliary indexes
- The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

|

| If any LOB columns are defined on the table, the LOB table space is dropped if it was implicitly created. You can use the DROP statement to drop a LOB table space only if one of the following conditions is true:

|

- The base table space is explicitly created
- The base table space is implicitly created but the LOB table space is explicitly created

You cannot use the DROP statement to drop a LOB table space if both the base table space and the LOB table space are implicitly created.

|

| *Dropping an index on an auxiliary table and an auxiliary table:* You can explicitly drop an empty index on an auxiliary table with the DROP INDEX statement, unless the base table space is implicitly created. An empty or populated index on an auxiliary table is implicitly dropped when:

|

- The auxiliary table is empty and it is explicitly dropped (empty indexes only).
- The associated base table for the auxiliary table is dropped.
- The base table space that contains the associated base table is dropped.

You can explicitly drop an empty auxiliary table with the DROP TABLE statement, unless the base table space is implicitly created. An empty or populated auxiliary table is implicitly dropped when:

- The associated base table for the auxiliary table is dropped.
- The base table space that contains the associated base table is dropped.

The following table shows which DROP statements implicitly or explicitly cause an auxiliary table and the index on that table to be dropped, as indicated by the 'D' in the column.

*Table 116. Effect of various DROP statements on auxiliary tables and indexes that are in explicitly created table spaces*

Statement	Auxiliary table		Index on auxiliary table	
	Populated	Empty	Populated	Empty
DROP TABLESPACE (base table space)	D	D	D	D
DROP TABLE (base table)	D	D	D	D
DROP TABLE (auxiliary table)		D		D
DROP INDEX (index on auxiliary table)				D

**Note:** D indicates that the table or index is dropped.

**Dropping a migrated index or table space:** Here, "migration" means migrated by the Hierarchical Storage Manager (DFSMShsm). DB2 does not wait for any recall of the migrated data sets. Hence, recall is not a factor in the time it takes to execute the statement.

**Dropping a trusted context:** The drop of a trusted context takes effect after the DROP TRUSTED CONTEXT statement is committed. If the DROP TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not dropped.

**Deleting SYSLGRNG records for dropped table spaces:** After dropping a table space, you cannot delete the associated records. If you want to remove the records, you must quiesce the table space, and then run the MODIFY RECOVERY utility before dropping the table space. If you delete the SYSLGRNG records and drop the table space, you cannot reclaim the table space.

**Dependencies when dropping objects:** Whenever an object is directly or indirectly dropped, other objects that depend on the dropped object might also be dropped. (The catalog stores information about the dependencies of objects on each other.) The following semantics determine what happens to a dependent object when the object that it depends on (the underlying object) is dropped:

#### Cascade (D)

Dropping the underlying object causes the dependent object to be dropped. However, if the dependent object cannot be dropped because it has a restrict dependency on another object, the drop of the underlying object fails.

#### Restrict (D)

The underlying object cannot be dropped if a dependent object exists.

### Inoperative (O)

Dropping the underlying object causes the dependent object to become inoperative.

### Invalidation (V)

Dropping the underlying object causes the dependent object to become invalidated.

For objects that directly depend on others, the following table uses the letter abbreviations above to summarize what happens to a dependent object when its underlying object is specified in a DROP statement. Additional objects can be indirectly affected, too.

To determine the indirect effects of a DROP statement, assess what happens to the dependent object and whether the dependent object has objects that depend on it. For example, assume that view B is defined on table A and view C is defined on view B. In the following table, the 'D' in the VIEW column of the DROP TABLE row indicates that view B is dropped when table A is dropped. Next, because view C is dependent on view B, check the VIEW column for DROP VIEW. The 'D' in the column indicates that view C will be dropped, too.

The letters in the following table have the following meanings:

- D** Dependent object is dropped.
- O** Dependent object is made inoperative.
- V** Dependent object is invalidated.
- R** DROP statement fails.

*Table 117. Effect of dropping objects that have dependencies*

Type of object												
				P					T	A		
	D	F		R	S	S			B			
	A	U		P	O	E	T	S	L	T		
	T	N		A	C	Q	O	Y	E	R		
	A	A	C	I	C	E	U	G	N	T	S	I
	L	B	T	N	K	D	E	R	O	A	P	G
	I	A	I	D	A	U	N	O	N	B	A	G
	A	S	O	E	G	R	C	U	Y	L	C	Y
DROP statement	S	E	N	X	E <sup>1</sup>	E	E	P	M	E	E	R
DROP ALIAS					V							
DROP DATABASE				D <sup>2</sup>					D	D	D	
DROP FUNCTION				R <sup>5</sup>	O					R	R	
DROP INDEX <sup>2,6</sup>					V					V		
DROP PACKAGE <sup>7</sup>												
DROP PROCEDURE					O					R		
DROP ROLE					V							
DROP SEQUENCE				R <sup>13</sup>	V					R		
DROP STOGROUP					R <sup>8</sup>					R <sup>8</sup>		
DROP SYNONYM												
DROP TABLE <sup>9,10</sup>				D	V			D		D <sup>11</sup>	D	

Table 117. Effect of dropping objects that have dependencies (continued)

	Type of object													
DROP statement	D	F	P	R	S	S	T	A	B	C	T			
	A	U	P	O	E	T	S	L	T					
	T	N	A	C	Q	O	Y	E	R					
	A	A	C	I	C	E	U	G	N	T	S	I		
	L	B	T	N	K	D	E	R	O	A	P	G	T	V
	I	A	I	D	A	U	N	O	N	B	A	G	Y	I
	A	S	O	E	G	R	C	U	Y	L	C	E	P	E
	S	E	N	X	E <sup>1</sup>	E	E	P	M	E	E	R	E	W
DROP TABLESPACE <sup>12</sup>	D	V						D						
DROP TRIGGER							V <sup>16</sup>							
DROP TYPE	R <sup>3</sup>	R <sup>14</sup>		R <sup>4</sup>	R			R						
DROP VIEW				V				D		D <sup>15</sup>		D		

**Note:**

1. The PACKAGE column represents packages for user-defined functions, procedures, and triggers, as well as other packages. The PACKAGE column also applies for plans.
2. The index space associated with the index is dropped.
3. If a function is dependent on the distinct type being dropped, the distinct type cannot be dropped unless the function is one of the cast functions that was created for the distinct type.
4. If the definition of a parameter of a stored procedure uses the distinct type, the distinct type cannot be dropped.
5. If other user-defined functions are sourced on the user-defined function being dropped, the function cannot be dropped.
6. An index on an auxiliary table cannot be explicitly dropped.
7. A trigger package cannot be explicitly dropped with DROP PACKAGE. A trigger package is implicitly dropped when the associated trigger or subject table is dropped.
8. A storage group cannot be dropped if it is used by any table space or index space.
9. An auxiliary table cannot be explicitly dropped with DROP TABLE. An auxiliary table is implicitly dropped when the associated base table is dropped.
10. If an implicit table space was created when the table was created, the table space is also dropped.
11. When a subject table is dropped, any associated triggers and related trigger packages are also dropped.
12. A LOB table space cannot be dropped until the base table with the LOB columns is dropped.
13. This restriction is only for SQL functions.
14. The index in this case must be defined on an expression.
15. When a subject view is dropped, any associated triggers and related trigger packages are also dropped.
16. Any packages that have a dependency on an INSTEAD OF trigger will be marked invalid.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- DATA TYPE or DISTINCT TYPE as a synonym for TYPE
- PROGRAM as a synonym for PACKAGE

## Examples

*Example 1:* Drop table DSN8910.DEPT.

```
DROP TABLE DSN8910.DEPT;
```

*Example 2:* Drop table space DSN8S91D in database DSN8D91A.

```
DROP TABLESPACE DSN8D91A.DSN8S91D;
```

*Example 3:* Drop the view DSN8910.VPROJRE1:

```
DROP VIEW DSN8910.VPROJRE1;
```

*Example 4:* Drop the package DSN8CC0 with the version identifier VERSZZZZ. The package is in the collection DSN8CC61. Use the version identifier to distinguish the package to be dropped from another package with the same name in the same collection.

```
DROP PACKAGE DSN8CC61.DSN8CC0 VERSION VERSZZZZ;
```

*Example 5:* Drop the package DSN8CC0 with the version identifier "1994-07-14-09.56.30.196952". When a version identifier is generated by the VERSION(AUTO) precompiler option, delimit the version identifier.

```
DROP PACKAGE DSN8CC61.DSN8CC0 VERSION "1994-07-14-09.56.30.196952";
```

*Example 6:* Drop the distinct type DOCUMENT, if it is not currently in use:

```
DROP TYPE DOCUMENT;
```

*Example 7:* Assume that you are SMITH and that ATOMIC\_WEIGHT is the only function with that name in schema CHEM. Drop ATOMIC\_WEIGHT.

```
DROP FUNCTION CHEM.ATOMIC_WEIGHT;
```

*Example 8:* Assume that you are SMITH and that you created the function CENTER in schema SMITH. Drop CENTER, using the function signature to identify the function instance to be dropped.

```
DROP FUNCTION CENTER(INTEGER, FLOAT);
```

*Example 9:* Assume that you are SMITH and that you created another function named CENTER, which you gave the specific name FOCUS97, in schema JOHNSON. Drop CENTER, using the specific name to identify the function instance to be dropped.

```
DROP SPECIFIC FUNCTION JOHNSON.FOCUS97;
```

*Example 10:* Assume that you are SMITH and that stored procedure OSMOSIS is in schema BIOLOGY. Drop OSMOSIS.

```
DROP PROCEDURE BIOLOGY.OSMOSIS;
```

*Example 11:* Assume that you are SMITH and that trigger BONUS is in your schema. Drop BONUS.

```
DROP TRIGGER BONUS;
```

*Example 12:* Drop the role CTXROLE:

```
DROP ROLE CTXROLE;
```

*Example 13:* Drop the trusted context CTX1:

```
DROP TRUSTED CONTEXT CTX1;
```

## END DECLARE SECTION

The END DECLARE SECTION statement marks the end of an SQL declare section.

### Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

### Authorization

None required.

### Syntax

```
►►—END DECLARE SECTION—————►►
```

### Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement described in “BEGIN DECLARE SECTION” on page 872.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) precompiler option is specified:

- A variable referred to in an SQL statement must be declared within an SQL declare section of the source program.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- SQL declare sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

### Notes

SQL declare sections are only required if the STDSQL(YES) option is specified or the host language is C. However, SQL declare sections can be specified for any host language so that the source program can conform to IBM SQL. If SQL declare sections are used, but not required, variables declared outside an SQL declare section should not have the same name as variables declared within an SQL declare section.

### Example

```
EXEC SQL BEGIN DECLARE SECTION;  
      -- host variable declarations  
EXEC SQL END DECLARE SECTION;
```

## EXCHANGE

The EXCHANGE statement switches the content of a base table and its associated clone table.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set that is defined below must include at least one of the following privileges:

- The INSERT and DELETE privileges on both the base table and the clone table
- Ownership of the both the base table and the clone table
- DBADM authority for the database
- SYSADM authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

### Syntax

```
►►EXCHANGE DATA BETWEEN TABLE—table-name1—AND—table-name2►►
```

### Description

*table-name1* and *table-name2*

Identifies the base table and the associated clone table for which the exchange of data will take place. Either *table-name1* or *table-name2* can identify the base table. The other table name must identify a clone table that is associated with the specified base table. The name of the base table and the name of the clone table remain unchanged after a data exchange.

### Notes

**Rules and restrictions:** When a data exchange is done, real time statistics for the base table are invalidated. Data exchanges cannot be done for a subset of a table's partitions. There must be a commit between consecutive data exchanges using the EXCHANGE statement.

### Examples

*Example:* Exchange the data of the EMPLOYEE table and its clone table, EMPCLONE.

```
EXCHANGE DATA BETWEEN TABLE EMPCLONE AND EMPLOYEE;
```

## EXECUTE

The EXECUTE statement executes a prepared SQL statement.

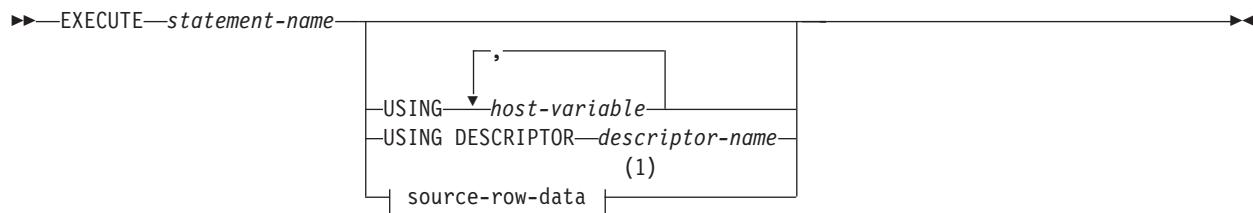

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

### Authorization

See “PREPARE” on page 1405 for the authorization required to create a prepared statement.

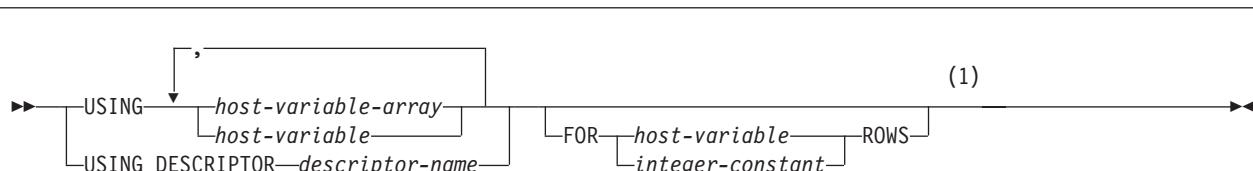

### Syntax

#### Notes:

- 1 This option can be specified only when *statement-name* refers to a dynamic INSERT or MERGE statement that is prepared with FOR MULTIPLE ROWS and is specified as part of the ATTRIBUTES clause on the PREPARE statement.

#### source-row-data:

#### Notes:

- 1 The FOR n ROWS clause is required on the EXECUTE statement if it is not specified as part of the MERGE statement and a host variable array is specified. The FOR n ROWS clause is also required if MERGE is used with multiple rows of source data. For an INSERT statement, the FOR n ROWS clause can only be specified for a dynamic statement that contains only a single multiple-row INSERT statement.

### Description

*statement-name*

Identifies the prepared statement to be executed. *statement-name* must identify a

statement that was previously prepared within the unit of work and the prepared statement must not be a SELECT statement.

#### **USING**

Introduces a list of host variables whose values are substituted for the parameter markers (question marks) in the prepared statement. (For an explanation of parameter markers, see “PREPARE” on page 1405.) If the prepared statement includes parameter markers, you must include USING in the EXECUTE statement. USING is ignored if there are no parameter markers.

For more on the substitution of values for parameter markers, see Parameter marker replacement.

*host-variable*,...

Identifies structures or variables that must be described in the application program in accordance with the rules for declaring host structures and variables. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable supplies the value for the *n*th parameter marker in the prepared statement.

#### **USING DESCRIPTOR** *descriptor-name*

Identifies an SQLDA that contains a valid description of the input host variables.

Before invoking the EXECUTE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences that are provided in the SQLDA  
A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA
- SQLD to indicate the number of variables that are used in the SQLDA when processing the statement
- SQLVAR entries to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR entries. If an SQLVAR entry includes a LOB value or a distinct type based on a LOB, there must be additional SQLVAR entries for each parameter. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR entries, see “SQL descriptor area (SQLDA)” on page 1656.

SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The *n*th variable described by the SQLDA corresponds to the *n*th parameter marker in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

#### **source-row-data**

The prepared statement must be an INSERT or MERGE statement for which the FOR MULTIPLE ROWS clause is specified as part of the ATTRIBUTES clause on the PREPARE statement.

#### **USING** *host-variable-array* **or** *host-variable*

Introduces a list of host variables or host variable arrays whose values are substituted for the parameter markers (question marks) in the prepared INSERT or MERGE statement. The number of columns specified in the INSERT

or MERGE statement must be less than or equal to the total number of host variables or host variable arrays that are specified.

*host-variable-array*

Identifies a host-variable array that must be defined in the application program in accordance with the rules for declaring a host variable array. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable supplies the value for the *n*th parameter marker in the prepared statement.

*host-variable*

Identifies a variable that must be described in the application program in accordance with the rules for declaring host variables.

**USING DESCRIPTOR** *descriptor-name*

Identifies an SQLDA that must contain a valid description of the host variable arrays or host variables that contain the values to insert.

Before invoking the EXECUTE statement for a dynamic INSERT or MERGE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR entries that are provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA.
- SQLD to indicate the number of variables, plus one, that are used in the SQLDA that provide values for columns that are the source of the INSERT or MERGE statement. SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN.
- SQLVAR entries to indicate the attributes of an element of the host variable array for the SQLVAR entries that correspond to values that are provided for the source columns of the INSERT or MERGE statement. Within each SQLVAR, the following fields are set:
  - SQLTYPE indicates the data type of the elements of the host variable array.
  - SQLDATA points to the corresponding host variable array.
  - SQLLEN and SQLLONGLEN indicate the length of a single element of the array.
- SQLNAME, the fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must contain a binary small integer (halfword) that contains the dimension of the host-variable array and, if specified, the corresponding indicator array.

The SQLDA must have enough storage to contain a SQLVAR entry for each target column for which values are provided, plus an additional SQLVAR entry for the number of rows. The DB2 system generates code to fill in the required information for this extra SQLVAR entry. Each SQLVAR entry describes a host variable, host variable array, or buffer that contains the values for a column of the source table. The last SQLVAR entry contains the number of rows of data. For example, if the INSERT or MERGE statement is providing values for five columns of the target table, six SQLVAR entries must be provided. If any value is a LOB value, twice as many SQLVAR entries must be provided, and SQLN must be set to the number of SQLVAR entries. Thus, if the INSERT or MERGE statement is providing values for five columns of the source table, and some of the values to insert are LOB values, 12 SQLVAR entries must be provided.

The SQLVAR entry for the number of rows must also contain a flag value. See “Field descriptions of an occurrence of a base SQLVAR” on page 1662 for more information.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays.

**FOR** *host-variable or integer-constant ROWS*

Specifies the number of rows of source data. The values for the insert or merge operation are specified in the USING clause.

*host-variable or integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. *k* must be in the range 0 to 32767.

FOR *n ROWS* cannot be specified on the EXECUTE statement if the statement being processed is a dynamic INSERT or MERGE statement that includes a FOR *n ROWS* clause.

## Notes

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much processor time to finish. When this happens, an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

**Parameter marker replacement:** Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in “Assignment and comparison” on page 102. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let *V* denote a host variable that corresponds to parameter marker *P*. The value of *V* is assigned to the target variable for *P* in accordance with the rules for assigning a value to a column:

- *V* must be compatible with the target.
- If *V* is a string, its length must not be greater than the length attribute of the target.
- If *V* is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of *V* are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, *V* must not be null.

When the prepared statement is executed, the value used in place of *P* is the value of the target variable for *P*. For example, if *V* is CHAR(6) and the target is CHAR(8), the value used in place of *P* is the value of *V* padded on the right with two blanks.

**Errors occurring on EXECUTE:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause

some errors that are normally issued during PREPARE processing to be issued on EXECUTE.

## Examples

*Example 1:* In this example, an INSERT statement with parameter markers is prepared and executed. S1 is a structure that corresponds to the format of DSN8910.DEPT.

```
EXEC SQL PREPARE DEPT_INSERT FROM
  'INSERT INTO DSN8910.DEPT VALUES(?, ?, ?, ?)';
-- Check for successful execution and read values into S1
EXEC SQL EXECUTE DEPT_INSERT USING :S1;
```

*Example 2:* Assume that the IWH.PROGPARM table has 9 columns. Prepare and execute a dynamic INSERT statement that inserts 5 rows of data into the IWH.PROGPARM table. The values to be inserted are provided in arrays, where all the values for a column are provided in an host-variable-array with the EXECUTE statement.

```
STMT = 'INSERT INTO IWH.PROGPARM (IWHID, UPDATE_BY, UPDATE_TS, NAME,
                                     SHORT_DESCRIPTION, ORDERNO, PARMDATA,
                                     PARMDATALONG, VWPROGKEY)
VALUES ( ?, ?, ?, ?, ?, ?, ?, ?, ? )';
ATTRVAR = 'FOR MULTIPLE ROWS';
EXEC SQL PREPARE INS_STMT ATTRIBUTES :ATTRVAR FROM :STMT;
NROWS = 5;
EXEC SQL EXECUTE INS_STMT FOR :NROWS ROWS
  USING :V1, :V2, :V3, :V4, :V5, :V6, :V7, :V8, :V9;
```

In this example, each host variable in the USING clause represents an array of values for the corresponding column of the target of the INSERT statement.

*Example 3:* Using dynamically supplied values for an employee row, update the master EMPLOYEE table if the data is for an existing employee or insert a new row if the data is for a new employee.

```
hv_stmt =
  "MERGE INTO EMPLOYEE AS T
   USING (VALUES (CAST (?) AS CHAR(6)), CAST (?) AS VARCHAR(12)),
         (CAST (?) AS CHAR(1)), CAST (?) AS VARCHAR(15)),
         (CAST (?) AS INTEGER))
   AS S (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
   ON T.EMPNO = S.EMPNO
   WHEN MATCHED THEN UPDATE
     SET SALARY = S.SALARY
   WHEN NOT MATCHED THEN INSERT (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
     VALUES (S.EMPNO, S.FIRSTNAME, S.MI, S.LASTNAME, S.SALARY)
   NOT ATOMIC CONTINUE ON SQLEXCEPTION";
hv_attr = 'FOR MULTIPLE ROWS';
EXEC SQL
  PREPARE merge_stmt
    ATTRIBUTES :hv_attr FROM :hv_stmt;
hv_nrows = 5;
/* Initialize the hostvar array of hv_empno, hv_firstname... */
EXEC SQL
  EXECUTE merge_stmt
  USING :hv_empno, :hv_firstname, :hv_mi,
        :hv_lastname, :hv_salary
  FOR :hv_nrows ROWS;
```

## EXECUTE IMMEDIATE

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute an SQL statement that contains neither host variables nor parameter markers.

The EXECUTE IMMEDIATE statement:

- Prepares an executable form of an SQL statement from a string form of the statement
- Executes the SQL statement
- Destroys the executable form

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

### Authorization

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by EXECUTE IMMEDIATE. For example, see “INSERT” on page 1367 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

### Syntax

```
►► EXECUTE IMMEDIATE [host-variable] [string-expression] ►►
```

### Description

#### *host-variable*

*host-variable* must be specified. It must identify a host variable that is described in the application program in accordance with the rules for declaring character or graphic string variables. If the source string is over 32KB in length, the *host-variable* must be a CLOB or DBCLOB variable. The maximum source length is 2MB although the host variable can be declared larger than 2MB. An indicator variable must not be specified. In Assembler, C, COBOL, and PL/I, the host variable must be a varying-length string variable. In C, it must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable and the value must not be null.

#### *string-expression*

*string-expression* is any PL/I expression that yields a string. *string-expression* cannot be preceded by a colon. Variables that are within *string-expression* that include operators or functions should not be preceded by a colon. When *string-expression* is specified, the precompiler-generated structures for *string-expression* use an EBCDIC CCSID and an informational message is returned.

## Notes

**Allowable SQL statements:** The value of the identified host variable or the specified *string-expression* is called the *statement string*.

The statement string must be one of the following SQL statements, and cannot be the *select-statement*:

ALLOCATE CURSOR	REVOKE
ALTER	ROLLBACK
ASSOCIATE LOCATORS	SAVEPOINT
COMMENT	SET CURRENT DEGREE
COMMIT	SET CURRENT DECFLOAT ROUNDING MODE
CREATE	SET CURRENT DEBUG MODE
DECLARE GLOBAL TEMPORARY TABLE	SET CURRENT LOCALE LC_CTYPE SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
DELETE	SET CURRENT OPTIMIZATION HINT
DROP	SET CURRENT PRECISION
EXPLAIN	SET CURRENT REFRESH AGE
FREE LOCATOR	SET CURRENT ROUTINE VERSION
GRANT	SET CURRENT RULES
HOLD LOCATOR	SET CURRENT SQLID
INSERT	SET ENCRYPTION PASSWORD
LABEL	SET PATH
LOCK TABLE	SET SCHEMA
MERGE	SIGNAL
REFRESH TABLE	TRUNCATE
RELEASE SAVEPOINT	UPDATE
RENAME	

The statement string must not:

- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables
- Include parameter markers

**Errors and error handling:** When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is invalid, it is not executed and the error condition that prevents its execution is reported in the SQLCA. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the SQLCA.

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much CPU time to finish. When this happens an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

**Performance considerations:** If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

## Examples

*Example 1:* In this PL/I example, the EXECUTE IMMEDIATE statement is used to execute a DELETE statement in which the rows to be deleted are determined by a search-condition specified by the value of PREDS.

```
EXEC SQL EXECUTE IMMEDIATE 'DELETE FROM DSN8910.DEPT  
WHERE' || PREDS;
```

*Example 2:* Use C to execute the SQL statement in the host variable Qstring.

```
EXEC SQL INCLUDE SQLCA;  
void main ()  
{  
    EXEC SQL BEGINDECLARE SECTION;  
    char Qstring[100M =  
        "INSERT INTO WORK_TABLE SELECT * FROM EMPPROJACT WHERE ACTNO >= 100";  
    EXEC SQL END DECLARE SECTION;  
    .  
    .  
    .  
    EXEC SQL EXECUTE IMMEDIATE :Qstring;  
    return;  
}
```

## EXPLAIN

The EXPLAIN statement obtains information about access path selection for an *explainable statement*. A statement is explainable if it is a SELECT, MERGE, or INSERT statement, or the searched form of an UPDATE or DELETE statement. The information obtained is placed in a user-supplied *plan table*.

Optionally, EXPLAIN can also obtain and place information in additional tables. A user-supplied *statement table* can be populated with information about the estimated cost of executing the explainable statement. A user-supplied *function table* can be populated with information about how DB2 resolves the user-defined functions that are referred to in the explainable statement. Other EXPLAIN tables can be populated with additional information about the execution of the explainable statement. For a complete list of EXPLAIN tables, see “EXPLAIN tables” on page 1929.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

The authorization rules are those defined for the SQL statement specified in the EXPLAIN statement. For example, see the description of the DELETE statement for the authorization rules that apply when a DELETE statement is explained.

If the EXPLAIN statement is embedded in an application program, the authorization rules that apply are those defined for embedding the specified SQL statement in an application program. In addition, the owner of the plan or package must also have one of the following characteristics:

- Be the owner of a plan table named PLAN\_TABLE
- Have an alias on a plan table named *owner.PLAN\_TABLE* and have SELECT and INSERT privileges on the table

If the EXPLAIN statement is dynamically prepared, the authorization rules that apply are those defined for dynamically preparing the specified SQL statement. In addition, the SQL authorization ID of the process or the role this is associated with the process (if the EXPLAIN statement is running in a trusted context that specifies the ROLE AS OBJECT OWNER AND QUALIFIER clause) must also have one of the following characteristics:

- Be the owner of a plan table named PLAN\_TABLE
- Have an alias on a plan table named *owner.PLAN\_TABLE* and have SELECT and INSERT privileges on the table

The authorization rules are different if the STMTCACHE keyword is specified to have a cached statement explained. The privilege set must include at least one of the following:

- SYSADM authority
- The authority that is required to share the cached statement.

For the STMTCACHE ALL keyword, the privilege set must include at least one of the following:

- SYSADM authority to explain all statements in the dynamic statement cache

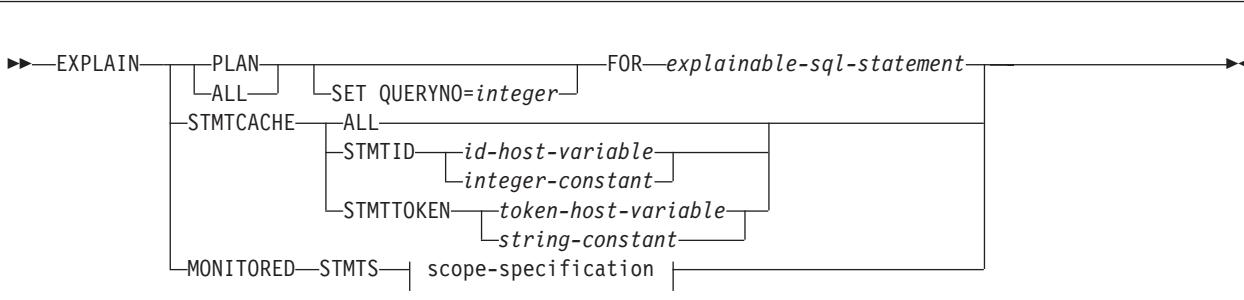

If the privilege set does not have the required authority, only those statements that have the same authorization ID as the privilege set are explained.

For the MONITOR STMTS keyword, the privilege set must include at least one of the following:

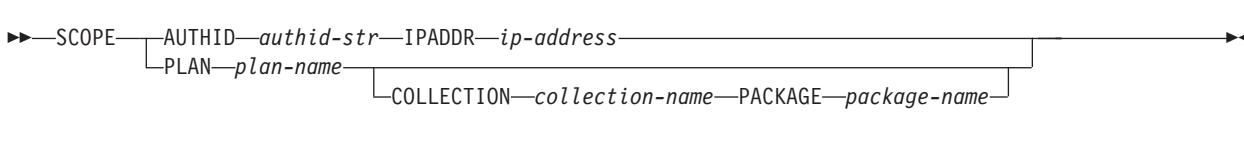

- SYSADM authority
- SYSOPR authority
- SYSCTRL authority

**Privilege set:** The privilege set comprises the union of authorities that are held by the authorization IDs of the process. If the process is running in a trusted context with a role, this role would be included as an authorization ID of the process.

## Syntax

scope-specification:

## Description

### PLAN

Inserts one row into the plan table for each step used in executing *explainable-sql-statement*. The steps for enforcing referential constraints are not included. See “PLAN\_TABLE” on page 1930 and for a description of the plan table.

If a statement table exists, one row that provides a cost estimate of processing the explainable statement is inserted into the statement table. If the explainable statement is a SELECT FROM *data-change-statement*, two rows are inserted into the statement table. See “DSN\_STATEMNT\_TABLE” on page 1985 for a description of the statement table.

If a function table exists, one row is inserted into the function table for each user-defined function that is referred to by the explainable statement. See “DSN\_FUNCTION\_TABLE” on page 1952 for a description of the function table.

If additional EXPLAIN tables exist, rows are also inserted into those tables. For a complete list of EXPLAIN tables, see “EXPLAIN tables” on page 1929.

#### ALL

Has the same effect as PLAN.

#### SET QUERYNO = *integer*

Associates *integer* with *explainable-sql-statement*. The column QUERYNO is given the value *integer* in every row inserted into the plan table, statement table, or function table by the EXPLAIN statement. If QUERYNO is not specified, DB2 itself assigns a number. For an embedded EXPLAIN statement, the number is the statement number that was assigned by the precompiler and placed in the DBRM.

#### FOR *explainable-sql-statement*

Specifies the SQL statement to be explained. *explainable-sql-statement* can be any explainable SQL statement. If EXPLAIN is embedded in a program, the statement can contain references to host variables. If EXPLAIN is dynamically prepared, the statement can contain parameter markers. Host variables that appear in the statement must be defined in the statement's program.

The statement must refer to objects at the current server.

*explainable-sql-statement* must not contain a QUERYNO clause. To specify the value of the QUERYNO column in plan table for the statement being explained, use the SET QUERYNO = clause of the EXPLAIN statement.

*explainable-sql-statement* cannot be a statement-name or a host-variable. To use EXPLAIN to get information about dynamic SQL statements, you must prepare the entire EXPLAIN statement dynamically.

To obtain information about an explainable SQL statement that references a declared temporary table, the EXPLAIN statement must be executed in the same application process in which the table was declared. For static EXPLAIN statements, the information is not obtained at bind-time but at runtime when the EXPLAIN statement is incrementally bound.

#### STMTCACHE

Specifies that statements in the dynamic statement cache are to be explained. In a data sharing environment, the statements in the dynamic statement cache of the data sharing member where EXPLAIN STMTCACHE is executed are explained.

#### ALL

Specifies that all of the cached statements are to be explained.

STMTCACHE ALL returns one row for each cached statement to the DSN\_STATEMENT\_CACHE\_TABLE. These rows contain identifying information about the statements in the cache, as well as statistics that reflect the execution of the statements by all processes that have executed the statement. See “DSN\_STATEMENT\_CACHE\_TABLE” on page 1981 for information about creating a statement cache table. See the Authorization

#### STMTID *id-host-variable* or *integer-constant*

Specifies that the cached statement with the specified statement ID is to be explained. The value contained *id-host-variable* or specified by *integer-constant* identifies the statement ID. The statement ID is an integer

that uniquely identifies a statement that has been cached in the dynamic statement cache. The statement ID of a cached statement can be retrieved through IFI monitor facilities from IFCID 316 or 124. Some diagnostic trace records, such as 173, 196, and 337, also show the statement ID.

For every row that the EXPLAIN statement inserts into the plan table, statement table, or function table, the QUERYNO column contains the value of the statement ID.

**STMTTOKEN** *id-host-variable* **or** *integer-constant*

Specifies that the cached statements with the specified statement token are to be explained. The value contained in *token-host-variable* or specified by *string-constant* identifies the statement token. The statement token must be a character string that is no longer than 240 bytes. The application program that originally prepares and inserts a statement into the cache associates a statement token with the cached statement. The program can make this association with the RRSAF SET\_ID function, or the sqleseti API if the program is connected remotely.

For every row that the EXPLAIN statement inserts into the plan table, statement table, or function table, the STMTTOKEN column contains the value of the statement token, and the QUERYNO column contains the value of the statement ID for the cached statement with the statement token.

**MONITORED STMTS**

Specifies that monitored statements, either dynamic or static, are to be explained. The MONITORED STMTS clause is deprecated and might not be available in releases of DB2 for z/OS after Version 9.1.

**SCOPE**

Specifies the scope of the filter for the statements. Only statements that are within the specified scope or match the filter will be explained.

**AUTHID** *authid-string*

Specifies that only statements that are executed by an authorization ID that matches the authorization ID that is specified in *authid-string* are to be explained. *authid-string* is a string constant or a host variable that represents an authorization ID. Any authorization ID sees only the statements with the same authorization ID, except SYSADM. SYSADM sees all authorization IDs.

**IPADDR** *ip-address*

Specifies the IP address of the client that is used to connect to the DB2 server. *ip-address* is the IP address string or a host variable.

**PLAN** *plan-name*

Specifies that only statements under the specified *plan-name* are to be explained. *plan-name* is a string constant or a host variable that represents the plan name.

**COLLECTION** *collection-name*

Specifies that only statements under the specified *collection-name* are to be explained. *collection-name* is a string constant or a host variable representing the collection name.

**PACKAGE** *package-name*

Specifies that only statements under the specified *package-name* are to be explained. *package-name* is a string constant or a host variable representing the package name.

## Notes

**Output from EXPLAIN:** DB2 inserts one or more rows of data into a plan table and other existing EXPLAIN tables. A plan table must exist before the operation that results in EXPLAIN output. For information about valid plan table formats see “PLAN\_TABLE” on page 1930. You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

Unless you need the information that is provided by the additional EXPLAIN tables, it is not necessary to create those tables to use EXPLAIN. However, a statement cache table is required when the STMTCACHE ALL keyword is specified as part of an EXPLAIN statement.

**EXPLAIN tables:** Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods.

Instances of these tables might also be created and used by certain optimization tools. For information about the meanings of different values in plan table and other EXPLAIN tables, see .

**Plan table**

*owner.PLAN\_TABLE.*

**Function table**

*owner.DSN\_FUNCTION\_TABLE.*

**Statement table**

*owner.DSN\_STATEMNT\_TABLE.*

**Statement cache table**

*owner.DSN\_STATEMENT\_CACHE\_TABLE.*

**Structure table**

*owner.DSN\_VIEWREF\_TABLE.*

**Query table**

*owner.DSN\_QUERY\_TABLE.*

**Query information table**

*owner.DSN\_QUERYINFO\_TABLE.*

## Examples

*Example 1:* Determine the steps required to execute the query 'SELECT X.ACTNO...'. Assume that no set of rows in the PLAN\_TABLE has the value 13 for the QUERYNO column.

```
EXPLAIN PLAN SET QUERYNO = 13
FOR SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
  FROM DSN8910.EMPPROJECT X, DSN8910.EMP Y
    WHERE X.EMPNO = Y.EMPNO
      AND X.EMPTIME > 0.5
      AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
ORDER BY X.ACTNO, X.PROJNO;
```

*Example 2:* Retrieve the information returned in Example 1. Assume that a statement table exists, so also retrieve the estimated cost of processing the query. Use the following query, which joins the plan table and the statement table.

```
SELECT * FROM PLAN_TABLE A, DSN_STATEMENT_TABLE B
  WHERE A.QUERYNO = 13 and B.QUERYNO = 13
  ORDER BY A.QBLOCKNO, A.PLANNO, A.MIXOPSEQ;
```

*Example 3:* Have the cached statement with statement ID 124 explained. Assume that host variable SID contains 124.

```
EXPLAIN STMTCACHE STMTID :SID;
```

*Example 4:* Have one row of data for each statement in the dynamic statement cache written to the DSN\_STATEMENT\_CACHE\_TABLE.

```
EXPLAIN STMTCACHE ALL;
```

*Example 5:* Assume that you want to use the plan table that was created by ADMF001 and your authorization ID is SYSADM. If you have an alias on ADMF001.PLAN\_TABLE (CREATE ALIAS SYSADM.PLAN\_TABLE FOR ADMF001.PLAN\_TABLE) and sufficient INSERT and SELECT privileges on the table, the following EXPLAIN statement will execute and ADMF001.PLAN\_TABLE will be populated.

```
EXPLAIN PLAN SET QUERYNO = 101
  FOR SELECT * FROM DSN8910.EMP;
```

## FETCH

The FETCH statement positions a cursor on a row of its result table. It can return zero, one, or multiple rows and assigns the values of the rows to host variables if there is a target specification.

There are two forms of this statement:

- **Single row fetch:** positions the cursor and, optionally, retrieves data from a single row of the result table.
- **Multiple row fetch:** positions the cursor on zero or more rows of the result table and, optionally, returns data if there is a target specification.

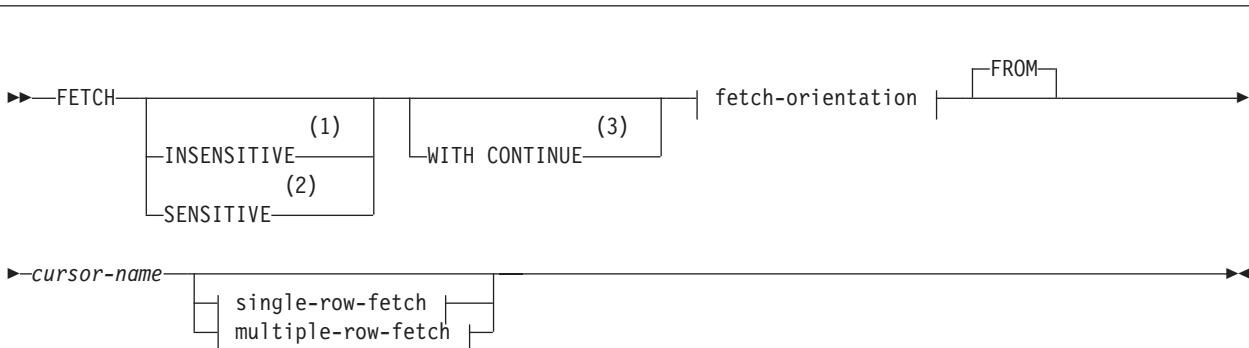

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not supported in REXX, Fortran<sup>34</sup>, or SQL Procedure applications.

### Authorization

See “DECLARE CURSOR” on page 1191 for an explanation of the authorization required to use a cursor.

### Syntax

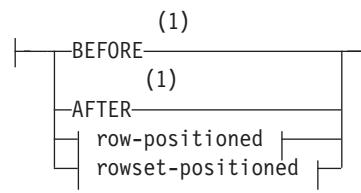

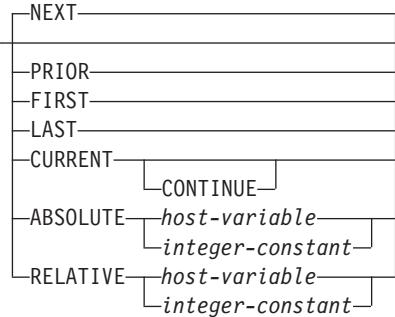

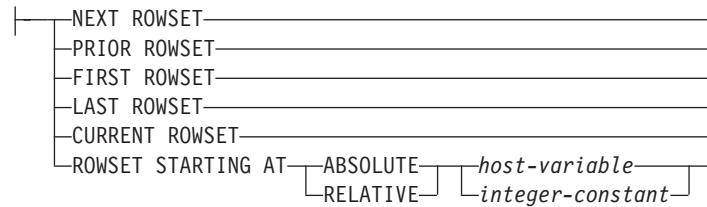

#### Notes:

- 1 The default depends on the sensitivity of the cursor. If INSENSITIVE is specified on the DECLARE CURSOR, then the default is INSENSITIVE and if SENSITIVE is specified on the DECLARE CURSOR, then the default is SENSITIVE.
- 2 If INSENSITIVE or SENSITIVE is specified, *single-row-fetch* or *multiple-row-fetch* must be specified.
- 3 If WITH CONTINUE is specified, *single-row-fetch* must be specified.

#### fetch-orientation

34. ASSEMBLER and other languages are supported, but this support is limited to statements that allow USING DESCRIPTOR. The precompiler does not recognize host-variable-arrays except in C/C++, COBOL, and PL/I.

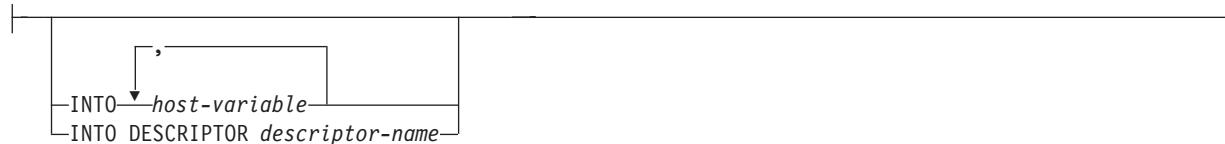

**fetch-orientation:****row-positioned:****rowset-positioned:****Notes:**

- 1 If BEFORE or AFTER is specified, SENSITIVE, INSENSITIVE, single-row-fetch, or multiple-row-fetch must not be specified.

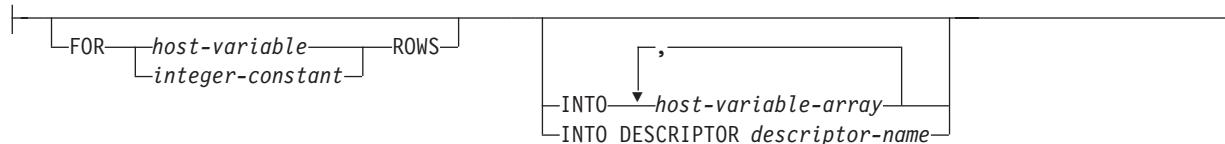

**fetch-type**

**single-row-fetch:**

(1)

**multiple-row-fetch:**

(2)

**Notes:**

- 1 For single-row-fetch, a host-variable-array can be specified instead of a host variable and the descriptor can describe host-variable-arrays. In either case, data is returned only for the first entry of the host-variable-array.
- 2 This clause is optional. If this clause is not specified and either a rowset size has not been established yet or a row positioned FETCH statement was the last type of FETCH statement issued for this cursor, the rowset size is implicitly one. If the last FETCH statement issued for this cursor was a rowset positioned FETCH statement and this clause is not specified, the rowset size is the same size as the previous rowset positioned FETCH.

## Description

### INSENSITIVE

Returns the row from the result table as it is. If the row has been previously fetched with a FETCH SENSITIVE, it reflects changes made outside this cursor before the FETCH SENSITIVE statement was issued. Positioned updates and deletes are reflected with FETCH INSENSITIVE if the same cursor was used for the positioned update or delete.

INSENSITIVE can only be specified for cursors declared as INSENSITIVE or SENSITIVE STATIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to INSENSITIVE). Otherwise, if the cursor is declared as SENSITIVE DYNAMIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to SENSITIVE DYNAMIC), an error occurs and the FETCH statement has no effect. For an INSENSITIVE cursor, specifying INSENSITIVE is optional because it is the default.

### SENSITIVE

Updates the fetched row in the result table from the corresponding row in the base table of the cursor's SELECT statement and returns the current values. Thus, it reflects changes made outside this cursor. SENSITIVE can only be specified for a sensitive cursor. Otherwise, if the cursor is insensitive, an error occurs and the FETCH statement has no effect. For a SENSITIVE cursor, specifying SENSITIVE is optional because it is the default.

When the cursor is declared as SENSITIVE STATIC and a FETCH SENSITIVE is requested, the following steps are taken:

1. DB2 retrieves the row of the database that corresponds to the row of the result table that is about to be fetched.
2. If the corresponding row has been deleted, a "delete hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole", and no data is fetched. (DB2 marks a row in the result table as a "delete hole" when the corresponding row in the database is deleted.)
3. If the corresponding row has not been deleted, the predicate of the underlying SELECT statement is re-evaluated. If the row no longer satisfies the predicate, an "update hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole," and no data is fetched. (DB2 marks a row in the result table as an "update hole" when an update to the corresponding row in the database causes the row to no longer qualify for the result table.)
4. If the corresponding row does not result in a delete or an update hole in the result table, the cursor is repositioned on the row of the result table and the data is fetched.

#### **WITH CONTINUE**

Specifies that the DB2 subsystem should prepare to allow subsequent FETCH CURRENT CONTINUE operations to access any truncated LOB or XML result column following an initial FETCH operation that provides output variables that are not large enough to hold the entire LOB or XML columns. When the WITH CONTINUE clause is specified, the DB2 subsystem takes the following actions that can differ from the case where the FETCH statement does not include the WITH CONTINUE clause:

- If truncation occurs when returning an XML or LOB column, the DB2 subsystem will remember the truncation position and will not discard the remaining data.
- If truncation occurs when returning an XML or LOB column, the DB2 subsystem returns the total length that would have been required to hold all of the data of the LOB or XML column. This will either be in the first four bytes of the LOB host variable structure or in the 4 byte area that is pointed to by the SQLDATALEN pointer in the SQLVAR entry of the SQLDA for that host variable. What is returned depends on the programming method that is used. See "SQL descriptor area (SQLDA)" on page 1656 for details about the SQLDA contents.
- If returning XML data, the result column will be fully materialized in the database before the data is returned.

If the CURRENT CONTINUE clause is specified, the WITH CONTINUE behavior is assumed.

#### **AFTER**

Positions the cursor after the last row of the result table. Values are not assigned to host variables. The number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for cursors with an effective sensitivity of INSENSITIVE or SENSITIVE STATIC.

#### **BEFORE**

Positions the cursor before the first row of the result table. Values are not assigned to host variables.

#### *row-positioned*

Positioning of the cursor with row-positioned fetch orientations NEXT, PRIOR, CURRENT and RELATIVE is done in relation to the current cursor position.

Following a successful row-positioned FETCH statement, the cursor is positioned on a single row of data. If the cursor is enabled for rowsets, positioning is performed relative to the current row or the first row of the current rowset, and the cursor is positioned on a rowset consisting of a single row.

#### **NEXT**

Positions the cursor on the next row or rows of the result table relative to the current cursor position, and returns data if a target is specified. NEXT is the only row-positioned fetch operation that can be explicitly specified for cursors that are defined as NO SCROLL. NEXT is the default if no other cursor positioning is specified. If a specified row reflects a hole, a warning is issued and data values are not assigned to host variables for that row.

Table 118 lists situations for different cursor positions and the results when NEXT is used.

*Table 118. Results when NEXT is used with different cursor positions*

Current state of the cursor	Result of FETCH NEXT
Before the first row	Cursor is positioned on the first row (1) and data is returned if requested.
On the last row or after the last row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
Before a hole	For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.
Unknown	An error occurs, values are not assigned to host variables, and the cursor position remains unknown.

**Note:**

(1)This row is not applicable in the case of a forward-only cursor (that is when NO SCROLL was specified implicitly or explicitly).

#### **PRIOR**

Positions the cursor on the previous row or rows of the result table relative to the current cursor position, and returns data if a target is specified. If a specified row reflects a hole, a warning is issued, and data values are not assigned to host variables for that row.

Table 119 lists situations for different cursor positions and the results when PRIOR is used.

*Table 119. Results when PRIOR is used with different cursor positions*

Current state of the cursor	Result of FETCH PRIOR
Before the first row or on the first row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
After a hole	For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.
After the last row	Cursor is positioned on the last row.

*Table 119. Results when PRIOR is used with different cursor positions (continued)*

Current state of the cursor	Result of <b>FETCH PRIOR</b>
Unknown	An error occurs, values are not assigned to host variables, and the cursor position remains unknown.

#### **FIRST**

Positions the cursor on the first row of the result table, and returns data if a target is specified. For a SENSITIVE STATIC cursor, if the first row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

#### **LAST**

Positions the cursor on the last row of the result table, and returns data if a target is specified. The number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for an insensitive or sensitive static cursor. For a SENSITIVE STATIC cursor, if the last row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

#### **CURRENT**

The cursor position is not changed, data is returned if a target is specified. If the cursor was positioned on a rowset of more than one row, the cursor position is on the first row of the rowset.

Table 120 lists situations in which errors occur with the CURRENT clause.

*Table 120. Situations in which errors occur with CURRENT*

Current state of the cursor	Result of <b>FETCH CURRENT</b>
Before the first row or after the last row	A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.
On a hole	For a SENSITIVE STATIC, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.
Unknown	If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the <b>FETCH</b> that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row of data.

#### **CONTINUE**

The cursor positioning is not changed, and data is returned if a target is specified. The **FETCH CURRENT CONTINUE** statement retrieves remaining data for any LOB or XML column result values that were truncated on a previous **FETCH** or **FETCH CURRENT CONTINUE** statement. It assigns the remaining data for those truncated columns to

the host variables that are referenced in the statement or pointed to by the descriptor. The data that is returned for previously-truncated result values begins at the point of truncation. This form of the CURRENT clause must only be used after a single-row FETCH WITH CONTINUE or FETCH CURRENT CONTINUE statement that has returned partial data for one or more LOB or XML columns. The cursor must be open and positioned on a row.

FETCH CURRENT CONTINUE must pass host variables entries for all columns in the SELECT list, even though the non-LOB columns or non-XML columns will not return any data.

#### ABSOLUTE

*host-variable* or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0). An *integer-constant* can be up to 31 digits, depending on the application language.

If *k*=0, the cursor is positioned before the first row of the result table. Otherwise, ABSOLUTE positions the cursor to row *k* of the result table if *k*>0, or to *k* rows from the bottom of the table if *k*<0. For example, "ABSOLUTE -1" is the same as "LAST".

Data is returned if the specified position is within the rows of the result table, and a target is specified.

If an absolute position is specified that is before the first row or after the last row of the result table, a warning occurs, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If row *k* of the result table is a hole, a warning occurs and values are not assigned to host variables.

FETCH ABSOLUTE 0 results in positioning before the first row and a warning is issued. FETCH BEFORE results in positioning before the first row and no warning is issued.

Table 121 lists some synonymous specifications.

Table 121. Synonymous scroll specifications for ABSOLUTE

Specification	Alternative
ABSOLUTE 0 (but with a warning)	BEFORE (without a warning)
ABSOLUTE +1	FIRST
ABSOLUTE -1	LAST
ABSOLUTE - <i>m</i> , 0< <i>m</i> $\leq$ <i>n</i>	ABSOLUTE <i>n</i> +1- <i>m</i>
ABSOLUTE <i>n</i>	LAST
ABSOLUTE - <i>n</i>	FIRST
ABSOLUTE <i>x</i> (with a warning)	AFTER (without a warning)
ABSOLUTE - <i>x</i> (with a warning)	BEFORE (without a warning)

**Note:** Assume: 0 $\leq$ *m* $\leq$ *n* $<$ *x* Where, *n* is the number of rows in the result table.

## RELATIVE

*host-variable* or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0).

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If *n* is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs
- If *n* is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting at row *n*
- If *n* is positive, and the cursor is positioned after the last row, a warning occurs
- If *n* is negative, and the cursor is positioned before the first row, a warning occurs
- If *n* is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting as row *n* from the end of the result table

An *integer-constant* can be up to 31 digits, depending on the application language.

Data is returned if the specified position is within the rows of the result table, and a target is specified.

RELATIVE positions the cursor to the row in the result table that is either *k* rows after the current row if *k*>0, or ABS(*k*) rows before the current row if *k*<0. For example, "RELATIVE -1" is the same as "PRIOR". If *k*=0, the position of the cursor does not change (that is, "RELATIVE 0" is the same as "CURRENT").

If a relative position is specified that results in positioning before the first row or after the last row, a warning is issued, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If the cursor is positioned on a hole and RELATIVE 0 is specified or if the target row is a hole, a warning occurs and values are not assigned to host variables.

If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row data.

If the cursor position is unknown and RELATIVE 0 is specified, an error occurs.

Table 122 lists some synonymous specifications.

Table 122. Synonymous Scroll Specifications for RELATIVE

Specification	Alternative
RELATIVE +1	NEXT

Table 122. Synonymous Scroll Specifications for RELATIVE (continued)

Specification	Alternative
RELATIVE -1	PRIOR
RELATIVE 0	CURRENT
RELATIVE +r (with a warning)	AFTER (without a warning)
RELATIVE -r (with a warning)	BEFORE (without a warning)

**Note:**

*r* has to be large enough to position the cursor beyond either end of the result table.

#### *rowset-positioned*

Positioning of the cursor with rowset-positioned fetch orientations NEXT ROWSET, PRIOR ROWSET, CURRENT ROWSET, and ROWSET STARTING AT RELATIVE is done in relation to the current cursor position. Following a successful row-positioned FETCH statement, the cursor is positioned on a rowset of data. The number of rows in the rowset is determined either explicitly or implicitly. The FOR *n* ROWS clause in the multiple-row-fetch clause is used to explicitly specify the size of the rowset. Positioning is performed relative to the current row or first row of the current rowset, and the cursor is positioned on all rows of the rowset.

A rowset-positioned fetch orientation must not be specified if the current cursor position is not defined to access rowsets. NEXT ROWSET is the only rowset-positioned fetch orientation that can be specified for cursors that are defined as NO SCROLL.

If a row of the rowset reflects a hole, a warning is returned, data values are not assigned to host variable arrays for that row (that is, the corresponding positions in the target host variable arrays are untouched), and -3 is returned in all provided indicator variables for that row. If a hole is detected, and at least one indicator variable is not provided, an error occurs.

#### **NEXT ROWSET**

Positions the cursor on the next rowset of the result table relative to the current cursor position, and returns data if a target is specified. The next rowset is logically obtained by fetching the row that follows the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR *n* ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned before the first row of the result table, the cursor is positioned on the first rowset.

If the cursor is positioned on the last row or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned. If a row of the rowset would be after the last row of the result table, values are not assigned to host-variable-arrays for that row and any subsequent requested rows of the rowset, and a warning is returned.

NEXT ROWSET is the only rowset positioned fetch orientation that can be explicitly be specified for cursors that are defined as NO SCROLL.

#### PRIOR ROWSET

Positions the cursor on the previous rowset of the result table relative to the current position, and returns data if a target is specified.

The prior rowset is logically obtained by fetching the row that precedes the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned after the last row of the result table, the cursor is positioned on the last rowset.

If the cursor is positioned before the first row or on the first row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.

If a row would be before the first row of the result table, the cursor is positioned on a partial rowset that consists of only those rows that are prior to the current position of the cursor starting with the first row of the result table, and a warning is returned. Values are not assigned to the host-variable-arrays for the rows in the rowset for which the warning is returned.

Although the rowset is logically obtained by fetching backwards from before the current rowset, the data is returned to the application starting with the first row of the rowset, to the end of the rowset.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned.

#### FIRST ROWSET

Positions the cursor on the first rowset of the result table, and returns data if a target is specified.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR  $n$  ROWS clause, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

#### LAST ROWSET

Positions the cursor on the last rowset of the result table and returns data if a target is specified. The last rowset is logically obtained by fetching the last row of the result table and fetching prior rows until the number of rows in the rowset is obtained or the first row of the result table is reached. Although the rowset is logically obtained by fetching backwards from the bottom of the result table, the data is returned to the application starting with the first row of the rowset, to the end of the rowset, which is also the end of the result table.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR  $n$  ROWS clause, the last rowset is the same as the first rowset, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

#### CURRENT ROWSET

If the FOR  $n$  ROWS clause specifies a number different from the number of rows specified implicitly or explicitly in the FOR  $n$  ROWS clause on the most recent FETCH statement for this cursor, the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset. If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs. If the FOR  $n$  ROWS clause is not specified, it is possible that the FETCH statement will position the cursor on a partial rowset when the FETCH CURRENT ROWSET statement is processed. In this case, DB2 attempts to position the cursor on a full rowset starting with the first row of the current rowset. Otherwise, the position of the cursor on the current rowset is unchanged. Data is returned if a target is specified.

With isolation level UR or a sensitive dynamic scrollable cursor, it is possible that different rows will be returned than the FETCH that established the most recent rowset cursor position. This can occur while refetching the first row of the rowset when it is determined to not be there anymore. In this case, fetching continues moving forward to get the first row of data for the rowset. This can also occur when changes have been made to other rows in the current rowset such that they no longer exist or have been logically moved within (or out of) the result table of the cursor.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error occurs.

If the current rowset contains fewer rows than specified implicitly or explicitly in the FOR *n* ROWS clause, values are not assigned to host-variable-arrays after the last row, and a warning is returned.

**ROWSET STARTING AT ABSOLUTE or RELATIVE *host-variable* or *integer-constant***

Positions the cursor on the rowset beginning at the row of the result table that is indicated by the ABSOLUTE or RELATIVE specification, and returns data if a target is specified.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. The possible data types for the host variable are DECIMAL(n,0) or integer, where the DECIMAL data type is limited to DECIMAL(18,0). If a constant is specified, the value must be an integer.

If a row of the result table would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row and a warning is returned.

**ABSOLUTE**

If *k*=0, an error occurs. If *k*>0, the first row of the rowset is row *k*. If *k*<0, the rowset is positioned on the ABS(*k*) rows from the bottom of the result table. Assume that ABS(*k*) is equal to the number of rows for the rowset and that there are enough row to return a complete rowset:

- FETCH ROWSET STARTING AT ABSOLUTE -*k* is the same as FETCH LAST ROWSET.
- FETCH ROWSET STARTING AT ABSOLUTE 1 is the same as FETCH FIRST ROWSET.

**RELATIVE**

If *k*=0 and the FOR *n* ROWS clause does not specify a number different from the number most recently specified implicitly or explicitly for this cursor, then the position of the cursor does not change (that is, "RELATIVE ROWSET 0" is the same as "CURRENT ROWSET"). If *k*=0 and the FOR *n* ROWS clause specifies a number different from the number most recently specified implicitly or explicitly for this cursor, then the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset.

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If *n* is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs. This is the same as FETCH CURRENT ROWSET.
- If *n* is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting a row *n*.
- If *n* is positive, and the cursor is positioned after the last row, a warning occurs.
- If *n* is negative, and the cursor is positioned before the first row, a warning occurs.
- If *n* is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting at row *n* from the bottom of the result table.

Otherwise, RELATIVE repositions the cursor so that the first row of the new rowset cursor position is on the row in the result table that is either k rows after the first row of the current rowset cursor position if  $k > 0$ , or ABS(k) rows before the first row of the current rowset cursor position if  $k < 0$ . Assume that ABS(k) is equal to the number of rows for the resulting rowset

- FETCH ROWSET STARTING AT RELATIVE -k is the same as FETCH PRIOR ROWSET.
- FETCH ROWSET STARTING AT RELATIVE k is the same as FETCH NEXT ROWSET.
- FETCH ROWSET STARTING AT RELATIVE 0 is the same as FETCH CURRENT ROWSET.

When ROWSET STARTING AT RELATIVE -n is specified and there are not enough rows between the current position of the cursor and the beginning of the result table to return a complete rowset:

- A warning is returned.
- Values are not assigned to the host-variable-arrays.
- The cursor is positioned before the first row.

If a row of the rowset reflects a hole, If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned. If a row of the rowset is unknown, values are not assigned to host variable arrays for that row, and an error is returned. If a row of the rowset would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row, and a warning is returned.

#### *cursor-name*

Identifies the cursor to be used in the fetch operation. The cursor name must identify a declared cursor, as explained in the description of the DECLARE CURSOR statement in “DECLARE CURSOR” on page 1191, or an allocated cursor, as explained in “ALLOCATE CURSOR” on page 696. When the FETCH statement is executed, the cursor must be in the open state.

If a single-row-fetch or multiple-row-fetch clause is not specified, the cursor position is adjusted as specified, but no data is returned to the user.

#### *single-row-fetch*

When *single-row-fetch* is specified, SENSITIVE or INSENSITIVE can be specified though there is a default. The default depends on the sensitivity of the cursor. If the sensitivity of the cursor is INSENSITIVE, then the default is INSENSITIVE. If the effective sensitivity of the cursor is SENSITIVE DYNAMIC or SENSITIVE STATIC, then the default is SENSITIVE. The single-row-fetch or multiple-row-fetch clause must not be specified when the FETCH BEFORE or FETCH AFTER option is specified. They are required when FETCH BEFORE or FETCH AFTER is not specified. If an individual fetch operation causes the cursor to be positioned or to remain positioned on a row if there is a target specification, the values of the result table are assigned to host variables as specified by the single-fetch-clause.

**INTO host-variable,...**

Specifies a list of host variables. Each *host-variable* must identify a structure or variable that is described in the application program in accordance with the rules for declaring host structures and variables. A reference to a structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first host variable, the second value to the second host variable, and so on.

**INTO DESCRIPTOR *descriptor-name***

Identifies an SQLDA that contains a valid description of the host output variables. Result values from the associated SELECT statement are returned to the application program in the output host variables.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA  
A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated in the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host variable or buffer into which a value in the result table is to be assigned. If LOBs are present in the results, there must be additional SQLVAR entries for each column of the result table. If the result table contains only base types and distinct types, multiple SQLVAR entries are not needed for each column. However, extra SQLVAR entries are needed for distinct types as well as for LOBs in DESCRIBE and PREPARE INTO statements. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see “SQL descriptor area (SQLDA)” on page 1656.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

***multiple-row-fetch***

Retrieves multiple rows of data from the result table of a query. The FOR *n* ROWS clause of the FETCH statement controls how many rows are returned on a single FETCH statement. The fetch orientation determines whether the resulting cursor position (for example, on a single row, rowset, before, or after the result table). Fetching stops when an error is returned, all requested rows are fetched, or the end of data condition is reached.

Fetching multiple rows of data can be done with scrollable or non-scrollable cursors. The operations used to define, open, and close a cursor used for fetching multiple rows of data are the same as for those used for single row FETCH statements.

If the BEFORE or AFTER option is specified, neither single-row-fetch or multiple-row-fetch can be specified.

**FOR** *host-variable or integer-constant ROWS*

*host-variable or integer-constant* is assigned to an integral value *k*. If a host variable is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. Furthermore, *k* must be in the range,  $0 < k \leq 32767$ .

This clause must not be specified if a row-positioned fetch-orientation clause was specified. This clause must also not be specified for a cursor that is defined without rowset access.

If a rowset fetch orientation is specified and this clause is not specified, the number of rows in the resulting rowset is determined as follows:

- If the most recent FETCH statement for this cursor was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that was most recently specified (implicitly or explicitly) for this cursor.
- When the most recent FETCH statement for this cursor was either FETCH BEFORE or FETCH AFTER and the most recent FETCH statement for this cursor prior to that was a rowset-positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that were most recently specified (implicitly or explicitly) for this cursor.
- Otherwise, the rowset consists of a single row.

For result set cursors, the number of rows for a rowset cursor position, established in the procedure that defined the rowset, is not inherited by the caller when the rowset is returned. Use the FOR *n ROWS* clause on the first rowset FETCH statement for the result set in the calling program to establish the number of rows for the cursor. Otherwise, the rowset consists of a single row.

The cursor is positioned on the row or rowset that is specified by the orientation clause (for example, NEXT ROWSET), and those rows are fetched if a target is specified. After the cursor is positioned on the first row being fetched, the next *k-1* rows are fetched. Fetching moves forward from the cursor position in the result table and continues until the end of data condition is returned, *k-1* rows have been fetched, or an assignment error is returned.

The resulting cursor position depends on the fetch orientation that is specified:

- For a row-positioned fetch orientation, the cursor is positioned at the last row successfully retrieved.
- For a rowset-positioned fetch orientation, the cursor is positioned on all the rows retrieved.

The values from each individual fetch are placed in data areas that are described in the INTO or USING clause. If a target specification is provided for a rowset-positioned FETCH, the host variable arrays must be specified as the target specification, and the arrays must be defined with a dimension of 1 or greater. The target specification must be defined as an array for a rowset-positioned FETCH even if the number of rows that is specified implicitly or explicitly is one. See Diagnostics information for rowset positioned FETCH statements.

**INTO** *host-variable-array*

Identifies for each column of the result table a host-variable-array to receive the data that is retrieved with this FETCH statement. If the number

of host-variable-arrays is less than the number of columns of the result table, the SQLWARN3 field of the SQLCA is set to 'W'. No warning is given if there are more host-variable-arrays than the number of columns in the result table.

Each host-variable-array must be defined in the application program in accordance with the rules for declaring an array. A host-variable-array is used to return the values for a column of the result table. The number of rows to be fetched must be less than or equal to the dimension of each of the host-variable-arrays.

An optional indicator array can be specified for a host-variable-array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the column of the result table is nullable. Additionally, if an operation may result in null values, such as an UPDATE operation that results in a hole, is performed in the application, an indicator array should be specified. Otherwise an error occurs if null values are encountered. The indicators are returned as small integers.

**INTO DESCRIPTOR *descriptor-name***

Identifies an SQLDA that must contain a valid description of zero or more host-variable-arrays or buffers into which the values for a column of the result table are to be returned.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of an element of the host-variable-array. Within each SQLVAR representing an array:
  - SQLTYPE indicates the data type of the elements of the host-variable-array.
  - SQLDATA field points to the first element of the host-variable-array.
  - The length fields (SQLLEN and SQLLONGLEN) are set to indicate the maximum length of a single element of the array.
  - SQLNAME - The length of SQLNAME must be set to 8, and the first two bytes of the data portion of SQLNAME must be initialized to X'0000'. The fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must be initialized to a binary small integer (half word) representation of the dimension of the host-variable-array, and the corresponding indicator array, if one is specified.

The SQLVAR entry for the number of rows must also contain a flag value. The number of rows to be fetched must be less than or equal to the dimension of each of the host variable arrays.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays. The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host-variable-array or buffer into which the values for a column in the result table are to be returned. If any column of the result table is a LOB, two SQLVAR entries must be provided for each SQLVAR, and SQLN must

be set to two times the number of SQLVARS. SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

## Notes

**Assignment to host variables:** The *n*th variable identified by the INTO clause or described in the SQLDA corresponds to the *n*th column of the result table of the cursor. The data type of a host variable must be compatible with its corresponding value. If the value is numeric, the variable must have the capacity to represent the whole part of the value. For a datetime value, the variable must be a character string variable of a minimum length as defined in “String representations of datetime values” on page 89. If the value is null, an indicator variable must be specified.

Assignments are made in sequence through the list. Each assignment to a variable is made according to the rules described in Chapter 2, “Language elements,” on page 47. If the number of variables is less than the number of values in the row, the SQLWARN3 field of the SQLCA is set to W. There is no warning if there are more variables than the number of result columns. If the value is null, an indicator variable must be provided. If an assignment error occurs, the value is not assigned to the variable and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with other data types. For more information on using locators, see *DB2 Application Programming and SQL Guide*.

**Restrictions on using the WITH CONTINUE and CURRENT CONTINUE clauses:** When using the WITH CONTINUE clause, the DB2 system will only reserve truncated data for result set columns of the BLOB, CLOB, DBCLOB, or XML data type, and only when the output host variable data type is the appropriate LOB data type.

If an application uses FETCH WITH CONTINUE, and truncated data remains after the FETCH operation, the application cannot perform any intervening operation on that cursor before performing the FETCH CURRENT CONTINUE. If intervening operations on that cursor are performed, the truncated data is lost.

FETCH CURRENT CONTINUE is not supported with multi-row fetch. Also, FETCH CURRENT CONTINUE is not supported for non-LOB and non-XML columns that have been truncated. If truncation occurs for these non-LOB and non-XML columns, the truncated data will be discarded as usual.

**Result column evaluation considerations:** If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero, or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If the specified host variable is not large enough to contain the result, a warning is returned and W is assigned to SQLWARN1 in the SQLCA. The actual length of the result is returned in the indicator variable associated with the host-variable, if an indicator is provided. It is possible that a warning may not be returned on a FETCH operation. This occurs as a result of optimizations, such as the use of system temporary tables or blocking. It is also possible that the returned warning applies to a previously fetched row. When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, a warning or an error is returned.

**Cursor positioning:** An open cursor has three possible positions:

- Before a row
- On a row or rowset
- After the last row

When a scrollable or non-scrollable cursor is opened, it is positioned before the first row in the result table. If a cursor is on a row, that row is called the current row of the cursor. If a cursor is on a rowset, the rows are called the current rowset of the cursor.

A cursor referred to in an UPDATE or DELETE statement must be positioned on a row or rowset. A cursor can only be on a row or rowset as a result of a FETCH statement.

If the cursor was declared SENSITIVE STATIC SCROLL, a row may be a *hole*, from which no values may be fetched, updated, or deleted. Holes do not exist with sensitive dynamic cursors because there is no temporary result table. For information about holes in the result table of a cursor, see *DB2 Application Programming and SQL Guide*.

For scrollable cursors, the cursor position after an error varies depending on the type of error:

- When an operation is attempted against an update or delete hole, or when an update or delete hole is detected, the cursor is positioned on the hole.
- When a FETCH operation is attempted past the end of file, the cursor is positioned after the last row.
- When a FETCH operation is attempted before the beginning of file, the cursor is positioned before the first row.
- When an error causes the cursor position to be invalid such as when a single row positioned update or positioned delete error occurs that causes a rollback, the cursor is closed.

**Cursor position after exception condition:** If an error occurs during the execution of a fetch operation, the position of the cursor and the result of any later fetch is unpredictable. It is possible for an error to occur that makes the position of the cursor invalid, in which case the cursor is closed.

If an individual fetch operation specifies a destination that is outside the range of the cursor, a warning is issued (except for FETCH BEFORE or FETCH AFTER), the cursor is positioned before or after the result table, and values are not assigned to host variables.

**Concurrency and scrollability:** The current row of a cursor cannot be updated or deleted by another application process if it is locked. Unless it is already locked

because it was inserted or updated by the application process during the current unit of work, the current row of a cursor is not locked if:

- The isolation level is UR, or
- The isolation level is CS, and
  - The result table of the cursor is read-only
  - The bind option CURRENTDATA(NO) is in effect

A dynamic scrollable cursor is useful when it is more important to the application to see updated rows and newly inserted rows and there is no need to see deleted rows. The isolation level of CS should be used for maximum concurrency with dynamic scrollable cursors. Specifying an isolation level of RR or RS severely restricts the update of the table, thus defeating the purpose of a SENSITIVE DYNAMIC scrollable cursor. If the application needs a constant result table, a SENSITIVE STATIC scrollable cursor with an isolation level of CS should be used.

*Sensitivity of SENSITIVE STATIC SCROLL cursors to database changes:* When SENSITIVE STATIC SCROLL has been declared, the following rules apply:

- For the result of an update operation to be visible within a cursor after "open," the update operation must be a positioned update executed against the cursor, or a FETCH SENSITIVE in a STATIC cursor must be executed against a row which has been updated by some other means (that is, a searched update, committed updates of others, or an update with another cursor in the same process).
- Another process can update the base table of the SELECT statement so that the current values no longer satisfy the WHERE clause. In this case, an "update hole" effectively exists during the time the values in the base table do not satisfy the WHERE clause, and the row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as an update hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, update holes are only identified during positioned update, positioned delete, and FETCH SENSITIVE operations. Each positioned update, positioned delete, and FETCH SENSITIVE operation does the necessary tests to determine if an update hole exists.

- For the result of a delete operation to be visible within a SENSITIVE STATIC SCROLL cursor, the delete operation must be a positioned delete executed against the cursor or a FETCH SENSITIVE in a STATIC cursor must be executed against a row that has been deleted by some other means (that is, a searched delete, committed deletes of others, or a delete with another cursor in the same process).
- Another process, or the even the same process, may delete a row in the base table of the SELECT statement so that a row of the cursor no longer has a corresponding row in the base table. In this case, a "delete hole" effectively exists, and that row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as a delete hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, delete holes are identified during positioned update, positioned delete, and FETCH SENSITIVE operations.

- Inserts into the base table or tables of SENSITIVE STATIC SCROLL cursors are not seen after the cursor is opened.

**LOB locators:** When information is retrieved into LOB locators and it is not necessary to retain the locator across FETCH statements, it is a good practice to issue a FREE LOCATOR statement before issuing another FETCH statement because locator resources are limited.

**Isolation level considerations:** The isolation level of the statement (specified implicitly or explicitly) can affect the result of a rowset-positioned FETCH statement. This is possible when changes are made to the tables underlying the cursor when isolation level UR is used with a dynamic scrollable cursor, or with other isolation levels when rows have been added by the application fetching from the cursor. These situations can occur with the following fetch orientations:

#### PRIOR ROWSET

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

#### CURRENT ROWSET

With a dynamic scrollable cursor, additional rows can be added between rows that form the rowset that was returned to the user. With isolation level RR, these rows can only be added by the application fetching from the cursor. For isolation levels other than RR, other applications can insert rows that can affect the results of a subsequent FETCH CURRENT ROWSET. To avoid this behavior, use a static scrollable cursor instead of a dynamic scrollable cursor.

#### LAST ROWSET

With a dynamic scrollable cursor and isolation level UR, the content of the last rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "last" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

#### ROWSET STARTING AT RELATIVE *-n* (where *-n* is a negative number)

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**Row positioned and rowset positioned FETCH statement interaction:** Table 123 on page 1310 demonstrates the interaction between row positioned and rowset positioned FETCH statements. The table is based on the following assumptions:

- TABLE T1 has 15 rows
- CURSOR CS1 is declared as follows:

```
DECLARE CS1 SCROLL CURSOR WITH ROWSET POSITIONING FOR  
SELECT * FROM T1;
```

- An OPEN CURSOR statement has been successfully executed for CURSOR CS1 and the FETCH statements in the table are executed in the order that they appear in the table.

*Table 123. Interaction between row positioned and rowset positioned FETCH statements*

FETCH Statement	Cursor Position
FETCH FIRST	Cursor is positioned on row 1.
FETCH FIRST ROWSET	Cursor is positioned on a rowset of size 1, consisting of row 1.
FETCH FIRST ROWSET FOR 5 ROWS	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH CURRENT ROWSET	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH CURRENT	Cursor is positioned on row 1
FETCH FIRST ROWSET FOR 5 ROWS	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5.
FETCH or FETCH NEXT	Cursor is positioned on row 2.
FETCH NEXT ROWSET	Cursor is positioned on a rowset of size 1, consisting of row 3.
FETCH NEXT ROWSET FOR 3 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 4, 5, and 6.
FETCH NEXT ROWSET	Cursor is positioned on a rowset of size 3, consisting of rows 7, 8, and 9.
FETCH LAST	Cursor is positioned on row 15.
FETCH LAST ROWSET FOR 2 ROWS	Cursor is positioned on a rowset of size 2, consisting of rows 14 and 15.
FETCH PRIOR ROWSET	Cursor is positioned on a rowset of size 2, consisting of rows 12 and 13.
FETCH ABSOLUTE 2	Cursor is positioned on row 2.
FETCH ROWSET STARTING AT ABSOLUTE 2 FOR 3 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 2, 3, and 4.
FETCH RELATIVE 2	Cursor is positioned on row 4.
FETCH ROWSET STARTING AT ABSOLUTE 2 FOR 4 ROWS	Cursor is positioned on a rowset of size 4, consisting of rows 2, 3, 4, and 5.
FETCH RELATIVE -1	Cursor is positioned on row 1.
FETCH ROWSET STARTING AT ABSOLUTE 3 FOR 2 ROWS	Cursor is positioned on a rowset of size 2, consisting of rows 3 and 4.
FETCH ROWSET STARTING AT RELATIVE 4	Cursor is positioned on a rowset of size 2, consisting of rows 7 and 8.
FETCH PRIOR	Cursor is positioned on row 6.
FETCH ROWSET STARTING AT ABSOLUTE 13 FOR 5 ROWS	Cursor is positioned on a rowset of size 3, consisting of rows 13, 14, and 15.
FETCH FIRST ROWSET	Cursor is positioned on a rowset of size 5, consisting of rows 1, 2, 3, 4, and 5. <b>Note:</b> Even though the previous FETCH statement returned only 3 rows because EOF was encountered, DB2 will remember that 5 rows were requested by the previous FETCH statement.

**Considerations for using the FOR *n* ROWS clause with the FETCH FIRST *n* ROWS ONLY clause:** A clause specifying the desired number of rows can be specified in the SELECT statement of a cursor or the FETCH statement for a cursor, or both. However, these clauses have different effects:

- In the SELECT statement, a FETCH FIRST  $n$  ROWS ONLY clause controls the maximum number of rows that can be accessed with the cursor. When a FETCH statement attempts to retrieve a row beyond the number specified in the FETCH FIRST  $n$  ROWS ONLY clause of the SELECT statement, an end-of-data condition occurs.
- In a FETCH statement, a FOR  $n$  ROWS clause controls the number of rows that are returned for a single FETCH statement.

Both of these clauses can be specified.

**Diagnostics information for rowset positioned FETCH statements:** A single FETCH statement from a rowset cursor might encounter zero, one, or more conditions. If the current cursor position is not valid for the fetch orientation, a warning occurs and the statement terminates. If a warning or non-terminating error (such as a bind out error) occurs during the fetch of a row, processing continues. In this case, a summary message is returned for the FETCH statement, and additional information about each fetched row is available with the GET DIAGNOSTICS statement. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these FETCH statements. See “GET DIAGNOSTICS” on page 1317 for more information.

The SQLCA returns some information about errors and warnings that are found while fetching from a rowset cursor. Processing stops when the end of data is encountered, or when a terminating condition occurs. After each FETCH statement from a rowset cursor, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD1 and SQLERRD2 contain the number of rows of the result table if the cursor is positioned on the last row of the result table.
- SQLERRD3 contains the actual number of rows returned. If SQLERRD3 is less than the number of rows requested, an error or end-of-data condition occurred.
- SQLWARN flags are set to represent all the warnings that were accumulated while processing the FETCH statement.

Consider the following examples, where 10 rows are fetched with a single FETCH statement.

- **Example 1:** Assume that an error is detected on the 5th row. SQLERRD3 is set to 4 for the 4 returned rows, SQLSTATE is set to 22537, and SQLCODE is set to -354. This information is also available from the GET DIAGNOSTICS statement (the information that is returned is generated from connected server, which may differ across different servers). For example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 4 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22537, sqlcode = -354, and row_num = 5
```

- **Example 2:** Assume that an end-of-data condition is detected on the 6th row and that the cursor does not have immediate sensitivity to updates. SQLERRD3 is set to 5 for the 5 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. This information is also available from the GET DIAGNOSTICS statement. For example:

```

GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 5 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 6

```

- **Example 3:** Assume that an bind out error condition is detected on the 5th row, the condition is recorded, and processing continues. Also, assume that an end-of-data condition is detected on the 8th row. SQLERRD3 is set to 7 for the 7 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. Processing to complete the FETCH statement is performed, and the bind out error that occurred is noted. An additional SQLCODE is recorded for the bind out error. SQLCODE is set to -354, and SQLSTATE is set to 01668. Use the GET DIAGNOSTICS statement to determine what went on. For example:

```

GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 7 and num_cond = 3 (3 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01668, sqlcode = -354, and row_num = 0
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 0
GET DIAGNOSTICS CONDITION 3 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -302, and row_num = 5

```

In some cases, DB2 returns a warning if indicator variables are provided, or an error if indicator variables are not provided. These errors can be thought of as data mapping errors that result in a warning if indicator variables are provided.

- If indicator variables are provided, DB2 returns all rows to the user, marking the errors in the indicator variables. The SQLCODE and SQLSTATE contain the warning from the last data mapping error. The GET DIAGNOSTICS statement can be used to retrieve information about all the data mapping errors that have occurred.
- If some or no indicator variables are provided, all rows are returned as above until the first data mapping error that does not have indicator variables is detected. The rows successfully fetched are returned and the SQLSTATE, SQLCODE, and SQLWARN flags are set, if necessary. (The SQLCODE may be 0 or a positive value).

It is possible, if a data mapping error occurs, for the positioning of the cursor to be successful. In this case, the cursor is positioned on the rowset that encountered the data mapping error.

Consider the following examples, which try to fetch 10 rows with a single FETCH statement.

- **Example 1:** Assume that indicators have been provided for values returned for column 1, but not for column 2. The 5th row has a data mapping error (+802) for column 1, and the 7th row has a data mapping error for column 2 (-802 is returned because an indicator was not provided for column 2). SQLERRD3 is set to 6 for the 6 returned rows, SQLSTATE and SQLCODE are set to the error from the 7th row fetched. The indicator variable for the 5th row column 1 indicates

that a data mapping error was found. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 6 and num_cond = 2 (2 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01519, sqlcode = +802, and row_num = 5
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -802, and row_num = 7
```

The resulting cursor position is unknown.

- **Example 2:** Assume that null indicators are provided, that rows 3 and 5 are holes, and that data exists for the other requested rows. SQLERRD3 is set to 10 to reflect that 10 fetches were completed and that information has been returned for the 10 requested rows. Eight rows actually contain data. For two rows, indicator variables are set to indicate no data was returned for those rows. SQLSTATE is set to 02502, SQLCODE is set to +222, and all null indicators for rows 3 and 5 are set to -3 to indicate that a hole was detected. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 10 and num_cond = 2 (2 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 3
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 5
```

If a null indicator was not provided for any variable in a row that was a hole, an error occurs.

**SQLCA usage summary:** For multiple-row-fetch, the fields of the SQLCA are set as follows:

Condition		Action: Resulting Values Stored in the SQLCA Fields		
Errors	Data	SQLSTATE	SQLCODE	SQLERRD3
No <sup>1</sup>	Return all requested rows	00000	0	Number of rows requested
No <sup>1</sup>	Return data for subset of requested rows, end of data	02000	+100	Number of rows rows
No <sup>1</sup>	Return all requested rows	sqlstate(2)	sqlcode(2)	Number of rows requested
Yes <sup>1</sup>	Return successfully fetched rows	sqlstate(3)	sqlcode(3)	Number of rows
Yes <sup>1</sup>	Return successfully fetched rows	sqlstate(4)	sqlcode(4)	Number of rows

Condition		Action: Resulting Values Stored in the SQLCA Fields		
Errors	Data	SQLSTATE	SQLCODE	SQLERRD3
<b>Notes:</b>				

1. SQLWARN flags may be set in all cases, even if there are no other warnings or errors indicated. The warning flags are an accumulation of all warning flags set while processing the multiple-row-fetch.

2. sqlcode is the last positive SQLCODE, and sqlstate is the corresponding SQLSTATE value.

3. Database Server detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is the corresponding SQLSTATE value.

4. Client detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is one of the following SQLSTATEs: 22002, 22008, 22509, 22518, or 55021.

**Providing indicator variables for error conditions:** If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.)

If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned. Additionally, a -3 is returned in all indicators provided by the application when a hole was detected for the row on a rowset positioned FETCH, and values were not returned for the row. Processing of the statement terminates if a hole is detected and at least one indicator variable was not provided by the application.

**Alternative syntax and synonyms:** USING DESCRIPTOR can be specified as a synonym for INTO DESCRIPTOR.

## Example

*Example 1:* The FETCH statement fetches the results of the SELECT statement into the application program variables DNUM, DNAME, and MNUM. When no more rows remain to be fetched, the not found condition is returned.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8910.DEPT
  WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```

*Example 2:* For an example of FETCH statements with a dynamic scrollable cursor, see Example 8.

*Example 3:* Fetch the last 5 rows of the result table C1 using cursor C1:

```
FETCH ROWSET STARTING AT ABSOLUTE -5
  FROM C1 FOR 5 ROWS INTO DESCRIPTOR :MYDESCR;
```

*Example 4:* Fetch 6 rows starting at row 10 for cursor CURS1, and fetch the data into three host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
  FROM CURS1 FOR 6 ROWS
  INTO :hav1, :hva2, :hva3;
```

Alternatively, a descriptor could have been specified in an INTO DESCRIPTOR clause where the information in the SQLDA reflects the data types of the host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
  FROM CURS1 FOR 6 ROWS
  INTO DESCRIPTOR :MYDESCR;
```

## FREE LOCATOR

The FREE LOCATOR statement removes the association between a LOB locator variable and its value.

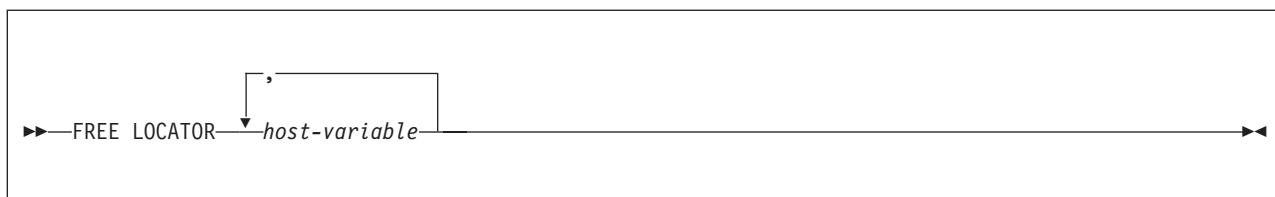

### Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java.

### Authorization

None required.

### Syntax

### Description

*host-variable*, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been freed and others have not been freed.

### Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. Free the CLOB locator variables LOCRE, LOCHIST, and the BLOB locator variable LOCPIC.

```
EXEC SQL FREE LOCATOR :LOCRE, :LOCHIST, :LOCPIC
```

## GET DIAGNOSTICS

The GET DIAGNOSTICS statement provides diagnostic information about the last SQL statement (other than a GET DIAGNOSTICS statement) that was executed. This diagnostic information is gathered as the previous SQL statement is executed. Some of the information available through the GET DIAGNOSTICS statement is also available in the SQLCA.

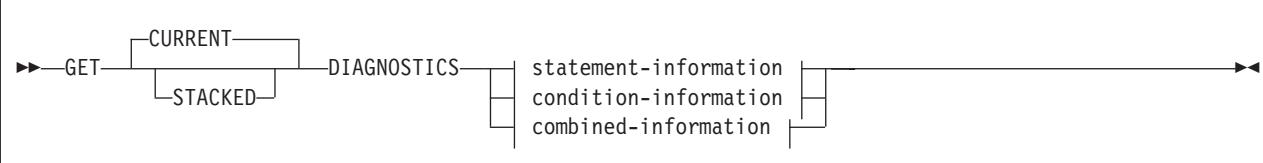

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

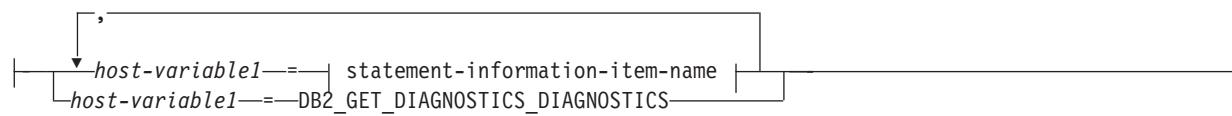

None required.

### Syntax

- 1 STATEMENT can only be specified once.
- 2 CONDITION and CONNECTION can only be specified once if host-variable5 or integer is not also specified.

## Description

Diagnostic information is provided in three main areas: statement information, condition information, and combined information. After the execution of an SQL statement, information about the execution of the statement is provided as statement information, and at least one instance of condition information is provided. The number of instances of the condition information is indicated by the NUMBER item that is available in the statement information. Combined information contains a text representation of all the information gathered about the execution of the SQL statement.

The diagnostic information that is provided is specific to the server. If you are connected to a server other than DB2 for z/OS, see that product's documentation for the diagnostic information that is returned.

**CURRENT**

Specifies that information is to be returned from the first diagnostics area. It corresponds to the previous SQL statement that was executed that was not a GET DIAGNOSTICS or compound statement. **CURRENT** is the default.

**STACKED**

Specifies that information is to be returned from the stacked diagnostics area. The stacked diagnostics area is only available within a handler in a native SQL procedure. The stacked diagnostics area corresponds to the previous SQL statement (that was not a GET DIAGNOSTICS or compound statement) that was executed before the handler was entered. If the GET DIAGNOSTICS statement is the first statement within a handler, the current diagnostics area and the stacked diagnostics area contain the same diagnostics information.

**statement-information**

Provides information about the last SQL statement executed.

**host-variable1**

Identifies a variable described in the program in accordance with the rules for declaring host variables. The data type of the host variable must be the data type as specified in Data types for GET DIAGNOSTICS items.

The host variable is assigned the value of the specified statement information item. If the value is truncated when assigning it to the host variable, a warning is returned and the GET\_DIAGNOSTICS\_DIAGNOSTICS item of the

diagnostics area is updated with the details of this condition. If a DIAGNOSTICS item is not set, then the host variable is set to a default value, based on its data type: 0 for an exact numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

#### **DB2\_GET\_DIAGNOSTICS\_DIAGNOSTICS**

Contains textual information about errors or warnings that might have occurred in the execution of the GET DIAGNOSTICS statement. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

*statement-information-item-name:*

#### **DB2\_LAST\_ROW**

For a multiple-row FETCH statement, contains a value of +100 if the last row currently in the table is in the set of rows that have been fetched. For cursors that are not sensitive to updates, there would be no need to do a subsequent FETCH, because the result would be an end-of-data indication. For cursors that are sensitive to updates, a subsequent FETCH may return more data if a row had been inserted before the FETCH was executed. For statements other than multiple-row FETCH statements, or for multiple-row FETCH statements that do not contain the last row, this variable contains the value 0.

An end of data warning might not occur and DB2\_LAST\_ROW might not contain +100 when the number of rows returned is equal to the number of rows requested and the last row of data returned is the last row of data.

#### **DB2\_NUMBER\_PARAMETER\_MARKERS**

For a PREPARE statement, contains the number of parameter markers in the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

#### **DB2\_NUMBER\_RESULT\_SETS**

For a CALL statement, contains the actual number of result sets returned by the procedure. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

#### **DB2\_NUMBER\_ROWS**

If the previous SQL statement was an OPEN or a FETCH that caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE DYNAMIC cursors, this value can be thought of as an approximation because rows that are inserted and deleted will affect the next retrieval of this value. If the previous SQL statement was a PREPARE statement, returns the estimated number of rows in the result table for the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

#### **DB2\_RETURN\_STATUS**

Identifies the status value returned from the stored procedure associated with the previously executed SQL statement, provided that the statement was a CALL statement that invoked a procedure that returns a status. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

#### **DB2\_SQL\_ATTR\_CURSOR\_HOLD**

For an ALLOCATE or OPEN statement, indicates whether a cursor can be held open across multiple units of work.

- N indicates that this cursor does not remain open across multiple units of work.

- Y indicates that this cursor remains open across multiple units of work.  
Otherwise, a blank is returned.

#### **DB2\_SQL\_ATTR\_CURSOR\_ROWSET**

For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be accessed using rowset positioning.

- N indicates that this cursor supports only row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.

Otherwise, a blank is returned.

#### **DB2\_SQL\_ATTR\_CURSOR\_SCROLLABLE**

For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be scrolled forward and backward.

- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.

Otherwise, a blank is returned.

#### **DB2\_SQL\_ATTR\_CURSOR\_SENSITIVITY**

For an ALLOCATE or OPEN statement, indicates whether or not a cursor does or does not show updates to cursor rows made by other connections.

- I indicates insensitive.
- S indicates sensitive.

Otherwise, a blank is returned.

#### **DB2\_SQL\_ATTR\_CURSOR\_TYPE**

For an ALLOCATE or OPEN statement, indicates the type of cursor, whether a cursor type is forward-only, static, or dynamic.

- F indicates a forward cursor.
- D indicates a dynamic cursor.
- S indicates a static cursor.

Otherwise, a blank is returned.

#### **MORE**

Indicates whether some of the warning and errors from the previous SQL statement were stored or discarded.

- N indicates that all the warnings and errors from the previous SQL statement are stored in the diagnostic area.
- Y indicates that some of the warnings and errors from the previous SQL statement were discarded because the amount of storage needed to record warnings and errors exceeded 65535 bytes.

#### **NUMBER**

Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL statement returned an SQLSTATE of 00000 or no previous SQL statement has been executed, the number returned is one.

The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2\_GET\_DIAGNOSTICS\_DIAGNOSTICS item.

**ROW\_COUNT**

Identifies the number of rows associated with the previous SQL statement that was executed.

If the previous SQL statement is a DELETE, INSERT, UPDATE, or MERGE statement, ROW\_COUNT indicates the number of rows that qualified to be deleted, inserted, or updated by that statement, excluding rows affected by either triggers or referential integrity constraints.

For the OPEN of a cursor for a SELECT with a data change statement, or a SELECT INTO statement, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled.

A value of -1 indicates a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria, or a truncate operation. If the delete was against a view, then neither the DELETE statement nor the definition of the view included selection criteria.

For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.

If the previous SQL statement is a multiple-row FETCH, ROW\_COUNT identifies the number of rows fetched.

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**condition-information**

Assigns the values of the specified condition information to the associated host variables. The host variable specified must be of the data type that is compatible with the data type of the specified diagnostic-ID or an error occurs. If the value of the condition is truncated when assigning it to the host variable, an error occurs. If an indicator variable was provided, the length of the value is returned in the indicator variable.

If a DIAGNOSTICS item is not set, then the host variable is set to a default value, based on the data type of the item. The specific value will be 0 for a numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

***host-variable2 or integer***

Identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic, and so on. If the value is 1, the diagnostic information that is retrieved corresponds to the condition that is indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The host variable specified must be an integer data type or an error occurs. An indicator variable is not allowed for this host variable. If a value is specified that is less than or equal to zero or greater than the number of available diagnostics, an error occurs.

***host-variable3***

Identifies a variable described in the program in accordance with the rules for declaring host variables. The data type of the host variable must be the data type as specified in Data types for GET DIAGNOSTICS items for the indicated condition-information item.

**condition-information-item-name****CATALOG\_NAME**

If the returned SQLSTATE is any one of the following values, the constraint that caused the error is a referential, check, or unique constraint. The location (RDB) name of the server that generated the condition is returned.

- Class 09 (Triggered Action Exception),
- Class 23 (Integrity Constraint Violation)
- Class 27 (Triggered Data Change Violation)
- 40002 (Transaction Rollback - Integrity Constraint Violation)
- 40004 (Transaction Rollback - Triggered Action Exception)

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned.

Otherwise, the empty string is returned.

The actual server name may be different than the server name specified, either implicitly or explicitly, on the CONNECT statement because of the use of aliases or synonyms.

**CONDITION\_NUMBER**

Returns the number of the diagnostic returned.

**CURSOR\_NAME**

If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

**DB2\_ERROR\_CODE1**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2\_ERROR\_CODE2**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2\_ERROR\_CODE3**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2\_ERROR\_CODE4**

Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

**DB2\_INTERNAL\_ERROR\_POINTER**

For some errors, this is a negative value that is an internal error pointer. Otherwise, the value 0 is returned.

**DB2\_LINE\_NUMBER**

Returns the line number where an error is encountered in parsing a dynamic statement. Also returns the line number where an error is encountered in parsing, binding, or executing a CREATE or ALTER statement for a native SQL procedure. DB2\_LINE\_NUMBER also returns the line number when a CALL statement invokes a native SQL procedure and the procedure returns with an error. This information is not returned for an external SQL procedure.

This value will only be meaningful if the statement source contains new line control characters.

**DB2\_MESSAGE\_ID**

Corresponds to the message that is contained in the MESSAGE\_TEXT diagnostic item (for example, DSNT102I or DSNU180I).

**DB2\_MODULE\_DETECTING\_ERROR**

Returns an identifier indicating which module detected the error. For a SIGNAL statement that is issued from a routine, the value 'ROUTINE' is returned. Otherwise, the string 'DSN' is returned.

**DB2\_ORDINAL\_TOKEN\_n**

Returns the *n*th token. *n* must be a value from 1 to 100. For example, DB2\_ORDINAL\_TOKEN\_1 would return the value of the first token, DB2\_ORDINAL\_TOKEN\_2 the second token, and so on. A numeric value for a token is converted to characters before being returned. If there is no value for the token, or if the server only returns an SQLCA, an empty string is returned.

**DB2\_REASON\_CODE**

Contains the reason code for errors that have a reason code token in the message text. Otherwise, the value zero is returned.

**DB2\_RETURNED\_SQLCODE**

Returns the SQLCODE for the specified diagnostic.

**DB2\_ROW\_NUMBER**

Returns the number of the row where the condition was encountered, when such information is available and applicable. If SQLCODE +1– or +20237 is returned, DB2\_ROW\_NUMBER returns a value of 0.

**DB2\_SQLERRD\_SET**

A value of Y indicates that the DB2\_SQLERRD1 through DB2\_SQLERRD items might be set. These items are set only when communicating with a server that returns the SQLCA SQL communications area and not the new diagnostics area. Otherwise, a blank is returned.

**DB2\_SQLERRD1**

Returns the value of sqlerrd(1) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_SQLERRD2**

Returns the value of sqlerrd(2) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_SQLERRD3**

Returns the value of sqlerrd(3) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_SQLERRD4**

Returns the value of sqlerrd(4) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_SQLERRD5**

Returns the value of sqlerrd(5) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_SQLERRD6**

Returns the value of sqlerrd(6) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2\_TOKEN\_COUNT**

Returns the number of tokens available for the specified diagnostic ID.

**MESSAGE\_TEXT**

Returns the message text that is associated with the SQLCODE. This is the short text, including substituted tokens. The message text does not contain the message number. When the SQLCODE is 0, the empty string is returned, even if the RETURNED\_SQLSTATE value indicates a warning condition.

**RETURNED\_SQLSTATE**

Returns the SQLSTATE for the specified diagnostic.

**SERVER\_NAME**

If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION statement, returns the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executes is returned.

**connection-information-item-name**

Provides information about the last SQL statement executed if it was a CONNECT statement.

**DB2\_AUTHENTICATION\_TYPE**

Contains an authentication type value of:

- 'S' for a server authentication
- 'C' for client authentication
- 'T' for trusted server authentication
- Otherwise, or if the server only returns an SQLCA, a blank is returned

**DB2\_AUTHORIZATION\_ID**

Authorization ID used by connected server. Because of user ID translation and authorization exits, the local user ID may not be the authorized ID used by the server.

**DB2\_CONNECTION\_STATE**

Contains the connection state:

- -1 if the connection is unconnected
- 1 if the connection is connected

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2\_CONNECTION\_STATUS**

Contains a value of:

- 1 if committable updates can be performed on the connection for this unit of work
- 2 if no committable updates can be performed on the connection for this unit of work

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2\_SERVER\_CLASS\_NAME**

For a CONNECT or SET CONNECTION statement, contains one of the following values:

- QAS for DB2 for iSeries
- QDB2 for DB2 for OS/390® and z/OS
- QDB2/2 for DB2 for OS/2
- QDB2/6000 for DB2 for AIX®
- QDB2/6000 PE for DB2 for AIX Parallel Edition

- QDB2/AIX64 for DB2 for AIX 64-bit
- QDB2/HPUX for DB2 for HP-UX
- QDB2/HP64 for DB2 for HP-UX 64-bit
- QDB2/LINUX for DB2 for Linux
- QDB2/LINUX390 for DB2 for Linux
- QDB2/LINUXIA64 for DB2 for Linux
- QDB2/LINUXPPC for DB2 for Linux
- QDB2/LINUXPPC64 for DB2 for Linux
- QDB2/LINUXZ64 for DB2 for Linux
- QDB2/NT for DB2 for NT
- QDB2/NT64 for DB2 for NT 64-bit
- QDB2/PTX for DB2 for NUMA-Q®
- QDB2/SCO for DB2 for SCO UnixWare
- QDB2/SGI for DB2 for Silicon Graphics
- QDB2/SNI for DB2 for Siemens Nixdorf
- QDB2/SUN for DB2 for SUN Solaris
- QDB2/SUN64 for DB2 for SUN Solaris 64-bit
- QDB2/Windows 95 for DB2 for Windows 95 or Windows 98
- QSQLDS/VM for DB2 for VM and VSE
- QSQLDS/VSE for DB2 for VM and VSE

Otherwise, the empty string is returned.

#### **DB2\_ENCRYPTION\_TYPE**

The level of encryption for the connection:

- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.
- Otherwise, a blank is returned.

#### **DB2\_PRODUCT\_ID**

Returns a product signature. If the application server is an IBM relational database product, the form is *pppvvrrm*, where:

- *ppp* identifies the product as follows:
  - ARI for DB2 Server for VSE & VM
  - DSN for DB2 for z/OS
  - QSQ for DB2 for i
  - SQL for all other DB2 products
- *vv* is a two-digit version identifier such as '09'
- *rr* is a two-digit release identifier such as '01'
- *m* is a one-digit maintenance level identifier such as '5' (Values 0, 1, 2, 3, and 4 are for maintenance levels in compatibility and enabling-new-function mode. Values 5, 6, 7, 8, and 9 are for maintenance levels in new-function mode.)

For example, if the application server is Version 9 of DB2 for z/OS in new-function mode with the latest maintenance, the value would be 'DSN09015'.

#### **combined-information**

Provides a text representation of all the information gathered about the execution of the SQL statement.

**ALL**

Indicates that all diagnostic items that are set for the last SQL statement executed are to be combined into one string. The format of the string is a semicolon separated list of all of the available diagnostic information in the form: <item-name>[(<condition-number>)]=<value-converted-to-character>... as shown in the following example:

```
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
```

*host-variable4*

Identifies a variable described in the program in accordance with the rules for declaring host variables. The data type of the host variable must be VARCHAR. If the length of *host-variable4* is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned, and the GET\_DIAGNOSTICS\_DIAGNOSITICS item of the diagnostics area is updated with the details of this condition.

**STATEMENT**

Indicates that all statement-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. The format is the same as described for the ALL option.

**CONDITION**

Indicates that all condition-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If *host-variable5* or integer is supplied after CONDITION, the format is the same as described above for the ALL option. If *host-variable5* or integer is not supplied, the format includes a condition number entry at the beginning of the information for that condition in the form:

CONDITION\_NUMBER=X;<item-name>=<value-converted-to-character>... where X is the number of the condition, as shown in the following example:

```
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED_SQLCODE=100;  
CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

**CONNECTION**

Indicates that all connection-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If *host-variable5* or integer is supplied after CONNECTION, the format is the same as described for the ALL option. If *host-variable5* or integer is not supplied, then the format includes a condition number entry at the beginning of the information for that condition in the form:

CONNECTION\_NUMBER=X;<item-name>=<value-converted-to-character>... where X is the number of the condition, as shown in the following example:

```
CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN08010;
```

*host-variable5 or integer*

Identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The host variable specified must be an integer data type or an error occurs. An indicator variable is not allowed for this host variable or an error occurs. If a value is specified that is less than or equal to zero or greater than the number of available diagnostics, an error occurs.

## Notes

*Effect of the statement in a native SQL procedure:* The GET DIAGNOSTICS statement does not change the contents of the diagnostics area (SQLCA), or the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables are declared in an SQL procedure, they will contain the same values as would be returned from issuing the GET DIAGNOSTICS statement specifying RETURNED\_SQLSTATE and DB2\_RETURNED\_SQLCODE.

If information is desired about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error condition.

If information is desired about a warning and a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first executable statement specified in that handler.

If information is desired about a warning and a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

*Data types for items:* When a diagnostic item is assigned to a host variable, SQL variable, or SQL parameter, the data type of the target must be compatible with the data type of the requested diagnostic item.

### Data types for GET DIAGNOSTICS items

Table 124. Data types for GET DIAGNOSTICS items

Type of information	Item	Data type
Statement Information	DB2_GET_DIAGNOSTICS_DIAGNOSTICS	VARCHAR(32672)
	DB2_LAST_ROW	INTEGER
	DB2_NUMBER_PARAMETER_MARKERS	INTEGER
	DB2_NUMBER_RESULT_SETS	INTEGER
	DB2_NUMBER_ROWS	DECIMAL(31,0)
	DB2_RETURN_STATUS	INTEGER
	DB2_SQL_ATTR_CURSOR_HOLD	CHAR(1)
	DB2_SQL_ATTR_CURSOR_ROWSET	CHAR(1)
	DB2_SQL_ATTR_CURSOR_SCROLLABLE	CHAR(1)
	DB2_SQL_ATTR_CURSOR_SENSITIVITY	CHAR(1)
	DB2_SQL_ATTR_CURSOR_TYPE	CHAR(1)
	MORE	CHAR(1)
	NUMBER	INTEGER
	ROW_COUNT	DECIMAL(31,0)

Table 124. Data types for GET DIAGNOSTICS items (continued)

Type of information	Item	Data type
Condition Information	CATALOG_NAME	VARCHAR(128)
	CONDITION_NUMBER	INTEGER
	CURSOR_NAME	VARCHAR(128)
	DB2_ERROR_CODE1	INTEGER
	DB2_ERROR_CODE2	INTEGER
	DB2_ERROR_CODE3	INTEGER
	DB2_ERROR_CODE4	INTEGER
	DB2_INTERNAL_ERROR_POINTER	INTEGER
	DB2_LINE_NUMBER	INTEGER
	DB2_MESSAGE_ID	CHAR(10)
	DB2_MODULE_DETECTING_ERROR	CHAR(8)
	DB2_ORDINAL_TOKEN_n	VARCHAR(515)
	DB2_REASON_CODE	INTEGER
	DB2_RETURNED_SQLCODE	INTEGER
	DB2_ROW_NUMBER	DECIMAL(31,0)
	DB2_TOKEN_COUNT	INTEGER
	MESSAGE_TEXT	VARCHAR(32672)
	RETURNED_SQLSTATE	CHAR(5)
	SERVER_NAME	VARCHAR(128)
Connection Information	DB2_AUTHENTICATION_TYPE	CHAR(1)
	DB2_AUTHORIZATION_ID	VARCHAR(128)
	DB2_CONNECTION_STATE	INTEGER
	DB2_CONNECTION_STATUS	INTEGER
	DB2_ENCRYPTION_TYPE	CHAR(1)
	DB2_PRODUCT_ID	VARCHAR(8)
	DB2_SERVER_CLASS_NAME	CHAR(128)
Combined Information	ALL	VARCHAR(32672)

**DRDA considerations** The GET DIAGNOSTICS statement is supported from a current DB2 for z/OS client, regardless of the level of the server (a DB2 for z/OS Version 7 or a DB2 for Windows Version 7, for example). When the application is connected to servers that do not support the Open Group Version 3 DRDA standard, the diagnostic information that is returned by the servers is available in the condition information.

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- RETURN\_STATUS as a synonym for DB2\_RETURN\_STATUS
- EXCEPTION as a synonym for CONDITION

## Examples

*Example 1:* In an application, use the GET DIAGNOSTICS statement to determine how many rows were updated.

```
long rcount;
EXEC SQL UPDATE T1 SET C1 = C1 + 1;
EXEC SQL GET DIAGNOSTICS :rcount = ROW_COUNT;
```

After execution of this code segment, rcount will contain the number of rows that were updated.

*Example 2:* In an application, use the GET DIAGNOSTICS statement to handle multiple SQL Errors.

```
long numerrors, counter;
char rtsqlstate[5];
long hva[5];
EXEC SQL INSERT INTO T1 FOR 5 ROWS VALUES (:hva) NOT ATOMIC
    CONTINUE ON SQLEXCEPTION;
EXEC SQL GET DIAGNOSTICS :numerrors = NUMBER;
for ( i=1;i < numerrors;i++)
{
    EXEC SQL GET DIAGNOSTICS CONDITION :i :rtsqlstate = RETURNED_SQLSTATE;
```

Execution of this code segment sets and prints rtsqlstate with the SQLSTATE for each error that was encountered in the previous SQL statement.

*Example 3:* Retrieve information about a connection.

```
EXEC SQL GET DIAGNOSTICS :HV_PRODUCT_ID = DB2_PRODUCT_ID;
```

*Example 4:* Use the GET DIAGNOSTICS statement to retrieve information that is similar to what is returned in the SQLCA:

```
EXEC SQL GET DIAGNOSTICS CONDITION 1
    :dasqlcode    = DB2_RETURNED_SQLCODE,
    :datokencnt   = DB2_TOKEN_COUNT,
    :datoken1     = DB2_ORDINAL_TOKEN_1,
    :datoken2     = DB2_ORDINAL_TOKEN_2,
    :datoken3     = DB2_ORDINAL_TOKEN_3,
    :datoken4     = DB2_ORDINAL_TOKEN_4,
    :datoken5     = DB2_ORDINAL_TOKEN_5,
    :dasqlerrd1b = DB2_MESSAGE_ID,
    :damsgtext    = MESSAGE_TEXT,
    :dasqlerrp    = DB2_MODULE_DETECTING_ERROR,
    :dasqlstate   = RETURNED_SQLSTATE;
```

*Example 5:* Specify the **STACKED** keyword on a GET DIAGNOSTICS statement that is used within a handler to access information in the diagnostics area that caused the handler to be activated:

```
CREATE PROCEDURE divide2 ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER,
                           OUT divide_error VARCHAR(70))
LANGUAGE SQL
BEGIN
    DECLARE msg_text      CHAR(70) DEFAULT '';
    DECLARE divide_error  CHAR(70) DEFAULT '';
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
```

```
BEGIN
    INSERT .....;    -- insert row into a log table

    -- get diagnostic information for the INSERT statement
    GET CURRENT DIAGNOSTICS CONDITION 1 msg_text = MESSAGE_TEXT;

    -- get information about condition that activated the handler
    GET STACKED DIAGNOSTICS CONDITION 1 divide_error = MESSAGE_TEXT;
END;

SET divide_result = numerator/denominator;
```

The first GET DIAGNOSTICS statement obtains diagnostic information about the INSERT statement.

The second GET DIAGNOSTICS statement specifies the STACKED keyword. The use of the STACKED keyword allows access the stacked diagnostics area which contains the diagnostic information for the condition that caused the handler to be activated. The information about the original condition is still accessible within the handler even after another statement has been issued, such as the INSERT statement in the example.

---

## GRANT

The DB2 GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Distinct type
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Use

The applicable objects are always at the current server. The grants are recorded in the current server's catalog.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

If the authorization mechanism was not activated when the DB2 subsystem was installed, an error condition occurs.

### Authorization

To grant a privilege P, the privilege set must include one of the following:

- The privilege P WITH GRANT OPTION
- Ownership of the object on which P is a privilege
- SYSADM authority

The presence of SYSCTRL authority in the privilege set allows the granting of all authorities except:

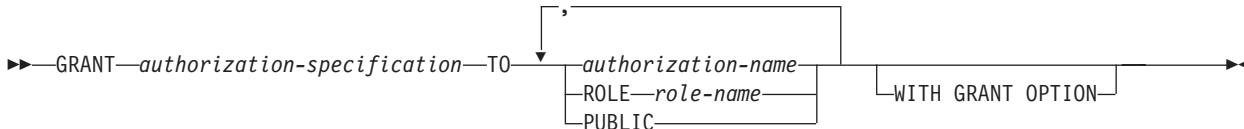

- DBADM on databases
- DELETE, INSERT, SELECT, and UPDATE on user tables or views
- EXECUTE on plans, packages, functions, or stored procedures
- PACKADM on collections
- SYSADM authority
- USAGE on distinct types, JARs, and sequences

Except for views, the GRANT option for privileges on a table is also inherent in DBADM authority for its database, provided DBADM authority was acquired with the GRANT option. See "CREATE VIEW" on page 1184 for a description of the rules that apply to views.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. The owner can be a

role. If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER CLAUSE, the privilege set is the privileges that are held by the role in effect.

## Syntax

## Description

### *authorization-specification*

Specifies one or more privileges for the class of privilege. The same privilege must not be specified more than once.

**TO** Specifies to what authorization IDs the privileges are granted.

### *authorization-name*,...

Lists one or more authorization IDs.

### **ROLE** *role-name*

Lists one or more role names. Each name must identify a role that exists at the current server.

The value of the CURRENT RULES special register determines whether you can use the ID or role of the GRANT statement itself (to grant privileges to yourself). When CURRENT RULES is:

**DB2** You cannot use the ID or role of the GRANT statement.

### **STD**

You can use the ID or role of the GRANT statement.

### **PUBLIC**

Grants the privileges to all users at the current server, including database requesters using DRDA access.

### **WITH GRANT OPTION**

Allows the named users to grant the privileges to others. Granting an administrative authority with this option allows the user to specifically grant any privilege belonging to that authority. If you omit WITH GRANT OPTION, the named users cannot grant the privileges to others unless they have that authority from some other source.

GRANT authority cannot be passed to PUBLIC. When WITH GRANT OPTION is used with PUBLIC, a warning is issued, and the named privileges are granted, but without GRANT authority.

## Notes

For more on DB2 privileges, read *DB2 Administration Guide*.

A *grant* is the granting of a specific privilege by a specific grantor to a specific grantee. The grantor for a given GRANT statement is the authorization ID for the

privilege set; that is, the SQL authorization ID of the process or a role, or the authorization ID of the owner of the plan or package. Grant statements that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the grantor being the role that is in effect. If the statement is prepared dynamically, the grantor is the role that is associated with the ID that is running the statement. If the statement is embedded in an application program that was bound in a trusted context that was defined with the ROLE AS OBJECT OWNER clause the owner of the plan or package is a role which is the grantor. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the grantor is the authorization ID of the process.

The grantee, as recorded in the catalog, is an authorization ID or PUBLIC.

Duplicate grants from the same grantor are not recorded in the catalog. Otherwise, the result of executing a GRANT statement is recorded as one or more grants in the current server's catalog.

If more than one privilege or *authorization-name* is specified after the TO keyword and one of the grants is in error, execution of the statement is stopped and no grants are made. The status of the privilege or privileges granted is recorded in the catalog for each *authorization-name*.

Different grantors can grant the same privilege to a single grantee. The grantee retains that privilege as long as one or more of those grants are recorded in the catalog. Privileges that imply other privileges are also termed *authorities*. Grants are removed from the catalog by executing SQL REVOKE statements.

Whenever a grant is made for a database, distinct type, package, plan, schema, stored procedure, table, trigger, user-defined function, view, or USE privilege for an object that does not exist, an SQL return code is issued and the grant is not made.

**PUBLIC AT ALL LOCATIONS:** PUBLIC AT ALL LOCATIONS can continue to be specified as an alternative to PUBLIC as in prior releases. PUBLIC AT ALL LOCATIONS specifies that the privileges are to be granted to all users in the network. The PUBLIC AT ALL LOCATIONS clause applies to table privileges only, excluding ALTER, INDEX, REFERENCES, and TRIGGER.

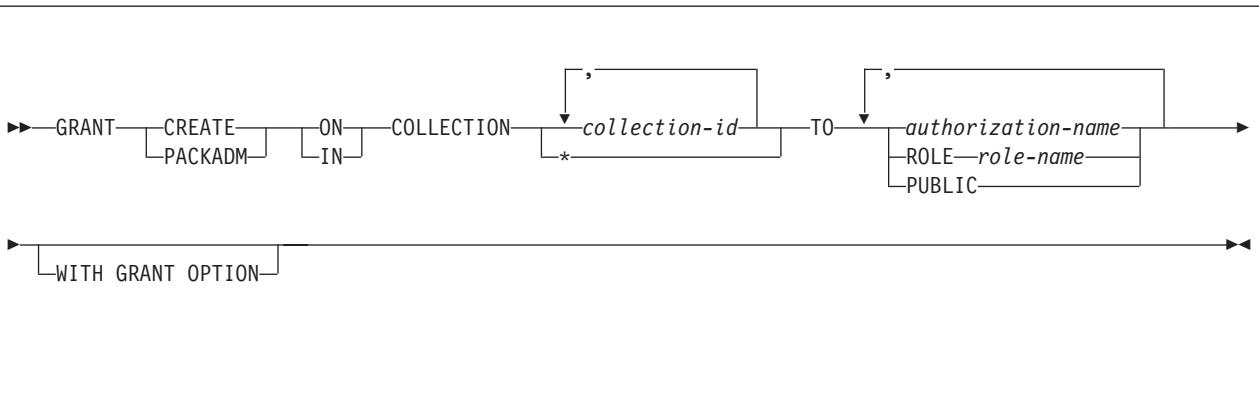

PUBLIC AT ALL LOCATIONS applies to DB2 private protocol access only.

The grantee, as recorded in the catalog for PUBLIC AT ALL LOCATIONS is PUBLIC\*.

## GRANT (collection privileges)

This form of the GRANT statement grants privileges on collections.

### Syntax

### Description

#### CREATE IN

Grants the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

#### PACKADM ON

Grants package administrator authority for the designated collections.

The word IN can be used instead of ON.

#### COLLECTION *collection-id*,...

Identifies the collections on which the specified privilege is granted. The collections do not have to exist.

#### COLLECTION \*

Indicates that the specified privilege is granted on all collections including those that do not currently exist.

#### TO

Refer to "GRANT" on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to "GRANT" on page 1333 for a description of the WITH GRANT OPTION clause.

### Examples

*Example 1:* Grant the privilege to create new packages in collections QAACLONE and DSN8CC61 to CLARK.

```
GRANT CREATE IN COLLECTION QAACLONE, DSN8CC61 TO CLARK;
```

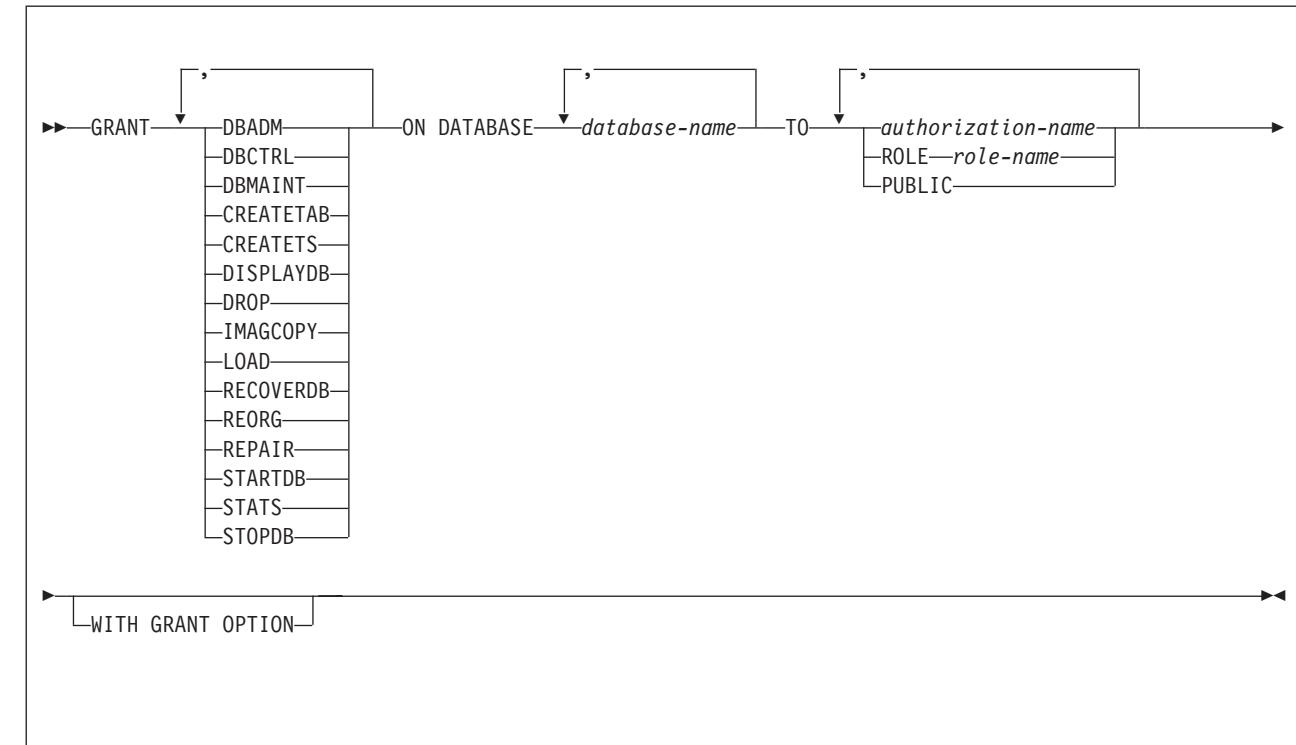

*Example 2:* Grant the privileges to create new packages in collection DSN8CC91 to role ROLE1:

```
GRANT CREATE IN COLLECTION DSN8CC91 TO ROLE ROLE1;
```

## GRANT (database privileges)

This form of the GRANT statement grants privileges on databases.

### Syntax

### Description

Each keyword listed grants the privilege described, but only as it applies to or within the databases named in the statement.

#### DBADM

Grants the database administrator authority.

#### DBCTRL

Grants the database control authority.

#### DBMAINT

Grants the database maintenance authority.

#### CREATETAB

Grants the privilege to create new tables. To create tables in an implicitly created database, CREATETAB privileges are needed on the DSNDB04 database. For a work file database, PUBLIC implicitly has the CREATETAB privilege (without GRANT authority) to define declared temporary tables; this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

#### CREATESTS

Grants the privilege to create new table spaces.

#### DISPLAYDB

Grants the privilege to issue the DISPLAY DATABASE command.

**DROP**

Grants the privilege to issue the DROP or ALTER DATABASE statements for the designated databases.

**IMAGCOPY**

Grants the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

**LOAD**

Grants the privilege to use the LOAD utility to load tables.

**RECOVERDB**

Grants the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

**REORG**

Grants the privilege to use the REORG utility to reorganize table spaces and indexes.

**REPAIR**

Grants the privilege to use the REPAIR and DIAGNOSE utilities.

**STARTDB**

Grants the privilege to issue the START DATABASE command.

**STATS**

Grants the privilege to use the RUNSTATS utility to update statistics, the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

**STOPDB**

Grants the privilege to issue the STOP DATABASE command.

**ON DATABASE *database-name*,...**

Identifies databases on which privileges are to be granted. For each named database, the grantor must have all the specified privileges with the GRANT option. Each name must identify a database that exists at the current server. DSNDB01 must not be identified; however, a grant of a privilege on DSNDB06 implies the granting of the same privilege on DSNDB01 for utility operations only.

Database privileges granted on DSNDB04 are applicable to all implicitly created databases. This means that a user with the STOPDB privilege on DSNDB04 can also stop database objects in any implicitly created database. Similarly, having DBADM on DSNDB04 allows access to all tables in all implicitly created databases. However, having a database privilege on DSNDB04 does not allow granting of this privilege on an implicitly created database to others.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

## Examples

*Example 1:* Grant drop privileges on database DSN8D91A to user PEREZ.

```
GRANT DROP  
ON DATABASE DSN8D91A  
TO PEREZ;
```

*Example 2:* Grant repair privileges on database DSN8D91A to all local users.

```
GRANT REPAIR  
ON DATABASE DSN8D91A  
TO PUBLIC;
```

*Example 3:* Grant authority to create new tables and load tables in database DSN8D91A to users WALKER, PIANKA, and FUJIMOTO, and give them grant privileges.

```
GRANT CREATETAB,LOAD  
ON DATABASE DSN8D91A  
TO WALKER,PIANKA,FUJIMOTO  
WITH GRANT OPTION;
```

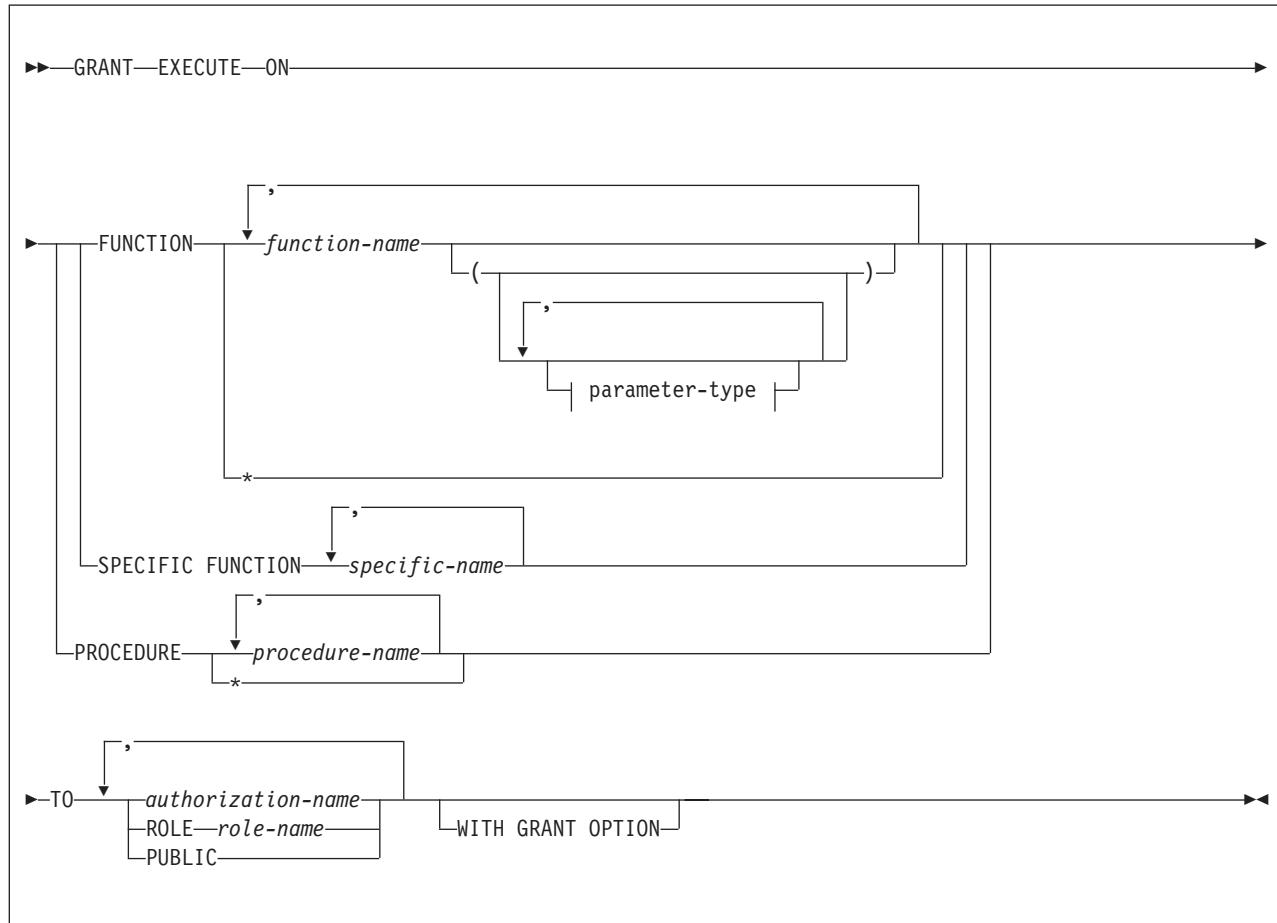

*Example 4:* Grant load privileges to database DSN9D91A to role ROLE1:

```
GRANT LOAD  
ON DATABASE DSN9D91A  
TO ROLE ROLE1;
```

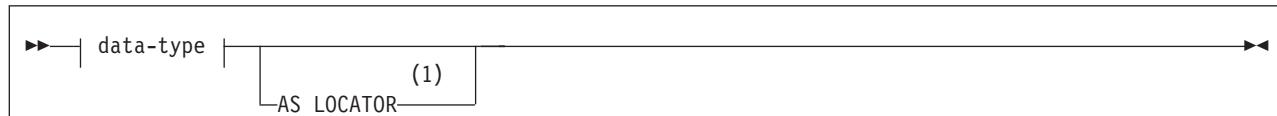

## **GRANT (function or procedure privileges)**

This form of the GRANT statement grants privileges on user-defined functions, cast functions that are generated for distinct types, and stored procedures.

## Syntax

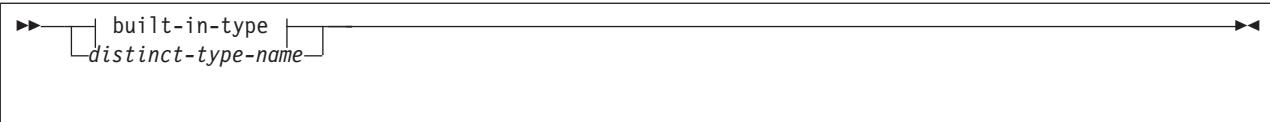

## parameter-type:

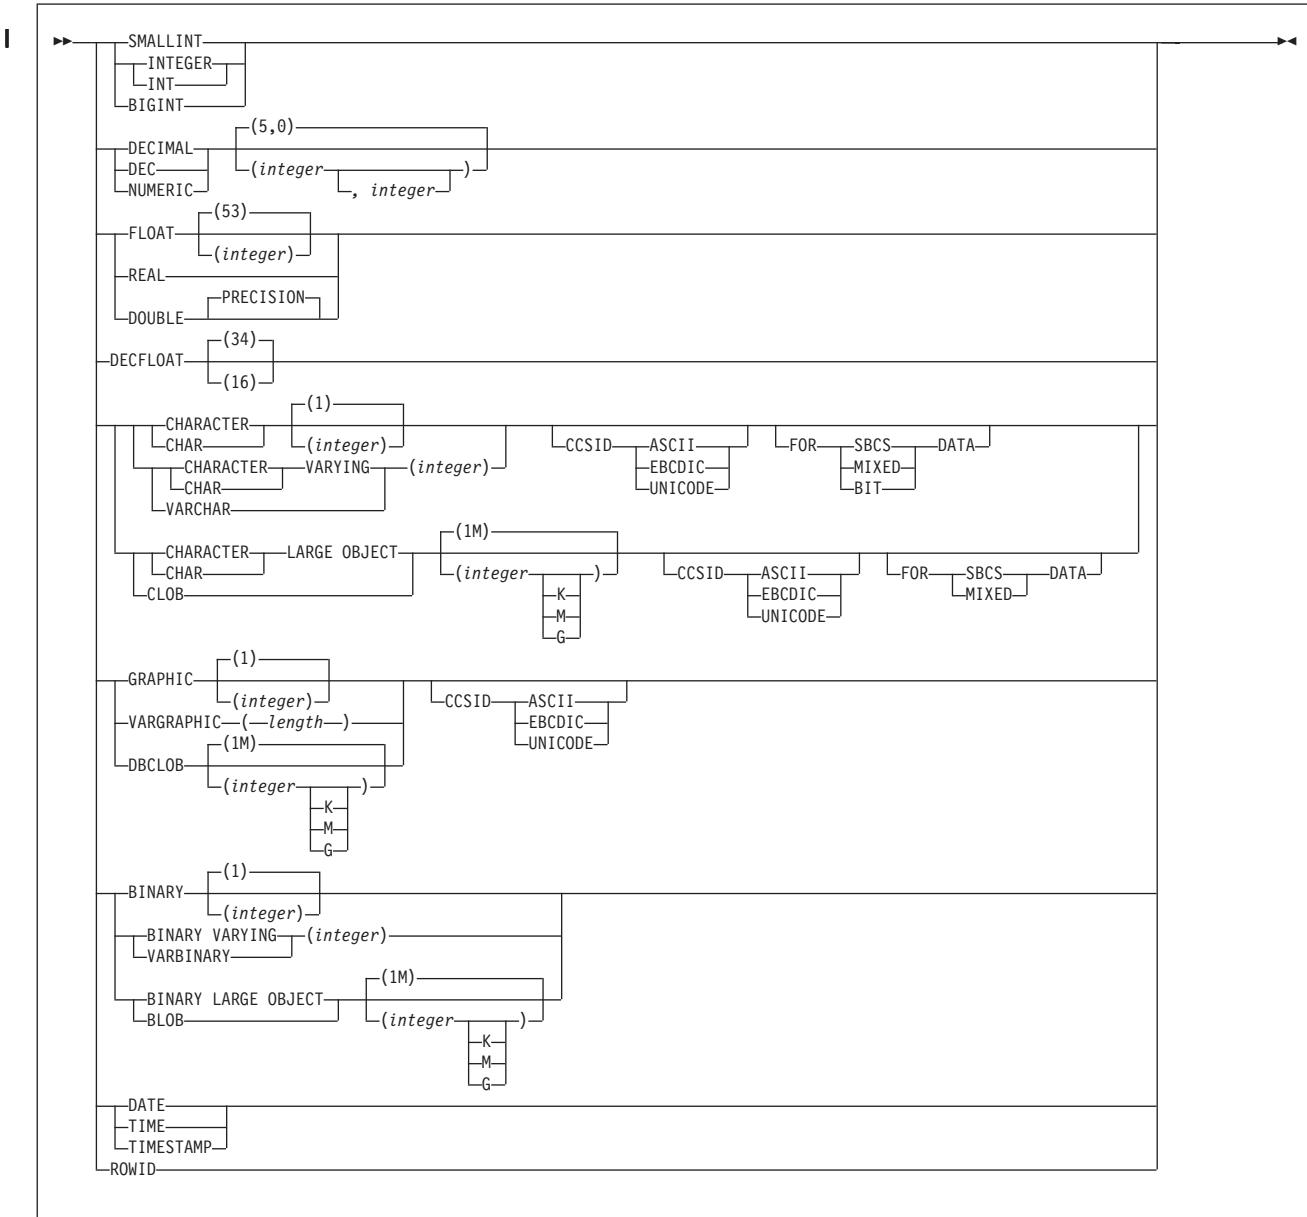

## Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.

**data-type:**

**built-in-type:**

## Description

### EXECUTE

Grants the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

### FUNCTION or SPECIFIC FUNCTION

Identifies the function on which the privilege is granted. The function must exist at the current server, and it must be a function that was defined with the

CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

**FUNCTION** *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An \* can be specified for a qualified or unqualified *function-name*. An \* (or *schema-name.\**) indicates that the privilege is granted on all the functions in the schema including those that do not currently exist. SYSADM authority is required if an \* (or *schema-name.\**) is specified. Specifying an \* does not affect any EXECUTE privileges that are already granted on a function.

**FUNCTION** *function-name* (*parameter-type*,...)

Identifies the function by its function signature, which uniquely identifies the function. The *function-name* (*parameter-type*, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name* () is specified, the function identified must have zero parameters.

*function-name*

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

(*parameter-type*,...)

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly, DECFLOAT() will be considered a match for DECFLOAT(16) or

| DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional.

Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

#### **AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

#### **SPECIFIC FUNCTION *specific-name***

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

#### **PROCEDURE *procedure-name***

Identifies a stored procedure that is defined at the current server. The name, including the implicit or explicit schema name, must identify a stored procedure that exists at the current server.

An \* can be specified for a qualified or unqualified *procedure-name*. An \* (or *schema-name.\**) indicates that the privilege is granted on all the stored procedures in the schema including those that do not currently exist. Specifying an \* does not affect any EXECUTE privileges that are already granted on a stored procedure.

**T0** Refer to “GRANT” on page 1333 for a description of the TO clause.

#### **WITH GRANT OPTION**

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

## **Examples**

*Example 1:* Grant the EXECUTE privilege on function CALC\_SALARY to user JONES. Assume that there is only one function in the schema with function name CALC\_SALARY.

```
GRANT EXECUTE ON FUNCTION CALC_SALARY TO JONES;
```

*Example 2:* Grant the EXECUTE privilege on procedure VACATION\_ACCR to all users at the current server.

```
GRANT EXECUTE ON PROCEDURE VACATION_ACCR TO PUBLIC;
```

*Example 3:* Grant the EXECUTE privilege on function DEPT\_TOTALS to the administrative assistant and give the assistant the ability to grant the EXECUTE privilege on this function to others. The function has the specific name DEPT85\_TOT. Assume that the schema has more than one function that is named DEPT\_TOTALS.

```
GRANT EXECUTE ON SPECIFIC FUNCTION DEPT85_TOT TO ADMIN_A  
WITH GRANT OPTION;
```

*Example 4:* Grant the EXECUTE privilege on function NEW\_DEPT\_HIRES to HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW\_DEPT\_HIRES.

```
GRANT EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))  
TO HR;
```

You can also code the CHAR(10) data type as CHAR().

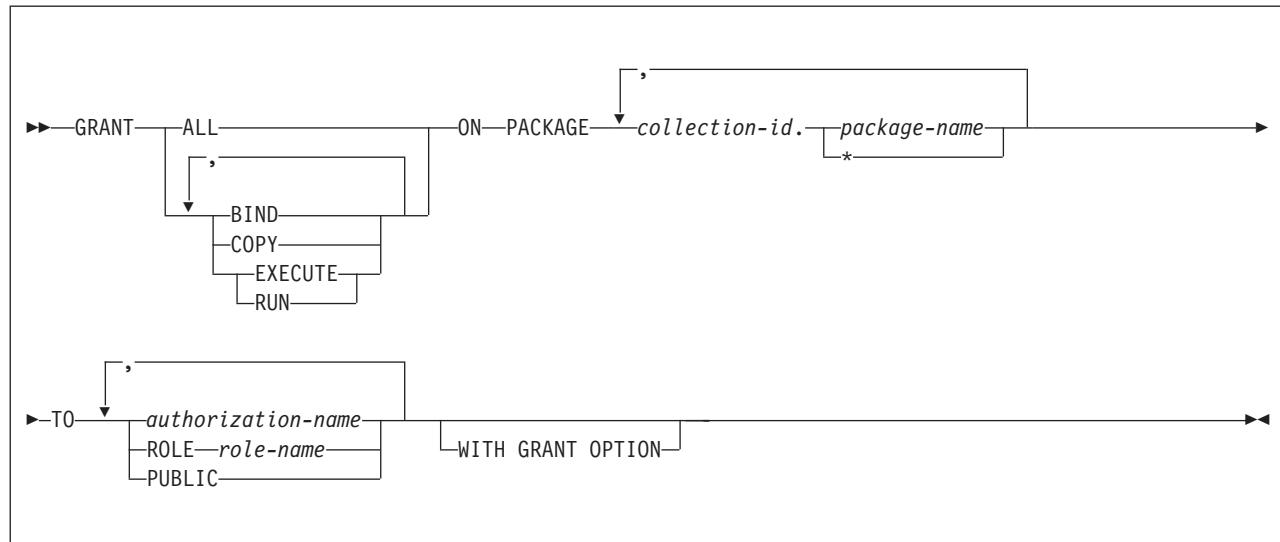

*Example 5:* Grant the EXECUTE privilege on function FIND\_EMPDEPT to role ROLE1:

```
GRANT EXECUTE ON FUNCTION FIND_EMPDEPT TO ROLE ROLE1;
```

## GRANT (package privileges)

This form of the GRANT statement grants privileges on packages.

### Syntax

### Description

#### BIND

Grants the privilege to use the BIND and REBIND subcommands for the designated packages.

The BIND package privilege can also be used to allow a user to add a new version of an existing package. For details on the authorization required to create new packages and new versions of existing packages, see "Notes" on page 1346.

#### COPY

Grants the privilege to use the COPY option of the BIND subcommand for the designated packages.

#### EXECUTE

Grants the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

#### ALL

Grants all package privileges for which you have GRANT authority for the packages named in the ON clause.

#### ON PACKAGE *collection-id.package-name*,...

Identifies packages for which you are granting privileges. The granting of a package privilege applies to all versions of a package. The list can simultaneously contain items of the following two forms:

- *collection-id.package-name* explicitly identifies a single package. The name must identify a package that exists at the current server.
- *collection-id.\** applies to every package in the indicated collection. This includes packages that currently exist and future packages. The grant applies

to a collection at the current server, but the *collection-id* does not have to identify a collection that exists when the grant is made.

To grant a privilege in this form requires PACKADM with the WITH GRANT OPTION over the collection or all collections, SYSADM, or SYSCTRL authority. Because of this fact, WITH GRANT OPTION, if included in the statement, is ignored for grants of this form, but not for grants for specific packages.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

#### **WITH GRANT OPTION**

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

### **Notes**

The authorization required to add a new package or a new version of an existing package depends on the value of field BIND NEW PACKAGE on installation panel DSNTIPP. The default value is BINDADD.

If the value of BIND NEW PACKAGE is BINDADD, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

If the value of BIND NEW PACKAGE is BIND, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority
- PACKADM authority for the collection or for all collections
- Users with the BIND package privilege can also add a new version of an existing package

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports specifying PROGRAM as a synonym for PACKAGE.

### **Examples**

*Example 1:* Grant the privilege to copy all packages in collection DSN8CC61 to LEWIS.

```
GRANT COPY ON PACKAGE DSN8CC61.* TO LEWIS;
```

*Example 2:* You have the BIND privilege with GRANT authority over the package CLCT1.PKG1. You have the EXECUTE privilege with GRANT authority over the package CLCT2.PKG2. You have no other privileges with GRANT authority over any package in the collections CLCT1 AND CLCT2. Hence, the following statement, when executed by you, grants LEWIS the BIND privilege on CLCT1.PKG1 and the EXECUTE privilege on CLCT2.PKG2, and makes no other grant. The privileges granted include no GRANT authority.

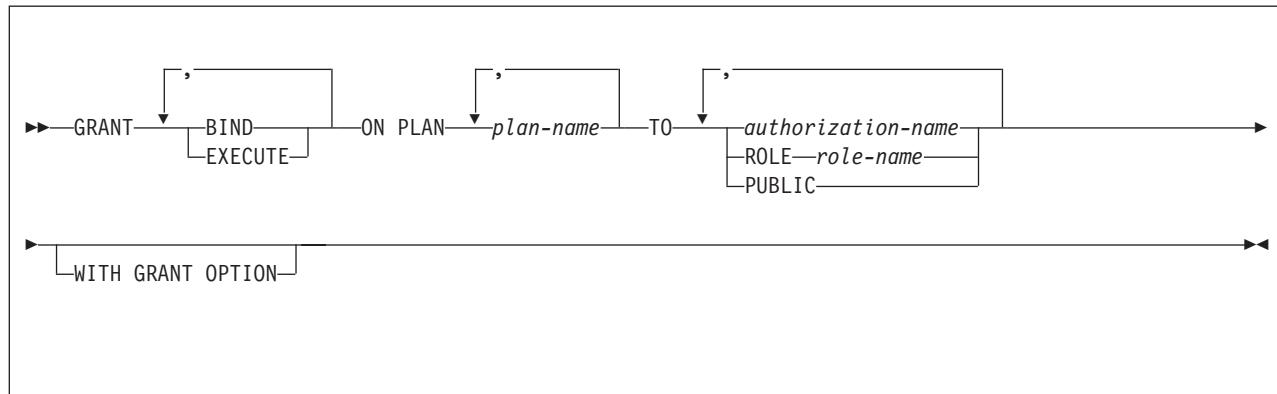

```
GRANT ALL ON PACKAGE CLCT1.PKG1, CLCT2.PKG2 TO JONES;
```

|     *Example 3:* Grant the privileges to run all packages in collection DSN9CC13 to role  
|     ROLE1:  
|     GRANT EXECUTE ON PACKAGE DSN9CC13.\* TO ROLE ROLE1;  
|

## GRANT (plan privileges)

This form of the GRANT statement grants privileges on plans.

### Syntax

### Description

#### BIND

Grants the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans. (The authority to create new plans using BIND ADD is a system privilege.)

#### EXECUTE

Grants the privilege to run programs that use the identified plans.

#### ON PLAN *plan-name*,...

Identifies the application plans on which the privileges are granted. For each identified plan, you must have all specified privileges with the GRANT option.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

### Examples

*Example 1:* Grant the privilege to bind plan DSN8IP91 to user JONES.

```
GRANT BIND ON PLAN DSN8IP91 TO JONES;
```

*Example 2:* Grant privileges to bind and execute plan DSN8CP91 to all users at the current server.

```
GRANT BIND,EXECUTE ON PLAN DSN8CP91 TO PUBLIC;
```

*Example 3:* Grant the privilege to execute plan DSN8CP91 to users ADAMSON and BROWN with grant option.

```
GRANT EXECUTE ON PLAN DSN8CP91 TO ADAMSON,BROWN WITH GRANT OPTION;
```

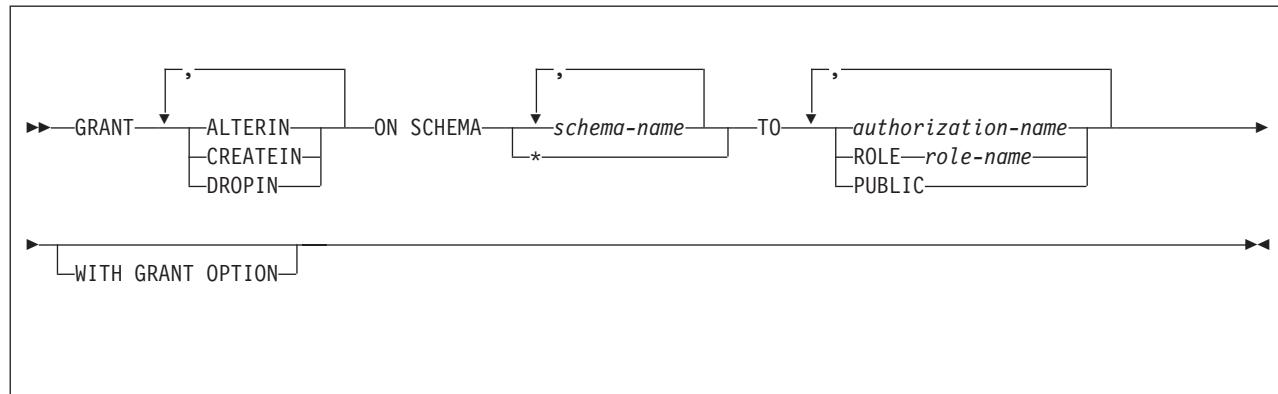

*Example 4:* Grant the privileges to bind the DSN91PLN plan to role ROLE1:

```
GRANT BIND ON PLAN DSN91PLN TO ROLE ROLE1;
```

## GRANT (schema privileges)

This form of the GRANT statement grants privileges on schemas.

### Syntax

### Description

#### ALTERIN

Grants the privilege to alter stored procedures and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### CREATEIN

Grants the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### DROPIN

Grants the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### SCHEMA *schema-name*

Identifies the schemas on which the privilege is granted. The schemas do not need to exist when the privilege is granted.

#### SCHEMA \*

Indicates that the specified privilege is granted on all schemas including those that do not currently exist.

**TO** Refer to "GRANT" on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to "GRANT" on page 1333 for a description of the WITH GRANT OPTION clause.

### Examples

*Example 1:* Grant the CREATEIN privilege on schema T\_SCORES to user JONES.

```
GRANT CREATEIN ON SCHEMA T_SCORES TO JONES;
```

*Example 2:* Grant the CREATEIN privilege on schema VAC to all users at the current server.

```
GRANT CREATEIN ON SCHEMA VAC TO PUBLIC;
```

*Example 3:* Grant the ALTERIN privilege on schema DEPT to the administrative assistant and give the grantee the ability to grant ALTERIN privileges on this schema to others.

```
GRANT ALTERIN ON SCHEMA DEPT TO ADMIN_A  
    WITH GRANT OPTION;
```

*Example 4:* Grant the CREATEIN, ALTERIN, and DROPIN privileges on schemas NEW\_HIRE, PROMO, and RESIGN to HR (Human Resources).

```
GRANT CREATEIN, ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN TO HR;
```

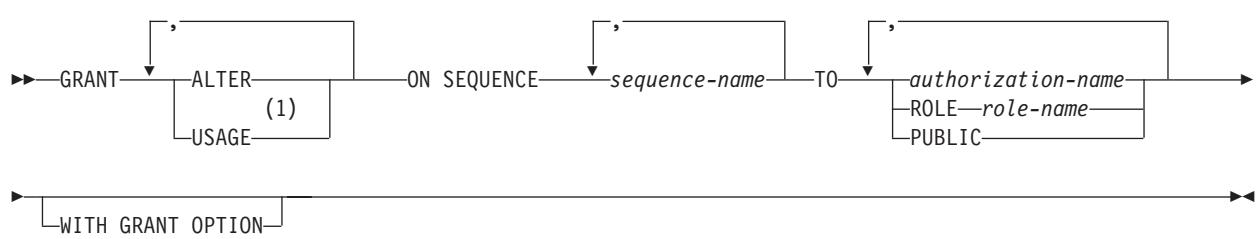

*Example 5:* Grant the ALTERIN privileges on the EMPLOYEE schema to role ROLE1:

```
GRANT ALTERIN ON SCHEMA EMPLOYEE TO ROLE ROLE1;
```

## GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a user-defined sequence.

### Syntax

#### Notes:

- 1 The keyword SELECT is an alternative keyword for USAGE.

### Description

#### ALTER

Grants the privilege to alter a sequence or record a comment on a sequence.

#### USAGE

Grants the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

#### SEQUENCE *sequence-name*

Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. *sequence-name* must not be the name of an internal sequence object that is used by DB2.

**TO** Refer to "GRANT" on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to "GRANT" on page 1333 for a description of the WITH GRANT OPTION clause.

### Examples

*Example 1:* Grant USAGE privilege on sequence MYNUM to user JONES.

```
GRANT USAGE  
  ON SEQUENCE MYNUM  
  TO JONES;
```

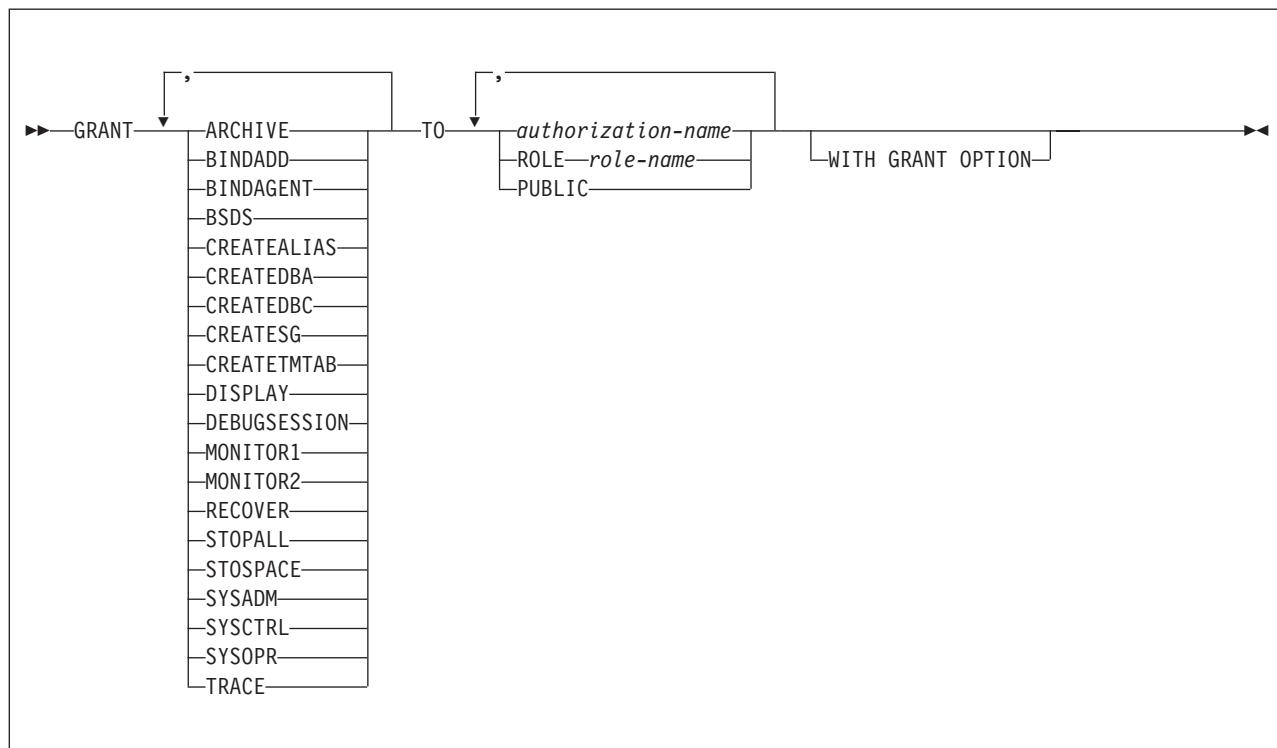

*Example 2:* Grant USAGE privileges on sequence ORDER\_SEQ to role ROLE1:

```
GRANT USAGE ON SEQUENCE ORDER_SEQ TO ROLE ROLE1;
```

## GRANT (system privileges)

This form of the GRANT statement grants system privileges.

### Syntax

### Description

#### ARCHIVE

Grants the privilege to use the ARCHIVE LOG and SET LOG commands.

#### BINDADD

Grants the privilege to create plans and packages by using the BIND subcommand with the ADD option.

#### BINDAGENT

Grants the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A warning is issued if WITH GRANT OPTION is specified when granting this privilege.

#### BSDS

Grants the privilege to issue the RECOVER BSDS command.

#### CREATEALIAS

Grants the privilege to use the CREATE ALIAS statement.

#### CREATEDBA

Grants the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

**CREATEDBC**

Grants the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

**CREATESTG**

Grants the privilege to create new storage groups.

**CREATETEMPTAB**

Grants the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

**DISPLAY**

Grants the privilege to use the following commands:

- The DISPLAY ARCHIVE command for archive log information
- The DISPLAY BUFFERPOOL command for the status of buffer pools
- The DISPLAY DATABASE command for the status of all databases
- The DISPLAY LOCATION command for statistics about threads with a distributed relationship
- The DISPLAY LOG command for log information, including the status of the offload task
- The DISPLAY THREAD command for information on active threads within DB2
- The DISPLAY TRACE command for a list of active traces

**DEBUGSESSION**

Grants the privilege to attach a debug client to the current application process connection, which enables client application debugging of native SQL or Java procedures that are executed within the session.

**MONITOR1**

Grants the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

**MONITOR2**

Grants the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. Users with MONITOR2 privileges have MONITOR1 privileges.

**RECOVER**

Grants the privilege to issue the RECOVER INDOUBT command.

**STOPALL**

Grants the privilege to issue the STOP DB2 command.

**STOSPACE**

Grants the privilege to use the STOSPACE utility.

**SYSADM**

Grants all DB2 privileges except for a few reserved for installation SYSADM authority. The privileges the user possesses are all grantable, including the SYSADM authority itself. The privileges the user lacks restrict what the user can do with the directory and the catalog. Using WITH GRANT OPTION when granting SYSADM is redundant but valid. For more on SYSADM and install SYSADM authority, see *DB2 Administration Guide*.

**SYSCTRL**

Grants the system control authority, which allows the user to have most of the privileges of a system administrator but excludes the privileges to read or

change user data. Using WITH GRANT OPTION when granting SYSCTRL is redundant but valid. For more information on SYSCTRL authority, see *DB2 Administration Guide*.

#### **SYSOPR**

Grants the privilege to have system operator authority.

#### **TRACE**

Grants the privilege to issue the MODIFY TRACE, START TRACE, and STOP TRACE commands.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

#### **WITH GRANT OPTION**

If you grant the SYSADM or SYSCTRL system privilege, WITH GRANT OPTION is valid but unnecessary. It is unnecessary because whoever is granted SYSADM or SYSCTRL has that authority and all the privileges it implies, with the GRANT option.

### **Examples**

*Example 1:* Grant DISPLAY privileges to user LUTZ.

```
GRANT DISPLAY  
  TO LUTZ;
```

*Example 2:* Grant BSDS and RECOVER privileges to users PARKER and SETRIGHT, with the WITH GRANT OPTION.

```
GRANT BSDS,RECOVER  
  TO PARKER,SETRIGHT  
  WITH GRANT OPTION;
```

*Example 3:* Grant TRACE privileges to all local users.

```
GRANT TRACE  
  TO PUBLIC;
```

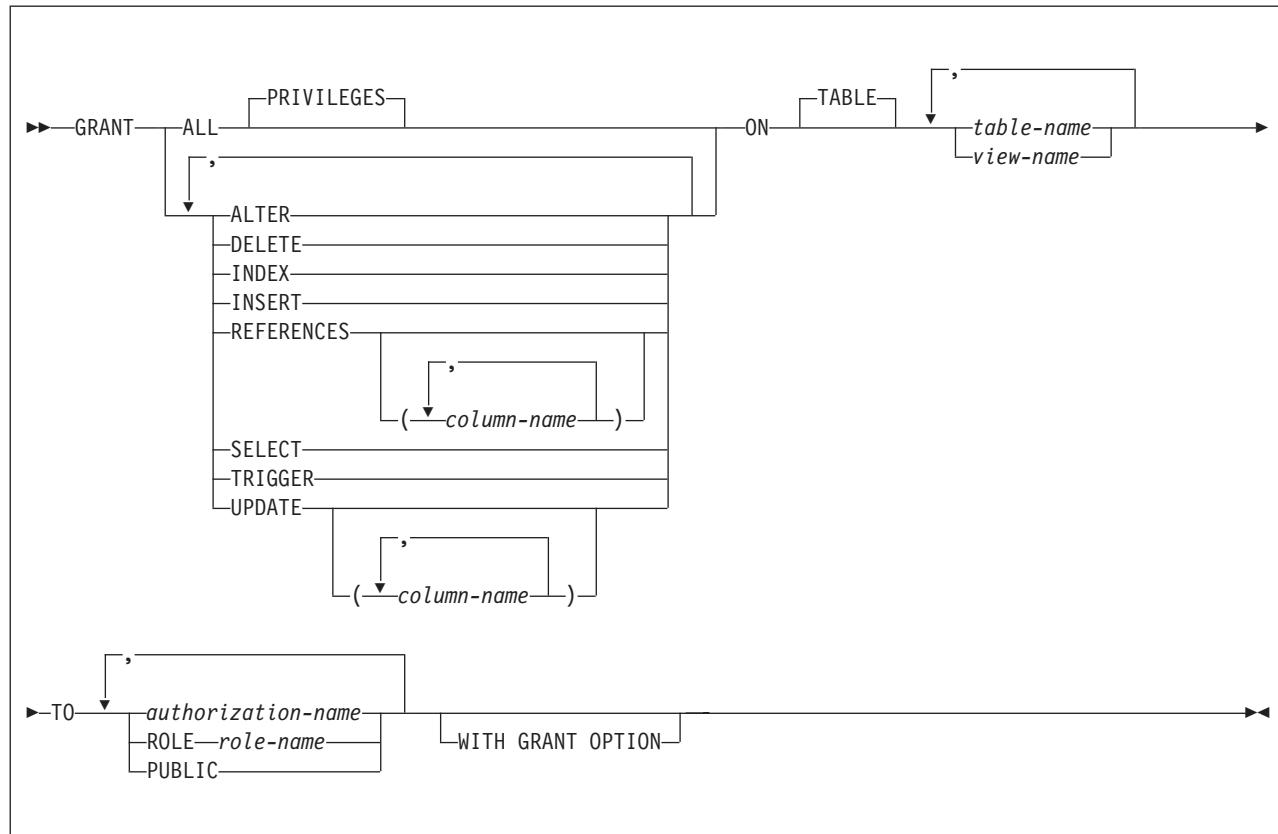

*Example 4:* Grant ARCHIVE privileges to role ROLE1:

```
GRANT ARCHIVE TO ROLE ROLE1;
```

## GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables and views.

### Syntax

### Description

#### ALL or ALL PRIVILEGES

Grants all table or view privileges for which you have GRANT authority, for the tables and views named in the ON clause.

If you do not use ALL, you must use one or more of the keywords in the following list. For each keyword that you use, you must have GRANT authority for that privilege on every table or view identified in the ON clause.

#### ALTER

Grants the privilege to alter the specified table or create a trigger on the specified table. ALTER cannot be used if the statement identifies an auxiliary table or a view.

#### DELETE

Grants the privilege to delete rows in the specified table or view. DELETE cannot be granted on an auxiliary table.

#### INDEX

Grants the privilege to create an index on the specified table. INDEX cannot be granted on a view.

**INSERT**

Grants the privilege to insert rows into the specified table or view. INSERT cannot be granted on an auxiliary table.

**REFERENCES**

Grants the privilege to add a referential constraint in which the specified table is a parent. If a list of column names is not specified or if REFERENCES is granted via the specification of ALL PRIVILEGES, the grantee can define referential constraints using all columns of the table as a parent key, even those added later via the ALTER TABLE statement. This privilege cannot be granted on a view or auxiliary table.

**REFERENCES(*column-name*,...)**

Grants the privilege to add or drop a referential constraint in which the specified table is a parent using only those columns that are specified in the column list as a parent key. Each *column-name* must be an unqualified name that identifies a column of the table identified in the ON clause. This privilege cannot be granted on a view or auxiliary table.

**SELECT**

Grants the privilege to create a view or read data from the specified table or view. SELECT cannot be granted on an auxiliary table.

**TRIGGER**

Grants the privilege to create a trigger on the specified table. TRIGGER cannot be granted on an auxiliary table or a view.

**UPDATE**

Grants the privilege to update rows in the specified table or view. UPDATE cannot be granted on an auxiliary table.

**UPDATE(*column-name*,...)**

Grants the privilege to update only the columns named. Each *column-name* must be the unqualified name of a column of every table or view identified in the ON clause. Each *column-name* must not identify a column of an auxiliary table.

**ON *table-name* or *view-name***

Specifies the tables or views on which you are granting the privileges. The list can be a list of table names or view names, or a combination of the two. A declared temporary table and a table that is implicitly created for an XML column must not be identified.

If you use GRANT ALL, then for each named table or view, the privilege set (described in “Authorization” on page 1333 in “GRANT” on page 1333) must include at least one privilege with the GRANT option.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

**WITH GRANT OPTION**

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

**Notes**

The REFERENCES privilege does not replace the ALTER privilege. It was added to conform to the SQL standard. To define a foreign key that references a parent table, you must have either the REFERENCES or the ALTER privilege, or both.

For a created temporary table or a view of a created temporary table, only ALL or ALL PRIVILEGES can be granted. Specific table or view privileges cannot be granted. In addition, only the ALTER, DELETE, INSERT, and SELECT privileges apply to a created temporary table.

To grant table privileges on a created temporary table, the privilege set must include one of the following:

- SYSADM
- DBADM on DSNDB06
- Ownership of the created temporary table

To grant table privileges on a view of a created temporary table, the privilege set must include one of the following:

- SYSADM
- ownership of the created temporary table

For a declared temporary table, no privileges can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the DB2 catalog, and they cannot be revoked.

For an auxiliary table, only the INDEX privilege can be granted. DELETE, INSERT, SELECT, and UPDATE privileges on the base table that is associated with the auxiliary table extend to the auxiliary table.

|  
| **PUBLIC AT ALL LOCATIONS:** PUBLIC AT ALL LOCATIONS can be specified as  
| an alternative to PUBLIC. PUBLIC AT ALL LOCATIONS is intended for use only  
| with DB2 private protocol access.  
|

The following privileges cannot be granted to PUBLIC AT ALL LOCATIONS:

- ALTER
- INDEX
- REFERENCES
- TRIGGER

In addition, ALL or ALL PRIVILEGES does not include ALTER, INDEX, REFERENCES, or TRIGGER privileges for a grant to PUBLIC AT ALL LOCATIONS.

## Examples

*Example 1:* Grant SELECT privileges on table DSN8910.EMP to user PULASKI.

```
GRANT SELECT ON DSN8910.EMP TO PULASKI;
```

*Example 2:* Grant UPDATE privileges on columns EMPNO and WORKDEPT in table DSN8910.EMP to all users at the current server.

```
GRANT UPDATE (EMPNO,WORKDEPT) ON TABLE DSN8910.EMP TO PUBLIC;
```

*Example 3:* Grant all privileges on table DSN8910.EMP to users KWAN and THOMPSON, with the WITH GRANT OPTION.

```
GRANT ALL ON TABLE DSN8910.EMP TO KWAN,THOMPSON WITH GRANT OPTION;
```

*Example 4:* Grant the SELECT and UPDATE privileges on the table DSN8910.DEPT to every user in the network.

```
GRANT SELECT, UPDATE ON TABLE DSN8910.DEPT  
TO PUBLIC;
```

Even with this grant, it is possible that some network users do not have access to the table at all, or to any other object at the subsystem where the table exists.

Controlling access to the subsystem involves the communications databases at the subsystems in the network. The tables for the communication databases are described in “DB2 catalog tables” on page 1677. Controlling access is described in *DB2 Administration Guide*.

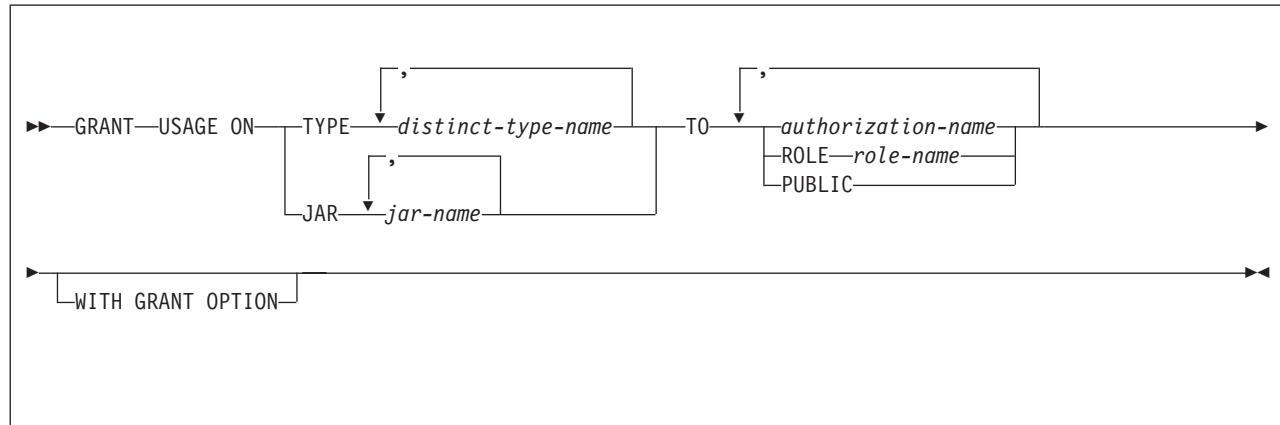

| *Example 5:* Grant ALTER privileges on table DSN9910.EMP to role ROLE1:

```
GRANT ALTER ON TABLE DSN9910.EMP TO ROLE ROLE1;
```

## GRANT (type or JAR file privileges)

This form of the GRANT statement grants the privilege to use distinct types (user-defined data types) or JAR files.

### Syntax

### Description

#### USAGE

Grants the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

#### TYPE *distinct-type-name*

Identifies the distinct type. The name, including the implicit or explicit schema name, must identify a unique distinct type that exists at the current server.

#### JAR *jar-name*

Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

#### TO

Refer to "GRANT" on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to "GRANT" on page 1333 for a description of the WITH GRANT OPTION clause.

### Notes

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

### Examples

**Example 1:** Grant the USAGE privilege on distinct type SHOE\_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE\_SIZE.

```
GRANT USAGE ON TYPE SHOE_SIZE TO JONES;
```

**Example 2:** Grant the USAGE privilege on distinct type US\_DOLLAR to all users at the current server.

```
GRANT USAGE ON TYPE US_DOLLAR TO PUBLIC;
```

*Example 3:* Grant the USAGE privilege on distinct type CANADIAN\_DOLLAR to the administrative assistant (ADMIN\_A), and give this user the ability to grant the USAGE privilege on the distinct type to others. The administrative assistant cannot grant the privilege to execute the cast functions that are associated with the distinct type CANADIAN\_DOLLAR because WITH GRANT OPTION does not give the administrative assistant the EXECUTE authority on these cast functions.

```
GRANT USAGE ON TYPE CANADIAN_DOLLAR TO ADMIN_A  
    WITH GRANT OPTION;
```

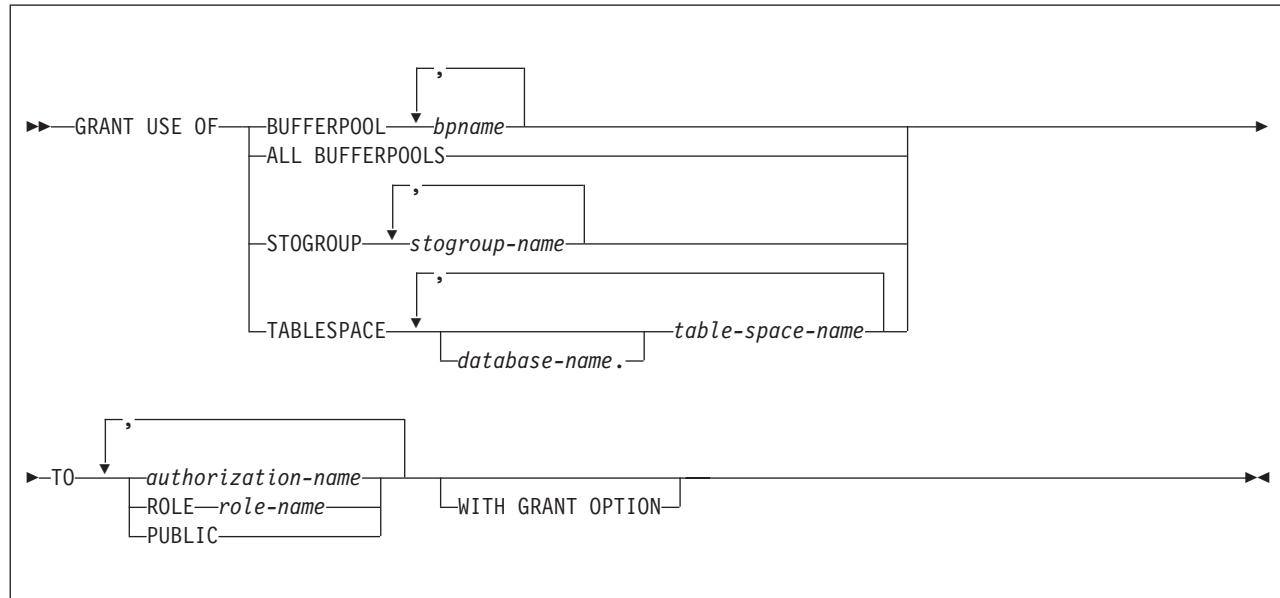

*Example 4:* Grant the USAGE privilege on the distinct type MILES to role ROLE1 at the current server:

```
GRANT USAGE ON TYPE MILES  
    TO ROLE ROLE1;
```

## GRANT (use privileges)

This form of the GRANT statement grants authority to use particular buffer pools, storage groups, or table spaces.

### Syntax

### Description

#### BUFFERPOOL *bpname*,...

Grants the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See “Naming conventions” on page 51 for more details about *bpname*.

#### ALL BUFFERPOOLS

Grants the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

#### STOGROUP *stogroup-name*,...

Grants the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

#### TABLESPACE *database-name.table-space-name*,...

Grants the privilege to refer to any of the identified table spaces in a CREATE TABLE statement. The default for *database-name* is DSNDB04.

You cannot grant the privilege for table spaces that are for declared temporary tables (table spaces in a work file database). For these table spaces, PUBLIC implicitly has the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**TO** Refer to “GRANT” on page 1333 for a description of the TO clause.

#### WITH GRANT OPTION

Refer to “GRANT” on page 1333 for a description of the WITH GRANT OPTION clause.

## Notes

You can grant privileges for only one type of object with each statement. Thus, you can grant the use of several table spaces with one statement, but not the use of a table space and a storage group. For each object you identify, you must have the USE privilege with GRANT authority.

## Examples

*Example 1:* Grant authority to use buffer pools BP1 and BP2 to user MARINO.

```
GRANT USE OF BUFFERPOOL BP1,BP2  
TO MARINO;
```

*Example 2:* Grant to all local users the authority to use table space DSN8S91D in database DSN8D91A.

```
GRANT USE OF TABLESPACE  
DSN8D91A.DSN8S91D  
TO PUBLIC;
```

*Example 3:* Grant authority to use storage group SG1 to role ROLE1:

```
GRANT USE OF STOGROUP SG1  
TO ROLE ROLE1;
```

## HOLD LOCATOR

The HOLD LOCATOR statement allows a LOB locator variable to retain its association with a value beyond a unit of work.

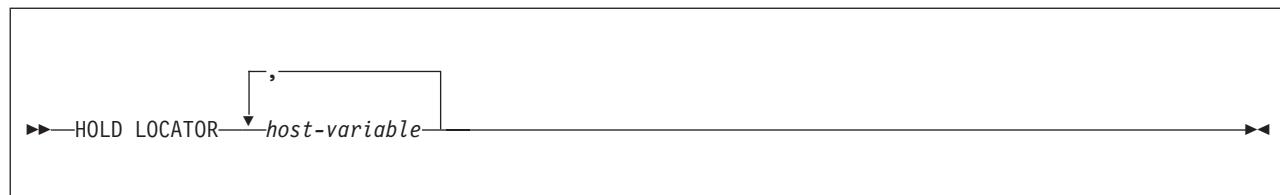

### Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement.

### Authorization

None required.

### Syntax

### Description

*host-variable*, ...

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been held and others have not been held.

### Notes

A host-variable LOB locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement is executed.
- The SQL session is terminated.

### Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the

values represented by the columns. Give the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC the hold property.

```
EXEC SQL HOLD LOCATOR :LOCRES, :LOCHIST, :LOCPIC
```

## INCLUDE

The INCLUDE statement inserts application code, including declarations and statements, into a source program.

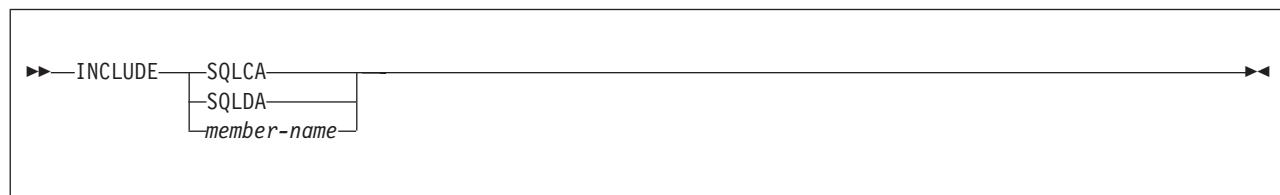

### Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

### Authorization

None required.

### Syntax

### Description

#### SQLCA

Indicates that the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified more than once in the same application program. In COBOL, INCLUDE SQLCA must be specified in the Working-Storage Section or the Linkage Section. INCLUDE SQLCA must not be specified if the program is precompiled with the STDSQL(YES) option.

For a description of the SQLCA, see “SQL communication area (SQLCA)” on page 1646.

#### SQLDA

Indicates that the description of an SQL descriptor area (SQLDA) is to be included. It must not be specified in a Fortran. For a description of the SQLDA, see “SQL descriptor area (SQLDA)” on page 1656.

#### member-name

NAMES a member of the partitioned data set to be the library input when your application program is precompiled. It must be an SQL identifier.

The member can contain any host language source statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE *member-name* must not be specified in other than the Data Division or the Procedure Division.

### Notes

When your application program is precompiled, the INCLUDE statement is replaced by source statements. Thus, the INCLUDE statement must be specified at a point in your application program where the resulting source statements are acceptable to the compiler.

The INCLUDE statement cannot refer to source statements that themselves contain INCLUDE statements.

The declarations that are generated by DCLGEN can be used in an application program by specifying the same member in the INCLUDE statement as in the DCLGEN LIBRARY parameter.

### **Example**

Include an SQL communications area in a PL/I program.

```
EXEC SQL INCLUDE SQLCA;
```

## INSERT

The INSERT statement inserts rows into a table or view or activates the INSTEAD OF INSERT trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Inserting a row into a view inserts the row into the table on which the view is based if no INSTEAD OF INSERT trigger is defined on the specified view. If an INSTEAD OF INSERT trigger is defined, the trigger is activated instead of the INSERT statement.

There are three forms of this statement:

- The INSERT via VALUES form is used to insert a single row into the table or view using the values provided or referenced.
- The INSERT via SELECT form is used to insert one or more rows into the table or view using values from other tables, or views, or both.
- The INSERT via FOR *n* ROWS form is used to insert multiple rows into the table or view using values provided or referenced. Although not required, the values can come from *host-variable arrays*. This form of INSERT is supported in SQL procedure applications. However, since host-variable arrays are not supported in SQL procedure applications, the support is limited to insertion of scalar values.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which inserts are allowed, or a view:

*When a user-defined table is identified:* The privilege set must include at least one of the following:

- The INSERT privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

*When a catalog table is identified:* The privilege set must include at least one of the following:

- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

*When a view is identified:* The privilege set must include at least one of the following:

- The INSERT privilege on the view
- SYSADM authority

The owner of a view, unlike the owner of a table, might not have INSERT authority on the view (or can have INSERT authority without being able to grant it

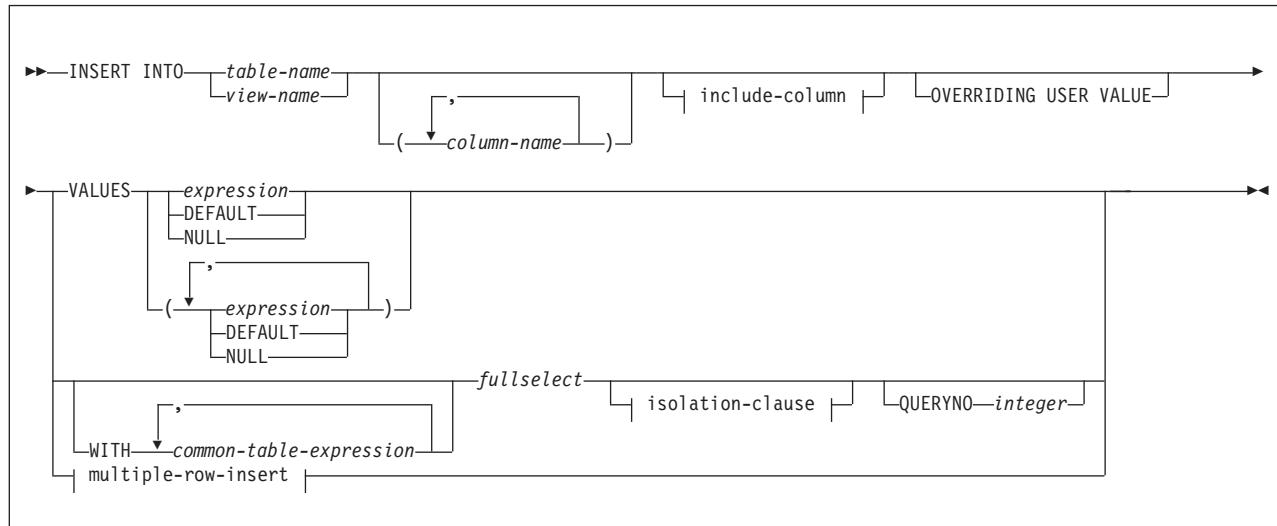

to others). The nature of the view itself can preclude its use for INSERT. For more information, see the discussion of authority in “CREATE VIEW” on page 1184.

If the INSERT statement is embedded in a SELECT statement, the privilege set must include the SELECT privilege on the table or view.

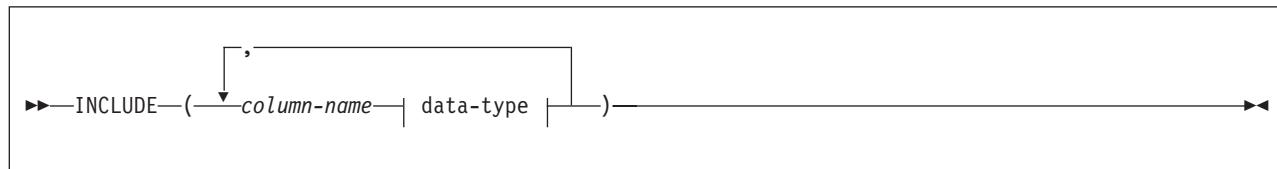

If a fullselect is specified, the privilege set must include authority to execute the fullselect. For more information about the authorization rules, see “Authorization” on page 630.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

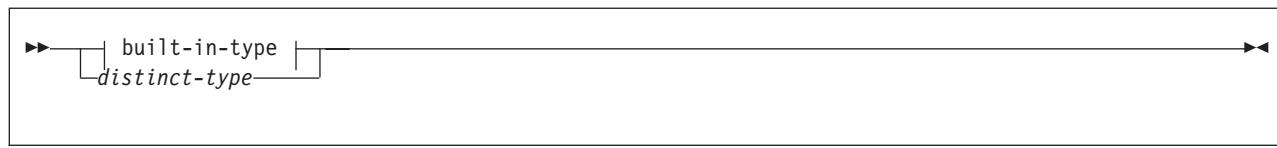

## Syntax

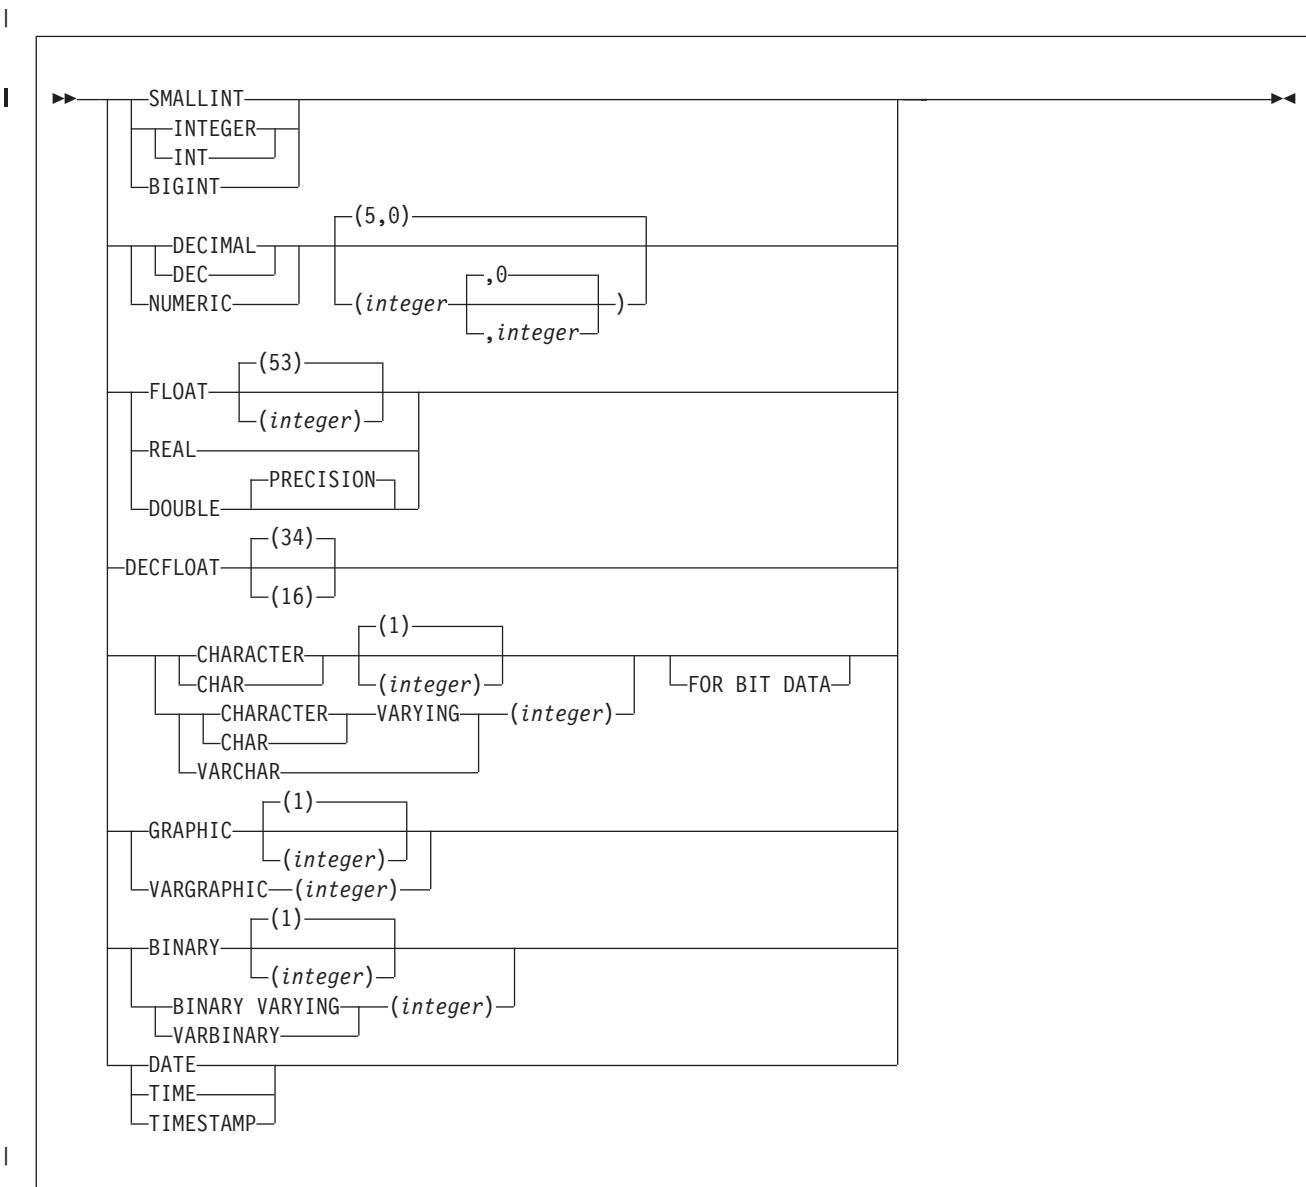

**include-column:**

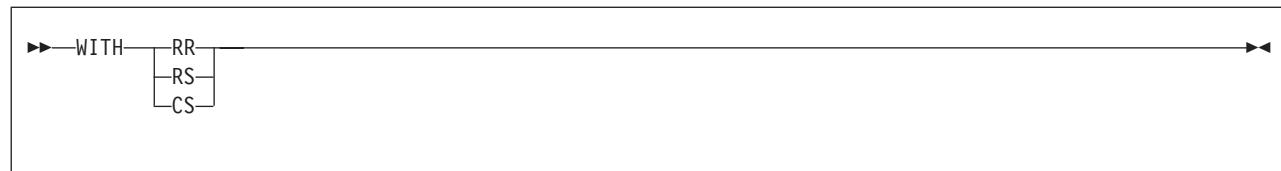

**data-type:**

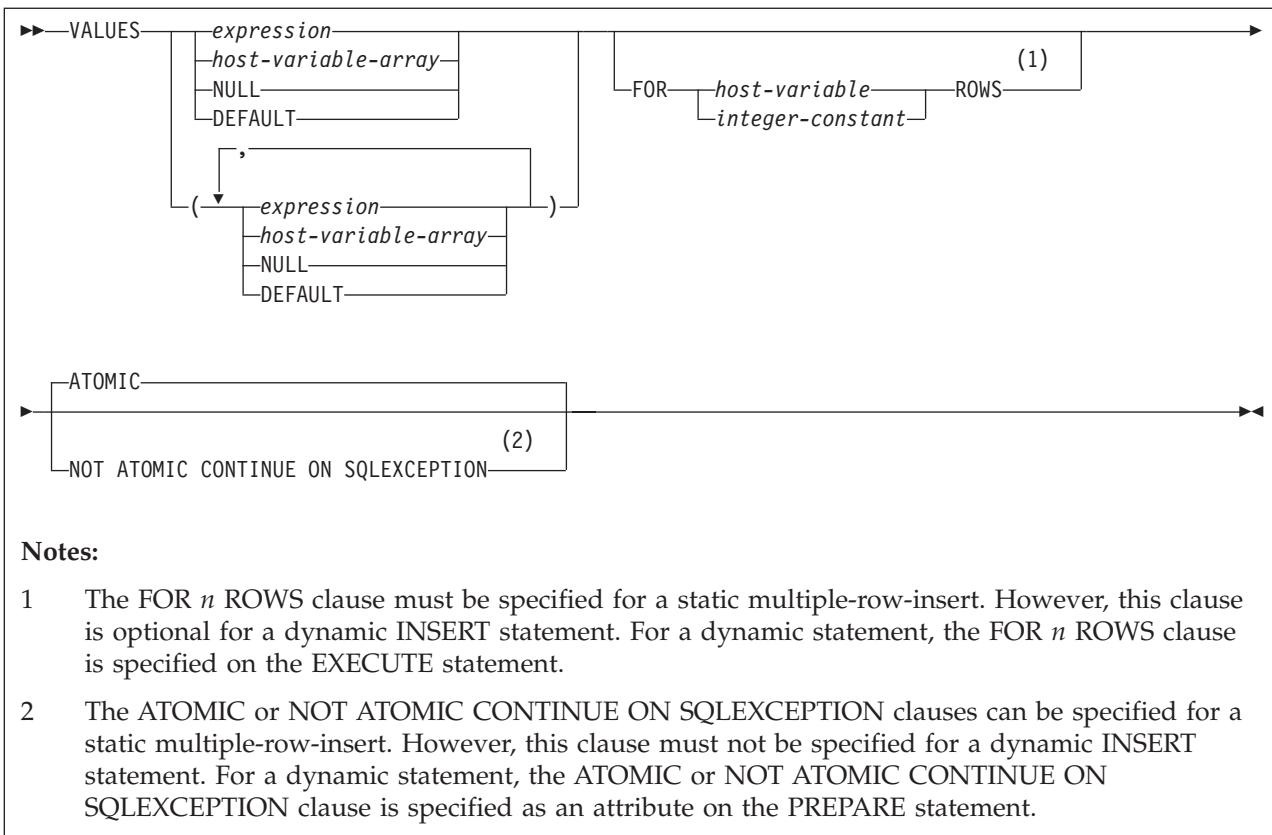

| **built-in-type:**

| **isolation-clause:**

| **multiple-row-insert:**

#### Notes:

- 1 The FOR *n* ROWS clause must be specified for a static multiple-row-insert. However, this clause is optional for a dynamic INSERT statement. For a dynamic statement, the FOR *n* ROWS clause is specified on the EXECUTE statement.
- 2 The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clauses can be specified for a static multiple-row-insert. However, this clause must not be specified for a dynamic INSERT statement. For a dynamic statement, the ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is specified as an attribute on the PREPARE statement.

## Description

**INTO** *table-name or view-name*

Identifies the object of the INSERT statement. The name must identify a table or view that exists at the current server. The name must not identify:

- An auxiliary table
- A catalog table
- A read-only view unless an instead of trigger is defined for the insert operation on the view. (For a description of a read-only view, see "CREATE VIEW" on page 1184.)
- A view column that is derived from a constant, expression, or scalar function
- A view column that is derived from the base table column as some other column of the view
- A materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

*column-name,...*

Specifies the columns for which insert values are provided. Each name must identify a column of the table or view. The columns can be identified in any order, but the same column must not be identified more than one time. A view column that cannot accept insert values must not be identified. If the object of the INSERT statement is a view with such columns, a list of column names must be specified, and the list must not identify these columns. If a qualifier is specified, it must be valid (that is, the table name must be the table or view

name specified after the INTO keyword, and if a qualifier is specified for the table name, it must match the default qualifier).

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

The effect of a rebind on INSERT statements that do not include a column list is that the implicit list of names is re-established. Therefore, the number of columns into which data is inserted can change and cause an error.

#### *include-column*

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the INSERT statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*.

#### **INCLUDE**

Introduces a list of columns that is to be included in the result table of the INSERT statement. The included columns are only available if the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

#### *column-name*

Specifies the name for a column of the result table of the INSERT statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

#### **data-type**

Specifies the data type of the included column. The included columns are nullable.

#### **built-in-type**

Specifies a built-in data type. See “CREATE TABLE” on page 1079 for a description of each built-in type.

#### **distinct-type**

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

#### **OVERRIDING USER VALUE**

Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.

If OVERRIDING USER VALUE is specified, the implicit or explicit list of column must include a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT. For example, a ROWID column, an identity column, or a row change timestamp column.

#### **VALUES**

Specifies one new row in the form of a list of values. The number of values in the VALUES clause must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The first value is inserted in the first column in the list, the second value in the second column,

and so on. If more than one value is specified, the list of values must be enclosed in parentheses. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause in a SELECT statement or a SELECT INTO statement.

***expression***

Any expression of the type described in “Expressions” on page 180. The expression must not include a column name. If *expression* is a host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

**DEFAULT**

The default value that is assigned to the column. If the column is a ROWID column or an identity column, DB2 will generate a value for the column. You can specify DEFAULT only for columns that have an assigned default value, ROWID columns, and identity columns.

For information on default values of data types, see the description of the DEFAULT clause for “CREATE TABLE” on page 1079.

**NULL**

Specifies the null value as the value of the column. Specify NULL only for nullable columns.

If the implicit or explicit list of columns includes a ROWID, an identity column, or a row change timestamp column that was defined as GENERATED ALWAYS, you must specify DEFAULT unless you specify the OVERRIDING USER VALUE clause to indicate that any user-specified value will be ignored and a unique system-generated value will be inserted.

For a ROWID or identity column that is defined as GENERATED BY DEFAULT, you can specify a value. However, a value can be inserted into ROWID column defined BY DEFAULT only if a single-column unique index is defined on the ROWID column and the specified value is a valid row ID value that was previously generated by DB2. When a value is inserted into an identity column defined BY DEFAULT, DB2 does not verify that the specified value is a unique value for the column unless the identity column has a single-column unique index.

Although an implicitly hidden DOCID column for XML values is defined as GENERATED ALWAYS, you can include the DOCID column in the explicit list of columns and specify a value for it. However, DB2 will ignore the value.

**WITH *common-table-expression***

Specifies a common table expression. For an explanation of common table expression, see “common-table-expression” on page 670.

***fullselect***

Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLCODE is set to +100, and SQLSTATE is set to '02000'.

When the base object of the INSERT and the base object of the fullselect or any subquery of the fullselect are the same table, the fullselect is evaluated completely before any rows are inserted.

For an explanation of fullselect, see “fullselect” on page 662.

The number of columns in the result table must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The value of the first column of the result is inserted in the first column

in the list, the second value in the second column, and so on. Any values that are produced for a generated column must conform to the rules that are described for those columns under the VALUES clause. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

If the object table is self-referencing, the fullselect must not return more than one row.

*isolation-clause*

Specifies the isolation level that is used when the fullselect is executed.

**WITH**

Introduces the isolation level, which can be one of the following:

- RR**    Repeatable read
- RS**    Read stability
- CS**    Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**QUERYNO** *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

*multiple-row-insert*

**VALUES**

Specifies the items for the rows to be inserted. The number of items in the VALUES clause must equal the number of names in the implicit or explicit column list. The first item in the list provides the value (or values) for the first column in the list. The second item in the list provides the value (or values) for the second column, and so on.

*expression*

Any expression of the type described in “Expressions” on page 180. The expression must not include a column name. For each row that is inserted, the corresponding column is assigned the value of the expression.

*host-variable-array*

Each host-variable array must be defined in the application program in

accordance with the rules for declaring an array. A host-variable array contains the data for a column of table that is a target of the INSERT. The number of rows to be inserted must be less than or equal to the dimension of each of the host-variable arrays.

An optional indicator array can be specified for each host-variable array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the SQLVAR is nullable. The indicators must be small integers. The indicator array must be large enough to contain an indicator for each row of input data.

#### **DEFAULT**

Specifies that the default value is assigned to the column. For each row inserted, the corresponding column is assigned its default value. DEFAULT can be specified only for columns that have a default value. For information on default values of data types, see the description of the DEFAULT clause for "CREATE TABLE" on page 1079.

#### **NULL**

Specifies the null value as the value of the column in each row inserted. For each row inserted, the corresponding column is assigned the NULL value. Specify NULL only for nullable columns.

#### **FOR *host-variable* or *integer-constant* ROWS**

Specifies the number of rows to be inserted. For a dynamic INSERT statement, this clause can be specified on the EXECUTE statement. For more information, see the EXECUTE statement. However, this clause is required when a dynamic SELECT statement contains more than one multiple-row INSERT statement.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. Furthermore, *k* must be in the range,  $0 < k \leq 32767$ . *k* rows are inserted into the target table from the specified source data.

If a parameter marker is specified in this clause, a value must be provided with the USING clause of the associated EXECUTE or OPEN statement.

#### **ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies whether all of the rows should be inserted as an atomic operation or not.

#### **ATOMIC**

Specifies that if the insert for any row fails, all changes made to the database by any of the inserts, including changes made by successful inserts, are undone. This is the default.

#### **NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert to complete), including any triggers that might have been executed as a result of the INSERT statement.

This clause is only valid for a static INSERT statement. This clause must also not be specified if the INSERT statement is contained within a SELECT statement. For a dynamic INSERT statement, specify the clause on the PREPARE statement. For more information, see "PREPARE" on page 1405.

## Notes

**Insert rules:** Insert values must satisfy the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted and the position of the cursors are not changed.

- *Default values.* The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.
- *Length.* If the insert value of a column is a number, the column must be a numeric column with the capacity to represent the integral part of the number. If the insert value of a column is a string, the column must be either a string column with a length attribute at least as great as the length of the string, or a datetime column if the string represents a date, time, or timestamp.
- *Assignment.* Insert values are assigned to columns in accordance with the assignment rules described in Chapter 2, “Language elements,” on page 47.
- *Uniqueness constraints.* If the identified table or the base table of the identified view has one or more unique indexes, each row inserted into the table must conform to the constraints imposed by those indexes.
- *Referential constraints.* Each nonnull insert value of a foreign key must be equal to some value of the parent key of the parent table in the relationship.
- *Check constraints.* The identified table or the base table of the identified view might have one or more check constraints. Each row inserted must conform to the conditions imposed by those constraints. Thus, each check condition must be true or unknown.
- *Field and validation procedures.* If the identified table or the base table of the identified view has a field or validation procedure, each row inserted must conform to the constraints imposed by that procedure.
- *Indexes with VARBINARY columns.* If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.
- *Views and the WITH CHECK OPTION.* For views defined with WITH CHECK OPTION, each row you insert into the view must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the inserted rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see “CREATE VIEW” on page 1184.

For views that are not defined with WITH CHECK OPTION, you can insert rows that do not conform to the definition of the view. Those rows cannot appear in the view but are inserted into the base table of the view.

- *Omitting the column list.* When you omit the column list, you must specify a value for every column that was present in the table when the INSERT statement was bound or (for dynamic execution) prepared.
- *Triggers.* An INSERT statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If an INSERT statement for a view activates an INSTEAD OF trigger, the validity, referential integrity, and check constraints are checked

against the data changes that are performed in the trigger, and not against the definition of the view that activates the trigger or the definition of the underlying tables or views.

When triggers are processed for an INSERT statement that inserts multiple rows depends on the atomicity option that is in effect for the INSERT statement:

- **ATOMIC.** The inserts are processed as a single statement. Any statement level triggers are activated one time for the statement, and the transition tables will include all of the rows that were inserted.
- **NOT ATOMIC CONTINUE ON SQLEXCEPTION.** The inserts are processed separately. Any statement level triggers are processed for each row that is inserted, and the transition table includes the individual row that is inserted. When errors are encountered with this option in effect, processing continues, and some of the specified rows will not be inserted. In this case, if an insert trigger is defined on the underlying base table, the statement level triggers will only be activated for rows that were successfully inserted.

Regardless of the failure of any particular source row, the INSERT statement will not undo any changes that are made to the database by the statement. Insert will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

**Inserting XML documents:** When XML documents are inserted into a table that contains an XML index, the XML values that are inserted into the index are cast to the data type that is specified on the CREATE INDEX statement. If the XML value cannot be cast to the specified data type, the XML value is ignored for the XML index but the document is still inserted into the table. If the data type that is specified for casting is DECFLOAT, values can be rounded when they are inserted into the index. If the index is unique, the rounding that happens during the cast can result in duplicate values.

**Number of rows inserted:** Normally, after an INSERT statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows inserted. (For a complete description of the SQLCA, including exceptions to the above statement, see “SQL communication area (SQLCA)” on page 1646.) The value in SQLERRD(3) does not include the number of rows that were inserted as the result of a trigger.

**Nesting user-defined functions or stored procedures:** An INSERT statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the INSERT must not access the table into which you are inserting values.

**Locking:** Unless appropriate locks already exist, one or more exclusive locks are acquired at the execution of a successful insert operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the inserted row. If LOBs are not inserted into the row, application processes that are running with uncommitted read can also access the inserted row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

**Inserting rows into a table with multilevel security :** When you insert rows into a table with multilevel security, DB2 determines the value for the security label column of the row according to the following rules:

- If the user (the primary authorization ID) has write-down privilege or write-down control is not enabled, the user can set the security label for the row to any valid security label. The value that is specified must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL. If the user does not specify a value for the security label or specifies DEFAULT, the security label of the row becomes the same as the security label of the user.
- If the user does not have write-down privilege and write-down control is enabled, the security label of the row becomes the same as the security label of the user.

**Inserting rows into a table with a row change timestamp column:** A row change timestamp column that is defined as GENERATED ALWAYS should not be specified in an INSERT statement, unless the OVERRIDING USER VALUE clause is specified to indicate that any specified value is ignored and a unique system-generated value is inserted.

**Considerations for an INSERT without a column list:** An INSERT statement without a column list does not include implicitly hidden columns, so columns that are defined as implicitly hidden must have a defined default value.

**Inserting a row into catalog table SYSIBM.SYSSTRINGS:** If the object table is SYSIBM.SYSSTRINGS, only certain values can be specified, as described in *DB2 Administration Guide*.

**Datetime representation when using datetime registers:** As explained under Datetime special registers, when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are inserted. When ATOMIC is in effect for the INSERT statement, the special registers are evaluated one time for the processing of the statement. If NOT ATOMIC is in effect, the special registers are evaluated as each row of source data is processed.

**Considerations for non-atomic processing of an INSERT statement:** When NOT ATOMIC is specified the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the INSERT statement are evaluated as each row of source data is processed. Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the execution of an insert of a row, processing continues. The row that was being inserted at the time of the error is not inserted. Execution continues with the next row to be inserted, and any other changes made during the execution of the multiple-row INSERT statement are not backed out. However, the insert of an individual row is an atomic action.

**Diagnostics information for a multiple-row INSERT statement:** A single multiple-row INSERT statement might encounter multiple conditions. These conditions can be errors or warnings. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these INSERT statements. See “GET DIAGNOSTICS” on page 1317 for more information.

If a warning occurs during the execution of an insert of a row, processing continues.

When multiple errors or warnings occur with a non-atomic INSERT statement, diagnostic information for each row is available using the GET DIAGNOSTICS statement. The SQLSTATE and SQLCODE reflect a summary of what happened during the INSERT statement:

- **SQLSTATE 01659, SQLCODE +252.** All rows were inserted, but one or more warnings occurred.
- **SQLSTATE 22529, SQLCODE -253.** At least one row was successfully inserted, but one or more errors occurred. Some warnings might also have occurred.
- **SQLSTATE 22530, SQLCODE -254.** No row was inserted. One or more errors occurred while trying to insert multiple rows of data.
- **SQLSTATE 429BI, SQLCODE -20252.** More errors occurred than DB2 is capable of recording. Statement processing is terminated.

When ATOMIC is in effect, if an insert value violates any constraints or if any other error occurs during the execution of an insert of a row, all changes made during the execution of the multiple-row INSERT statement are backed out. The SQLCA reflects the last warning encountered.

After an INSERT statement that inserts multiple rows of data, both atomic and non-atomic, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD3 contains the number of rows actually inserted. SQLERRD3 is the number of rows inserted, if this is less than the number of rows requested, then an error occurred.
- SQLWARN flags are set if they were set during any single insert operation.

The SQLCA is used to return information on errors and warnings found during a multiple-row insert. If indicator arrays are provided, the indicator variable values are used to determine if the value from the host-variable array, or NULL, will be used. The SQLSTATE contains the warning from the last data mapping error.

*Considerations for specifying the number of rows for a dynamic multiple-row INSERT statement:* Be aware of these considerations when specifying the number of rows to be inserted with a dynamic multiple-row INSERT statement that uses host-variable arrays:

- The FOR n ROWS clause can be specified as part of an INSERT statement or as part of an EXECUTE statement, but not both
- In the INSERT statement, you can specify a numeric constant in the FOR n ROWS clause to indicate the number of rows to be inserted or specify a parameter marker to indicate that the number of rows will be specified with the associated EXECUTE or OPEN statement. A multiple-row INSERT statement that is contained within a SELECT statement must include a FOR n ROWS clause.
- In an EXECUTE statement, when a dynamic INSERT statement is not contained within a SELECT statement, the number of rows can be specified with either the FOR n ROWS clause or the USING clause of the EXECUTE statement:
  - If the INSERT statement did not contain a FOR n ROWS clause, a value for the number of rows to be inserted can be specified in the FOR n ROWS clause of the EXECUTE statement with a numeric constant or host variable.
  - If a parameter marker was specified as part of a FOR n ROWS clause in the INSERT statement, a value for the number of rows must be specified with the USING clause of the EXECUTE statement.

- In an OPEN statement, when a dynamic SELECT statement contains one or more INSERT statements that have FOR n ROWS clauses with parameter markers, the values for the number of rows to be inserted (that is, the values for the parameter markers) must be specified with the USING clause of the OPEN statement.

**DRDA considerations for a multiple-row INSERT statement:** DB2 for z/OS limits the size of user data and control information to 10M (except for LOBs, which are processed in a different data stream) for a single multiple-row INSERT statement using host-variable arrays.

Multiple-row insert and fetch statements are supported by any requester or server that supports the DRDA Version 3 protocols. If an attempt is made to issue a multiple-row INSERT or FETCH statement on a server that does not support DRDA Version 3 protocols, an error occurs.

When a multiple-row INSERT statement is executed at a DB2 for z/OS requester, the number of rows being inserted at the requester might not be known in some cases. These cases include:

- The FOR n ROWS clause contains a constant value for *n* for either a static or dynamic INSERT statement.
- Host variables are specified on the USING clause of an EXECUTE statement for a dynamic INSERT statement.

In either case, if the number of rows that is being inserted is not known, the requester might flow more data than is required to the server. The number of rows that is actually inserted will be correct because the server knows the correct number of rows to insert. However, performance can be adversely affected. Consider the following scenario:

```
...
long serial_num [10];
struct {
short len;
char data [18];
}name [20]
...
EXEC SQL INSERT INTO T1 VALUES (:serial_num, :name) FOR 5 ROWS
```

At the requester, when this statement is executed, the number of rows being inserted, 5, is not known. As a result, the requester will flow 10 values for serial\_num and 10 values for name to the server (because the maximum number of rows that can be inserted without error is 10, which is the size of the smallest host-variable array).

Use the following programming techniques to avoid or minimize problems:

- Avoid using constant values for *n* in the FOR *n* ROWS clause of INSERT statements. For static INSERT statements, this technique ensures that the value for *n* will be known at the requester.
- For dynamic INSERT statements, use the USING DESCRIPTOR clause instead of the USING *host-variables* clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for 'n' must be indicated in the DESCRIPTOR.
- If neither of the above methods can be used:

- Declare your host-variable arrays as small as possible, or indicate that the size of your host-variable arrays are the size of 'n' in your descriptor. This avoids sending large numbers of host-variable-array entries that will not be used to the server.
- Ensure that varying length string arrays are initialized to a length of 0 (zero). This minimizes the amount of data that is sent to the server.
- Ensure that decimal host-variable arrays are initialized to valid values. This avoids a negative SQLCODE from being returned if the requester encounters invalid decimal data.

*Other SQL statements in the same unit of work:* The following statements cannot follow an INSERT statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)

## Examples

*Example 1:* Insert values into sample table DSN8910.EMP.

```
INSERT INTO DSN8910.EMP
VALUES ('000205','MARY','T','SMITH','D11','2866',
       '1981-08-10','ANALYST',16,'F','1956-05-22',
       16345,500,2300);
```

*Example 2:* Assume that SMITH.TEMPEMPL is a created temporary table. Populate the table with data from sample table DSN8910.EMP.

```
INSERT INTO SMITH.TEMPEMPL
SELECT *
FROM DSN8910.EMP;
```

*Example 3:* Assume that SESSION.TEMPEMPL is a declared temporary table. Populate the table with data from department D11 in sample table DSN8910.EMP.

```
INSERT INTO SESSION.TEMPEMPL
SELECT *
FROM DSN8910.EMP
WHERE WORKDEPT='D11';
```

*Example 4:* Insert a row into sample table DSN8910.EMP\_PHOTO\_RESUME. Set the value for column EMPNO to the value in host variable HV\_ENUM. Let the value for column EMP\_ROWID be generated because it was defined with a row ID data type and with clause GENERATED ALWAYS.

```
INSERT INTO DSN8910.EMP_PHOTO_RESUME(EMPNO, EMP_ROWID)
VALUES (:HV_ENUM, DEFAULT);
```

You can only insert user-specified values into ROWID columns that are defined as GENERATED BY DEFAULT and not as GENERATED ALWAYS. Therefore, in the above example, if you were to try to insert a value into EMP\_ROWID instead of specifying DEFAULT, the statement would fail unless you also specify OVERRIDING USER VALUE. For columns that are defined as GENERATED ALWAYS, the OVERRIDING USER VALUE clause causes DB2 to ignore any user-specified value and generate a value instead.

For example, assume that you want to copy the rows in DSN8910.EMP\_PHOTO\_RESUME to another table that has a similar definition (both tables have a ROWID columns defined as GENERATED ALWAYS). For the

following INSERT statement, the OVERRIDING USER VALUE clause causes DB2 to ignore the EMP\_ROWID column values from DSN8910.EMP\_PHOTO\_RESUME and generate values for the corresponding ROWID column in B.EMP\_PHOTO\_RESUME.

```
INSERT INTO B.EMP_PHOTO_RESUME
OVERRIDING USER VALUE
SELECT * FROM DSN8910.EMP_PHOTO_RESUME;
```

*Example 5:* Assume that the T1 table has one column. Insert a variable (:hv) number of rows of data into the T1 table. The values to be inserted are provided in a host-variable array (:hva).

```
EXEC SQL INSERT INTO T1 FOR :hv ROWS VALUES (:hva:hvind) ATOMIC;
```

In this example, :hva represents the host-variable array and :hvind represents the array of indicator variables.

*Example 6:* Assume that the T2 table has 2 columns, C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 10 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values). The data values for :hva1 and :hva2 are represented in Table 125:

*Table 125. Data values for :hva1 and :hva2*

Array entry	:hva1	:hva2
1	1	32768
2	-12	90000
3	79	2
4	32768	19
5	8	36
6	5	24
7	400	36
8	73	4000000000
9	-200	2000000000
10	35	88

```
EXEC SQL INSERT INTO T2 (C1, C2)
FOR 10 ROWS VALUES (:hva1:hvind1, :hva2:hvind2)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

After execution of the INSERT statement, the following information will be in the SQLCA:

```
SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 8
```

Although an attempt was made to insert 10 rows, only 8 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num\_rows = 8 and num\_cond = 2 (2 conditions).

```

GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
                           :sqlcode = DB2_RETURNED_SQLCODE,
                           :row_num = DB2_ROW_NUMBER;

```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row\_num = 4.

```

GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
                           :sqlcode = DB2_RETURNED_SQLCODE,
                           :row_num = DB2_ROW_NUMBER;

```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row\_num = 8.

*Example 7:* Assume the above table T2 with two columns. C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 8 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values.) The data values for :hva1 and :hva2 are represented in Table 125 on page 1381.

```

EXEC SQL INSERT INTO T2 (C1, C2)
  FOR 8 ROWS VALUES (:hva1:hvind1, :hva2:hvind2)
    NOT ATOMIC CONTINUE ON SQLEXCEPTION;

```

After execution of the INSERT statement, the following information will be in the SQLCA:

```

SQLCODE = -253
SQLSTATE = 22529
SQLERRD3 = 6

```

Although an attempt was made to insert 8 rows, only 6 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num\_rows = 68 and num\_cond = 2 (2 conditions).

```

GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
                           :sqlcode = DB2_RETURNED_SQLCODE,
                           :row_num = DB2_ROW_NUMBER;

```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row\_num = 4.

```

GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
                           :sqlcode = DB2_RETURNED_SQLCODE,
                           :row_num = DB2_ROW_NUMBER;

```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row\_num = 8.

*Example 8:* Assume that table T1 has two columns. Insert a variable number (:hvn) or rows into T1. The values to be inserted are in host-variable arrays :hva and :hvb. In this example, the INSERT statement is contained within the SELECT statement of cursor CS1. The SELECT statement makes use of two other input host variables (:hv1 and :hv2) in the WHERE clause. Either a static or dynamic INSERT statement can be used.

```

-- Static INSERT statement:
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR
  SELECT *
    FROM FINAL TABLE
      (INSERT INTO T1 VALUES (:hva, :hvb) FOR :hvn ROWS)
    WHERE C1 > :hv1 AND C2 < :hv2;
OPEN CS1;
-- Dynamic INSERT statement:

```

```
PREPARE INSSTMT FROM
  'SELECT *
   FROM FINAL TABLE
     (INSERT INTO T1 VALUES ( ? , ? ) FOR ? ROWS)
    WHERE C1 > ? AND C2 < ?';
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR :INSSTMT;
OPEN CS1 USING :hva, :hvb, :hvn, :hv1, :hv2; (or OPEN CS1 USING DESCRIPTOR ...)
```

If the host-variable arrays for the multiple-row INSERT statement were to be specified using a descriptor, that descriptor (SQLDA) would have to describe all input host variables in the statement, and the order of the entries in the SQLDA should be the same as the order of the order of the host variables, host-variable arrays, and values for the FOR n ROWS clauses in the statement. For example, given the statement above, the SQLVAR entries in the descriptor must be assigned in the following order: :hvn, :hva, :hvb, :hv1, hv2. In addition, the SQLVAR entries for host-variable arrays must be tagged in the SQLDA as column arrays (by specifying a special value in part of the SQLNAME field for a host variable), and the SQLVAR entry for the number of rows value must be tagged in the SQLDA (by specifying another special value in part of the SQLNAME field for the host variable).

## LABEL

The LABEL statement adds or replaces labels in the descriptions of tables, views, aliases, or columns in the catalog at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

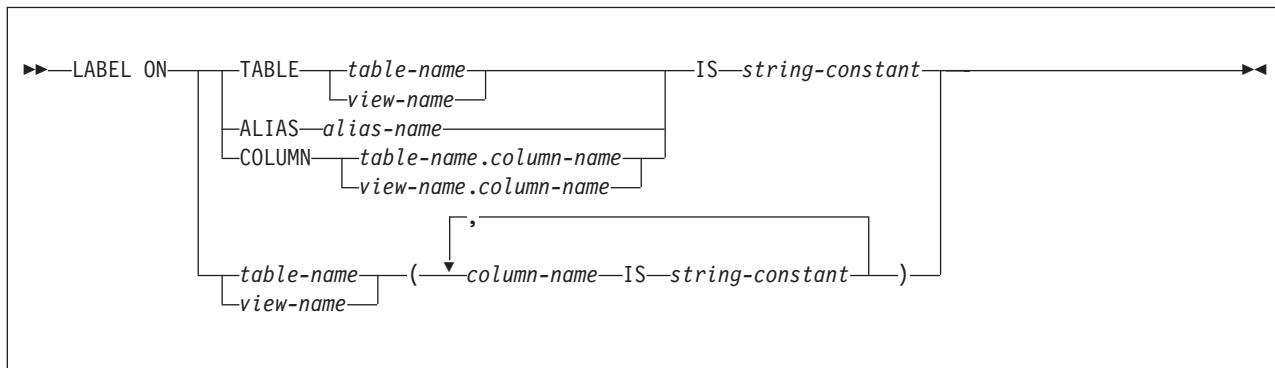

The privilege set that is defined below must include at least one of the following:

- Ownership of the table, view, or alias
- DBADM authority for its database (tables only)
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

### Syntax

### Description

#### TABLE *table-name* or *view-name*

Identifies the table or view to which the label applies. The name must identify a table or view that exists at the current server. *table-name* must not identify a declared temporary table. The label is placed into the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

#### ALIAS *alias-name*

Identifies the alias to which the label applies. The name must identify an alias that exists at the current server. The label is placed in the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.

**COLUMN** *table-name.column-name or view-name.column-name*

Identifies the column to which the label applies. The name must identify a column of a table or view that exists at the current server. The name must not identify a column of a declared temporary table. The label is placed in the LABEL column of the SYSIBM.SYSCOLUMNS catalog table in the row that describes the column.

**Do not use TABLE or COLUMN to define a label for more than one column in a table or view.** Give the table or view name and then, in parentheses, a list in the form:

*column-name IS string-constant,  
column-name IS string-constant,...*

See Example 2 below.

The column names must not be qualified, each name must identify a column of the specified table or view, and that table or view must exist at the current server.

**IS** Introduces the label you want to provide.

*string-constant*

Can be any SQL character string constant of up to 30 bytes in length.

## Examples

*Example 1:* Enter a label on the DEPTNO column of table DSN8910.DEPT.

```
LABEL ON COLUMN DSN8910.DEPT.DEPTNO  
IS 'DEPARTMENT NUMBER';
```

*Example 2:* Enter labels on two columns in table DSN8910.DEPT.

```
LABEL ON DSN8910.DEPT  
(MGRNO IS 'EMPLOYEE NUMBER FOR THE MANAGER',  
ADMRDEPT IS 'ADMINISTERING DEPARTMENT');
```

## LOCK TABLE

The LOCK TABLE statement requests a lock on a table or table space at the current server. The lock is not acquired if the process already holds an appropriate lock.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

The privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the identified table (the SELECT privilege does not apply to the auxiliary table)
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

### Syntax

```
►►—LOCK TABLE—table-name—[PARTITION—integer]—IN—[SHARE—|EXCLUSIVE—]—MODE—►►
```

### Description

#### *table-name*

Identifies the table to be locked. The name must identify a table that exists at the current server. It must not identify a view, a temporary table (created or declared), or a catalog table. The lock might or might not apply exclusively to the table. The effect of locking an auxiliary table is to lock the LOB table space that contains the auxiliary table.

#### PARTITION *integer*

Identifies the partition of a partitioned table space to lock. The table identified by *table-name* must belong to a partitioned table space. The value specified for *integer* must be an integer that is no greater than the number of partitions in the table space.

#### IN SHARE MODE

For a lock on a table that is not an auxiliary table, requests the acquisition of a lock that prevents other processes from executing anything but read-only

operations on the table. For a lock on a LOB table space, IN SHARE mode requests a lock that prevents storage from being reallocated. When a LOB table space is locked, other processes can delete LOBs or update them to a null value, but they cannot insert LOBs with a nonnull value. The type of lock that the process holds after execution of the statement depends on what lock, if any, the process already holds.

#### IN EXCLUSIVE MODE

Requests the acquisition of an exclusive lock for the application process. Until the lock is released, it prevents concurrent processes from executing any operations on the table. However, unless the lock is on a LOB table space, concurrent processes that are running at an isolation level of uncommitted read (UR) can execute read-only operations on the table.

### Notes

**Releasing locks:** If LOCK TABLE is a static SQL statement, the RELEASE option of bind determines when DB2 releases a lock. For RELEASE(COMMIT), DB2 releases the lock at the next commit point. For RELEASE(DEALLOCATE), DB2 releases the lock when the plan is deallocated (the application ends).

If LOCK TABLE is a dynamic SQL statement, DB2 uses RELEASE(COMMIT) and releases the lock at the next commit point, *unless* the table or table space is referenced by cached dynamic statements. Caching allows DB2 to keep prepared statements in memory past commit points. In this case, DB2 holds the lock until deallocation or until the commit after the prepared statements are freed from memory. Under some conditions, if a lock is held past a commit point, DB2 demotes the lock state of a segmented table or a nonsegmented table space to an intent lock at the commit point.

For more information on using LOCK TABLE (such as the size and duration of locks), and on locking in general, see *DB2 Application Programming and SQL Guide* or *DB2 Performance Monitoring and Tuning Guide*.

**Syntax alternatives and synonyms:** For compatibility with previous releases of DB2, PART can be specified as a synonym for PARTITION.

### Example

Obtain a lock on the sample table named DSN8910.EMP, which resides in a partitioned table space. The lock obtained applies to every partition and prevents other application programs from either reading or updating the table.

```
LOCK TABLE DSN8910.EMP IN EXCLUSIVE MODE;
```

---

## MERGE

The MERGE statement updates a target (a table or view, or the underlying tables or views of a fullselect) using the specified input data. Rows in the target that match the input data are updated as specified, and rows that do not exist in the target are inserted. Updating or inserting a row into a view updates or inserts the row into the tables on which the view is based, if no INSTEAD OF trigger is defined on this view.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

The privileges that are held by the privilege set that is defined below must include at least one of the following privileges:

- SYSADM authority
- Ownership of the table
- If the search condition contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view
- If the insert operation is specified, the INSERT privilege for the table or view
- If the update operation is specified, at least one of the following privileges is required:
  - the UPDATE privilege for the table or view
  - the UPDATE privilege on each column that is updated
  - If the right side of the assignment clause contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view

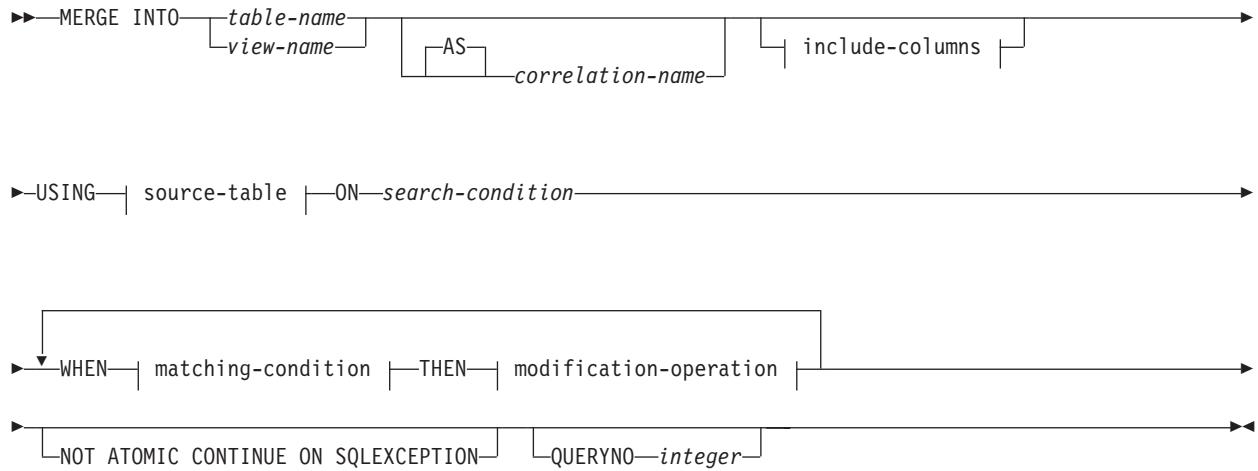

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the insert operation or assignment clause includes a subquery, the privileges that are held by the privilege set must also include at least one of the following privileges:

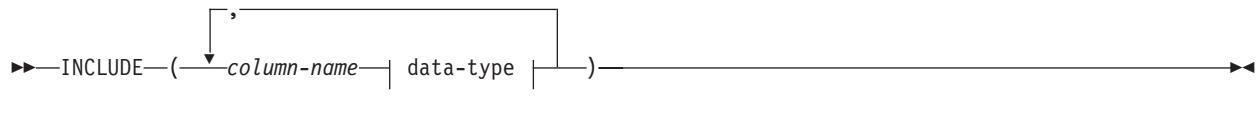

- SYSADM authority
- The SELECT privilege on every table or view that is identified in the subquery
- Ownership of the tables or views that are identified in the subquery

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

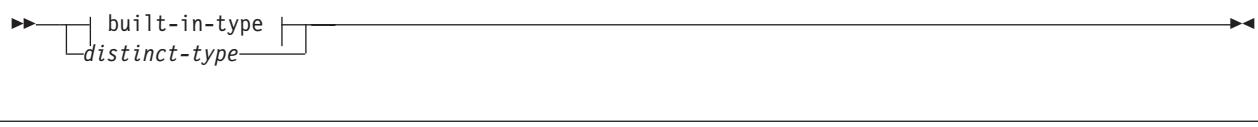

## Syntax

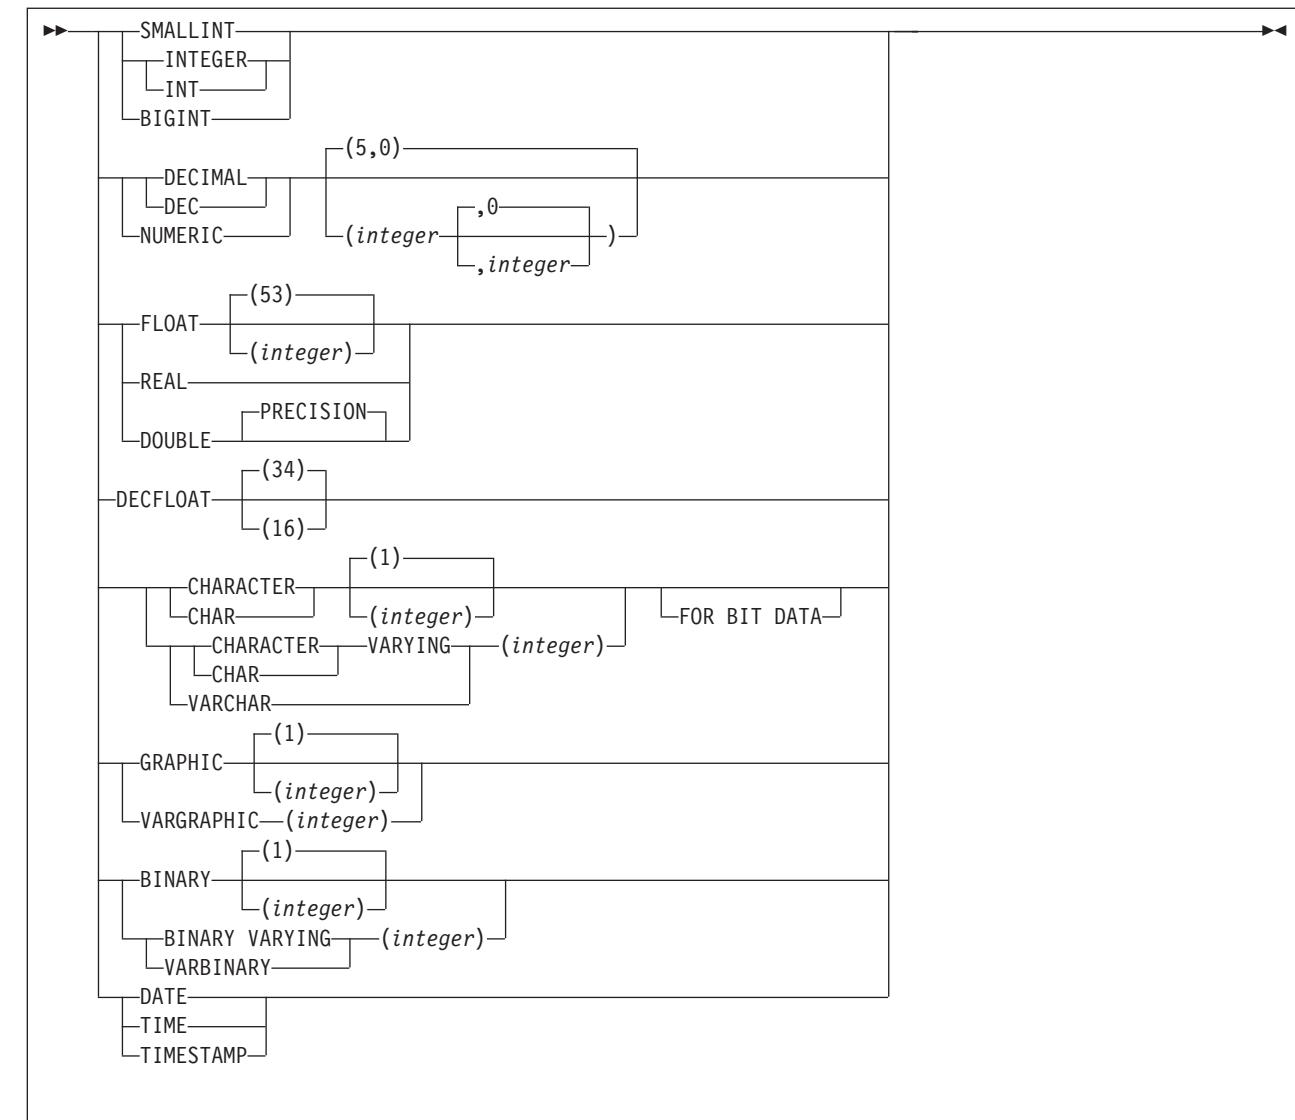

include-columns:

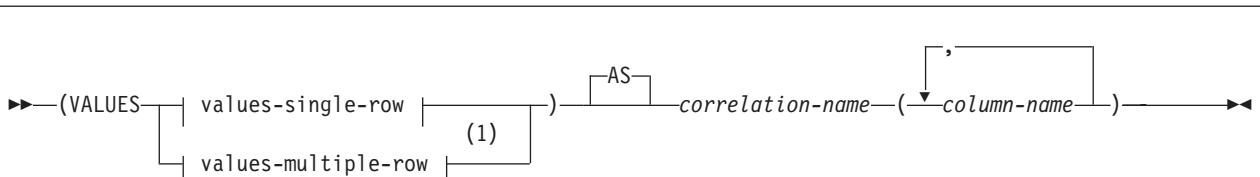

data-type:

built-in-type:

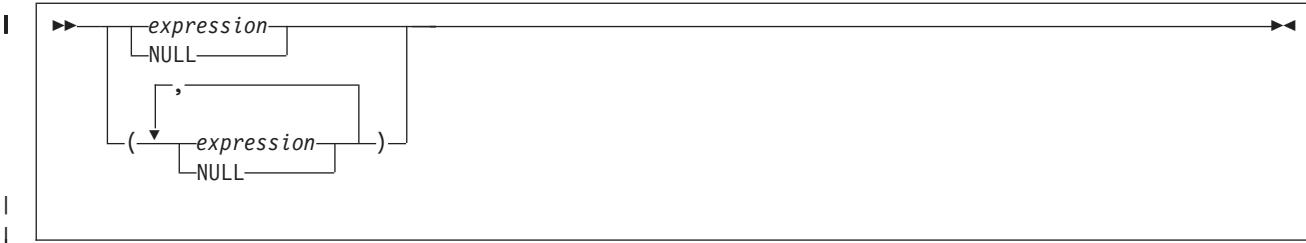

### source-table:

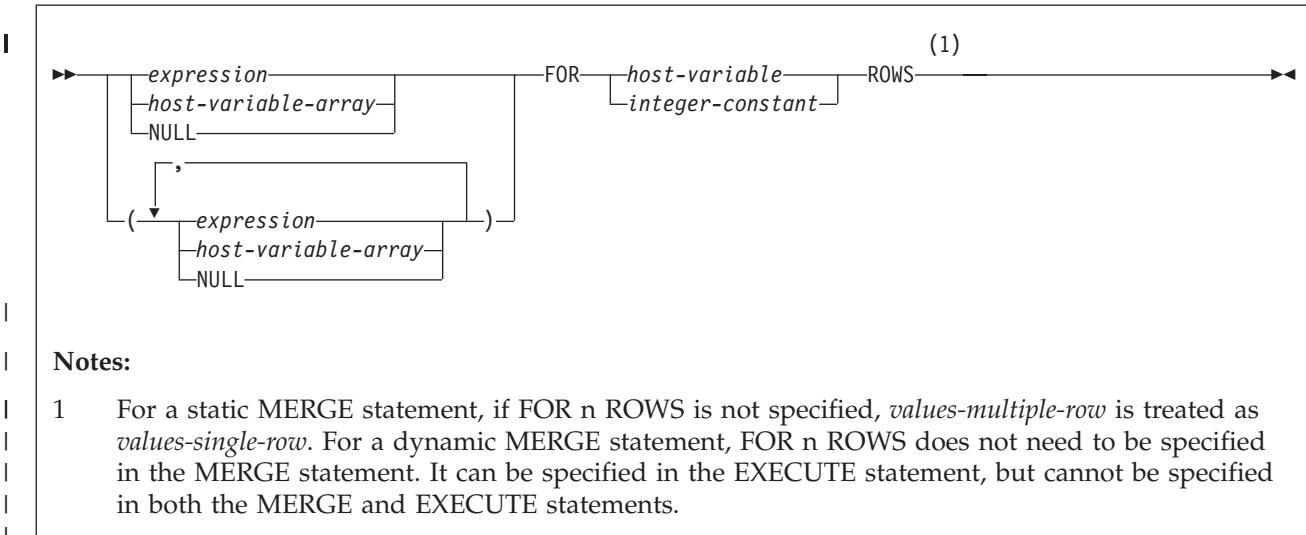

## Notes:

- <sup>1</sup> The NOT ATOMIC clause must be specified when *values-multiple-row* is specified.

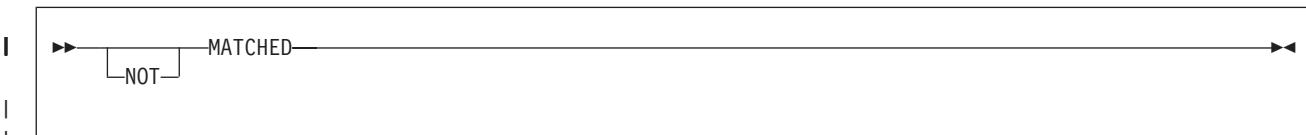

## values-single-row:

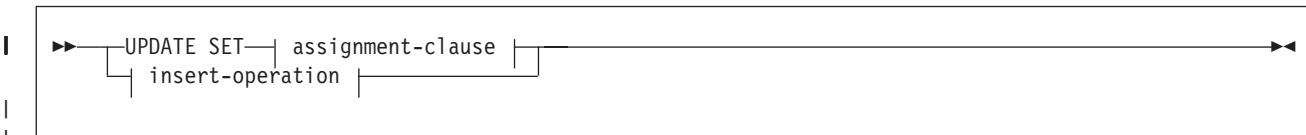

**values-multiple-row:**

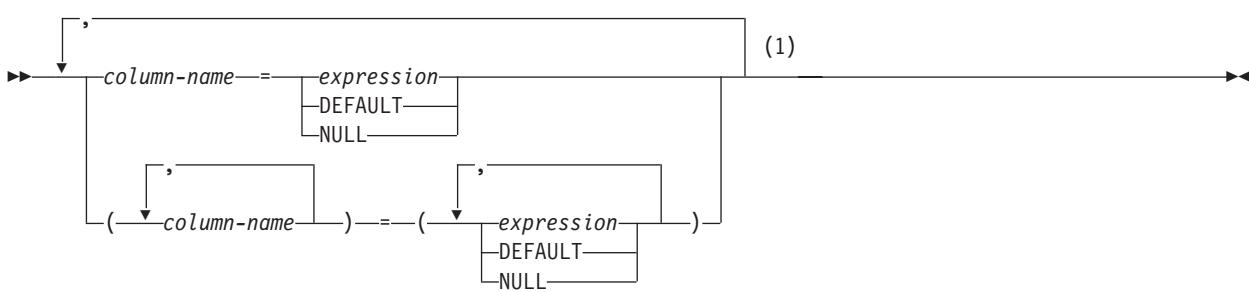

**matching-condition:**

**modification-operation:**

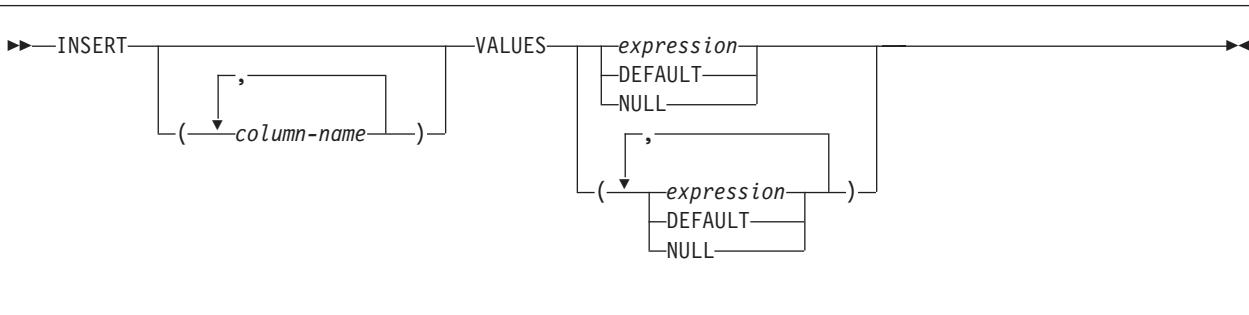

**assignment-clause:**

#### Notes:

- The number of expressions, DEFAULT, and NULL keywords must match the number of column-names.

#### insert-operation:

## Description

### **INTO** *table-name* **or** *view-name*

Identifies the target of the insert or update operations of the MERGE statement. The name must identify a table or view that exists at the current server. The name must not identify:

- A catalog table
- A created global temporary table
- A read-only view
- A system-maintained materialized query table
- A table that is implicitly created for an XML column

If a view is specified as the target of the MERGE statement, the view must not be defined with any INSTEAD OF triggers.

### **AS** *correlation-name*

*correlation-name* provides an alternate name that can be used when referencing columns of the intermediate result table. If no *correlation-name* is specified, the name of the intermediate result table is the name of the target table or view of the MERGE statement. Otherwise, the name is the *correlation-name*.

### *include-column*

Specifies a set of columns that are included, along with the columns of the specified table or view, in the result table of the MERGE statement when it is nested in the FROM clause of the outer fullselect that is used in a SELECT statement, or in a SELECT INTO statement. The included columns are

appended to the end of the list of columns that are identified by *table-name* or *view-name*. If a value is not specified for an included column, a null value is returned for that column.

#### **INCLUDE**

Introduces a list of columns that is to be included in the result table of the MERGE statement. The included columns are only available if the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. INCLUDE can only be specified when the MERGE statement is nested in the FROM clause of a SELECT statement.

#### *column-name*

Specifies the name for a column of the result table of the MERGE statement that is not the same name as another included column or a column in the table or view that is specified in *table-name* or *view-name*.

#### **data-type**

Specifies the data type of the included column. The included columns are nullable.

#### **built-in-type**

Specifies a built-in data type. See “CREATE TABLE” on page 1079 for a description of each built-in type.

#### **distinct-type**

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

### **USING VALUES** *values-single-row* **or** *values-multiple-row*

Specifies the values for the row data to merge into the target table or view. *values-single-row* specifies a single row of source data. *values-multiple-row* specifies multiple rows of source data.

#### *expression*

Specifies an expression of the type that is described in “Expressions” on page 180. The expression must not include a column name. The expression must not reference a NEXT VALUE or PREVIOUS VALUE expression. If the expression is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

To provide a null value, specify the NULL keyword on a CAST specification.

#### *host-variable-array*

Specifies a host variable array. Each host variable array must be defined in the application program in accordance with the rules for declaring an array. A host variable array contains the data to merge into a target column. The number of rows must be less than or equal to the dimension of each of the host variable arrays. An optional indicator array can be specified for each host variable array. An indicator array should be specified if the SQLTYPE of any SQLVAR occurrence indicates that a column is nullable. The dimension of the indicator array must be large enough to contain an indicator for each row of input data.

A host structure is not supported in *host-variable-array*.

*host-variable-array* is supported in C/C++, COBOL, and PL/I.

**FOR** *host-variable or integer-constant ROWS*

Specifies the number of rows to merge. For a dynamic MERGE statement, this clause can be specified on the EXECUTE statement. *host-variable* or *integer-constant* is assigned to a value *k*. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. *k* must be in the range of 1 to 32767. *k* rows are merged into the target from the specified source data.

If a parameter marker is specified in FOR *n* ROWS, a value must be provided with the USING clause of the associated EXECUTE statement.

**AS** *correlation-name*

Specifies a correlation name for the *source-table*.

*column-name*

Specifies a column name to associate the input data to the SET *assignment-clause* for an update operation or the VALUES clause for an insert operation.

**ON** *search-condition*

Specifies join conditions between the *source-table* and the target table or view.

Each *column-name* in the search condition must name a column of the target table, view, or *source-table*. A subquery is not allowed in the *search-condition*. If a *column-name* exists in both the target and the *source-table*, the column name must be qualified.

For each row of the *source-table*, the *search-condition* is applied to each row of the target. If the *search-condition* is evaluated as true and the target is not empty, the specified WHEN MATCHED clause is used. Otherwise, the specified WHEN NOT MATCHED clause is used.

**WHEN MATCHED or WHEN NOT MATCHED**

Specifies the condition under which the *modification-operation* is run.

**WHEN MATCHED**

Specifies the operation to perform on the rows where the ON *search-condition* is true and the target is not empty. Only UPDATE can be specified after the THEN clause. WHEN MATCHED must not be specified more than one time.

**WHEN NOT MATCHED**

Specifies the operation to perform on the rows where the ON *search-condition* is false or unknown, or the target is empty. Only INSERT can be specified after the THEN clause. WHEN NOT MATCHED must not be specified more than one time.

**THEN** *update-operation or THEN insert-operation*

Specifies the operation to run when the *matching-condition* evaluates to true.

**UPDATE SET**

Specifies the update operation to run when the *matching-condition* evaluates to true.

The rows that are updated from a *source-row* are subject to more updates by subsequent *source-rows* in the same statement. The update is cumulative.

*assignment-clause*

Specifies a list of column updates.

*column-name*

Identifies a column to update. *column-name* must identify a column of the specified table or view, and that column must be updatable. The

column must not be a generated column, or a column of a view that is derived from a scalar function, a constant, or a expression. *column-name* can also identify an included column. The same *column-name* must not be specified more than one time.

Assignments to included columns are only processed when the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a *column-name* that is not an included column. A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

#### *expression*

Specifies the new value of the column. The expression is any expression of the type that is described in “Expressions” on page 180. The expression must not include an aggregate function.

An expression can contain references to columns of *source-table* or target. A column name is first checked as a column of the target, and then checked as a column of the source table. For each row that is updated, the value of a target column in an expression is the value of the column in the row before the row is updated. *expression* cannot contain references to an included column.

#### **DEFAULT**

Specifies the default value for the column. The value that is assigned depends on how the column is defined.

A ROWID column must not be set to the DEFAULT keyword.

An identity column or a row change timestamp column that is defined as GENERATED ALWAYS can be set only to the DEFAULT keyword.

If the column is defined using the NOT NULL clause and the GENERATED clause is not used, or the WITH DEFAULT clause is not used, the DEFAULT keyword cannot be specified for that column.

#### **NULL**

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

#### *insert-operation*

Specifies the insert operation to run for the rows where the *matching-condition* evaluates to true.

The rows that are inserted from a source-row are immediately subject for update by subsequent source-rows in the same statement.

#### **INSERT**

Specifies a list of column names and row value expressions to use of the insert operation.

The number of values for the row in the row-value expression must be equal to the number of names in the insert column list. The first value is inserted into the first column in the list, the second value into the second column, and so on.

#### *column-name*

Specifies the columns for which the insert values are provided. Each name must identify a column of the table or view

If an included column is not specified in the list of column names, the value of the included column is set to null. The column list cannot contain only included columns.

The same column must not be specified more than one time. A view column that cannot accept insert values must not be specified. A value cannot be inserted into a view column that is derived from one of the following:

- a constant, an expression, or a scalar function
- the same column of the base table as another column of the view

If the object of the operation is a view that contains columns that cannot accept insert values, a list of column names must be specified and the list must not specify these columns.

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

#### **VALUES**

Introduces one or more rows of values to insert.

#### *expression*

Specifies an expression of the type that does not include a column name of the target. If *expression* is a host variable, the host variable can identify a host structure.

#### **DEFAULT**

Specifies to assign the default value to the column. DEFAULT must only be specified for columns that have a default value. If the column is specified in the INCLUDE column list, the column value is set to null.

DEFAULT must be specified for a column that is defined as GENERATED ALWAYS. A valid value can be specified for a column that is defined as GENERATED BY DEFAULT.

#### **NULL**

Specifies the null value as the value of the column. Specify NULL only for nullable columns.

#### **NOT ATOMIC CONTINUE ON SQLEXCEPTION**

The rows of input data are processed separately. Any statement level triggers are processed for each row of source data that is processed, and the transition table includes the individual row that was processed. When errors are encountered and this option is in effect, processing continues, and some of the specified rows will not be processed. In this case, if an appropriate trigger is defined on the underlying base table, the statement level trigger will only be activated for rows that were successfully processed.

Regardless of the failure of any particular source row, the MERGE statement will not undo any changes that are made to the database by the statement. Merge will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial merge to complete), including any triggers that might have been activated as a result of the MERGE statement.

**QUERYNO** *integer*

Specifies the number for this SQL statement that is used in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If QUERYNO is not specified, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, the statement number might change.

## Notes

**SQLCA and GET DIAGNOSTICS considerations:** The GET DIAGNOSTICS statement can be used immediately after the MERGE statement to check which input rows fail during the merge operation. The GET DIAGNOSTICS statement information item, NUMBER, indicates the number of conditions that are raised. The GET DIAGNOSTICS condition information item, DB2\_ROW\_NUMBER, indicates the input source rows that cause an error.

**Trigger considerations:** A MERGE statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions based on the source data values. A before-update or before-insert trigger processes immediately before the update or insert operation.

If a source row results in an insert, any after-insert triggers are activated after the insert operation completes.

If a source row results in updates, any after-update triggers are activated after all of the update operations complete.

**Indexes with VARBINARY columns:** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

**Considerations for a MERGE without a column list in insert-operation:** A MERGE statement without a column list specified as part of *insert-operation* does not include implicitly hidden columns, so such columns must have a defined default value.

**Considerations for non-atomic processing of a MERGE statement:** When NOT ATOMIC is specified the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the MERGE statement are evaluated as each row of source data is processed. Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the operation for a row of source data, processing continues. The row that was being processed at the time of the error is not inserted or updated. Execution continues with the next row to be processed, and any other changes made during the execution of the multiple-row MERGE statement are not backed out. However, the processing of an individual row is an atomic action.

**DRDA considerations:** DB2 Connect™ Version 9.1 and subsequent releases support the MERGE statement. The support is for CLI only, with no embedded static SQL support.

When running a MERGE statement at a DB2 for z/OS requester, cases might exist where the requestor does not know the number of rows in the source table. This includes the following cases:

- For static or dynamic MERGE statements, of the FOR *n* ROWS clause contains a constant value for *n*.
- For dynamic MERGE statements, of host variables are specified on the USING clause of an EXECUTE statement.

For both of these cases, if the number of rows in the source table is not known, the requester might send more data than is required to the server. The number of rows that are actually processed will be correct because the server knows the correct numbers of rows to process. However, performance might be adversely affected. Consider the following example:

```
...long serial_num [10];
struct { short len;
char data [18];
}
name[20]...
EXEC SQL
MERGE INTO T1
  USING (VALUES (:serial_num, :name))
FOR 5 ROWS...
```

When this statement is run at the requester, the number of rows to merge (five) is not known. As a result, the requester will send 10 values for serial-name and name to the server because 10 is the size of the smallest host variable array and is, therefore, the maximum number of rows that can merge without causing an error.

Do the following to help minimize performance problems:

- Avoid using numeric constants in the FOR *n* ROWS clause of the MERGE statement. For static MERGE statements, avoiding numeric constants ensures that the values for *n* will be known at the requester.
- For dynamic MERGE statements, use the USING DESCRIPTOR clause instead of the USING *host-variable* clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for *n* must be indicated in the descriptor.
- If either of the previous methods cannot be used, do the following:
  - Make your host variable arrays as small as possible, or declare that the size of your host variable arrays are the size of *n* in the descriptor. This avoids sending a large number of unused host variable array entries to the server.
  - Ensure that varying length string arrays are initialized to a length of 0 (zero). Doing so minimizes the amount of data that is sent to the server.
  - Ensure that decimal host variable arrays are initialized to valid values. Doing so causes the requester to avoid sending a negative SQLCODE if the requester encounters invalid decimal data.

## Examples

*Example 1:* For activities that exist in the archive table, update the description in the archive table. Otherwise, insert the activity and its description into the archive table:

```

MERGE INTO ARCHIVE AR
  USING (VALUES (:hv_activity, :hv_description)
        FOR :hv_nrows ROWS)
        AS AC (ACTIVITY, DESCRIPTION)
    ON (AR.ACTIVITY = AC.ACTIVITY)
WHEN MATCHED THEN UPDATE SET DESCRIPTION = AC.DESCRIPTION
WHEN NOT MATCHED THEN INSERT (ACTIVITY, DESCRIPTION)
    VALUES (AC.ACTIVITY, AC.DESCRIPTION)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

```

*Example 2:* Use the transaction data to merge rows into the account table. Update the balance from the transaction data against an account ID and insert new accounts from the transaction data where the accounts do not already exist.

```

MERGE INTO ACCOUNT AS A
  USING (VALUES (:hv_id, :hv_amount)
        FOR 3 ROWS)
        AS T (ID, AMOUNT)
    ON (A.ID = T.ID)
WHEN MATCHED THEN UPDATE SET BALANCE = A.BALANCE + T.AMOUNT
WHEN NOT MATCHED THEN INSERT (ID, BALANCE)
    VALUES (T.ID, T.AMOUNT)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

```

*Example 3:* Update the list of activities that are organized by group A in the archive table. Update the activities information (description and date when last modified) in the archive table if the activities exist in the archive table and are also organized by group A. Insert new activities into the archive table.

```

-- hv_nrows = 3
-- hv_activity(1) = 'D'; hv_description(1) = 'Dance'; hv_date(1) = '03/01/07'
-- hv_activity(2) = 'S'; hv_description(2) = 'Singing'; hv_date(2) = '03/17/07'
-- hv_activity(3) = 'T'; hv_description(3) = 'Tai-chi'; hv_date(3) = '05/01/07'
-- hv_group = 'A';
-- note that hv_group is not an array. All 3 values contain the same values
MERGE INTO ARCHIVE AR
  USING (VALUES (:hv_activity, :hv_description, :hv_date, :hv_group)
        FOR :hv_nrows ROWS)
        AS AC (ACTIVITY, DESCRIPTION, DATE, GROUP)
    ON AR.ACTIVITY = AC.ACTIVITY AND AR.GROUP = AC.GROUP
WHEN MATCHED
THEN UPDATE SET (DESCRIPTION, DATE, LAST_MODIFIED)
    = (AC.DESCRIPTION, AC.DATE, CURRENT_TIMESTAMP)
WHEN NOT MATCHED
THEN INSERT (GROUP, ACTIVITY, DESCRIPTION, DATE, LAST_MODIFIED)
    VALUES (AC.GROUP, AC.ACTIVITY, AC.DESCRIPTION, AC.DATE, CURRENT_TIMESTAMP)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

```

**OPEN**

The OPEN statement opens a cursor so that it can be used to process rows from its result table.

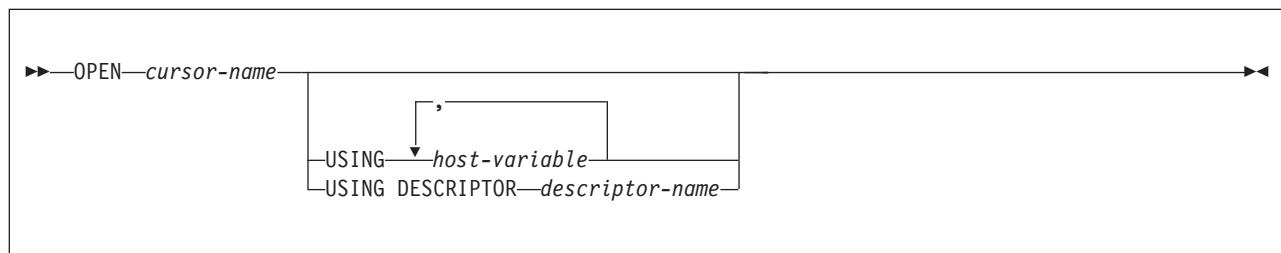

## Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

## Authorization

See “DECLARE CURSOR” on page 1191 for the authorization required to use a cursor.

## Syntax

## Description

*cursor-name*

Identifies the cursor to be opened. The *cursor-name* must identify a declared cursor as explained in “DECLARE CURSOR” on page 1191. When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement of the cursor is either one of the following types of SELECT statements:

- The *select-statement* that is specified in the DECLARE CURSOR statement
  - The prepared *select-statement* that is identified by the *statement-name* that is specified in the DECLARE CURSOR statement.

If the statement has not been successfully prepared, or is not a *select-statement*, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers or PREVIOUS VALUE expressions that are specified in the SELECT statement and the current values of any host variables that are specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement and a temporary copy of a result table can be created to hold those rows. They can be derived during the execution of later FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table. If the table is empty, the position of the cursor is effectively "after the last row." The DB2 system does not indicate an empty table when the OPEN statement is executed. But it does indicate that condition, on the first execution of FETCH, by returning values of +100 for SQLCODE and '02000' for SQLSTATE.

## USING

Introduces a list of host variables whose values are substituted for the parameter markers (question marks) or host variables in the statement of the cursor, depending on the declaration of the cursor:

- If the DECLARE CURSOR statement included *statement-name*, the statement was prepared with a PREPARE statement. The host variables specified in the USING clause of the OPEN statement replace any parameter markers in the prepared statement. This reflects the typical use of the USING clause of the OPEN statement. For an explanation of parameter marker replacement, see "PREPARE" on page 1405.

If the prepared statement includes parameter markers, you must use USING. If the prepared statement does not include parameter markers, USING is ignored.

- If the DECLARE CURSOR statement included *select-statement* and the SELECT statement included host variables, the USING clause of the OPEN statement can be used to specify host variables that are to override the values that were specified when the cursor was defined. In this case, the OPEN statement is executed as if each host variable in the SELECT statement were a parameter marker except that the attributes of the target variable are the same as the host variables in the SELECT statement. The effect is to override the values of the host variables in the SELECT statement of the cursor with the values of the host variables specified in the USING clause. The overriding value is always the value of the main variable because indicator variables are ignored in this context without warning.

### *host-variable*,...

Identifies host structures or variables that must be described in the application program in accordance with the rules for declaring host structures and variables. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter marker in the prepared statement. Where appropriate, locator variables can be provided as the source of values for parameter markers.

## DESCRIPTOR *descriptor-name*

Identifies an SQLDA that contains a valid description of the input host variables.

Before the OPEN statement is processed, the user must set the following fields in the SQLDA:

- SQL to indicate the number of SQLVAR occurrences provided in the SQLDA  
A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the result table, there must be additional SQLVAR entries for each input host variable. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see "SQL descriptor area (SQLDA)" on page 1656.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement.

See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

## Notes

**Errors occurring on OPEN:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive “delayed” errors. For example, an OPEN statement might receive an SQLCODE that normally occurs during PREPARE processing. Or a FETCH statement might receive an SQLCODE that normally occurs at OPEN time.

**Closed state of cursors:** All cursors in an application process are in the closed state when:

- The application process is started.
- A new unit of work is started for the application process unless the WITH HOLD option has been used in the DECLARE CURSOR statement.
- The application was precompiled with the CONNECT(1) option (which implicitly closes any open cursors).

A cursor can also be in the closed state because:

- A CLOSE statement was executed.
- An error was detected that made the position of the cursor unpredictable.

To retrieve rows from the result table of a cursor, you must execute a FETCH statement when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

**Effect of a temporary copy of a result table:** DB2 can process a cursor in two different ways:

- It can create a temporary copy of the result table during the execution of the OPEN statement. You can specify INSENSITIVE SCROLL on the cursor to force the use of a temporary copy of the result table.
- It can derive the result table rows as they are needed during the execution of later FETCH statements.

If the result table is not read-only, DB2 uses the latter method. If the result table is read-only, either method could be used. The results produced by these two methods could differ in the following respects:

**When a temporary copy of the result table is used:** An error can occur that would otherwise not occur until some later FETCH statement. Insert operations that are executed while the cursor is open cannot affect the result table once all the rows have been materialized in the temporary copy of the result table. For a scrollable insensitive cursor, update and delete operations that are executed while the cursor is open cannot affect the result table. For a scrollable sensitive static cursor, update and delete operations can affect the result table if the rows are subsequently fetched with sensitive FETCH statements.

**When a temporary copy of the result table is not used:** Insert, update, and delete operations that are executed while the cursor is open can affect the result table. The effect of such operations is not always predictable.

For example, if cursor C is positioned on a row of its result table defined as SELECT \* FROM T, and you insert a row into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A later FETCH C might or might not retrieve the new row of T. To avoid these changes, you can specify INSENSITIVE SCROLL for the cursor to force the use of a temporary copy of the result table.

**Parameter marker replacement:** Before the OPEN statement is executed, each parameter marker in the query is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in “Assignment and comparison” on page 102. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

- V must be compatible with the target.
- If V is a string, its length (excluding trailing blanks) must not be greater than the length attribute of the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, V must not be null.

When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by the value of its corresponding host variable. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks. For more on the process of replacement, see Parameter marker replacement.

**Considerations for scrollable cursors:** Following an OPEN cursor statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see “GET DIAGNOSTICS” on page 1317):

- DB2\_SQL\_ATTR\_CURSOR\_HOLD. Whether the cursor was defined with the WITH HOLD attribute.
- DB2\_SQL\_ATTR\_CURSOR\_SCROLLABLE. Scrollability of the cursor.
- DB2\_SQL\_ATTR\_CURSOR\_SENSITIVITY. Effective sensitivity of the cursor.

The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.

- DB2\_SQL\_ATTR\_CURSOR\_ROWSET. Whether the cursor can be used to access rowsets.
- DB2\_SQL\_ATTR\_CURSOR\_TYPE. Whether a cursor type is forward-only, static, or dynamic.

In addition, if subsystem parameter DISABSCL is set to NO, a subset of the above information is returned in the SQLCA:

- The scrollability of the cursor is in SQLWARN1.
- The sensitivity of the cursor is in SQLWARN4.
- The effective capability of the cursor is in SQLWARN5.

*Number of rows inserted:* SQL data change statements and routines that modify SQL data embedded in the cursor definition are completely executed, and the result table is stored in a temporary table when the cursor opens. If statement execution is successful, the SQLERRD(3) field contains the sum of the number of rows that qualified for insert, update, and delete operations. If an error occurs during execution of an OPEN statement that involves a cursor that contains a data change statement within a fullselect, the results of that data change statement are rolled back.

*Materialization of the rows of the result table and NEXT VALUE expressions:* If the rows of the result table of a cursor are materialized when the cursor is opened and the SELECT statement of the cursor contains NEXT VALUE expressions, the expressions are processed when the cursor is opened. Otherwise, the NEXT VALUE expressions are evaluated as the rows of the result table are retrieved.

## Example

The OPEN statement in the following example places the cursor at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8910.DEPT
  WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```

# PREPARE

The PREPARE statement creates an executable SQL statement from a string form of the statement. The character-string form is called a *statement string*. The executable form is called a *prepared statement*.

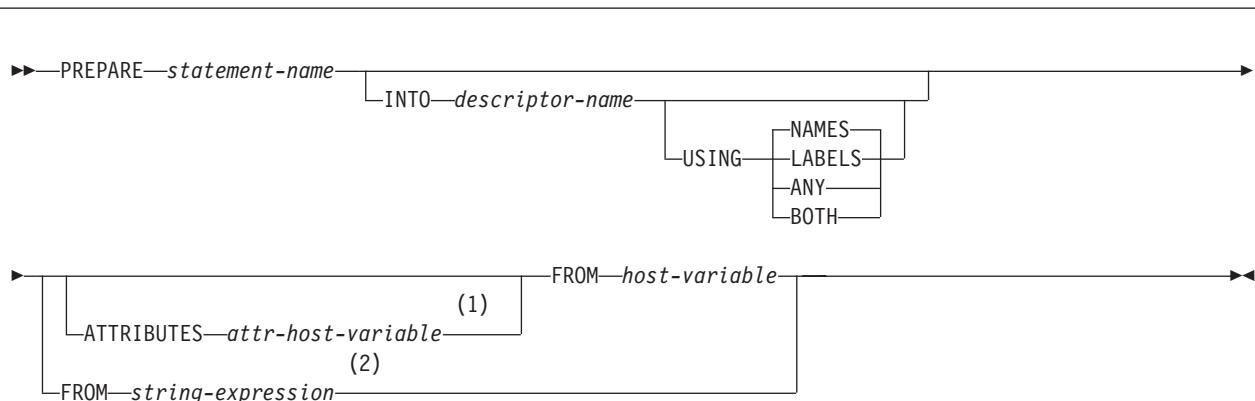

## Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

## Authorization

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by the PREPARE statement. For example, see Chapter 4, “Queries,” on page 629 for the authorization rules that apply when a SELECT statement is prepared.

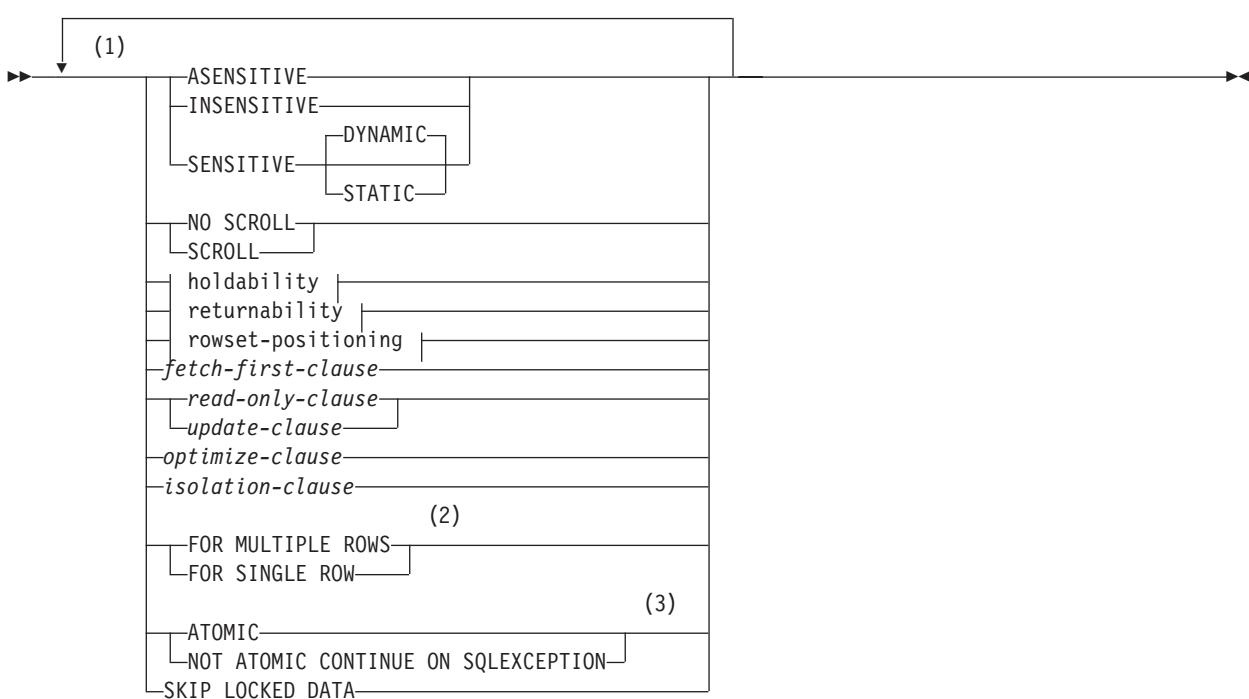

## Syntax

### Notes:

- attr-host-variable* must be a string host variable and the content must conform to the rules for attribute-string. The ATTRIBUTES clause can only be specified before *host-variable*.
  - string-expression* is only supported for PLI.

## attribute-string

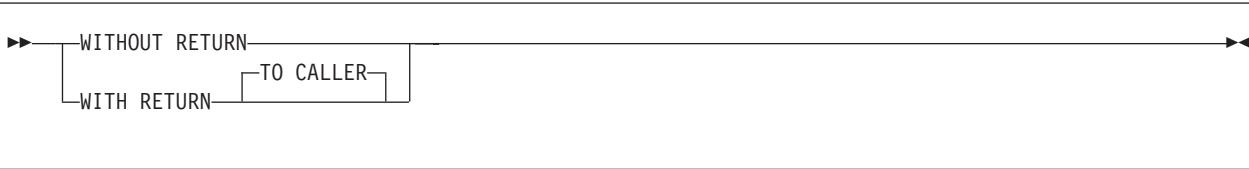

#### Notes:

- 1 The same clause must not be specified more than once. If the options are not specified, their defaults are whatever was specified for the corresponding option in an associated DECLARE CURSOR or INSERT statement.
- 2 The FOR SINGLE ROW or FOR MULTIPLE ROWS clause must only be specified for an INSERT or a MERGE statement.
- 3 The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause must only be specified for an INSERT statement.

#### holdability:

#### returnability:

#### rowset-positioning:

## Description

*statement-name*

Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed. The name must not identify a prepared statement that is the SELECT statement of an open cursor.

### INTO

If you use INTO, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the descriptor name. Thus, the PREPARE statement:

```
EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;
```

is equivalent to:

```
EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 INTO :SQLDA;
```

*descriptor-name*

Identifies the SQLDA. For languages other than REXX, SQLN must be set to indicate the number of SQLVAR occurrences. See “DESCRIBE” on page 1237 and “SQL descriptor area (SQLDA)” on page 1656 for information about how to determine the number of SQLVAR occurrences to use and for an explanation of the information that is placed in the SQLDA.

See “Identifying an SQLDA in C or C++” on page 1674 for how to represent *descriptor-name* in C.

### USING

Indicates what value to assign to each SQLNAME variable in the SQLDA when INTO is used. If the requested value does not exist, SQLNAME is set to length 0.

#### NAMES

Assigns the name of the column. This is the default.

#### LABELS

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

#### ANY

Assigns the column label, and, if the column has no label, the column name.

#### BOTH

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to  $2 \times n$  or  $3 \times n$ , where  $n$  is the number of columns in the object being described. For each of the columns, the first  $n$  occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third  $n$  occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are

no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

A REXX SQLDA does not include the SQLN field, so you do not need to set SQLN for REXX programs.

#### **ATTRIBUTES** *attr-host-variable*

Specifies the attributes for this cursor that are in effect if a corresponding attribute has not been specified as part of the outermost fullselect of the associated SELECT statement. If attributes are specified for the outermost fullselect, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

*attr-host-variable* must identify a host variable that is described in the program in accordance with the rules for declaring string variables. *attr-host-variable* must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed the maximum length of a CHAR or VARCHAR. Leading and trailing blanks are removed from the value of the host variable. The host variable must contain a valid *attribute-string*.

An indicator variable can be used to indicate whether or not attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not.

The options that can be specified as part of the *attribute-string* are as follows:

#### **ASENSITIVE, INSENSITIVE, SENSITIVE STATIC, or SENSITIVE DYNAMIC**

Specifies the desired sensitivity of the cursor to inserts, updates, or deletes that made to the rows underlying the result table. The sensitivity of the cursor determines whether DB2 can materialize the rows of the result into a temporary table. The default is ASESENTIVE.

##### **ASENSITIVE**

Specifies that the cursor should be as sensitive as possible. A cursor that defined as ASESENTIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 1400.

##### **INSENSITIVE**

Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or *attribute-string* of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

##### **SENSITIVE**

Specifies that the cursor has sensitivity to changes made to the database after the result table is materialized. The cursor is always

---

35. The scrollability and sensitivity of the cursor are independent and do not have to be specified together. Thus, the cursor might be defined as SCROLL INSENSITIVE, but the PREPARE statement might specify SENSITIVE STATIC as an override for the sensitivity.

sensitive to positioned updates and deletes that are made using the same cursor. However, the *select-statement* of the cursor must not contain an SQL data change statement if the cursor is defined as either SENSITIVE DYNAMIC or SENSITIVE STATIC. When the current value of a row no longer satisfies the *select-statement* or *statement-name*, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

In addition, the cursor has sensitivity to changes made to values outside the cursor (that is, by other cursors or committed changes by other application processes). If DB2 can not make changes made outside the cursor visible to the cursor, an error is issued at OPEN CURSOR. Whether the cursor is sensitive to changes made outside this cursor depends on whether DYNAMIC or STATIC is in effect for the cursor and whether SENSITIVE or INSENSITIVE FETCH statements are used.

Whether the cursor is sensitive to newly inserted rows depends on whether DYNAMIC or STATIC is in effect for the cursor. The default is DYNAMIC.

#### **DYNAMIC**

Specifies that the result table of the cursor is dynamic in that the size of the result table can change after the cursor is opened as rows are inserted into or deleted from the underlying table, and the order of the rows can change. Inserts, deletes, and updates that are made by the same application process are immediately visible. Inserts, deletes, and updates that are made by other application processes are visible after they are committed.

All FETCH statements for sensitive dynamic cursors are sensitive to changes made by this cursor, changes made by other cursors in the same application process, and committed changes made by other application processes.

If a SENSITIVE DYNAMIC cursor is not possible, an error is returned, an error is returned.

#### **STATIC**

Specifies that the order of the rows and size of the result table is static. The size of the result table does not grow after the cursor is opened and the rows are materialized. The order of the rows is established as the result table is materialized. Rows that are inserted into the underlying table are not added to the result table of the cursor regardless of how the rows were inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized.

Whether the changes that are made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor. For more information, see Considerations for FETCH statements used with a sensitive static cursor.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of *select-statement* or *statement-name* of a SENSITIVE STATIC cursor can cause misleading results. This occurs because DB2 constructs a temporary result table and retrieves rows from this table for INSENSITIVE FETCH statements.

When DB2 processes a SENSITIVE FETCH statement, rows are fetched from the underlying table and predicates are re-evaluated if they contain non-correlated subqueries. Using a function that is not deterministic can yield a different result for the re-evaluated query causing the row to no longer be considered a match.

If SENSITIVE STATIC is specified and a sensitive static cursor is not possible, then an error is returned.

If ASENSITIVE, INSENSITIVE, SENSITIVE DYNAMIC, or SENSITIVE STATIC is specified as part of the ATTRIBUTES clause, SCROLL must be specified.

**SCROLL or NO SCROLL**

Specifies whether the cursor is scrollable.

**SCROLL**

Specifies that the cursor is scrollable.

**NO SCROLL**

Specifies that the cursor is not scrollable.

**WITHOUT RETURN or WITH RETURN TO CALLER**

Specifies the intended use of the result table of the cursor.

**WITHOUT RETURN**

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from the program or procedure.

**WITH RETURN TO CALLER**

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from the program or procedure to the caller. Specifying TO CALLER is optional.

When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or procedure, that cursor defines a result set from the program or procedure. Use the CLOSE statement to close cursors that are not intended to be a result set from the program or procedure. Although DB2 will automatically close any cursors that are not declared using WITH RETURN TO CALLER, the use of the CLOSE statement is recommended to increase the portability of applications. (For Java external procedures, all cursors are implicitly declared WITH RETURN TO CALLER.)

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

The caller is the program or procedure that executed the SQL CALL statement that either invokes a procedure that contains the DECLARE CURSOR statement, or directly or indirectly invokes a program that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

*rowset-positioning*

Specifies whether rows of data can be accessed as a rowset on a single FETCH statement for this cursor.

#### **WITHOUT ROWSET POSITIONING**

Specifies that the cursor can only be used with row positioned FETCH statements.

#### **WITH ROWSET POSITIONING**

Specifies that this cursor can be used with rowset positioned or row positioned FETCH statements

##### *fetch-first-clause*

Limits the number of rows that can be fetched. It improves the performance of queries with potentially large result sets when only a limited number of rows are needed. If the clause is specified, the number of rows retrieved will not exceed  $n$ , where  $n$  is the value of the integer. An attempt to fetch  $n+1$  rows is handled the same way as normal end of date. The value of integer must be positive and non-zero. The default is 1.

If the OPTIMIZE FOR clause is not specified, a default of "OPTIMIZE FOR integer ROWS" is assumed. If both the FETCH FIRST and OPTIMIZE FOR clauses are specified, the lower of the integer values from these clauses is used to influence optimization and the communications buffer size.

##### *read-only-clause*

Declares that the result table is read-only and therefore the cursor cannot be referred to in positioned UPDATE and DELETE statements.

##### *update-clause*

Identifies the columns that can be updated in a later positioned UPDATE statement. Each column must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only. The clause must also not be specified if a created temporary table is referenced in the first FROM clause of the select-statement.

If the clause is specified without a list of columns, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

##### *optimize-clause*

Requests special optimization of the *select-statement*. If the clause is omitted, optimization is based on the assumption that all rows of the result table will be retrieved. If the clause is specified, optimization is based on the assumption that the number of rows retrieved will not exceed  $n$ , where  $n$  is the value of the integer. The clause does not limit the number of rows that can be fetched or affect the result in any way other than performance.

##### *isolation-clause*

Specifies the isolation level at which the statement is executed and, for *select-statement*, the type of locks that are acquired. See "isolation-clause" on page 676.

#### **FOR MULTIPLE ROWS or FOR SINGLE ROW**

Specifies if a variable number of rows will be provided for a dynamic INSERT or MERGE statement.

#### **FOR MULTIPLE ROWS**

Specifies that multiple rows can be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR MULTIPLE ROWS must only be specified for an INSERT or a MERGE statement.

**FOR SINGLE ROW**

Specifies that multiple rows must not be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR SINGLE ROW must only be specified for an INSERT or a MERGE statement.

**ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies if all rows are inserted as an atomic operation. This clause can only be specified for dynamic INSERT statements.

**ATOMIC**

Specifies that if the insert for any row fails, all changes that are made to the database by any of the inserts, including changes that are made by successful inserts, are undone. This is the default.

**NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes that are made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

This clause must not be specified if the INSERT statement is contained within a SELECT statement.

For preparing the MERGE statement, atomicity is specified only on the MERGE statement itself.

**SKIP LOCKED DATA**

Specifies that the select-statement, searched UPDATE statement (including a searched update operation in a MERGE statement), or searched DELETE statement that is prepared in the PREPARE statement will skip rows when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

SKIP LOCKED DATA can be specified only in the searched UPDATE statement. SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR).

**FROM**

Specifies the statement string. The statement string is the value of the specified *string-expression* or the identified *host-variable*.

***host-variable***

Must identify a host variable that is described in the application program in accordance with the rules for declaring string variables. If the source string is over 32KB in length, the *host-variable* must be a CLOB or DBCLOB variable. The maximum source string length is 2MB although the host variable can be declared larger than 2MB. An indicator variable must not be specified. In PL/I, COBOL and Assembler language, the host variable must be a varying-length string variable. In C, the host variable must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable and the value must not be null.

***string-expression***

*string-expression* is any PL/I expression that yields a string. *string-expression*

cannot be preceded by a colon. Variables that are within *string-expression* that include operators or functions should not be preceded by a colon. When *string-expression* is specified, the precompiler-generated structures for *string-expression* use an EBCDIC CCSID and an informational message is returned.

## Notes

**Rules for statement strings:** The value of the specified *statement-name* is called the *statement string*. The statement string must be one of the following SQL statements:

ALLOCATE CURSOR	RELEASE SAVEPOINT
ALTER	RENAME
ASSOCIATE LOCATORS	REVOKE
COMMENT	ROLLBACK
COMMIT	SAVEPOINT
CREATE	<i>select-statement</i>
DECLARE GLOBAL TEMPORARY TABLE	SET CURRENT DEGREE
DELETE	SET CURRENT DEBUG MODE
DROP	SET CURRENT DECFLOAT ROUNDING MODE
EXPLAIN	SET CURRENT LOCALE LC_CTYPE
FREE LOCATOR	SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
GRANT	SET CURRENT OPTIMIZATION HINT
HOLD LOCATOR	SET CURRENT PRECISION
INSERT	SET CURRENT REFRESH AGE
LABEL	SET CURRENT ROUTINE VERSION
LOCK TABLE	SET CURRENT RULES
MERGE	SET CURRENT SQLID
REFRESH TABLE	SET ENCRYPTION PASSWORD
	SET PATH
	SET SCHEMA
	SIGNAL
	TRUNCATE
	UPDATE

The statement string must not:

- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables

**Parameter markers:** Although a statement string cannot include references to host variables, it can include *parameter markers*. The parameter markers are replaced by the values of host variables when the prepared statement is executed. A parameter marker is a question mark (?) that appears where a host variable could appear if the statement string were a static SQL statement. For an explanation of how parameter markers are replaced by values, see the EXECUTE statement, “OPEN” on page 1400, and *DB2 Application Programming and SQL Guide*.

The two types of parameter markers are typed and untyped:

### Typed parameter marker

A parameter marker that is specified with its target data type. A typed parameter marker has the general form:

CAST(? AS data-type)

This invocation of a CAST specification is a “promise” that the data type of the parameter at run time will be of the data type that is specified or some data type that is assignable to the specified data type. For example, in the following UPDATE statement, the value of the argument of the TRANSLATE function will be provided at run time:

```
UPDATE EMPLOYEE
  SET LASTNAME = TRANSLATE(CAST(? AS VARCHAR(12)))
 WHERE EMPNO = ?
```

The data type of the value that is provided for the TRANSLATE function will either be VARCHAR(12), or some data type that can be converted to VARCHAR(12). For more information, refer to “Assignment and comparison” on page 102.

#### Untyped parameter marker

A parameter marker that is specified without its target data type. An untyped parameter marker has the form of a single question mark. The context in which the parameter marker appears determines its data type. For example, in the above UPDATE statement, the data type of the untyped parameter marker in the predicate is the same as the data type of the EMPNO column.

Typed parameter markers can be used in dynamic SQL statements wherever a host variable is supported and the data type is based on the promise made in the CAST specification.

Untyped parameters markers can be used in dynamic SQL statements in selected locations where host variables are supported. Table 126, Table 127 on page 1416, Table 128 on page 1417, and Table 129 on page 1418 show these locations and the resulting data type of the parameter. The tables group the locations into expressions, predicates, functions, and other statements to help show where untyped parameter markers are allowed.

*Table 126. Untyped parameter marker usage in expressions (including select list, CASE, and VALUES)*

Location of untyped parameter marker	Data type (or error if not supported)
Alone in a select list. For example:  SELECT ?	Error
Both operands of a single arithmetic operator, after considering operator precedence and the order of operation rules.  Includes cases such as:  ? + ? + 10	Error
One operand of a single operator in an arithmetic expression (except datetime arithmetic expressions). Includes cases such as:  ? + ? * 10	The data type of the other operand
Any operand of a datetime expression. For example:  'timecol + ?' or '? - datecol'	Error
Labeled duration in a datetime expression	Error
Both operands of a CONCAT operator	Error

*Table 126. Untyped parameter marker usage in expressions (including select list, CASE, and VALUES) (continued)*

Location of untyped parameter marker	Data type (or error if not supported)
One operand of a CONCAT operator when the other operand is any character data type except CLOB	If the other operand is CHAR( <i>n</i> ) or VARCHAR( <i>n</i> ), where <i>n</i> is less than 128, the data type is VARCHAR(254 - <i>n</i> ). In all other cases, the data type is VARCHAR(254).
One operand of a CONCAT operator when the other operand is any graphic data type except DBCLOB	If the other operand is GRAPHIC( <i>n</i> ) or VARGRAPHIC( <i>n</i> ), where <i>n</i> is less than 64, the data type is VARGRAPHIC(127 - <i>n</i> ). In all other cases, the data type is VARGRAPHIC(127).
One operand of a CONCAT operator when the other operand is any binary type except BLOB	If the other operand is BINARY( <i>n</i> ) or VARBINARY( <i>n</i> ) where <i>n</i> is less than 128, the data type is VARBINARY(255- <i>n</i> ). In all other cases, the data type is VARBINARY(255)
One operand of a CONCAT operator when the other operand is a LOB string	The data type of the other operand (the LOB string)
The <i>expression</i> following the CASE keyword in a simple CASE expression	Error
Any or all <i>expressions</i> following the WHEN keyword in a simple CASE expression	The result of applying the “Rules for result data types” on page 119 to the expression following CASE and the expressions following WHEN that are not untyped parameter markers
A <i>result-expression</i> in any CASE expression when all the other <i>result-expressions</i> are either NULL or untyped parameter markers.	Error
A <i>result-expression</i> in any CASE expression when at least one other <i>result-expression</i> is neither NULL nor an untyped parameter marker.	The result of applying the “Rules for result data types” on page 119 to all the <i>result-expressions</i> that are not NULL or untyped parameter markers
Alone as a <i>column-expression</i> in a single-row VALUES clause that is not within an INSERT statement or the VALUES clause of an insert operation of a MERGE statement	Error
Alone as a <i>column-expression</i> in a single-row VALUES clause within an INSERT statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type
Alone as a <i>column-expression</i> in a <i>values-single-row</i> or <i>values-multiple-row</i> clause of <i>source-table</i> for a MERGE statement	The data type of the column of the source-table, or if the data type is a distinct type, the source data type of the distinct type. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type.
Alone as a <i>column-expression</i> in the VALUES clause of an insert operation of a MERGE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type
Alone as a <i>column-expression</i> on the right side of <i>assignment-clause</i> for an update operation of a MERGE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type

*Table 126. Untyped parameter marker usage in expressions (including select list, CASE, and VALUES) (continued)*

Location of untyped parameter marker	Data type (or error if not supported)
Alone as a <i>column-expression</i> on the right side of a SET clause in an UPDATE statement	The data type of the column or, if the column is defined as a distinct type, the source data type of the distinct type

*Table 127. Untyped parameter marker usage in predicates*

Location of untyped parameter marker	Data type (or error if not supported)
Both operands of a comparison operator	Error
One operand of a comparison operator when the other operand is not an untyped parameter marker	The data type of the other operand. If the operand has a datetime data type, the result of DESCRIBE INPUT will show the data type as CHAR(255) although DB2 uses the datetime data type in any comparisons.
All the operands of a BETWEEN predicate	Error
Two operands of a BETWEEN predicate (either the first and second, or the first and third)	The data type of the operand that is not a parameter marker
Only one operand of a BETWEEN predicate	The result of applying the “Rules for result data types” on page 119 on the other operands that are not parameter markers
All the operands of an IN predicate, for example, ? IN (?, ?, ?)	Error
The first and second operands of an IN predicate, for example, ? IN (?, A, B)	The result of applying the “Rules for result data types” on page 119 on the operands in the IN list that are not parameter markers
The first operand of an IN predicate and zero or more operands of the IN list except for the first operand of the IN list, for example, ? IN (A, ?, B, ?)	The result of applying the “Rules for result data types” on page 119 on the operands in the IN list that are not parameter markers
The first operand of an IN predicate when the right side is a fullselect or fullselect, for example, ? IN (fullselect)	The data type of the selected column
Any or all operands of the IN list of the IN predicate and the first operand of the IN predicate is not an untyped parameter marker, for example, A IN (?, A, ?)	The data type of the first operand (the operand on the left side of the IN list)
All the operands of a LIKE predicate	The first and second operands ( <i>match-expression</i> and <i>pattern-expression</i> ) are VARCHAR(4000). The third operand ( <i>escape-expression</i> ) is VARCHAR(1).
The first operand (the <i>match-expression</i> ) when at least one other operand (the <i>pattern-expression</i> or <i>escape-expression</i> ) is not an untyped parameter marker.	VARCHAR(4000), VARGRAPHIC(2000), or VARBINARY(4000), depending on the data type of the first operand that is not an untyped parameter marker

*Table 127. Untyped parameter marker usage in predicates (continued)*

<b>Location of untyped parameter marker</b>	<b>Data type (or error if not supported)</b>
The second operand (the <i>pattern-expression</i> ) when at least one other operand (the <i>match-expression</i> or <i>escape-expression</i> ) is not an untyped parameter marker. When the pattern specified in a LIKE predicate is a parameter marker and a fixed-length character host variable is used to replace the parameter marker, specify a value for the host variable that is the correct length. If you do not specify the correct length, the select does not return the intended results.	VARCHAR(4000), VARGRAPHIC(2000), or VARBINARY(4000), depending on the data type of the first operand that is not an untyped parameter marker.
The third operand (the <i>escape-expression</i> ) when at least one other operand (the <i>match-expression</i> or <i>pattern-expression</i> ) is not an untyped parameter marker	CHAR(1), GRAPHIC(1), or BINARY(1), depending on the data type of the first operand that is not an untyped parameter marker
Operand of a NULL predicate	Error

*Table 128. Untyped parameter marker usage in functions*

<b>Location of untyped parameter marker</b>	<b>Data type (or error if not supported)</b>
All arguments of COALESCE or NULLIF	Error
Any argument of COALESCE or NULLIF when at least one other argument is not an untyped parameter marker	The result of applying the “Rules for result data types” on page 119 on the arguments that are not untyped parameter markers, the data type of the other argument
First argument of COLLATION_KEY	VARGRAPHIC(2000)
Second argument of COLLATION_KEY	VARCHAR(255)
First argument of LOWER	VARCHAR(4000)
Second argument of LOWER	VARCHAR(255)
Any argument other than the first argument of MAX	The data type of the corresponding parameter in the function instance
Any argument other than the first argument of MIN	The data type of the corresponding parameter in the function instance
Both arguments of POSSTR or POSITION	VARCHAR(4000) for both arguments
One argument of POSSTR or POSITION when the other argument is a character data type	VARCHAR(4000)
One argument of POSSTR or POSITION when the other argument is a graphic data type	VARGRAPHIC(2000)
One argument of POSSTR or POSITION when the other argument is a BINARY or VARBINARY data type	VARBINARY(4000)
One argument of POSSTR or POSITION when the other argument is a BLOB	BLOB(4000)
First argument of SUBSTR or SUBSTRING	VARCHAR(4000)
Second or third argument of SUBSTR or SUBSTRING	INTEGER
One argument of TIMESTAMP	TIME

*Table 128. Untyped parameter marker usage in functions (continued)*

<b>Location of untyped parameter marker</b>	<b>Data type (or error if not supported)</b>
First argument of TIMESTAMP_FORMAT	VARCHAR(255)
First argument of TRANSLATE	Error
Second or third argument of TRANSLATE	VARCHAR(4000), VARGRAPHIC(2000), depending on whether the data type of the first argument is character or graphic
Fourth argument of TRANSLATE	VARCHAR(1) or VARGRAPHIC(1), depending on whether the data type of the first argument is character or graphic
First argument of UPPER	VARCHAR(4000)
Second argument of UPPER	VARCHAR(255)
First argument of VARCHAR_FORMAT	TIMESTAMP
Unary minus	DOUBLE PRECISION
Unary plus	DOUBLE PRECISION
The argument of any built-in scalar function (except those that are described in this table)	Error
The argument of a built-in aggregate function	Error
The argument of a user-defined scalar function, user-defined aggregate function, or user-defined table function	The data type of the corresponding parameter in the function instance

*Table 129. Untyped parameter marker usage in statements*

<b>Location of untyped parameter marker</b>	<b>Data type (or error if not supported)</b>
FOR <i>n</i> ROWS clause of an INSERT or MERGE statement	Integer
The value on the right side of a SET clause in an UPDATE statement or the UPDATE clause of the MERGE statement	The data type of the column of the source-table, or if the column is defined as a distinct type, the source data type of the distinct type. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type.

**Considerations for FETCH statements used with a sensitive static cursor:** Whether changes made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor:

- A SENSITIVE FETCH is sensitive to all updates and deletes that are made by this cursor (including changes made by triggers) and committed updates and deletes by all other application processes because every fetched row is retrieved from the underlying base table and not a temporary table. This is the default type of FETCH statement for a SENSITIVE cursor.

Changes that are made to the underlying data using this cursor result in an automatic refresh of the row. The changes that are made using this type of cursor can result in holes in the result table of the cursor. In addition, re-fetching rows (fetching rows that have already been retrieved) can result in holes in the result table. If a sensitive FETCH is issued to re-fetch a row and the row no

longer qualifies for the search condition of the query, it results in a "delete hole" or an "update hole". In this case, no data is returned, and the cursor is left positioned on the hole.

- An INSENSITIVE FETCH is not sensitive to updates and deletes that are made outside this cursor; however, it is sensitive to all updates and deletes that are made by this cursor. Changes that made with triggers are not visible with an INSENSITIVE FETCH until the content of the rows are updated in the result table with a SENSITIVE FETCH statement. If an application does not want to be sensitive to changes that are made outside this cursor (that is, the application does not want to see changes made either with another cursor or by another application process), INSENSITIVE can be explicitly specified as part of the FETCH statement for a SENSITIVE STATIC cursor. This type of FETCH is useful for refreshing data in user data buffers. For more information, see INSENSITIVE.

**Error checking:** When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is invalid, a prepared statement is not created and the error condition that prevents its creation is reported in the SQLCA.

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive "delayed" errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

**Reference and execution rules:** Prepared statements can be referred to in the following kinds of statements, with the following restrictions shown:

**In... The prepared statement...**

**DESCRIBE**

has no restrictions

**DECLARE CURSOR**

must be SELECT when the cursor is opened

**EXECUTE**

must *not* be SELECT

A prepared statement can be executed many times. Indeed, if a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.

**Prepared statement persistence:** All prepared statements created by a unit of work are destroyed when the unit of work is terminated, with the following exceptions:

- A SELECT statement whose cursor is declared with the option WITH HOLD persists over the execution of a commit operation if the cursor is open when the commit operation is executed.
- SELECT, INSERT, UPDATE, MERGE, and DELETE statements that are bound with KEEPDYNAMIC(YES) are kept past the commit operation if your system is enabled for dynamic statement caching, and none of the following are true:
  - SQL RELEASE has been issued for the site
  - Bind option DISCONNECT(AUTOMATIC) was used
  - Bind option DISCONNECT(CONDITIONAL) was used and there are no hold cursors for the site

**Scope of a statement name:** The scope of a *statement-name* is the same as the scope of a *cursor-name*. See “DECLARE CURSOR” on page 1191 for more information about the scope of a *cursor-name*.

**Preparation with PREPARE INTO and REOPT bind option:** If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, PREPARE INTO is equivalent to a PREPARE and a DESCRIBE being performed. If a statement has input variables, the DESCRIBE causes the statement to be prepared with default values, and the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid having a statement prepared twice, avoid using PREPARE INTO when REOPT(ALWAYS) or REOPT(ONCE) is in effect.

**Relationship of cursor attributes on PREPARE statements and SELECT or DECLARE CURSOR statements:** Cursor attributes that are specified as part of the *select-statement* are used instead of any corresponding options that specified with the ATTRIBUTES clause on PREPARE. Attributes that are specified as part of the ATTRIBUTES clause of PREPARE take precedence over any corresponding option that is specified with the DECLARE CURSOR statement. The order for using cursor attributes is as follows:

- SELECT (highest priority)
- PREPARE statement ATTRIBUTES clause
- DECLARE CURSOR (lowest priority)

For example, assume that host variable MYQ has been set to the following SELECT statement:

```
SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM  
      FROM EMP  
     WHERE WORKDEPT IN ('D11', 'D21')  
        FOR UPDATE OF SALARY, BONUS, COMM
```

If the following PREPARE statement were issued, then the FOR UPDATE clause specified as part of the SELECT statement would be used instead of the FOR READ ONLY clause specified with the ATTRIBUTES clause as part of the PREPARE statement. Thus, the cursor would be updatable.

```
attrstring = 'FOR READ ONLY';  
EXEC SQL PREPARE stmt1 ATTRIBUTES :attrstring FROM :MYQ;
```

## Examples

*Example 1:* In this PL/I example, an INSERT statement with parameter markers is prepared and executed. Before execution, values for the parameter markers are read into the host variables S1, S2, S3, S4, and S5.

```
EXEC SQL PREPARE DEPT_INSERT FROM  
  'INSERT INTO DSN8910.DEPT VALUES(?,?,?,?,?)';  
-- Check for successful execution and read values into host variables  
EXEC SQL EXECUTE DEPT_INSERT USING :S1, :S2, :S3, :S4, :S5;
```

*Example 2:* Prepare a dynamic SELECT statement specifying the attributes of the cursor with a host variable on the PREPARE statement. Assume that the text of the SELECT statement is in a variable named stmttxt, and that the desired attributes of the cursor are in a variable named attrvar.

```
EXEC SQL DECLARE mycursor CURSOR FOR mystmt;  
EXEC SQL PREPARE mystmt ATTRIBUTES :attrvar  
      FROM :stmttxt;
```

```
EXEC SQL DESCRIBE mystmt INTO :mysqllda;
EXEC SQL OPEN mycursor;
EXEC SQL FETCH FROM mycursor USING DESCRIPTOR :mysqllda;
```

## REFRESH TABLE

The REFRESH TABLE statement refreshes the data in a materialized query table. The statement deletes all rows in the materialized query table, executes the fullselect in the table definition to recalculate the data from the tables specified in the fullselect, inserts the calculated result into the materialized query table, and updates the catalog for the refresh timestamp and cardinality of the table. The table can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

The privilege set for REFRESH TABLE must include at least one of the following authorities:

- Ownership of the materialized query table
- DBADM or DBCTRL authority on the database that contains the materialized query table
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statements dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke). For more information on these behaviors, including a list of the DYNAMICRULES bind option values, see “Authorization IDs and dynamic SQL” on page 64.

### Syntax

```
►►REFRESH TABLE—table-name►►
    [QUERYNO—integer]►►
```

### Description

#### *table-name*

Identifies the table to be refreshed. The name must identify a materialized query table. REFRESH TABLE evaluates the fullselect in the *materialized-query-definition* clause to refresh the table. The isolation level for the fullselect is the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued.

#### QUERYNO *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan

table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

## Notes

Automatic query rewrite using materialized query tables is not attempted for the fullselect in the materialized query table definition during the processing of REFRESH TABLE statement.

After successful execution of a REFRESH TABLE statement, the SQLCA field SQLERRD(3) will contain the number of rows inserted into the materialized query table.

The EXPLAIN output for REFRESH TABLE *table-name* is the same as the EXPLAIN output for INSERT INTO *table-name* *fullselect* where *fullselect* is from the materialized query table definition.

The REFRESH TABLE statement is supported over DRDA protocol, but not supported over DB2 private protocol.

If the materialized query table has a security label column, the REFRESH TABLE statement does not do any checking for multilevel security with row-level granularity when it deletes and repopulates the data in the table by executing the fullselect. Instead, DB2 performs the checking for multilevel security with row-level granularity when the materialized query table is exploited in automatic query rewrite or is used directly.

The REFRESH TABLE statement can be used to remove a table space from the logical page list and reset recover-pending status. This can only be done by using REFRESH TABLE to repopulate a materialized query table where the materialized query table is the only table in the table space.

## Example

Issue a statement to refresh the content of a materialized query table that is named SALES COUNT. The statement recalculates the data from the fullselect that was used to define SALES COUNT and refreshes the content of SALES COUNT with the recalculated results.

```
REFRESH TABLE SALES COUNT;
```

# **RELEASE (connection)**

The RELEASE (connection) statement places one or more connections in the release pending state.

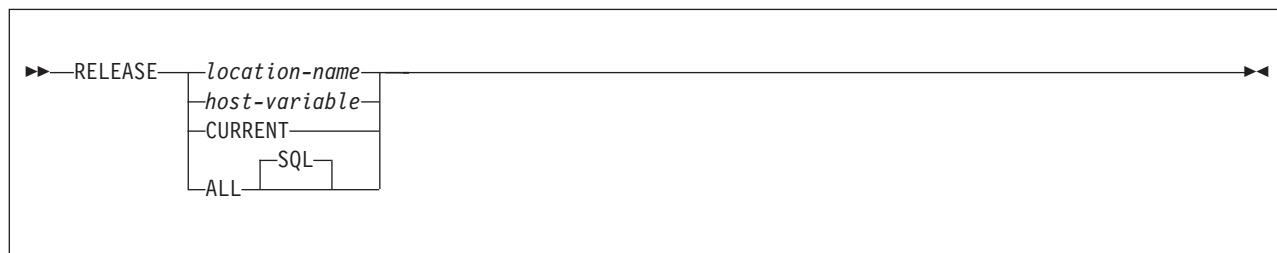

## Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

## Authorization

None required.

## Syntax

## Description

*location-name or host-variable*

Identifies an SQL connection or a DB2 private connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
  - It must not be followed by an indicator variable.
  - The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
  - If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

The specified location name or the location name contained in the host variable must identify an existing SQL connection or DB2 private connection of the application process.

CURRENT

Identifies the current SQL connection of the application process. The application process must be in the connected state.

ALL or ALL SOL

Identifies all existing connections (including local, and SQL, and DB2 private connections) of the application process. An error or warning does not occur if no connections exist when the statement is executed.

If the RELEASE (connection) statement is successful, each identified connection is placed in the release-pending state and, therefore, will be ended during the next

commit operation. If the RELEASE (connection) statement is unsuccessful, the connection state of the application process and the states of its connections are unchanged.

## Notes

***RELEASE and CONNECT (Type 1):*** Using CONNECT (Type 1) semantics does not prevent using RELEASE (connection).

***Scope of RELEASE:*** RELEASE (connection) does not close cursors, does not release any resources, and does not prevent further use of the connection.

***Resource considerations for remote connections:*** Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be in the release pending status and one that is going to be reused should not be in the release pending status. Remote connections can also be ended during a commit operation as a result of the DISCONNECT(AUTOMATIC) or DISCONNECT(CONDITIONAL) bind option.

If the current SQL connection is in the release pending status when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement should be CONNECT or SET CONNECTION.

***Connection states:*** ROLLBACK does not reset the state of a connection from release pending to held.

If the current SQL connection is in the release pending state when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement must be CONNECT or SET CONNECTION.

For further information, see “Application process connection states” on page 34.

***Location names CURRENT and ALL:*** A database server named CURRENT or ALL can only be identified by a host variable or a delimited identifier. A connection in the release pending state is ended during a commit operation even though it has an open cursor defined with WITH HOLD.

***Encoding scheme of a host variable:*** If the RELEASE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

***ALL PRIVATE:*** ALL PRIVATE can continue to be specified as in prior releases. The clause was introduced and was intended for use only with DB2 private protocol access. ALL PRIVATE specifies that all existing DB2 private connections of the application process are to be released. An error or warning does not occur if no DB2 private connections exist when the statement is executed.

## Examples

***Example 1:*** The SQL connection to TOROLAB1 is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```
EXEC SQL RELEASE TOROLAB1;
```

*Example 2:* The current SQL connection is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```
EXEC SQL RELEASE CURRENT;
```

*Example 3:* The first phase of an application involves explicit CONNECTs to remote servers and the second phase involves the use of DB2 private protocol access with the local DB2 subsystem as the server. None of the existing connections are needed in the second phase and their existence could prevent the allocation of DB2 private connections. Accordingly, the following statement is executed before the commit operation that separates the two phases:

```
EXEC SQL RELEASE ALL SQL;
```

## RELEASE SAVEPOINT

The RELEASE SAVEPOINT statement releases the identified savepoint and any subsequently established savepoints within a unit of recovery.

### Invocation

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►—RELEASE—T0—SAVEPOINT—savepoint-name—►►
```

### Description

*savepoint-name*

Identifies the savepoint to release. If the named savepoint does not exist, an error occurs. The name must identify a savepoint that exists at the current server. After a savepoint is released, it is no longer maintained and rollback to the savepoint is no longer possible.

### Notes

**Savepoint names:** The name of the savepoint that was released can be reused in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement that specified this same savepoint name.

### Example

Assume that a main routine sets savepoint A and then invokes a subroutine that sets savepoints B and C. When control returns to the main routine, release savepoint A and any subsequently set savepoints. Savepoints B and C, which were set by the subroutine, are released in addition to A.

```
:  
RELEASE SAVEPOINT A;
```

## RENAME

The RENAME statement renames an existing table or index.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

### Authorization

To rename a table, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the table
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

To rename an index, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table for which the index is defined
- Ownership of the index that is being renamed
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the index
- SYSADM or SYSCTRL authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

### Syntax

```
►►RENAME [TABLE] source-table-name TO new-table-identifier  
        INDEX source-index-name TO new-index-identifier
```

### Description

*source-table-name*

Identifies the existing table that is to be renamed. The name, including the implicit or explicit qualifier, must identify a table that exists at the current server. The name must not identify a declared temporary table, a catalog table, an active resource limit specification table, a materialized query table, a clone

table, a table with a trigger defined on it, a view, or a synonym. If you specify a three-part name or alias for the source table, the source table must exist at the current server. If any view definitions or materialized query table definitions currently refer to the source table, an error occurs.

*new-table-identifier*

Specifies the new name for the table without a qualifier. The qualifier of the *source-table-name* is used to qualify the new name for the table. The qualified name must not identify a table, view, alias, or synonym that exists at the current server.

*source-index-name*

Identifies the existing index that is to be renamed. The name, including an implicit or explicit qualifier, must identify an index that exists at the current server. The name must not identify a system defined catalog index, an index for a declared temporary table, or an index for an active resource limit specification table.

*new-index-identifier*

Specifies that new name for the index without a qualifier. The qualifier of the *source-index-name* is used to qualify the new name for the index. The qualified name must not identify an index that exists at the current server.

## Notes

**Effects of the statement:** The specified table or index is renamed to the new name. For a renamed table, all privileges and indexes on the table are preserved. For a renamed index, all privileges are preserved.

**Invalidation of plans and packages:** When any table except an auxiliary table is renamed, plans and packages that refer to that table are invalidated. When an auxiliary table is renamed, plans and packages that refer to the auxiliary table are not invalidated.

**Considerations for aliases:** If an alias name is specified for *table-name*, the table must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table name after the rename.

Changing the name of an alias with the RENAME statement is not supported. To change the name to which an alias refers, you must drop the alias and then recreate it.

**Considerations for plan tables:** The RENAME INDEX statement does not update the contents of a plan table. Rows that exist in a plan table that are generated from a EXPLAIN statement can contain the name of an index in the access path selections. When an index is renamed, any entries in existing plan tables that refer to the old index name are not updated.

**Transfer of authorization, referential integrity constraints, and indexes:** All authorizations associated with the source table name are transferred to the new (target) table name. The authorization catalog tables are updated appropriately.

Referential integrity constraints involving the source table are updated to refer to the new table. The catalog tables are updated appropriately.

Indexes that are defined for the source table are *transferred* to the new table. The index catalog tables are updated appropriately.

| *Object identifier:* Renamed tables and indexes keep the same object identifier as the original table or index.

| *Renaming registration tables:* If an application registration table (ART) or object registration table (ORT) or an index of an ART or ORT is specified as the source table for RENAME, when RENAME completes, it is as if that table had been dropped. There is no ART or ORT once the ART or ORT table has been renamed.

*Catalog table updates:* Entries in the following catalog tables are updated to reflect the new table:

- SYSAUXRELS
- SYSCHECKS
- SYSCHECKS2
- SYSCHECKDEP
- SYSCOLAUTH
- SYSCOLDIST
- SYSCOLDIST\_HIST
- SYSCOLDISTSTATS
- SYSCOLSTATS
- SYSCOLUMNS
- SYSCOLUMNS\_HIST
- SYSCONSTDEP
- SYSFIELDS
- SYSFOREIGNKEYS
- SYSINDEXES
- SYSINDEXES\_HIST
- SYSKEYCOLUSE
- SYSPLANDEP
- SYSPACKDEP
- SYSRELS
- SYSSEQUENCESDEP
- SYSSYNONYMS
- SYSTABAUTH
- SYTABCONST
- SYSTABLES
- SYSTABLES\_HIST
- SYSTABSTATS
- SYSTABSTATS\_HIST

Entries in SYSSTMT and SYSPACKSTMT are not updated.

| Entries in the following catalog tables are updated to reflect the new index:

- SYSDEPENDENCIES
- SYSINDEXES
- SYSINDEXES\_HIST

- SYSINDEXESPART
- SYSINDEXESPART\_HIST
- SYSINDEXSPACESTATS
- SYSINDEXSTATS
- SYSINDEXSTATS\_HIST
- SYSKEYS
- SYSKEYTARGETS
- SYSKEYTARGETS\_HIST
- SYSKEYTARGETSTATS
- SYSKEYTGTDIST
- SYSKEYTGTDIST\_HIST
- SYSKEYTGTDISTSTATS
- SYSOBJROLEDEP
- SYSPACKDEP
- SYSPLANDEP
- SYSRELS
- SYSTABCONST
- SYSTABLEPART
- SYSVTREE

## **Examples**

*Example 1:* Change the name of the EMP table to EMPLOYEE:

```
RENAME TABLE EMP TO EMPLOYEE;
```

*Example 2:* Change the name of the EMP\_USA\_HIS2002:

```
RENAME TABLE EMP_USA_HIS2002 TO EMPLOYEE_UNITEDSTATES_HISTORY2002;
```

*Example 3:* Change the name of the EMPIDX1 to EMPLOYEE\_INDEX:

```
RENAME INDEX COMPANY.EMPIDX1 TO EMPLOYEE_INDEX;
```

---

## REVOKE

The REVOKE statement revokes privileges from authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Distinct type
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Use

The applicable objects are always at the current server.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

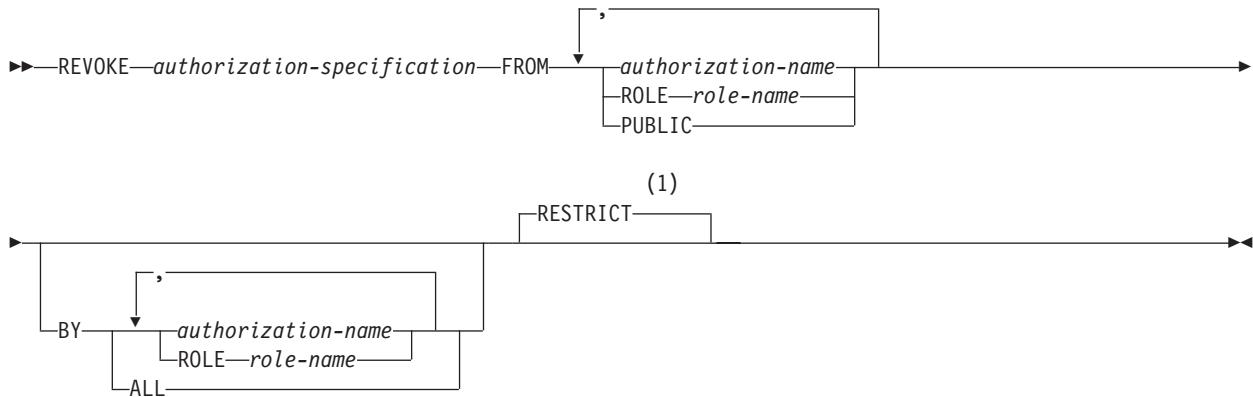

If the authorization mechanism was not activated when the DB2 subsystem was installed, an error condition occurs.

### Authorization

If the BY clause is not specified, the authorization ID of the statement must have granted at least one of the specified privileges to every *authorization-name* specified in the FROM clause (including PUBLIC, if specified). If the BY clause is specified, the authorization ID of the statement must have SYSADM or SYSCTRL authority.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. The owner can be a role. If the statement is dynamically prepared, the privilege set is the privileges that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER CLAUSE, the privilege set is the privileges that are held by the role that is in effect.

## Syntax

### Notes:

- 1 The RESTRICT clause is the default only for the forms of the REVOKE statement that allow it.

## Description

### *authorization-specification*

Specifies one or more privileges for the class of privilege. The same privilege must not be specified more than once.

### **FROM**

Specifies from what authorization IDs the privileges are revoked.

### *authorization-name*,...

Lists one or more authorization IDs. Do not use the same authorization ID more than one time. If the *authorization-name* is specified in lowercase, it must be delimited using double quotes.

The value of CURRENT RULES determines if you can use the ID of the REVOKE statement itself (to revoke privileges from yourself). When CURRENT RULES is:

**DB2** You cannot use the ID of the REVOKE statement.

### **STD**

You can use the ID of the REVOKE statement.

### **ROLE** *role-name*

Lists one or more roles. Do not specify the same role more than one time.

### **PUBLIC**

Revokes a grant of privileges to PUBLIC.

**BY** Lists grantors who have granted privileges and revokes each named privilege that was explicitly granted to some named user by one of the named grantors. Only an authorization ID or role with SYSADM or SYSCTRL authority can use BY, even if the authorization ID or role names only itself in the BY clause.

### *authorization-name*,...

Lists one or more authorization IDs of users who were the grantors of the privileges named. Do not use the same authorization ID more than once. Each grantor that is listed must have explicitly granted some named privilege to all of the named users or roles.

|     **ROLE** *role-name*  
|         Lists one or more roles that were the grantors of the privileges named. Do  
|         not specify the same role more than one time. Each grantor that is listed  
|         must have explicitly granted some named privilege to all of the named  
|         users or roles.

|     **ALL**

|         Revokes each named privilege from all named users who were explicitly  
|         granted the privilege, regardless of who granted it.

|     **RESTRICT**

|         Prevents the named privilege from being revoked when certain conditions  
|         apply. RESTRICT is the default only for the forms of the REVOKE statement  
|         that allow it. These forms are revoking the USAGE privilege on distinct types,  
|         the EXECUTE privilege on user-defined functions and stored procedures, and  
|         the USAGE privilege on sequences.

## Notes

*Revoked privileges:* The privileges revoked from an authorization ID or a role are those that are identified in the statement and which were granted to the user by the grantor. Other privileges can be revoked as the result of a cascade revoke. For more on DB2 privileges, see *DB2 Administration Guide*.

*Cascade revoke:* Revoking a privilege from a user can also cause that privilege to be revoked from other users. This is called a *cascade revoke*. The following rules must be true for privilege P' to be revoked from U3 when U1 revokes privilege P from U2:

- P and P' are the same privilege.
- U2 granted privilege P' to U3.
- No one granted privilege P to U2 prior to the grant by U1.
- U2 does not have installation SYSADM authority.

The rules also apply to the implicit grants that are made as a result of a CREATE VIEW statement.

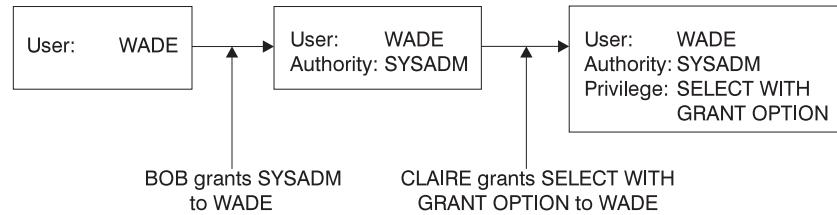

Cascade revoke does not occur under any of the following conditions:

- The privilege was granted by a current install SYSADM.
- The privilege is the USAGE privilege on a distinct type and the revokee owns any of these items:
  - A user-defined function or stored procedure that uses the distinct type
  - A table that has a column that uses the distinct type
  - A sequence whose data type is the distinct type
- The privilege is the USAGE privilege on a sequence and the revokee owns any of these items:
  - A trigger that has a NEXT VALUE or PREVIOUS VALUE expression that specifies the sequence
  - An inline SQL function that has a NEXT VALUE or PREVIOUS VALUE expression in the function body that specifies the sequence
- The privilege is the EXECUTE privilege on a user-defined function and the revokee owns any of these items:
  - A user-defined function that is sourced on the function
  - A view that uses the function

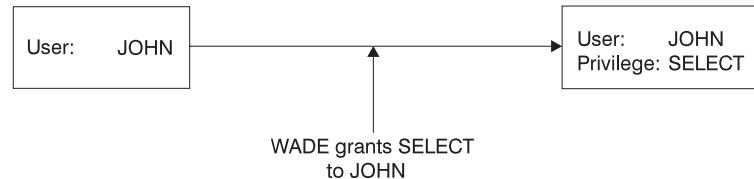

- A trigger package that uses the function
- A table that uses the function in a check constraint or a user-defined default type
- The privilege is the EXECUTE privilege on a stored procedure and the revoker owns any of these items:
  - A trigger package that refers to the stored procedure in a CALL statement.

Refer to the diagrams for the following example:

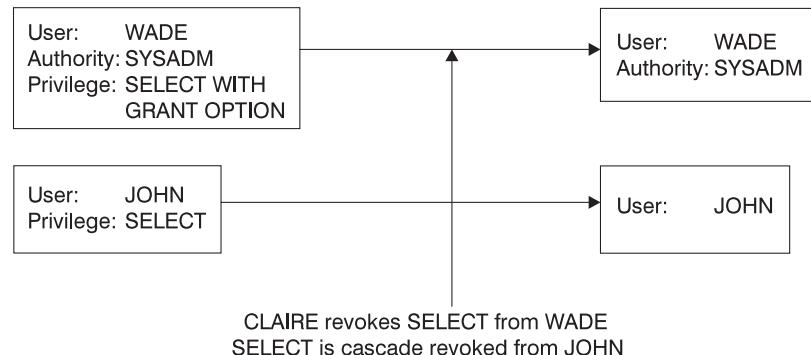

1. Suppose BOB grants SYSADM authority to WADE. Later, CLAIRE grants the SELECT privilege on a table with the WITH GRANT OPTION to WADE.

2. WADE grants the SELECT privilege to JOHN on the same table.

3. When CLAIRE revokes the SELECT privilege on the table from WADE, the SELECT privilege on that table is also revoked from JOHN.

The grant from WADE to JOHN is removed because WADE had not been granted the SELECT privilege from any other source before CLAIRE made the grant. The SYSADM authority granted to WADE from BOB does not affect the cascade revoke. For more on SYSADM and install SYSADM authority, see *DB2 Administration Guide*. For another example of cascading revokes, see *DB2 Administration Guide*.

Revoking a SELECT privilege that was exercised to create a view or materialized query table causes the view to be dropped, unless the owner of the view was directly granted the SELECT privilege from another source before the view was created. Revoking a SYSADM privilege that was required to create a view causes

the view to be dropped. For details on when SYSADM authority is required to create a view, see *Authorization* in “CREATE VIEW” on page 1184.

***Invalidation of plans and packages:*** A revoke or cascaded revoke of any privilege or role that was exercised to create a plan or package makes the plan or package invalid when the revoker no longer holds the privilege from any other source. Corresponding authorization caches are cleared even if the revoker has the privilege from any other source.<sup>36</sup>

***Inoperative plans and packages:*** A revoke or cascaded revoke of the EXECUTE privilege on a user-defined function that was exercised to create a plan or package makes the plan or package inoperative and causes the corresponding authorization caches to be cleared when the revoker no longer holds the privilege from any other source.<sup>36</sup>

***Privileges belonging to an authority:*** You can revoke an administrative authority, but you cannot separately revoke the specific privileges inherent in that administrative authority.

Let P be a privilege inherent in authority X. A user with authority X can also have privilege P as a result of an explicit grant of P. In this case:

- If X is revoked, the user still has privilege P.
- If P is revoked, the user still has the privilege because it is inherent in X.

***Revoking of privileges in a trusted context:*** Revokes that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the revoker being the role in effect. If the statement is prepared dynamically, the revoker is the role that is associated with the user that is running the statement. If the statement is embedded in a program, the revoker is the owner of the plan or package. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the revoker is the authorization ID of the process.

***Ownership privileges:*** The privileges inherent in the ownership of an object cannot be revoked.

***PUBLIC AT ALL LOCATIONS:*** PUBLIC AT ALL LOCATIONS can continue to be specified as an alternative to PUBLIC as in prior releases. PUBLIC AT ALL LOCATIONS was introduced and was intended for use only with DB2 private protocol access. PUBLIC AT ALL LOCATIONS revokes a grant of the specified privileges from PUBLIC at all locations.

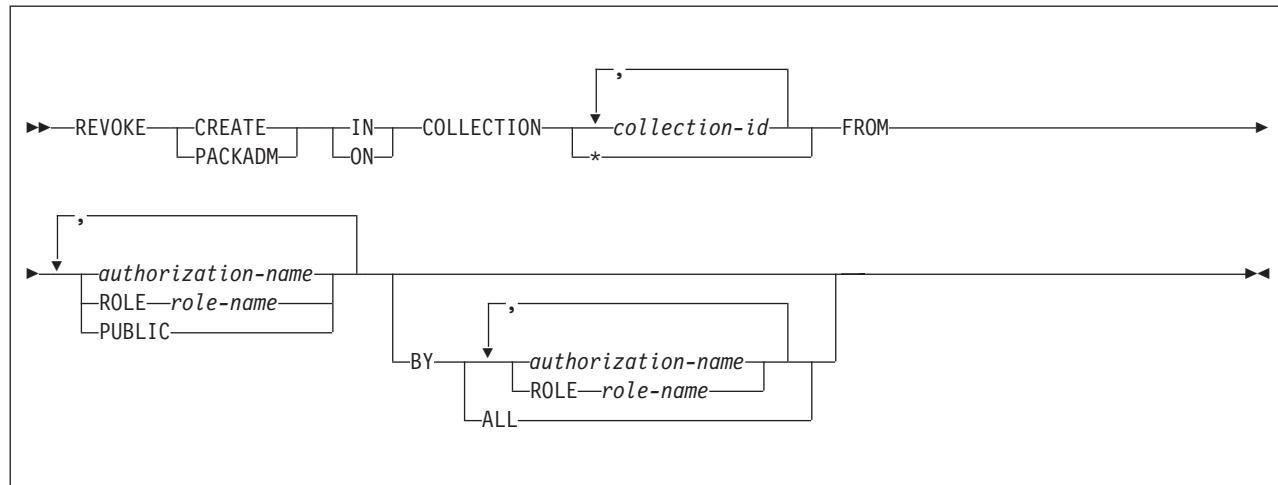

---

36. Dependencies on stored procedures can be checked only if the procedure name is specified as a constant and not via a host variable in the CALL statement.

## REVOKE (collection privileges)

This form of the REVOKE statement revokes privileges on collections.

### Syntax

### Description

#### CREATE IN

Revokes the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

#### PACKADM ON

Revokes the package administrator authority for the designated collections.

The word IN can be used instead of ON.

#### COLLECTION *collection-id*,...

Identifies the collections on which the specified privilege is revoked. For each identified collection, you (or the indicated grantors) must have granted the specified privilege on that collection to all identified users (including PUBLIC if specified). The same collection must not be identified more than once.

#### COLLECTION \*

Indicates that the specified privilege on COLLECTION \* is revoked. You (or the indicated grantors) must have granted the specified privilege on COLLECTION \* to all identified users (including PUBLIC if specified). Privileges granted on specific collections are not affected.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

#### BY

Refer to "REVOKE" on page 1432 for a description of the BY clause.

### Examples

*Example 1:* Revoke the privilege to create new packages in collections QAACLONE and DSN8CC61 from CLARK.

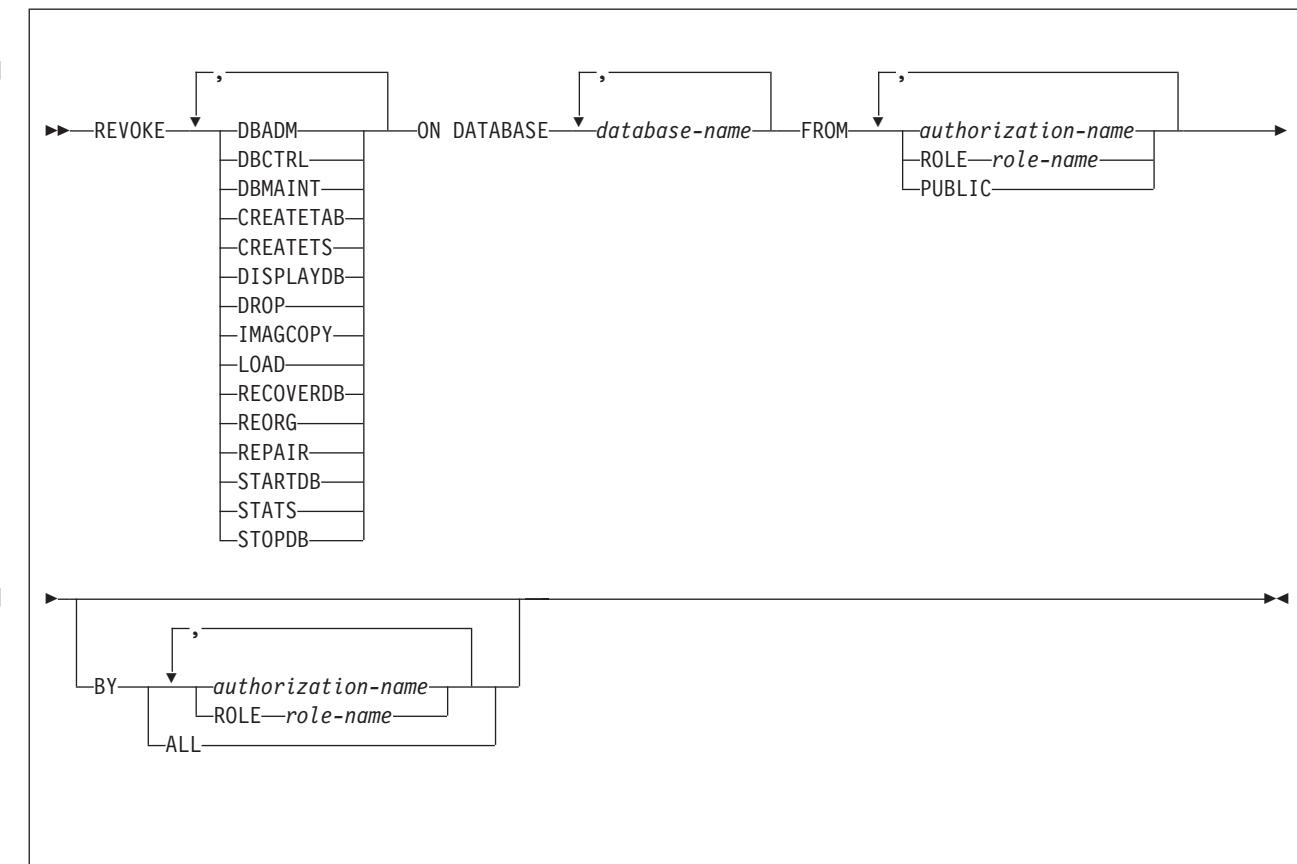

```
REVOKE CREATE IN COLLECTION QAACLONE, DSN8CC61 FROM CLARK;
```

| *Example 2:* Revoke the privilege to create new packages in collections DSN8CC91  
| from role ROLE1:  
| REVOKE CREATE IN COLLECTION DSN8CC91 FROM ROLE ROLE1;  
|

## REVOKE (database privileges)

This form of the REVOKE statement revokes database privileges.

### Syntax

### Description

Each keyword listed revokes the privilege described, but only as it applies to or within the databases named in the statement.

#### DBADM

Revokes the database administrator authority.

#### DBCTRL

Revokes the database control authority.

#### DBMAINT

Revokes the database maintenance authority.

#### CREATETAB

Revokes the privilege to create new tables. If CREATETAB privilege is revoked from DSNDB04, tables cannot be created in implicitly created databases. For a work file database, you cannot revoke the privilege from PUBLIC. When a work file database is created, PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

#### CREATESTS

Revokes the privilege to create new table spaces.

**DISPLAYDB**

Revokes the privilege to issue the DISPLAY DATABASE command.

**DROP**

Revokes the privilege to issue the DROP or ALTER statements in the specified databases.

**IMAGCOPY**

Revokes the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

**LOAD**

Revokes the privilege to use the LOAD utility to load tables.

**RECOVERDB**

Revokes the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

**REORG**

Revokes the privilege to use the REORG utility to reorganize table spaces and indexes.

**REPAIR**

Revokes the privilege to use the REPAIR and DIAGNOSE utilities.

**STARTDB**

Revokes the privilege to issue the START DATABASE command.

**STATS**

Revokes the privilege to use the RUNSTATS utility to update statistics, and the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

**STOPDB**

Revokes the privilege to issue the STOP DATABASE command.

**ON DATABASE *database-name*, ...**

Identifies databases on which you are revoking the privileges. For each database you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that database to all identified users (including PUBLIC, if specified). The same database must not be identified more than once.

**FROM**

Refer to “REVOKE” on page 1432 for a description of the FROM clause.

**BY** Refer to “REVOKE” on page 1432 for a description of the BY clause.

## Examples

*Example 1:* Revoke drop privileges on database DSN8D91A from user PEREZ.

```
REVOKE DROP  
  ON DATABASE DSN8D91A  
  FROM PEREZ;
```

*Example 2:* Revoke repair privileges on database DSN8D91A from all local users.  
(Grants to specific users will not be affected.)

```
REVOKE REPAIR  
  ON DATABASE DSN8D91A  
  FROM PUBLIC;
```

*Example 3:* Revoke authority to create new tables and load tables in database DSN8D91A from users WALKER, PIANKA, and FUJIMOTO.

```
REVOKE CREATETAB,LOAD  
ON DATABASE DSN8D91A  
FROM WALKER,PIANKA,FUJIMOTO;
```

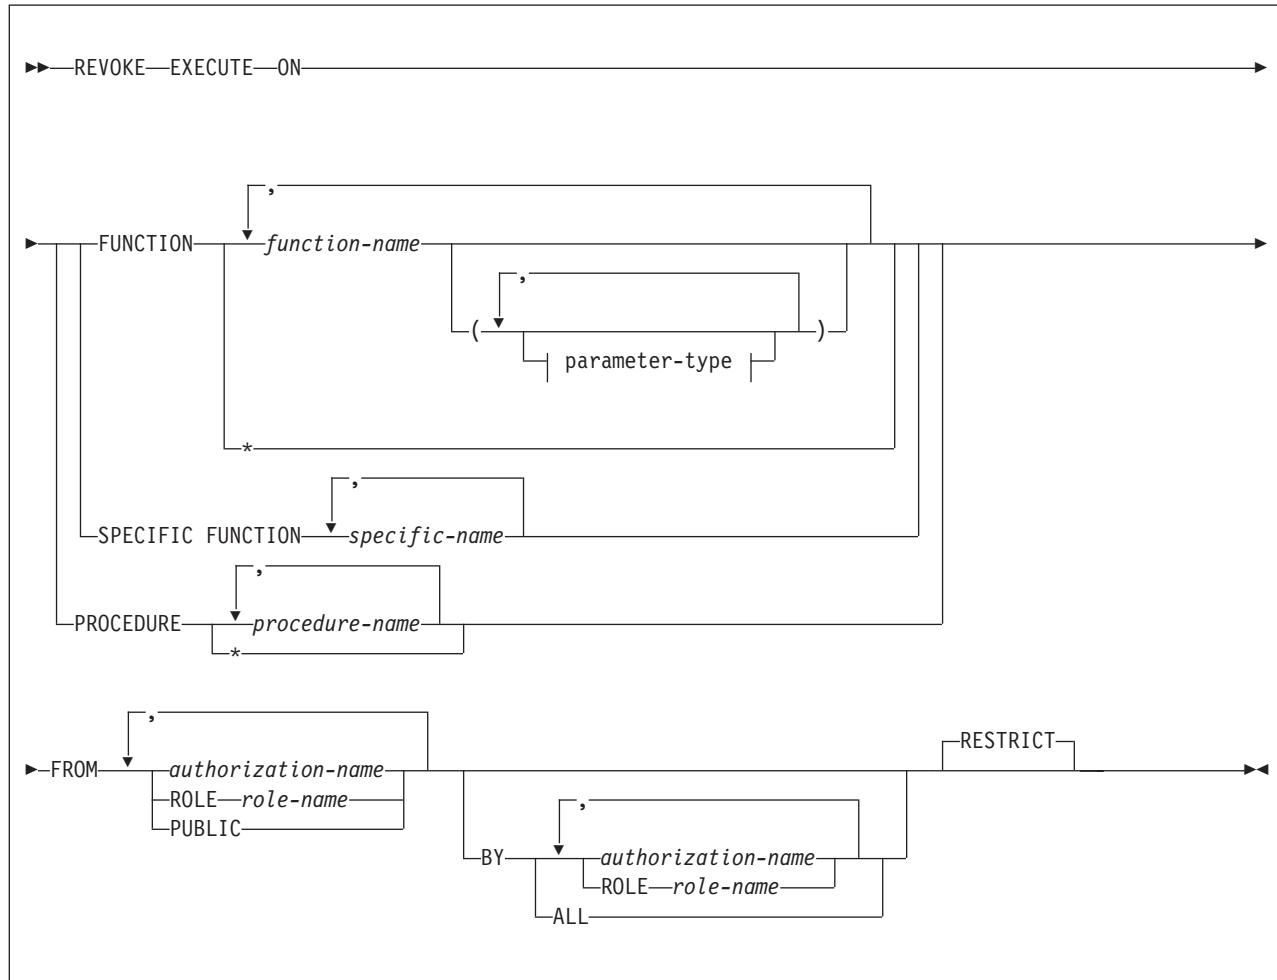

*Example 4:* Revoke load privileges on database DSN8D91A from role ROLE1:

```
REVOKE LOAD  
ON DATABASE DSN8D91A  
FROM ROLE ROLE1;
```

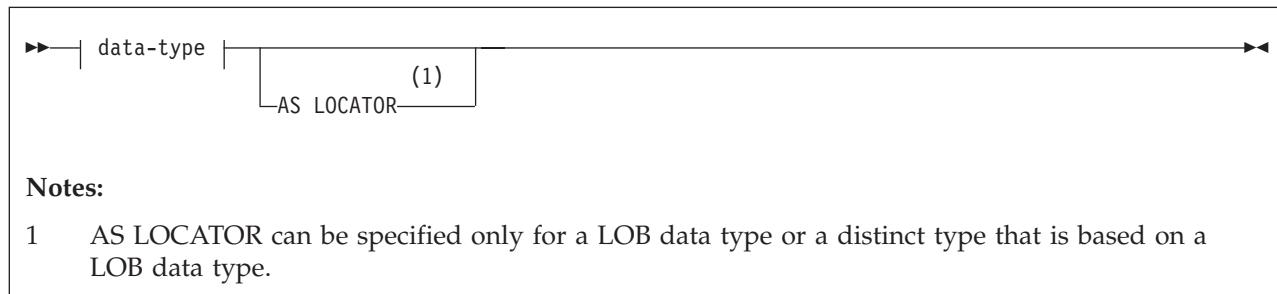

## REVOKE (function or procedure privileges)

This form of the REVOKE statement revokes privileges on user-defined functions, cast functions that were generated for distinct types, and stored procedures.

### Syntax

parameter-type:

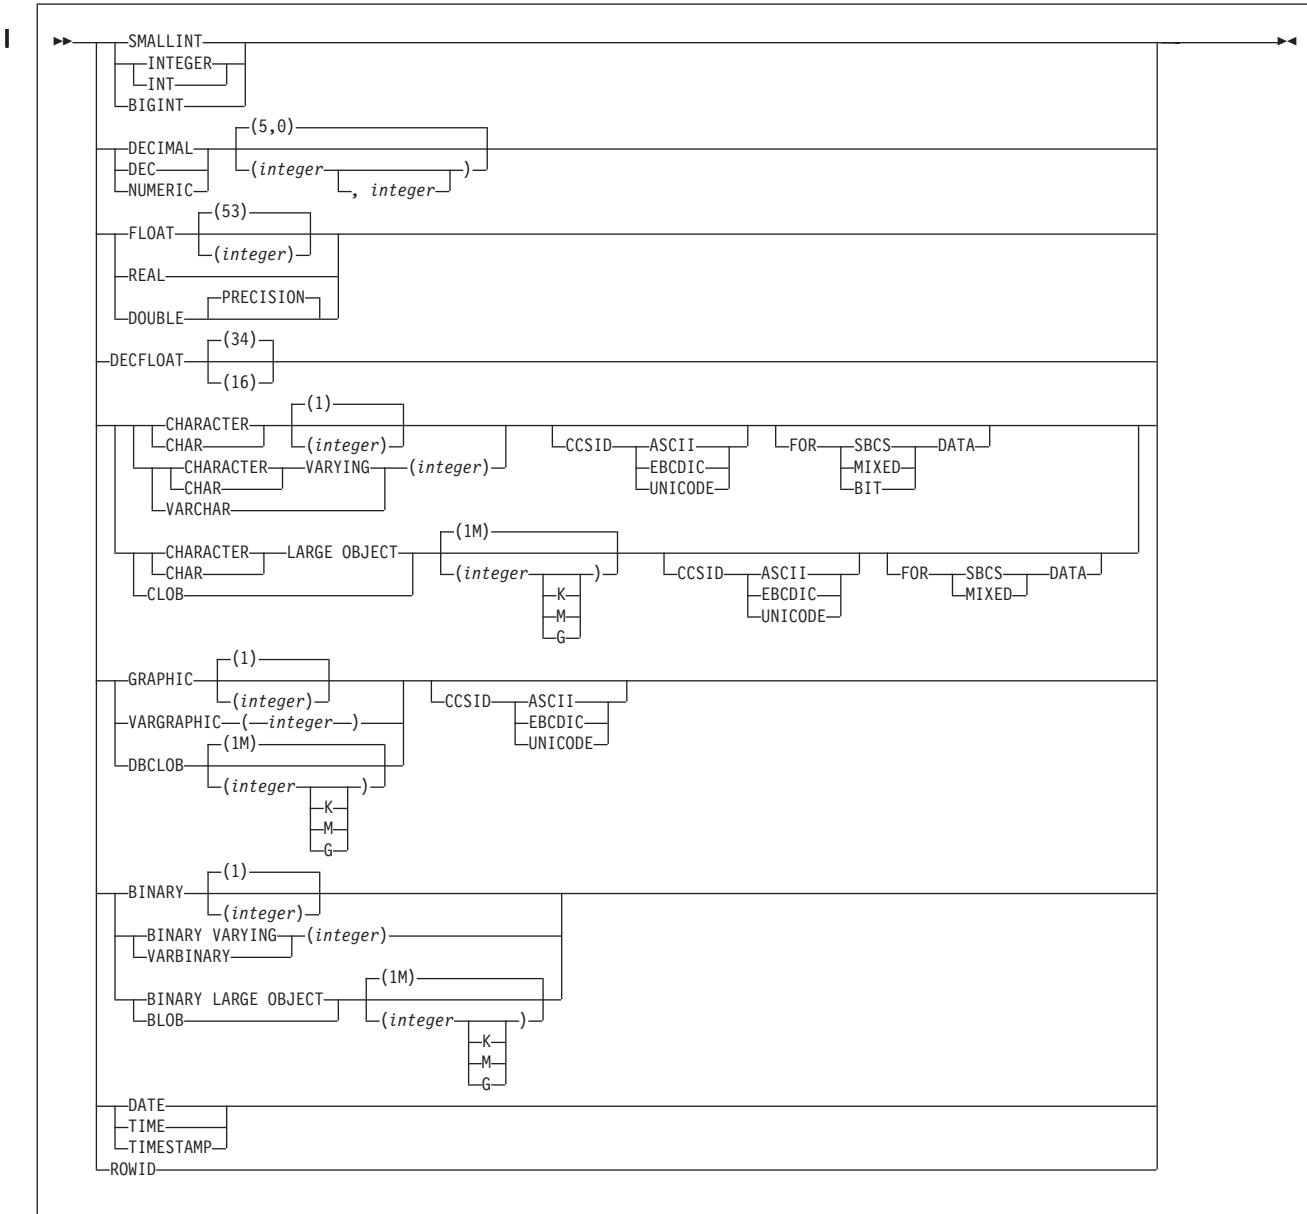

#### Notes:

- 1 AS LOCATOR can be specified only for a LOB data type or a distinct type that is based on a LOB data type.

data-type:

**built-in-type:**

## Description

### EXECUTE

Revokes the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

### FUNCTION or SPECIFIC FUNCTION

Identifies the function from which the privilege is revoked. The function must exist at the current server, and it must be a function that was defined with the

CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

**FUNCTION** *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An \* can be specified for a qualified or unqualified *function-name*. An \* (or *schema-name.\**) indicates that the privilege is revoked for all the functions in the schema. You (or the indicated grantors) must have granted the privilege on FUNCTION \* to all identified users (including PUBLIC if specified). Privileges granted on specific functions are not affected.

**FUNCTION** *function-name (parameter-type, ...)*

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

*function-name*

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

*(parameter-type, ...)*

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or

| DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).
- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR *subtype* DATA clause or the CCSID clause is optional.

Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

**SPECIFIC FUNCTION** *specific-name*

Identifies the function by its specific name. The *specific-name* must identify a specific function that exists at the current server.

**PROCEDURE** *procedure-name*

Identifies a stored procedure that is defined at the current server.

An \* can be specified for a qualified or unqualified *procedure-name*. An \* (or *schema-name.\**) indicates that the privilege is revoked for all the procedures in the schema. You (or the indicated grantors) must have granted the privilege on PROCEDURE \* to all identified users (including PUBLIC if specified). Privileges granted on specific procedures are not affected.

**FROM**

Refer to “REVOKE” on page 1432 for a description of the FROM clause.

**BY** Refer to “REVOKE” on page 1432 for a description of the BY clause.

**RESTRICT**

Prevents the EXECUTE privilege from being revoked on a user-defined function or stored procedure if the revoker owns any of the following objects and does not have the EXECUTE privilege from another source:

- A function that is sourced on the function
- A view that uses the function
- A trigger package that uses the function or stored procedure
- A table that uses the function in a check constraint or user-defined default clause
- A materialized query table whose fullselect uses the function
- An extended index that uses the function

|

## Examples

*Example 1:* Revoke the EXECUTE privilege on function CALC\_SALARY for user JONES. Assume that there is only one function in the schema with function CALC\_SALARY.

```
REVOKE EXECUTE ON FUNCTION CALC_SALARY FROM JONES;
```

*Example 2:* Revoke the EXECUTE privilege on procedure VACATION\_ACCR from all users at the current server.

```
REVOKE EXECUTE ON PROCEDURE VACATION_ACCR FROM PUBLIC;
```

*Example 3:* Revoke the privilege of the administrative assistant to grant EXECUTE privileges on function DEPT\_TOTAL to other users. The administrative assistant will still have the EXECUTE privilege on function DEPT\_TOTALS.

```
REVOKE EXECUTE ON FUNCTION DEPT_TOTALS  
FROM ADMIN_A;
```

*Example 4:* Revoke the EXECUTE privilege on function NEW\_DEPT\_HIRES for HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW\_DEPT\_HIRES.

```
REVOKE EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))  
FROM HR;
```

You can also code the CHAR(10) data type as CHAR().

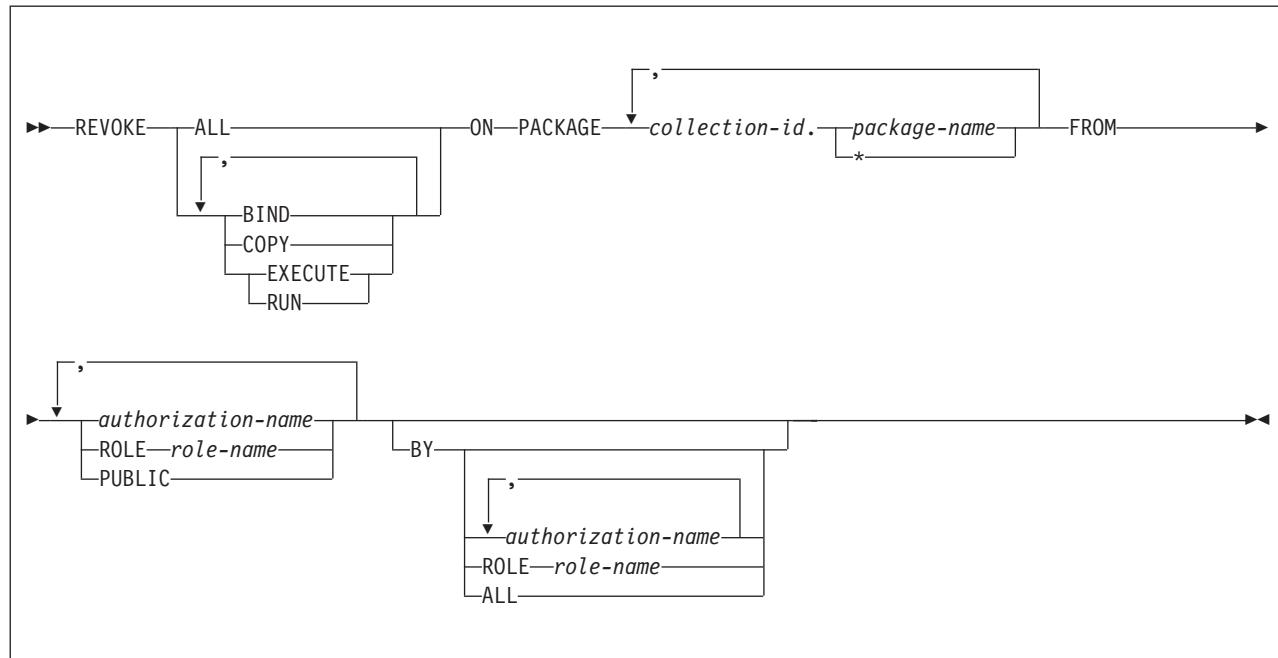

*Example 5:* Revoke the EXECUTE privilege on function FIND\_EMPDEPT from role ROLE1:

```
REVOKE EXECUTE ON FUNCTION FIND_EMPDEPT  
FROM ROLE ROLE1;
```

## REVOKE (package privileges)

This form of the REVOKE statement revokes privileges on packages.

### Syntax

### Description

#### BIND

Revokes the privilege to use the BIND and REBIND subcommands for the designated packages. In addition, if the value of field BIND NEW PACKAGE on installation panel DSNTIPP is BIND, the additional BIND privilege of adding new versions of packages is revoked. (For details, see "Notes" on page 1346 for "GRANT (package privileges)" on page 1345.)

#### COPY

Revokes the privilege to use the COPY option of the BIND subcommand for the designated packages.

#### EXECUTE

Revokes the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

#### ALL

Revokes all package privileges for which you have authority for the packages named in the ON clause.

#### ON PACKAGE *collection-id.package-name*,...

Identifies packages for which you are revoking privileges. The revoking of a package privilege applies to all versions of that package. For each package that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that package to all identified users (including PUBLIC, if specified). An authorization ID with PACKADM authority over the

collection or all collections, SYSADM, or SYSCTRL authority can specify all packages in the collection by using \* for *package-name*. The same package must not be specified more than once.

**FROM**

Refer to “REVOKE” on page 1432 for a description of the FROM clause.

**BY** Refer to “REVOKE” on page 1432 for a description of the BY clause.

**Notes**

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports specifying PROGRAM as a synonym for PACKAGE.

**Examples**

*Example 1:* Revoke the privilege to copy all packages in collection DSN8CC61 from LEWIS.

```
REVOKE COPY ON PACKAGE DSN8CC61.* FROM LEWIS;
```

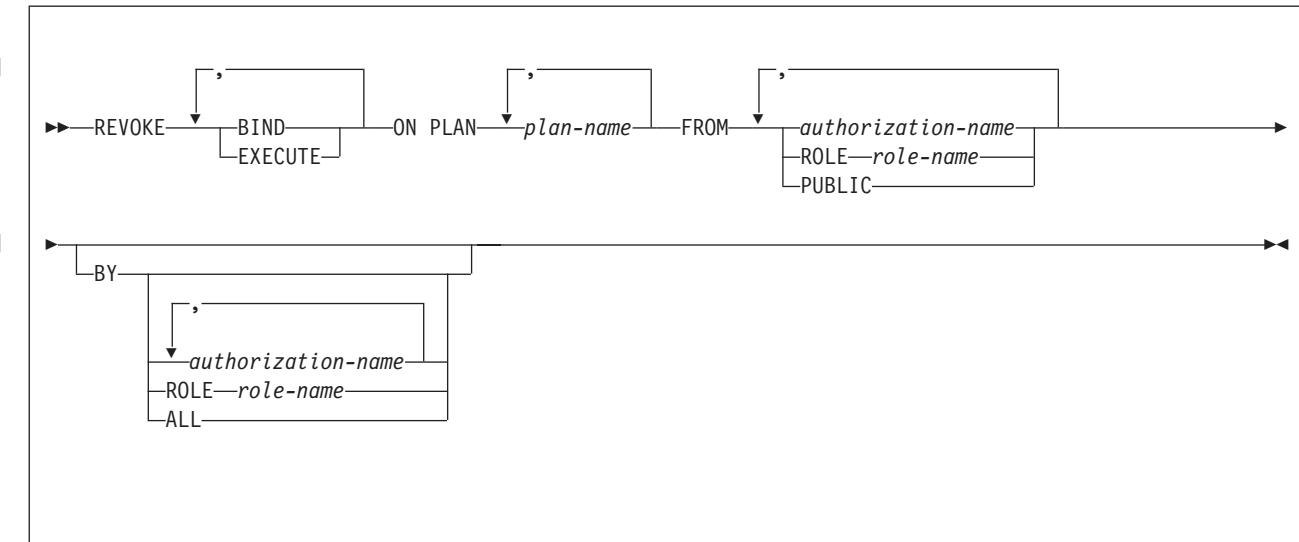

*Example 2:* Revoke the privilege to run all packages in collection DSN9CC13 from role ROLE1:

```
REVOKE EXECUTE ON PACKAGE DSN9CC13.* FROM ROLE ROLE1;
```

## REVOKE (plan privileges)

This form of the REVOKE statement revokes privileges on application plans.

### Syntax

### Description

#### BIND

Revokes the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans.

#### EXECUTE

Revokes the privilege to run application programs that use the identified plans.

#### ON PLAN *plan-name*,...

Identifies application plans for which you are revoking privileges. For each plan that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that plan to all identified users (including PUBLIC, if specified). The same plan must not be specified more than once.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

#### BY

Refer to "REVOKE" on page 1432 for a description of the BY clause.

### Examples

*Example 1:* Revoke authority to bind plan DSN8IP91 from user JONES.

```
REVOKE BIND ON PLAN DSN8IP91 FROM JONES;
```

*Example 2:* Revoke authority previously granted to all users at the current server to bind and execute plan DSN8CP91. (Grants to specific users will not be affected.)

```
REVOKE BIND,EXECUTE ON PLAN DSN8CP91 FROM PUBLIC;
```

*Example 3:* Revoke authority to execute plan DSN8CP91 from users ADAMSON and BROWN.

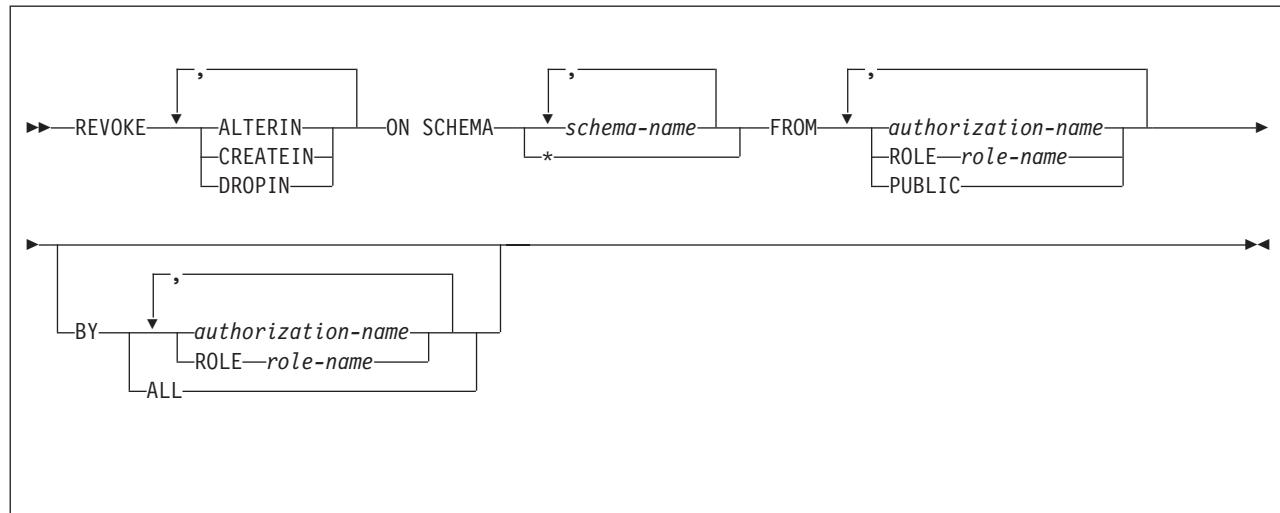

```
REVOKE EXECUTE ON PLAN DSN8CP91 FROM ADAMSON,BROWN;
```

| *Example 4:* Revoke authority to bind plan DSN91PLN from role ROLE1:  
| REVOKE BIND ON PLAN DSN91PLN FROM ROLE ROLE1;  
|

## REVOKE (schema privileges)

This form of the REVOKE statement revokes privileges on schemas.

### Syntax

### Description

#### ALTERIN

Revokes the privilege to alter sequences, stored procedures, and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### CREATEIN

Revokes the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### DROPIN

Revokes the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

#### SCHEMA *schema-name*

Identifies the schema on which the privilege is revoked.

#### SCHEMA \*

Indicates that the specified privilege on all schemas is revoked. You (or the indicated grantors) must have previously granted the specified privilege on SCHEMA \* to all identified users (including PUBLIC if specified). Privileges granted on specific schemas are not affected.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

#### BY

Refer to "REVOKE" on page 1432 for a description of the BY clause.

### Examples

*Example 1:* Revoke the CREATEIN privilege on schema T\_SCORES from user JONES.

```
REVOKE CREATEIN ON SCHEMA T_SCORES FROM JONES;
```

*Example 2:* Revoke the CREATEIN privilege on schema VAC from all users at the current server.

```
REVOKE CREATEIN ON SCHEMA VAC FROM PUBLIC;
```

*Example 3:* Revoke the ALTERIN privilege on schema DEPT from the administrative assistant.

```
REVOKE ALTERIN ON SCHEMA DEPT FROM ADMIN_A;
```

*Example 4:* Revoke the ALTERIN and DROPIN privileges on schemas NEW\_HIRE, PROMO, and RESIGN from HR (Human Resources).

```
REVOKE ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN FROM HR;
```

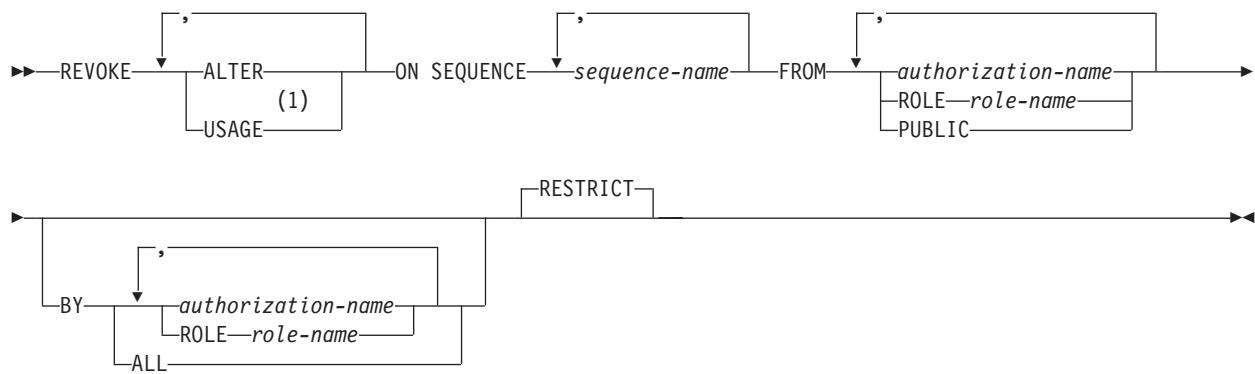

*Example 5:* Revoke the ALTERIN privilege on schemas EMPLOYEE from role ROLE1:

```
REVOKE ALTERIN ON SCHEMA EMPLOYEE FROM ROLE ROLE1;
```

## REVOKE (sequence privileges)

This form of the REVOKE statement revokes the privileges on a user-defined sequence.

### Syntax

#### Notes:

- 1 The keyword SELECT is an alternative keyword for USAGE.

### Description

#### ALTER

Revokes the privilege to alter a sequence or record a comment on a sequence.

#### USAGE

Revokes the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

#### SEQUENCE *sequence-name*

Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. *sequence-name* must not be the name of an internal sequence object that is generated by the system for an identity column.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

#### BY

Refer to "REVOKE" on page 1432 for a description of the BY clause.

#### RESTRICT

Prevents the USAGE privilege from being revoked on a sequence if the revokee owns one of the following objects and does not have the USAGE privilege from another source:

- A trigger that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression
- An inline SQL function that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression

## Examples

*Example 1:* Revoke USAGE privilege on sequence MYNUM to user JONES.

```
REVOKE USAGE  
  ON SEQUENCE MYNUM  
  FROM JONES;
```

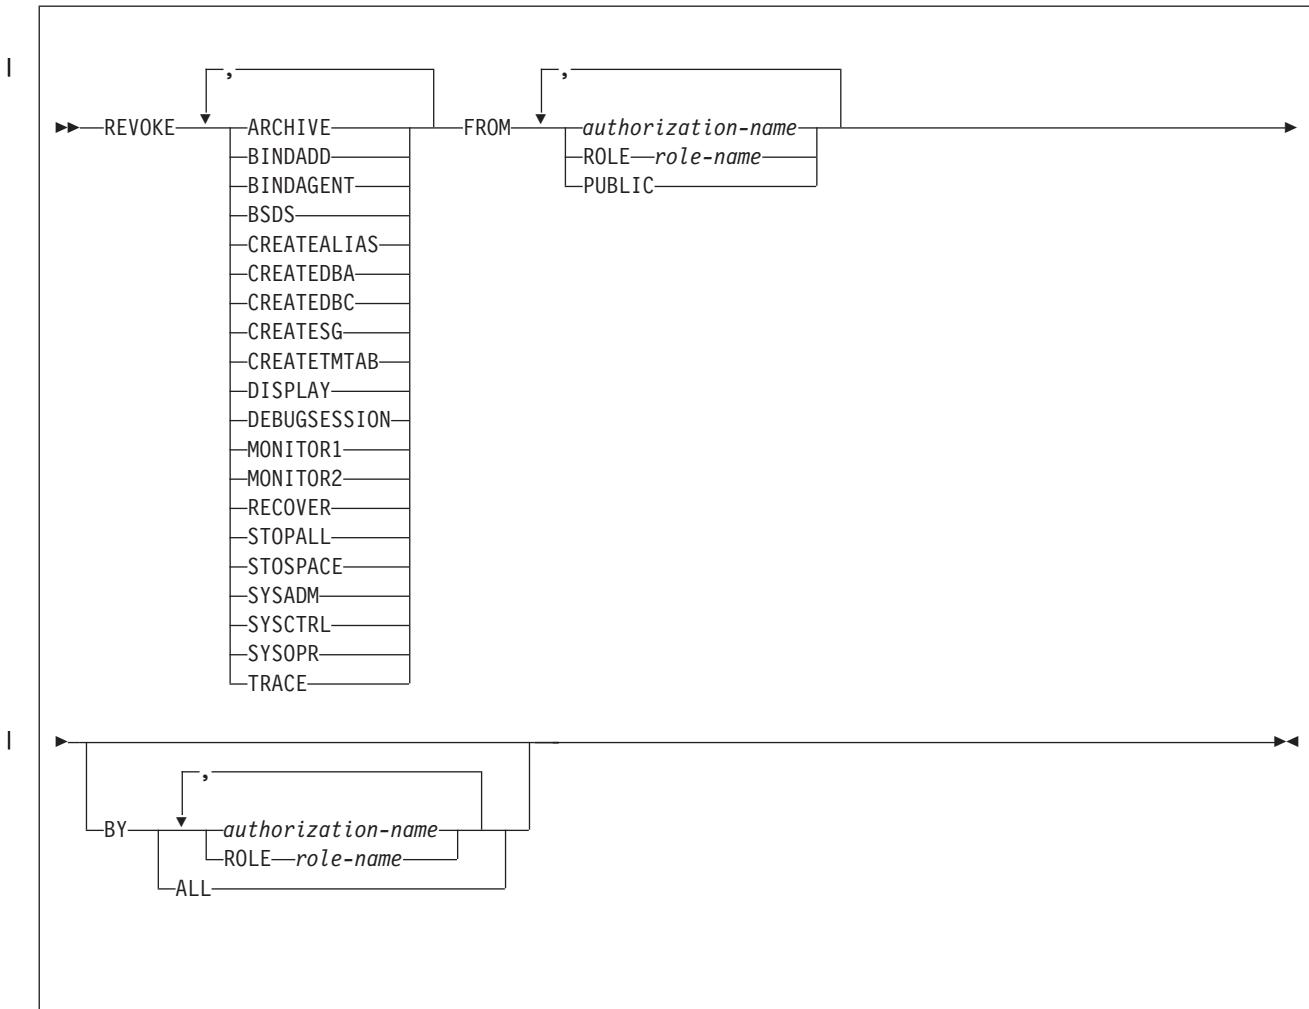

*Example 2:* Revoke the USAGE privilege on sequence ORDER\_SEQ from role ROLE1:

```
REVOKE USAGE  
  ON SEQUENCE ORDER_SEQ  
  FROM ROLE ROLE1;
```

## REVOKE (system privileges)

This form of the REVOKE statement revokes system privileges.

### Syntax

### Description

#### ARCHIVE

Revokes the privilege to use the ARCHIVE LOG command.

#### BINDADD

Revokes the privilege to create plans and packages using the BIND subcommand with the ADD option.

#### BINDAGENT

Revokes the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A revoke of this privilege does not cascade.

#### BSDS

Revokes the privilege to issue the RECOVER BSDS command.

**CREATEALIAS**

Revokes the privilege to use the CREATE ALIAS statement.

**CREATEDBA**

Revokes the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

**CREATEDBC**

Revokes the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

**CREATESG**

Revokes the privilege to create new storage groups.

**CREATETMTAB**

Revokes the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

**DISPLAY**

Revokes the privilege to use the following commands:

- The DISPLAY ARCHIVE command for archive log information
- The DISPLAY BUFFERPOOL command for the status of buffer pools
- The DISPLAY DATABASE command for the status of all databases
- The DISPLAY FUNCTION SPECIFIC command for statistics about accessed external user-defined functions
- The DISPLAY LOCATION command for statistics about threads with a distributed relationship
- The DISPLAY PROCEDURE command for statistics about accessed stored procedures
- The DISPLAY THREAD command for information on active threads with in DB2
- The DISPLAY TRACE command for a list of active traces

**DEBUGSESSION**

Revokes the privilege to create a debug session, which prevents client application debugging of native SQL or Java procedures that are executed within the session.

**MONITOR1**

Revokes the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

**MONITOR2**

Revokes the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. (Having the MONITOR2 privilege also implies having MONITOR1 privileges, however, revoking the MONITOR2 privilege does not cause the revoke of an explicitly granted MONITOR1 privilege.)

**RECOVER**

Revokes the privilege to issue the RECOVER INDOUBT command.

**STOPALL**

Revokes the privilege to use the STOP DB2 command.

**STOSPACE**

Revokes the privilege to use the STOSPACE utility.

**SYSADM**

Revokes the system administrator authority.

**SYSCTRL**

Revokes the system control authority.

**SYSOPR**

Revokes the system operator authority.

**TRACE**

Revokes the privilege to use the MODIFY TRACE, START TRACE, and STOP TRACE commands.

**FROM**

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

**BY** Refer to "REVOKE" on page 1432 for a description of the BY clause.

## Examples

*Example 1:* Revoke DISPLAY privileges from user LUTZ.

```
REVOKE DISPLAY  
  FROM LUTZ;
```

*Example 2:* Revoke BSDS and RECOVER privileges from users PARKER and SETRIGHT.

```
REVOKE BSDS,RECOVER  
  FROM PARKER,SETRIGHT;
```

*Example 3:* Revoke TRACE privileges previously granted to all local users. (Grants to specific users will not be affected.)

```
REVOKE TRACE  
  FROM PUBLIC;
```

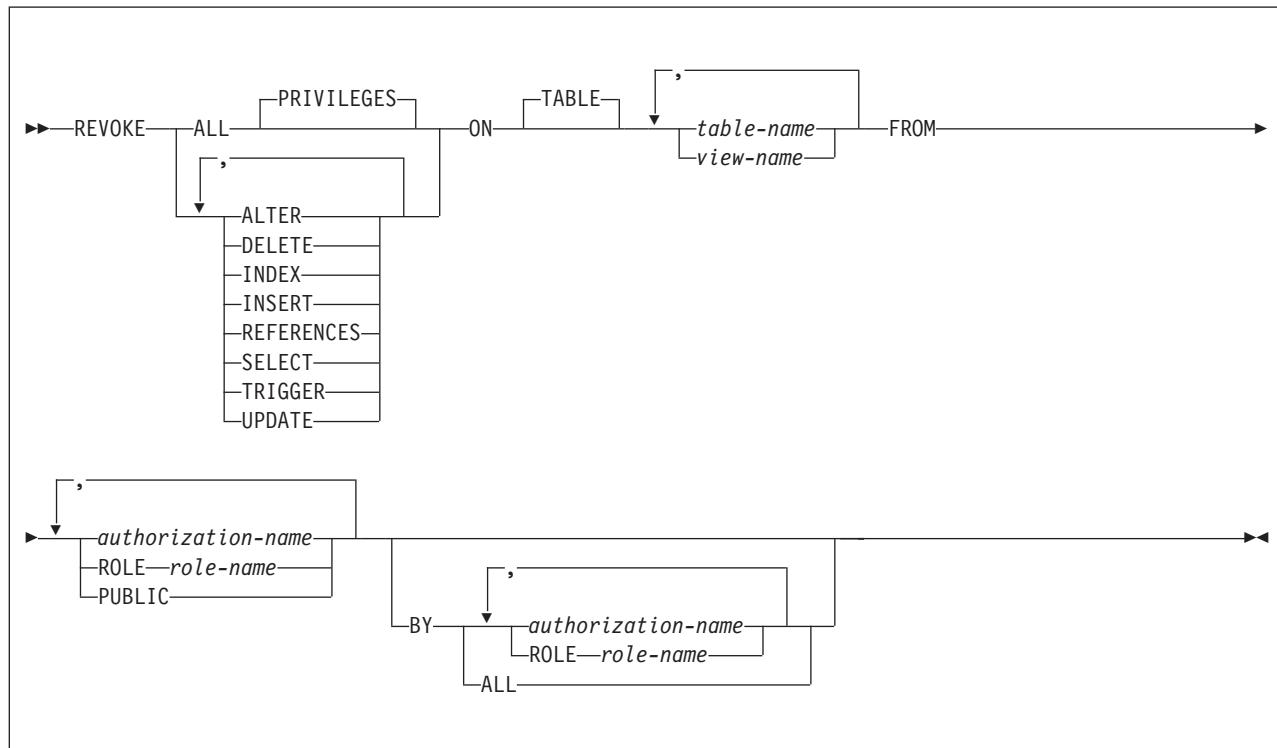

*Example 4:* Revoke ARCHIVE privileges from role ROLE1:

```
REVOKE ARCHIVE  
  FROM ROLE ROLE1;
```

## REVOKE (table or view privileges)

This form of the REVOKE statement revokes privileges on one or more tables or views.

### Syntax

### Description

#### ALL or ALL PRIVILEGES

If you specify ALL, the authorization ID of the statement must have granted at least one privilege on each identified table or view to each *authorization-name*. The privilege revoked from an authorization ID are those privileges on the table or view that the authorization ID of the statement granted to the authorization ID.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described, but only as it applies to the tables or views named in the ON clause.

#### ALTER

Revokes the privilege to alter the specified table or create a trigger on the specified table.

#### DELETE

Revokes the privilege to delete rows in the specified table or view.

#### INDEX

Revokes the privilege to create an index on the specified table.

#### INSERT

Revokes the privilege to insert rows into the specified table or view.

## REFERENCES

Revokes the privilege to define and drop referential constraints. Although you can use a list of column names with the GRANT statement, you cannot use a list of column names with REVOKE; the privilege is revoked for all columns.

## SELECT

Revokes the privilege to create a view or read data from the specified table or view. A view or a materialized query table is dropped when the SELECT privilege that was used to create it is revoked, unless the owner of the view or materialized query table was directly granted the SELECT privilege from another source before the view or materialized query table was created.

## TRIGGER

Revokes the privilege to create a trigger on the specified table.

## UPDATE

Revokes the privilege to update rows in the specified table or view. A list of column names can be used only with GRANT, not with REVOKE.

## ON *table-name* or *view-name*

Names one or more tables or views on which you are revoking the privileges. The list can consist of table names, view names, or a combination of the two. A table or view must not be identified more than one time, and a declared temporary table and a table that is implicitly created for an XML column must not be identified.

## FROM

Refer to “REVOKE” on page 1432 for a description of the FROM clause.

**BY** If you omit BY, you must have granted each named privilege to each of the named users. More precisely, each privilege must have been granted to each user by a GRANT statement whose authorization ID is also the authorization ID of your REVOKE statement. Each of these grants is then revoked. (No single privilege need be granted on all tables and views.)

If BY is specified, each named grantor must satisfy the above requirement. In that case, the authorization ID of the statement need not satisfy the requirement unless it is one of the named grantors.

Refer to “REVOKE” on page 1432 for a description of the BY clause.

## Notes

For a created temporary table or a view of a created temporary table, only ALL or ALL PRIVILEGES can be revoked. Specific table or view privileges cannot be revoked.

For a declared temporary table, no privileges can be revoked because none can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the DB2 catalog.

**PUBLIC AT ALL LOCATIONS:** PUBLIC AT ALL LOCATIONS can continue to be specified as an alternative to PUBLIC as in prior releases. PUBLIC AT ALL LOCATIONS was introduced and was intended for use only with DB2 private protocol access.

## Examples

*Example 1:* Revoke SELECT privileges on table DSN8910.EMP from user PULASKI.

```
REVOKE SELECT ON TABLE DSN8910.EMP FROM PULASKI;
```

*Example 2:* Revoke update privileges on table DSN8910.EMP previously granted to all local DB2 users. (Grants to specific users are not affected.)

```
REVOKE UPDATE ON TABLE DSN8910.EMP FROM PUBLIC;
```

*Example 3:* Revoke all privileges on table DSN8910.EMP from users KWAN and THOMPSON.

```
REVOKE ALL ON TABLE DSN8910.EMP FROM KWAN,THOMPSON;
```

*Example 4:* Revoke the grant of SELECT and UPDATE privileges on the table DSN8910.DEPT to every user in the network. Doing so does not affect users who obtained these privileges from some other grant.

```
| REVOKE SELECT, UPDATE ON TABLE DSN8910.DEPT  
|   FROM PUBLIC;
```

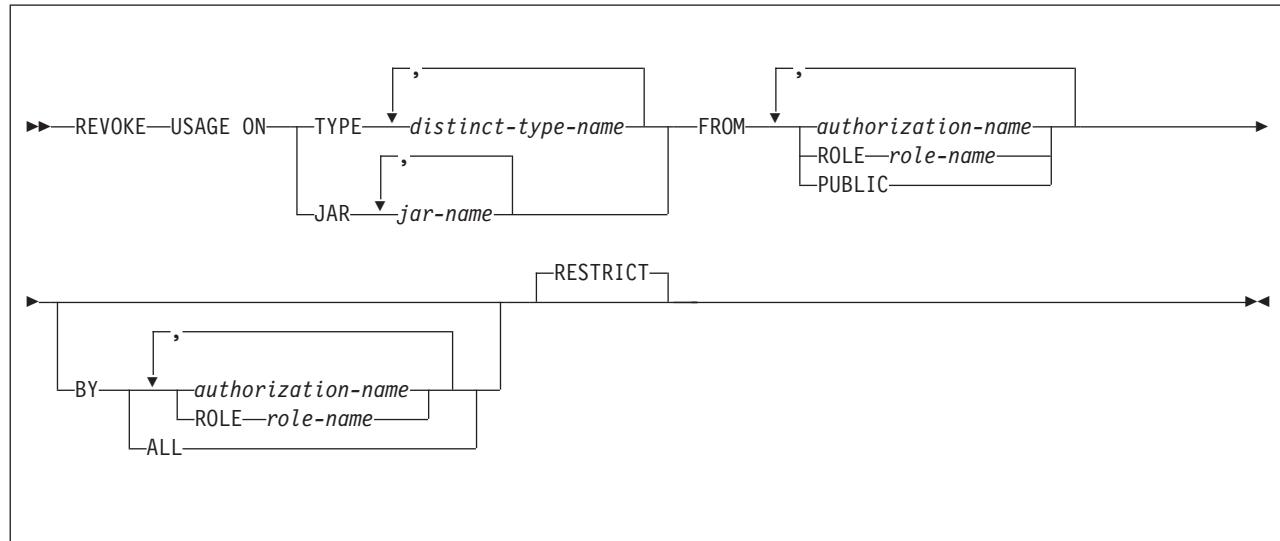

*Example 5:* Revoke the ALTER privileges on the table DSN8910.EMP that were previously granted to role ROLE1:

```
| REVOKE ALTER ON TABLE DSN8910.EMP  
|   FROM ROLE ROLE1;
```

## REVOKE (type or JAR file privileges)

This form of the REVOKE statement revokes the privilege to use distinct types (user-defined data types) or JAR files.

### Syntax

### Description

#### USAGE

Revokes the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

#### TYPE *distinct-type-name*

Identifies a distinct type. The name, including the implicit or explicit schema qualifier, must identify a unique distinct type that exists at the current server.

#### JAR *jar-name*

Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

#### BY

Refer to "REVOKE" on page 1432 for a description of the BY clause.

#### RESTRICT

Prevents the USAGE privilege from being revoked on a distinct type or JAR file if any of the following conditions exist and the revokee does not have the USAGE privilege from another source:

- The revokee owns a function or stored procedure that uses the distinct type or references the JAR file.
- The revokee owns a JAR file whose path references the JAR file for which USAGE is being revoked.
- The revokee owns a table that has a column that uses the distinct type.
- A sequence exists for which the data type of the sequence is the distinct type.

## Notes

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

## Examples

*Example 1:* Revoke the USAGE privilege on distinct type SHOESIZE from user JONES.

```
REVOKE USAGE ON TYPE SHOESIZE FROM JONES;
```

*Example 2:* Revoke the USAGE privilege on distinct type US\_DOLLAR from all users at the current server except for those who have been specifically granted USAGE and not through PUBLIC.

```
REVOKE USAGE ON TYPE US_DOLLAR FROM PUBLIC;
```

*Example 3:* Revoke the USAGE privilege on distinct type CANADIAN\_DOLLARS from the administrative assistant (ADMIN\_A).

```
REVOKE USAGE ON TYPE CANADIAN_DOLLARS  
FROM ADMIN_A;
```

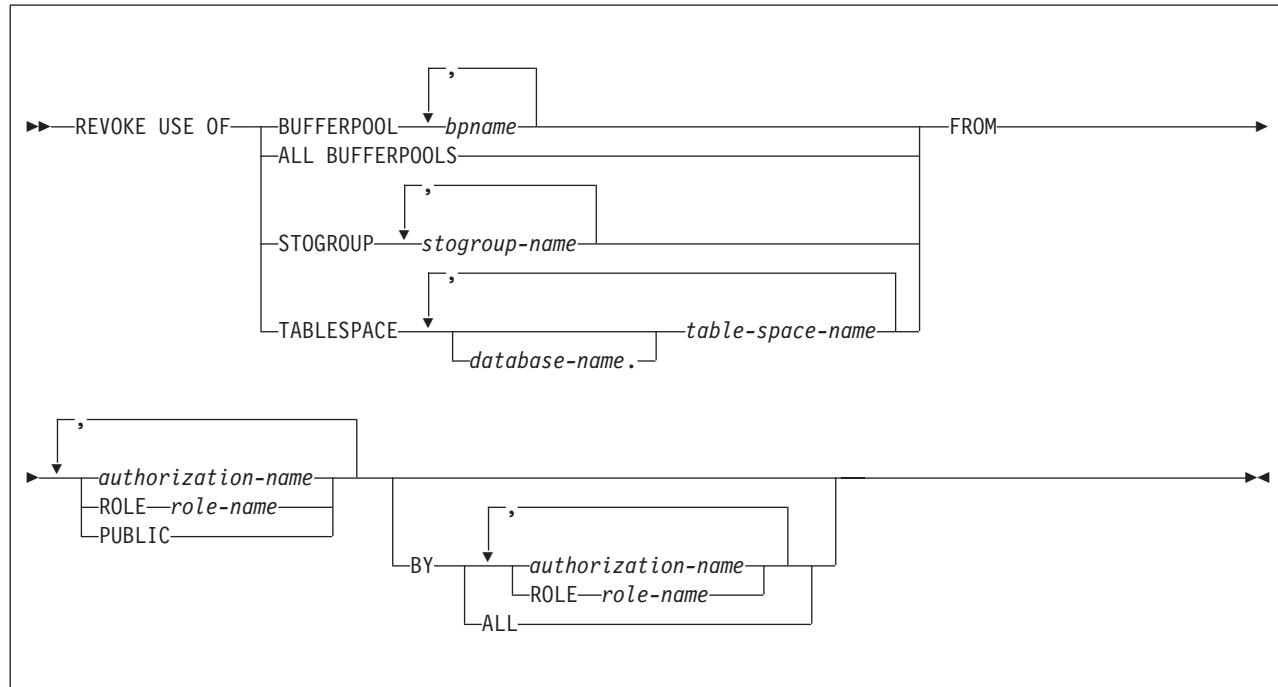

*Example 4:* Revoke the USAGE privilege on distinct type MILES from the role ROLE1:

```
REVOKE USAGE ON TYPE MILES  
FROM ROLE ROLE1;
```

## REVOKE (use privileges)

This form of the REVOKE statement revokes authority to use particular buffer pools, storage groups, or table spaces.

### Syntax

### Description

#### BUFFERPOOL *bpname*,...

Revokes the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See "Naming conventions" on page 51 for more details about *bpname*.

#### ALL BUFFERPOOLS

Revokes the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

#### STOGROUP *stogroup-name*,...

Revokes the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

#### TABLESPACE *database-name.table-space-name*,...

Revokes the privilege to refer to any of the specified table spaces in a CREATE TABLE statement. The default *database-name* is DSNDB04.

For table spaces in a work file database you cannot revoke the privilege from PUBLIC. When a table space is created in a work file database, PUBLIC implicitly receives the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

#### FROM

Refer to "REVOKE" on page 1432 for a description of the FROM clause.

**BY** Refer to “REVOKE” on page 1432 for a description of the BY clause.

## Notes

You can revoke privileges for only one type of object with each statement. Thus you can revoke the use of several table spaces with one statement, but not the use of a table space and a storage group.

For each object you name, you (or the indicated grantors) must have granted the USE privilege on that object to all identified users (including PUBLIC, if specified). The same object must not be identified more than once.

Revoking the privilege USE OF ALL BUFFERPOOLS does not cascade to all other privileges that can be granted under that privilege. A user with the privilege USE OF ALL BUFFERPOOLS WITH GRANT OPTION can make two types of grants:

- GRANT USE OF ALL BUFFERPOOLS TO *userid*. This privilege is revoked when the original user's privilege is revoked.
- GRANT USE OF BUFFERPOOL BP*n* TO *userid*. This privilege is *not revoked* when the original user's privilege is revoked.

## Examples

*Example 1:* Revoke authority to use buffer pool BP2 from user MARINO.

```
REVOKE USE OF BUFFERPOOL BP2  
      FROM MARINO;
```

*Example 2:* Revoke a grant of the USE privilege on the table space DSN8S91D in the database DSN8D91A. The grant is to PUBLIC, that is, to everyone at the local DB2 subsystem. (Grants to specific users are not affected.)

```
REVOKE USE OF TABLESPACE DSN8D91A.DSN8S91D  
      FROM PUBLIC;
```

*Example 3:* Revoke the authority to use storage group SG1 from role ROLE1:

```
REVOKE USE OF STOGROUP SG1  
      FROM ROLE ROLE1;
```

## ROLLBACK

The ROLLBACK statement can be used to end a unit of recovery and back out all the relational database changes that were made by that unit of recovery. If relational databases are the only recoverable resources used by the application process, ROLLBACK also ends the unit of work. ROLLBACK can also be used to back out only the changes made after a savepoint was set within the unit of recovery without ending the unit of recovery. Rolling back to a savepoint enables selected changes to be undone.

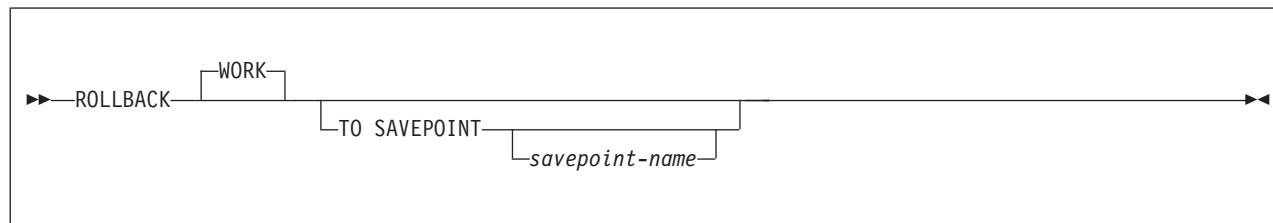

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It can be used in the IMS or CICS environment only if the TO SAVEPOINT clause is specified.

### Authorization

None required.

### Syntax

### Description

When ROLLBACK is used without the SAVEPOINT clause, the unit of recovery in which the ROLLBACK statement is executed is ended and a new unit of recovery is started.

All changes that are made by the following statements during the unit of recovery are backed out:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL
- MERGE
- REFRESH TABLE
- RENAME
- REVOKE
- SELECT INTO with an SQL data change statement

- select-statement with an SQL data change statement
- TRUNCATE when the IMMEDIATE clause is not specified
- UPDATE

ROLLBACK without the TO SAVEPOINT clause also causes the following actions to occur:

- All locks that are implicitly acquired during the unit of recovery are released. See “LOCK TABLE” on page 1386 for an explanation of the duration of explicitly acquired locks.
- All cursors are closed, all prepared statements are destroyed, and any cursors that are associated with the prepared statements are invalidated.
- All rows and all logical work files of every created temporary table of the application process are deleted. (All the rows of a declared temporary table are not implicitly deleted. As with base tables, any changes that are made to a declared temporary table during the unit of recovery are undone to restore the table to its state at the last commit point.)
- All LOB locators, including those that are held, are freed.

#### **TO SAVEPOINT**

Specifies that the unit of recovery is not to be ended and that only a partial rollback (to a savepoint) is to be performed. If a savepoint name is not specified, rollback is to the last active savepoint. For example, if in a unit of recovery, savepoints A, B, and C are set in that order and then C is released, ROLLBACK TO SAVEPOINT causes a rollback to savepoint B.

##### *savepoint-name*

Identifies the savepoint to which to roll back. The name must identify a savepoint that exists at the current server.

All database changes (including changes made to a declared temporary tables but excluding changes made to created temporary tables) that were made after the savepoint was set are backed out. Changes that are made to created temporary tables are not logged and are not backed out; a warning is issued instead. (A warning is also issued when a created temporary table is changed and there is an active savepoint.)

In addition, none of the following items are backed out:

- The opening or closing of cursors
- Changes in cursor positioning
- The acquisition and release of locks
- The caching of the rolled back statements

Any savepoints that are set after the one to which rollback is performed are released. The savepoint to which rollback is performed is not released.

ROLLBACK with or without the TO SAVEPOINT clause has no effect on connections.

#### **Notes**

The following information applies only to rolling back all changes in the unit of recovery (the ROLLBACK statement without the TO SAVEPOINT clause):

- *Stored procedures.* The ROLLBACK statement cannot be used if the procedure is in the calling chain of a user-defined function or a trigger or if DB2 is not the commit coordinator.

- *IMS or CICS.* Using a ROLLBACK to SAVEPOINT statement in an IMS or CICS environment only rolls back DB2 resources. Any other recoverable resources updated in the environment are not rolled back. To do a rollback operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these rollback operations on DB2 data is the same as that of the SQL ROLLBACK statement.

A rollback operation in an IMS or CICS environment might handle the closing of cursors that were declared with the WITH hold option differently than the SQL ROLLBACK statement does. If an application requests a rollback operation from CICS or IMS, but no work has been performed in DB2 since the last commit point, the rollback request will not be broadcast to DB2. If the application had opened cursors using the WITH HOLD option in a previous unit of work, the cursors will not be closed, and any prepared statements associated with those cursors will not be destroyed.

- *Implicit rollback operations:* In all DB2 environments, the abend of a process is an implicit rollback operation.

**ROLLBACK and table spaces that are not logged:** If ROLLBACK is executed for a unit of work that includes changes to a non-LOB table space that is not logged (specifies the NOT LOGGED attribute), that table space is marked RECOVER-pending and the table space is placed in the logical page list. The table space is therefore not available after the rollback operation completes. See *DB2 Utility Guide and Reference* for more information about the RECOVER utility.

## Examples

*Example 1:* Roll back all DB2 database changes made since the unit of recovery was started.

```
ROLLBACK WORK;
```

*Example 2:* After a unit of recovery started, assume that three savepoints A, B, and C were set and that C was released:

```
...
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
...
SAVEPOINT B ON ROLLBACK RETAIN CURSORS;
...
SAVEPOINT C ON ROLLBACK RETAIN CURSORS;
...
RELEASE SAVEPOINT C;
...
```

Roll back all DB2 database changes only to savepoint A:

```
ROLLBACK WORK TO SAVEPOINT A;
```

If a savepoint name was not specified (that is, ROLLBACK WORK TO SAVEPOINT), the rollback would be to the last active savepoint that was set, which is B.

## SAVEPOINT

The SAVEPOINT statement sets a savepoint within a unit of recovery to identify a point in time within the unit of recovery to which relational database changes can be rolled back.

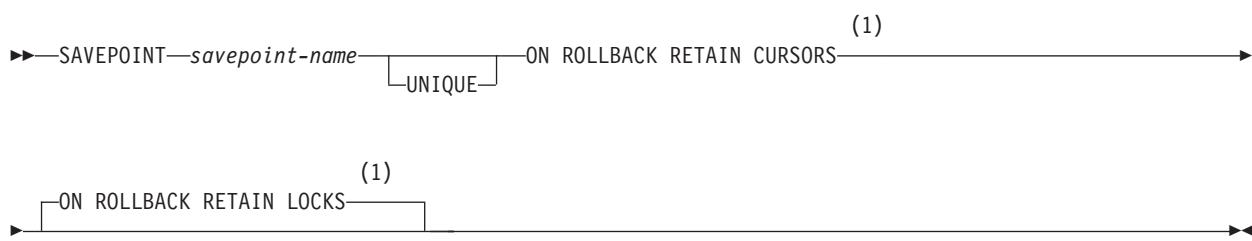

### Invocation

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

#### Notes:

- 1 These clauses can be specified in either order.

### Description

#### *savepoint-name*

Names the savepoint. *savepoint-name* must not begin with 'SYS'.

#### UNIQUE

Specifies that the application program cannot reuse the savepoint name within the unit of recovery. An error occurs if a savepoint with the same name as *savepoint-name* already exists within the unit of recovery.

Omitting UNIQUE indicates that the application can reuse the savepoint name within the unit of recovery. If *svpt-name* identifies a savepoint that already exists within the unit of recovery and the savepoint was not created with the UNIQUE option, the existing savepoint is destroyed and a new savepoint is created. Destroying a savepoint to reuse its name for another savepoint is not the same as releasing the savepoint. Reusing a savepoint name destroys only one savepoint. Releasing a savepoint with the RELEASE SAVEPOINT statement releases the savepoint and all savepoints that have been subsequently set.

#### ON ROLLBACK RETAIN CURSORS

Specifies that any cursors that are opened after the savepoint is set are not tracked, and thus, are not closed upon rollback to the savepoint. Although these cursors remain open after rollback to the savepoint, they might not be usable. For example, if rolling back to the savepoint causes the insertion of a

row on which the cursor is positioned to be rolled back, using the cursor to update or delete the row results in an error.

#### **ON ROLLBACK RETAIN LOCKS**

Specifies that any locks that are acquired after the savepoint is set are not tracked, and thus, are not released on rollback to the savepoint.

### **Example**

Assume that you want to set three savepoints at various points in a unit of recovery. Name the first savepoint A and allow the savepoint name to be reused. Name the second savepoint B and do not allow the name to be reused. Because you no longer need savepoint A when you are ready to set the third savepoint, reuse A as the name of the savepoint.

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;  
:  
SAVEPOINT B UNIQUE ON ROLLBACK RETAIN CURSORS;  
:  
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
```

---

## **SELECT**

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR statement, or prepared and then referenced in a DECLARE CURSOR statement. It can also be issued interactively using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the table specified by *select-statement* is the result of the fullselect.

For a description of the SELECT statement, see “*select-statement*” on page 669.

---

## **SELECT INTO**

The SELECT INTO statement produces a result table that contains at most one row, and assigns the values in that row to host variables. If the table is empty, the statement assigns +100 to SQLCODE, '02000' to SQLSTATE, and does not assign values to the host variables. The tables or views identified in the statement can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

### **Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

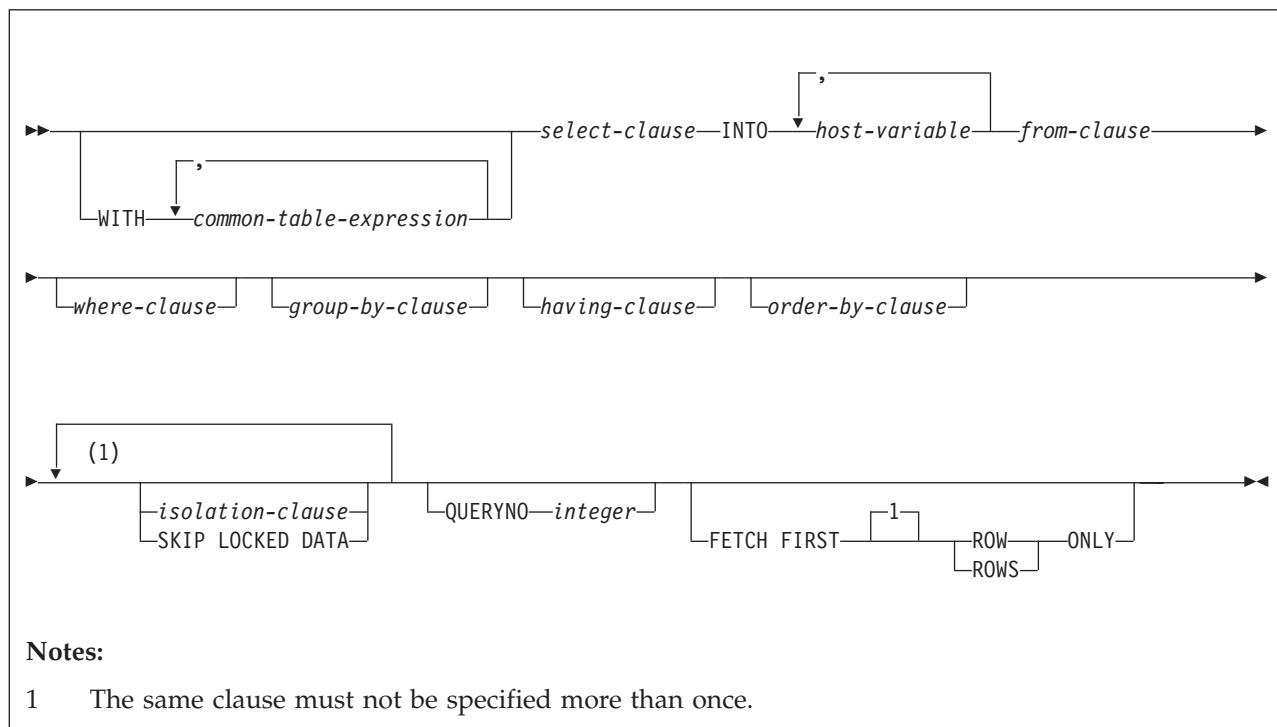

### **Authorization**

The privileges that are held by the authorization ID of the owner of the plan or package must include at least one of the following for every table and view identified in the statement:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)

If the SELECT INTO statement includes an SQL data change statement, the privilege set must also include at least the privileges (INSERT, UPDATE, or DELETE) that are associated with that SQL data change statement on the table or view.

## Syntax

## Description

The table is derived by evaluating the *isolation-clause*, *from-clause*, *where-clause*, *group-by-clause*, *having-clause*, *order-by-clause*, and the *select-clause*, in this order. See Chapter 4, “Queries,” on page 629 for a description of these clauses.

### **WITH common-table-expression**

Refer to “common-table-expression” on page 670 for information about specifying a *common-table-expression*.

### **INTO host-variable,...**

Each *host-variable* must identify a structure or variable that is described in the program in accordance with the rules for declaring host structures and variables. In the operational form of the INTO clause, a reference to a structure is replaced by a reference to each of its host variables.

The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on. If the number of host variables is less than the number of column values, the value W is assigned to the SQLWARN3 field of the SQLCA. (See “SQL communication area (SQLCA)” on page 1646.)

The data type of a variable must be compatible with the value assigned to it. If the value is numeric, the variable must have the capacity to represent the integral part of the value. For a date or time value, the variable must be a character string variable of a minimum length as defined in Chapter 2, “Language elements,” on page 47. If the value is null, an indicator variable must be specified.

Each assignment to a variable is made according to the rules described in Chapter 2, “Language elements,” on page 47. Assignments are made in sequence through the list.

If an error occurs as the result of an arithmetic expression in the SELECT list of a SELECT INTO statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered.

If an error occurs, no value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If an error occurs because the result table has more than one row, values may or may not be assigned to the host variables. If values are assigned to the host variables, the row that is the source of the values is undefined and not predictable.

*isolation-clause*

Specifies the isolation level at which the statement is executed and, optionally, the type of locks that are acquired.

**SKIP LOCKED DATA**

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR).

**QUERYNO** *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

**FETCH FIRST ROW ONLY** *integer*

The FETCH FIRST ROW ONLY clause can be used in the SELECT INTO statement when the query can result in more than a single row. The clause indicates that only one row should be retrieved regardless of how many rows might be in the result table. When a number is explicitly specified, it must be 1.

Using the FETCH FIRST ROW ONLY clause to explicitly limit the result table to a single row provides a way for the SELECT INTO statement to be used with a query that returns more than a single row. Using the clause helps you to avoid using a cursor when you know that you want to retrieve only one row. To influence which row is returned, you can use the *order-by-clause*. When you specify *order-by-clause*, the rows of the result are ordered and then the first row is returned. If the FETCH FIRST ROW ONLY clause is not specified and the result table contains more than a single row, an error occurs.

## Notes

**Number of rows inserted:** If the SELECT INTO statement of the cursor contains an SQL data change statement, the SELECT INTO operation sets SQLERRD(3) to the number of rows inserted.

**Using locators:** Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data types.

## Examples

*Example 1:* Put the maximum salary in DSN8910.EMP into the host variable MAXSALRY.

```
EXEC SQL SELECT MAX(SALARY)
  INTO :MAXSALRY
  FROM DSN8910.EMP;
```

*Example 2:* Put the row for employee 528671, from DSN8910.EMP, into the host structure EMPREC.

```
EXEC SQL SELECT * INTO :EMPREC
  FROM DSN8910.EMP
  WHERE EMPNO = '528671'
END-EXEC.
```

*Example 3:* Put the row for employee 528671, from DSN8910.EMP, into the host structure EMPREC. Assume that the row will be updated later and should be locked when the query executes.

```
EXEC SQL SELECT * INTO :EMPREC
  FROM DSN8910.EMP
  WHERE EMPNO = '528671'
    WITH RS USE AND KEEP EXCLUSIVE LOCKS
END-EXEC.
```

## SET CONNECTION

The SET CONNECTION statement establishes the database server of the process by identifying one of its existing connections.

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

### Authorization

None required.

### Syntax

```
►►—SET CONNECTION—location-name—►►
          |host-variable|
```

### Description

*location-name or host-variable*

Identifies the SQL connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

Let S denote the specified location name or the location name contained in the host variable. S must identify an existing SQL connection of the application process. If S identifies the current SQL connection, the state of S and all other connections of the application process are unchanged. The following rules apply when S identifies a dormant SQL connection.

If the SET CONNECTION statement is successful:

- SQL connection S is placed in the current state.
- S is placed in the CURRENT SERVER special register.
- Information about server S is placed in the SQLERRP field of the SQLCA. If the server is an IBM product, the information has the form *pppvvrrm*, where:
  - *ppp* is:
    - ARI for DB2 Server for VSE & VM
    - DSN for DB2 for z/OS
    - QSQ for DB2 for i
    - SQL for all other DB2 products
  - *vv* is a two-digit version identifier such as '09'.

- *rr* is a two-digit release identifier such as '01'.
- *m* is a one-digit maintenance level such as '5' (Values 0, 1, 2, 3, and 4 are for maintenance levels in compatibility and enabling-new-function mode. Values 5, 6, 7, 8, and 9 are for maintenance levels in new-function mode.)

For example, if the server is Version 9 of DB2 for z/OS in new-function mode with the latest maintenance, the value of SQLERRP is 'DSN09015'.

- Any previously current SQL connection is placed in the dormant state.

If the SET CONNECTION statement is unsuccessful, the connection state of the application process and the states of its SQL connections are unchanged.

## Notes

The use of CONNECT (Type 1) statements does not prevent the use of SET CONNECTION, but the statement either fails or does nothing because dormant SQL connections do not exist. The SQLRULES(DB2) bind option does not prevent the use of SET CONNECTION, but the statement is unnecessary because CONNECT (Type 2) statements can be used instead. Use the SET CONNECTION statement to conform to the SQL standard.

When an SQL connection is used, made dormant, and then restored to the current state in the same unit of work, the status of locks, cursors, and prepared statements for that SQL connection reflects its last use by the application process.

If the SET CONNECTION statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

## Example

Execute SQL statements at TOROLAB1, execute SQL statements at TOROLAB2, and then execute more SQL statements at TOROLAB1.

```
EXEC SQL CONNECT TO TOROLAB1;
-- execute statements referencing objects at TOROLAB1

EXEC SQL CONNECT TO TOROLAB2;
-- execute statements referencing objects at TOROLAB2

EXEC SQL SET CONNECTION TOROLAB1;
-- execute statements referencing objects at TOROLAB1
```

The first CONNECT statement creates the TOROLAB1 connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION statement returns it to the current state.

## SET CURRENT APPLICATION ENCODING SCHEME

The SET CURRENT APPLICATION ENCODING SCHEME statement assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register. This special register allows users to control which encoding scheme will be used for dynamic SQL statements after the SET statement has been executed.

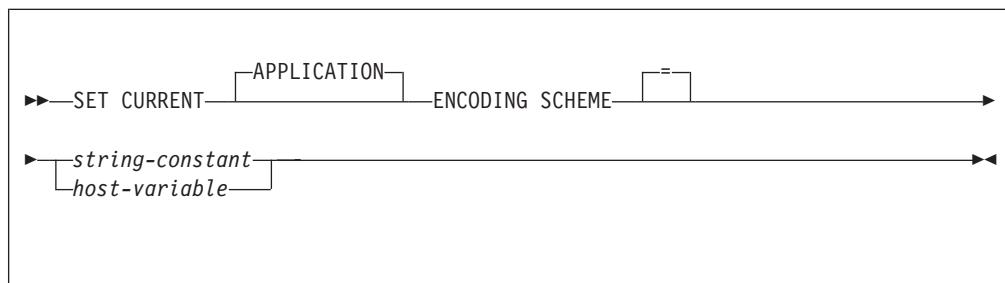

### Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### *string-constant*

A character string constant that represents a valid encoding scheme (ASCII, EBCDIC, UNICODE, or a character representation of a number between 1 and 65533).

#### *host variable*

A variable with a data type of CHAR or VARCHAR. The value of *host-variable* must not be null and must represent a valid encoding scheme or a character representation of a number between 1 and 65533). An associated indicator variable must not be provided.

The value must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

### Examples

The following examples set the CURRENT APPLICATION ENCODING SCHEME special register to 'EBCDIC' (in the second example, Host variable HV1 = 'EBCDIC').

```
EXEC SQL SET CURRENT APPLICATION ENCODING SCHEME = 'EBCDIC';  
EXEC SQL SET CURRENT ENCODING SCHEME = :HV1;
```

## SET CURRENT DEBUG MODE

The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

The special register sets the default value for the DEBUG MODE option for the following statements:

- CREATE PROCEDURE statements that define a native SQL or Java procedure
- ALTER PROCEDURE statements that create or replace a version of a native SQL procedure

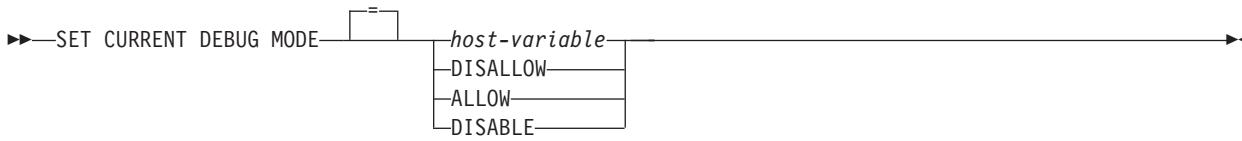

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### *host-variable*

Specifies a host variable that contains the debugging option. The host variable must conform to the following rules:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of the special register.
- Include a keyword value of DISALLOW, ALLOW, or DISABLE that is left justified
- Be padded on the right with blanks if the host variable is a fixed length character
- Not contain lowercase letters or characters that cannot be specified in an ordinary identifier
- Not be empty or contain only blanks
- Not be the null value

#### **DISALLOW**

Specifies that DISALLOW DEBUG MODE is the default option for CREATE PROCEDURE statements when defining an SQL or Java procedure, or ALTER PROCEDURE statements that create or replace a version of a native SQL procedure.

**ALLOW**

Specifies that ALLOW DEBUG MODE is the default option for CREATE PROCEDURE statements when defining an SQL or Java procedure, or ALTER PROCEDURE statements that create or replace a version of a native SQL procedure.

**DISABLE**

Specifies that DISABLE DEBUG MODE is the default option for CREATE PROCEDURE statements when defining an SQL or Java procedure, or ALTER PROCEDURE statements that add a version of a native SQL procedure.

**Examples**

*Example:* The following statement sets the CURRENT DEBUG MODE special register so that the default option for CREATE PROCEDURE statements will be ALLOW DEBUG MODE:

```
SET CURRENT DEBUG MODE = ALLOW;
```

## SET CURRENT DECFLOAT ROUNDING MODE

The SET CURRENT DECFLOAT ROUNDING MODE statement assigns a value to the CURRENT DECFLOAT ROUNDING MODE special register. The special register sets the default rounding mode that is used with decimal floating point values (DECFLOAT).

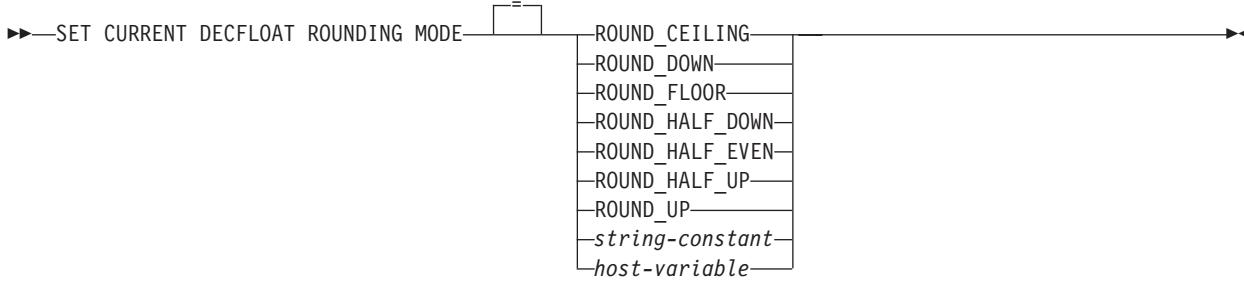

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### ROUND\_CEILING

Round towards positive infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up).

#### ROUND\_DOWN

Round towards 0 (truncation). The discarded digits are ignored.

#### ROUND\_FLOOR

Round towards negative infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1 (round down).

#### ROUND\_HALF\_DOWN

Round to nearest value; if values are equidistant, rounds down. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise, the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

#### ROUND\_HALF\_EVEN

Round to nearest value; if values are equidistant, round so that the final digit

is even. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). If the discarded digits represent less than half of the value, the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise, the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 (round up) if its rightmost digit is odd (to make an even digit).

#### **ROUND\_HALF\_UP**

Round to nearest value; if values are equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise the discarded digits are ignored.

#### **ROUND\_UP**

Round away from 0. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up). This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

#### *string-constant*

Specifies a string constant that contains a specification of the rounding mode. The string-constant must have the following characteristics:

- Must be a string constant. The actual length of the contents of the string constant, after trailing blanks have been removed, must not exceed 19 characters.
- Must not be the null value.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must specify one of the seven rounding mode keywords as a string constant.

#### *host-variable*

Specifies a variable that contains a specification of the rounding mode. The variable must have the following characteristics:

- Must have a length, after trailing blanks have been removed, that does not exceed 19 bytes.
- Must not be followed by an indicator variable.
- Must not be a CLOB or DBCLOB.
- Must include a rounding mode that is left justified and conforms to the rules for forming an ordinary identifier.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must be padded on the right with blanks if the variable is a fixed length string.
- Must contain one of the seven rounding mode keywords.

## **Examples**

*Example:* The following statement sets the CURRENT DECFLOAT ROUNDING MODE to ROUND\_CEILING, using a string constant and a keyword.

```
SET CURRENT DECFLOAT ROUNDING MODE = ROUND_CEILING;
```

## SET CURRENT DEGREE

The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►SET CURRENT DEGREE = string-constant | host-variable►►
```

### Description

The value of CURRENT DEGREE is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 3 bytes and the value must be 'ANY', '1', or '1 '.

### Notes

If the value of CURRENT DEGREE is '1' when a query is dynamically prepared, the execution of that query will not use parallel operations. If the value of CURRENT DEGREE is 'ANY' when a query is dynamically prepared, the execution of that query can involve parallel operations.

For distributed applications, the default value at the server is used unless the requesting application issues the SQL statement SET CURRENT DEGREE. For requests using DRDA, the SET CURRENT DEGREE statement must be within the scope of the CONNECT statement.

The value specified in the SET CURRENT DEGREE statement remains in effect until it is changed by the execution of another SET CURRENT DEGREE statement or until deallocation of the application process. For applications that connect to DB2 using the call attachment facility, the value of register CURRENT DEGREE can be requested to remain in effect for a longer duration. For more information, see the description of the call attachment facility CONNECT statement in *DB2 Application Programming and SQL Guide*.

### Examples

*Example 1:* The following statement inhibits parallel operations:

```
SET CURRENT DEGREE = '1';
```

*Example 2:* The following statement allows parallel operations:

```
SET CURRENT DEGREE = 'ANY';
```

## SET CURRENT LOCALE LC\_CTYPE

The SET CURRENT LOCALE LC\_CTYPE statement assigns a value to the CURRENT LOCALE LC\_CTYPE special register. The special register allows control over the LC\_CTYPE locale for statements that use a built-in function that refers to a locale, such as LCASE, UCASE, and TRANSLATE (with a single argument).

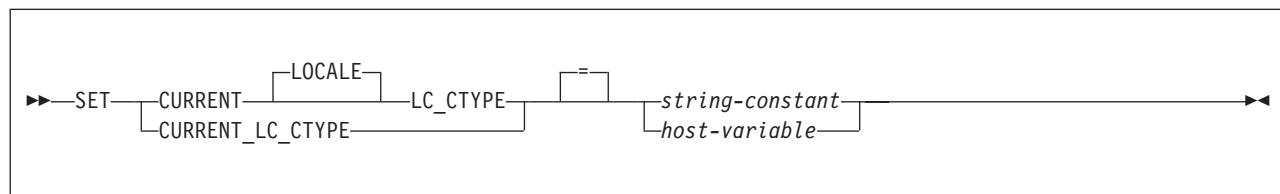

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

The value of CURRENT LOCALE LC\_CTYPE is replaced by the string constant or host variable specified. The value must be a CHAR or VARCHAR character string that is no longer than 50 bytes.

The value of CURRENT LOCALE LC\_CTYPE is replaced by the value specified. The value must not be longer than 50 bytes and must be a valid locale.

#### *string-constant*

A character string constant that must not be longer than 50 bytes and must represent a valid locale.

#### *host-variable*

A variable with a data type of CHAR or VARCHAR and a length that is not longer than 50 bytes. The value of *host-variable* must not be null and must represent a valid locale. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value.

The locale must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

A locale can be specified in uppercase characters, lowercase characters, or a combination of the two. For information on locales and their naming conventions, see *z/OS C/C++ Programming Guide*. Some examples of locales include:

Fr\_BE  
Fr\_FR@EURO  
En\_US  
Ja\_JP

For Unicode data, there are three options for this special register:

- blank — simple casting on A-Z, a-z, and fullwidth Latin lowercase letters a- $\text{z}$  and fullwidth Latin capital letters A-Z. Characters with diacritics are not affected.
- "UNI" — If the value "UNI" is specified, casting will use both the "NORMAL" and "SPECIAL" casing capabilities as described in *z/OS Support for Unicode™: Using Conversion Services*.
- a locale — In this case, locale specific casing will be performed using the "LOCALE" casing capabilities as described in *z/OS Support for Unicode™: Using Conversion Services*. See the preceding paragraph for examples of specifying a locale.

## Examples

*Example 1:* Set the CURRENT LOCALE LC\_CTYPE special register to the locale 'En\_US'.

```
EXEC SQL SET CURRENT LOCALE LC_CTYPE = 'En_US';
```

*Example 2:* Set the CURRENT LOCALE LC\_CTYPE special register to the value of host variable HV1, which contains 'Fr\_FR@EURO'.

```
EXEC SQL SET CURRENT LOCALE LC_CTYPE = :HV1;
```

## SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

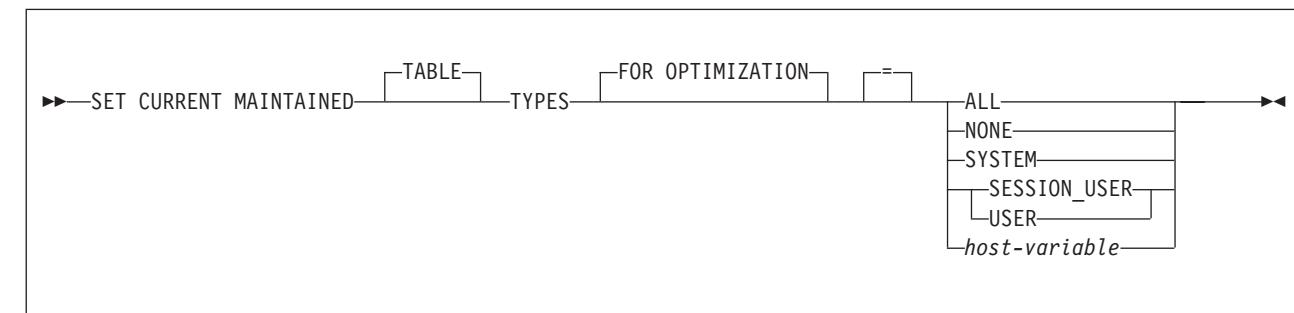

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

The value indicates which materialized query tables that are enabled for optimization are considered when optimizing the processing of dynamic SQL queries.

#### ALL

Indicates that all materialized query tables will be considered.

#### NONE

Indicates that no materialized query tables will be considered.

#### SYSTEM

Indicates that only system-maintained materialized query tables that are refresh deferred will be considered.

#### SESSION\_USER or USER

Indicates that only user-maintained materialized query tables that are refresh deferred will be considered.

#### *host-variable*

A variable of type CHAR or VARCHAR. The length of the contents of *host-variable* must not exceed 255 bytes. It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value.

The characters of *host-variable* must be left justified. The content of the host variable must be a string that would match what can be specified as keywords for the special register in the exact case intended as there is no conversion to uppercase characters.

## Notes

The CURRENT REFRESH AGE special register needs to be set to a value other than zero in order for the specified types of objects to be considered for optimizing the processing of dynamic SQL queries.

The CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register affects dynamic statement cache matching.

## Examples

*Example 1:* The following statement sets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register:

```
SET CURRENT MAINTAINED TABLE TYPES ALL;
```

*Example 2:* The following example retrieves the current value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register into the host variable called CURMAINTYPES.

```
EXEC SQL VALUES (CURRENT MAINTAINED TABLE TYPES) INTO :CURMAINTYPES;
```

The value would be ALL if set by the previous example.

*Example 3:* The following example resets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that no materialized query tables can be considered to optimize the processing of dynamic SQL queries.

```
SET CURRENT MAINTAINED TABLE TYPES NONE;
```

## SET CURRENT OPTIMIZATION HINT

The SET CURRENT OPTIMIZATION HINT statement assigns a value to the CURRENT OPTIMIZATION HINT special register.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►—SET CURRENT OPTIMIZATION HINT—=—string-constant  
                                          |  
                                          host-variable—►►
```

### Description

The value of special register CURRENT OPTIMIZATION HINT is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 128 bytes.

### Notes

*Using the OPTIMIZATION HINT special register:* The CURRENT OPTIMIZATION HINT special register specifies whether optimization hints are used in determining the access path of dynamic statements. See “CURRENT OPTIMIZATION HINT” on page 141 for additional information. An empty string or all blanks indicates that DB2 uses normal optimization techniques and ignores optimization hints.

### Example

*Example 1:* Assume that string constant 'NOHYB' identifies a user-defined optimization hint in owner.PLAN\_TABLE. Set the CURRENT OPTIMIZATION HINT special register so that DB2 uses this optimization hint to generate the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = 'NOHYB';
```

If you set the register this way, DB2 validates and considers information in the rows in owner.PLAN\_TABLE where the value in the OPTHINT column matches 'NOHYB' for dynamic SQL statements.

*Example 2:* Clear the CURRENT OPTIMIZATION HINT special register by specifying an empty string.

```
SET CURRENT OPTIMIZATION HINT = '';
```

## SET CURRENT PACKAGE PATH

The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

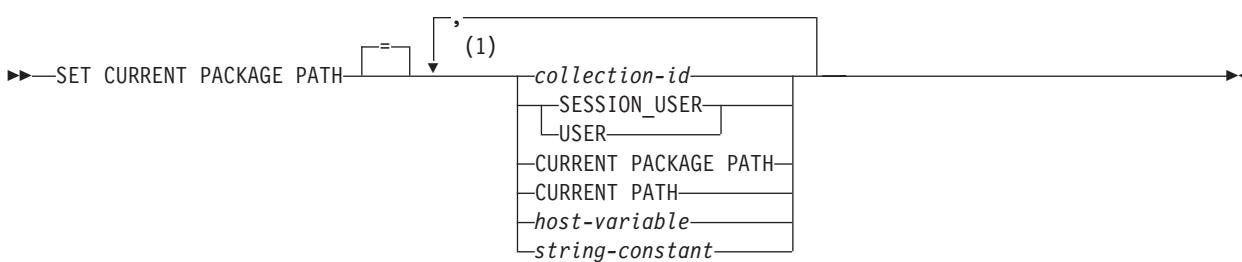

### Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

The value of CURRENT PACKAGE PATH is replaced by the values specified.

#### *collection-id*

Identifies a collection. *collection-id* must not be a delimited identifier that is empty or contains only blanks.

#### **SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register.

#### **CURRENT PACKAGE PATH**

Specifies the value of the CURRENT PACKAGE PATH special register before the execution of the SET CURRENT PACKAGE PATH statement.

#### **CURRENT PATH**

Specifies the value of the CURRENT PATH special register.

#### *host-variable*

Specifies a host variable that contains one or more collection IDs, separated by commas. The host variable must:

- Have a data type of CHAR or VARCHAR. The actual length of the contents of the host variable must not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Not be the null value if an indicator variable is provided.

- Contain an empty or blank string, or one or more collection IDs that are separated by commas.
- Be padded on the right with blanks if the host variable is fixed-length, or if the actual length of the host variable is longer than the content.
- Not contain a delimited identifier that is empty or contains only blanks.

*string-constant*

Specifies a string constant that contains one or more collection IDs, separated by commas. The string constant must:

- Have a length that does not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Contain an empty or blank string, or one or more collection IDs separated by commas.
- Not contain a delimited identifier that is empty or contains only blanks.

## Notes

*Contents of host variable or string constant:* The contents of a host variable or string constant are interpreted as a list of collection IDs if the value contains at least one comma. If multiple collection IDs are specified, they must be separated by commas. Each collection ID in the list must conform to the rules for forming an ordinary identifier or be specified as a delimited identifier.

*Checking for the existence of collections:* No validation that the collections exist is made at the time that the CURRENT PACKAGE PATH special register is set. For example, a collection ID that is misspelled is not detected, which could affect the way subsequent SQL operates. At package execution time, authorization to the specific package is checked, and if this authorization check fails, an error is issued.

*Resulting contents of the special register:* The special register string is built by taking each collection ID specified and removing trailing blanks, delimiting with double quotation marks, doubling any double quotation marks within the collection ID as necessary, and then separating each collection ID by a comma. If the same collection ID appears more than once in the list, the first occurrence of the collection is used, and a warning is issued. The length of the resulting list cannot exceed the length of the special register. For example, assume that the following statements are issued:

```
SET CURRENT PACKAGE PATH = MYPKGS, "ABC E", SYSIBM
SET :HVPKLIST = CURRENT PACKAGE PATH
```

These statements result in the value of the host variable being set to: "MYPKGS", "ABC E", "SYSIBM".

A collection ID that does not conform to the rules for an ordinary identifier must be specified as a delimited collection ID and must not be specified within a host variable or string constant.

*Considerations for keywords:* A difference exists between specifying a single keyword, such as SESSION\_USER, as a single keyword or as a delimited identifier. To indicate that the current value of a special register that is specified as a single keyword should be used in the package path, specify the name of the special register as a keyword. If you specify the name of the special register as a delimited identifier, it is interpreted as a collection ID of that value. For example, assume that the current value of the SESSION\_USER special register is SMITH and that the following statement is issued:

```
|           SET CURRENT PACKAGE PATH = SYSIBM, SESSION_USER, "USER"
```

| The result is that the value of the CURRENT PACKAGE PATH special register is  
| set to: "SYSIBM, "SMITH", "USER".

**Specifying a collection ID in an SQL procedure:** Because a host variable (SQL variable) in an SQL procedure does not begin with a colon, DB2 uses the following rules to determine whether a value that is specified in a SET PACKAGE PATH = *name* statement is a variable or a collection ID:

- If *name* is the same as a parameter or SQL variable in the SQL procedure, DB2 uses *name* as a parameter or SQL variable and assigns the value in *name* to the package path.
- If *name* is not the same as a parameter or SQL variable in the SQL procedure, DB2 uses *name* as a collection ID and assigns the value in *name* is the package path.

**DRDA classification:** The SET CURRENT PACKAGE PATH statement is executed by the database server and, therefore, is classified as a non-local SET statement in DRDA. The SET CURRENT PACKAGE PATH statement requires a new level of DRDA support. If SET CURRENT PACKAGE PATH is issued when connected to the local server, the SET CURRENT PACKAGE PATH special register at the local server is set. Otherwise, when SET CURRENT PACKAGE PATH is issued when connected to a remote server, the SET CURRENT PACKAGE PATH special register at the remote server is set.

## Examples

*Example 1:* Set the CURRENT PACKAGE PATH special register to the list of collections COLL4 and COLL5, where :hvar1 contains the value COLL4,COLL5:

```
SET CURRENT PACKAGE PATH :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following two collection IDs: "COLL4","COLL5".

*Example 2:* Set the CURRENT PACKAGE PATH special register to the list of collections: COLL1, COLL#2, COLL3, COLL4, and COLL5, where :hvar1 contains the value COLL4,COLL5:

```
SET CURRENT PACKAGE PATH = "COLL1","COLL#2","COLL3", :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following five collection IDs: "COLL1","COLL#2","COLL3","COLL4","COLL5".

*Example 3:* Clear the CURRENT PACKAGE PATH special register.

```
SET CURRENT PACKAGE PATH = ' ';
```

*Example 4:* In preparation of calling a stored procedure that is named SUMARIZE, temporarily add two collections, COLL\_PROD1" and "COLL\_PROD2, to the end of the CURRENT PACKAGE PATH special register (the values of the collections are in host variables :prodcoll1 and prodcoll2, respectively). Because the stored procedure SUMARIZE is not defined with a COLLID value and is defined with INHERIT SPECIAL REGISTERS, the stored procedure will inherit the value of CURRENT PACKAGE PATH. When the stored procedure returns, set the value of the CURRENT PACKAGE PATH special register back to its original value.

```
SET :oldCPP = CURRENT PACKAGE PATH;
SET CURRENT PACKAGE PATH = CURRENT PACKAGE PATH, :prodcoll1, :prodcoll2;
CALL SUMARIZE(:V1,:V2);
SET CURRENT PACKAGE PATH = :oldCPP;
```

## SET CURRENT PACKAGESET

The SET CURRENT PACKAGESET statement assigns a value to the CURRENT PACKAGESET special register.

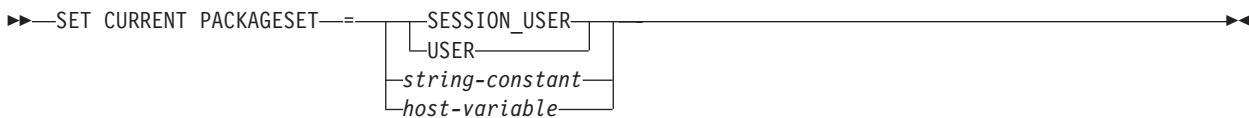

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

The value of CURRENT PACKAGESET is replaced by the value of the SESSION\_USER special register, *string-constant*, or *host-variable*. The value specified by *string-constant* or *host-variable* must be a character string that is not longer than 128 bytes.

### Notes

**Selection of plan elements:** A *plan element* is a DBRM that has been bound into the plan or a package that is implicitly or explicitly identified in the package list of the plan. Plan elements contain the control structures used to execute certain SQL statements.

Since a plan can have many elements, one of the first steps involved in the execution of an SQL statement that requires a control structure is the selection of the plan element that contains its control structure. The information used by DB2 to select plan elements includes the value of CURRENT PACKAGESET.

SET CURRENT PACKAGESET is used to specify the collection ID of a package that exists at the current server. SET CURRENT PACKAGESET is optional and should not be used without an understanding of the following rules for selecting a plan element.

If the CURRENT PACKAGESET special register is an empty string, DB2 searches for a DBRM or a package in one of these sequences:

**At the local location** (if CURRENT SERVER is blank or explicitly names that location), the order is:

1. All DBRMs bound directly to the plan
2. All packages that have already been allocated for the application process

3. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan. The order of search is the order those packages are named in the package list.

**At a remote location**, the order is:

1. All packages that have already been allocated for the application process at that location
2. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan, whose locations match the value of CURRENT SERVER. The order of search is the order those packages are named in the package list.

If the special register CURRENT PACKAGESET is set, DB2 skips the check for programs that are part of the plan and uses the value of CURRENT PACKAGESET as the collection. For example, if CURRENT PACKAGESET contains COL5, then DB2 uses COL5.PROG1.timestamp for the search. For additional information, see *DB2 Application Programming and SQL Guide*.

**DRDA classification:** SET CURRENT PACKAGESET is executed by the requester and is therefore classified as a local SET statement in DRDA.

**CURRENT PACKAGESET special register with stored procedures and user-defined functions:** The initial value of the CURRENT PACKAGESET special register in a stored procedure or user-defined function is the value of the COLLID parameter with which the stored procedure or user-defined function was defined. If the routine was defined without a value for the COLLID parameter, the value of the special register is inherited from the calling program. A stored procedure or user-defined function can use the SET CURRENT PACKAGESET statement to change the value of the special register. This allows the routine to select the version of the DB2 package that is used to process the SQL statements in a called routine that is not defined with a COLLID value.

When control returns from the stored procedure to the calling program, the special register CURRENT PACKAGESET is restored to the value it contained before the stored procedure was called.

## Examples

*Example 1:* Limit the plan element selection to packages in the PERSONNEL collection at the current server.

```
EXEC SQL SET CURRENT PACKAGESET = 'PERSONNEL';
```

*Example 2:* Eliminate collections as a factor in plan element selection.

```
EXEC SQL SET CURRENT PACKAGESET = '';
```

## SET CURRENT PRECISION

The SET CURRENT PRECISION statement assigns a value to the CURRENT PRECISION special register.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►SET CURRENT PRECISION = [string-constant |  
                           host-variable]►►
```

### Description

This statement replaces the value of the CURRENT PRECISION special register with the value of the string constant or host variable. The value must be a character string 5 bytes in length. The value must be 'DEC15,' 'DEC31,' or 'Dpp.s,' where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used with the rules that are used for DEC15 or DEC31, and 's' represents the minimum divide scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

### Example

Set the CURRENT PRECISION special register so that subsequent statements that are prepared use DEC15 rules for decimal arithmetic.

```
EXEC SQL SET CURRENT PRECISION = 'DEC15';
```

## SET CURRENT REFRESH AGE

The SET CURRENT REFRESH AGE statement changes the value of the CURRENT REFRESH AGE special register.

The CURRENT REFRESH AGE value corresponding to ANY (99 999 999 999 999) cannot be used in timestamp arithmetic operations because the result would be outside the valid range of dates.

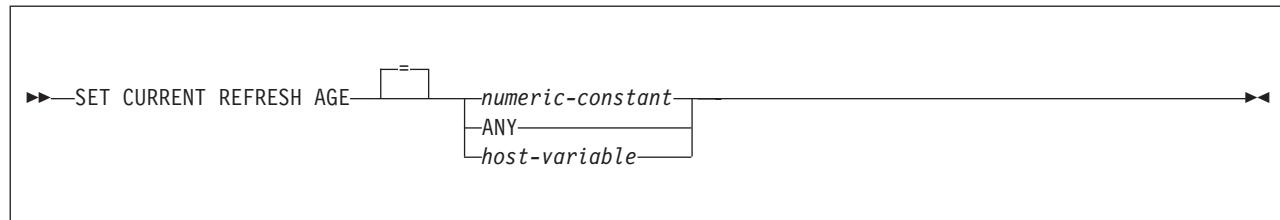

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### *numeric-constant*

A DECIMAL(20,6) value representing a timestamp duration. The value must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.

**0**      Indicates that query optimization using materialized query tables will not be attempted.

#### **999999999999999**

Indicates that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register may be used to optimize the processing of a query. This value represents 9999 years, 99 months, 99 days, 99 hours, 99 minutes, and 99 seconds.

#### **ANY**

Shorthand for 999999999999999.

#### *host-variable*

A variable of type DECIMAL(20,6) or other type that is assignable to DECIMAL(20,6). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of *host-variable* must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.

## Notes

Materialized query tables created or altered with DISABLE QUERY OPTIMIZATION specified are not eligible for automatic query rewrite. Thus, they are not affected by the setting of this special register.

Setting the CURRENT REFRESH AGE special register to a value other than zero should be done with caution. Allowing a materialized query table that may not represent the values of the underlying base table to be used to optimize the processing of a query may produce results that do not accurately represent the data in the underlying table. This situation may be acceptable when you know the underlying data has not changed or you are willing to accept the degree of error in the results based on your knowledge of the data.

## Examples

*Example:* Set the CURRENT REFRESH AGE special register to 99 999 999 999 999 to indicate that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register can be used to optimize the processing of a query.

```
SET CURRENT REFRESH AGE ANY;
```

## SET CURRENT ROUTINE VERSION

The SET CURRENT ROUTINE VERSION statement assigns a value to the CURRENT ROUTINE VERSION special register. The special register sets the override value for the version identifier of native SQL procedures when they are invoked.

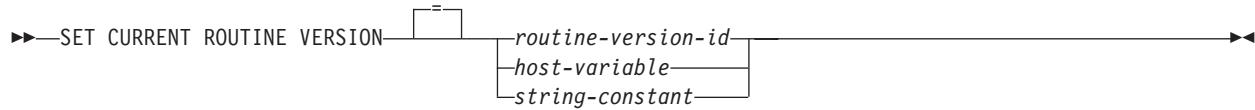

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### *routine-version-id*

Specifies a routine version identifier.

#### *host-variable*

Specifies a host variable that contains a version identifier. The host variable must conform to the following rules:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of a version identifier.
- Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or empty.
- Be padded on the right with blanks if the host variable is a fixed length character.
- Not be empty or contain only blanks if the identifier is delimited.
- Not be the null value.

#### *string-constant*

Specifies a string constant that contains a version identifier. The string constant must conform to the following rules:

- Have a length that does not exceed the length of a *routine-version-id*.
- Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or an empty string
- Not be empty or contain only blanks if the identifier is delimited

## Notes

*Resetting the special register:* To reset the special register, specify an empty string constant, a string of blanks, or a host variable that is empty or contains only blanks. A routine version override is not in effect when the special register is reset.

*Implications of using the special register:* Setting the CURRENT ROUTINE VERSION special register to a version identifier will affect all SQL procedures that are subsequently invoked using CALL statements that specify the name of the procedure using a host variable, until the value of CURRENT ROUTINE VERSION is changed. If a version of the procedure that is identified by the version identifier in the special register exists for an SQL procedure that is being invoked, that version of the procedure is used. Otherwise, the currently active version of the procedure (as noted in the catalog) is used.

When you use the CURRENT ROUTINE VERSION special register to test a version of one or more native SQL procedures, you should use a routine version identifier that is a value other than the default value (V1) on the CREATE PROCEDURE statement. This will avoid having the special register affect more procedures than you intend when testing a new version of a procedure. For example, assume that you want to run version VER2 of procedure P1, and procedure P1 invokes another procedure, P2. If a version exists for both procedures P1 and P2 with the routine version identifier VER2, that version will be used for both procedures.

## Examples

*Example:* The following statement sets the CURRENT ROUTINE VERSION special register so that the override value for the version identifier of native SQL procedures will be the value that is specified in the host variable *rvid*:

```
SET CURRENT ROUTINE VERSION = :rvid;
```

## SET CURRENT RULES

The SET CURRENT RULES statement assigns a value to the CURRENT RULES special register.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

```
►►SET CURRENT RULES = [string-constant] [host-variable]►►
```

### Description

This statement replaces the value of the CURRENT RULES special register with the value of the string constant or host variable. The value must be a character string that is 3 bytes in length, and the value must be 'DB2' or 'STD'.

### Notes

For the effect of the values 'DB2' and 'STD' on the execution of certain SQL statements, see "CURRENT RULES" on page 145.

### Example

Set the SQL rules to be followed to DB2.

```
EXEC SQL SET CURRENT RULES = 'DB2';
```

## SET CURRENT SQLID

The SET CURRENT SQLID statement assigns a value to the CURRENT SQLID special register.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only if DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.

### Authorization

If any of the authorization IDs of the process has SYSADM authority, CURRENT SQLID can be set to any value . Otherwise, the specified value must be equal to one of the authorization IDs of the application process. This rule always applies, even when SET CURRENT SQLID is a static statement.CURRENT SQLID cannot be set to the name of a role.

### Syntax

### Description

The value of CURRENT SQLID is replaced by the value of SESSION\_USER, *string-constant*, or *host-variable*. The value specified by a *string-constant* or *host-variable* must be a character string that contains 8 characters or less. Unless some authorization ID of the process has SYSADM authority, the value must be equal to one of the authorization IDs of the process.

### Notes

**Effect on authorization IDs:** SET CURRENT SQLID does not change the primary authorization ID of the process.

If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see the discussion of DYNAMICRULES in *DB2 Command Reference*.

**Effect on special register CURRENT PATH:** When the value of the PATH special register depends on the value of the CURRENT SQLID special register, any changes to the CURRENT SQLID special register are not reflected in the value of

the PATH special register until a commit operation is performed or a SET PATH statement is issued to change the SQL path to use the new value of the CURRENT SQLID.

*DRDA classification:* SET CURRENT SQLID is executed by the database server and is therefore classified as a non-local SET statement in DRDA.

## Examples

*Example 1:* Set the CURRENT SQLID to the primary authorization ID.

```
SET CURRENT SQLID = SESSION_USER;
```

## SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the value of the encryption password and, optionally, the password hint. The encryption and decryption built-in functions use this password and password hint for data encryption unless the functions are invoked with an explicitly specified password and hint. The password is not tied to DB2 authentication and is used only for data encryption.

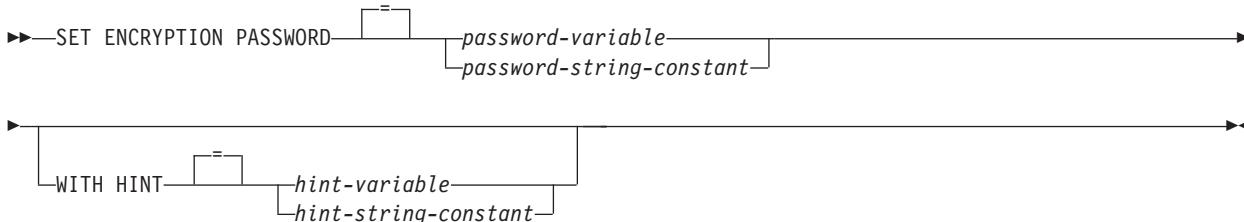

### Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

No authorization is required to execute this statement.

### Syntax

### Description

#### *password-variable*

Specifies a variable that contains an encryption password. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

#### *password-string-constant*

A character constant that contains an encryption password. The length of the constant must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value. All characters are case-sensitive and are not converted to uppercase characters.

#### **WITH HINT**

Indicates that a value is specified that will help you remember passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value is specified, the hint is used as the default for encryption functions. The hint can subsequently be retrieved for an encrypted value using the GETHINT function.

If this clause is not specified and a hint is not explicitly specified on the encryption function, no hint will be embedded in encrypted data result.

*hint-variable*

Specifies a variable that contains an encryption password hint. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must not be greater than 32. If an empty string is specified, the default encryption password hint is set to an empty string.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

*hint-string-constant*

A character string constant that contains an encryption password hint. The length of the constant must not be greater than 32. If the value is an empty string, the default encryption password hint is set to an empty string.

## Notes

Normal DB2 mechanisms are used to transmit the host variable or constant to the database server.

For more information about using this statement, see “[ENCRYPT\\_TDES](#)” on page 363 and “[DECRYPT\\_BINARY](#), [DECRYPT\\_BIT](#), [DECRYPT\\_CHAR](#), and [DECRYPT\\_DB](#)” on page 346..

## Examples

*Example 1:* Set the ENCRYPTION PASSWORD to the value in :hv1. Do not specify a hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1
```

*Example 2:* Set the ENCRYPTION PASSWORD to the value in :hv1. Specify the value in :hv2 as the hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1 WITH HINT :hv2
```

## SET host-variable assignment

The SET host-variable assignment statement assigns values, either of expressions or NULL values, to host variables.

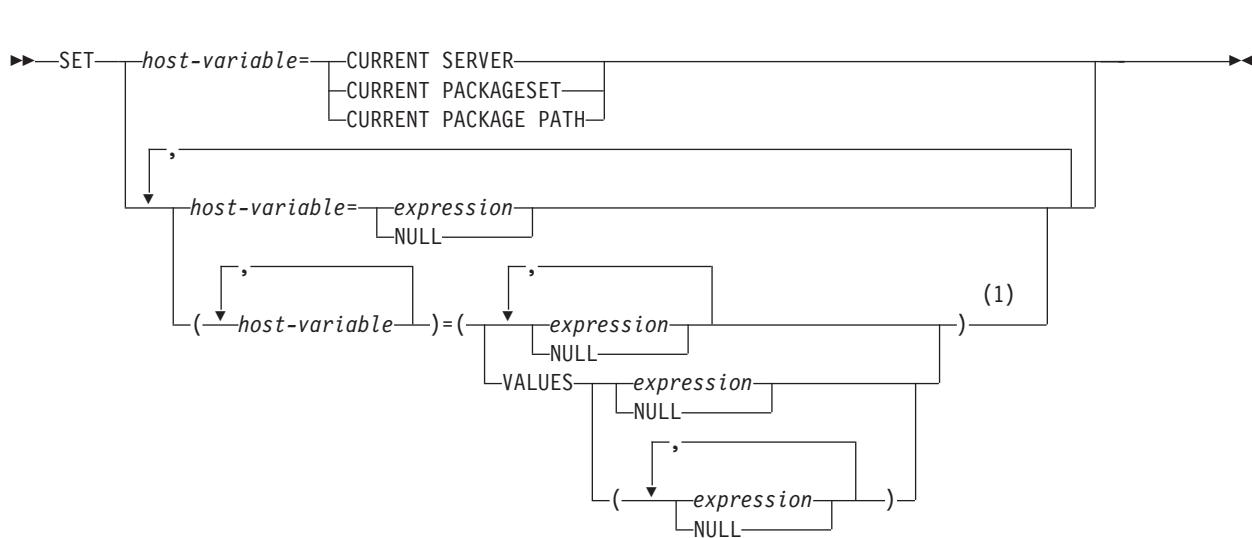

### Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

The privileges that are held by the current authorization ID must include those required to execute any of the expressions.

### Syntax

#### Notes:

- 1 The number of *expressions* and NULL keywords must match the number of *host-variables*.

### Description

#### host-variable

Identifies one or more host variables or transition variables that are used to receive the corresponding *expression* or NULL value on the right side of the statement.

For the triggered action of a CREATE TRIGGER statement, use the SET *transition-variable* instead.

The value to be assigned to each *host-variable* can be specified immediately following the item reference, for example, *host-variable* = *expression*, *host-variable*=*expression*. Or, sets of parentheses can be used to specify all the *host-variables* and then all the values, for example, (*host-variable*, *host-variable*) = (*expression*, *expression*).

### **host-variable**

Identifies one or more host variables that are used to receive the corresponding *expression* or NULL value on the right side of the statement. Each host variable must be defined in the program as described under the rules for declaring host variables. A parameter marker must not be specified in place of *host-variable*.

The value to be assigned to each *host-variable* can be specified immediately following the host variable, for example, *host-variable* = *expression*, *host-variable* = *expression*. Or, sets of parentheses can be used to specify all the *host-variables* and then all the values, for example, (*host-variable*, *host-variable*) = (*expression*, *expression*).

### **expression**

Specifies the value to be assigned to the corresponding *host-variable*. The expression is any expression of the type described in “Expressions” on page 180, except it cannot contain a reference to CURRENT PACKAGE PATH or to local special registers (CURRENT SERVER or CURRENT PACKAGESET).

All expressions are evaluated before any result is assigned to a host variable. If an expression refers to a host variable that is used in the host variable list, the value of the variable in the expression is the value of the variable prior to any assignments.

Each assignment to a host variable is made according to the assignment rules described in “Assignment and comparison” on page 102. Assignments are made in sequence through the list. When the *host-variables* are enclosed within parentheses, for example, (*host-variable*, *host-variable*, ...) = (*expression*, *expression*, ...), the first value is assigned to the first host variable in the list, the second value to the second host variable in the list, and so on.

### **NULL**

Specifies the null value and can only be specified for host variables that have an associated indicator variable.

### **VALUES**

Specifies the value to be assigned to the corresponding host variable. When more than one value is specified, the values must be enclosed in parentheses. Each value can be an expression or NULL, as described above. The following syntax is equivalent:

- (*host-variable*, *host-variable*) = (VALUES(*expression*, NULL))
- (*host-variable*, *host-variable*) = (*expression*, NULL)

Local special registers and the CURRENT PACKAGE PATH special register can be referenced only in a VALUES host-variable statement that results in the assignment of a single host variable and not those that result in setting more than one value.

## **Notes**

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specified by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

|

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with other data types. For more information on using locators, see *DB2 Application Programming and SQL Guide*.

## Examples

*Example 1:* Set the host variable HVL to the value of the CURRENT PATH special register.

```
SET :HVL = CURRENT PATH;
```

*Example 2:* Set the host variable PATH to the contents of the SQL PATH special register, the host variable XTIME to the local time at the current server, and the host variable MEM to the current member of the data sharing environment.

```
SET :SERVER = CURRENT PATH,  
      :XTIME = CURRENT TIME,  
      :MEM = CURRENT MEMBER;
```

*Example 3:* Set the host variable DETAILS to a portion of a LOB value, using a LOB expression with a LOB locator to refer the extracted portion of the value.

```
SET :DETAILS = SUBSTR(:LOCATOR,1,35);
```

If the LOB data that is specified by the LOB locator LOCATOR is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the SET statement:

```
SELECT SUBSTR(:LOCATOR,1,35)  
      INTO :DETAILS  
      FROM SYSIBM.SYSDUMMYU;
```

*Example 4:* Set host variable HV1 to the results of external function CALC\_SALARY and host variable HV2 to the value of special register CURRENT PATH. Use an indicator value with HV1 in case CALC\_SALARY returns a null value.

```
SET (:HV1:IND1, :HV2) =  
      (CALC_SALARY(:HV3, :HF4), CURRENT PATH);
```

## SET PATH

The SET PATH statement assigns a value to the CURRENT PATH special register.

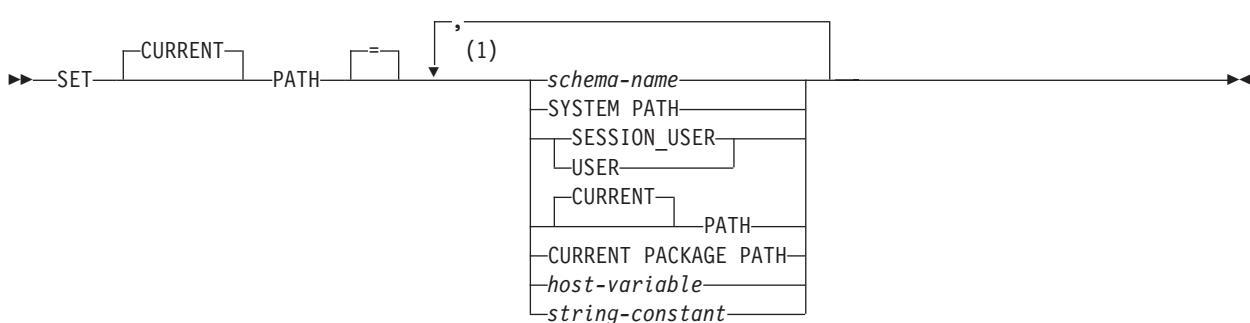

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

#### Notes:

- 1 SYSTEM PATH, SESSION\_USER or USER, and CURRENT PATH can be specified only once each.

### Description

The value of PATH is replaced by the values specified.

#### *schema-name*

Identifies a schema. DB2 does not verify that the schema exists. For example, a schema name that is misspelled is not detected, which could affect the way subsequent SQL operates.

#### **SYSTEM PATH**

Specifies the schema names "SYSIBM", "SYSFUN", or "SYSPROC".

#### **SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register.

#### **PATH**

Specifies the value of the CURRENT PATH special register before the execution of this statement.

#### **CURRENT PACKAGE PATH**

Specifies the value of the CURRENT PACKAGE PATH special register.

#### *host-variable*

A variable with a data type of CHAR or VARCHAR. The value of *host-variable* must not be null and must represent a valid schema name.

The schema name must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

*string-constant*

A character string constant that represents a valid schema name.

If the schema name specified in *string-constant* will also be specified in other SQL statements and the schema name does not conform to the rules for ordinary identifiers, the schema name must be specified as a delimited identifier in the other SQL statements.

## Notes

**Restrictions on SET PATH:** These restrictions apply to the SET PATH statement:

- If the same schema name appears more than once in the path, the first occurrence of the name is used and a warning is issued.
- The length of the CURRENT PATH special register limits the number of schema names that can be specified. The special register string is built by taking each schema name that is specified and removing trailing blanks, delimiting with double quotes, changing each double quote character to two double quote characters within the schema name as necessary, and then separating each schema name with a comma. The length of the resulting string cannot exceed 2048 bytes.

**Specifying SYSIBM, SYSPROC, and SYSFUN:** Schemas SYSIBM, SYSPROC, and SYSFUN do not need to be specified in the special register. If these schemas are not explicitly specified in the CURRENT PATH special register, each schema is implicitly assumed at the front of the SQL path; if any of these schemas are not specified, they are assumed in the order of SYSIBM, SYSPROC, SYSFUN (see "SQL path" on page 56 for an example). Only the schemas that are explicitly specified in the CURRENT PATH register are included in the 2048 byte limit.

To avoid having SYSIBM, SYSPROC, or SYSFUN implicitly added to the front of the SQL path, explicitly specify them in the path when setting the value of the register. If you specify them at the end of the path, DB2 will check all the other schemas in the path first.

**Specifying keywords versus delimited identifiers:** There is a difference between specifying a keyword and specifying a delimited identifier. For example, specifying SESSION\_USER with and without escape characters. To indicate that the value of the SESSION\_USER special register should be used in the SQL path, specify the keyword SESSION\_USER. If you specify SESSION\_USER as a delimited identifier instead (for example, "SESSION\_USER"), it is interpreted as a schema name of 'SESSION\_USER'. For example, assume that the current value of the SESSION\_USER special register is SMITH and that the following statement is issued:

```
SET PATH = SYSIBM, SYSPROC, SESSION_USER, "SESSION_USER"
```

The result is that the value of the SQL path is set to:  
"SYSIBM","SYSPROC","SMITH","SESSION\_USER".

**Specifying a schema name in an SQL procedure:** Because a host variable (SQL variable) in an SQL procedure does not begin with a colon, DB2 uses the following rules to determine whether a value that is specified in a SET PATH=*name* statement is a variable or a *schema-name*:

- If *name* is the same as a parameter or SQL variable in the SQL procedure, DB2 uses *name* as a parameter or SQL variable and assigns the value in *name* to PATH.
- If *name* is not the same as a parameter or SQL variable in the SQL procedure, DB2 uses *name* as a *schema-name* and assigns the value *name* to PATH.

**The use of the path to resolve object names:** For information on when the SQL path is used to resolve unqualified data type, function, and procedure names and when the CURRENT PATH special register provides the SQL path, see “SQL path” on page 56.

**DRDA classification:** The SET PATH statement is executed by the database server and, therefore, is classified as a non-local SET statement in DRDA.

**Alternative syntax and synonyms:** For compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports CURRENT FUNCTION PATH or CURRENT\_PATH as a synonym for CURRENT PATH. CURRENT\_PATH is consistent with the SQL standard name of the special register.

## Examples

*Example 1:* Set the CURRENT PATH special register to the list of schemas: "SCHEMA1", "SCHEMA#2", "SYSIBM".

```
SET PATH = SCHEMA1,"SCHEMA#2", SYSIBM;
```

When the special register provides the SQL path, SYSPROC which was not explicitly specified in the special register, is implicitly assumed at the front of the SQL path, making the effective value of the path:

```
SYSPROC, SCHEMA1, SCHEMA#2, SYSIBM
```

*Example 2:* Add schema SMITH and SYSPROC to the value of the CURRENT PATH special register that was set in Example 1.

```
SET PATH = CURRENT PATH, SMITH, SYSPROC;
```

The value of the special register becomes:

```
SCHEMA1, SCHEMA#2, SYSIBM, SMITH, SYSPROC
```

## SET SCHEMA

The SET SCHEMA statement assigns a value to the CURRENT SCHEMA special register. If the package is bound with the DYNAMICRULES BIND option, this statement does not affect the qualifier that is used for unqualified database object references.

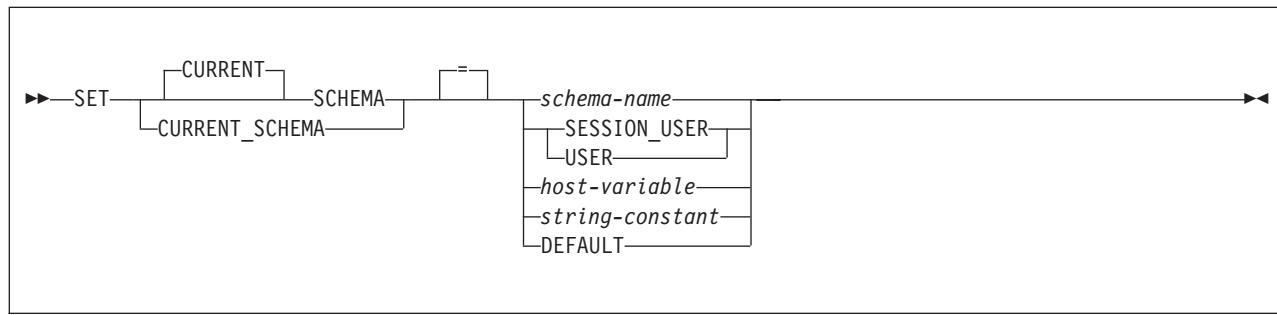

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

None required.

### Syntax

### Description

#### *schema-name*

Identifies a schema. No validation that the schema exists is made at the time the CURRENT SCHEMA is set. For example, if a schema name is misspelled, it could affect the way subsequent SQL operates.

#### **SESSION\_USER or USER**

Specifies the value of the SESSION\_USER (USER) special register.

#### *host-variable*

Specifies a host variable that contains a schema name. The content is not folded to uppercase.

The host variable must:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the *host-variable* must not exceed the length of a schema name.
- Not be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value.
- Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
- Be padded on the right with blanks if the host variable is fixed length.
- Not contain SESSION\_USER, USER, or DEFAULT.

*string-constant*

Specifies a string constant that contains a schema name. The content is not folded to uppercase.

The string constant must:

- Have a length that does not exceed the maximum length of a schema name.
- Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
- Not contain SESSION\_USER, USER, or DEFAULT.

**DEFAULT**

Specifies that CURRENT SCHEMA is to be set to its initial value, as if it had never been explicitly set during the application process. For information about the initial value of CURRENT SCHEMA, see "CURRENT SCHEMA" on page 147.

## Notes

*Considerations for keywords:* There is a difference between specifying a single keyword (such as SESSION\_USER or DEFAULT) as a single keyword or as a delimited identifier. To indicate that the current value of the SESSION\_USER special register should be used for setting the current schema, specify SESSION\_USER as a keyword. To indicate that the special register should be set to its default value, specify DEFAULT as a keyword. If SESSION\_USER or DEFAULT is specified as a delimited identifier instead (for example, "SESSION\_USER"), it is interpreted as a schema name of that value ("SESSION\_USER").

*Transaction considerations:* The SET SCHEMA statement is not a committable operation. ROLLBACK has no effect on CURRENT SCHEMA.

*Usage of the assigned value:* The value of the CURRENT SCHEMA special register, as set by this statement, is used as the schema name in all dynamic SQL statements. The QUALIFIER bind option specifies the schema name for use as the qualifier for unqualified database object names in static SQL statements.

*Impact on other special registers:* Setting the CURRENT SCHEMA special register does not affect any other special register. Therefore, the CURRENT SCHEMA is not be included in the SQL path that is used to resolve the schema name for unqualified references to function, procedures and user-defined types in dynamic SQL statements. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.

## Examples

*Example 1:* The following statement sets the CURRENT SCHEMA special register.

```
EXEC SQL SET SCHEMA RICK;
```

*Example 2:* The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.

```
EXEC SQL SELECT CURRENT SCHEMA INTO :CURSCHEMA  
FROM SYSIBM.SYSDUMMY;
```

The value of the host variable is RICK.

| *Example 3:* Assume that the following statements are issued:

```
| SET CURRENT SQLID = 'USR001';
| SET CURRENT SCHEMA = 'USR002';
```

| At this point, the two special registers contain different values. Any subsequent  
| CREATE statements will use USR002 as the implicit qualifier, but the owner of  
| the newly created objects is USR001.

| *Example 4:* Assume that the value of CURRENT SCHEMA is 'Jane' and that the  
| default value of the PATH special register was established using that value (that is,  
| the value of PATH is "SYSIBM", "SYSFUN", "SYSPROC", "Jane"). Change the value  
| of the CURRENT SCHEMA special register to 'John'.

```
| SET CURRENT SCHEMA = 'JOHN';
```

| To change the SQL path to use the updated CURRENT SCHEMA value of 'John',  
| issue a SET PATH statement to change the value of the PATH special register.  
| Alternatively, a commit would cause PATH to be re-initialized. Otherwise, the path  
| remains "SYSIBM", "SYSFUN", "SYSPROC", "Jane"), which might cause unqualified  
| object names to resolve to 'Jane' when you want them to resolve to "John".

## SET transition-variable assignment

The SET transition-variable assignment statement assigns values, either of expressions or NULL values, to transition variables.

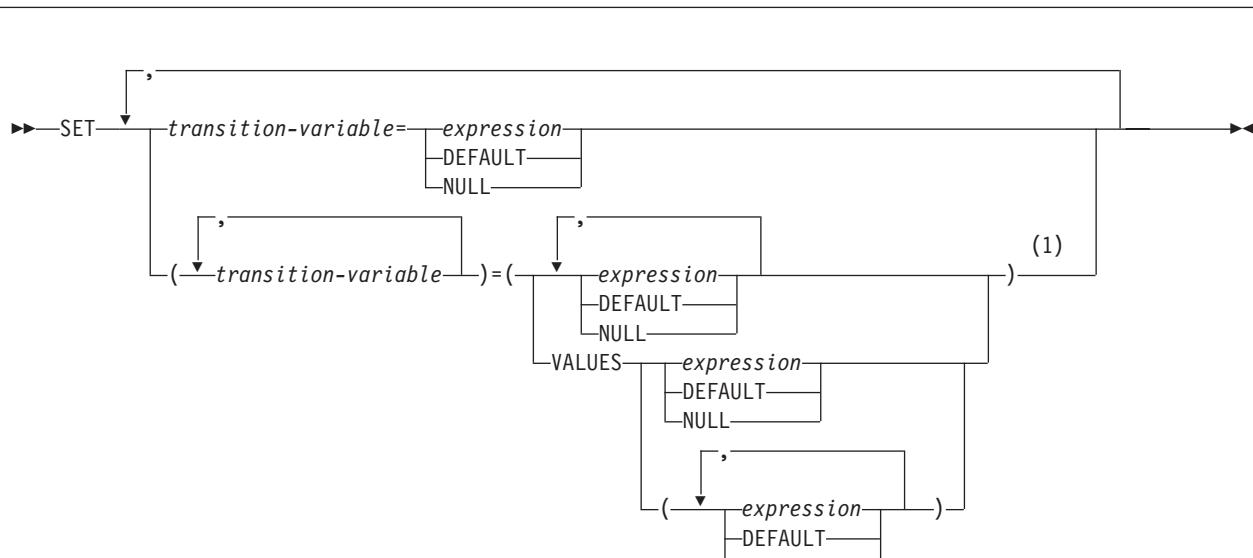

### Invocation

This statement can be used as a triggered SQL statement in the triggered action of a before trigger whose granularity is FOR EACH ROW.

### Authorization

The privileges that are held by the current authorization ID must include those required to execute any of the expressions or assignments to transition variables.

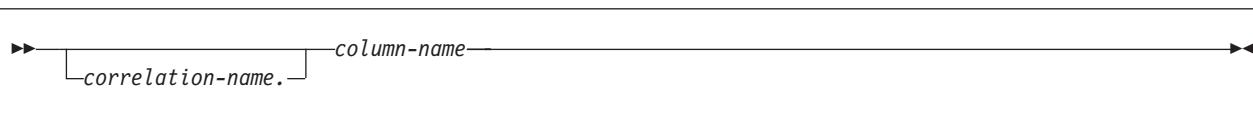

### Syntax

#### Notes:

- 1 The number of *expressions*, DEFAULT, and NULL keywords must match the number of *transition-variables*.

*transition-variable:*

### Description

*transition-variable*

Identifies a column in the set of affected rows for the trigger that is used to receive the corresponding *expression*, default value, or NULL value on the right side of the statement.

The value to be assigned to each *transition-variable* can be specified immediately following the transition variable, for example, *transition-variable* = *expression*, *transition-variable*=*expression*. Or, sets of parentheses can be used to specify all the *transition-variables* and then all the values, for example, (*transition-variable*, *transition-variable*) = (*expression*, *expression*).

*correlation-name*

Identifies the correlation name given for referencing the NEW transition variables. The name must match the correlation name specified following NEW in the REFERENCING clause of the CREATE TRIGGER statement.

If OLD is not specified in the REFERENCING clause, *correlation-name* defaults to the correlation name following NEW.

*column-name*

Identifies the column to be updated. The name must identify a column of the subject table. The name can identify a column that is defined as GENERATED BY DEFAULT but not one defined as GENERATED ALWAYS, unless the DEFAULT keyword is specified on the right side of the statement. You must not specify the same column more than once.

The effect of a SET *transition-variable* statement is equivalent to the effect of an SQL UPDATE statement.

*expression*

Specifies the value to be assigned to the corresponding *transition-variable*. The expression is any expression of the type described in "Expressions" on page 180. A reference to a *local special register* is the value of that special register at the *server* when the trigger body is activated. If the expression contains a scalar fullselect, the scalar fullselect cannot reference columns of the triggering table. The expression cannot include a aggregate function except when it occurs within a scalar fullselect.

An expression can contain references to OLD and NEW transition variables that are qualified with a correlation name.

All expressions are evaluated before any result is assigned to a transition variable. If an expression refers to a transition variable that is used in the list of transition variables, the value of the variable in the expression is the value of the variable prior to any assignments.

Each assignment to a transition variable column is made according to the assignment rules described in "Assignment and comparison" on page 102. Assignments are made in sequence through the list. When the *transition-variables* are enclosed within parentheses, for example, (*transition-variable*, *transition-variable*, ...) = (*expression*, *expression*, ...), the first value is assigned to the first transition variable in the list, the second value to the second transition variable in the list, and so on.

**DEFAULT**

Specifies that the default value is used based on how the corresponding column is defined in the table. The value that is assigned depends on how the column is defined.

- If the column is defined using the IDENTITY clause, the column is generated by the DB2 system.
- If the column is defined as a row change timestamp column, the column value is generated by the DB2 system.

- If the column is defined using the WITH DEFAULT clause, the value is set to the default that is defined for the column.
- If the column is defined without specifying the WITH DEFAULT clause, the GENERATED clause, or the NOT NULL clause, the value is NULL
- If the column is specified in the INCLUDE column list, the column value is set to null.

A ROWID column must not be set to the DEFAULT keyword.

An identity column or a row change timestamp column that is defined as GENERATED ALWAYS can be set only to the DEFAULT keyword.

If the column is defined using the NOT NULL clause and the GENERATED clause is not used, or the WITH DEFAULT clause is not used, the DEFAULT keyword cannot be specified for that column.

#### **NULL**

Specifies the null value and can only be specified for nullable transition variables.

#### **VALUES**

Specifies the value to be assigned to the corresponding transition variable. When more than one value is specified, the values must be enclosed in parentheses. Each value can be an expression or NULL, as described above. The following syntax is equivalent:

- $(transition-variable, transition-variable) = (VALUES(expression, NULL))$
- $(transition-variable, transition-variable) = (expression, NULL)$

### **Examples**

*Example 1:* Assume that you want to create a before trigger that sets the salary and commission columns to default values for newly inserted rows in the EMPLOYEE table and that you will define the trigger only with NEW in the REFERENCING clause. Write the SET transition-variable statement that assigns the default values to the SALARY and COMMISSION columns.

```
SET (SALARY, COMMISSION) = (50000, 8000);
```

*Example 2:* Assume that you want to create a before trigger that detects any commission increases greater than 10% for updated rows in the EMPLOYEE table and limits the commission increase to 10%. You will define the trigger with both OLD and NEW in the REFERENCING clause. Write the SET transition-variable statement that limits an increase to the COMMISSION column to 10%.

```
SET NEWROW.COMMISSION = 1.1 * OLDROW.COMMISSION;
```

---

## SIGNAL

The SIGNAL statement is used to signal an error. It causes an error to be returned with the specified SQLSTATE and error description.

For a description of the statement, see “[SIGNAL statement](#)” on page 1582.

## TRUNCATE

The DB2 TRUNCATE statement deletes all rows for either base tables or declared global temporary tables. The base table can be in a simple table space, a segmented table space, a partitioned table space, or a universal table space. If the table contains LOB or XML columns, the corresponding table spaces and indexes are also truncated.

### Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

### Authorization

The privilege set that is defined below must include at least one of the following privileges:

- The DELETE privilege for the table
- Ownership of the table
- DBADM authority for the database
- SYSADM authority

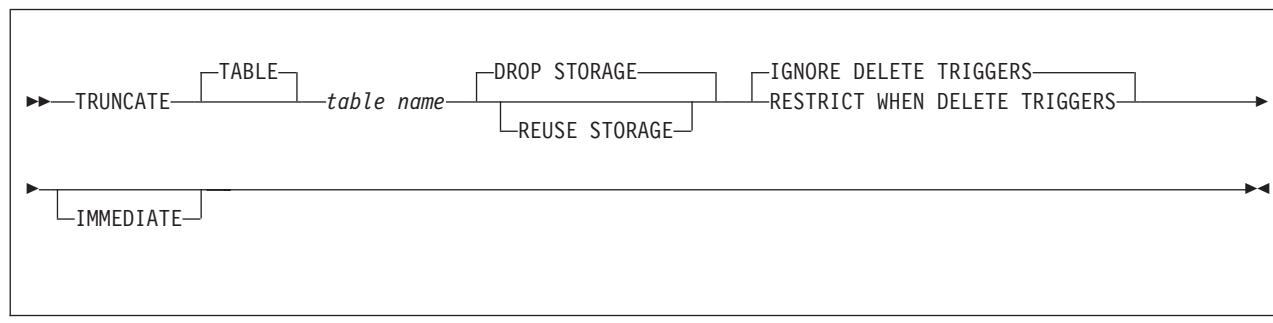

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Additionally, if the IGNORE DELETE TRIGGERS option is specified, the privilege set must include at least one of the following privileges:

- The ALTER privilege for the table
- Ownership of the table
- DBADM authority for the database
- SYSADM authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 64.)

### Syntax

## Description

### *table-name*

Identifies the table that is to be truncated. The name must identify a table that exists at the current server. The name must not identify the following objects:

- a view
- an auxiliary table
- an XML table
- a catalog table

If *table-name* is a base table of a table space, all tables that are defined under the table will also be truncated (for example: auxiliary LOB table spaces and XML table spaces), and all of its associated indexes will also be truncated.

### **DROP STORAGE or REUSE STORAGE**

Specifies whether to drop or reuse the existing storage that is allocated for the table.

#### **DROP STORAGE**

Specifies that all storage that is allocated for the table is released and made available for use for the same table or any other table that resides in the table space. The scope of **DROP STORAGE** is always at the table space level and the deallocated space is always available for reuse by all tables in the table space.

**DROP STORAGE** is the default.

#### **REUSE STORAGE**

Specifies that all storage that is allocated for the table will be emptied, but will continue to be allocated for the table. **REUSE STORAGE** is ignored for a table in a simple table space and the statement is processed as if **DROP STORAGE** is specified.

### **RESTRICT WHEN DELETE TRIGGERS or IGNORE DELETE TRIGGERS**

Specifies what to do when delete triggers are defined on the table.

#### **RESTRICT WHEN DELETE TRIGGERS**

Specifies that an error is returned if delete triggers are defined on the table.

#### **IGNORE DELETE TRIGGERS**

Specifies that any delete triggers that are defined for the table are not activated by the truncate operation.

**IGNORE DELETE TRIGGERS** is the default.

### **IMMEDIATE**

Specifies that the truncate operation is processed immediately and cannot be undone. If the **IMMEDIATE** option is specified, the table must not contain any uncommitted updates. In the case of a table in a simple table space, the entire table space must not contain any uncommitted updates or the truncate operation will fail. Also, if any uncommitted CREATE or ALTER statement has been executed, the truncate operation will fail.

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

If IMMEDIATE is not specified, a ROLLBACK statement can undo the truncate operation.

The IMMEDIATE option can be specified for a table in a segmented table space or a universal table space which allows deallocated spaces to be reclaimed immediately for subsequent insert operations in the same unit of work without committing the truncate operation.

## Notes

**Rules and restrictions:** The truncate operation cannot be executed if the table is a parent table in a defined referential constraint. The DB2 subsystem issues an error when it detects the existence of rule violations. Therefore, if the referential integrity constraint exists, the TRUNCATE statement will be restricted regardless of whether the child table contains rows.

If the TRUNCATE statement is used on a tables where any of the following conditions is true, the truncate operation will perform in a similar way to a mass delete operation:

- Tables with Change Data Capture (CDC) attribute

The DB2 subsystem allows a table with the CDC-enabled attribute to be truncated without imposing any new restrictions.

- Tables with multi-level security

If the table contains a column that is defined as a security label, the truncate operation needs to examine each row to determine if the security label of the authorization ID or role has the authority to delete that row. However, if the primary authorization ID or role has write-down privilege, verification of each row in the table is not necessary.

- Tables with a VALIDPROC attribute

If a VALIDPROC is defined for the table, the truncate operation needs to verify the validity of each row in the table.

**TRUNCATE and table spaces that are not logged:** The TRUNCATE TABLE statement can be used to remove a table space from the logical page list and to reset recover-pending status. When the table space is segmented or universal, the table is the only table in the table space, and the table does not have a VALIDPROC, referential constraints, delete triggers, or a SECURITY LABEL column, use the TRUNCATE TABLE statement to empty the table and the table space will be removed from the LPL and recover-pending status will be reset.

## Examples

*Example 1:* Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```
TRUNCATE TABLE INVENTORY  
DROP STORAGE  
IGNORE DELETE TRIGGERS;
```

*Example 2:* Empty an unused inventory table regardless of any existing delete triggers but preserve its allocated space for later reuse.

```
TRUNCATE TABLE INVENTORY  
REUSE STORAGE  
IGNORE DELETE TRIGGERS;
```

*Example 3:* Empty an unused inventory table permanently (a ROLLBACK statement cannot undo the truncate operation when the **IMMEDIATE** option is specified) regardless of any existing delete triggers and preserve its allocated space for immediate use.

```
TRUNCATE TABLE INVENTORY  
REUSE STORAGE  
IGNORE DELETE TRIGGERS  
IMMEDIATE;
```

## UPDATE

The UPDATE statement updates the values of specified columns in rows of a table or view or activates an instead of update trigger. Updating a row of a view updates a row of the table on which the view is based if no instead of update trigger is defined for the update operation on the view. If such a trigger is defined, the trigger is activated instead of the UPDATE statement. The table or view can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

There are two forms of this statement:

- The *searched* UPDATE form is used to update one or more rows optionally determined by a search condition.
- The *positioned* UPDATE form specifies that one or more rows corresponding to the current cursor position are to be updated.

### Invocation

This statement can be embedded in an application program or issued interactively. A positioned UPDATE can be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

### Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which updates are allowed, or a view, and whether SQL standard rules are in effect:

*When a user-defined table is identified:* The privilege set must include at least one of the following:

- The UPDATE privilege on the table
- The UPDATE privilege on each column to be updated
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

*When a catalog table is identified:* The privilege set must include at least one of the following:

- The UPDATE privilege on each column to be updated
- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

*When a view is identified:* The privilege set must include at least one of the following:

- The UPDATE privilege on the view
- The UPDATE privilege on each column to be updated
- SYSADM authority

**When SQL standard rules are in effect:** If SQL standard rules are in effect and an expression in the SET clause contains a reference to a column of the table or view, or if the search-condition in a searched UPDATE contains a reference to a column of the table or view, the privilege set must include at least one of the following:

- The SELECT privilege on the table or view
- SYSADM authority

SQL standard rules are in effect as follows:

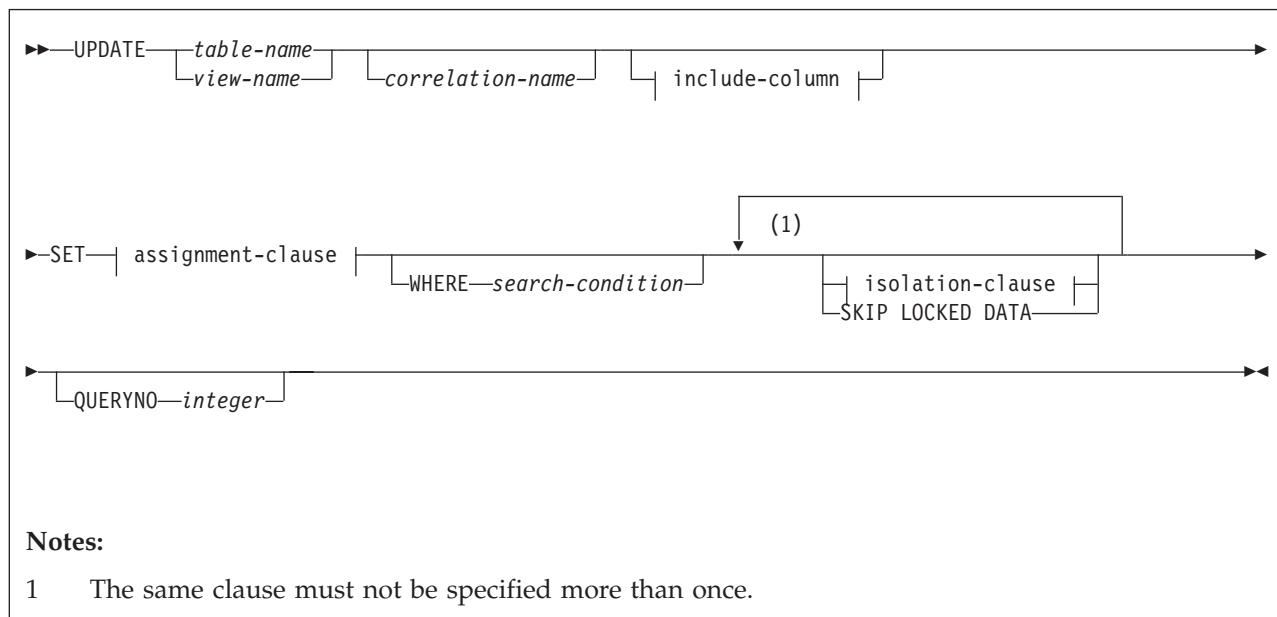

- For static SQL statements, if the SQLRULES(STD) bind option was specified
- For dynamic SQL statements, if the CURRENT RULES special register is set to 'STD'

The owner of a view, unlike the owner of a table, might not have UPDATE authority on the view (or might have UPDATE authority without being able to grant it to others). The nature of the view itself can preclude its use for UPDATE. For more information, see the discussion of authority in "CREATE VIEW" on page 1184.

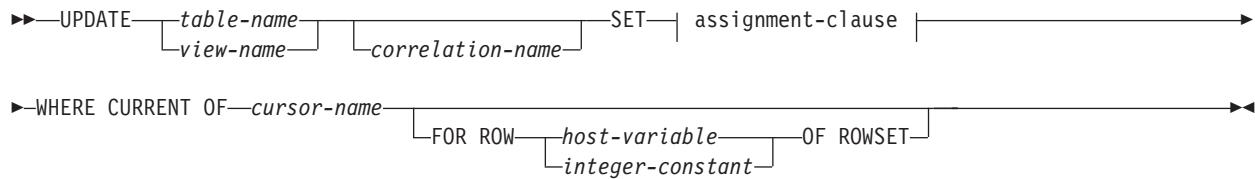

If a fullselect is specified, the privilege set must include authority to execute the fullselect. For more information about the authorization rules, see "Authorization" on page 630.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 81 on page 691. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 64).

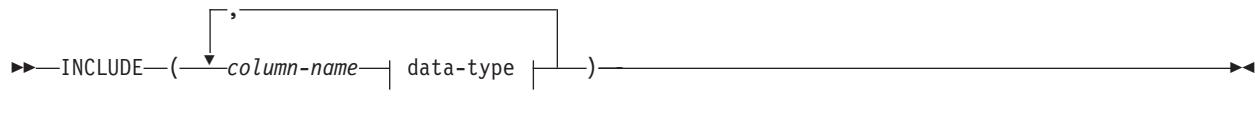

#### searched update:

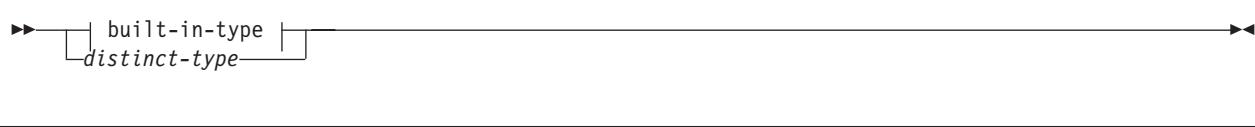

**positioned update:**

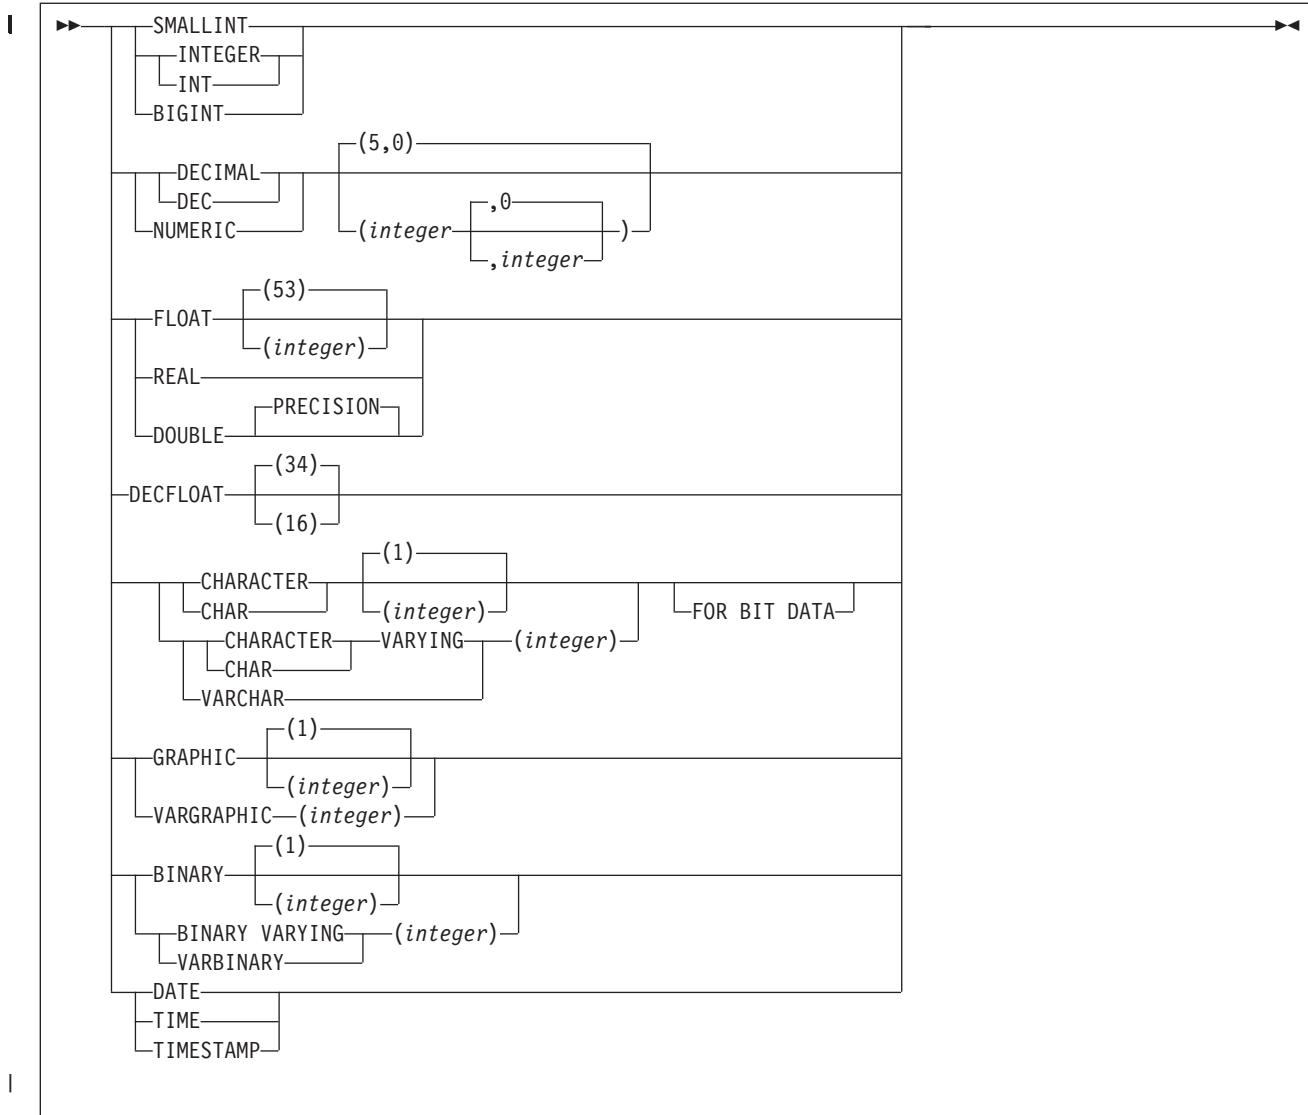

| **include-column:**

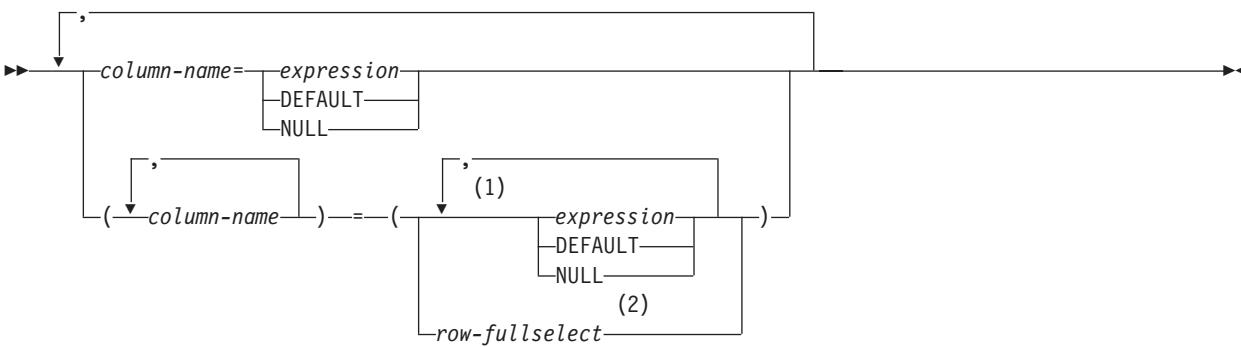

| **data-type:**

| **built-in-type:**

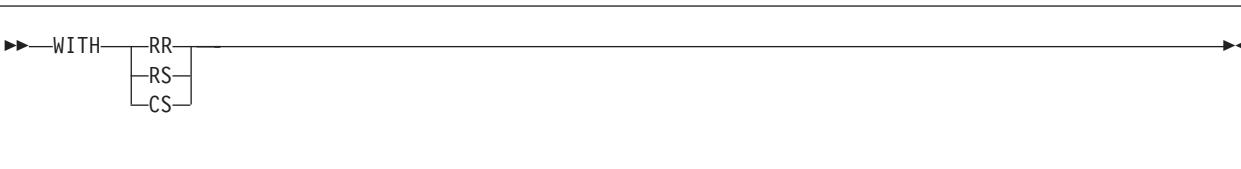

## assignment clause:

## Notes:

- 1 The number of *expressions*, DEFAULT, and NULL keywords must match the number of *column-names*.
  - 2 The number of columns in the select list must match the number of *column-names*.

**isolation-clause:**

## Description

*table-name or view-name*

Identifies the object of the UPDATE statement. The name must identify a table or view that exists at the DB2 subsystem identified by the implicitly or explicitly specified location name. The name must not identify:

- An auxiliary table
  - A created temporary table or a view of a created temporary table
  - A catalog table with no updatable columns or a view of a catalog table with no updatable columns
  - A read-only view that has no INSTEAD OF trigger defined for its update operations. (For a description of a read-only view, see “CREATE VIEW” on page 1184.)
  - A system-maintained materialized query table
  - A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

A catalog table or a view of a catalog table can be identified if every column identified in the SET clause is an updatable column. If a column of a catalog table is updatable, its description in “DB2 catalog tables” on page 1677 indicates that the column can be updated. If the object table is SYSIBM.SYSSTRINGS, any column other than IBMREQD can be updated, but the rows selected for update must be rows provided by the user (the value of the IBMREQD column is N) and only certain values can be specified as explained in *DB2 Administration Guide*.

*correlation-name*

Can be used within *search-condition* or *assignment-clause* to designate the table or view. (For an explanation of *correlation-name*, see “Correlation names” on page 154.)

*include-column*

Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the result table of the UPDATE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by *table-name* or *view-name*. If no value is assigned to a column that is specified by an *include-column*, a NULL value is returned for that column.

**INCLUDE**

Introduces a list of columns that are to be included in the result table of the UPDATE statement. The included columns are only available if the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

*column-name*

Specifies the name for a column of the result table of the UPDATE statement that is not the same name as another included column nor a column in the table or view that is specified in *table-name* or *view-name*.

*data-type*

Specifies the data type of the included column. The included columns are nullable.

*built-in-type*

Specifies a built-in data type. See “CREATE TABLE” on page 1079 for a description of each built-in type.

*distinct-type*

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**SET**

Introduces the assignment of values to column names.

*assignment-clause*

If *row-fullselect* is specified, the number of columns in the result of *row-fullselect* must match the number of *column-names* that are specified. If *row-fullselect* is not specified, the number of expressions, and NULL and DEFAULT keywords must match the number of *column-names* that are specified.

*column-name*

Identifies a column that is to be updated. *column-name* must identify a column of the specified table or view, and that column must be updatable. The column must not identify a generated column or a view column where the column is derived from a scalar function, constant, or expression. *column-name* can also identify an INCLUDE column that must not be qualified. The same column must not be specified more than one time.

Assignments to included columns are only processed when the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause

that specifies a *column-name* that is not an INCLUDE column. The null value is returned for an included column that is not set by using an explicit SET clause.

For a positioned update, allowable column names can be further restricted to those in a certain list. This list appears in the FOR UPDATE clause of the SELECT statement for the associated cursor. The clause can be omitted by using the conditions that are described in “Positioned updates of columns” on page 256.

A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same UPDATE statement.

#### *expression*

Indicates the new value of the column. The *expression* is any expression of the type described in “Expressions” on page 180. It must not include an aggregate function.

A *column-name* in an expression must identify a column of the table or view. For each row that is updated, the value of the column in the expression is the value of the column in the row before the row is updated.

#### **DEFAULT**

Specifies that the default value is used based on how the corresponding column is defined in the table. The value that is assigned depends on how the column is defined.

- If the column is defined using the **IDENTITY** clause, the column is generated by the DB2 system.
- If the column is defined as a row change timestamp column, the column value is generated by the DB2 system.
- If the column is defined using the **WITH DEFAULT** clause, the value is set to the default that is defined for the column.
- If the column is defined without specifying the **WITH DEFAULT** clause, the **GENERATED** clause, or the **NOT NULL** clause, the value is **NULL**.
- If the column is specified in the **INCLUDE** column list, the column value is set to null.

A ROWID column must not be set to the **DEFAULT** keyword.

An identity column or a row change timestamp column that is defined as **GENERATED ALWAYS** can be set only to the **DEFAULT** keyword.

If the column is defined using the **NOT NULL** clause and the **GENERATED** clause is not used, or the **WITH DEFAULT** clause is not used, the **DEFAULT** keyword cannot be specified for that column.

#### **NULL**

Specifies the null value as the new value of the column. Specify **NULL** only for nullable columns.

#### *row-fullselect*

Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding *column-names*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column to be updated is not nullable. An error also occurs if there is more than one row in the result.

For a positioned update, if the table or view that is the object of the UPDATE statement is used in the fullselect, a column from the instance of the table or view in the fullselect cannot be the same as *column-name*, a column being updated.

If the fullselect refers to columns to be updated, the value of such a column in the fullselect is the value of the column in the row before the row is updated.

#### WHERE

Specifies the rows to be updated. You can omit the clause, give a search condition, or specify a cursor. If you omit the clause, all rows of the table or view are updated.

##### *search-condition*

Specifies any search condition described in Chapter 2, “Language elements,” on page 47. Each *column-name* in the search condition, other than in a subquery, must identify a column of the table or view.

The *search-condition* is applied to each row of the table or view and the updated rows are those for which the result of the *search-condition* is true. If the unique key or primary key is a parent key, the constraints are effectively checked at the end of the operation.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

#### WHERE CURRENT OF *cursor-name*

Identifies the cursor to be used in the update operation. *cursor-name* must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in “DECLARE CURSOR” on page 1191. If the UPDATE statement is embedded in a program, the DECLARE CURSOR statement must include *select-statement* rather than *statement-name*.

The object of the UPDATE statement must also be identified in the FROM clause of the SELECT statement of the cursor. The columns to be updated can be identified in the FOR UPDATE clause of that SELECT statement though they do not have to be identified. If the columns are not specified, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

The result table of the cursor must not be read-only. For an explanation of read-only result tables, see Read-only cursors. Note that the object of the UPDATE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

When the UPDATE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

- If the cursor is positioned on a single row, that row is the one updated.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are updated.

A positioned UPDATE must not be specified for a cursor that references a view on which an instead of update trigger is defined, even if the view is an updatable view.

#### **FOR ROW *n* OF ROWSET**

Specifies which row of the current rowset is to be updated. The corresponding row of the rowset is updated, and the cursor remains positioned on the current rowset.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range of 1 to 32767.

The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor. If the specified row cannot be updated, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If this clause is not specified, the cursor position determines the rows that will be affected. If the cursor is positioned on a single row, that row is the one updated. In the case where the most recent FETCH statement returned multiple rows of data (but not as a rowset), this position would be on the last row of data that was returned. If the cursor is positioned on a rowset, all rows corresponding to the current rowset are updated. The cursor position remains unchanged.

It is possible for another application process to update a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to update such a row results in an error.

#### *isolation-clause*

Specifies the isolation level used when locating the rows to be updated by the statement.

#### **WITH**

Introduces the isolation level, which may be one of the following:

- RR**    Repeatable read
- RS**    Read stability
- CS**    Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

#### **SKIP LOCKED DATA**

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. **SKIP LOCKED DATA** can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

**SKIP LOCKED DATA** can be specified only in the searched UPDATE statement (or the searched update operation of a MERGE statement). **SKIP LOCKED DATA** is ignored if it is specified when the isolation level that is in effect is repeatable read (**WITH RR**) or uncommitted read (**WITH UR**). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

### **QUERYNO** *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the **QUERYNO** clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *DB2 Performance Monitoring and Tuning Guide*.

## **Notes**

**Update rules:** Update values must satisfy the following rules. If they do not, or if other errors occur during the execution of the UPDATE statement, no rows are updated and the position of the cursors are not changed.

- *Assignment.* Update values are assigned to columns using the assignment rules described in Chapter 2, “Language elements,” on page 47.
- *Validity.* Updates must obey the following rules. If they do not, or if any other errors occur during the execution of the UPDATE statement, no rows are updated.
  - *Fullselects:* The row-fullselect and expressions that contain a *scalar-fullselect* must return no more than one row.
  - *Unique constraints and unique indexes:* If the identified table (or base table of the identified view) has any unique indexes or unique constraints, each row that is updated in the table must conform to the limitations that are imposed by those indexes and constraints.
- All uniqueness checks are effectively made at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.
- *Check constraints:* If the identified table (or base table of the identified view) has any check constraints, each check constraint must be true or unknown for each row that is updated in the table.
- All checks constraints are effectively validated at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.
- *Views and the WITH CHECK OPTION.* For views defined with WITH CHECK OPTION, an updated row must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the updated rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see “CREATE VIEW” on page 1184.

For views that are not defined with WITH CHECK OPTION, you can change the rows so that they no longer conform to the definition of the view. Such rows are updated in the base table of the view and no longer appear in the view.

- *Field and validation procedures.* The updated rows must conform to any constraints imposed by any field or validation procedures on the identified table (or on the base table of the identified view).
- *Referential constraints.* The value of the parent key in a parent row must not be changed. If the update value produces a foreign key that is nonnull, the foreign key must be equal to some value of the parent key of the parent table of the relationship.

All referential constraints are effectively checked at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.

- *Indexes with VARBINARY columns.* If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.
- *Triggers.* An UPDATE statement might cause triggers to activate. A trigger might cause other statements to be executed or raise error conditions based on the update values. If an UPDATE statement for a view causes an instead of trigger to activate, validity, referential integrity, and check constraints are checked against the data changes that are performed in the trigger and not against the view that causes the trigger to activate or its underlying base tables.

**Number of rows updated:** Normally, after an UPDATE statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows updated. (For a complete description of the SQLCA, including exceptions to the preceding sentence, see “SQL communication area (SQLCA)” on page 1646.)

**Nesting user-defined functions or stored procedures:** An UPDATE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the UPDATE must not access the table being updated.

**Locking:** Unless appropriate locks already exist, one or more exclusive locks are acquired by the execution of a successful update operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the updated row. If LOBs are not updated, application processes that are running with uncommitted read can also access the updated row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

**Datetime representation when using datetime registers:** As explained under Datetime special registers, when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are updated.

**Rules for positioned UPDATE with a SENSITIVE STATIC scrollable cursor:** When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- *Update attempt of delete holes.* If, with a positioned update against a SENSITIVE STATIC scrollable cursor, an attempt is made to update a row that has been identified as a delete hole, an error occurs.
- *Update operations.* Positioned update operations with SENSITIVE STATIC scrollable cursors perform as follows:
  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, then the update operation is rejected, and an error occurs. The operation may be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT have not changed, the update operation is allowed to proceed. Otherwise, the update operation is rejected, an error occurs, and an *update hole* appears in the cursor.
- *Update of update holes.* Update holes are not permanent. It is possible for another process, or a searched update in the same process, to update an update hole row so that it is no longer an update hole. Update holes become visible with a FETCH SENSITIVE for positioned updates and positioned deletes.
- *Result table.* After the base table is updated, the row is re-evaluated and updated in the temporary result table. At this time, it is possible that the positioned update changed the data such that the row does not qualify the search condition, in which case the row is marked as an update hole for subsequent FETCH operations.

**Updating rows in a table with multilevel security:** When you update rows in a table with multilevel security, DB2 compares the security label of the user (the primary authorization ID) to the security label of the row. The update proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is updated and the value of the security label is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the user can set the security label of the row to any valid security label. The value that is specified for the security label column must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL.
  - If the user does not have write-down privilege and write-down control is enabled, the security label of the row is set to the value of the security label of the user.
- If the security label of the user dominates the security label of the row, the result of the UPDATE statement is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the row is updated and the user can set the security label of the row to any valid security label.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not updated.
- If the security label of the row dominates the security label of the user, the row is not updated.

**Other SQL statements in the same unit of work:** The following statements cannot follow an UPDATE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)

## Examples

*Example 1:* Change employee 000190's telephone number to 3565 in DSN8910.EMP.

```
UPDATE DSN8910.EMP  
SET PHONENO='3565'  
WHERE EMPNO='000190';
```

*Example 2:* Give each member of department D11 a 100-dollar raise.

```
UPDATE DSN8910.EMP  
SET SALARY = SALARY + 100  
WHERE WORKDEPT = 'D11';
```

*Example 3:* Employee 000250 is going on a leave of absence. Set the employee's pay values (SALARY, BONUS, and COMMISSION) to null.

```
UPDATE DSN8910.EMP  
SET SALARY = NULL, BONUS = NULL, COMM = NULL  
WHERE EMPNO='000250';
```

Alternatively, the statement could also be written as follows:

```
UPDATE DSN8910.EMP  
SET (SALARY, BONUS, COMM) = (NULL, NULL, NULL)  
WHERE EMPNO='000250';
```

*Example 4:* Assume that a column named PROJSIZE has been added to DSN8910.EMP. The column records the number of projects for which the employee's department has responsibility. For each employee in department E21, update PROJSIZE with the number of projects for which the department is responsible.

```
UPDATE DSN8910.EMP  
SET PROJSIZE = (SELECT COUNT(*)  
                FROM DSN8910.PROJ  
                WHERE DEPTNO = 'E21')  
WHERE WORKDEPT = 'E21';
```

*Example 5:* Double the salary of the employee represented by the row on which the cursor C1 is positioned.

```
EXEC SQL UPDATE DSN8910.EMP  
SET SALARY = 2 * SALARY  
WHERE CURRENT OF C1;
```

*Example 6:* Assume that employee table EMP1 was created with the following statement:

```
CREATE TABLE EMP1  
(EMP_ROWID    ROWID GENERATED ALWAYS,  
 EMPNO        CHAR(6),  
 NAME          CHAR(30),  
 SALARY        DECIMAL(9,2),  
 PICTURE       BLOB(250K),  
 RESUME        CLOB(32K));
```

Assume that host variable *HV\_EMP\_ROWID* contains the value of the ROWID column for employee with employee number '350000'. Using that ROWID value to identify the employee and user-defined function *UPDATE\_RESUME*, increase the employee's salary by \$1000 and update that employee's resume.

```
EXEC SQL UPDATE EMP1
  SET SALARY = SALARY + 1000,
      RESUME = UPDATE_RESUME(:HV_RESUME)
 WHERE EMP_ROWID = :HV_EMP_ROWID;
```

*Example 7:* In employee table X, give each employee whose salary is below average a salary increase of 10%.

```
EXEC SQL UPDATE EMP X
  SET SALARY = 1.10 * SALARY
 WHERE SALARY < (SELECT AVG(SALARY) FROM EMP Y
 WHERE X.JOBCODE = Y.JOBCODE);
```

*Example 8:* Raise the salary of the employees in department 'E11' whose salary is below average to the average salary.

```
EXEC SQL UPDATE EMP T1
  SET SALARY = (SELECT AVG(T2.SALARY) FROM EMP T2
 WHERE WORKDEPT = 'E11' AND
       SALARY < (SELECT AVG(T3.SALARY) FROM EMP T3));
```

*Example 9:* Give the employees in department 'E11' a bonus equal to 10% of their salary.

```
EXEC SQL
  DECLARE C1 CURSOR FOR
    SELECT BONUS
      FROM DSN8710.EMP
     WHERE WORKDEPT = 'E12'
       FOR UPDATE OF BONUS;
EXEC SQL
  UPDATE DSN8710.EMP
    SET BONUS = ( SELECT .10 * SALARY FROM DSN8710.EMP Y
                  WHERE EMPNO = Y.EMPNO )
   WHERE CURRENT OF C1;
```

*Example 10:* Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update all 10 rows in the rowset.

```
EXEC SQL UPDATE T1 SET C1 = 5 WHERE CURRENT OF CS1;
```

*Example 11:* Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update the fourth row of the rowset.

```
short ind1, ind2;

int n, upd_value;

stmt = 'UPDATE T1 SET C1 = ? WHERE CURRENT OF CS1 FOR ROW ? OF ROWSET'

ind1 = 0;

ind2 = 0;

n = 4;

upd_value = 5;

...

strcpy(my_sqlda.sqlaid,"SQLDA");
```

```
my_sqlda.sqln = 2;
my_sqlda.sqld = 2;
my_sqlda.sqlvar[0].sqltype = 497;
my_sqlda.sqlvar[0].sqllen = 4;
my_sqlda.sqlvar[0].sqldata = (int *) &upd_value;
my_sqlda.sqlvar[0].sqlind = (short *) &ind1;

my_sqlda.sqlvar[1].sqltype = 497;
my_sqlda.sqlvar[1].sqllen = 4;
my_sqlda.sqlvar[1].sqldata = (int *) &n;
my_sqlda.sqlvar[1].sqlind = (short *) &ind2;

EXEC SQL PREPARE S1 FROM :stmt;
EXEC SQL EXECUTE S1 USING DESCRIPTOR :my_sqlda;
```

## VALUES

The VALUES statement provides a method for invoking a user-defined function from a trigger. Transition variables and transition tables can be passed to the user-defined function.

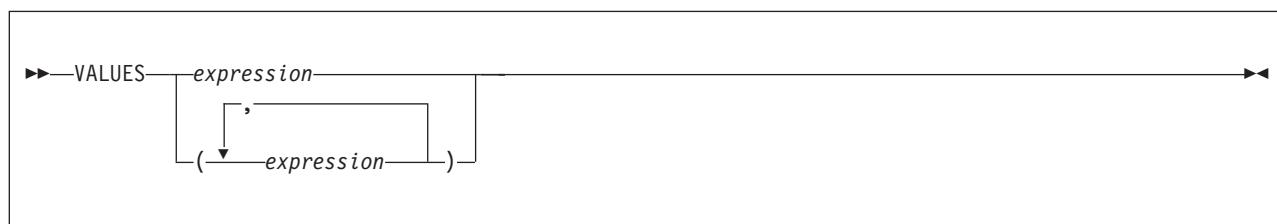

### Invocation

This statement can only be used in the triggered action of a trigger.

### Authorization

Authorization is required for any expressions that are used in the statement. For more information, see “Expressions” on page 180.

### Syntax

### Description

#### VALUES

Specifies one or more expressions. If more than one expression is specified, the expressions must be enclosed within parentheses.

#### expression

Any expression of the type described in “Expressions” on page 180. The expression must not contain a host variable.

The expressions are evaluated, but the resulting values are discarded and are not assigned to any output variables.

If a user-defined function is specified as part of an expression, the user-defined function is invoked. If a negative SQLCODE is returned when the function is invoked, DB2 stops executing the trigger and rolls back any triggered actions that were performed.

### Example

*Example:* Create an after trigger EMPISRT1 that invokes user-defined function NEWEMP when the trigger is activated. An insert operation on table EMP activates the trigger. Pass transition variables for the new employee number, last name, and first name to the user-defined function.

```
CREATE TRIGGER EMPISRT1
  AFTER INSERT ON EMP
  REFERENCING NEW AS N
  FOR EACH ROW
  MODE DB2SQL
  BEGIN ATOMIC
    VALUES(NEWEMP(N.EMPNO, N.LASTNAME, N.FIRSTNAME));
  END
```

## VALUES INTO

The VALUES INTO statement assigns one or more values to host variables.

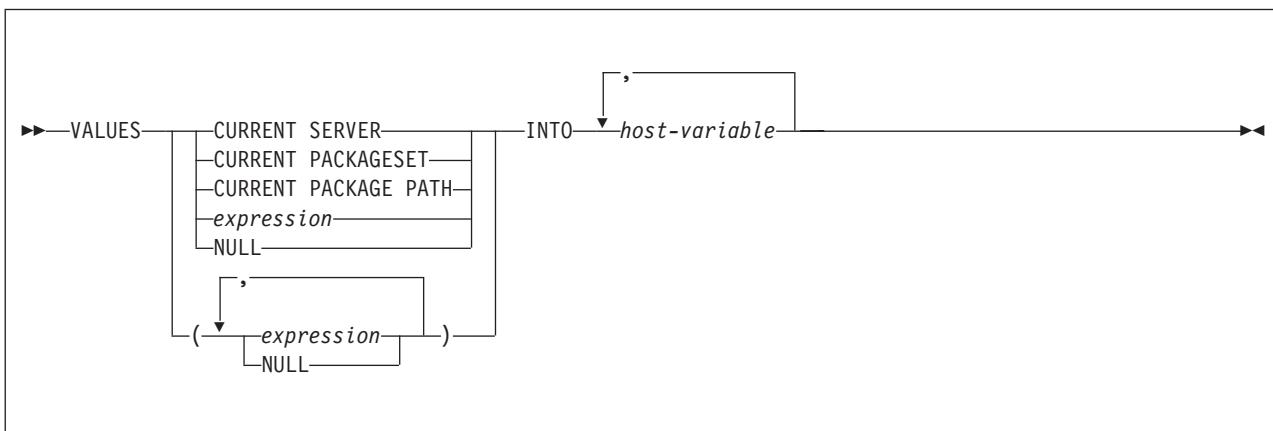

### Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

### Authorization

Authorization is required for any expressions that are used in the statement. For more information, see “Expressions” on page 180.

### Syntax

### Description

#### VALUES

Introduces one or more values. If more than one value is specified, the list of values must be enclosed within parentheses.

#### expression

The expression is any expression of the type described in “Expressions” on page 180 except it cannot contain a reference to local special registers (CURRENT SERVER, CURRENT PACKAGESET, or CURRENT PACKAGE PATH). The expression must not include a column name.

#### NULL

The null value. NULL can only be specified for host variables that have an associated indicator variable.

#### INTO

Introduces one or more host variables. The values that are specified in the **VALUES** clause are assigned to these host variables. The first value specified is assigned to the first host variable, the second value to the second host variable, and so on. Each assignment is made according to the rules described in “Assignment and comparison” on page 102. Assignments are made in sequence through the list. If there are fewer host variables than values, the value 'W' is assigned to the SQLWARN3 field of the SQLCA. (See “SQL communication area (SQLCA)” on page 1646.)

*host-variable*

Identifies a variable that is described in the program according to the rules for declaring host variables.

## Notes

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specified by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

If an error occurs, no value is assigned to any host variable. However, if LOB values are involved, there is a possibility that the corresponding host variable was modified, but the variable's contents are unpredictable.

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with other data types. For more information on using locators, see *DB2 Application Programming and SQL Guide*.

## Examples

*Example 1:* Assign the value of the CURRENT PATH special register to host variable HV1.

```
EXEC SQL VALUES(CURRENT PATH)
  INTO :HV1;
```

*Example 2:* Assign the value of the CURRENT MEMBER special register to host variable MEM.

```
EXEC SQL VALUES(CURRENT MEMBER)
  INTO :MEM;
```

*Example 3:* Assume that LOB locator *LOB1* is associated with a CLOB value. Assign a portion of the CLOB value to host variable *DETAILS* using the LOB locator.

```
EXEC SQL VALUES (SUBSTR(:LOB1,1,35))
  INTO :DETAILS;
```

If the LOB data that is specified by the LOB locator *LOB1* is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the VALUES INTO statement:

```
EXEC SQL SELECT SUBSTR(:LOB1,1,35)
  INTO :DETAILS
  FROM SYSIBM.SYSDUMMYU;
```

## WHENEVER

The WHENEVER statement specifies the host language statement to be executed when a specified exception condition occurs.

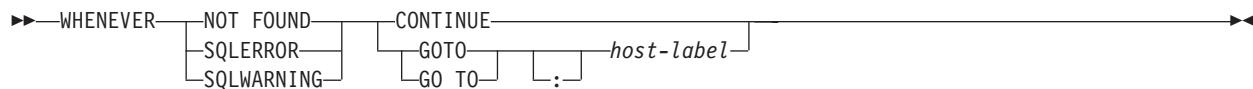

### Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

### Authorization

None required.

### Syntax

### Description

The NOT FOUND, SQLERROR, or SQLWARNING clause is used to identify the type of exception condition.

#### NOT FOUND

Identifies any condition that results in an SQLCODE of +100 (equivalently, an SQLSTATE code of '02000').

#### SQLERROR

Identifies any condition that results in a negative SQLCODE.

#### SQLWARNING

Identifies any condition that results in a warning condition (SQLWARN0 is W), or that results in a positive SQLCODE other than +100.

The CONTINUE or GO TO clause specifies the next statement to be executed when the identified type of exception condition exists.

#### CONTINUE

Specifies the next sequential statement of the source program.

#### GOTO or GO TO host-label

Specifies the statement identified by host-label. For host-label, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language. In COBOL, for example, it can be section-name or an unqualified paragraph-name.

### Notes

There are three types of WHENEVER statements:

- WHENEVER NOT FOUND
- WHENEVER SQLERROR
- WHENEVER SQLWARNING

Every executable SQL statement in an application program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the application program, not their execution sequence.

An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which CONTINUE is specified. If a WHENEVER statement is specified in a Fortran subprogram, its scope is that subprogram, not the source program.

| The GET DIAGNOSTICS statement can be used to provide additional information.

## Examples

The following statements can be embedded in a COBOL program.

*Example 1:* Go to the label HANDLER for any statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR GOTO HANDLER END-EXEC.
```

*Example 2:* Continue processing for any statement that produces a warning.

```
EXEC SQL WHENEVER SQLWARNING CONTINUE END-EXEC.
```

*Example 3:* Go to the label ENDDATA for any statement that does not return.

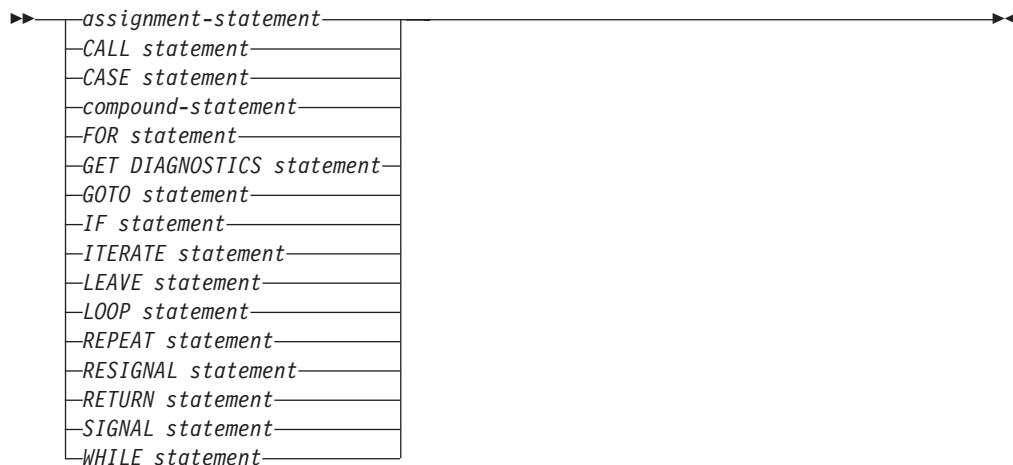

```
EXEC SQL WHENEVER NOT FOUND GO TO ENDDATA END-EXEC.
```

---

## Chapter 6. SQL control statements for native SQL procedures

SQL control statements for SQL routines can be used in SQL functions and native SQL procedures. *SQL control statements* provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

### SQL-control-statement:

Control statements are supported in SQL procedures. SQL procedures are created by specifying an SQL routine body on the “CREATE PROCEDURE (SQL - native)” on page 1046 statement. The SQL routine body must be a single SQL statement which might be an SQL control statement.

The remainder of this section contains a description of the control statements that are supported by native SQL procedures, and includes syntax diagrams, semantic descriptions, usage notes, and examples of the use of the statements that constitute the SQL routine body. In addition, you can find information about referencing SQL parameters and variables in “References to SQL parameters and SQL variables” on page 1542.

Refer to “SQL control statements for external SQL procedures” on page 1610 for information about the control statements that are supported by external SQL procedures.

The two common elements that are used in describing specific SQL control statements are:

- SQL control statements as described above
- “SQL-procedure-statement” on page 1546

## References to SQL parameters and SQL variables

SQL parameters and SQL variables can be referenced anywhere in the statement where an expression or a variable can be specified. Host variables cannot be specified in SQL routines. SQL parameters can be referenced anywhere in the routine and can be qualified with the routine name. SQL variables can be referenced anywhere in the compound statement in which they are declared, including any statement that is directly or indirectly nested within that compound statement.

If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label.

All SQL parameters and SQL variables are considered nullable. The name of an SQL parameter or an SQL variable in an SQL routine can be the same as the name of a column in a table or view that is referenced in the routine. The name of an SQL variable can also be the same as the name of another SQL variable that is declared in the same routine. This can occur when the two SQL variables are declared in different *compound-statements*. The *compound-statement* that contains the declaration of an SQL variable determines the scope of that variable. See “compound-statement” on page 1554 for additional information.

Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, an SQL variable, or an SQL parameter. If the name is not qualified or is qualified but is still ambiguous, the following rules describe whether the name refers to a column or to an SQL variable or an SQL parameter in an SQL routine:

- The name is checked to see if it is the name of a column of any existing table or a view that is specified in the SQL routine body at the current server. If the name is found as a column name, but the privilege set that is used to issue the CREATE PROCEDURE or ALTER PROCEDURE statement does not have the proper authority to access the table or view, the VALIDATE option that is in effect for the procedure determines what happens:
  - If VALIDATE BIND is in effect, an error is returned.
  - If VALIDATE RUN is in effect, the name is assumed to be a column name. If the privilege set that is used to issue the CREATE statement does not have the proper authority to access the table or view at run time, an error is returned.
- If the referenced tables or views do not exist at the current server, the name will be checked first as an SQL variable name in the compound statement and then as an SQL parameter name. The variable can be declared within the *compound-statement* that contains the reference, or within a compound statement in which that compound statement is nested. If two SQL variables are within the same scope and have the same name, the SQL variable that is declared in the innermost compound statement is used.

If the name is not found as an SQL parameter or SQL variable, the VALIDATE option that is in effect for the procedure determines what happens:

- If VALIDATE BIND is in effect, an error is returned.
- If VALIDATE RUN is in effect, the name is assumed to be a column name. If a column does not exist with that name at run time, an error is returned.

The name of an SQL variable or an SQL parameter in an SQL routine can be the name of an identifier that is used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to an identifier, an SQL variable, or an SQL parameter:

- In the SET CURRENT PACKAGE PATH, SET PATH and SET SCHEMA statements, the name is checked as an SQL variable name or an SQL parameter name. If an SQL variable or SQL parameter with that name is not found, the name is assumed to be an identifier.
- In the ASSOCIATE LOCATORS, CONNECT, RELEASE (connection), and SET CONNECTION statements, the name is used as an identifier.

---

## References to SQL condition names

A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used.

The name of an SQL condition can be the same as the name of another SQL condition that is declared in the same routine. This can occur when the two SQL conditions are declared in different *compound-statements*. The *compound-statement* that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. See “*compound-statement*” on page 1554 for additional information.

---

## References to SQL cursor names

A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

The name of an SQL cursor can not be the same as the name of another SQL cursor that is declared on the same routine. The *compound-statement* that contains the declaration of an SQL cursor name determines the scope of that cursor name. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. See “*compound-statement*” on page 1554 for additional information.

---

## References to labels

Specifying a label for an SQL procedure statement defines that label and determines the scope of that label. A label name can only be referenced within the compound statement in which it is defined, including a reference from any statement that is directly or indirectly nested within that compound statement. The FOR statement is considered the same as a compound statement with respect to defining and referencing labels. A label can be specified as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for the statement that references the label as a target.

Labels can be specified on most SQL procedure statements. If a label is specified on an SQL procedure statement, it must be unique from other labels within the same scope. A label must not be the same as any other label within the same compound statement, must not be the same as a label specified on the compound statement itself, and if the compound statement is nested within another compound statement, the label must not be the same as the label specified on any higher level compound statement. The label must not be the same as the name of the SQL procedure.

## Nested compound statements and scope of names

Nested compound statements can be used within an SQL routine to define the scope of SQL variable declarations, cursors, condition names, and condition handlers.

In addition, labels have a defined scope in the context of nested compound statements. However, the rules for name spaces and how non-unique names can be referenced, differs depending on the type of name. The following table summarizes these differences:

*Table 130. Scope and qualification of names within nested compound statements*

Type of name	Name can be qualified	Name must be unique within	Name can be referenced within
SQL variable	Yes. The name can be qualified with the label of the compound statement in which the variable is declared	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement	The compound statement in which it is declared, including any compound statements that are nested within that compound statement.  When multiple SQL variables are defined with the same name, a label can be used to explicitly refer to a specific variable that is not the most local in scope
condition name	No	the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement	The compound statement in which it is declared, including any compound statements that are nested within that compound statement.  Condition names can be used in the declaration of a condition handler, or in a SIGNAL or RESIGNAL statement.  If multiple conditions are defined with the same name, there is no way to explicitly refer to the condition that is not the most local in scope.

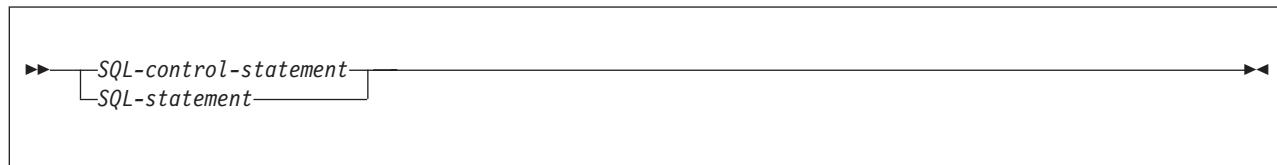

*Table 130. Scope and qualification of names within nested compound statements (continued)*

Type of name	Name can be qualified	Name must be unique within	Name can be referenced within
cursor name	No	the routine	The compound statement in which it is declared, including any compound statements that are nested within that compound statement.
			If the cursor is defined as a result set cursor, the invoking application can access the result set.
label	No	the compound statement that defined the label, including any definitions in compound statements that are nested within that compound statement	<p>The compound statement in which it is defined, including any compound statements that are nested within that compound statement.</p> <p>Use a label to qualify the name of an SQL variable or as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for these statements.</p>

## SQL-procedure-statement

An SQL control statement can allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

### Syntax

### Description

#### *SQL-control-statement*

Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL routines.

#### *SQL-statement*

Specifies an SQL statement as listed in Table 139 on page 1608. These statements are described in Chapter 5, “Statements,” on page 683.

### Notes

**Comments:** Comments can be included within the body of an SQL routine. In addition to the double-dash form of comments (--), a comment can begin with /\* and end with \*/. The following rules apply to this form of comment:

- The beginning characters /\* must be adjacent and on the same line.
- The ending characters \*/ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

**Detecting and processing error and warning conditions:** As an SQL statement is executed, DB2 stores information about the processing of the statement in a diagnostics area (including the SQLSTATE and SQLCODE), unless otherwise noted in the description of the SQL statement. A completion condition can indicate that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the SQL statement was not successful.

A condition handler can be defined to execute when an exception condition, a warning condition, or a not found condition occurs in a compound statement. The declaration of a condition handler includes the code that is executed when the condition handler is activated. When a condition other than a successful completion occurs in the processing of *SQL-procedure-statement* and a condition handler that can handle the condition is within scope, one such condition handler will be activated to process the condition. See “compound-statement” on page 1554 for information about defining condition handlers. The code in the condition handler can check for a warning condition, a not found condition, or an exception condition and can take the appropriate action. Use one of the following methods at the beginning of the body of a condition handler to check the condition in the diagnostics area that caused the handler to be activated.

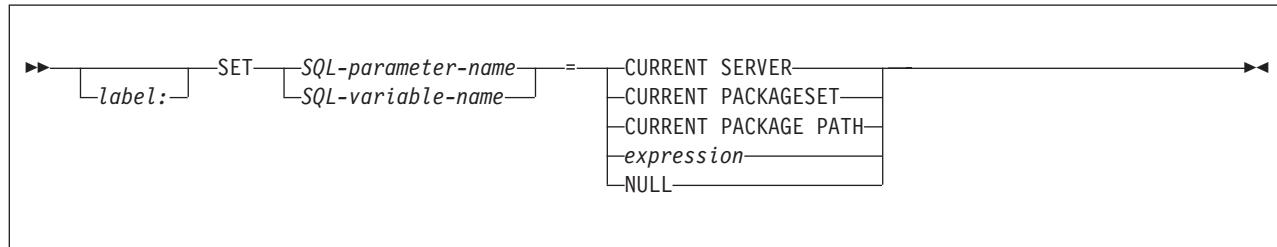

- Issue a GET DIAGNOSTICS statement to request the desired information from the diagnostics area. See “GET DIAGNOSTICS” on page 1317.
- Test the SQLSTATE and SQLCODE SQL variables.

If the condition is a warning and no handler exists for the condition, the previous two methods can be used outside of the body of a condition handler if they are used immediately following the statement for which the condition is desired. If the condition is an error and no handler exists for the condition, the routine terminates with the error condition.

## assignment-statement

The assignment statement assigns a value to a SQL parameter or to an SQL variable.

### Syntax

### Description

#### *label*

Specifies the label for *assignment-statement*. The label name cannot be the same as the name of the SQL routine, or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *SQL-parameter-name*

Identifies the parameter that is the assignment target. The parameter must be specified in *parameter-declaration* in the CREATE statement.

#### *SQL-variable-name*

Identifies the SQL variable that is the assignment target. SQL variables can only be declared in a *compound-statement* and must be declared before they are used. For information on declaring SQL variables, see “compound-statement” on page 1554.

#### *expression or NULL*

Specifies the expression or value that is the source for the assignment. The expression can be any expression of the type described in “Expressions” on page 180 except it cannot contain a reference to local special registers (CURRENT SERVER, CURRENT PACKAGESET, or CURRENT PACKAGE PATH).

### Notes

**Assignment rules:** Assignment statements in SQL routines must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See “Assignment and comparison” on page 102 for assignment rules.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

**Assignments involving SQL parameters for SQL procedures:** An IN parameter can appear on the left or right side in an assignment statement. When control returns

to the caller, the original value of the IN parameter is retained. An OUT parameter can also appear on the left or right side in an assignment statement. If used without first being assigned a value, the value is undefined. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller. For an INOUT parameter, the first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

*Considerations for SQLSTATE and SQLCODE SQL variables:* Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

## Examples

*Example 1:* Increase the SQL variable *p\_salary* by 10 percent.

```
SET p_salary = p_salary + (p_salary * .10)
```

*Example 2:* Set SQL variable *p\_salary* to the null value.

```
SET p_salary = NULL
```

*Example 3:* Set SQL variable *midinit* to the first character of SQL variable *midname*.

```
SET midinit = SUBSTR(midname,1,1)
```

## CALL statement

The CALL statement invokes a stored procedure.

### Syntax

```
►► CALL—procedure-name—argument-list
      |  
      |  label:
```

#### argument-list:

```
►► (—

```

### Description

#### label

Specifies the label for the CALL statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### procedure-name

Identifies the stored procedure to call. The procedure name must identify a stored procedure that exists at the current server.

#### argument-list

Identifies a list of values to be passed as parameters to the stored procedure. The *n*th value corresponds to the *n*th parameter in the procedure. The number of parameters must be the same as the number of parameters defined for the stored procedure. See “CALL” on page 874 for more information.

Control is passed to the stored procedure according to the calling conventions for SQL routines. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

#### SQL-variable-name

Specifies an SQL variable as an argument to the stored procedure. For an explanation of references to SQL variables, see “References to SQL parameters and SQL variables” on page 1542.

#### SQL-parameter-name

Specifies an SQL parameter as an argument to the stored procedure. For an explanation of references to SQL parameters, see “References to SQL parameters and SQL variables” on page 1542.

#### expression

The parameter is the result of the specified *expression*, which is evaluated

before the stored procedure is invoked. If *expression* is a single *SQL-parameter-name* or *SQL-variable-name*, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. If the result of the *expression* can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple SQL parameters or variables. In addition to the rules stated in “Expressions” on page 180 for *expression*, *expression* cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single SQL parameter or variable.

#### NULL

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

## Notes

See “CALL” on page 874 for more information on the SQL CALL statement.

## Examples

Call stored procedure proc1 and pass SQL variables as parameters.

```
CALL proc1(v_empno, v_salary)
```

## CASE statement

The CASE statement selects an execution path based on multiple conditions. A CASE statement operates in the same way as a CASE expression.

### Syntax

```
|    ►► [label:] CASE [simple-when-clause] [searched-when-clause] [else-clause] END CASE ──────────►
```

#### simple-when-clause:

```
►► expression WHEN expression THEN SQL-procedure-statement ; ──────────►
```

#### searched-when-clause:

```
►► WHEN search-condition THEN SQL-procedure-statement ; ──────────►
```

#### else-clause:

```
►► ELSE SQL-procedure-statement ; ──────────►
```

### Description

#### *label*

Specifies the label for the CASE statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### **CASE**

Begins a *case-expression*.

#### *simple-when-clause*

The value of the *expression* prior to the first WHEN keyword is tested for equality with the value of the *expression* that follows each WHEN keyword. If the comparison is true, the statements in the associated THEN clause are

executed and processing of the CASE statement ends. If the result is unknown or false, processing continues to the next comparison. If the result does not match any of the comparisons, and an ELSE clause is present, the statements in the ELSE clause are executed.

#### *searched-when-clause*

The *search-condition* following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If it evaluates to false, or unknown, the next *search-condition* is evaluated. If no *search-condition* evaluates to true and an ELSE clause is present, the statements in the ELSE clause are executed.

When *searched-when-clause* is used, *search-condition* cannot contain a *fullselect*.

#### *SQL-procedure-statement*

Specifies a statement to execute. See “SQL-procedure-statement” on page 1546.

#### *search-condition*

Specifies a condition that is true, false, or unknown about a row or group of table data.

#### **ELSE** *SQL-procedure-statement*

If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, the statements specified in *SQL-procedure-statement* are executed.

If none of the conditions specified in the WHEN clauses are true and an ELSE is not specified, an error is issued when the statement executes, and the execution of the CASE statement is terminated.

#### **END CASE**

Ends a *case-statement*.

## Examples

*Example 1:* Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v\_workdept*.

```
CASE v_workdept
  WHEN 'A00'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 2';
  ELSE UPDATE DEPT SET
    DEPTNAME = 'DATA ACCESS 3';
END CASE
```

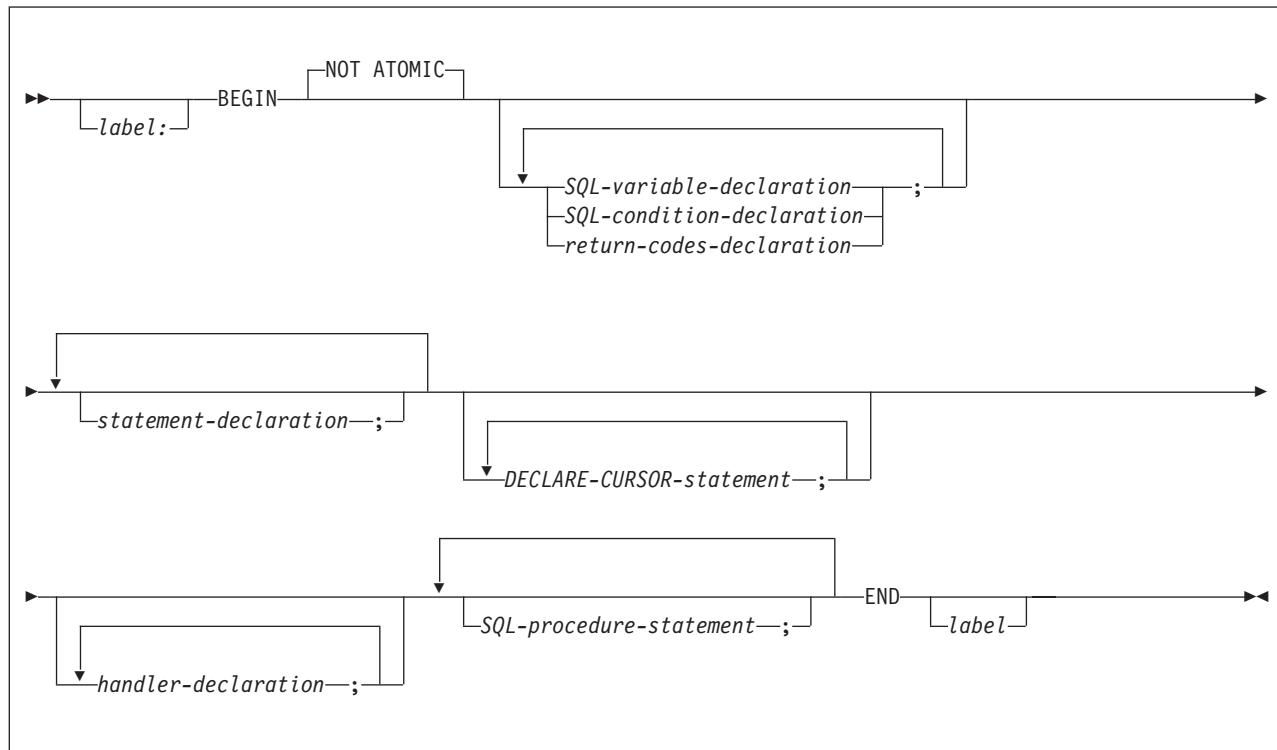

*Example 2:* Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v\_workdept*.

```
CASE
  WHEN v_workdept < 'B01'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 1';
  WHEN v_workdept < 'C01'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 2';
  ELSE UPDATE DEPT SET
    DEPTNAME = 'DATA ACCESS 3';
END CASE
```

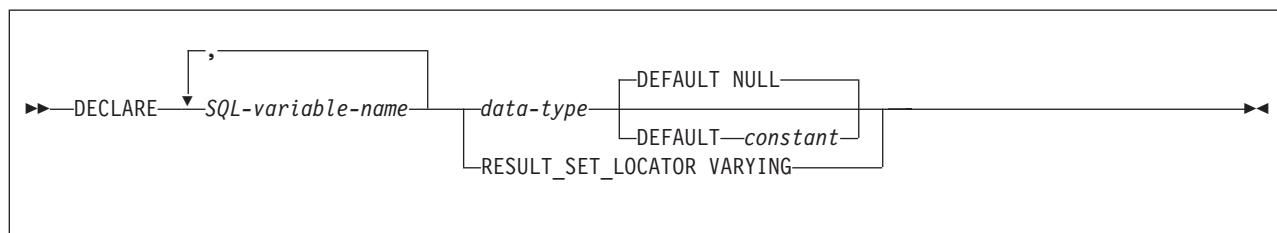

## compound-statement

A compound statement groups other statements together in an SQL routine. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

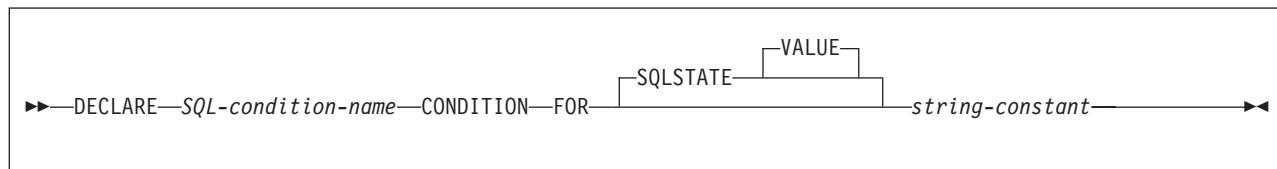

### Syntax

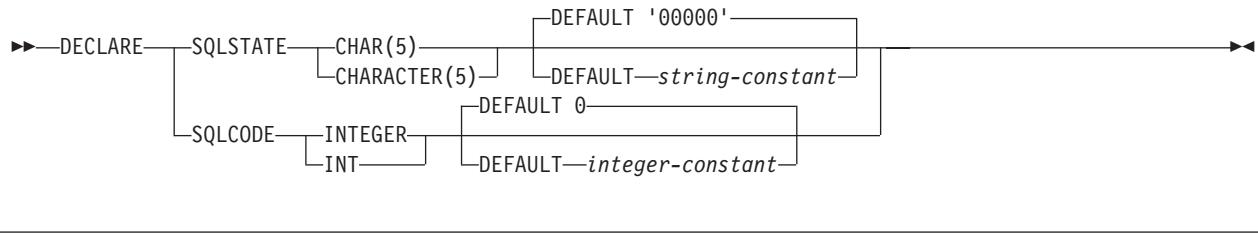

#### SQL-variable-declaration:

#### SQL-condition-declaration:

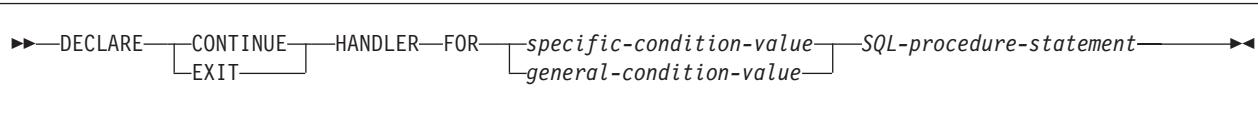

#### return-codes-declaration:

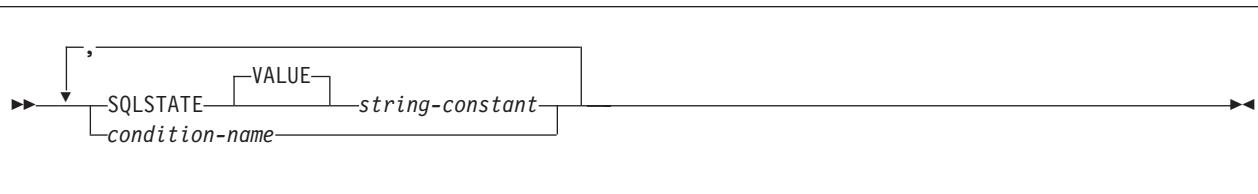

**statement-declaration:**

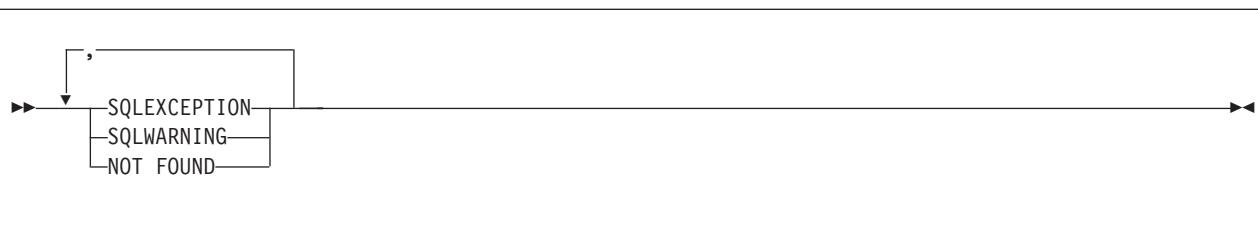

**handler-declaration:**

**specific-condition-value:**

**general-condition-value:**

## Description

### *label*

Specifies the label for the *compound-statement*. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified as the target on a LEAVE statement. If the ending label is specified, it must be the same as beginning label. The label name cannot be the same as the routine name or another label within the same scope.

**NOT ATOMIC**

NOT ATOMIC indicates that an unhandled exception condition within the *compound-statement* does not cause the *compound-statement* to be rolled back.

***SQL-variable-declaration***

Declares a variable that is local to the compound statement.

***SQL-variable-name***

Defines the name of a variable. DB2 converts all SBCS SQL variable names that are not delimited to uppercase. *SQL-variable-name* must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. *SQL-variable-name* must not be the same as a parameter name. See “References to SQL parameters and SQL variables” on page 1542 for information about how SQL variable names are resolved when there are columns with the same name as an SQL variable involved in a statement, or when multiple SQL variables exist with the same name in the routine body.

*SQL-variable-name* can only be referenced within the compound statement in which it is declared, including any compound statement that is nested within that compound statement. If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label. For example, an SQL variable V that is declared in a compound statement that is labeled C can be referenced as C.V.

***data-type***

Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL routine parameters. *data-type* must not be XML. See “CREATE PROCEDURE (SQL - native)” on page 1046 for a description of SQL data types and lengths.

***DEFAULT constant or NULL***

Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in “Assignment and comparison” on page 102. The variable is initialized when the compound statement begins processing. If a default value is not specified, the SQL variable is initialized to NULL.

***RESULT\_SET\_LOCATOR VARYING***

Specifies the data type for a result set locator variable.

***SQL-condition-declaration***

Declares a condition name and corresponding SQLSTATE value.

***SQL-condition-name***

Specifies the name of the condition. The condition name must be unique within the compound statement in which it is declared, excluding any declarations that are in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

***FOR SQLSTATE string-constant***

Specifies the SQLSTATE that is associated with the condition. The string must be specified as five characters enclosed in single quotes, and the SQLSTATE class (the first two characters) must not be '00'.

***return-codes-declaration***

Declares special variables named SQLSTATE and SQLCODE. These variables

are automatically set to the SQLSTATE and SQLCODE values for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty compound statement.

The SQLSTATE and SQLCODE SQL variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these variables is ignored by condition handlers, and processing an assignment to these special variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment. The SQLSTATE and SQLCODE SQL variables cannot be set to NULL.

#### *statement-declaration*

Declares a list of one or more names that are local to the compound statement. A statement name cannot be the same as another statement name within the same compound statement.

#### *DECLARE-CURSOR-statement*

Declares a cursor in the procedure body. Each cursor must have a unique name within the routine. The cursor can only be referenced from within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Use an OPEN statement to open the cursor, a FETCH statement to read a row using the cursor, and a CLOSE statement to close the cursor. If the cursor is intended for use as a result set cursor:

- Specify WITH RETURN when the cursor is declared
- Create the procedure using the DYNAMIC RESULT SETS clause with a non-zero value
- Do not specify a CLOSE statement for the cursor in the compound statement

For additional information about declaring a cursor, see “**DECLARE CURSOR**” on page 1191.

#### *handler-declaration*

Specifies a condition handler, an *SQL-procedure-statement* to execute when an exception or completion condition occurs in the *compound-statement*. The *SQL-procedure-statement* executes when a condition handler receives control.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than one time. It cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value.

When two or more condition handlers are declared in a compound statement, no two condition handler declarations can specify the same:

- general condition category
- specific condition, either as an SQLSTATE value or as a condition name that represents the same value

A condition handler is active for the set of *SQL-procedure-statements* that follow the condition handler declarations within the compound statement in which the condition handler is declared, including any nested compound statements.

#### **CONTINUE**

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, FOR, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END FOR, END IF, END REPEAT, or END WHILE.

#### **EXIT**

Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound statement that declared the condition handler.

The conditions that can cause the handler to gain control are:

#### **SQLSTATE *string-constant***

Specifies that the handler is invoked when the specific SQLSTATE occurs. The first two characters of the SQLSTATE value must not be '00'.

#### ***SQL-condition-name***

Specifies that the handler is invoked when the specific SQLSTATE that is associated with the condition name occurs. The *SQL-condition-name* must be declared within the compound statement that contains the handler declarations, or within a compound statement in which that compound statement is nested.

#### **SQLEXCEPTION**

Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see *DB2 Codes*.

#### **SQLWARNING**

Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

#### **NOT FOUND**

Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

## **Notes**

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

**Nesting compound statements:** Compound statements can be nested. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in a routine. This can simplify the processing that is done for each SQL routine statement. Nested compound statements enable the use of a compound statement within the declaration of a condition handler.

**The scope of a cursor:** The scope of a cursor name is the compound statement in which it is declared, including any compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

**Considerations for statement-name:** The scope of a *statement-name* that is declared in a compound statement is the compound statement and any nested compound statements (unless the same *statement-name* is declared in a nested compound statement). If a *statement-name* is used in a DECLARE CURSOR statement or a PREPARE statement and has not been declared in the compound statement where it is used or any outer compound statements in which it is nested, the *statement-name* is assumed to be declared globally for the routine.

**Condition handlers:** Condition handlers in SQL routines are similar to WHENEVER statements that are used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as the result of an exception, a warning, or a not found condition that is returned by DB2 for the processing of an SQL statement. Or the condition that activates the handler can be the result of a SIGNAL or RESIGNAL statement that is issued within the SQL routine body.

A condition handler is declared within a compound statement, and it is active for the set of *SQL-procedure-statements* that follow all of the condition handler declarations within the compound statement in which the condition handler is declared. For example, the scope of a condition handler declaration H is the list of *SQL-procedure-statements* that follow the condition handler declarations that are contained within the compound statement in which H appears. This means that the scope of H does not include the statements that are contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 that are declared in the same compound statement, H1 will not handle conditions that arise in the body of H2, and H2 will not handle conditions that arise in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of condition handler (CONTINUE or EXIT), and the handler action. The type of condition handler determines to where control is returned after the handler action successfully completes.

**Condition handler activation:** When a condition other than a successful completion occurs in the processing of *SQL-procedure-statement*, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a routine with nested compound statements, condition handlers that could handle a specific condition might exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at the nesting level could handle the condition, the condition handler that is activated is the most appropriate handler that is declared in that compound statement.

The most appropriate handler is the condition handler that most closely matches the SQLSTATE or the exception or completion condition. For a given compound statement, when both a specific handler for a condition and a general handler are declared that address the same condition, the specific handler takes precedence over the general handler.

For example, if the innermost compound statement declares a specific handler for SQLSTATE '22001', as well as a general handler for SQLEXCEPTION, the specific handler for SQLSTATE '22001' is the most appropriate handler when SQLSTATE '22001' is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (CONTINUE or EXIT handler) determines to where control is returned. Additionally, the SQLSTATE and SQLCODE SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully and an appropriate handler exists for the condition that is encountered in the handler action, that condition handler is activated. Otherwise, the condition that is encountered within the condition handler is unhandled.

***Unhandled conditions:*** If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the SQL routine that contains the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or is a not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

***Considerations for using SIGNAL and RESIGNAL statements with nested compound statements:*** If an SQL-procedure-statement that is specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound statement terminates with the specified exception. This happens even when this condition handler or another condition handler in the same compound statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a compound statement is nested in another compound statement, condition handlers in the higher level compound statement can handle the exception because those condition handlers are within the scope of the exception.

***SQLSTATE and SQLCODE variables in SQL routines:*** To help debug your SQL routines, you might find it useful to check the SQLSTATE and SQLCODE value after executing a statement. An SQLCODE or SQLSTATE variable can be declared and subsequently referenced in an SQL routine. You could insert the value of the SQLCODE and SQLSTATE into a table at various points in the SQL routine, or return the SQLCODE and SQLSTATE values in a diagnostics string as an OUT parameter. To use the SQLCODE and SQLSTATE values, you must declare the following SQL variables in the SQL routine body:

```
DECLARE SQLCODE INTEGER DEFAULT 0;  
DECLARE SQLSTATE CHAR(5) DEFAULT '00000';
```

When you reference the SQLCODE or SQLSTATE variables in an SQL routine, DB2 sets the value of SQLCODE to 0 and SQLSTATE to '00000' for the subsequent statement. You can also use CONTINUE condition handlers to assign the value of the SQLSTATE and SQLCODE variables to variables in your SQL routine body. You can then use these SQL variables to control your routine logic, or pass the value back as an output parameter. In the following example, the SQL routine returns control to the statement following each SQL statement with the SQLCODE set in a SQL variable called RETCODE:

```
DECLARE SQLCODE INTEGER DEFAULT 0;
DECLARE retnode INTEGER DEFAULT 0;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION SET retnode = SQLCODE;
DECLARE CONTINUE HANDLER FOR SQLWARNING SET retnode = SQLCODE;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET retnode = SQLCODE;
```

The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement, the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within the compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

**Null values in SQL parameters and SQL variables:** If the value of an SQL parameter or SQL variable is null and it is used in an SQL statement that does not allow an indicator variable, an error is returned.

**Effect on open cursors:** At the end of the compound statement, all open cursors that are declared in that compound statement, except cursors that are used to return result sets, are closed.

**Atomic processing of a compound statement:** Atomic processing is not supported for a compound statement. If atomic behavior is needed for a block of code in a compound statement, set a savepoint before the nested compound statement is entered. This will allow changes to be undone with a ROLLBACK TO SAVEPOINT statement.

## Examples

**Example 1:** Create a procedure body with a compound statement that performs the following actions:

- Declares SQL variables.
- Declares a cursor to return the salary of employees in a department determined by an IN parameter.
- Declares an EXIT handler for the condition NOT FOUND (end of file) which assigns the value 6666 to the OUT parameter *medianSalary*.
- Select the number of employees in the given department into the SQL variable *v\_numRecords*.
- Fetch rows from the cursor in a WHILE loop until 50% + 1 of the employees have been retrieved.
- Return the median salary.

```
CREATE PROCEDURE DEPT_MEDIAN
  (IN deptNumber SMALLINT,
   OUT medianSalary DOUBLE)
LANGUAGE SQL
```

```

BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE c1 CURSOR FOR
        SELECT salary FROM staff
        WHERE DEPT = deptNumber
        ORDER BY salary;
    DECLARE EXIT HANDLER FOR NOT FOUND
        SET medianSalary = 6666;
        /* initialize OUT parameter */
        SET medianSalary = 0;
        SELECT COUNT(*) INTO v_numRecords FROM staff
        WHERE DEPT = deptNumber;
    OPEN c1;
    WHILE v_counter < (v_numRecords / 2 + 1) DO
        FETCH c1 INTO medianSalary;
        SET v_counter = v_counter + 1;
    END WHILE;
    CLOSE c1;
END

```

**Example 2:** Define an exit handler for any error, warning, or case of end of data. When this procedure is invoked and it returns to the caller, the value 45000 is returned for the output parameter:

```

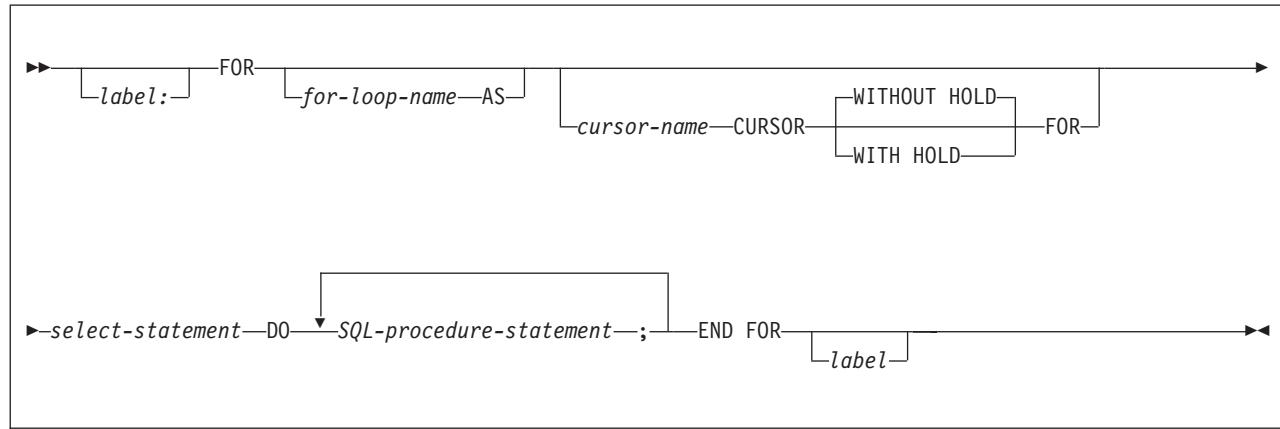

CREATE PROCEDURE JMBLIB.PROCL(OUT MEDIANSLARY INT)
    LANGUAGE SQL
    BEGIN
        DECLARE CHAR1 CHAR;
        DECLARE C1 CURSOR FOR SELECT *
            FROM SYSIBM.SYSDUMMY1;
        DECLARE EXIT HANDLER FOR NOT FOUND,
            SQLEXCEPTION,
            SQLWARNING
            OPEN C1;
        FETCH C1 INTO CHAR1;
        SET MEDIANSLARY = 45000;
        FETCH C1 INTO CHAR1;
        SET MEDIANSLARY = 50000;
    END

```

## FOR statement

The FOR statement executes a statement for each row of a table. An implicit compound statement is generated to implement the FOR statement.

### Syntax

### Description

#### *label*

Specifies the label for the FOR statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to labels” on page 1543.

#### *for-loop-name*

Specifies the label for the implicit compound statement that is generated to implement the FOR statement. *for-loop-name* follows the rules for the label of a compound statement except that it cannot be used with an ITERATE, GOTO, or LEAVE statement within the FOR statement. *for-loop-name* must not be the same as any label within the same scope.

*for-loop-name* can be used to qualify generated SQL variables that correspond to the columns that are returned by *select-statement*.

#### *cursor-name*

Names a cursor that is generated to select rows from the result table of *select-statement*. If *cursor-name* is not specified, a unique cursor name is generated.

*cursor-name* cannot be referenced outside of the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

#### **WITH HOLD or WITHOUT HOLD**

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

#### **WITHOUT HOLD**

Specifies that the cursor is not prevented from being closed as a consequence of a commit operation. **WITHOUT HOLD** is the default.

#### **WITH HOLD**

Specifies that the cursor should not be closed as a consequence of a commit operation. A cursor that is declared using the **WITH HOLD** clause is implicitly closed at commit time only if the connection that is associated

with the cursor is ended during the commit operation. For more information, see "DECLARE CURSOR" on page 1191.

*select-statement*

Specifies the select statement of the cursor.

Each expression in the SELECT list must have a name. If an expression is not a simple column name, the AS clause must be used to name the expression. If the AS clause is specified, that name is used for the generated SQL variable that corresponds to the column returned by *select-statement*. The names for all of the generated SQL variables must be unique.

*SQL-procedure-statement*

Specifies the SQL statements to be executed for each row of the table. The SQL statements must not include an OPEN, FETCH, or CLOSE statement that specifies the cursor name of the FOR statement.

## Notes

**FOR statement rules:** The FOR statement executes one or multiple statements for each row in a table. The cursor is defined by specifying a SELECT list that describes the columns and rows selected. The statements within the FOR statement are executed for each row selected.

The SELECT list must consist of unique column names and the table that is specified in the FROM clause of *select-statement* must exist when the routine is created.

**Handler warning:** Handlers can be used to handle errors that might occur on the open of the cursor or fetch of a row using the cursor in the FOR statement. Handlers defined to handle these open or fetch conditions should not be CONTINUE handlers as they might cause the FOR statement to loop indefinitely.

## Examples

In the following example, the FOR statement is used to specify a cursor that selects three columns from the employee table. For every row selected, SQL variable *fullname* is set to the last name followed by a comma, the first name, a blank, and the middle initial. Each value for *fullname* is inserted into table TNAMES.

```
BEGIN
    DECLARE fullname CHAR(40);
    FOR v1 AS
        c1 CURSOR FOR
            SELECT firstname, midinit, lastname FROM employee
        DO
            SET fullname =
                lastname CONCAT ', '
                CONCAT firstname
                CONCAT ' '
                CONCAT midinit;
            INSERT INTO TNAMES VALUES ( fullname );
        END FOR;
    END;
```

---

## GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

See “GET DIAGNOSTICS” on page 1317.

When you need to specify a variable in a GET DIAGNOSTICS statement that is used within an SQL routine, you would use either *SQL-variable-name* or *SQL-parameter-name*. In an embedded GET DIAGNOSTICS statement, you would use a *host-variable*. You can replace the instances of *host-variable* in the description of “GET DIAGNOSTICS” on page 1317 with *SQL-variable-name* or *SQL-parameter-name*.

*Effects of the statement:* The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2\_GET\_DIAGNOSTICS\_DIAGNOSTICS.

*Considerations for the SQLSTATE and SQLCODE SQL variables:* The GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables.

## GOTO statement

The GOTO statement is used to branch to a user-defined label within an SQL routine. The GOTO statement is used to branch to a user-defined label within an SQL procedure.

### Syntax

```
|    ►► ┌───────────┐  
|    |  label:  GOTO target-label ──────────►►  
|    └──────────┘
```

### Description

#### *label*

Specifies the label for the GOTO statement. The label name cannot be the same as the name of the SQL routine in which the label is used or another label in the same scope.

#### *target-label*

Specifies a label of the statement where processing is to continue. *target-label* must be defined as a label for an SQL procedure statement. The target label must be accessible to the GOTO statement as defined in "References to labels" on page 1543, subject to the following restrictions:

- If the GOTO statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the GOTO statement is not defined in a condition handler, *target-label* must not be defined in a condition handler.

### Notes

**Using a GOTO statement:** It is recommended that the GOTO statement be used sparingly. This statement interferes with the normal sequence of processing SQL statements, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

**Effect on open cursors:** When a GOTO statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the GOTO statement are closed, unless those statements are declared to return result sets. If the GOTO statement transfers control out of any directly or indirectly nested compound statements, all open cursors that are declared in those nested compound statements are also closed, unless those cursors are declared to return result sets.

### Examples

**Example 1:** In the following procedure, the GOTO statement branches outside of the current compound statement to a higher level:

```
CREATE PROCEDURE TESTGOT05 ( )  
P1: BEGIN  
    DECLARE I ,A INTEGER;  
    SET I = 1;  
    LAB1: SET A = 1;
```

```

BEGIN
  LAB2: SET A = 2;
  BEGIN
    SET I = I+1;
    IF I<3 THEN GOTO LAB1;
    END IF;
  END;
END;
END P1

```

*Example 2:* In the following example, cursors are declared at multiple levels. The GOTO statement that specified TargLabel as the target label, results in the closing of cursors C1, C2, and C3. This is because cursors C1, C2, and C3 are all declared directly or indirectly in the compound statement with the label L1. The GOTO statement causes control to transfer out of the compound statement with label L1, so the cursors that are defined within that compound statement (at any level) are closed.

```

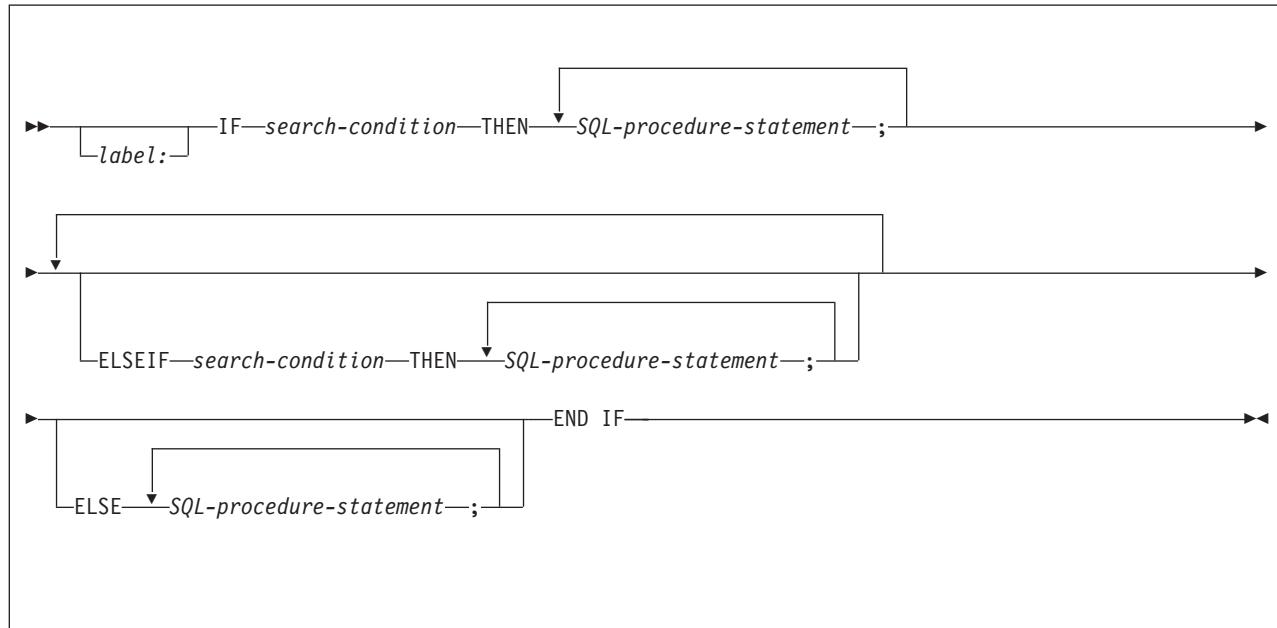

L0: BEGIN
  DECLARE CURSOR C0 ...
  ...
  TARGLABEL: ...
  ...
  L1: BEGIN
    DECLARE CURSOR C1 ...
    ...
    L2: BEGIN
      DECLARE CURSOR C2 ...
      ...
      GOTO TARGLABEL;
      ...
      L3: BEGIN
        DECALEUE CURSOR C3 ...
        ...
      END L3;
    END L2;
  END L1;
END L0

```

## IF statement

The IF statement executes different sets of SQL statements based on the result of search conditions.

### Syntax

### Description

#### *label*

Specifies the label for the IF statement. The label name cannot be the same as the name of the SQL routine or another label name within the same scope. For additional information, see “References to labels” on page 1543.

#### *search-condition*

Specifies the *search-condition* for which an SQL statement should be executed. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

#### *SQL-procedure-statement*

Specifies an SQL statement to be executed if the preceding *search-condition* is true. See “SQL-procedure-statement” on page 1546.

### Examples

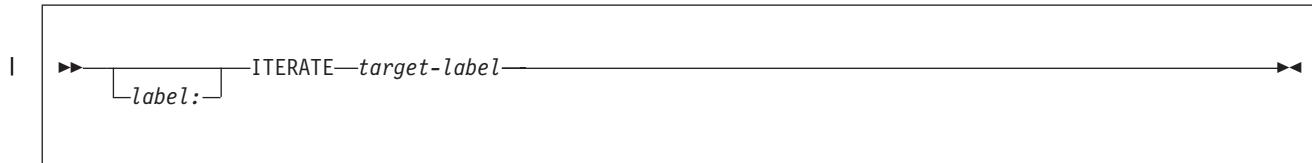

Assign a value to the SQL variable *new\_salary* based on the value of SQL variable *rating*.

```
IF rating = 1
  THEN SET new_salary =
    new_salary + (new_salary * .10);
ELSEIF rating = 2
  THEN SET new_salary =
    new_salary + (new_salary * .05);
ELSE SET new_salary =
  new_salary + (new_salary * .02);
END IF
```

## ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

### Syntax

### Description

#### *label*

Specifies the label for the ITERATE statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *target-label*

Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the flow of control is passed. *target-label* must be defined as a label for a FOR, LOOP, REPEAT, or WHILE statement. The ITERATE statement must be in that FOR, LOOP, REPEAT, or WHILE statement, or in the block of code that is directly or indirectly nested within that statement, subject to the following restrictions:

- If the ITERATE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the ITERATE statement is not in a condition handler, *target-label* must not be defined in a condition handler.

### Examples

*Example 1:* This example uses a cursor to return information for a new department. If the *not\_found* condition handler is invoked, the flow of control passes out of the loop. If the value of *v\_dept* is 'D11', an ITERATE statement causes the flow of control to be passed back to the top of the LOOP statement. Otherwise, a new row is inserted into the table.

```
CREATE PROCEDURE ITERATOR ()  
LANGUAGE SQL  
MODIFIES SQL DATA  
BEGIN  
    DECLARE v_dept CHAR(3);  
    DECLARE v_deptname VARCHAR(29);  
    DECLARE v_admdept CHAR(3);  
    DECLARE at_end INTEGER DEFAULT 0;  
    DECLARE not_found CONDITION FOR SQLSTATE '02000';  
    DECLARE c1 CURSOR FOR  
        SELECT deptno,deptname,admrdept  
        FROM department  
        ORDER BY deptno;  
    DECLARE CONTINUE HANDLER FOR not_found  
        SET at_end = 1;  
    OPEN c1;  
    ins_loop:  
    LOOP  
        FETCH c1 INTO v_dept, v_deptname, v_admdept;  
        IF at_end = 1 THEN
```

```

        LEAVE ins_loop;
ELSEIF v_dept = 'D11' THEN
    ITERATE ins_loop;
END IF;
INSERT INTO department (deptno,deptname,admrdept)
    VALUES('NEW', v_deptname, v_admdept);
END LOOP;
CLOSE c1;
END

```

*Example 2:* An ITERATE statement can be issued from a nested block to cause that flow of control to return to the beginning of a loop at a higher level. In the following example, the ITERATE statement within the LAB2 compound statement causes the flow of control to return to the beginning of the LAB1 LOOP statement:

```

LAB1: LOOP
    SET A = 0;
    LAB2: BEGIN
        ...
        LAB3: BEGIN
            ...
            ITERATE LAB1; -- Multilevel ITERATE
            ...
        END LAB3;
        ...
        ITERATE LAB1; -- Multilevel ITERATE
        ...
    END LAB2;
END LOOP;S

```

## LEAVE statement

The LEAVE statement transfers program control out of a FOR, LOOP, REPEAT, WHILE, or compound statement.

### Syntax

```
►► [label:] LEAVE —target-label—
```

### Description

#### *label*

Specifies the label for the LEAVE statement. The label name cannot be the same as the name of the SQL routine or the same as another label that is within the same scope. For additional information, see “References to labels” on page 1543.

#### *target-label*

Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit. *target-label* must be defined as a label for a compound, FOR, LOOP, REPEAT, or WHILE statement, or in a block of code that is directly or indirectly nested within that statement, subject to the following rules:

- If the LEAVE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the LEAVE statement is not in a condition handler, *target-label* must not be defined in a condition handler.

### Notes

*Effect on open cursors:* When a LEAVE statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contain the LEAVE statement are closed, except cursors that are used to return result sets.

### Examples

*Example 1:* The example contains a loop that fetches data for cursor c1. If the value of SQL variable *at\_end* is not zero, the LEAVE statement transfers control out of the loop.

```
CREATE PROCEDURE LEAVE_LOOP (OUT COUNTER INTEGER)
LANGUAGE SQL
BEGIN
    DECLARE v_counter INTEGER;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
        SELECT firstname, midinit, lastname
        FROM employee;
    DECLARE CONTINUE HANDLER FOR not_found
        SET at_end = 1;
    SET v_counter = 0;
```

```

OPEN c1;
fetch_loop:
LOOP
    FETCH c1 INTO v_firstname, v_midinit, v_lastname;
    IF at_end <> 0 THEN
        LEAVE fetch_loop;
    END IF;
    SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END

```

*Example 2:* A LEAVE statement can be issued from a nested block to leave a statement at a higher level. In the following example, the LEAVE statement within the LAB2 compound statement causes the LAB1 LOOP statement to terminate:

```

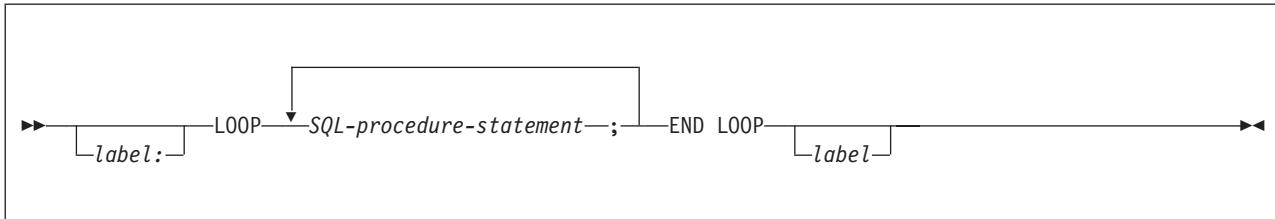

LAB1: LOOP
...
LAB2: BEGIN
    SET A = 0;
    ...
    LAB3: BEGIN
        ...
        LEAVE LAB1; -- Multilevel LEAVE
        ...
    END LAB3;
    ...
    LEAVE LAB1; -- Multilevel LEAVE
    ...
END LAB2;
END LOOP;S

```

## LOOP statement

The LOOP statement executes a statement or group of statements multiple times.

### Syntax

### Description

#### *label*

Specifies the label for the LOOP statement. If the ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *SQL-procedure-statement*

Specifies an SQL statement to be executed in the loop. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1546.

### Notes

*Considerations for the diagnostics area:* At the beginning of the first iteration of the LOOP statement, and with every subsequent iteration, the diagnostics area is cleared.

*Considerations for the SQLSTATE and SQLCODE SQL variables:* Prior to executing the first SQL-procedure-statement within that LOOP statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the LOOP statement. If the loop is terminated with a GOTO or a LEAVE statement, the SQLSTATE and SQLCODE values reflect successful completion of that statement. When the LOOP statement iterates, the SQLSTATE and SQLCODE values reflect the result of the last SQL statement that is executed within the LOOP statement.

### Examples

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter counter is incremented and the value of *v\_midinit* is checked to ensure that the value is not a single space (' '). If *v\_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

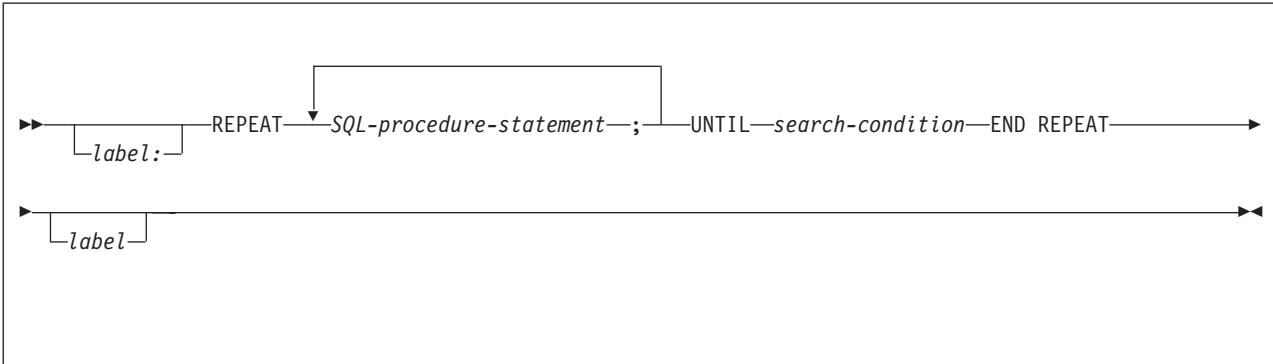

```
CREATE PROCEDURE LOOP_UNTIL_SPACE(OUT counter INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
      SELECT firstname, midinit, lastname
      FROM employee;
    DECLARE EXIT HANDLER FOR NOT FOUND
```

```
SET counter = -1;
OPEN c1;
fetch_loop:
LOOP
    FETCH c1 INTO v_firstname, v_midinit, v_lastname;
    IF v_midinit = ' ' THEN
        LEAVE fetch_loop;
    END IF;
    SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END
```

## REPEAT statement

The REPEAT statement executes a statement or group of statements until a search condition is true.

### Syntax

### Description

#### *label*

Specifies the label for the REPEAT statement. If an ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *SQL-procedure-statement*

Specifies an SQL statement to be executed within the REPEAT loop. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1546.

#### *search-condition*

Specifies a condition that is evaluated after each execution of the REPEAT loop. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the looping continues.

### Notes

*Considerations for the diagnostics area:* At the beginning of the first iteration of the REPEAT statement, and with every subsequent iteration, the diagnostics area is cleared.

*Considerations for the SQLSTATE and SQLCODE SQL variables:* At the beginning of the first iteration of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the values that were set prior to the REPEAT statement. At the beginning of iterations 2 through *n* of the REPEAT statement, the SQLSTATE and SQLCODE SQL values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END REPEAT of the REPEAT statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement.

## Examples

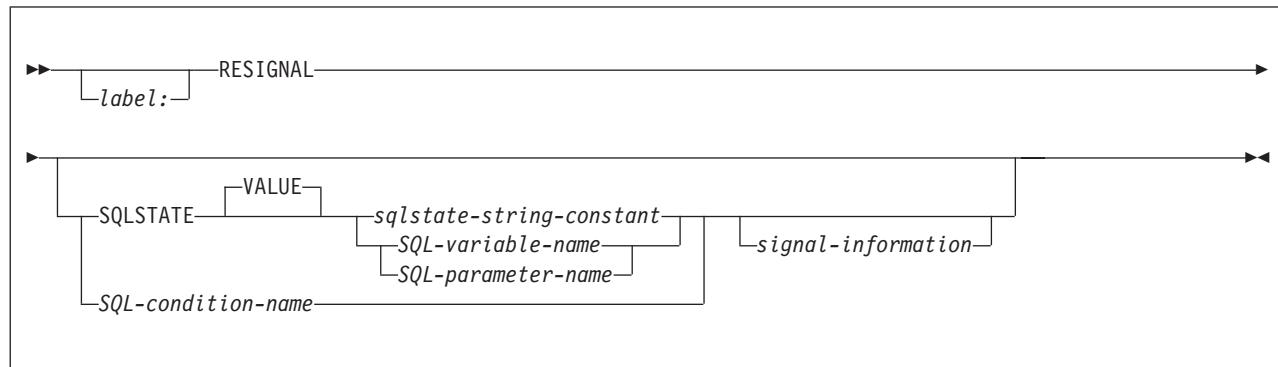

Use a REPEAT statement to fetch rows from a table.

```
fetch_loop:  
REPEAT  
    FETCH c1 INTO  
        v_firstname, v_midinit, v_lastname;  
UNTIL  
    SQLCODE <> 0  
END REPEAT fetch_loop
```

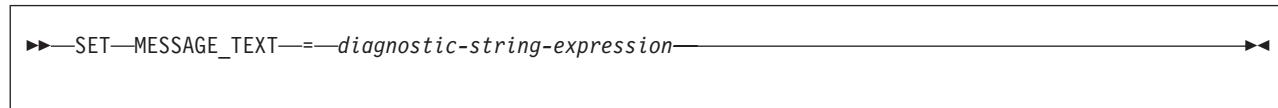

## RESIGNAL statement

The RESIGNAL statement is used within a condition handler to resignal the condition that activated the handler, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned along with optional message text.

### Syntax

**signal-information:**

### Description

#### *label*

Specifies the label for the RESIGNAL statement. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 1543.

#### **SQLSTATE VALUE**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATE values:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

#### *sqlstate-string-constant*

A character string constant with an actual length of five bytes that is a valid SQLSTATE value.

#### *SQL-variable-name* or *SQL-parameter-name*

Specifies an SQL variable or SQL parameter that is defined for the routine.

#### *SQL-variable-name*

Specifies an SQL variable that is declared within the *compound-statement* that contains the RESIGNAL statement or within a compound statement in which that compound statement is nested.

*SQL-variable-name* must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL\_parameter-name*

Specifies an SQL parameter that is defined for the routine that contains the SQLSTATE value. The SQL parameter must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL-condition-name*

Specifies the name of the condition that will be returned. *SQL-condition-name* must be declared within the *compound-statement* that contains the RESIGNAL statement, or within a compound statement in which that compound statement is nested.

**SET MESSAGE\_TEXT**

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

*diagnostic-string-expression*

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

## Notes

While any valid SQLSTATE value can be used in the RESIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled (SQLSTATE class other than '01' or '02'):

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If an SQLSTATE or a condition indicates that a warning or a not found condition is signaled:

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified

- | SQLSTATE or condition, the warning or not found condition is handled and  
| control is returned to that condition handler.  
| • Otherwise, the warning is not handled and processing continues with the next  
| statement.

| *Considerations for the diagnostics area:* The RESIGNAL statement might modify  
| the contents of the current diagnostics area. If an SQLSTATE or *condition-name* is  
| specified as part of the RESIGNAL statement, the RESIGNAL statement starts with  
| a clear diagnostics area and sets the RETURNED\_SQLSTATE to reflect the specified  
| SQLSTATE or *condition-name*. If message text is specified, the MESSAGE\_TEXT  
| item of the condition area is assigned the specified value.  
| DB2\_RETURNED\_SQLCODE is set to +438 or -438 corresponding to the specified  
| SQLSTATE or *condition-name*.

## Examples

The following example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE to the client application.

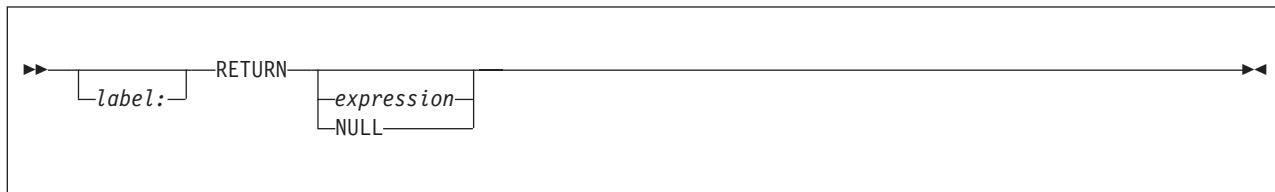

```
CREATE PROCEDURE divide (IN numerator INTEGER,  
                        IN denominator INTEGER,  
                        OUT divide_result INTEGER)  
LANGUAGE SQL  
CONTAINS SQL  
BEGIN  
    DECLARE overflow CONDITION for SQLSTATE '22003';  
    DECLARE CONTINUE HANDLER FOR overflow  
        RESIGNAL SQLSTATE '22375';  
    IF denominator = 0 THEN  
        SIGNAL overflow;  
    ELSE  
        SET divide_result = numerator / denominator;  
    END IF;  
END
```

## RETURN statement

The RETURN statement is used to return from the routine.

For SQL functions, it returns the result of the function. For an SQL procedure, it optionally returns an integer status value.

### Syntax

### Description

#### *label*

Specifies the label for the RETURN statement. *label* must not be specified within an SQL function. A label name cannot be the same as the name of the SQL procedure or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *expression*

Specifies a value that is returned from the routine.

- If the routine is a function, *expression* must be specified and the value of *expression* must conform to the SQL assignment rules as described in “Assignment and comparison” on page 102. If the value is being assigned to a string variable, storage assignment rules apply.
- If the routine is a procedure, the data type of *expression* must be INTEGER. If *expression* evaluates to the null value, a value of 0 is returned.

The *expression* cannot include a column name. See “Expressions” on page 180 for information on expressions. For an SQL function, the *expression* cannot contain a scalar fullselect.

#### *NULL*

The null value is returned from the SQL routine. NULL is not allowed in SQL procedures.

### Notes

#### *Considerations for SQL procedures:*

- **When a RETURN statement is used within an SQL procedure:** If a RETURN statement with a specified return value was used to return from a procedure, the SQLCODE, SQLSTATE, and message length in the SQLCA are initialized to zeros and the message text is set to blanks. An error is not returned to the caller.
- **When a RETURN statement is not used within an SQL procedure or when no value is specified:** If a RETURN statement was not used to return from a procedure or if a value is not specified on the RETURN statement, one of the following values is set:
  - If the procedure returns with an SQLCODE that is greater or equal to zero, the specified target for DB2\_RETURN\_STATUS in a GET DIAGNOSTICS statement will be set to a value of zero.

- If the procedure returns with an SQLCODE that is less than zero, the specified target for DB2\_RETURN\_STATUS in a GET DIAGNOSTICS statement will be set to a value of '-1'.
- **When the value is returned from an SQL procedure:** When a value is returned from a procedure, the caller may access the value using one of the following methods:
  - The GET DIAGNOSTICS statement to retrieve the RETURN\_STATUS when the SQL procedure was called from another SQL procedure.
  - The parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a CLI application.
  - Directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqlerrd[0]. When the SQLCODE is less than zero, the sqlerrd[0] value is not set. The application should assume a return status value of '-1'.

## Examples

*Example 1:* Use a RETURN statement to return from an SQL procedure with a status value of zero if successful or '-200' if not successful.

```
BEGIN
  . . .
  GOTO FAIL;
  . . .
SUCCESS: RETURN 0;
FAIL: RETURN -200;
END
```

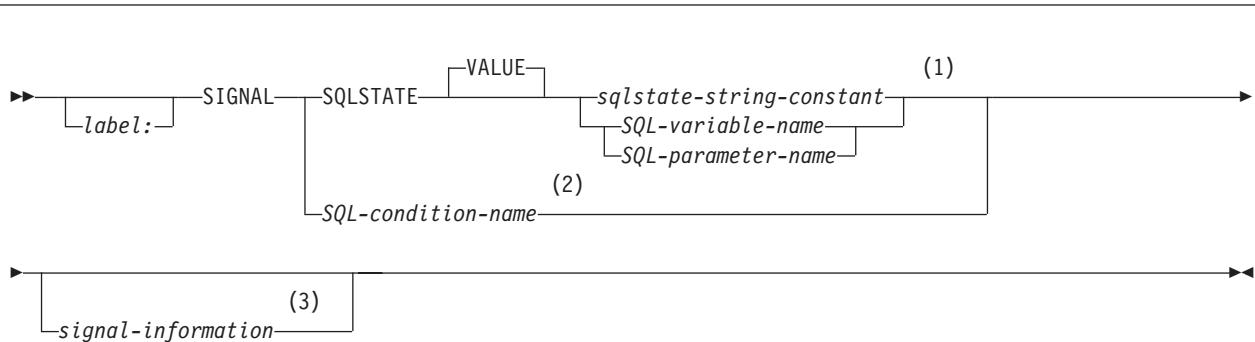

*Example 2:* Define a scalar function that returns the tangent of a value using the existing sine and cosine functions:

```
CREATE FUNCTION TAN (X DOUBLE)
RETURNS DOUBLE
LANGUAGE SQL CONTAINS SQL NO EXTERNAL ACTION
DETERMINISTIC
RETURN SIN(x)/COS(x)
```

## SIGNAL statement

The SIGNAL statement is used to return an exception or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text. The SIGNAL statement places the specified condition information in the cleared diagnostics area.

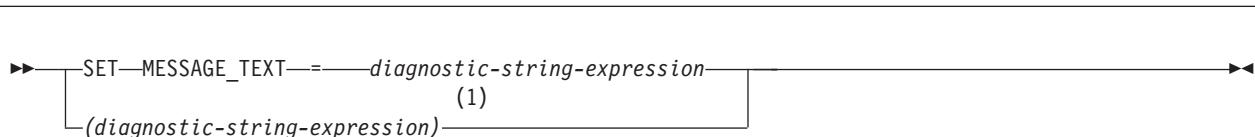

### Syntax

#### Notes:

- 1 The **SQLSTATE** variation must be used within a trigger body.
- 2 *SQL-condition-name* must not be specified within a trigger body.
- 3 *signal-information* must be specified within a trigger body

### signal-information:

#### Notes:

- 1 *(diagnostic-string-expression)* must only be specified within a trigger body.

## Description

### *label*

Specifies the label for the SIGNAL statement. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

### **SQLSTATE** **VALUE**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').

- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

*sqlstate-string-constant*

A character string constant with an actual length of five bytes that is a valid SQLSTATE value.

*SQL-variable-name or SQL-parameter-name*

Specifies an SQL variable or SQL parameter that contains a valid SQLSTATE value.

*SQL-variable-name*

Specifies an SQL variable that is declared within the *compound-statement* that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested. *SQL-variable-name* must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL-parameter-name*

Specifies an SQL parameter that is defined for the routine and contains the SQLSTATE value. The SQL parameter must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL-condition-name*

Specifies the name of the condition that will be returned. The *SQL-condition-name* must be declared within the compound statement that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested.

**SET MESSAGE\_TEXT**

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

*diagnostic-string-expression*

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

*(diagnostic-string-expression)*

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

This syntax variation is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of DB2. To conform with the ANSI and ISO standards, this form should not be used.

## Notes

While any valid SQLSTATE value can be used in the SIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled:

- If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- If the compound statement is nested and the outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning or not found condition is signaled:

- If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- Otherwise, the warning or not found condition is not handled and processing continues with the next statement.

*Considerations for the diagnostics area:* The SIGNAL statement starts with a clear diagnostics area and sets the RETURNED\_SQLSTATE to reflect the specified SQLSTATE or *condition-name*. If message text is specified, the MESSAGE\_TEXT item of the condition area is assigned the specified value.

DB2\_RETURNED\_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or *condition-name*.

*Using a SIGNAL statement in the body of a trigger:* Within the triggered action of a CREATE TRIGGER statement, the message text can be specified using only these variations:

```
SIGNAL SQLSTATE sqlstate-string-constant  
      SET MESSAGE_TEXT = diagnostic-string-expression  
SIGNAL SQLSTATE sqlstate-string-constant  
      (diagnostic-string-expression)
```

## Examples

*Example 1:* The following example shows an SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```
CREATE PROCEDURE SUBMIT_ORDER  
      (IN ONUM INTEGER, IN CNUM INTEGER,  
       IN PNUM INTEGER, IN QNUM INTEGER)  
LANGUAGE SQL  
SPECIFIC SUBMIT_ORDER  
MODIFIES SQL DATA  
BEGIN  
    DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'  
      SIGNAL SQLSTATE '75002'
```

```

SET MESSAGE_TEXT = 'Customer number is not known';
INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
    VALUES (ONUM, CNUM, PNUM, QNUM);
END

```

**Example 2:** The following example shows a trigger for an order system that allows orders to be recorded in an ORDERS table (ORDERNO, CUSTNO, PARTNO, QUANTITY) only if there is sufficient stock in the PARTS tables. When there is insufficient stock for an order, SQLSTATE '75001' is returned along with an appropriate error description.

```

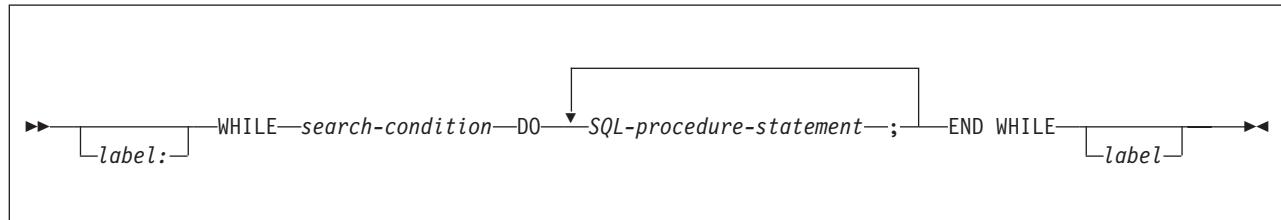

CREATE TRIGGER CK_AVAIL
    NO CASCADE BEFORE INSERT ON ORDERS
    REFERENCING NEW AS NEW_ORDER
    FOR EACH ROW MODE DB2SQL
    WHEN (NEW_ORDER.QUANTITY > (SELECT ON_HAND FROM PARTS
                                    WHERE NEW_ORDER.PARTNO = PARTS.PARTNO))
        BEGIN ATOMIC
            SIGNAL SQLSTATE '75001' ('Insufficient stock for order');
        END

```

## WHILE statement

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

### Syntax

### Description

#### *label*

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 1543.

#### *search-condition*

Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL procedure statements in the loop are executed.

#### *SQL-procedure-statement*

Specifies a statement to be run within the WHILE loop. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1546.

### Notes

*Considerations for the diagnostics area:* At the beginning of the first iteration of the WHILE statement, and with every subsequent iteration, the diagnostics area is cleared.

*Considerations for the SQLSTATE and SQLCODE SQL variables:* With each iteration of the WHILE statement, when the first SQL-procedure-statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search condition of that WHILE statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END WHILE of the WHILE statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating that search condition of that WHILE statement.

### Examples

Use a WHILE statement to fetch rows from a table while SQL variable `at_end`, which indicates whether the end of the table has been reached, is 0.

```
WHILE at_end = 0 DO
  FETCH c1 INTO
    v_firstname, v_midinit,
    v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN SET at_end=1;
  END IF;
END WHILE
```

---

## **Appendix. Additional information for DB2 SQL**

These topics contain additional information for DB2 SQL.

## Limits in DB2 for z/OS

DB2 for z/OS has system limits, object and SQL limits, length limits for identifiers and strings, and limits for certain data type values.

System storage limits might preclude the limits specified in this section. The limit for items not that are not specified below is limited by system storage.

The following table shows the length limits for identifiers.

*Table 131. Identifier length limits.* The term *byte(s)* in this table means the number of bytes for the UTF-8 representation unless noted otherwise.

Item	Limit
External-java-routine-name	1305 bytes
Name of an alias , auxiliary table, collection, clone table, constraint, correlation, cursor (except for DECLARE CURSOR WITH RETURN or the EXEC SQL utility), distinct type (both parts of two-part name), function (both parts of two-part name), host identifier, index, JARs, parameter, procedure, role, schema, sequence, specific, statement, storage group, savepoint, SQL condition, SQL label, SQL parameter, SQL variable, synonym, table, trigger, view, XML attribute name, XML element name	128 bytes
Name of an authorization ID or name of a security label.	8 bytes
Routine version identifier	64 EBCDIC bytes, and the UTF-8 representation of the name must not exceed 122 bytes.
Name of a column	30 bytes
Name of cursor that is created with DECLARE CURSOR WITH RETURN	30 bytes
Name of cursor that is created with the EXEC SQL utility	8 bytes
Name of a location	16 bytes
Name of buffer pool name, catalog, database, plan, program, table space	8 bytes
Name of package	8 bytes (Only 8 EBCDIC characters are used for packages that are created with the BIND PACKAGE command. 128 bytes can be used for packages that are created as a result of the CREATE TRIGGER statement.)
Name of a profile that is created with CREATE TRUSTED CONTEXT or ALTER TRUSTED CONTEXT	127 bytes

Table 132 shows the minimum and maximum limits for numeric values.

*Table 132. Numeric limits*

Item	Limit
Smallest SMALLINT value	-32768
Largest SMALLINT value	32767
Smallest INTEGER value	-2147483648
Largest INTEGER value	2147483647
Smallest BIGINT value	-9223372036854775808

Table 132. Numeric limits (continued)

The following table shows the length limits for strings.

*Table 133. String length limits*

Item	Limit
Maximum length of CHAR	255 bytes
Maximum length of GRAPHIC	127 double-byte characters
Maximum length of BINARY	255 bytes
Maximum length <sup>1</sup> of VARCHAR	4046 bytes for 4 KB pages 8128 bytes for 8 KB pages 16320 bytes for 16 KB pages 32704 bytes for 32 KB pages
Maximum length of VARCHAR that can be indexed by an XML index	1000 bytes after conversion to UTF-8

*Table 133. String length limits (continued)*

Item	Limit
Maximum length <sup>1</sup> of VARGRAPHIC	2023 double-byte characters for 4 KB pages 4064 double-byte characters for 8 KB pages 8160 double-byte characters for 16 KB pages 16352 double-byte characters for 32 KB pages
I Maximum length of VARBINARY	32704 bytes
Maximum length of CLOB	2 147 483 647 bytes (2 GB - 1 byte)
Maximum length of DBCLOB	1 073 741 823 double-byte characters
Maximum length of BLOB	2 147 483 647 bytes (2 GB - 1 byte)
Maximum length of a character constant	32704 UTF-8 bytes
Maximum length of a hexadecimal character constant	32704 hexadecimal digits
Maximum length of a graphic string constant	16352 double-byte characters (32704 bytes when expressed in UTF-8)
Maximum length of a hexadecimal graphic string constant	32704 hexadecimal digits
I Maximum length of a text string used for a scalar expression	4000 UTF-8 bytes
Maximum length of a concatenated character string	2 147 483 647 bytes (2 GB - 1 byte)
Maximum length of a concatenated graphic string	1 073 741 824 double-byte characters
Maximum length of a concatenated binary string	2 147 483 647 bytes (2 GB - 1 byte)
I Maximum length of XML pattern text	4000 bytes after conversion to UTF-8
I Maximum length of an XML element or attribute name in an XML document	1000 bytes
I Maximum length of a namespace uri	1000 bytes
I maximum length of a namespace prefix	998 bytes
I largest depth of an internal XML tree	128 levels

**Note:**

1. The maximum length can be achieved only if the column is the only column in the table. Otherwise, the maximum length depends on the amount of space remaining on a page.

The following table shows the minimum and maximum limits for datetime values.

*Table 134. Datetime limits*

Item	Limit
Smallest DATE value (shown in ISO format)	0001-01-01
Largest DATE value (shown in ISO format)	9999-12-31
Smallest TIME value (shown in ISO format)	00.00.00
Largest TIME value (shown in ISO format)	24.00.00
Smallest TIMESTAMP value	0001-01-01-00.00.00.000000
Largest TIMESTAMP value	9999-12-31-24.00.00.000000

The following table shows the DB2 limits on SQL statements.

Table 135. DB2 limits on SQL statements

Item	Limit
Maximum number of columns that are in a table or view (the value depends on the complexity of the CREATE VIEW statement) or columns returned by a table function.	750 or fewer (including hidden columns) 749 if the table is a dependent
Maximum number of base tables in a view, SELECT, UPDATE, INSERT, MERGE, or DELETE	225
Maximum number of rows that can be inserted with a single INSERT or MERGE statement	32767
Maximum row and record sizes for a table	See Maximum record size under CREATE TABLE.
Maximum number of volume IDs in a storage group	133
Maximum number of partitions in a partitioned table space or partitioned index	64 for table spaces that are not defined with LARGE or a DSSIZE greater than 2 GB.  4096, depending on what is specified for DSSIZE or LARGE and the page size.
Maximum sum of the lengths of limit key values of a partition boundary	765 UTF-8 bytes
Maximum size of a partition (table space or index)	For table spaces that are not defined with LARGE or a DSSIZE greater than 2 GB: 4 GB, for 1 to 16 partitions 2 GB, for 17 to 32 partitions 1 GB, for 33 to 64 partitions  For table spaces that are defined with LARGE: 4 GB, for 1 to 4096 partitions  For table spaces that are defined with a DSSIZE greater than 2 GB: 64 GB, depending on the page size (for 1 to 256 partitions for 4 KB pages, for 1 to 512 partitions for 8 KB pages, for 1 to 1024 partitions for 16 KB pages, and 1 to 2048 partitions for 32 KB pages)
Maximum length of an index key	Partitioning index: $255-n$ Nonpartitioning index that is padded: $2000-n$ Nonpartitioning index that is not padded: $2000-n-2m$  Where $n$ is the number of columns in the key that allow nulls and $m$ is the number of varying-length columns in the key
Maximum number of bytes used in the partitioning of a partitioned index	255 (This maximum limit is subject to additional limitations, depending on the number of partitions in the table space. The number of partitions * (106 + limit key size) must be less than 65394.)
Maximum number of columns in an index key	64
Maximum number of expressions in an index key	64
Maximum number of tables in a FROM clause	225 or fewer, depending on the complexity of the statement
Maximum number of subqueries in a statement	224
Maximum total length of host and indicator variables pointed to in an SQLDA	32767 bytes  2 147 483 647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language

*Table 135. DB2 limits on SQL statements (continued)*

Item	Limit
Longest host variable used for insert or update operation	32704 bytes for a non-LOB 2 147 483 647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language
Longest SQL statement	2 097 152 bytes
Maximum number of elements in a select list	750 or fewer, depending on whether the select list is for the result table of static scrollable cursor <sup>1</sup>
Maximum number of predicates in a WHERE or HAVING clause	Limited by storage
Maximum total length of columns of a query operation requiring a sort key (SELECT DISTINCT, ORDER BY, GROUP BY, UNION, EXCEPT, and INTERSECT, without the ALL keyword, and the DISTINCT keyword for aggregate functions)	4000 bytes
Maximum total length of columns of a query operation requiring sort and evaluating column functions (MULTIPLE DISTINCT and GROUP BY)	32600 bytes
Maximum length of a sort key	16000 bytes
Maximum length of a check constraint	3800 bytes
Maximum number of bytes that can be passed in a single parameter of an SQL CALL statement	32765 bytes for a non-LOB 2 147 483 647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations imposed by the application environment and host language
Maximum number of stored procedures, triggers, and user-defined functions that an SQL statement can implicitly or explicitly reference	16 nesting levels
Maximum length of the SQL path	2048 bytes
Maximum length of a WLM environment name in a CREATE PROCEDURE, CREATE FUNCTION, ALTER PROCEDURE, or ALTER FUNCTION statement.	32 bytes
Maximum number of XPath level in the XMLPATTERN clause of the CREATE INDEX statement.	50 nesting levels
<b>Note:</b>	
1. If the scrollable cursor is read-only, the maximum number is 749 less the number of columns in the ORDER BY that are not in the select list. If the scrollable cursor is not read-only, the maximum number is 747.	

The following table shows the DB2 system limits.

*Table 136. DB2 system limits*

Item	Limit
Maximum number of concurrent DB2 or application agents	Limited by the EDM pool size, buffer pool size, and the amount of storage that is used by each DB2 or application agent
Largest non-LOB table or table space	128 terabytes (TB)
Largest simple or segmented table space	64 GB
Largest log space	$2^{48}$ bytes

*Table 136. DB2 system limits (continued)*

Item	Limit
Largest active log data set	4 GB -1 byte
Largest archive log data set	4 GB -1 byte
Maximum number of active log copies	2
Maximum number of archive log copies	2
Maximum number of active log data sets (each copy)	93
Maximum number of archive log volumes (each copy)	10000
Maximum number of databases accessible to an application or end user	Limited by system storage and EDM pool size
Maximum number of databases	65271
Maximum number of implicitly created databases	10000
Maximum number of indexes on declared global temporary tables	10000
Largest EDM pool	The installation parameter maximum depends on available space
Maximum number of rows per page	255 for all table spaces except catalog and directory tables spaces, which have a maximum of 127
Maximum simple or segmented data set size	2 GB
Maximum partitioned data set size	See item "maximum size of a partition" in Table 135 on page 1591
Maximum LOB data set size	64 GB
Maximum number of table spaces that can be defined in a work file database	500
Maximum number of tables and triggers that can be defined in a work file database	11767

---

## **Reserved schema names and reserved words**

Restrictions exist on the use of certain names that are used by DB2. In some cases, names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented by the database manager.

## Reserved schema names

In general, for distinct types, user-defined functions, stored procedures, sequences, and triggers, schema names that begin with the prefix SYS are reserved. The schema name for these objects cannot begin with SYS except for certain exceptions.

The schema name for distinct types, user-defined functions, stored procedures, sequences, and triggers cannot begin with SYS with these exceptions:

- SYSADM. The schema name can be SYSADM for all these objects.
- SYSIBM. The schema name can be SYSIBM for procedures.
- SYSPROC. The schema name can be SYSPROC for procedures.
- SYSTOOLS. The schema name can be SYSTOOLS for distinct types, user-defined functions, procedures, and triggers if the user who executes the CREATE statement has the SYSADM or SYSCTRL privilege.
- SYSFUN. The schema name can be SYSFUN for external user-defined scalar functions or external user-defined table functions if the user who executes the CREATE statement has the SYSADM or SYSCTRL privilege.

**Recommendation:** Do not to use SESSION name as a schema name.

## Reserved words

Certain words cannot be used as ordinary identifiers in some contexts because those words might be interpreted as SQL keywords. For example, ALL cannot be a column name in a SELECT statement. Each word, however, can be used as a delimited identifier in contexts where it otherwise cannot be used as an ordinary identifier. For example, if the quotation mark ("") is the escape character that begins and ends delimited identifiers, "ALL" can appear as a column name in a SELECT statement.

New reserved words for this version of DB2 for z/OS are identified with notes in this topic. In addition, some topics in this information might indicate words that cannot be used in the specific context that is being described.

IBM SQL has additional reserved words that DB2 for z/OS does not enforce. Therefore, you should not use these additional reserved words as ordinary identifiers in names that have a continuing use. See *IBM DB2 SQL Reference for Cross-Platform Development* for a list of the words.

## **Characteristics of SQL statements in DB2 for z/OS**

DB2 allows specific actions on each SQL statement, and only certain SQL statements are allowed in external routines and SQL procedures.

## Actions allowed on SQL statements

Specific DB2 statements can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler.

The following table shows whether a specific DB2 statement can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler. The letter Y means yes.

*Table 137. Actions allowed on SQL statements in DB2 for z/OS*

SQL statement	Executable	Interactively or dynamically prepared	Processed by		
			Requesting system	Server	Precompiler
ALLOCATE CURSOR <sup>1</sup>	Y	Y	Y		
ALTER <sup>2</sup>	Y	Y		Y

SQL statement	Executable	Interactively or dynamically prepared	Processed by		
			Requesting system	Server	Precompiler
VALUES <sup>6</sup>	Y			Y	
VALUES INTO <sup>7</sup>	Y			Y	
WHENEVER					Y

**Note:**

1. The statement can be dynamically prepared. It cannot be issued dynamically.
2. The statement can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
3. The statement can be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements.
4. The requesting system processes the PREPARE statement when the statement being prepared is ALLOCATE CURSOR or ASSOCIATE LOCATORS.
5. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only when DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.
6. This statement can be used only in the triggered action of a trigger.
7. Local special registers can be referenced in a VALUES INTO statement if it results in the assignment of a single host-variable, not if it results in setting more than one value.
8. Some processing also occurs at the requester.

## SQL statements allowed in external functions and stored procedures

Certain SQL statements can be executed in an external stored procedure or in an external user-defined function. Whether the statements can be executed depends on the level of SQL data access with which the stored procedure or external function is defined.

The following table shows which SQL statements in an external stored procedure or in an external user-defined function can execute. The letter **Y** means *yes*.

In general, if an executable SQL statement is encountered in a stored procedure or function defined as NO SQL, SQLSTATE 38001 is returned. If the routine is defined to allow some level of SQL access, SQL statements that are not supported in any context return SQLSTATE 38003. SQL statements not allowed for routines defined as CONTAINS SQL return SQLSTATE 38004, and SQL statements not allowed for READS SQL DATA return SQL STATE 38002.

*Table 138. SQL statements in external user-defined functions and stored procedures*

SQL statement	Level of SQL access			
	NO SQL	CONTAINS SQL	READS SQL DATA	MODIFIES SQL DATA
ALLOCATE CURSOR			Y	Y
ALTER				Y
ASSOCIATE LOCATORS			Y	Y

VALUES			Y	Y
VALUES INTO		Y <sup>5</sup>	Y	Y
WHENEVER	Y <sup>1</sup>	Y	Y	Y

*Table 138. SQL statements in external user-defined functions and stored procedures (continued)*

SQL statement	Level of SQL access		
	NO SQL	CONTAINS SQL	READS SQL DATA
<b>Notes:</b>			
1.	Although the SQL option implies that no SQL statements can be specified, non-executable statements are not restricted.		
2.		The stored procedure that is called must have the same or more restrictive level of SQL data access than the current level in effect. For example, a routine defined as MODIFIES SQL DATA can call a stored procedure defined as MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL. A routine defined as CONTAINS SQL can call a procedure defined as CONTAINS SQL or NO SQL.	
3.		The COMMIT statement cannot be executed in a user-defined function. The COMMIT statement cannot be executed in a stored procedure if the procedure is in the calling chain of a user-defined function or trigger.	
4.		The statement specified for the EXECUTE statement must be a statement that is allowed for the particular level of SQL data access in effect. For example, if the level in effect is READS SQL DATA, the statement must not be an INSERT, UPDATE, MERGE, or DELETE statement.	
5.		The statement is supported only if it does not contain a subquery or query-expression.	
6.		RELEASE SAVEPOINT, SAVEPOINT, and ROLLBACK (with the TO SAVEPOINT clause) cannot be executed from a user-defined function.	
7.		If the ROLLBACK statement (without the TO SAVEPOINT clause) is executed in a user-defined function, an error is returned to the calling program, and the application is placed in a <i>must rollback</i> state.	
8.		The ROLLBACK statement (without the TO SAVEPOINT clause) cannot be executed in a stored procedure if the procedure is in the calling chain of a user-defined function or trigger.	

## SQL statements allowed in SQL procedures

Certain SQL statements that are valid in an SQL procedure body in addition to SQL procedure statements. Some SQL statements can be used as the only statement in the SQL procedure. An SQL statement can be executed in an SQL procedure depending on whether MODIFIES SQL DATA, CONTAINS SQL, or READS SQL DATA is specified in the stored procedure definition.

The following table lists the statements that are valid in an SQL procedure body, in addition to SQL procedure statements. The table lists the statements that can be used as the only statement in the SQL procedure and as the statements that can be nested in a compound statement. An SQL statement can be executed in an SQL procedure depending on whether MODIFIES SQL DATA, CONTAINS SQL, or READS SQL DATA is specified in the stored procedure definition. See Table 138 on page 1605 for a list of SQL statements that can be executed for each of these parameter values.

*Table 139. Valid SQL statements in an SQL procedure body*

SQL statement	The only statement in the procedure	Nested in a compound statement
ALLOCATE CURSOR		Y
ALTER DATABASE	Y	Y
ALTER FUNCTION	Y	Y
ALTER INDEX	Y	Y
ALTER PROCEDURE	Y	Y
ALTER SEQUENCE	Y	Y
ALTER STOGROUP	Y	Y
ALTER TABLE	Y	Y
ALTER TABLESPACE	Y	Y
ALTER TRUSTED CONTEXT	Y	Y
ALTER VIEW	Y	Y
ASSOCIATE LOCATORS		Y
CALL		Y
CLOSE		Y
COMMENT	Y	Y
COMMIT <sup>1</sup>	Y	Y
CONNECT	Y	Y
CREATE ALIAS	Y	Y
CREATE DATABASE	Y	Y
CREATE TYPE	Y	Y
CREATE FUNCTION <sup>2</sup>	Y	Y
CREATE GLOBAL TEMPORARY TABLE	Y	Y
CREATE INDEX	Y	Y
CREATE PROCEDURE <sup>2</sup>	Y	Y
CREATE ROLE	Y	Y
CREATE SEQUENCE	Y	Y

*Table 139. Valid SQL statements in an SQL procedure body (continued)*

SQL statement	The only statement in the procedure	Nested in a compound statement
CREATE STOGROUP	Y	Y
CREATE SYNONYM	Y	Y
CREATE TABLE	Y	Y
CREATE TABLESPACE	Y	Y
CREATE TRUSTED CONTEXT	Y	Y
CREATE VIEW	Y	Y
DECLARE CURSOR		Y
DECLARE GLOBAL TEMPORARY TABLE	Y	Y
DELETE	Y	Y
DROP INDEX	Y	Y
DROP ROLE	Y	Y
DROP TABLE	Y	Y
DROP TRUSTED CONTEXT	Y	Y
DROP VIEW	Y	Y
EXCHANGE	Y	Y
EXECUTE		Y
EXECUTE IMMEDIATE	Y	Y
FETCH <sup>3</sup>		Y
GET DIAGNOSTICS	Y	Y
GRANT	Y	Y
INSERT	Y	Y
LABEL	Y	Y
LOCK TABLE	Y	Y
MERGE	Y	Y
OPEN		Y
PREPARE		Y
REFRESH TABLE	Y	Y
RELEASE connection	Y	Y
RELEASE SAVEPOINT	Y	Y
RENAME	Y	Y
REVOKE	Y	Y
ROLLBACK <sup>1</sup>	Y	Y
SAVEPOINT	Y	Y
SELECT INTO	Y	Y
SET CONNECTION	Y	Y
SET CURRENT DEBUG MODE	Y	Y
SET CURRENT DECFLOAT ROUNDING MODE	Y	Y

Table 139. Valid SQL statements in an SQL procedure body (continued)

SQL statement	SQL statement is...	
	The only statement in the procedure	Nested in a compound statement
SET CURRENT ROUTINE VERSION	Y	Y
SET ENCRYPTION PASSWORD	Y	Y
SET PATH	Y	Y
SET SCHEMA	Y	Y
TRUNCATE	Y	Y
UPDATE	Y	Y
VALUES INTO	Y	Y

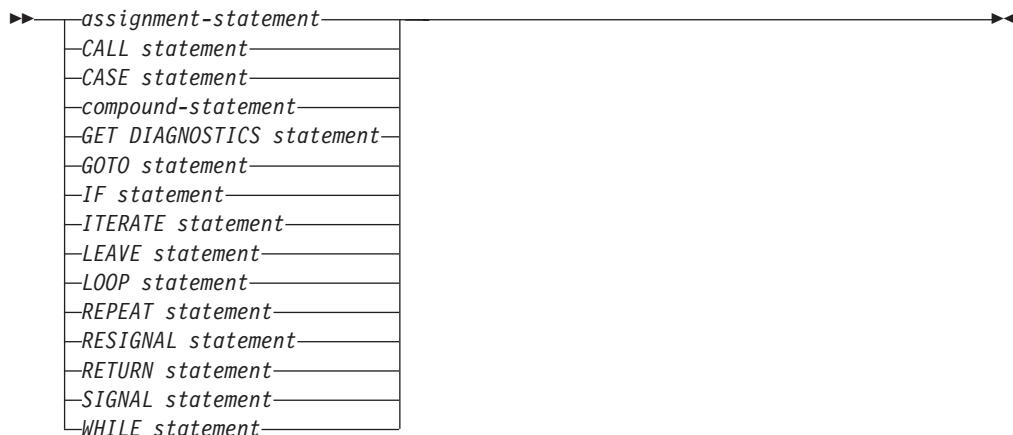

**Notes:**

1. The COMMIT statement and the ROLLBACK statement (without the TO SAVEPOINT clause) cannot be executed in a procedure if the procedure is in the calling chain of a user-defined function or trigger
2. CREATE FUNCTION with LANGUAGE SQL (specified either implicitly or explicitly) and CREATE PROCEDURE with LANGUAGE SQL are not allowed within the body of an SQL procedure.
3. The FETCH statement cannot specify the WITH CONTINUE or CURRENT CONTINUE clauses within an SQL procedure body.

## SQL control statements for external SQL procedures

SQL control statements for external SQL procedures can be used only with SQL procedures that are created with the FENCED or EXTERNAL clause. *SQL control statements* provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

### SQL-control-statement:

Control statements are supported in SQL procedures. External SQL procedures are created by specifying either FENCED or EXTERNAL, LANGUAGE SQL, and an SQL routine body on the “CREATE PROCEDURE (SQL - external)” on page 1035 statement. The SQL routine body must be a single SQL statement which may be an SQL control statement.

The remainder of this chapter contains a description of the control statements that are supported for external SQL procedures, and includes syntax diagrams, semantic descriptions, usage notes, and examples of the use of the statements that constitute the SQL routine body. In addition, you can find information about referencing SQL parameters and variables in “References to SQL parameters and SQL variables.”

The two common elements that are used in describing specific SQL control statements are:

- SQL control statements as described above
- “SQL-procedure-statement” on page 1612

## References to SQL parameters and SQL variables

SQL parameters and SQL variables can be referenced anywhere in the statement where an expression or a host variable can be specified. Host variables can be specified in SQL routines. SQL parameters and SQL variables can be referenced anywhere in the compound statement in which they are declared and can be qualified with the label name that is specified at the beginning of the compound statement.

All SQL parameters and SQL variables are considered nullable. The name of an SQL parameter or SQL variable in an SQL routine can be the same as the name of a column in a table or view that the SQL routine references. Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, SQL variable, or SQL parameter.

If the name is not qualified, the following rules describe whether the name refers to the column, the SQL variable, or the SQL parameter:

- The name is checked first as an SQL variable name and then as an SQL parameter name.
- If an SQL variable or SQL parameter by that name is not found, the name is assumed to be a column name.

The name of an SQL variable or SQL parameter in an SQL routine can be the name of an identifier that is used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier, the SQL variable, or the SQL parameter:

- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL variable name or an SQL parameter name. If an SQL variable or SQL parameter by that name is not found, the name is assumed to be an identifier.
- In the ASSOCIATE LOCATORS, CONNECT statement, the SET CONNECTION statement, and the RELEASE (connection) statement the name is used as an identifier.

## SQL-procedure-statement

An SQL control statement may allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

### Syntax

### Description

#### *SQL-label*

Specifies a label for the statement. *SQL-label* must not be a delimited identifier that includes lowercase letters or special characters. The label must be unique within the procedure.

#### *SQL-control-statement*

Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL procedures.

#### *SQL-statement*

Specifies an SQL statement as listed in Table 139 on page 1608. These statements are described in Chapter 5, “Statements,” on page 683.

### Notes

**Comments:** Comments can be included within the body of an SQL procedure. In addition to the double-dash form of comments (--), a comment can begin with /\* and end with \*/. The following rules apply to this form of comment:

- The beginning characters /\* must be adjacent and on the same line.
- The ending characters \*/ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

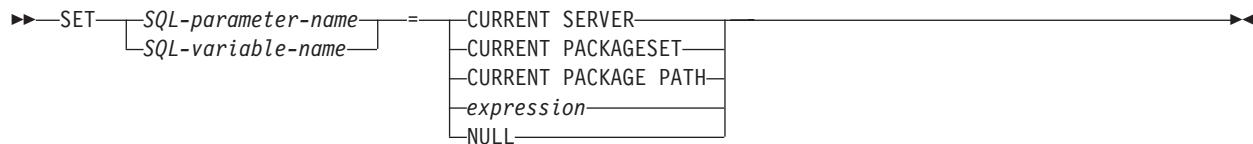

**Handling errors and warnings:** Conditions can be detected within an SQL procedure by using the following methods:

- Test the special SQL variables SQLSTATE and SQLCODE.
- Issue a GET DIAGNOSTICS statement to request the condition information. See “GET DIAGNOSTICS” on page 1317.
- Define condition handlers to detect and process conditions. See “compound-statement” on page 1620 for information about defining condition handlers.

## assignment-statement (SQL control statements for external routines)

The assignment statement assigns a value to an SQL parameter or to an SQL variable.

### Syntax

### Description

#### *SQL-parameter-name*

Identifies the parameter that is the assignment target. The parameter must be specified in *parameter-declaration* in the CREATE PROCEDURE statement and must be defined as OUT or INOUT.

#### *SQL-variable-name*

Identifies the SQL variable that is the assignment target. SQL variables can be declared in a compound-statement and must be declared before it is used. For information on declaring SQL variables, see “compound-statement” on page 1620.

#### *expression or NULL*

Specifies the expression or value that is the assignment source. The expression can be any expression of the type described in “Expressions” on page 180 except it cannot contain a reference to local special registers (CURRENT SERVER, CURRENT PACKAGESET, or CURRENT PACKAGE PATH).

### Notes

**Assignment rules:** Assignment statements in SQL procedures must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See “Assignment and comparison” on page 102 for assignment rules.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

The ENCODING bind option is not used during processing of assignments to string variables. For example, assume that the system does not use mixed or DBCS, and the system EBCDIC SBCS CCSID is 37. Character conversion will not occur on assignment even if CCSID 500 is specified for the ENCODING bind parameter for the package for the procedure.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

**Assignments involving SQL parameters:**

- An IN parameter can appear on the left side of an assignment statement. When control returns to the caller, the original value of an IN parameter is passed to the caller.
- An OUT parameter can appear on the left or right side of an assignment statement. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller.
- An INOUT parameter can appear on the left or right side of an assignment statement. The first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.
- A LOB parameter can not be used as an output value in an SQL statement in an SQL procedure when connected to a remote site. To circumvent the restriction, use a LOB SQL variable instead of a LOB parameter.

**Considerations for SQLSTATE and SQLCODE SQL variables:** Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

## Examples

Increase the SQL variable *p\_salary* by 10 percent.

```
SET p_salary = p_salary + (p_salary * .10)
```

Set SQL variable *p\_salary* to the null value.

```
SET p_salary = NULL
```

Set SQL variable *midinit* to the first character of SQL variable *midname*.

```
SET midinit = SUBSTR(midname,1,1)
```

## CALL statement

The CALL statement invokes a stored procedure.

### Syntax

```
►►—CALL—procedure-name—argument-list—►►
```

#### argument-list:

```
►►—(—SQL-variable-name—,—SQL-parameter-name—,—expression—,—NULL—)—►►
```

### Description

#### procedure-name

Identifies the stored procedure to call. The procedure name must identify a stored procedure that exists at the current server.

#### argument-list

Identifies a list of values to be passed as parameters to the stored procedure. The number of parameters must be the same as the number of parameters defined for the stored procedure. See “CALL” on page 874 for more information.

Control is passed to the stored procedure according to the calling conventions for SQL procedures. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

#### SQL-variable-name

Specifies an SQL variable as an argument to the stored procedure. For an explanation of references to SQL variables, see “References to SQL parameters and SQL variables” on page 1611.

#### SQL-parameter-name

Specifies an SQL parameter as an argument to the stored procedure. For an explanation of references to SQL parameters, see “References to SQL parameters and SQL variables” on page 1611.

#### expression

The parameter is the result of the specified *expression*, which is evaluated before the stored procedure is invoked. If *expression* is a single *SQL-parameter-name* or *SQL-variable-name*, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. If the result of the *expression* can be the null value, either the description of the

procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN *expression* can contain references to multiple SQL parameters or variables. In addition to the rules stated in “Expressions” on page 180 for *expression*, *expression* cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT *expression* can only be a single SQL parameter or variable.

#### **NULL**

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

#### **Notes**

See “CALL” on page 874 for more information on the SQL CALL statement.

#### **Examples**

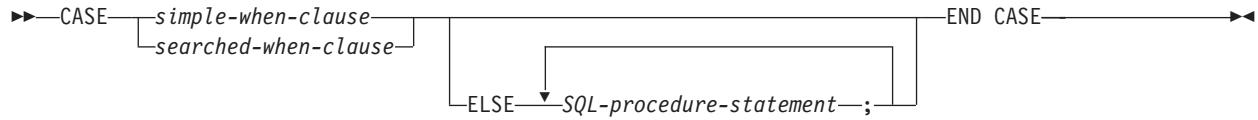

Call stored procedure proc1 and pass SQL variables as parameters.

```
CALL proc1(v_empno, v_salary)
```

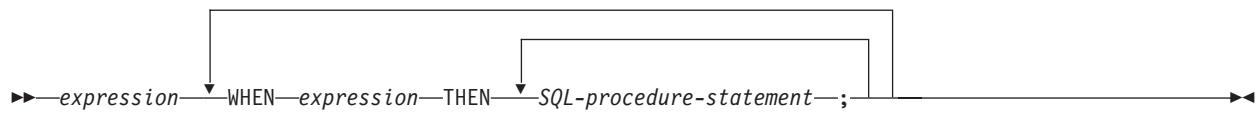

## CASE statement

The CASE statement selects an execution path based on the evaluation of one or more conditions. A CASE statement operates in the same way as a CASE expression.

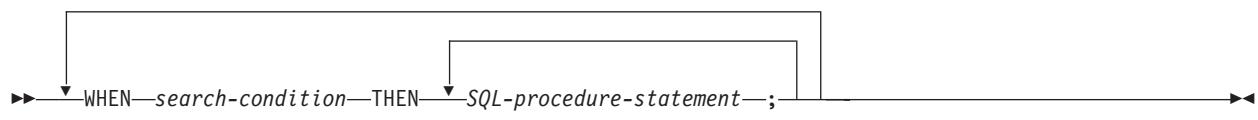

### Syntax

#### simple-when-clause:

#### searched-when-clause:

### Description

#### CASE

Begins a *case-expression*.

#### simple-when-clause

Specifies the *expression* prior to the first WHEN keyword that is tested for equality with the value of each *expression* that follows the WHEN keyword, and the result to be executed when those expressions are equal. If the comparison is true, the THEN statement is executed. If the result is unknown or false, processing continues to the next expression or the ELSE statement.

The data type of the *expression* prior to the first WHEN keyword must be comparable to the data types of each *expression* that follows the WHEN keywords.

#### searched-when-clause

Specifies the *search-condition* that is applied to each row or group of table data presented for evaluation, and the result when that condition is true. *search-condition* cannot contain a fullselect. If the search condition is true, the

THEN statement is executed. If the condition is unknown or false, processing continues to the next search condition or the ELSE statement.

*SQL-procedure-statement*

Specifies a statement that follows the THEN and ELSE keyword. The statement specifies the result of a *searched-when-clause* or a *simple-when-clause* that is true, or the result if no case is true. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1612.

*search-condition*

Specifies a condition that is true, false, or unknown about a row or group of table data.

**ELSE** *SQL-procedure-statement*

If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, the statements in the *else-clause* are executed.

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

**END CASE**

Ends a *case-statement*.

## Notes

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

CASE statements that use a simple case statement WHEN clause can be nested up to three levels. CASE statements that use a searched statement WHEN clause have no limit to the number of nesting levels.

**Considerations for the SQLSTATE and SQLCODE SQL variables:** When the first SQL-procedure-statement in the CASE statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the expression or search conditions of that CASE statement. If a CASE statement does not include an ELSE clause and none of the search conditions evaluate to true, an error is returned.

## Examples

*Example 1:* Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v\_workdept*.

```
CASE v_workdept
  WHEN 'A00'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE DEPT SET
      DEPTNAME = 'DATA ACCESS 2';
  ELSE UPDATE DEPT SET
    DEPTNAME = 'DATA ACCESS 3';
END CASE
```

*Example 2:* Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable *v\_workdept*.

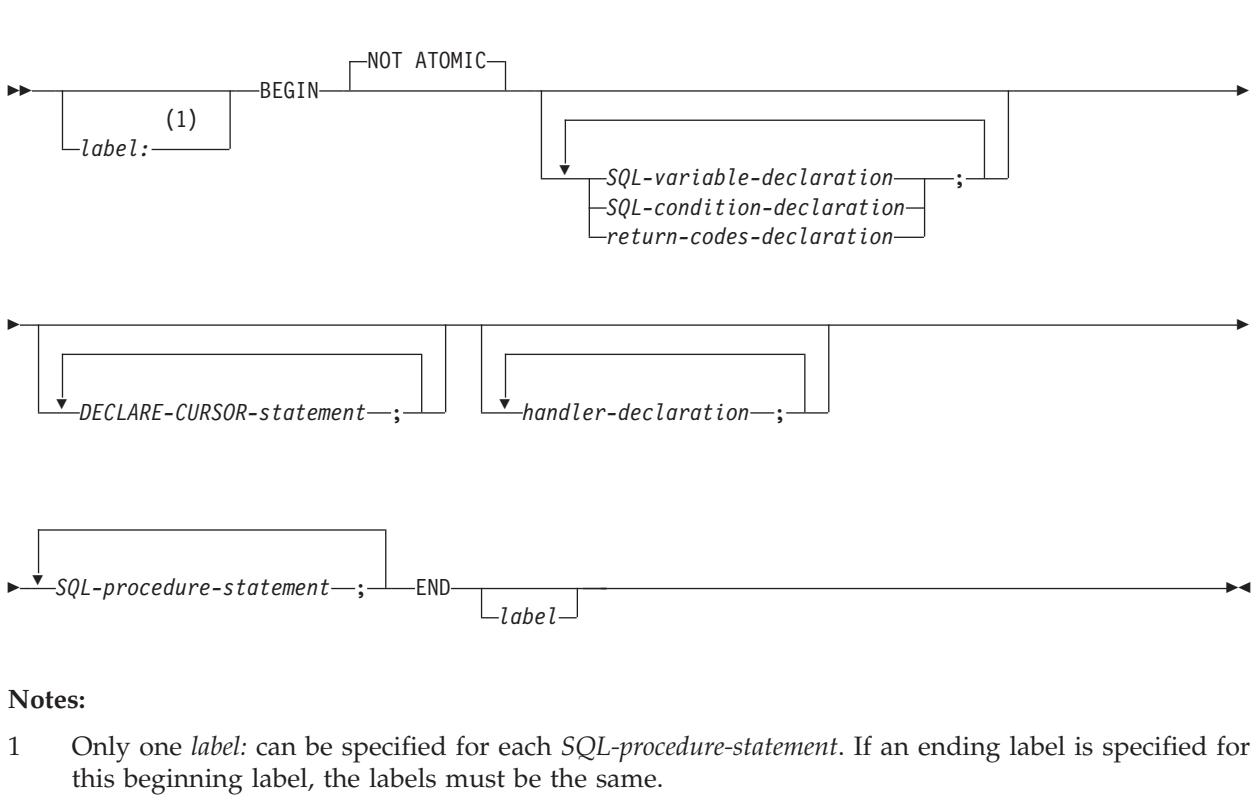

```
CASE
  WHEN v_workdept < 'B01'
    THEN UPDATE DEPT SET
```

```
|           DEPTNAME = 'DATA ACCESS 1';
|           WHEN v_workdept < 'C01'
|           THEN UPDATE DEPT SET
|               DEPTNAME = 'DATA ACCESS 2';
|           ELSE UPDATE DEPT SET
|               DEPTNAME = 'DATA ACCESS 3';
|           END CASE
|
|
```

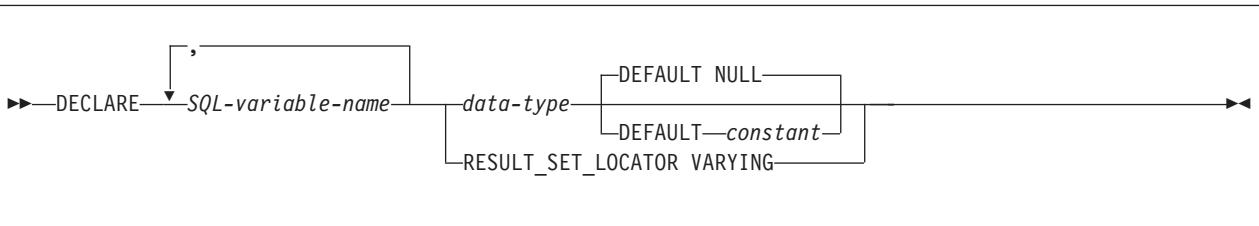

## compound-statement

A compound statement contains a group of statements and declarations for SQL variables, cursors, and condition handlers.

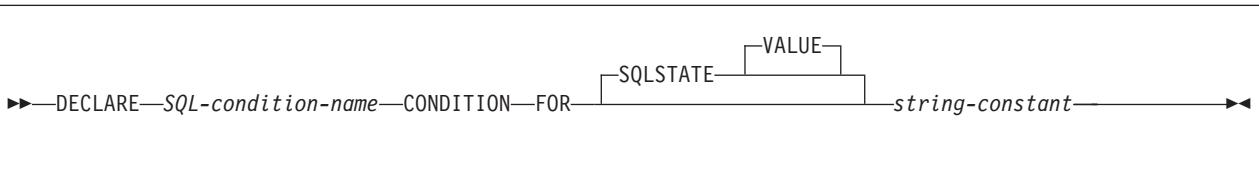

### Syntax

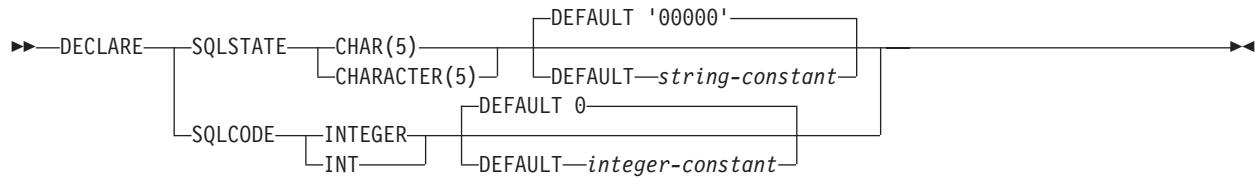

#### SQL-variable-declaration:

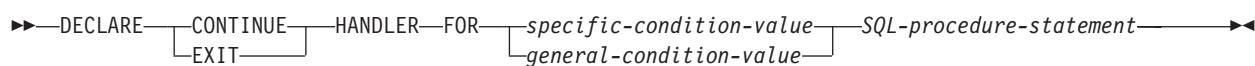

#### SQL-condition-declaration:

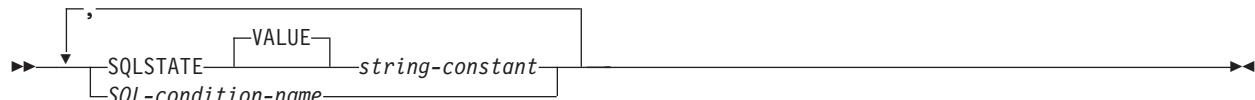

#### return-codes-declaration:

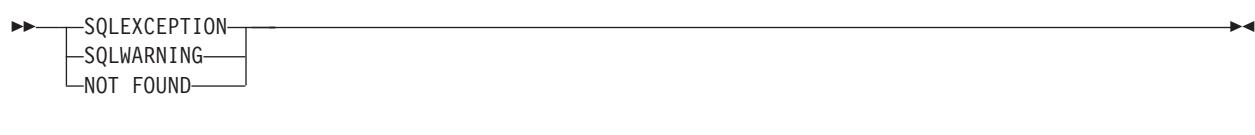

**handler-declaration:**

**specific-condition-value:**

**general-condition-value:**

## Description

*label*

Defines the label for the code block. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified on a LEAVE statement. If the ending label is specified, it must be the same as the beginning label.

**NOT ATOMIC**

NOT ATOMIC indicates that an error within the compound statement does not cause the compound statement to be rolled back.

*SQL-variable-declaration*

Declares a variable that is local to the compound statement.

*SQL-variable-name*

A qualified or unqualified name that designates a variable in an SQL procedure body. The unqualified form of *SQL-variable-name* is an SQL identifier and must not be a delimited identifier that contains lowercase letters or special characters. The qualified form is an SQL procedure statement label followed by a period (.) and an SQL identifier.

DB2 folds all SBCS SQL variable names to uppercase. SQL variable names should not be the same as column names. If an SQL statement contains an SQL variable or parameter and a column reference with the same name, DB2 interprets the name as an SQL variable or parameter name. To refer to the column, qualify the column name with the table name. Further, to avoid ambiguous variable references and to ensure compatibility with other DB2 platforms, qualify the SQL variable or parameter name with the label of the SQL procedure statement.

*data-type*

Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL procedure parameters. See “CREATE PROCEDURE (SQL - external)” on page 1035 for a description of SQL data types and lengths.

**DEFAULT** *constant* **or** **NULL**

Defines the default for the SQL variable. The variable is initialized when the SQL procedure is called. If a default value is not specified, the variable is initialized to NULL.

**RESULT\_SET\_LOCATOR VARYING**

Specifies the data type for a result set locator variable.

*SQL-condition-declaration*

Declares a condition name and corresponding SQLSTATE value.

*SQL-condition-name*

Specifies the name of the condition. The condition name is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. *SQL-condition-name* must be unique within the procedure body and can be referenced only within the compound statement in which it is declared.

**FOR SQLSTATE** *string-constant*

Specifies the SQLSTATE that is associated with the condition. The string must be specified as five characters enclosed in single quotes, and cannot be '00000'.

*return-codes-declaration*

Declares special variables called SQLSTATE and SQLCODE that are set automatically to the value returned after processing an SQL statement. Both the SQLSTATE and SQLCODE variables can be declared only in the outermost compound statement of the SQL procedure. Assignment to these variables is not prohibited; however, assignment is ignored by exception handlers, and processing the next SQL statement replaces the assigned value.

**DECLARE-CURSOR-statement**

Declares a cursor. Each cursor in the procedure body must have a unique name. An OPEN statement must be specified to open the cursor, and a FETCH statement can be specified to read rows. The cursor can be referenced only from within the compound statement. For more information on declaring a cursor, see “DECLARE CURSOR” on page 1191.

*handler-declaration*

Specifies a set of statements to execute when an exception or completion condition occurs in the compound statement. *SQL-procedure-statement* is the set of statements that execute when the handler receives control. See “SQL-procedure-statement” on page 1612 for information on *SQL-procedure-statement*.

A handler is active only within the compound statement in which it is declared.

The actions that a handler can perform are:

#### **CONTINUE**

Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END IF, END REPEAT, or END WHILE.

#### **EXIT**

After the handler is invoked successfully, control is returned to the end of the compound statement.

The conditions that can cause the handler to gain control are:

#### **SQLSTATE *string-constant***

Specifies an SQLSTATE for which the handler is invoked. The SQLSTATE cannot be '00000'.

#### ***SQL-condition-name***

Specifies a condition name for which the handler is invoked. The condition name must be previously defined in a condition declaration.

#### **SQLEXCEPTION**

Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see *DB2 Codes*.

#### **SQLWARNING**

Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

#### **NOT FOUND**

Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

## **Notes**

The order of statements in a compound statement must be:

1. SQL variable, condition declarations, and return codes declarations
2. Cursor declarations
3. Handler declarations
4. SQL procedure statements

Compound statements cannot be nested.

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

The following rules apply to handlers:

- A handler declaration that contains SQLEXCEPTION, SQLWARNING, or NOT FOUND cannot contain additional SQLSTATE or condition names.

- Handler declarations within the same compound statement cannot contain duplicate conditions.
- A handler declaration cannot contain the same condition code or SQLSTATE value more than once, and cannot contain an SQLSTATE value and a condition name that represent the same SQLSTATE value.
- A handler is activated when it is the most appropriate handler for an exception or completion condition.
- If there is no handler for an SQL error, the error is passed to the caller in the SQLCA.
- A handler cannot be activated by an assignment statement that assigns a value to SQLSTATE.

The following rules and recommendations apply to the SQLCODE and SQLSTATE SQL variables:

- A null value cannot be assigned to SQLSTATE or SQLCODE.
- The SQLSTATE and SQLCODE variable values should be saved immediately to temporary variables if there is any intention to use the values. If a handler exists for SQLSTATE, this assignment must be done as the first statement to be processed in the handler to avoid having the value replaced by the next SQL procedure statement. If the condition raised by the SQL statement is handled, the value is changed by the first SQL statement contained in the handler.

*Considerations for the SQLSTATE and SQLCODE SQL variables:* The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement, the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within the compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

## Examples

Create a procedure body with a compound statement that performs the following actions:

- Declares SQL variables, a condition for SQLSTATE '02000', a handler for the condition, and a cursor
- Opens the cursor, fetches a row, and closes the cursor

```
CREATE PROCEDURE PROC1(OUT NOROWS INT) LANGUAGE SQL
BEGIN
  DECLARE v_firstname VARCHAR(12);
  DECLARE v_midinit CHAR(1);
  DECLARE v_lastname VARCHAR(15);
  DECLARE v_edlevel SMALLINT;
  DECLARE v_salary DECIMAL(9,2);
  DECLARE at_end INT DEFAULT 0;
  DECLARE not_found
    CONDITION FOR '02000';
  DECLARE c1 CURSOR FOR
    SELECT FIRSTNAME, MIDINIT, LASTNAME,
      EDLEVEL, SALARY
    FROM EMP;
  DECLARE CONTINUE HANDLER FOR not_found SET NOROWS=1;
```

```
|           OPEN c1;
|           FETCH c1 INTO v_firstname,
|                           v_midinit,
|                           v_lastname, v_edlevel, v_salary;
|           END
```

```
|
```

## GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

See “GET DIAGNOSTICS” on page 1317.

When you need to specify a variable in a GET DIAGNOSTICS statement that is used within an SQL procedure, you would use either *SQL-variable-name* or *SQL-parameter-name*. In an embedded GET DIAGNOSTICS statement, you would use a *host-variable*. You can replace the instances of *host-variable* in the description of “GET DIAGNOSTICS” on page 1317 with *SQL-variable-name* or *SQL-parameter-name*.

## GOTO statement

The GOTO statement is used to branch to a user-defined label within an SQL procedure.

### Syntax

```
►►—GOTO—label—►►
```

### Description

#### *label*

Specifies a labeled statement at which processing is to continue.

The labeled statement and the GOTO statement must be in the same scope. The following rules apply to the scope:

- If the GOTO statement is defined in a compound statement, *label* must be defined inside the same compound statement.
- If the GOTO statement is defined in a handler, *label* must be defined in the same handler and follow the other scope rules.
- If the GOTO statement is defined outside of a handler, *label* must not be defined within a handler.

If *label* is not defined within a scope that the GOTO statement can reach, an error is returned.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

### Notes

Use the GOTO statement sparingly. Because the GOTO statement interferes with the normal sequence of processing, it makes an SQL procedure more difficult to read and maintain. Before using a GOTO statement, determine whether some other statement, such as an IF statement or LEAVE statement, can be used instead.

### Examples

Use a GOTO statement to transfer control to the end of a compound statement if the value of an SQL variable is less than 600.

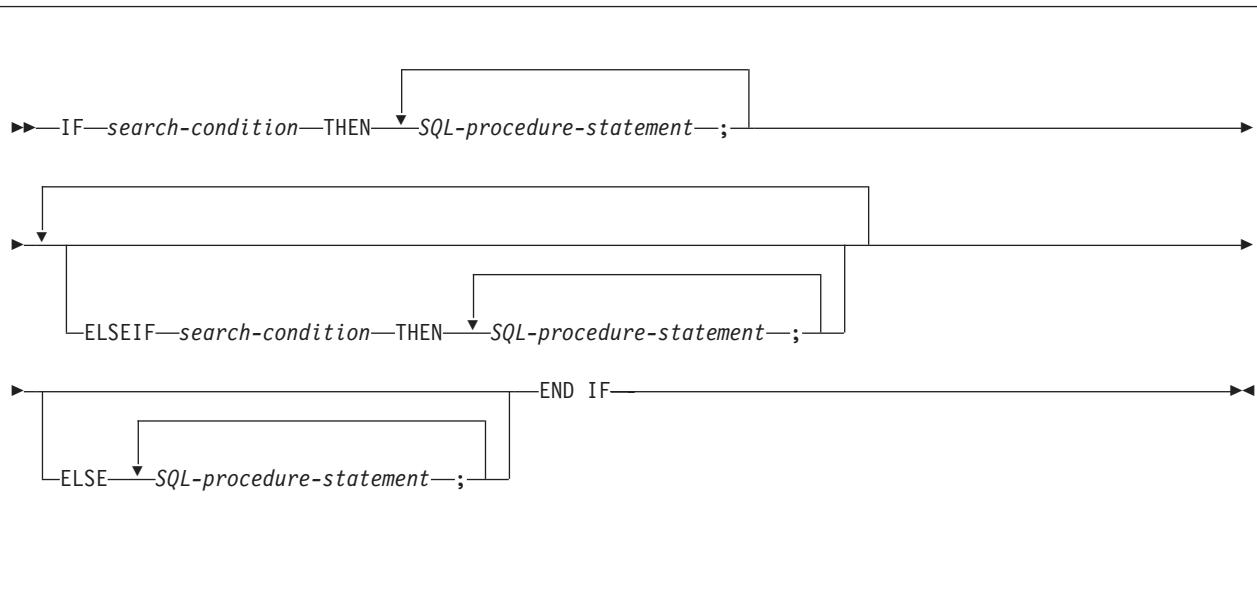

```
BEGIN
  DECLARE new_salary DECIMAL(9,2);
  DECLARE service DECIMAL(8,2);
  SELECT SALARY, CURRENT_DATE - HIREDATE
    INTO new_salary, service
   FROM EMP
  WHERE EMPNO = v_empno;
  IF service < 600
    THEN GOTO EXIT;
  END IF;
  IF rating = 1
    THEN SET new_salary =
      new_salary + (new_salary * .10);
  ELSEIF rating = 2
    THEN SET new_salary =
      new_salary + (new_salary * .05);
```

```
|           END IF;  
|           UPDATE EMP  
|           SET SALARY = new_salary  
|           WHERE EMPNO = v_empno;  
|           EXIT: SET return_parm = service;  
|           END
```

## IF statement

The IF statement selects an execution path based on the evaluation of a condition.

### Syntax

### Description

#### *search-condition*

Specifies the condition for which an SQL statement should be invoked. If the condition is unknown or false, processing continues to the next search condition until either a condition is true or processing reaches the ELSE clause.

#### *SQL-procedure-statement*

Specifies the statement to be invoked if the preceding *search-condition* is true. If no *search-condition* evaluates to true, then the *SQL-procedure-statement* following the ELSE keyword is invoked. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1612.

### Notes

*Considerations for the SQLSTATE and SQLCODE SQL variables:* When the first SQL-procedure-statement in the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement. If an IF statement does not include an ELSE clause and none of the search conditions evaluate to true, then when the statement that follows that IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement.

### Examples

Assign a value to the SQL variable *new\_salary* based on the value of SQL variable *rating*.

```
IF rating = 1  
  THEN SET new_salary =  
    new_salary + (new_salary * .10);  
ELSEIF rating = 2
```

```
|           THEN SET new_salary =
|             new_salary + (new_salary * .05);
|           ELSE SET new_salary =
|             new_salary + (new_salary * .02);
|           END IF
```

## ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

### Syntax

```
►►—ITERATE—label—►►
```

### Description

*label*

Specifies the label of the LOOP, REPEAT, or WHILE statement to which the flow of control is passed.

### Examples

This example uses a cursor to return information for a new department. If the not\_found condition handler is invoked, the flow of control passes out of the loop. If the value of *v\_dept* is 'D11', an ITERATE statement causes the flow of control to be passed back to the top of the LOOP statement. Otherwise, a new row is inserted into the table.

```
CREATE PROCEDURE ITERATOR ()
  LANGUAGE SQL
  MODIFIES SQL DATA
  BEGIN
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT deptno,deptname,admrdept
        FROM department
       ORDER BY deptno;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    OPEN c1;
    ins_loop:
    LOOP
      FETCH c1 INTO v_dept, v_deptname, v_admdept;
      IF at_end = 1 THEN
        LEAVE ins_loop;
      ELSEIF v_dept = 'D11' THEN
        ITERATE ins_loop;
      END IF;
      INSERT INTO department (deptno,deptname,admrdept)
        VALUES('NEW', v_deptname, v_admdept);
    END LOOP;
    CLOSE c1;
  END
```

## LEAVE statement

The LEAVE statement transfers program control out of a loop or a compound statement.

### Syntax

```
►►—LEAVE—label—►►
```

### Description

*label*

Specifies the label of the compound statement or loop to exit.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

### Notes

When a LEAVE statement transfers control out of a compound statement, all open cursors in the compound statement, except cursors that are used to return result sets, are closed.

### Examples

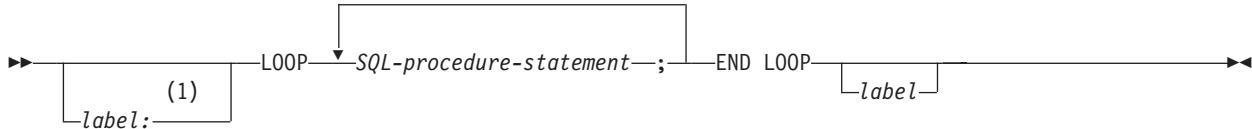

Use a LEAVE statement to transfer control out of a LOOP statement when a negative SQLCODE occurs.

```
ftch_loop: LOOP
  FETCH c1 INTO
    v_firstname, v_midinit,
    v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN LEAVE ftch_loop;
  END IF;
END LOOP
```

## LOOP statement

The LOOP statement executes a statement or group of statements multiple times.

### Syntax

#### Notes:

- 1 Only one *label*: can be specified for each *SQL-procedure-statement*.

### Description

#### *label*

Specifies the label for the LOOP statement. If the ending label is specified, the beginning label must be specified, and the two must match.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

#### *SQL-procedure-statement*

Specifies the statements to be executed in the loop. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1612.

### Examples

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter counter is incremented and the value of *v\_midinit* is checked to ensure that the value is not a single space (' '). If *v\_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

```
CREATE PROCEDURE LOOP_UNTIL_SPACE(OUT counter INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
      SELECT firstname, midinit, lastname
      FROM employee;
    DECLARE EXIT HANDLER FOR NOT FOUND
      SET counter = -1;
    OPEN c1;
    fetch_loop:
    LOOP
      FETCH c1 INTO v_firstname, v_midinit, v_lastname;
      IF v_midinit = ' ' THEN
        LEAVE fetch_loop;
      END IF;
      SET v_counter = v_counter + 1;
```

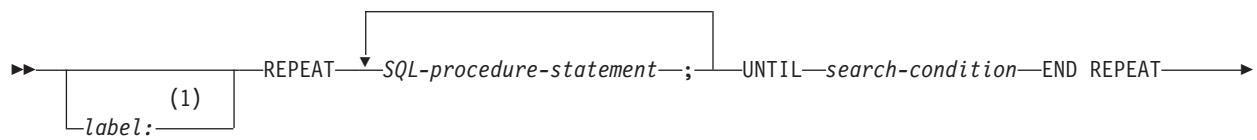

```
|           END LOOP fetch_loop;
|           SET counter = v_counter;
|           CLOSE c1;
|       END
```

```
|
```

## REPEAT statement

The REPEAT statement executes a statement or group of statements until a search condition is true.

### Syntax

#### Notes:

- 1 Only one *label*: can be specified for each *SQL-procedure-statement*.

### Description

#### *label*

Specifies the label for the REPEAT statement. If the ending label is specified, the beginning label must be specified, and the two must match.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

#### *SQL-procedure-statement*

Specifies the statements to be executed. The statement must be one of the statements listed under “SQL-procedure-statement” on page 1612.

#### *search-condition*

Specifies a condition that is evaluated after each execution of the REPEAT statement. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the REPEAT loop continues.

### Examples

Use a REPEAT statement to fetch rows from a table.

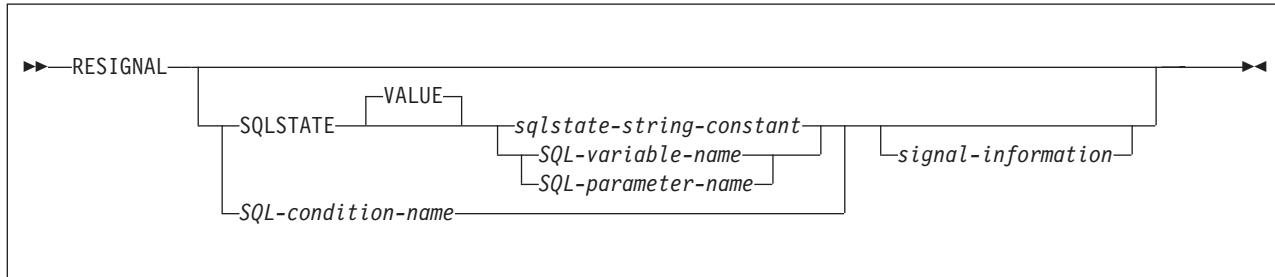

```
fetch_loop:  
REPEAT  
  FETCH c1 INTO  
    v_firstname, v_midinit, v_lastname;  
UNTIL  
  SQLCODE <> 0  
END REPEAT fetch_loop
```

## **RESIGNAL statement**

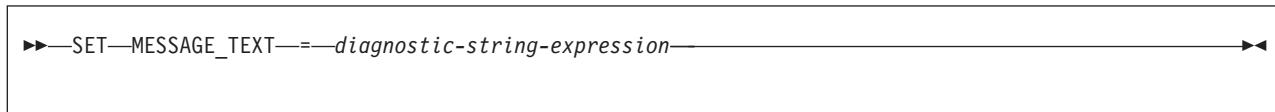

The RESIGNAL statement is used within a condition handler to re-raise the current condition, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned along with optional message text.

Issuing the RESIGNAL statement without an operand causes the current condition to be passed upwards.

## Syntax

### **signal-information:**

## Description

## SQLSTATE VALUE

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATE values:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
  - The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

*sqlstate-string-constant*

A character string constant with a length of five bytes that is a valid SQLSTATE value.

*SQL-variable-name* or *SQL-parameter-name*

Specifies an SQL variable or SQL parameter that is defined for the procedure.

*SQL-variable-name*

Specifies an SQL variable that is declared within the *compound-statement* that contains the RESIGNAL statement. *SQL-variable-name* must be defined as CHAR or VARCHAR data type with a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL parameter-name*

Specifies an SQL parameter that is defined for the procedure that contains the SQLSTATE value. The SQL parameter must be defined as

a CHAR or VARCHAR value and have a length of five bytes and must not be null. The SQL parameter must contain a valid SQLSTATE value.

*SQL-condition-name*

Specifies the name of the condition that will be returned. *condition-name* must be declared within the *compound-statement*.

**SET MESSAGE\_TEXT**

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

*diagnostic-string-expression*

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

## Notes

While any valid SQLSTATE value can be used in the RESIGNAL statement, programmers should define new SQLSTATE values based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the RESIGNAL statement is issued without an SQLSTATE clause or a *condition-name*, the RESIGNAL statement must be in a handler and the identical condition that activated the handler is returned. The SQLSTATE, SQLCODE, and the SQLCA associated with the condition are unchanged.

If an SQLSTATE clause or a *condition-name* was specified, the SQLCODE returned is based on the SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not-found message is returned, and the SQLCODE is set to +438.
- Otherwise, an exception is returned and the SQLCODE is set to -438.

The other fields of the SQLCA are set as follows:

- SQLERRDx fields are set to zero.
- SQLWARNx fields are set to blank.
- SQLERRMC is set to the first 70 bytes of MESSAGE\_TEXT.
- SQLERRML is set to the length of SQLERRMC.
- SQLERRP is set to ROUTINE.

When the SQLSTATE or condition indicates that an exception is returned (an SQLSTATE class other than '01' or '02'), the exception is not handled, and control is immediately returned to the end of the compound statement.

When the SQLSTATE or condition indicates that a warning (SQLSTATE class '02') is returned, the warning is not handled, and processing continues with the next statement.

When the SQLSTATE or condition indicates that a not-found condition (SQLSTATE class '02') is returned, the not-found condition is not handled, and processing continues with the next statement.

## Examples

The following example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE to the client application.

```
CREATE PROCEDURE divide ( IN numerator INTEGER,
                           IN denominator INTEGER,
                           OUT divide_result INTEGER)
LANGUAGE SQL
CONTAINS SQL
BEGIN
    DECLARE overflow CONDITION for SQLSTATE '22003' ;
    DECLARE CONTINUE HANDLER FOR overflow
        RESIGNAL SQLSTATE '22375';
    IF denominator = 0 THEN
        SIGNAL overflow;
    ELSE
        SET divide_result = numerator / denominator;
    END IF;
END
```

## RETURN statement

The RETURN statement is used to return from the routine. For SQL functions, it returns the result of the function. For an SQL procedure, it optionally returns an integer status value.

### Syntax

```
►►—RETURN—►►
```

### Description

#### *expression*

Specifies a value that is returned from the routine.

- If the routine is a function, *expression* must be specified and the value of *expression* must conform to the SQL assignment rules as described in "Assignment and comparison" on page 102. If the value is being assigned to a string variable, storage assignment rules apply.
- If the routine is a procedure, the data type of *expression* must be INTEGER. If *expression* evaluates to the null value, a value of 0 is returned.

The *expression* cannot include a column name or a host variable. See "Expressions" on page 180 for information on expressions. The *expression* cannot contain a scalar fullselect.

#### **NULL**

The null value is returned from the SQL function. NULL is not allowed in SQL procedures.

### Notes

**When a RETURN statement is not used within an SQL procedure or when no value is specified:** If a RETURN statement was not used to return from a procedure or if a value is not specified on the RETURN statement, one of the following values is set:

- If the procedure returns with an SQLCODE that is greater or equal to zero, the return status is set to a value of '0'.
- If the procedure returns with an SQLCODE that is less than zero, the return status is set to a value of '-1'.

**When a RETURN statement is used within an SQL procedure:** If a RETURN statement with a specified return value was used to return from a procedure, the SQLCODE, SQLSTATE, and message length in the SQLCA are initialized to zeros and the message text is set to blanks. An error is not returned to the caller.

**When the value is returned:** When a value is returned from a procedure, the caller may access the value using one of the following methods:

- The GET DIAGNOSTICS statement to retrieve the RETURN\_STATUS when the SQL procedure was called from another SQL procedure.
- The parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a CLI application.

- Directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqlerrd[0]. When the SQLCODE is less than zero, the sqlerrd[0] value is not set. The application should assume a return status value of '-1'.

## Examples

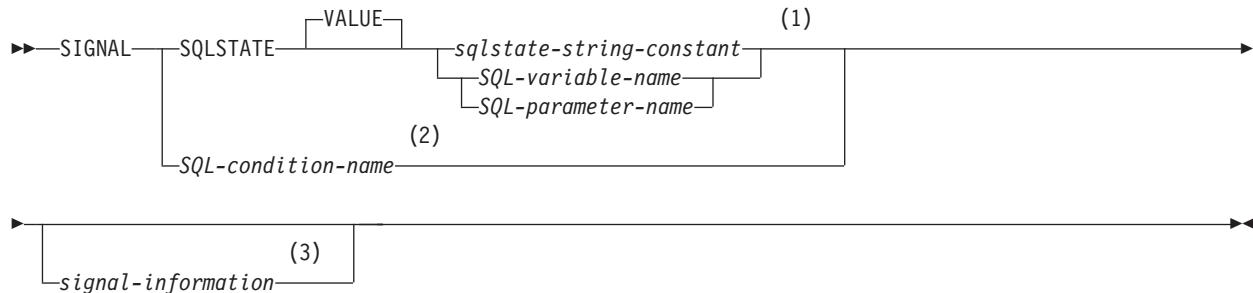

Use a RETURN statement to return from an SQL procedure with a status value of zero if successful or '-200' if not successful.

```
BEGIN
    . . .
    GOTO FAIL;
    . . .
SUCCESS: RETURN 0;
FAIL: RETURN -200;
END
```

## SIGNAL statement

The SIGNAL statement is used to return an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text.

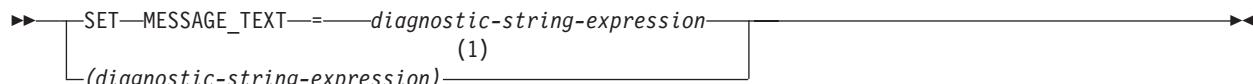

### Syntax

#### Notes:

- 1 The `SQLSTATE` variation must be used within a trigger body.
- 2 `SQL-condition-name` must not be specified within a trigger body.
- 3 `signal-information` must be specified within a trigger body

### signal-information:

#### Notes:

- 1 `(diagnostic-string-expression)` must only be specified within a trigger body.

## Description

### SQLSTATE VALUE

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

### sqlstate-string-constant

A character string constant with a length of five bytes that is a valid SQLSTATE value.

*SQL-variable-name* or *SQL-parameter-name*

Specifies an SQL variable or SQL parameter that contains a valid SQLSTATE value.

*SQL-variable-name*

Specifies an SQL variable that is declared within the *compound-statement*. *SQL-variable-name* must be defined as a CHAR or VARCHAR data type, have a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL-parameter-name*

Specifies an SQL parameter that is defined for the procedure and contains the SQLSTATE value. The SQL parameter must be defined as a CHAR or VARCHAR value, have a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

*SQL-condition-name*

Specifies the name of the condition that will be returned. *condition-name* must be declared within the *compound-statement*.

#### **SET MESSAGE\_TEXT**

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

*diagnostic-string-expression*

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

(*diagnostic-string-expression*)

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see "GET DIAGNOSTICS" on page 1317.

This syntax variation is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of DB2. To conform with the ANS and ISO standards, this form should not be used.

## **Notes**

While any valid SQLSTATE value can be used in the SIGNAL statement, programmers should define new SQLSTATES based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If a SIGNAL statement is issued, the SQLCODE that is returned is based on the SQLSTATE as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not-found message is returned, and the SQLCODE is set to +438.
- Otherwise, an exception is returned and the SQLCODE is set to -438.

The other fields of the SQLCA are set as follows:

- SQLERRDx fields are set to zero.
- SQLWARNx fields are set to blank.
- SQLERRMC is set to the first 70 bytes of MESSAGE\_TEXT.

- SQLERRML is set to the length of SQLERRMC.
- SQLERRP is set to ROUTINE.

When the SQLSTATE or condition indicates that an exception (an SQLSTATE class other than '01' or '02') is returned, one of the following actions occurs:

- If a handler exists for the specified SQLSTATE, condition, or SQLEXCEPTION, the exception is handled, and control is transferred to that handler.
- Otherwise, the exception is not handled, and control is immediately returned to the end of the compound statement.

When the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') is returned, one of the following actions occurs:

- If an active handler exists for the specified SQLSTATE, condition, or SQLWARNING, the warning is handled, and control is transferred to that handler.
- Otherwise, the warning is not handled, and processing continues with the next statement.

When the SQLSTATE or condition indicates that a not-found condition (SQLSTATE class '02') is returned, one of the following actions occurs:

- If an active handler exists for the specified SQLSTATE, condition, or not-found condition, the not-found condition is handled, and control is transferred to that handler.
- Otherwise, the not-found condition is not handled, and processing continues with the next statement.

When the SIGNAL statement is issued in a handler, no active handler exists.

**Using a *SIGNAL* statement in the body of a trigger:** Within the triggered action of a CREATE TRIGGER statement, the message text can be specified using only these variations:

```
SIGNAL SQLSTATE sqlstate-string-constant
      SET MESSAGE_TEXT = diagnostic-string-expression
SIGNAL SQLSTATE sqlstate-string-constant
      (diagnostic-string-expression)
```

## Examples

**Example 1:** The following example shows an SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```
CREATE PROCEDURE SUBMIT_ORDER
      (IN ONUM INTEGER, IN CNUM INTEGER,
       IN PNUM INTEGER, IN QNUM INTEGER)
LANGUAGE SQL
SPECIFIC SUBMIT_ORDER
MODIFIES SQL DATA
BEGIN
      DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
      SIGNAL SQLSTATE '75002'
      SET MESSAGE_TEXT = 'Customer number is not known';
      INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
      VALUES (ONUM, CNUM, PNUM, QNUM);
END
```

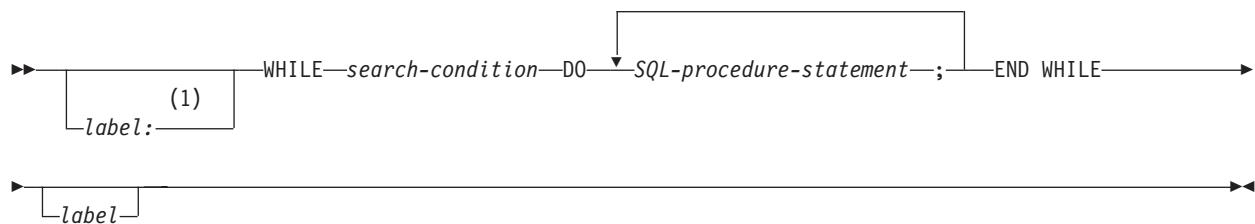

*Example 2:* The following example shows a trigger for an order system that allows orders to be recorded in an ORDERS table (ORDERNO, CUSTNO, PARTNO, QUANTITY) only if there is sufficient stock in the PARTS tables. When there is insufficient stock for an order, SQLSTATE '75001' is returned along with an appropriate error description.

```
CREATE TRIGGER CK_AVAIL
    NO CASCADE BEFORE INSERT ON ORDERS
    REFERENCING NEW AS NEW_ORDER
    FOR EACH ROW MODE DB2SQL
    WHEN (NEW_ORDER.QUANTITY > (SELECT ON_HAND FROM PARTS
                                    WHERE NEW_ORDER.PARTNO = PARTS.PARTNO))
        BEGIN ATOMIC
            SIGNAL SQLSTATE '75001' ('Insufficient stock for order');
        END
```

## WHILE statement

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

### Syntax

#### Notes:

- 1 Only one *label*: can be specified for each *SQL-procedure-statement*. If an ending label is specified for this beginning label, the labels must be the same.

### Description

#### *label*

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

#### *search-condition*

Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL procedure statement in the loop is executed.

#### *SQL-procedure-statement*

Specifies the statements to be executed in the loop. The statement must be one of the statements listed under "SQL-procedure-statement" on 1612.

### Examples

Use a WHILE statement to fetch rows from a table while SQL variable *at\_end*, which indicates whether the end of the table has been reached, is 0.

```
WHILE at_end = 0 DO
  FETCH c1 INTO
    v_firstname, v_midinit,
    v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN SET at_end=1;
  END IF;
END WHILE
```

---

## SQL communication area (SQLCA)

An SQLCA is a structure or collection of variables that is updated after each SQL statement executes. An application program that contains executable SQL statements must provide exactly one SQLCA, with a few exceptions.

There are three exceptions:

- A program that is precompiled with the STDSQL(YES) option must not provide an SQLCA
- In some cases a Fortran program must provide more than one SQLCA.
- A Java program where an SQLCA is not applicable.

In all host languages except REXX (and Java where the SQLCA is not applicable), the SQL INCLUDE statement can be used to provide the declaration of the SQLCA.

*In COBOL and assembler:* The name of the storage area must be SQLCA.

*In PL/I, and C:* The name of the structure must be SQLCA. Every executable SQL statement must be within the scope of its declaration.

Unless noted otherwise, C is used to represent C/370<sup>TM</sup> and C/C++ programming languages.

*In Fortran:* The name of the COMMON area for the INTEGER variables of the SQLCA must be SQLCA1; the name of the COMMON area for the CHARACTER variables must be SQLCA2. An SQLCA definition is required for every subprogram that contains SQL statements. One is also needed for the main program if it contains SQL statements.

*In REXX:* DB2 generates the SQLCA automatically. A REXX procedure cannot use the INCLUDE statement. The REXX SQLCA has a somewhat different format from SQLCAs for the other languages. See “The REXX SQLCA” on page 1654 for more information on the REXX SQLCA.

## Description of SQLCA fields

For the most part, COBOL, C, PL/I, and assembler use the same names for the SQLCA fields, and Fortran uses different names. However, there is one instance where C, PL/I, and assembler names differ from COBOL.

The names in the following table are those provided by the SQL INCLUDE statement.

*Table 140. Fields of SQLCA*

assembler, COBOL, or PL/I Name	C Name	Fortran Name	Data type	Purpose								
SQLCAID	sqlcaid	Not used.	CHAR(8)	An "eye catcher" for storage dumps, containing the text 'SQLCA'. The sixth byte is 'L' if line number information is returned from parsing a dynamic statement or a native SQL procedure. The sixth byte is not set when processing an external SQL procedure.								
SQLCABC	sqlcbc	Not used.	INTEGER	Contains the length of the SQLCA: 136.								
SQLCODE (See note 1)	SQLCODE	SQLCOD	INTEGER	Contains the SQL return code. (See note 2)								
				<table> <thead> <tr> <th>Code</th><th>Means</th></tr> </thead> <tbody> <tr> <td>0</td><td>Successful execution (though there might have been warning messages).</td></tr> <tr> <td>positive</td><td>Successful execution, but with a warning condition or other information.</td></tr> <tr> <td>negative</td><td>Error condition.</td></tr> </tbody> </table>	Code	Means	0	Successful execution (though there might have been warning messages).	positive	Successful execution, but with a warning condition or other information.	negative	Error condition.
Code	Means											
0	Successful execution (though there might have been warning messages).											
positive	Successful execution, but with a warning condition or other information.											
negative	Error condition.											
SQLERRML (See note 3)	sqlerrml (See note 3)	SQLTXL	SMALLINT	Length indicator for SQLERRMC, in the range 0 through 70. 0 means that the value of SQLERRMC is not pertinent.								
SQLERRMC (See note 3)	sqlerrmc (See note 3)	SQLTXT	VARCHAR(70)	Contains one or more tokens, separated by X'FF', that are substituted for variables in the descriptions of error conditions. It may contain truncated tokens. A message length of 70 bytes indicates a possible truncation.								
SQLERRP	sqlerrp	SQLERP	CHAR(8)	Provides a product signature and, in the case of an error, diagnostic information such as the name of the module that detected the error. In all cases, the first three characters are 'DSN' for DB2 for z/OS.								
SQLERRD(1)	sqlerrd[0]	SQLERR(1)	INTEGER	<p>For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100).</p> <p>On successful return from an SQL procedure, contains the return status value from the SQL procedure.</p> <p>SQLERRD(1) can also contain an internal error code.</p>								

*Table 140. Fields of SQLCA (continued)*

assembler, COBOL, or PL/I Name	C Name	Fortran Name	Data type	Purpose
SQLERRD(2)	sqlerrd[1]	SQLERR(2)	INTEGER	For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100).  SQLERRD(2) can also contain an internal error code.

Table 140. Fields of SQLCA (continued)

assembler, COBOL, or PL/I Name	C Name	Fortran Name	Data type	Purpose
SQLERRD(3)	sqlerrd[2]	SQLERR(3)	INTEGER	Contains the number of rows that qualified to be deleted, inserted, or updated after a DELETE, INSERT, UPDATE, or MERGE statement. The number excludes rows affected by either triggers or referential integrity constraints. For the OPEN of a cursor for a SELECT with a data change statement or for a SELECT INTO, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled.
				For a DELETE statement the value will be -1 if the operation is a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria. If the delete was against a view, neither the DELETE statement nor the definition of the view included selection criteria.
				For a TRUNCATE statement, the value will be -1.
				For a PREPARE statement, contains the estimated number of rows selected. If the number of rows is greater than 2 147 483 647, a value of 2 147 483 647 is returned.
				For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.
				For a rowset-oriented FETCH, contains the number of rows fetched.
				For SQLCODES -911 and -913, SQLERRD(3) contains the reason code for the timeout or deadlock.
				When an error is encountered in parsing a dynamic statement, or when parsing, binding, or executing a native SQL procedure, SQLERRD(3) will contain the line number where the error was encountered. The sixth byte of SQLCAID must be 'L' for this to be a valid line number. This value will be meaningful only if the statement source contains new line control characters. This information is not returned for an external SQL procedure.

Table 140. Fields of SQLCA (continued)

assembler, COBOL, or PL/I Name	C Name	Fortran Name	Data type	Purpose
SQLERRD(4)	sqlerrd[3]	SQLERR(4)	INTEGER	Generally, contains timerons, a short floating-point value that indicates a rough relative estimate of resources required (See note 4). It does not reflect an estimate of the time required. When preparing a dynamically defined SQL statement, you can use this field as an indicator of the relative cost of the prepared SQL statement. For a particular statement, this number can vary with changes to the statistics in the catalog. It is also subject to change between releases of DB2 for z/OS.
SQLERRD(5)	sqlerrd[4]	SQLERR(5)	INTEGER	Contains the position or column of a syntax error for a PREPARE or EXECUTE IMMEDIATE statement.
SQLERRD(6)	sqlerrd[5]	SQLERR(6)	INTEGER	Contains an internal error code.
SQLWARN0	SQLWARN0	SQLWRN(0)	CHAR(1)	Contains a blank if no other indicator is set to a warning condition (that is, no other indicator contains a W or Z). Contains a W if at least one other indicator contains a W or Z.
SQLWARN1	SQLWARN1	SQLWRN(1)	CHAR(1)	Contains a W if the value of a string column was truncated when assigned to a host variable. Contains an N for non-scrollable cursors and S for scrollable cursors after the OPEN CURSOR or ALLOCATE CURSOR statement. If subsystem parameter DISABSCL is set to YES, the field will not be set to N for non-scrollable cursors.
SQLWARN2	SQLWARN2	SQLWRN(2)	CHAR(1)	Contains a W if null values were eliminated from the argument of an aggregate function; not necessarily set to W for the MIN function because its results are not dependent on the elimination of null values.
SQLWARN3	SQLWARN3	SQLWRN(3)	CHAR(1)	Contains a W if the number of result columns is larger than the number of host variables. Contains a Z if fewer locators were provided in the ASSOCIATE LOCATORS statement than the stored procedure returned.
SQLWARN4	SQLWARN4	SQLWRN(4)	CHAR(1)	Contains a W if a prepared UPDATE or DELETE statement does not include a WHERE clause. For a scrollable cursor, contains a D for sensitive dynamic cursors, I for insensitive cursors, and S for sensitive static cursors after the OPEN CURSOR or ALLOCATE CURSOR statement; blank if cursor is not scrollable. If subsystem parameter DISABSCL is set to YES, the field will not be set to N for non-scrollable cursors.

Table 140. Fields of SQLCA (continued)

assembler, COBOL, or PL/I Name	C Name	Fortran Name	Data type	Purpose
SQLWARN5	SQLWARN5	SQLWRN(5)	CHAR(1)	Contains a W if the SQL statement was not executed because it is not a valid SQL statement in DB2 for z/OS. Contains a character value of 1 (read only), 2 (read and delete), or 4 (read, delete, and update) to reflect capability of the cursor after the OPEN CURSOR or ALLOCATE CURSOR statement. If subsystem parameter DISABSCL is set to YES, the field will not be set to N for non-scrollable cursors.
SQLWARN6	SQLWARN6	SQLWRN(6)	CHAR(1)	Contains a W if the addition of a month or year duration to a DATE or TIMESTAMP value results in an invalid day (for example, June 31). Indicates that the value of the day was changed to the last day of the month to make the result valid.
SQLWARN7	SQLWARN7	SQLWRN(7)	CHAR(1)	Contains a W if one or more nonzero digits were eliminated from the fractional part of a number used as the operand of a decimal multiply or divide operation.
SQLWARN8	SQLWARN8	SQLWRX(1)	CHAR(1)	Contains a W if a character that could not be converted was replaced with a substitute character. Contains a Y if there was an unsuccessful attempt to establish a trusted connection.
SQLWARN9	SQLWARN9	SQLWRX(2)	CHAR(1)	Contains a W if arithmetic exceptions were ignored during COUNT or COUNT_BIG processing. Contains a Z if the stored procedure returned multiple result sets.
SQLWARNA	SQLWARNA	SQLWRX(3)	CHAR(1)	Contains a W if at least one character field of the SQLCA or the SQLDA names or labels is invalid due to a character conversion error.
SQLSTATE	sqlstate	SQLSTT	CHAR(5)	Contains a return code for the outcome of the most recent execution of an SQL statement (See note 5).

**Notes:**

- With the precompiler option STDSQL(YES) in effect, SQLCODE is replaced by SQLCADE in SQLCA.
- For the specific meanings of SQL return codes, see *DB2 Codes*.
- In COBOL, SQLERRM includes SQLERRML and SQLERRMC. In PL/I and C, the varying-length string SQLERRM is equivalent to SQLERRML prefixed to SQLERRMC. In assembler, the storage area SQLERRM is equivalent to SQLERRML and SQLERRMC. See the examples for the various host languages in “The included SQLCA” on page 1652.
- The use of timerons may require special handling because they are floating-point values in an INTEGER array. In PL/I, for example, you could first copy the value into a BIN FIXED(31) based variable that coincides with a BIN FLOAT(24) variable.
- For a description of SQLSTATE values, see *DB2 Codes*.

## The included SQLCA

The description of the SQLCA that is given by INCLUDE SQLCA is shown for each of the host languages.

### Assembler:

```

## The REXX SQLCA

The REXX SQLCA consists of a set of variables, rather than a structure. DB2 makes the SQLCA available to your application automatically.

The following table lists the variables in a REXX SQLCA.

Table 141. Variables in a REXX SQLCA

Variable	Contents
SQLCODE	Contains the SQL return code.
SQLERRMC	Contains one or more tokens, separated by X'FF', that are substituted for variables in the descriptions of error conditions. It might contain truncated tokens. A message length of 70 bytes indicates a possible truncation.
SQLERRP	Provides a product signature and, in the case of an error, diagnostic information such as the name of the module that detected the error. For DB2 for z/OS, the product signature is 'DSN'.
SQLERRD.1	For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100).  SQLERRD(1) can also contain an internal error code.
SQLERRD.2	For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100).  SQLERRD(2) can also contain an internal error code.
SQLERRD.3	Contains the number of rows that qualified for the operation after an SQL data change statement (but not rows deleted as a result of CASCADE delete). For the OPEN of a cursor for a SELECT with an SQL data change statement or for a SELECT INTO, SQLERRD(3) contains the number of rows affected by the embedded data change statement. Set to 0 if the SQL statement fails, indicating that all changes made in executing the statement were canceled. Set to -1 for a mass delete from a table in a segmented table space, for a truncate operation, or a delete from a view when neither the DELETE statement nor the definition of the view included selection criteria.  For rowset-oriented FETCH statements, contains the number of rows returned in the rowset.  For SQLCODES -911 and -913, SQLERRD(3) contains the reason code for the timeout or deadlock.  After successful execution of the REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.  When an error is encountered in parsing a dynamic statement, or when parsing, binding, or executing a native SQL procedure, SQLERRD(3) will contain the line number where the error was encountered. The sixth byte of SQLCAID must be 'L' for this to be a valid line number. This value will be meaningful only if the statement source contains new line control characters. This information is not returned for an external SQL procedure.
SQLERRD.4	Generally, contains timerons, a short floating-point value that indicates a rough relative estimate of resources required. This value does not reflect an estimate of the time required to execute the SQL statement. After you prepare an SQL statement, you can use this field as an indicator of the relative cost of the prepared SQL statement. For a particular statement, this number can vary with changes to the statistics in the catalog. This value is subject to change between releases of DB2 for z/OS.
SQLERRD.5	Contains the position or column of a syntax error for a PREPARE or EXECUTE IMMEDIATE statement.
SQLERRD.6	Contains an internal error code.

*Table 141. Variables in a REXX SQLCA (continued)*

Variable	Contents
SQLWARN.0	Contains a blank if no other indicator is set to a warning condition (that is, no other indicator contains a W or Z). Contains a W if at least one other indicator contains a W or Z.
SQLWARN.1	Contains a W if the value of a string column was truncated when assigned to a host variable. Contains an N for non-scrollable cursors and S for scrollable cursors after the OPEN CURSOR or ALLOCATE CURSOR statement.
SQLWARN.2	Contains a W if null values were eliminated from the argument of an aggregate function; not necessarily set to W for the MIN function because its results are not dependent on the elimination of null values.
SQLWARN.3	Contains a W if the number of result columns is larger than the number of host variables. Contains Z if the ASSOCIATE LOCATORS statement contains fewer locators than the stored procedure returned.
SQLWARN.4	Contains a W if a prepared UPDATE or DELETE statement does not include a WHERE clause. For a scrollable cursor, contains a D for sensitive dynamic cursors, I for insensitive cursors, and S for sensitive static cursors after the OPEN CURSOR or ALLOCATE CURSOR statement; otherwise, blank if cursor is not scrollable.
SQLWARN.5	Contains a W if the SQL statement was not executed because it is not a valid SQL statement in DB2 for z/OS. Contains a character value of 1 (read only), 2 (read and delete), or 4 (read, delete, and update) to reflect capability of the cursor after the OPEN CURSOR or ALLOCATE CURSOR statement.
SQLWARN.6	Contains a W if the addition of a month or year duration to a DATE or TIMESTAMP value results in an invalid day (for example, June 31). Indicates that the value of the day was changed to the last day of the month to make the result valid.
SQLWARN.7	Contains a W if one or more nonzero digits were eliminated from the fractional part of a number that was used as the operand of a decimal multiply or divide operation.
SQLWARN.8	Contains a W if a character that could not be converted was replaced with a substitute character.
SQLWARN.9	Contains a W if arithmetic exceptions were ignored during COUNT or COUNT_BIG processing. Contains a Z if the stored procedure returned multiple result sets.
SQLWARN.10	Contains a W if at least one character field of the SQLCA is invalid due to a character conversion error.
SQLSTATE	Contains a return code for the outcome of the most recent execution of an SQL statement.

---

## SQL descriptor area (SQLDA)

An SQLDA is a collection of variables that is required for execution of the SQL DESCRIBE statement, and can be optionally used by the PREPARE, OPEN, FETCH, EXECUTE, and CALL statements. An SQLDA can be used in a DESCRIBE or PREPARE INTO statement, modified with the addresses of host variables, and then reused in a FETCH statement.

The meaning of the information in an SQLDA depends on the context in which it is used. For DESCRIBE and PREPARE INTO, DB2 sets the fields in the SQLDA to provide information to the application program. For OPEN, EXECUTE, FETCH, and CALL, the application program sets the fields in the SQLDA to provide DB2 with information:

### **DESCRIBE *statement-name* or PREPARE INTO**

With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about a prepared statement. Each SQLVAR occurrence describes a column of the result table.

### **DESCRIBE TABLE**

With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the columns of a table or view. Each SQLVAR occurrence describes a column of the specified table or view.

### **DESCRIBE CURSOR**

With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the result set that is associated with the specified cursor. Each SQLVAR occurrence describes a column of the result set.

### **DESCRIBE INPUT**

With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the input parameter markers of a prepared statement. Each SQLVAR occurrence describes an input parameter marker.

### **DESCRIBE PROCEDURE**

With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the result sets returned by the specified stored procedure. Each SQLVAR occurrence describes a returned result set.

### **OPEN, EXECUTE, FETCH, and CALL**

The application program sets fields of the SQLDA to provide information about host variables or output buffers in the application program to DB2. Each SQLVAR occurrence describes a host variable or output buffer.

- For OPEN and EXECUTE, each SQLVAR occurrence describes an input value that is substituted for a parameter marker in the associated SQL statement that was previously prepared.
- For FETCH, each SQLVAR occurrence describes a host variable or buffer in the application program that is to be used to contain an output value from a row of the result.
- For CALL, each SQLVAR occurrence describes a host variable that corresponds to a parameter in the parameter list for the stored procedure.

For information on the way to use the SQLDA, see *DB2 Application Programming and SQL Guide*.

## Description of SQLDA fields

An SQLDA consists of four variables, a header, and an arbitrary number of occurrences of a sequence of variables collectively named SQLVAR.

In DESCRIBE and PREPARE INTO, each occurrence of the SQLVAR describes the column of a table. In FETCH, OPEN, EXECUTE, and CALL, each occurrence describes a host variable.

### The SQLDA Header

The fields in the SQLDA header have different usage depending on whether the SQLDA is being used in a DESCRIBE or PREPARE INTO statement or the SQLDA is being used in a FETCH, INSERT, OPEN, EXECUTE, or CALL statement.

The following table describes the fields in the SQLDA header.

Table 142. Fields of the SQLDA header

C name assembler, COBOL or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH,INSERT, OPEN, EXECUTE, and CALL
sqldaid SQLDAID	CHAR(8)	<p>An "eye catcher" for storage dumps, containing the text 'SQLDA'.</p> <p>The 7th byte of the field is a flag that can be used to determine if more than one SQLVAR entry is needed for each column. For details, see "Determining how many SQLVAR occurrences are needed" on page 1661.</p> <p>For DESCRIBE CURSOR, the field is set to 'SQLRS'. If the cursor is declared WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set to 1.</p> <p>For DESCRIBE PROCEDURE, it is set to 'SQLPR'.</p>	<p>A plus sign (+) in the 6th byte indicates that SQLNAME contains an overriding CCSID.</p> <p>A '2' in the 7th byte indicates the two SQLVAR entries were allocated for each column or parameter.</p> <p>A '3' in the 7th byte indicates that three SQLVAR entries were allocated for each column or parameter.</p> <p>Although three entries are never needed on input to DB2, an SQLDA with three entries might be used when the SQLDA was initialized by a DESCRIBE or PREPARE INTO with a USING BOTH clause.</p> <p>Otherwise, SQLDAID is not used.</p>
sqldabc SQLDABC	INTEGER	Length of the SQLDA, equal to SQLNx * 44+16.	Length of the SQLDA, greater than or equal to SQLNx * 44+16.

Table 142. Fields of the SQLDA header (continued)

C name assembler, COBOL or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH,INSERT, OPEN, EXECUTE, and CALL
sqln SQLN	SMALLINT	<p>Unchanged by DB2. The field must be set to a value greater than or equal to zero before the statement is executed. The field indicates the total number of occurrences of SQLVAR. At the very least, the number should be:</p> <ul style="list-style-type: none"> <li>• For DESCRIBE INPUT, the number of parameter markers to be described.</li> <li>• For other DESCRIBE or PREPARE INTO: the number of columns of the result, or a multiple of the columns of the result when there are multiple sets of SQLVAR entries because column labels are returned in addition to column names.</li> </ul>	Total number of occurrences of SQLVAR provided in the SQLDA. SQLN must be set to a value greater than or equal to zero.
sqld SQLD	SMALLINT	<p>The number of columns described by occurrences of SQLVAR. Double that number if USING BOTH appears in the DESCRIBE or PREPARE INTO statement. Contains a 0 if the statement string is not a query.</p> <p>For DESCRIBE PROCEDURE, the number of result sets returned by the stored procedure. Contains a 0 if no result sets are returned.</p>	The number of host variables described by occurrences of SQLVAR.

**Note:**

1. The third column of this table represents several forms of the DESCRIBE statement:
  - For DESCRIBE *output* and PREPARE INTO, the column pertains to columns of the result table.
  - For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
  - For DESCRIBE INPUT, the column pertains to parameter markers.
  - For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

## SQLVAR entries

For each column or host variable described by the SQLDA, there are both base SQLVAR entries and extended SQLVAR entries.

### Base SQLVAR entry

The base SQLVAR entry is always present. The fields of this entry contain the base information about the column or host variable such as data type code, length attribute (except for LOBs), column name (or label), host variable address, and indicator variable address.

### Extended SQLVAR entry

The extended SQLVAR entry is needed (for each column) if the result

includes any LOB or distinct type<sup>37</sup> columns. For distinct types, the extended SQLVAR contains the distinct type name. For LOBs, the extended SQLVAR contains the length attribute of the host variable and a pointer to the buffer that contains the actual length. If locators are used to represent LOBs, an extended SQLVAR is not necessary.

The extended SQLVAR entry is also needed for each column when the USING BOTH clause was specified, which indicates that both column names and labels are returned. (**DESCRIBE output** is the only statement with the **USING BOTH** clause).

The fields in the extended SQLVAR that return LOB and distinct type information do not overlap, and the fields that return LOB and label information do not overlap. Depending on the combination of labels, LOBs and distinct types, more than one extended SQLVAR entry per column may be required to return the information. See “Determining how many SQLVAR occurrences are needed” on page 1661.

The following table shows how to map the base and extended SQLVAR entries. For an SQLDA that contains both base and extended SQLVAR entries, the base SQLVAR entries are in the first block, followed by a block of extended SQLVAR entries, which if necessary, are followed by a second block of extended SQLVAR entries. In each block, the number of occurrences of the SQLVAR entry is equal to the value in SQLD<sup>38</sup> even though many of the extended SQLVAR entries might be unused.

*Table 143. Contents of SQLVAR arrays*

Set of SQLVAR entries							
LOBs	Distinct types <sup>1</sup>	7th byte of SQLDAID	SQLD	Minimum for SQLN <sup>2</sup>	First set (Base)	Second set (Extended)	Third set (Extended)
<b>USING BOTH clause not specified:</b>							
No	No	Space	$n$	$n$	Column names, labels	Not Used	Not Used
Yes <sup>3</sup>	Yes <sup>3</sup>	2	$n$	$2n$	Column names, labels	LOBs, distinct types, or both	Not used
<b>USING BOTH clause was specified:</b>							
No	No	Space	$2n$	$2n$	Column names	Labels	Not used
Yes	No	2	$n$	$2n$	Column names	LOBs and labels	Not used
No	Yes	3	$n$	$3n$	Column names	Distinct types	Labels
Yes	Yes	3	$n$	$3n$	Column names	LOBs and distinct types	Labels

37. DESCRIBE INPUT does not return information about distinct types.

38. When an extended SQLVAR entry is present for each column for *labels* (and there are no LOB or distinct type columns in the result),

Table 143. Contents of SQLVAR arrays (continued)

LOBs	Distinct types <sup>1</sup>	7th byte of SQLDAID	SQLD	Minimum for SQLN <sup>2</sup>	Set of SQLVAR entries		
					First set (Base)	Second set (Extended)	Third set (Extended)
<b>Notes:</b>							
1.	DESCRIBE INPUT does not return information about distinct types.						
2.	The number of columns or host variables that the SQLDA describes.						
3.	Either LOBs, distinct types, or both are present.						
4.	Here, the 7th byte is set to a space and SQLD is set to two times the number of columns in the result. For all other values of the 7th byte for USING BOTH, SQLD is set to the number of columns in the result, and the 7th byte can be used to determine how many SQLVAR entries are needed for each column of the result.						

#### Determining how many SQLVAR occurrences are needed:

The number of SQLVAR occurrences needed depends on the statement that the SQLDA was provided for and the data types of the columns or parameters being described.

If the USING BOTH clause was not specified for the statement and neither LOBs nor distinct types are present in the result, only one SQLVAR entry (a base entry) is needed for each column. The 7th byte of SQLDAID is set to a space. The SQLD is set to the number of columns in the result and represents the number of SQLVAR occurrences needed. If an insufficient number of SQLVAR occurrences were provided, DB2 returns a +236 warning in SQLCODE if the standards option was set. Otherwise, SQLCODE is zero.

If USING BOTH is specified and neither LOBs nor distinct types are present in the result, an extended SQLVAR entry per column is needed for the labels in addition to the base SQLVAR entry. The 7th byte of the SQLDAID is set to space. SQLD is set to the twice the number of columns in the result and represents the combined number of base and extended SQLVAR occurrences needed.

If LOBs, distinct types, or both are present in the results, one extended SQLVAR entry is needed per column in addition to the base SQLVAR entry with one exception. The exception is that when the USING BOTH clause is specified and distinct types are present in the results, two extended SQLVAR entries per column are needed. When a sufficient number of SQLVAR entries are provided in the SQLDA for both the base and extended SQLVARs, information for the LOBs and distinct types is returned. The 7th byte of SQLDAID is set to the number of SQLVAR entries that were used for each column:

- 2 Two SQLVAR entries per column (a base and an extended)
- 3 Three SQLVAR entries per column (a base and two extended)

SQLD is set to the number of columns in the result. Therefore, the value of the 7th byte of SQLDAID multiplied by the value of SQLD is the total number SQLVAR entries that were provided.

Otherwise, when an insufficient number of SQLVAR entries have been provided when LOBs or distinct types are present, DB2 indicates that by returning one of the following warnings in SQLCODE. DB2 also sets the 7th byte of SQLDAID to indicate how many SQLVAR entries are needed for each column of the result.

- +237 There are insufficient SQLVAR entries to describe the data, and the data

includes distinct types. In this case, there were enough base SQLVAR entries to describe the data, so the base SQLVAR entries are set. However, sufficient extended SQLVAR entries were not provided so the distinct type names are not returned.

- +238 There are insufficient SQLVAR entries to describe the data, and the data includes LOBs. In this case no information is returned in the SQLVAR entries.
- +239 There are insufficient SQLVAR entries to describe the data, and the data includes distinct types. There weren't even enough base SQLVAR entries. In this case no information is returned in the SQLVAR entries.

#### Field descriptions of an occurrence of a base SQLVAR:

The fields of a base SQLVAR have different uses depending on the SQL statement.

The following table describes the contents of the fields of a base SQLVAR.

*Table 144. Fields in an occurrence of a base SQLVAR*

C name assembler COBOL, or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
sqltype SQLTYPE	SMALLINT	<p>Indicates the data type of the column or parameter and whether it can contain null values. For a description of the type codes, see Table 146 on page 1666.</p> <p>For a distinct type, the data type on which the distinct type was based is placed in this field. The base SQLVAR provides no indication that this is part of the description of a distinct type.</p>	<p>Indicates the data type of the host variable and whether an indicator variable is provided. Host variables for datetime values must be character string variables. For FETCH, a datetime type code means a fixed-length character string. For a description of the type codes, see "SQLTYPE and SQLLEN" on page 1666.</p>
sqllen SQLLEN	SMALLINT	<p>The length attribute of the column or parameter. For datetime data, the length of the string representation of the value. See "SQLTYPE and SQLLEN" on page 1666 for a description of allowable values.</p> <p>For LOBs, the value is 0 regardless of the length attribute of the LOB. For XML, the value is 0. Field SQLLONGLEN in the extended SQLVAR contains the length attribute.</p>	<p>The length attribute of the host variable. See "SQLTYPE and SQLLEN" on page 1666 for a description of allowable values.</p> <p>For LOBs, the value is 0 regardless of the length attribute of the LOB. Field SQLLONGLEN in the extended SQLVAR contains the length attribute.</p> <p>For XML AS BLOB, CLOB, or DBCLOB, sqllen is 0 as for LOB types.</p>

Table 144. Fields in an occurrence of a base SQLVAR (continued)

C name assembler COBOL, or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
sqldata SQLDATA	pointer	<p>For string columns or parameters, SQLDATA contains X'0000zzzz', where zzzz is the associated CCSID.</p> <p>For character strings, SQLDATA can alternatively contain X'FFFF', which indicates bit data. Not used for other types of data.</p> <p>For datetime columns, SQLDATA can contain the CCSID of the string representation of the datetime value.</p> <p>For DESCRIBE PROCEDURE, the result set locator value associated with the result set.</p>	Contains the address of the host variable.
sqlind SQLIND	pointer	<p>Reserved</p> <p>For DESCRIBE PROCEDURE, it is set to -1.</p>	Contains the address of an associated indicator variable, if SQLTYPE is odd. Otherwise, the field is not used.
sqlname SQLNAME	VARCHAR(30)	<p>Contains the unqualified name or label of the column, or a string of length zero if the name or label does not exist. If the name is longer than 30 bytes, it is truncated at a byte boundary. For more information about column names, see Names of result columns.</p> <p>For DESCRIBE PROCEDURE, SQLNAME contains the cursor name used by the stored procedure to return the result set. The values for SQLNAME appear in the order the cursors were opened by the stored procedure.</p> <p>For DESCRIBE INPUT, SQLNAME is not used.</p>	<p>Can contain CCSID and/or host-variable-array dimension information. DB2 interprets the third and fourth byte of the data portion of SQLNAME as the CCSID of the host variable if all of the following are true and the third and fourth byte are not X'0000':</p> <ul style="list-style-type: none"> <li>• The 6th byte of SQLDAID is '+' (x'4E')</li> <li>• SQLTYPE indicates the host variable is a string variable</li> <li>• The length of SQLNAME is 8</li> <li>• The first two bytes of the data portion of SQLNAME are X'0000'.</li> </ul> <p>If the third and fourth byte of the data portion of SQLNAME are X'0000', DB2 uses the appropriate default CCSID.</p> <p>For FETCH, OPEN, INSERT, and EXECUTE, if the length of SQLNAME is 8, and the first two bytes of the data portion of SQLNAME are X'0000', DB2 interprets the fifth through eighth bytes of the data portion of the SQLNAME field as follows:</p>

Table 144. Fields in an occurrence of a base SQLVAR (continued)

C name assembler COBOL, or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
(cont.) sqlname SQLNAME			<ul style="list-style-type: none"> <li>• <b>fifth and sixth bytes:</b> a flag field that indicates the type of host variable that is being described by the current SQLDA entry. The values of this field are as follows:           <ul style="list-style-type: none"> <li>– X'0000' - host variable</li> <li>– X'0100' - XML host variable (XML AS BLOB, XML AS CLOB, XML AS DBCLOB)</li> <li>– X'0001' - host variable array</li> <li>– X'0101' - XML host variable array</li> <li>– X'0002' - special host variable that represents the value for 'n' in a multiple-row INSERT statement.</li> </ul> </li> <li>• <b>seventh and eighth bytes:</b> if the sixth byte is X'01', a binary small integer (halfword) that represents the dimension of the host-variable-array, and the corresponding indicator-array if one is specified.</li> </ul>

**Notes:**

1. The third column of this table represents several forms of the DESCRIBE statement.
  - For DESCRIBE *output* and PREPARE INTO, the column pertains to columns of the result table.
  - For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
  - For DESCRIBE INPUT, the column pertains to parameter markers.
  - For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

#### Field descriptions of an occurrence of an extended SQLVAR:

The fields of an extended SQLVAR have different uses depending on the SQL statement.

The following table describes the contents of the fields of an extended SQLVAR entry.

Table 145. Fields in an occurrence of an extended SQLVAR

C name assembler, COBOL, or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
len.sqllonglen SQLLONGL SQLLONGLEN	INTEGER	The length attribute of a LOB (BLOB, CLOB, or DBCLOB) column.	The length attribute of a LOB (BLOB, CLOB, or DBCLOB) host variable. DB2 ignores the SQLLEN field in the base SQLVAR for these data types. The length attribute indicates the number of bytes for a BLOB or CLOB, and the number of characters for a DBCLOB.
*	INTEGER	Reserved.	Reserved.
sqldatalen SQLDATA SQLDATALEN	pointer	Not used.	Used only for LOB (BLOB, CLOB, and DBCLOB) host variables.
			If the value of the field is null, the actual length of the LOB is stored in the 4 bytes immediately before the start of the data, and SQLDATA points to the first byte of the field length. The actual length indicates the number of bytes for a BLOB or CLOB, and the number of characters for a DBCLOB.
			If the value of the field is not null, the field contains a pointer to a 4-byte long buffer that contains the actual length <i>in bytes</i> (even for DBCLOBS) of the data in the buffer pointed to from the SQLDATA field in the matching base SQLVAR.
			Regardless of whether this field is used, field SQLLONGLEN must be set.

Table 145. Fields in an occurrence of an extended SQLVAR (continued)

C name assembler, COBOL, or PL/I name	Data type	Usage in DESCRIBE <sup>1</sup> and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
sqldatatype_name SQLNAME SQLDATATYPE- NAME	VARCHAR(30)	<p>A SQLNAME field of the extended SQLVAR is set to one of the following:</p> <ul style="list-style-type: none"> <li>• For a distinct type column, the database manager sets this field to the fully qualified distinct type name. If the qualified name is longer than 30 bytes, it is truncated.</li> <li>• For a label, the database manager sets this field to label.</li> </ul> <p>In the case that both a distinct type name and a label need to be returned in extended SQLVAR entries (USING BOTH has been specified), the distinct type name is returned in the first extended SQLVAR entry and the label in the second extended SQLVAR entry.</p>	Not used.

**Note:**

1. The third column of this table represents several forms of the DESCRIBE statement.
  - For DESCRIBE *output* and PREPARE INTO, the column pertains to columns of the result table.
  - For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
  - For DESCRIBE INPUT, the column pertains to parameter markers.
  - For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

#### SQLTYPE and SQLLEN:

The contents of the SQLTYPE and SQLLEN fields of the SQLDA depends on the SQL statement that is returning the value.

The following table shows the values that can appear in the SQLTYPE and SQLLEN fields of the SQLDA. In DESCRIBE and PREPARE INTO, an even value of SQLTYPE means the column does not allow nulls, and an odd value means the column does allow nulls. In DESCRIBE INPUT statements, only odd values are returned for SQLTYPE. In FETCH, OPEN, EXECUTE, and CALL, an even value of SQLTYPE means no indicator variable is provided, and an odd value means that SQLIND contains the address of an indicator variable.

Table 146. SQLTYPE and SQLLEN values for DESCRIBE, PREPARE INTO, FETCH, OPEN, EXECUTE, and CALL

SQLTYPE	For DESCRIBE and PREPARE INTO		For FETCH, OPEN, EXECUTE, and CALL	
	Column or parameter data type	SQLLEN	Host variable data type	SQLLEN
384/385	date	10 <sup>1</sup>	fixed-length character string representation of a date	length attribute of the host variable

Table 146. SQLTYPE and SQLLEN values for DESCRIBE, PREPARE INTO, FETCH, OPEN, EXECUTE, and CALL (continued)

SQLTYPE	For DESCRIBE and PREPARE INTO		For FETCH, OPEN, EXECUTE, and CALL	
	Column or parameter data type	SQLLEN	Host variable data type	SQLLEN
388/389	time	8 <sup>2</sup>	fixed-length character string representation of a time	length attribute of the host variable
392/393	timestamp	26	fixed-length character string representation of a timestamp	length attribute of the host variable
400/401	N/A	N/A	NUL-terminated graphic string	length attribute of the host variable
404/405	BLOB	0 <sup>3</sup>	BLOB or XML AS BLOB	Not used. <sup>3</sup>
408/409	CLOB	0 <sup>3</sup>	CLOB or XML AS CLOB	Not used. <sup>3</sup>
412/413	DBCLOB	0 <sup>3</sup>	DBCLOB or XML AS DBCLOB	Not used. <sup>3</sup>
448/449	varying-length character string	length attribute of the column	varying-length character string	length attribute of the host variable
452/453	fixed-length character string	length attribute of the column	fixed-length character string	length attribute of the host variable
456/457	long varying-length character string	length attribute of the column	long varying-length character string	length attribute of the host variable
SQLTYPE values   448/449 are returned   instead of 456/457 for   statements that are   bound in Version 9 or   later.				
460/461	N/A	N/A	NUL-terminated character string	length attribute of the host variable
464/465	varying-length graphic string	length attribute of the column	varying-length graphic string	length attribute of the host variable
468/469	fixed-length graphic string	length attribute of the column	fixed-length graphic string	length attribute of the host variable
472/473	long graphic string	length attribute of the column	long graphic string	length attribute of the host variable
SQLTYPE values   464/465 are returned   instead of 472/473 for   statements that are   bound in Version 9 or   later.				
480/481	floating point	4 for single precision, 8 for double precision	floating point	4 for single precision, 8 for double precision
484/485	packed decimal		packed decimal	
492/493	big integer <sup>4</sup>	8	big integer	8
496/497	large integer	4	large integer	4
500/501	small integer	2	small integer	2

Table 146. SQLTYPE and SQLLEN values for DESCRIBE, PREPARE INTO, FETCH, OPEN, EXECUTE, and CALL (continued)

SQLTYPE	For DESCRIBE and PREPARE INTO		For FETCH, OPEN, EXECUTE, and CALL	
	Column or parameter data type	SQLLEN	Host variable data type	SQLLEN
504/505	N/A	N/A	DISPLAY SIGN LEADING SEPARATE, NATIONAL SIGN LEADING SEPARATE	precision in byte 1; scale in byte 2
908/909	varying-length binary string	length attribute of the column	varying-length binary string	length attribute of the host variable
912/913	fixed-length binary string	length attribute of the column	fixed-length binary string	length attribute of the host variable
916/917	BLOB_FILE	267		
920/921	CLOB_FILE	267		
924/925	DBCLOB_FILE	267		
996/997	DECFLOAT(16)	8	DECFLOAT(16)	8
996/997	DECFLOAT(34)	16	DECFLOAT(34)	16
988/989	XML	0	Invalid. Instead, use one of the following: XML AS BLOB, XML AS CLOB, XML AS DBCLOB	Not used

**Note:**

1. SQLLEN might be different if a date installation exit is specified.
2. SQLLEN might be different if a time installation exit is specified.
3. Field SQLLONGLEN in the extended SQLVAR contains the length attribute of the column.
4. BIGINT is supported by other DB2 platforms.

### SQLDATA:

Depending on the data type of the string column that the SQLVAR is describing, the SQLDATA field can contain different CCSID values.

The following table identifies the CCSID values that appear in the SQLDATA field when the SQLVAR element describes a string column.

Table 147. CCSID values for SQLDATA

Data type	Subtype	Bytes 1 and 2	Bytes 3 and 4
Character	SBCS data	X'0000'	CCSID
Character	mixed data	X'0000'	CCSID
Character	BIT data	X'0000'	X'FFFF'
Graphic	N/A	X'0000'	CCSID
Any other data type	N/A	N/A	N/A

## Unrecognized and unsupported SQLTYPES

The values that appear in the SQLTYPE field of the SQLDA are dependent on the level of data type support available at the sender as well as at the receiver of the data. This support is particularly important as new data types are added to the product.

New data types might not be supported by the sender or receiver of the data and might not be recognized by the sender or receiver of the data. Depending on the situation, the new data type might be returned, a compatible data type that is agreed to by both the sender and the receiver of the data might be returned, or an error might occur.

When the sender and receiver agree to use a compatible data type, the following table indicates the mapping that takes place. This mapping takes place when at least one of the sender or receiver does not support the data type provided. The unsupported data type can be provided by either the application or the database manager.

*Table 148. Compatible data types for unsupported data types*

Data type	Compatible data type
ROWID	VARCHAR(40) FOR BIT DATA

No indication is given in the SQLDA that the data type is substituted.

## The included SQLDA

Only assembler, C, C++, COBOL, and PL/I C are supported for the SQLDA that is given by INCLUDE SQLDA.

### assembler:

```
SQLTRIPL EQU    C'3'
SQLDOUBL EQU    C'2'
SQLSINGL EQU    C' '
*
        SQLSECT SAVE
*
SQLDA    DSECT
SQLDAID  DS     CL8      ID
SQLDABC  DS     F       BYTE COUNT
SQLN    DS     H       COUNT SQLVAR/SQLVAR2 ENTRIES
SQLD    DS     H       COUNT VARS (TWICE IF USING BOTH)
*
SQLVAR   DS     OF      BEGIN VARS
SQLVARN  DSECT  ,
SQLTYPE  DS     H       DATA TYPE CODE
SQLLEN   DS     OH      LENGTH
SQLPRCSN DS     X       DEC PRECISION
SQLSCALE DS     X       DEC SCALE
SQLDATA  DS     A       ADDR OF VAR
SQLIND   DS     A       ADDR OF IND
SQLNAME  DS     H,CL30  DESCRIBE NAME
SQLVSIZ  EQU    *-SQLDATA
SQLSIZV  EQU    *-SQLVARN
*
SQLDA    DSECT
SQLVAR2  DS     OF      BEGIN EXTENDED FIELDS OF VARS
SQLVAR2N DSECT  ,
SQLLONGL DS     F       LENGTH
SQLRSVDL DS     F       RESERVED
SQLDATA1 DS     A       ADDR OF LENGTH IN BYTES
SQLTNAME DS     H,CL30  DESCRIBE NAME
*
        SQLSECT RESTORE
```

In the above declaration, SQLSECT SAVE is a macro invocation that remembers the current CSECT name. SQLSECT RESTORE is a macro invocation that continues that CSECT.

### C and C++:

```
#ifndef SQLDASIZE                      /* Permit duplicate Includes */

```

## Identifying an SQLDA in C or C++

A *descriptor-name* can be specified in the CALL, DESCRIBE, EXECUTE, FETCH, and OPEN statements. When the host application is written in C or C++, *descriptor-name* can be a pointer variable with pointer notation.

For example, *descriptor-name* could be declared as

```
sqlca *outsqlda;
```

Afterwards, it could be used in a statement like the following:

```
EXEC SQL DESCRIBE STMT1 INTO DESCRIPTOR :*outsqlda;
```

## The REXX SQLDA

A REXX SQLDA consists of a set of REXX variables with a common stem. The stem must be a REXX variable name that contains no periods and is the same as the value of *descriptor-name* that you specify when you use the SQLDA in an SQL statement. DB2 does not support the INCLUDE SQLDA statement in REXX.

The following table shows the variable names in a REXX SQLDA. The values in the second column of the table are values that DB2 inserts into the SQLDA when the statement executes. Except where noted otherwise, the values in the third column of the table are values that the application must put in the SQLDA before the statement executes.

Table 149. Fields of a REXX SQLDA

Variable name	Usage in DESCRIBE and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
<i>stem.SQLD</i>	<p>The number of columns that are described in the SQLDA. Double that number if USING BOTH appears in the DESCRIBE or PREPARE INTO statement. Contains a 0 if the statement string is not a query.</p> <p>For DESCRIBE PROCEDURE, the number of result sets returned by the stored procedure. Contains a 0 if no result sets are returned.</p>	The number of host variables that are used by the SQL statement.
Each SQLDA contains <i>stem.SQLD</i> of the following variables. Therefore, $1 \leq n \leq stem.SQLD$ . There is one occurrence of each variable for each column of the result table or host variable that is described by the SQLDA. This set of variables is equivalent to the SQLVAR structure in the SQLDA for other languages.		
<i>stem.n.SQLTYPE</i>	<p>Indicates the data type of the column or parameter and whether it can contain null values. For a description of the type codes, see "SQLTYPE and SQLLEN" on page 1666.</p> <p>For a distinct type, the data type on which the distinct type was based is placed in this field. The base SQLVAR provides no indication that this is part of the description of a distinct type.</p>	Indicates the data type of the host variable and whether an indicator variable is provided. Host variables for datetime values must be character string variables. For FETCH, a datetime type code means a fixed-length character string. For a description of the type codes, see "SQLTYPE and SQLLEN" on page 1666.
<i>stem.n.SQLLEN</i>	For a column other than a DECIMAL or NUMERIC column, the length attribute of the column or parameter. For datetime data, the length of the string representation of the value. See "SQLTYPE and SQLLEN" on page 1666 for a description of allowable values.	For a host variable that does not have a decimal data type, the length attribute of the host variable. See "SQLTYPE and SQLLEN" on page 1666 for a description of allowable values.
<i>stem.n.SQLLEN.SQLPRECISION</i>	For a DECIMAL or NUMERIC column, the precision of the column or parameter.	For a host variable with a decimal data type, the precision of the host variable.
<i>stem.n.SQLLEN.SQLSCALE</i>	For a DECIMAL or NUMERIC column, the scale of the column or parameter.	For a host variable with a decimal data type, the scale of the host variable.

Table 149. Fields of a REXX SQLDA (continued)

Variable name	Usage in DESCRIBE and PREPARE INTO	Usage in FETCH, OPEN, EXECUTE, and CALL
<i>stem.n.SQLCCSID</i>	For a string column or parameter, the CCSID of the column or parameter.	For a string host variable, the CCSID of the host variable.
<i>stem.n.SQLUSECCSID</i>	Not used.	Set to a new CCSID. If set, REXX will change the CCSID of the SQLDATA.
<i>stem.n.SQLLOCATOR</i>	For DESCRIBE PROCEDURE, the value of a result set locator.	Not used.
<i>stem.n.SQLDATA</i>	Not used.	Before EXECUTE or OPEN, contains the value of an input host variable. The application must supply this value.  After FETCH, contains the values of an output host variable.
<i>stem.n.SQLIND</i>	Not used.	Before EXECUTE or OPEN, contains a negative number to indicate that the input host variable in <i>stem.n.SQLDATA</i> is null. The application must supply this value.  After FETCH, contains a negative number if the value of the output host variable in <i>stem.n.SQLDATA</i> is null.
<i>stem.n.SQLNAME</i>	The name of the <i>n</i> th column in the result table. For DESCRIBE PROCEDURE, contains the cursor name that is used by the stored procedure to return the result set. The values for SQLNAME appear in the order that the cursors were opened by the stored procedure.	Not used.

---

## DB2 catalog tables

DB2 for z/OS maintains a set of tables (in database DSNDB06) called the DB2 catalog.

### About these topics

These topics describe that catalog by describing the columns of each catalog table.

The catalog tables describe such things as table spaces, tables, columns, indexes, privileges, application plans, and packages. Authorized users can query the catalog; however, it is primarily intended for use by DB2 and is therefore subject to change. All catalog tables are qualified by SYSIBM. Do not use this qualifier for user-defined tables.

The catalog tables are updated by DB2 during normal operations in response to certain SQL statements, commands, and utilities.

### Additional information

**Release dependency indicators:** Some objects depend on functions in particular releases of DB2. If you are running on a release of DB2 and fall back to a previous release, an object that depends on the more recent release becomes frozen. The object is marked with a release dependency indicator and is unavailable until remigration. The release dependency indicator, which is listed in the IBMREQD column of the catalog tables, shows the release of DB2 upon which the objects depends. Release dependency indicators in IBMREQD are defined by the following values:

Value	Meaning
B	Version 1R3 dependency indicator, not from the machine-readable material (MRM) tape
C	Version 2R1 dependency indicator, not from MRM tape
D	Version 2R2 dependency indicator, not from MRM tape
E	Version 2R3 dependency indicator, not from MRM tape
F	Version 3R1 dependency indicator, not from MRM tape
G	Version 4 dependency indicator, not from MRM tape
H	Version 5 dependency indicator, not from MRM tape
I	Version 6 dependency indicator, not from MRM tape
J	Version 6 dependency indicator, not from MRM tape
K	Version 7 dependency indicator, not from MRM tape
L	Version 8 dependency indicator, not from MRM tape
M	Version 9 dependency indicator, not from MRM tape
N	Not from MRM tape, no dependency

- |   |   |
|---|---|
| B | Version 1R3 dependency indicator, not from the machine-readable material (MRM) tape |
| C | Version 2R1 dependency indicator, not from MRM tape                                 |
| D | Version 2R2 dependency indicator, not from MRM tape                                 |
| E | Version 2R3 dependency indicator, not from MRM tape                                 |
| F | Version 3R1 dependency indicator, not from MRM tape                                 |
| G | Version 4 dependency indicator, not from MRM tape                                   |
| H | Version 5 dependency indicator, not from MRM tape                                   |
| I | Version 6 dependency indicator, not from MRM tape                                   |
| J | Version 6 dependency indicator, not from MRM tape                                   |
| K | Version 7 dependency indicator, not from MRM tape                                   |
| L | Version 8 dependency indicator, not from MRM tape                                   |
| M | Version 9 dependency indicator, not from MRM tape                                   |
| N | Not from MRM tape, no dependency  |

## **Programming interface information**

Not all catalog table columns are part of the general-use programming interface. Whether a column is part of this interface is indicated in a column labeled “Use” in the table that describes the column. The values that “Use” can assume are as follows:

**Value    Meaning**

<b>G</b>	Column is part of the general-use programming interface
<b>S</b>	Column is part of the product-sensitive interface
<b>I</b>	Column is for internal use only
<b>N</b>	Column is not used

For columns for which “Use” is N or I, the name of the column and its description do not appear in the explanation of the column.

## Table spaces and indexes

DB2 catalog tables are contained in certain table spaces and have indexes.

The following table lists the table space and indexes for each catalog table and lists the index fields for each index. The indexes are in ascending order, except where noted.

*Table 150. Table spaces and indexes for the catalog tables*

## SQL statements allowed on the catalog

Certain SQL statements can be used to change the value of certain options for existing catalog indexes, sequences, and table spaces, or to add indexes to any of the catalog tables.

Table 151. SQL statements that can be used to change existing catalog indexes, sequences, and table spaces, or to add indexes to any of the catalog tables

SQL statement	Index	Allowable clauses and usage notes
ALTER INDEX	IBM-defined	<p>Only these clauses are allowed:</p> <ul style="list-style-type: none"> <li>CLOSE</li> <li>COPY</li> <li>FREEPAGE</li> <li>GBPCACHE</li> <li>NOT PADDED</li> <li>PADDED</li> <li>PCTFREE</li> <li>PIECESIZE</li> <li>BUFFERPOOL</li> <li>COMPRESS YES</li> </ul> <p>Any partitioning clause</p> <p>You cannot alter the GBPCACHE value for indexes DSNDXX01, DSNDXX02, and DSNDXX03, which are on catalog table SYSIBM.SYSINDEXES.</p>

*Table 151. SQL statements that can be used to change existing catalog indexes, sequences, and table spaces, or to add indexes to any of the catalog tables (continued)*

<b>SQL statement</b>	<b>Index</b>	<b>Allowable clauses and usage notes</b>
ALTER INDEX	User-created	All clauses are allowed, except for BUFFERPOOL.
ALTER SEQUENCE		The only clause allowed is MAXVALUE.
		You can only change the MAXVALUE value of the catalog sequence DSNSEQ_IMPLICITDB. The only value specific must be an integer between 1 and 60000, inclusive.
ALTER TABLE		The only clause allowed is DATA CAPTURE CHANGES.
ALTER TABLESPACE		Only these clauses are allowed: CLOSE FREEPAGE GBPCACHE LOCKMAX MAXROWS PCTFREE TRACKMOD
		You cannot alter the GBPCACHE or MAXROWS value of some catalog table spaces. Do not specify GBPCACHE for the following table spaces: <ul style="list-style-type: none"> <li>• DSNDB06.SYSDBASE</li> <li>• DSNDB06.SYSDBAUT</li> <li>• DSNDB06.SYSPKAGE</li> <li>• DSNDB06.SYSPLAN</li> <li>• DSNDB06.SYSUSER (exception: the attribute can be altered if authorization includes installation SYSADM authority.)</li> </ul>
		Do not specify MAXROWS or the LOCKSIZE keyword for the following table spaces: <ul style="list-style-type: none"> <li>• DSNDB06.SYSDBASE</li> <li>• DSNDB06.SYSDBAUT</li> <li>• DSNDB06.SYSGROUP</li> <li>• DSNDB06.SYSPLAN</li> <li>• DSNDB06.SYSSEQ</li> <li>• DSNDB06.SYSVIEWS</li> </ul>
		You can specify the LOCKSIZE keyword on the ALTER TABLESPACE statement for any catalog table spaces that are not LOB table spaces and that do not contain links.
		For DSNDB06.SYSSEQ, MAXROW can be specified only with a value of 1.

*Table 151. SQL statements that can be used to change existing catalog indexes, sequences, and table spaces, or to add indexes to any of the catalog tables (continued)*

SQL statement	Index	Allowable clauses and usage notes
CREATE INDEX	User-created	All clauses are allowed, except for: CLOSE YES CLUSTER UNIQUE DEFER YES (only on tables SYSINDEXES, SYSINDEXPART, and SYSKEYS) COMPRESS YES Any partitioning clause
		Indexes that are created with <i>key-expressions</i> are not allowed on the catalog.
		The only value allowed for BUFFERPOOL is BP0.
		You can create up to 500 indexes on the catalog.
DROP INDEX	User-created	The statement has no clauses.

## Reorganizing the catalog

The REORG TABLESPACE utility can be run on all the table spaces in the catalog database (DSNDB06) to reclaim unused or wasted space, which can affect performance.

The utility observes the PCTFREE and FREEPAGE values specified in the ALTER INDEX statement for all the catalog indexes and the following table spaces:

- DSNDB06.SYSCOPY
- DSNDB06.SYSDDF
- DSNDB06.SYSGPAUT
- DSNDB06.SYSGRTNS
- DSNDB06.SYSHIST
- DSNDB06.SYSJAVA
- DSNDB06.SYSJAUXA
- DSNDB06.SYSJAUXB
- DSNDB06.SYSOBJ
- DSNDB06.SYSPKAGE
- DSNDB06.SYSSEQ
- DSNDB06.SYSSEQ2
- DSNDB06.SYSSTR
- DSNDB06.SYSSTATS
- DSNDB06.SYSUSER
- DSNDB01.SCT02
- DSNDB01.SPT01

For details on running REORG TABLESPACE, see *DB2 Utility Guide and Reference*.

## New and changed catalog tables

This release of DB2 for z/OS includes many new catalog tables as well as many catalog tables that have new or changed content.

Descriptions of the following catalog tables have been added:

- SYSIBM.SYSCONTEXT
- SYSIBM.SYSCTXTRUSTATTRS
- SYSIBM.SYSCONTEXTAUTHIDS
- SYSIBM.SYSDEPENDENCIES
- SYSIBM.SYSENVIRONMENT
- SYSIBM.SYSINDEXSPACESTATS
- SYSIBM.SYSJAVAPATHS
- SYSIBM.SYSKEYTARGETS
- SYSIBM.SYSKEYTARGETS\_HIST
- SYSIBM.SYSKEYTARGETSTATS
- SYSIBM.SYSKEYTGTDIST
- SYSIBM.SYSKEYTGTDIST\_HIST
- SYSIBM.SYSKEYTGTDISTSTATS
- SYSIBM.SYSOBJROLEDEP
- SYSIBM.SYSROLES
- SYSIBM.SYSROUTINESTEXT
- SYSIBM.SYSTABLESPACESTATS
- SYSIBM.SYSXMLRELS
- SYSIBM.SYSXMLSTRINGS

The catalog tables that are listed in the following table have new or revised columns, column values, or column descriptions to support the new function in this release of DB2 for z/OS.

*Table 152. Tables with new or revised columns, column values, or column descriptions*

Table name	New column	Revised column

## SYSIBM.IPLIST table

The SYSIBM.IPLIST table allows multiple IP addresses to be specified for a given LOCATION.

Insert rows into this table when you want to define a remote DB2 data sharing group. The same value for the IPADDR column cannot appear in both the SYSIBM.IPNAME table and the SYSIBM.IPLIST table. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LINKNAME	VARCHAR(24) NOT NULL	This column is associated with the value specified in the LINKNAME column in the SYSIBM.LOCATIONS table and the SYSIBM.IPNAME table. The values of the other columns in the SYSIBM.IPNAME table apply to the server identified by the LINKNAME column in this row.	G
IPADDR	VARCHAR(254) NOT NULL	<p>This column contains an IPv4 or IPv6 address, or domain name of a remote TCP/IP host of the server. If WLM Domain Name Server workload balancing is used, this column must contain the member specific domain name. If Dynamic VIPA workload balancing is used, this column must contain the member specific Dynamic VIPA address. The IPADDR column must be specified as follows:</p> <ul style="list-style-type: none"> <li>• An IPv4 address must be left justified and is represented as a dotted decimal address. For example, '123.456.78.912' would be interpreted as an IPv4 address.</li> <li>• An IPv6 address must be left justified and is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0008:0800:200C:417A', which can also be expressed in compressed form as '2001:DB8::8:800:200C:417A'.</li> <li>• A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is 'stlmvs1.svl.ibm.com'.</li> </ul>	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.IPNAMES table

The SYSIBM.IPNAMES table defines the remote DRDA servers DB2 can access using TCP/IP.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LINKNAME	VARCHAR(24) NOT NULL	The value specified in this column must match the value specified in the LINKNAME column of the associated row in SYSIBM.LOCATIONS.	G
SECURITY_OUT	CHAR(1) NOT NULL WITH DEFAULT 'A'	<p>This column defines the DRDA security option that is used when local DB2 SQL applications connect to any remote server associated with this TCP/IP host:</p> <p><b>A</b>      The option is "already verified". Outbound connection requests contain an authorization ID and no password. The authorization ID used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending upon the value of the USERNAMES column.            The authorization ID is not encrypted when it is sent to the partner. For encryption, refer to 'D'.</p> <p><b>D</b>      The option is "userid and security-sensitive data encryption". Outbound connection requests contain an authorization ID and no password. The authorization ID used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending upon the value of the USERNAMES column.            This option indicates that the userid and security-sensitive data are to be encrypted. For non-encryption, refer to 'A'.</p> <p><b>E</b>      The option is "userid, password, and security-sensitive data encryption". Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USERNAMES table. The USERNAMES column must specify 'O'.            This option indicates that the userid, password, and security-sensitive data are to be encrypted. For non-security-sensitive data encryption, refer to 'P'.            If the applications connect to any remote server as trusted, the USERNAMES column must specify 'O' or 'S'.</p>	G

Column name	Data type	Description	Use
SECURITY_OUT (continued)			
	P	<p>The option is "password". Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USERNAMES table. The USERNAMES column must specify 'O'.</p> <p>This option indicates that the userid and the password are to be encrypted if cryptographic services are available at the requester and if the server supports encryption. Otherwise, the userid and the password are sent to the partner in clear text. For security-sensitive data encryption, see 'E'.</p>	
		If the applications connect to any remote server as trusted, the USERNAMES column must specify 'O' or 'S'.	
	R	The option is "RACF PassTicket". Outbound connection requests contain a userid and a RACF PassTicket. The value specified in the LINKNAME column is used as the RACF PassTicket application name for the remote server.	
		The authorization ID used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending upon the value of the USERNAMES column.	
		The authorization ID is not encrypted when it is sent to the partner.	
USERNAMES	CHAR(1) NOT NULL WITH DEFAULT	<p>This column controls outbound authorization ID translation. Outbound translation is performed when an authorization ID is sent by DB2 to a remote server.</p> <p><b>O</b> An outbound ID is subject to translation. Rows in the SYSIBM.USERNAMES table are used to perform ID translation.</p> <p>No translation or "come from" checking is performed on inbound IDs.</p> <p><b>S</b> Row in the SYSIBM.USERNAMES table is used to obtain the system AUTHID used to establish a trusted connection.</p> <p><b>blank</b> No translation occurs.</p>	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
IPADDR	VARCHAR(254) NOT NULL WITH DEFAULT	<p>This column contains an IPv4 or IPv6 address, or domain name of a remote TCP/IP host. The IPADDR column must be specified as follows:</p> <ul style="list-style-type: none"> <li>• An IPv4 address must be left justified and is represented as a dotted decimal address. For example, '123.456.78.91' would be interpreted as an IPv4 address.</li> <li>• An IPv6 address must be left justified and is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0000:0800:200C:417A', which can also be expressed in compressed form as '2001:DB8::8:800:200C:417A'.</li> <li>• A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is 'stlmvs1.svl.ibm.com'.</li> </ul>	G

## SYSIBM.LOCATIONS table

The SYSIBM.LOCATIONS table contains a row for every accessible remote server. The row associates a LOCATION name with the TCP/IP or SNA network attributes for the remote server. Requesters are not defined in this table.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LOCATION	VARCHAR(128) NOT NULL	A unique location name for the accessible server. This is the name by which the remote server is known to local DB2 SQL applications.	G
LINKNAME	VARCHAR(24) NOT NULL	<p>Identifies the VTAM® or TCP/IP attributes associated with this location. For any LINKNAME specified, one or both of the following statements must be true:</p> <ul style="list-style-type: none"> <li>• A row exists in SYSIBM.LUNAMES whose LUNAME matches the value specified in the SYSIBM.LOCATIONS LINKNAME column. This row specifies the VTAM communication attributes for the remote location.</li> <li>• A row exists in SYSIBM.IPNAMES whose LINKNAME matches the value specified in the SYSIBM.LOCATIONS LINKNAME column. This row specifies the TCP/IP communication attributes for the remote location.</li> </ul>	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PORt	VARCHAR(96) NOT NULL WITH DEFAULT	<p>TCP/IP is used for outbound DRDA connections when the following statement is true:</p> <ul style="list-style-type: none"> <li>• A row exists in SYSIBM.IPNAMES, where the LINKNAME column matches the value specified in the SYSIBM.LOCATIONS LINKNAME column.</li> </ul> <p>If the above mentioned row is found, the value of the PORT column is interpreted as follows:</p> <ul style="list-style-type: none"> <li>• If PORT is blank, the default DRDA port (446) is used.</li> <li>• If PORT is nonblank, the value specified for PORT can take one of two forms: <ul style="list-style-type: none"> <li>– If the value in PORT is left justified with 1-5 numeric characters, the value is assumed to be the TCP/IP port number of the remote database server.</li> <li>– Any other value is assumed to be a TCP/IP service name, which can be converted to a TCP/IP port number using the TCP/IP getservbyname socket call. TCP/IP service names are not case sensitive.</li> </ul> </li> </ul>	G

Column name	Data type	Description	Use
TPN	VARCHAR(192) NOT NULL WITH DEFAULT	Used only when the local DB2 begins an SNA conversation with another server. When used, TPN indicates the SNA LU 6.2 transaction program name (TPN) that will allocate the conversation. A length of zero for the column indicates the default TPN. For DRDA conversations, this is the DRDA default, which is X'07F6C4C2'. For DB2 private protocol conversations, this column is not used.	G
		When the server is DB2 Server for VSE & VM, TPN should contain the resource ID of that machine.	
DBALIAS	VARCHAR(128) NOT NULL	Database alias. The name associated with the server. This name is used to access a remote database server. If DBALIAS is blank, the location name is used to access the remote database server. This column does not change the name of any database objects sent to the remote site that contains the location qualifier.	G
TRUSTED	CHAR(1) NOT NULL WITH DEFAULT 'N'	<p>Indicates whether the connection to the remote server can be trusted. This is restricted to TCP/IP only. This column is ignored for connections using SNA.</p> <p><b>Y</b>     Location is trusted. Access to the remote location requires trusted context defined at the remote location.</p> <p><b>N</b>     Location is not trusted.</p>	G
SECURE	CHAR(1) NOT NULL WITH DEFAULT 'N'	<p>Indicates the use of the Secure Socket Layer (SSL) protocol for outbound DRDA connections when local DB2 applications connects to the remote database server using TCP/IP.</p> <p><b>Y</b>     Indicates a secure connection using SSL is required for the outbound DRDA connection.</p> <p><b>N</b>     Indicates a secure connection is not required for the outbound DRDA connection.</p>	G

## SYSIBM.LULIST table

The SYSIBM.LULIST table allows multiple LU names to be specified for a given LOCATION.

Insert rows into this table when you want to define a remote DB2 data sharing group. The same value for LUNAME column cannot appear in both the SYSIBM.LUNAMES table and the SYSIBM.LULIST table. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LINKNAME	VARCHAR(24) NOT NULL	The value of the LINKNAME column in the SYSIBM.LOCATIONS table with which this row is associated. This is also the value of the LUNAME column in the SYSIBM.LUNAMES table. The values of the other columns in the SYSIBM.LUNAMES row apply to the LU identified by the LUNAME column in this row of SYSIBM.LULIST.	G
LUNAME	VARCHAR(24) NOT NULL	The VTAM logical unit name (LUNAME) of the remote database system. This LUNAME must not exist in the LUNAME column of SYSIBM.LUNAMES.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.LUMODES table

Each row of the SYSIBM.LUMODES table provides VTAM with conversation limits for a specific combination of LUNAME and MODENAME. The table is accessed only during the initial conversation limit negotiation between DB2 and a remote LU. This negotiation is called *change-number-of-sessions* (CNOS) processing.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LUNAME	VARCHAR(24) NOT NULL	LU name of the server involved in the CNOS processing.	G
MODENAME	VARCHAR(24) NOT NULL	Name of a logon mode description in the VTAM logon mode table.	G
CONVLIMIT	SMALLINT NOT NULL	Maximum number of active conversations between the local DB2 and the other system for this mode. Used to override the number in the DSESLIM parameter of the VTAM APPL definition statement for this mode.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.LUNAMES table

The SYSIBM.LUNAMES table must contain a row for each remote SNA client or server that communicates with DB2.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
LUNAME	VARCHAR(24) NOT NULL	Name of the LU for one or more accessible systems. A blank string indicates the row applies to clients whose LU name is not specifically defined in this table.  All other column values for a given row in this table are for clients and servers associated with the row's LU name.	G
SYSMODENAME	VARCHAR(24) NOT NULL WITH DEFAULT	Mode used to establish inter-system conversations. A blank indicates the default mode IBMDB2LM (DB2 private protocol access and for collecting sysplex balancing information from remote data sharing groups).  If private protocols are used to access a remote DB2 LU or if the remote LU is a member of a DB2 data sharing group, use a separate mode other than the default mode.	G
SECURITY_IN	CHAR(1) NOT NULL WITH DEFAULT 'A'	<p>This column defines the security options that are accepted by this DB2 when an SNA client connects to DB2:</p> <p><b>V</b> The option is "verify". An incoming connection request must include one of the following: a userid and password, a userid and RACF PassTicket, or a Kerberos security ticket.</p> <p><b>A</b> The option is "already verified". A request does not need a password, although a password is checked if it is sent.</p> <p>With this option, an incoming connection request is accepted if it includes any of the following: a userid, a userid and password, a userid and RACF PassTicket, or a Kerberos security ticket.</p> <p>If the USERNAMES column contains 'T' or 'B', RACF is not invoked to validate incoming connection requests that contain only a userid.</p>	G

Column name	Data type	Description	Use
SECURITY_OUT	CHAR(1) NOT NULL WITH DEFAULT 'A'	This column defines the security option that is used when local DB2 SQL applications connect to any remote server associated with this LUNAME:  <b>A</b> The option is "already verified". Outbound connection requests contain an authorization ID and no password.  <b>R</b> The authorization ID used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending upon the value of the USERNAMES column.  <b>P</b> The option is "RACF PassTicket". Outbound connection requests contain a userid and a RACF PassTicket. The server's LU name is used as the RACF PassTicket application name.  The authorization ID used for an outbound request is either the DB2 user's authorization ID or a translated ID, depending upon the value of the USERNAMES column.  <b>P</b> The option is "password". Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USERNAMES table or RACF, depending upon the value specified in the ENCRYPTPSWDS column.  The USERNAMES column must specify 'B' or 'O'.	G
ENCRYPTPSWDS	CHAR(1) NOT NULL WITH DEFAULT 'N'	This column only applies to DB2 for z/OS partners. It is provided to support connectivity to prior releases of DB2 that are unable to support RACF PassTickets.  For connections between DB2 Version 5 and later, use the SECURITY_OUT='R' option instead of the ENCRYPTPSWDS='Y' option.  <b>N</b> No, passwords are not in internal RACF encrypted format. This is the default.  <b>Y</b> Yes for outbound requests, the encrypted password is extracted from RACF and sent to the server. For inbound requests, the password is treated as encrypted.	G
MODESELECT	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether to use the SYBIBM.MODESELECT table:  <b>N</b> Use default modes: IBMDB2LM (for DB2 private protocol) and IBMRDB (for DRDA).  <b>Y</b> Searches SYSIBM.MODESELECT for appropriate mode name.	G

Column name	Data type	Description	Use
USERNAMES	CHAR(1) NOT NULL WITH DEFAULT	<p>This column controls inbound and outbound authorization ID translation, and “come from” checking.</p> <p>Inbound translation and “come from” checking are performed when an authorization ID is received from a remote client.</p> <p>Outbound translation is performed when an authorization ID is sent by DB2 to a remote server.</p> <p>When 'T', 'O', or 'B' is specified in this column, rows in the SYSIBM.USERNAMES table are used to perform ID translation.</p> <ul style="list-style-type: none"> <li><b>I</b> An inbound ID is subject to translation and “come from” checking.</li> <li><b>O</b> No translation is performed on outbound IDs.</li> <li><b>O</b> No translation or “come from” checking is performed on inbound IDs.</li> <li><b>B</b> An outbound ID is subject to translation.</li> <li><b>B</b> An inbound ID is subject to translation and “come from” checking.</li> <li><b>blank</b> An outbound ID is subject to translation.</li> </ul>	G
GENERIC	CHAR(1) NOT NULL WITH DEFAULT 'N'	<p>Indicates whether DB2 should use its real LU name or generic LU name to identify itself to the partner LU, which is identified by this row.</p> <ul style="list-style-type: none"> <li><b>N</b> The real VTAM LU name of this DB2 subsystem</li> <li><b>Y</b> The VTAM generic LU name of this DB2 subsystem</li> </ul>	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.MODESELECT table

The SYSIBM.MODESELECT table associates a mode name with any conversation created to support an outgoing SQL request. Each row represents one or more combinations of LUNAME, authorization ID, and application plan name.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
AUTHID	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the SQL request. Blank (the default) indicates that the MODENAME specified for the row is to apply to all authorization IDs.	G
PLANNNAME	VARCHAR(24) NOT NULL WITH DEFAULT	Plan name associated with the SQL request. Blank (the default) indicates that the MODENAME specified for the row is to apply to all plan names.	G
LUNAME	VARCHAR(24) NOT NULL	LU name associated with the SQL request.	G
MODENAME	VARCHAR(24) NOT NULL	Name of the logon mode in the VTAM logon mode table to be used in support of the outgoing SQL request. If blank, IBMDB2LM is used for DB2 private protocol connections and IBMRDB is used for DRDA connections.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSAUXRELS table

The SYSIBM.SYSAUXRELS table contains one row for each auxiliary table created for a LOB column. A base table space that is partitioned must have one auxiliary table for each partition of each LOB column.

Column name	Data type	Description	Use
TBOWNER	VARCHAR(128) NOT NULL	The schema of the base table.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the base table.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the LOB column in the base table.	G
PARTITION	SMALLINT NOT NULL	Partition number if the base table space is partitioned. Otherwise, the value is 0.	G
AUXTBOWNER	VARCHAR(128) NOT NULL	The schema of the auxiliary table.	G
AUXTBNAME	VARCHAR(128) NOT NULL	Name of the auxiliary table.	G
AUXRELOBID	INTEGER NOT NULL	Internal identifier of the relationship between the base table and the auxiliary table.	S
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSCHECKDEP table

The SYSIBM.SYSCHECKDEP table contains one row for each reference to a column in a check constraint.

Column name	Data type	Description	Use
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table on which the check constraint is defined.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the check constraint is defined.	G
CHECKNAME	VARCHAR(128) NOT NULL	Name of the check constraint.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the column that the check constraint refers to.	G
IBREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSCHECKS table

The SYSIBM.SYSCHECKS table contains one row for each check constraint.

Column name	Data type	Description	Use
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table on which the check constraint is defined.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the creator of the check constraint.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database for the check constraint.	S
OBID	SMALLINT NOT NULL	Internal identifier of the check constraint.	S
TIMESTAMP	TIMESTAMP NOT NULL	Time when the check constraint was created.	G
RBA	CHAR(6) FOR BIT DATA NOT NULL WITH DEFAULT	The log RBA when the check constraint was created.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the check constraint is defined.	G
CHECKNAME	VARCHAR(128) NOT NULL	Check constraint name.	G
CHECKCONDITION	VARCHAR(7400) NOT NULL	Text of the check constraint.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSCHECKS2 table

The SYSIBM.SYSCHECKS2 table contains one row for each check constraint for catalog tables created in or after Version 7. Check constraints for catalog tables created before Version 7 are not included in this table.

Column name	Data type	Description	Use
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table on which the check constraint is defined.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the check constraint is defined.	G
CHECKNAME	VARCHAR(128) NOT NULL	Check constraint name.	G
PATHSCHEMAS	VARCHAR(2048) NOT NULL	SQL path at the time the check constraint was created. The path is used to resolve unqualified cast function names that are used in the constraint definition.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSCOLAUTH table

The SYSIBM.SYSCOLAUTH table records the UPDATE or REFERENCES privileges that are held by users on individual columns of a table or view.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID or role of the user who granted the privileges. Could also be PUBLIC or PUBLIC followed by an asterisk. (PUBLIC followed by an asterisk (PUBLIC*) denotes PUBLIC AT ALL LOCATIONS. For the conditions where GRANTOR can be PUBLIC or PUBLIC*, see <i>DB2 Administration Guide</i> .)	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID or role of the user who holds the privilege or the name of an application plan or package that uses the privilege. PUBLIC for a grant to PUBLIC. PUBLIC followed by an asterisk for a grant to PUBLIC AT ALL LOCATIONS.	G
GRANTEETYPE	CHAR(1) NOT NULL	Type of grantee: <b>b</b> lank An authorization ID <b>L</b> Role <b>P</b> An application plan or a package. The grantee is a package if COLLID is not blank.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the table or view on which the update privilege is held.	G
TNAME	VARCHAR(128) NOT NULL	Name of the table or view.	G
	CHAR(12) NOT NULL	Internal use only	I
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N
COLNAME	VARCHAR(128) NOT NULL	Name of the column to which the UPDATE privilege applies.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
	VARCHAR(128) NOT NULL WITH DEFAULT	Not used	N
COLLID	VARCHAR(128) NOT NULL WITH DEFAULT	If GRANTEE is a package, its collection name. Otherwise, the value is blank.	G

Column name	Data type	Description	Use
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	If GRANTEE is a package, the consistency token of the DBRM from which the package was derived. Otherwise, the value is blank.	S
PRIVILEGE	CHAR(1) NOT NULL WITH DEFAULT	Indicates which privilege this row describes: <b>R</b> Row pertains to the REFERENCES privilege. <b>blank</b> Row pertains to the UPDATE privilege.	G
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed.	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>L</b> Role <b>blank</b> Authorization ID that is not a role	G

## SYSIBM.SYSCOLDIST table

The SYSIBM.SYSCOLDIST table contains one or more rows for the first key column of an index key.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
		Not used	N
	SMALLINT NOT NULL		
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table that contains the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
NAME	VARCHAR(128) NOT NULL	Name of the column. If NUMCOLUMNS is greater than 1, this name identifies the first column name of the set of columns associated with the statistics.	G
COLVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Contains the data of a frequently occurring value. Statistics are not collected for an index on a ROWID column. If the value has a non-character data type, the data might not be printable.	S
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics gathered:  C      Cardinality F      Frequent value H      Histogram Statistics N      Non-padded frequent value	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	For TYPE='C', the number of distinct values for the column group. For TYPE='H', the number of distinct values for the column group in a quantile indicated by QUANTILENO.	S
COLGROUPCOLNO	VARCHAR(254) NOT NULL WITH DEFAULT FOR BIT DATA	Identifies the set of columns associated with the statistics. If the statistics are only associated with a single column, the field contains a zero length. Otherwise, the field is an array of SMALLINT column numbers with a dimension equal to the value in NUMCOLUMNS. This is an updatable column.	S
NUMCOLUMNS	SMALLINT NOT NULL WITH DEFAULT 1	Identifies the number of columns associated with the statistics.	G

Column name	Data type	Description	Use
FREQUENCYF	FLOAT NOT NULL WITH DEFAULT -1	Gives the percentage of rows in the table with the value specified in COLVALUE when the number is multiplied by 100. For example, a value of '1' indicates 100%. A value of '.153' indicates 15.3%.	G
		When TYPE='H', this is the percentage of rows in table which falls in the quantile indicated by QUANTILENO whose range is limited by [LOWVALUE, HIGHVALUE].	
		Statistics are not collected for an index on a ROWID column.	
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	Ordinary sequence number of a quantile in the whole consecutive value range, from low to high. This column is not updatable.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the lower bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the higher bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G

## SYSIBM.SYSCOLDISTSTATS table

The SYSIBM.SYSCOLDISTSTATS table contains zero or more rows per partition for the first key column of a partitioning index or a data-partitioned secondary index.

No row is inserted if the index is a non-partitioned index. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
	SMALLINT NOT NULL	Not used	N
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PARTITION	SMALLINT NOT NULL	Partition number for the table space that contains the table in which the column is defined.	G
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table that contains the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
NAME	VARCHAR(128) NOT NULL	Name of the column. If NUMCOLUMNS is greater than 1, this name identifies the first column name of the set of columns associated with the statistics.	G
COLVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Contains the data of a frequently occurring value. Statistics are not collected for an index on a ROWID column. If the value has a non-character data type, the data might not be printable.	S
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics gathered:  C Cardinality F Frequent value H Histogram statistics N Non-padded frequent value	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	If TYPE is C, the value is the number of distinct values for the column group. If TYPE is N or TYPE is F, the value is the number of rows or keys in the partition for which the FREQUENCYF value applies. If TYPE is H, the number of distinct values for the column group in a quantile indicated by QUANTILENO.	S
COLGROUPCOLNO	VARCHAR(254) NOT NULL WITH DEFAULT FOR BIT DATA	Identifies the set of columns associated with the statistics. If the statistics are only associated with a single column, the field contains a zero length. Otherwise, the field is an array of SMALLINT column numbers with a dimension equal to the value in NUMCOLUMNS. This is an updatable column.	S

Column name	Data type	Description	Use
NUMCOLUMNS	SMALLINT NOT NULL WITH DEFAULT 1	Identifies the number of columns associated with the statistics.	G
FREQUENCYF	FLOAT NOT NULL WITH DEFAULT -1	Gives the percentage of rows in the table with the value specified in COLVALUE when the number is multiplied by 100. For example, a value of '1' indicates 100%. A value of '.153' indicates 15.3%.	G
		When TYPE='H', this is the percentage of rows in table which falls in the quantile indicated by QUANTILENO whose range is limited by [LOWVALUE, HIGHVALUE].	
		Statistics are not collected for an index on a ROWID column.	
	VARCHAR(1000) NOT NULL WITH DEFAULT FOR BIT DATA	Internal use only	I
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	Ordinary sequence number of a quantile in the whole consecutive value range, from low to high. This column is not updatable.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the lower bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the higher bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G

## SYSIBM.SYSCOLDIST\_HIST table

The SYSIBM.SYSCOLDIST\_HIST table contains rows from SYSCOLDIST.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics.	G
TBOWNER	VARCHAR(128) NOT NULL	The schema of the table that contains the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
NAME	VARCHAR(128) NOT NULL	Name of the column. If NUMCOLUMNS is greater than 1, this name identifies the first column name of the set of columns associated with the statistics.	G
COLVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Contains the data of a frequently occurring value. Statistics are not collected for an index on a ROWID column. If the value has a non-character data type, the data might not be printable.	S
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics gathered:  C Cardinality F Frequent value H Histogram Statistics N Non-padded frequent value	G
CARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	When TYPE='C', this is the number of distinct values for the column group. When TYPE='H', this is the number of distinct values for the column group in a quantile indicated by QUANTILENO. The value is -1 if statistics have not been gathered.	S
COLGROUPCOLNO	VARCHAR(254) NOT NULL WITH DEFAULT FOR BIT DATA	Identifies the set of columns associated with the statistics. If the statistics are only associated with a single column, the field contains a zero length. Otherwise, the field is an array of SMALLINT column numbers with a dimension equal to the value in NUMCOLUMNS.	S
NUMCOLUMNS	SMALLINT NOT NULL WITH DEFAULT 1	Identifies the number of columns associated with the statistics.	G

Column name	Data type	Description	Use
FREQUENCYF	FLOAT(8) NOT NULL DEFAULT -1	Gives the percentage of rows in the table with the value specified in COLVALUE when the number is multiplied by 100. For example, a value of '1' indicates 100%. A value of '.153' indicates 15.3%.	G
		When TYPE='H', this is the percentage of rows in table which falls in the quantile indicated by QUANTILENO whose range is limited by [LOWVALUE, HIGHVALUE].	
		Statistics are not collected for an index on a ROWID column. The value is -1 if statistics have not been gathered.	
IBMREQD	CHAR(1) NOT NULL DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	Ordinary sequence number of a quantile in the whole consecutive value range, from low to high. This column is not updatable.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the lower bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	For TYPE='H', this is the higher bound for the quantile indicated by QUANTILENO. Not used if TYPE is not 'H'. This column is not updatable.	G

## SYSIBM.SYSCOLSTATS table

The SYSIBM.SYSCOLSTATS table contains partition statistics for selected columns. For each column, a row exists for each partition in the table.

Rows are inserted when RUNSTATS collects either indexed column statistics or non-indexed column statistics for a partitioned table space. No row is inserted if the table space is nonpartitioned. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
HIGHKEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Highest value of the column within the partition. Blank if statistics have not been gathered or the column is an indicator column, a node ID column, or a column of an XML table. If the column has a non-character data type, the data might not be printable. If the partition is empty, the value is a string of length 0.	S
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second highest value of the column within the partition. Blank if statistics have not been gathered or the column is an indicator column, a node ID column, or a column of an XML table. If the column has a non-character data type, the data might not be printable. If the partition is empty, the value is a string of length 0.	S
LOWKEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Lowest value of the column within the partition. Blank if statistics have not been gathered or the column is an indicator column, a node ID column, or a column of an XML table. If the column has a non-character data type, the data might not be printable. If the partition is empty, the value is a string of length 0.	S
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second lowest value of the column within the partition. Blank if statistics have not been gathered or the column is an indicator column, a node ID column, or a column of an XML table. If the column has a non-character data type, the data might not be printable. If the partition is empty, the value is a string of length 0.	S
COLCARD	INTEGER NOT NULL	Number of distinct column values in the partition.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. If the value is '0001-01-02.00.00.000000', which indicates that an ALTER TABLE statement was executed to change the length of a VARCHAR column, RUNSTATS should be run to update the statistics before they are used.	G
IBMRQD	CHAR(1) NOT NULL	Whether the row came from the basic machine-readable material (MRM) tape: N No Y Yes	G
PARTITION	SMALLINT NOT NULL	Partition number for the table space that contains the table in which the column is defined.	G
TBOWNER	VARCHAR(128) NOT NULL	Schema or qualifier of the table that contains the column.	G

Column name	Data type	Description	Use
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
NAME	VARCHAR(128) NOT NULL	Name of the column.	G
COLCARDDATA	VARCHAR(1000) NOT NULL WITH DEFAULT FOR BIT DATA	Internal use only	I
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	<p>The type of statistics gathered:</p> <p><b>blank</b> Statistics have not been collected or varchar column statistical values are padded.</p> <p><b>N</b> Varchar column statistical values are not padded.</p> <p>This is an updatable column.</p>	G

## SYSIBM.SYSCOLUMNS table

The SYSIBM.SYSCOLUMNS table contains one row for every column of each table and view.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table or view which contains the column.	G
TBCREATOR	VARCHAR(128) NOT NULL	The schema of the table or view that contains the column.	G
COLNO	SMALLINT NOT NULL	Numeric place of the column in the table or view; for example 4 (out of 10).	G

Column name	Data type	Description	Use
COLTYPE	CHAR(8) NOT NULL	The type of the column specified in the definition of the column:	G
	<b>INTEGER</b>	Large integer	
	<b>SMALLINT</b>	Small integer	
	<b>FLOAT</b>	Floating-point	
	<b>CHAR</b>	Fixed-length character string	
	<b>VARCHAR</b>	Varying-length character string	
	<b>LONGVAR</b>	Varying-length character string (for columns that were added before Version 9)	
	<b>DECIMAL</b>	Decimal	
	<b>GRAPHIC</b>	Fixed-length graphic string	
	<b>VARG</b>	Varying-length graphic string	
	<b>LONGVARG</b>	Varying-length graphic string (for columns that were added before Version 9)	
	<b>DATE</b>	Date	
	<b>TIME</b>	Time	
	<b>TIMESTAMP</b>	Timestamp	
	<b>BLOB</b>	Binary large object	
	<b>CLOB</b>	Character large object	
	<b>DBCLOB</b>	Double-byte character large object	
	<b>ROWID</b>	Row ID data type	
	<b>DISTINCT</b>	Distinct type	
	<b>XML</b>	XML data type	
	<b>BIGINT</b>	Big integer	
	<b>BINARY</b>	Fixed-length binary string	
	<b>VARBIN</b>	Varying-length binary string	
	<b>DECFLOAT</b>	Decimal floating point	

Column name	Data type	Description	Use
LENGTH	SMALLINT NOT NULL	Length attribute of the column or, in the case of a decimal column, its precision. The number does not include the internal prefixes that are used to record the actual length and null state, where applicable.	G
	INTEGER 4		
	SMALLINT 2		
	BIGINT 8		
	FLOAT 4 or 8		
	CHAR Length of string		
	VARCHAR Maximum length of string		
	LONGVAR Maximum length of string (for columns that were added before Version 9)		
	DECIMAL Precision of number		
	DECFLOAT 8 or 16		
	GRAPHIC Number of DBCS characters		
	VARGRAPHIC Maximum number of DBCS characters		
	LONGVARG Maximum number of DBCS characters (for columns that were added before Version 9)		
	BINARY Length of string		
	VARBINARY Maximum length of string		
	DATE 4		
	TIME 3		
	TIMESTAMP 10		
LENGTH (continued)	SMALLINT NOT NULL	<b>BLOB</b> 4 - For a table, a field of length of 4 is stored in the base table. The maximum length of the LOB column is found in LENGTH2.  <b>CLOB</b> 4 - For a table, a field of length of 4 is stored in the base table. The maximum length of the CLOB column is found in LENGTH2.  <b>DBCLOB</b> 4 - For a table, a field of length of 4 is stored in the base table. The maximum length of the DBCLOB column is found in LENGTH2.	G
		<b>ROWID</b> 17 - The maximum length of the stored portion of the identifier.	
	XML 6		
	DISTINCT	The length of the source data type.	
SCALE	SMALLINT NOT NULL	Scale of decimal data. Zero if not a decimal column.	G

Column name	Data type	Description	Use
NULLS		Whether the column can contain null values: N No Y Yes	G
	CHAR(1) NOT NULL	The value can be N for a view column that is derived from an expression or a function. Nevertheless, such a column allows nulls when an outer select list refers to it.	
	INTEGER NOT NULL	Not used	N
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second highest value of the column. Blank if statistics have not been gathered, or the column is an indicator column or a column of an auxiliary table. If the column has a non-character data type, the data might not be printable. If the table is empty, the value is a string of length 0. This is an updatable column.	S
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second lowest value of the column. Blank if statistics have not been gathered, or the column is an indicator column or a column of an auxiliary table. If the column has a non-character data type, the data might not be printable. If the table is empty, the value is a string of length 0. This is an updatable column.	S
UPDATES		Whether the column can be updated: N No Y Yes	G
	CHAR(1) NOT NULL	The value is N if the column is: <ul style="list-style-type: none"><li>• Derived from a function or expression</li><li>• A column with a row ID data type (or a distinct type based on a row ID type)</li><li>• A read-only view</li></ul>	
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
REMARKS	VARCHAR(762) NOT NULL	A character string provided by the user with the COMMENT statement.	G

Column name	Data type	Description	Use
DEFAULT	CHAR(1) NOT NULL	The contents of this column are meaningful only if the TYPE column for the associated SYSTABLES row indicates that this is for a table (T) or a created temporary table (G).	G
		Default indicator:	
	A	The column has a row ID data type (COLTYPE='ROWID') and the GENERATED ALWAYS attribute.	
	B	The column has a default value that depends on the data type of the column.	
		<b>Data type</b>	
		<b>Default Value</b>	
	Numeric		
		0	
	Fixed-length character or graphic string		
		Blanks	
	Fixed-length binary string		
		Hexadecimal zeros	
	Varying-length string		
		A string length of 0	
	Date	The current date	
	Time	The current time	
	Timestamp	The current timestamp	
	D	The column has a row ID data type (COLTYPE='ROWID') and the GENERATED BY DEFAULT attribute.	
	E	The column is defined with the FOR EACH ROW ON UPDATE and GENERATED ALWAYS attributes.	
	F	The column is defined with the FOR EACH ROW ON UPDATE and GENERATED BY DEFAULT attributes.	
	I	The column is defined with the AS IDENTITY and GENERATED ALWAYS attributes.	
	J	The column is defined with the AS IDENTITY and GENERATED BY DEFAULT attributes.	
	K	The column is defined for the implicit DOCID column for a base table that contains XML data.	
	L	The column is defined with the AS SECURITY LABEL attribute.	
	N	The column has no default value.	

Column name	Data type	Description	Use																		
DEFAULT (continued)		Default indicator:	G																		
	CHAR(1) NOT NULL	<p><b>S</b> The column has a default value that is the value of the SQL authorization ID of the process at the time a default value is used.</p> <p><b>U</b> The column has a default value that is the value of the SESSION_USER special register at the time a default value is used.</p> <p><b>Y</b> If the NULLS column is Y, the column has a default value of null. If the NULLS column is N, the default value depends on the data type of the column.</p>																			
		<table> <thead> <tr> <th>Data type</th><th>Default Value</th></tr> </thead> <tbody> <tr> <td>Numeric</td><td>0</td></tr> <tr> <td>Fixed-length character string</td><td>Blanks</td></tr> <tr> <td>Fixed-length graphic string</td><td>Blanks</td></tr> <tr> <td>Fixed-length binary string</td><td>Hexadecimal blanks</td></tr> <tr> <td>Varying-length string</td><td>A string length of 0</td></tr> <tr> <td>Date</td><td>The current date</td></tr> <tr> <td>Time</td><td>The current time</td></tr> <tr> <td>Timestamp</td><td>The current timestamp</td></tr> </tbody> </table>	Data type	Default Value	Numeric	0	Fixed-length character string	Blanks	Fixed-length graphic string	Blanks	Fixed-length binary string	Hexadecimal blanks	Varying-length string	A string length of 0	Date	The current date	Time	The current time	Timestamp	The current timestamp	
Data type	Default Value																				
Numeric	0																				
Fixed-length character string	Blanks																				
Fixed-length graphic string	Blanks																				
Fixed-length binary string	Hexadecimal blanks																				
Varying-length string	A string length of 0																				
Date	The current date																				
Time	The current time																				
Timestamp	The current timestamp																				
		<p><b>1</b> The column has a default value that is the string constant found in the DEFAULTVALUE column of this table row.</p> <p><b>2</b> The column has a default value that is the floating-point constant found in the DEFAULTVALUE column of this table row.</p> <p><b>3</b> The column has a default value that is the decimal constant found in the DEFAULTVALUE column of this table row.</p> <p><b>4</b> The column has a default value that is the integer constant found in the DEFAULTVALUE column of this table row.</p> <p><b>5</b> The column has a default value that is the hexadecimal character string found in the DEFAULTVALUE column of this table row.</p>																			

Column name	Data type	Description	Use
DEFAULT (continued)		Default indicator:	G
	CHAR(1) NOT NULL	<p><b>6</b> The column has a default value that is the UX string found in the DEFAULTVALUE column of this table row.</p> <p><b>7</b> The column has a graphic data type and has a default value that is the character string constant found in the DEFAULTVALUE column of this table row.</p> <p><b>8</b> The column has a character data type and has a default value that is the graphic string constant found in the DEFAULTVALUE column of this table row.</p> <p><b>9</b> The column has a default value that is the DECFLOAT constant found in the DEFAULTVALUE column of this table row.</p>	
KEYSEQ	SMALLINT NOT NULL	The numeric position of the column within the primary key of the table. The value is 0 if it is not part of a primary key.	G
FOREIGNKEY	CHAR(1) NOT NULL	<p>Applies to character or CLOB columns, where it indicates the subtype of the data:</p> <p><b>B</b> BIT data</p> <p><b>M</b> MIXED data</p> <p><b>S</b> SBCS data</p> <p><b>blank</b> Indicates one of the following subtypes:</p> <ul style="list-style-type: none"> <li>MIXED data if the encoding scheme is UNICODE, or if the encoding scheme is not UNICODE and the value of MIXED DATA on installation panel DSNTIPS is YES</li> <li>SBCS data if the encoding scheme is not UNICODE and the value of MIXED DATA on the installation panel DSNTIPS is NO.</li> </ul> <p>For views defined prior to Version 7, subtype information is not available and the default (MIXED or SBCS) is used. This is an updatable column.</p>	G
FLDPROC	CHAR(1) NOT NULL	<p>Whether the column has a field procedure:</p> <p><b>N</b> No</p> <p><b>Y</b> Yes</p> <p><b>blank</b> The column is for a view defined prior to Version 7. Views defined after Version 7 contain Y or N.</p>	G
LABEL	VARCHAR(90) NOT NULL	The column label provided by the user with a LABEL statement; otherwise, the value is an empty string.	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'. If the value is '0001-01-02.00.00.00.000000', which indicates that an ALTER TABLE statement was executed to change the length of a VARCHAR column, RUNSTATS should be run to update the statistics before they are used. This is an updatable column.	G

Column name	Data type	Description	Use
DEFAULTVALUE	VARCHAR(1536) NOT NULL WITH DEFAULT	This field is meaningful only if the column being described is for a table (the TYPE column of the associated SYSTABLES row is T for table or G for created temporary table).	G
		When the DEFAULT column is 1, 2, 3, 4, 5, 6, 7, 8, or 9, this field contains the default value of the column.	
		If the default value is a string constant or a hexadecimal constant (DEFAULT is 1, 5, 6, 7, or 8 respectively), the value is stored without delimiters.	
		If the default value is a numeric constant (DEFAULT is 2, 3, 4, or 9), the value is stored as specified by the user, including sign and decimal point representation, or special constant values, as appropriate for the constant.	
		When the DEFAULT column is S or U and the default value was specified when a new column was defined with the ALTER TABLE statement, this field contains the value of the CURRENT_SQLID or SESSION_USER special register at the time the ALTER TABLE statement was executed. Remember that this default value applies only to rows that existed before the ALTER TABLE statement was executed.	
		When the DEFAULT column is L and the column was added as a new column with the ALTER TABLE statement, this field contains the security label of the user at the time the ALTER TABLE statement was executed. Remember that this default value applies only to rows that existed before the ALTER TABLE statement was executed.	
COLCARDF	FLOAT NOT NULL WITH DEFAULT	Estimated number of distinct values in the column. For an indicator column, this is the number of LOBs that are not null and have a length greater than zero. The value is -1 if statistics have not been gathered. The value is -2 for the first column of an index of an auxiliary table. This is an updatable column.	S
COLSTATUS	CHAR(1) NOT NULL WITH DEFAULT	Indicates the status of the definition of a column:  I      The definition is incomplete because a LOB table space, auxiliary table, or index on an auxiliary table has not been created for the column.  blank    The definition is complete.	G
LENGTH2	INTEGER NOT NULL WITH DEFAULT	Maximum length of the data retrieved from the column. Possible values are:  0      Column is not a LOB or ROWID column 40     For a ROWID column, the length of the returned value  <b>1 to 2,147,483,647 bytes</b> For a LOB column, the maximum length	G
DATATYPEID	INTEGER NOT NULL WITH DEFAULT	For a built-in data type, the internal ID of the built-in type. For a distinct type, the internal ID of the distinct type.  If the column was created prior to Version 6, the value is 0.	S

Column name	Data type	Description	Use
SOURCETYPEID	INTEGER NOT NULL WITH DEFAULT	For a built-in data type, 0. For a distinct type, the internal ID of the built-in data type upon which the distinct type is based.  If the column was created prior to Version 6, the value is 0.	S
TYPESCHEMA	VARCHAR(128) NOT NULL WITH DEFAULT 'SYSIBM'	If COLTYPE is 'DISTINCT', the schema of the distinct type. Otherwise, the value is 'SYSIBM'.	G
TYPENAME	VARCHAR(128) NOT NULL WITH DEFAULT	If COLTYPE is 'DISTINCT', the name of the distinct type. Otherwise, the value is the same as the value of the COLTYPE column. TYPENAME is set only for columns created in Version 6 or later. The value for columns created earlier is not filled in.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Timestamp when the column was created. The value is '0001-01-01.00.00.00.000000' if the column was created prior to migration to Version 6 or if the column is in a catalog table.	G
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	The type of statistics gathered:  <b>blank</b> Statistics have not been collected or varchar column statistical values are padded. <b>N</b> Varchar column statistical values are not padded. This is an updatable column.	G
PARTKEY_COLSEQ	SMALLINT NOT NULL WITH DEFAULT	The numeric position of the column within the partitioning key of the table. The value is 0 if it is not part of the partitioning key.  This column is applicable only if the table uses table-controlled partitioning.	G
PARTKEY_ORDERING	CHAR(1) NOT NULL WITH DEFAULT	Order of the column in the partitioning key:  <b>A</b> Ascending <b>D</b> Descending <b>blank</b> Column is not used as part of a partitioning key  This column is applicable only if the table uses table-controlled partitioning.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Timestamp when alter occurred.	G
CCSID	INTEGER NOT NULL WITH DEFAULT	CCSID of the column. 0 if the object was created prior to Version 8 or is not a string column	G
HIDDEN	CHAR(1) NOT NULL WITH DEFAULT 'N'	Indicates whether the column is implicitly hidden:  <b>P</b> Partially hidden. The column is implicitly hidden from SELECT *. <b>N</b> Not hidden. The column is visible to all SQL statements.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSCOLUMNS\_HIST table

The SYSIBM.SYSCOLUMNS\_HIST table contains rows from SYSCOLUMNS.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table or view that contains the column.	G
TBCREATOR	VARCHAR(128) NOT NULL	Schema or qualifier of the table or view that contains the column.	G
COLNO	SMALLINT NOT NULL	Numeric place of the column in the table or view. For example 4 (out of 10).	G

Column name	Data type	Description	Use
COLTYPE		The type of the column specified in the definition of the column:	G
	CHAR(8)	<b>INTEGER</b>	
	NOT NULL	Large integer	
		<b>SMALLINT</b>	
		Small integer	
		<b>FLOAT</b>	Floating-point
		<b>CHAR</b>	Fixed-length character string
		<b>VARCHAR</b>	Varying-length character string
		<b>LONGVAR</b>	Varying-length character string (for columns that were added before Version 9)
		<b>DECIMAL</b>	
		Decimal	
		<b>GRAPHIC</b>	
		Fixed-length graphic string	
		<b>VARG</b>	Varying-length graphic string
		<b>LONGVARG</b>	Varying-length graphic string (for columns that were added before Version 9)
		<b>DATE</b>	Date
		<b>TIME</b>	Time
		<b>TIMESTAMP</b>	Timestamp
		<b>BLOB</b>	Binary large object
		<b>CLOB</b>	Character large object
		<b>DBCLOB</b>	Double-byte character large object
		<b>ROWID</b>	Row ID data type
		<b>DISTINCT</b>	Distinct type
		<b>XML</b>	XML data type
		<b>BIGINT</b>	Big integer
		<b>BINARY</b>	Fixed-length binary string
		<b>VARBIN</b>	Varying-length binary string
		<b>DECFLOAT</b>	Decimal floating point

Column name	Data type	Description	Use
LENGTH	SMALLINT NOT NULL	Length attribute of the column or, in the case of a decimal column, its precision. The number does not include the internal prefixes that are used to record the actual length and null state, where applicable.	G
	INTEGER 4		
	SMALLINT 2		
	FLOAT 4 or 8		
	CHAR Length of string		
	VARCHAR	Maximum length of string	
	LONGVAR		
		Maximum length of string (for columns that were added before Version 9)	
	DECIMAL	Precision of number	
	GRAPHIC	Number of DBCS characters	
	VARGRAPHIC	Maximum number of DBCS characters	
	LONGVARG	Maximum number of DBCS characters (for columns that were added before Version 9)	
	DATE 4		
	TIME 3		
	TIMESTAMP		
		10	
	BLOB	4 - The length of the field that is stored in the base table. The maximum length of the LOB column is found in LENGTH2.	
	CLOB	4 - The length of the field that is stored in the base table. The maximum length of the CLOB	
	DBCLOB		
		4 - The length of the field that is stored in the base table. The maximum length of the DBCLOB column is found in LENGTH2.	
	ROWID		
		17 - The maximum length of the stored portion of the identifier.	
	DISTINCT		
		The length of the source data type.	
	XML 6		
	BIGINT		
		8	
	BINARY		
		The length of the string	
	VARBINARY		
		The maximum length of string	
	DECFLOAT		
		8 or 16	
LENGTH2	INTEGER NOT NULL	Maximum length of the data retrieved from the column. Possible values are: <b>0</b> Column is not a LOB or ROWID column <b>40</b> For a ROWID column, the length of the returned value <b>1 to 2 147 483 647 bytes</b> For a LOB column, the maximum length	G

Column name	Data type	Description	Use
NULLS	CHAR(1) NOT NULL	Whether the column can contain null values:  N No Y Yes	G
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second highest value of the column. Blank if statistics have not been gathered, or the column is an indicator column or a column of an auxiliary table. If the column has a non-character data type, the data might not be printable.	S
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	Second lowest value of the column. Blank if statistics have not been gathered, or the column is an indicator column or a column of an auxiliary table. If the column has a non-character data type, the data might not be printable.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'. If the value is '0001-01-02.00.00.00.000000', which indicates that an ALTER TABLE statement was executed to change the length of a VARCHAR column, RUNSTATS should be run to update the statistics before they are used.	G
COLCARDDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Estimated number of distinct values in the column. For an indicator column, this is the number of LOBs that are not null and have a length greater than zero. The value is -1 if statistics have not been gathered. The value is -2 for the first column of an index of an auxiliary table.	S
IBMRREQD	CHAR(1) NOT NULL DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	The type of statistics gathered:  <b>blank</b> Statistics have not been collected or varchar column statistical values are padded. <b>N</b> Varchar column statistical values are not padded. This is an updatable column.	G

## SYSIBM.SYSCONSTDEP table

The SYSIBM.SYSCONSTDEP table records dependencies on check constraints or user-defined defaults for a column.

Column name	Data type	Description	Use
BNAME	VARCHAR(128) NOT NULL	Name of the object on which the dependency exists.	G
BSHEMA	VARCHAR(128) NOT NULL	Schema of the object on which the dependency exists.	G
BTYPE	CHAR(1) NOT NULL	Type of object on which the dependency exists:  F Function instance	G
DTBNAME	VARCHAR(128) NOT NULL	Name of the table to which the dependency applies.	G
DTBCREATOR	VARCHAR(128) NOT NULL	The schema of the table to which the dependency applies.	G
DCONSTNAME	VARCHAR(128) NOT NULL	If DTTYPE = 'C', the unqualified name of the check constraint. If DTTYPE = 'D', a column name.	G
DTTYPE	CHAR(1) NOT NULL	Type of object:  C Check constraint D User-defined default constant	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DTBOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the table or a zero length string for tables that were created in a DB2 release prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner:  blank Authorization ID R Role	G

## SYSIBM.SYSCONTEXT table

The SYSIBM.SYSCONTEXT table contains one row for each trusted context.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the trusted context.	G
CONTEXTID	INTEGER NOT NULL GENERATED ALWAYS AS IDENTITY	Internal context ID.	G
DEFINER	VARCHAR(128) NOT NULL	Authorization ID or role that defined the trusted context.	G
DEFINERTYPE	CHAR(1) NOT NULL	The type of the definer:  <b>L</b> Role <b>blank</b> Authorization ID	G
SYSTEMAUTHID	VARCHAR(128) NOT NULL	The DB2 primary authorization ID that is used to establish the connection. For remote requests, SYSTEMAUTHID is derived from the system user ID that is provided by an external entity, such as a middleware server.  For local requests, SYSTEMAUTHID depends on one of the following sources of the address space:	G
		<b>BATCH</b> USER parameter on JOB statement	
		<b>RRSAF</b> USER parameter on JOB statement or RACF user	
		<b>TSO</b> TSO logon ID	
DEFAULTROLE	VARCHAR(128) NOT NULL	Name of the trusted context default role.	G
OBJECTOWNERTYPE	CHAR(1) NOT NULL	Whether the ROLE AS OBJECT OWNER AND QUALIFIER clause is specified in the definition of this trusted context:  <b>L</b> ROLE AS OBJECT OWNER AND QUALIFIER is specified. A role owns any object created in the trusted context. The role is used as the default for the CURRENT SCHEMA special register. The role is included in the SQL PATH.  <b>blank</b> ROLE AS OBJECT OWNER is not specified. An authorization ID owns any object created in the trusted context.	G
CREATEDTS	TIMESTAMP NOT NULL	The time when the trusted context is created.	G
ALTEREDTS	TIMESTAMP NOT NULL	The time when the trusted context is last altered.	G

Column name	Data type	Description	Use
ENABLED	CHAR(1) NOT NULL	The status of the trusted context:  Y      Enabled N      Disabled	G
ALLOWPUBLIC	CHAR(1) NOT NULL	Whether the connection is allowed to be reused for PUBLIC:  Y      Connection reuse is allowed N      Connection reuse is not allowed	G
AUTHENTICATE-PUBLIC	CHAR(1) NOT NULL	Whether authentication is required for PUBLIC when ALLOWPUBLIC is Y:  Y      Authentication token is required for PUBLIC. For local requests, the token is the password. For remote requests, the token can be a password, a RACF passticket, or a KERBEROS token  N      Authentication is not required	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
REMARKS	VARCHAR(762) NOT NULL	A character string that is provided using the COMMENT statement.	G
DEFAULT-SECURITYLABEL	VARCHAR(24) NOT NULL	Name of the context default RACF security label.	G

## SYSIBM.SYSCONTEXTAUTHIDS table

The SYSIBM.SYSCONTEXTAUTHIDS table contains one row for each authorization ID with which the trusted context can be used.

Column name	Data type	Description	Use
CONTEXTID	INTEGER NOT NULL	The internal trusted context ID.	G
AUTHID	VARCHAR(128) NOT NULL	The primary authorization ID that can reuse a connection or the RACF profile name that contains the primary authorization IDs that are permitted to use the connection in the identified trusted context. The AUTHID value starts with and is a profile name.	G
AUTHENTICATE	CHAR(1) NOT NULL	Whether authentication is required for the authorization ID in the AUTHID column:  Y     Authentication token is required for the authorization ID. For local requests, the token is the password. For remote requests, the token can be a password, a RACF passticket, or a Kerberos token  N     Authentication is not required	G
ROLE	VARCHAR(128) NOT NULL	The role for the authorization ID in the AUTHID column. The role supersedes the default role that is defined for the trusted context.	G
CREATEDTS	TIMESTAMP NOT NULL	The time when the authorization ID is added to the trusted context.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
SECURITYLABEL	VARCHAR(24) NOT NULL	RACF security label for AUTHID. The security label supersedes the default security label, if any, that is defined for the context.	G

## SYSIBM.SYSCOPY table

The SYSIBM.SYSCOPY table contains information needed for recovery.

Column name	Data type	Description	Use
DBNAME	CHAR(8) NOT NULL	Name of the database.	G
TSNAME	CHAR(8) NOT NULL	Name of the target table space or index space.	G
DSNUM	INTEGER NOT NULL	Data set number within the table space. For partitioned table spaces, this value corresponds to the partition number for a single partition copy, or 0 for a copy of an entire partitioned table space or index space.	G
ICTYPE	CHAR(1) NOT NULL	Type of operation:  A      ALTER B      REBUILD INDEX C      CREATE D      CHECK DATA LOG(NO) (no log records for the range are available for RECOVER utility) E      RECOVER (to current point) F      COPY FULL YES I      COPY FULL NO M      MODIFY RECOVERY utility P      RECOVER TOCOPY or RECOVER TORBA (partial recovery point) Q      QUIESCE R      LOAD REPLACE LOG(YES) S      LOAD REPLACE LOG(NO) T      TERM UTILITY command V      REPAIR VERSIONS utility W      REORG LOG(NO) X      REORG LOG(YES) Y      LOAD LOG(NO) Z      LOAD LOG(YES)	G
		Not used	N
	CHAR(6) NOT NULL		
START_RBA	CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA	A 48-bit positive integer that contains the LRSN of a point in the DB2 recovery log. (The LRSN is the RBA in a non-data-sharing environment.)  <ul style="list-style-type: none"> <li>• For ICTYPE I or F, the starting point for all updates since the image copy was taken</li> <li>• For ICTYPE P, the point after the log-apply phase of point-in-time recovery</li> <li>• For ICTYPE Q, the point after all data sets have been successfully quiesced</li> <li>• For ICTYPE R or S, the end of the log before the start of the LOAD utility and before any data is changed</li> <li>• For ICTYPE T, the end of the log when the utility is terminated</li> <li>• For other values of ICTYPE, the end of the log before the start of the RELOAD phase of the LOAD or REORG utility.</li> </ul>	G

Column name	Data type	Description	Use
FILESEQNO	INTEGER NOT NULL	Tape file sequence number of the copy.	G
DEVTYPE	CHAR(8) NOT NULL	Device type the copy is on.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DSNAME	CHAR(44) NOT NULL	For ICTYPE='P' (RECOVER TOCOPY only), 'I', or 'F', DSNAME contains the data set name. Otherwise, DSNAME contains the name of the database and table space or index space in the form, <i>database-name.space-name</i> , or DSNAME is blank for any row migrated from a DB2 release prior to Version 4.	G
	CHAR(6) NOT NULL	Not used	N
SHRLEVEL	CHAR(1) NOT NULL	SHRLEVEL parameter on COPY (for ICTYPE F or I only):  <b>C</b> Change <b>R</b> Reference <b>blank</b> Does not describe an image copy or was migrated from Version 1 Release 1 of DB2.	G
DSVOLSER	VARCHAR(1784) NOT NULL	The volume serial numbers of the data set. A list of 6-byte numbers separated by commas. Blank if the data set is cataloged.	G
TIMESTAMP	TIMESTAMP NOT NULL WITH DEFAULT	The date and time when the row was inserted. This is the date and time recorded in ICDATE and ICTIME. The use of TIMESTAMP is recommended over that of ICDATE and ICTIME, because the latter two columns might not be supported in later DB2 releases. For the COPYTOCOPY utility, this value is the date and time when the row was inserted for the primary local site or primary recovery site copy. For an EXCHANGE DATA statement, this is the time that the statement is run.	G
ICBACKUP	CHAR(2) NOT NULL WITH DEFAULT	Specifies the type of image copy contained in the data set:  <b>blank</b> LOCALSITE primary copy (first data set named with COPYDDN) <b>LB</b> LOCALSITE backup copy (second data set named with COPYDDN) <b>RP</b> RECOVERYSITE primary copy (first data set named with RECOVERYDDN) <b>RB</b> RECOVERYSITE backup copy (second data set named with RECOVERYDDN)	G
ICUNIT	CHAR(1) NOT NULL WITH DEFAULT	Indicates the media that the image copy data set is stored on:  <b>D</b> DASD <b>T</b> Tape <b>blank</b> Medium is neither tape nor DASD, the image copy is from a DB2 release prior to Version 2 Release 3, or ICTYPE is not 'T' or 'F'.	G

Column name	Data type	Description	Use
STYPE	CHAR(1) NOT NULL WITH DEFAULT	When <b>ICTYPE=A</b> , the values are:  <b>A</b> A partition was added to a table. <b>C</b> A column was added to a table and an index in different commit scopes. <b>E</b> The data set numbers of a base table and its associated clone table are exchanged. <b>G</b> An index was regenerated <b>L</b> The logging attribute of the table space was altered to LOGGED. <b>N</b> An index was altered to not padded <b>O</b> The logging attribute of the table space was altered to NOT LOGGED. <b>P</b> An index was altered to padded <b>R</b> A table was altered to rotate partitions. <b>V</b> A column in a table was altered for a numeric data type change and the column is in an index. <b>Z</b> A column that is in the key of an index that was versioned prior to DB2 Version 8 was altered.	G
		When <b>ICTYPE=C</b> , the values are:  <b>L</b> The logging attribute of the table space was altered to LOGGED. <b>O</b> The logging attribute of the table space was altered to NOT LOGGED.	
		When <b>ICTYPE=F</b> , the values are:  <b>C</b> DFSMS concurrent copy ("I" instance of the table space) <b>J</b> DFSMS concurrent copy ("J" instance of the table space) <b>S</b> LOAD REPLACE(NO) <b>V</b> ALTER INDEX NOT PADDED <b>W</b> REORG LOG(NO) <b>X</b> REORG LOG(YES) <b>blank</b> DB2 image copy	

Column name	Data type	Description	Use
STYPE (continued)		The MERGECOPY utility, when used to merge an embedded copy with subsequent incremental copies, also produces a record that contains ICTYPE=F and the STYPE of the original image copy (R, S, W, or X).	
		When <b>ICTYPE = M</b> and the MODIFY RECOVERY utility was executed to delete SYSCOPY and/or SYSLGRNX records, the value is R.	
		When <b>ICTYPE=P</b> , the values are:	
	C	Recover to a point in time without using logonly with consistency.	
	L	Recover to a point in time using logonly without consistency.	
	M	Recover to a point in time using logonly with consistency.	
	blank	Recover to a point in time without using logonly without consistency.	
		When <b>ICTYPE=Q</b> and option WRITE(YES) is in effect when the quiesce point is taken, the value is W.	
		When <b>ICTYPE=R or S</b> , the values are:	
	A	Resetting REORG pending status	
	T	First materializing the default value for a row change timestamp column	
		When <b>ICTYPE=T</b> , this field indicates which COPY utility was terminated by the TERM UTILITY command or the START DATABASE command with the ACCESS(FORCE) option. The values are:	
	F	COPY FULL YES	
	I	COPY FULL NO	
		When <b>ICTYPE=W or X</b> , the values are:	
	A	Resetting REORG pending status or REBALANCE	
	T	First materializing the default value for a row change timestamp column	
		For other values of ICTYPE, the value is blank.	
PIT_RBA	CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA	When ICTYPE=P, this field contains the LRSN for the point in the DB2 log. (The LRSN is the RBA in a non-data-sharing environment). For other ICTYPES, this field is X'000000000000'.	G
		When ICTYPE=P, this field indicates the stop location of a point-in-time recovery. If a record contains ICTYPE=P and PIT_RBA=X'000000000000', the copy pending status is active and a full image copy is required. If such a record is encountered during fallback processing of RECOVER, the recover job fails, and a point-in-time recovery is required. PIT_RBA can be zero if the point-in-time recovery is completed by the fall-back processing of RECOVER, or if ICTYPE=P from a prior release of DB2.	
		When ICTYPE=F or I and SHRLEVEL=C, this column contains the current RBA or LRSN that corresponds to the point in the DB2 log when the SHRLEVEL CHANGE copy completes.	

Column name	Data type	Description	Use
GROUP_MEMBER	CHAR(8) NOT NULL WITH DEFAULT	The DB2 data sharing member name of the DB2 subsystem that performed the operation. This column is blank if the DB2 subsystem was not in a DB2 data sharing environment at the time the operation was performed.	G
OTYPE	CHAR(1) NOT NULL WITH DEFAULT 'T'	Type of object that the recovery information is for:  I Index space T Table space	G
LOWDSNUM	INTEGER NOT NULL WITH DEFAULT	Partition number of the lowest partition in the range for SYSCOPY records created for REORG and LOAD REPLACE for resetting a REORG pending status. Version number of an index for SYSCOPY records created for a COPY (ICTYPE=F) of an index space (OTYPE=I). (An index is versioned when a VARCHAR column in the index key is lengthened.) When ICTYPE = F or I, DSNUM = 0 and OTYPE is not equal to I, LOWDSNUM = 1.	G
HIGHDSNUM	INTEGER NOT NULL WITH DEFAULT	Partition number of the highest partition in the range. This column is valid only for SYSCOPY records created for REORG and LOAD REPLACE for resetting REORG pending status. When ICTYPE = F or I, DSNUM = 0 and OTYPE is not equal to I, HIGHDSNUM is the number of the highest partition that is copied.	G
COPYPAGESF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of pages written to the copy data set. For inline copies, this number might include pages appearing more than once in the copy data set.	G
NPAGESF	FLOAT(8) NOT NULL WITH DEFAULT -1	The number of pages in the table space or index at the time of COPY. This number might include pre-formatted pages that are not actually copied.	G
CPAGESF	FLOAT(8) NOT NULL WITH DEFAULT -1	Total number of changed pages.	G
JOBNAME	CHAR(8) NOT NULL WITH DEFAULT	Job name of the utility.	G
AUTHID	CHAR(8) NOT NULL WITH DEFAULT	Authorization ID of the utility.	G
OLDEST_VERSION	SMALLINT NOT NULL WITH DEFAULT	When ICTYPE= B, F, I, S, W, or X, the version number of the oldest format of data for an object. For other values of ICTYPE, the value is -1.	G
LOGICAL_PART	INTEGER NOT NULL WITH DEFAULT	Logical partition number.	G

Column name	Data type	Description	Use
LOGGED	CHAR(1) NOT NULL WITH DEFAULT	Indicates the logging attribute of the table space at the time the SYSCOPY record is written: <ul style="list-style-type: none"><li>• Y — indicates that the logging attribute of the table space is LOGGED</li><li>• N — indicates that the logging attribute of the table spaces is NOT LOGGED</li><li>• blank — indicates that the row was inserted prior to Version 9. For a non-LOB table spaces or an index space, blank indicates that the logging attribute is LOGGED.</li></ul>	G
TTYPE	CHAR(8) NOT NULL WITH DEFAULT		G
TTYPE (cont)		<p>When <b>ICTYPE=E</b>, this column indicates if the full recovery reset the object: <b>blank</b> The full recovery reset the object <b>N</b> The full recovery did not reset the object</p> <p>When <b>ICTYPE=I</b>, TTYPE of S indicates that the directory pages for the index image copy are at the front of each partition and are indicated with a 'V' or '8'.</p> <p>When <b>ICTYPE=P, R, S, W, X</b>, this column indicates the row format for the table space or partition. <b>RRF</b> Indicates that the row format is the reordered row format <b>BRF</b> Indicates that the row format is the basic row format</p> <p>When <b>ICTYPE=M and STYPE=R</b>, this column indicates whether the MODIFY RECOVERY utility deleted rows from SYSIBM.SYSLGRNX. <b>blank</b> MODIFY RECOVERY deleted rows from SYSIBM.SYSLGRNX. <b>N</b> MODIFY RECOVERY did not delete rows from SYSIBM.SYSLGRNX.</p> <p>When <b>ICTYPE=T</b>, TTYPE of B indicates that a broken page was detected during copy.</p>	
INSTANCE	SMALLINT NOT NULL WITH DEFAULT 1	When STYPE = E and ICTYPE = A, INSTANCE indicates the data set instance number of a base object after an EXCHANGE statement completes. The value of the INSTANCE column for the last data exchange will match the value of the INSTANCE column for the SYSIBM.SYSTABLESPACE table.	G
		For an image copy, INSTANCE indicates the instance number of the current base objects (table and index).	
RELCREATED	CHAR(1) NOT NULL WITH DEFAULT	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSCTXTRUSTATTRS table

The SYSIBM.SYSCTXTRUSTATTRS table contains one row for each list of attributes for a given trusted context.

Column name	Data type	Description	Use
CONTEXTID	INTEGER NOT NULL	The internal trusted context ID.	G
NAME	VARCHAR(128) NOT NULL	Name of the trust attribute. Possible values including the following attributes: <ul style="list-style-type: none"> <li>An IPv4 address is represented as a dotted decimal IP address. An example of an IPv4 address is '9.112.46.111'.</li> <li>An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0000:0008:0800:200C:417A', which can also be expressed in a compressed form as '2001:DB8::8:800:200C:417A'.</li> <li>A domain name which is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined.</li> <li>A job or started task name for local applications. If the job name ends with *, any job name that matches the characters prior to * in the specified job name are considered for establishing the trusted connection.</li> <li>A network access security zone name in the RACF SERVAUTH class.</li> </ul>	G
VALUE	VARCHAR(254) NOT NULL	The value of the trust attribute.	G
CREATEDTS	TIMESTAMP NOT NULL	The time when the attribute is created.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSDATABASE table

The SYSIBM.SYSDATABASE table contains one row for each database, except for database DSNDB01.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Database name.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the database.	G
STGROU P	VARCHAR(128) NOT NULL	Name of the default storage group of the database; blank for a system database.	G
BPOOL	CHAR(8) NOT NULL	Name of the default buffer pool of the table space; blank for a system table space.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database. If there were 32511 databases or more when this database was created, the DBID is a negative number.	S
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the database.	G
	CHAR(1) NOT NULL WITH DEFAULT	Not used	N
	TIMESTAMP NOT NULL WITH DEFAULT	Not used	N
TYPE	CHAR(1) NOT NULL WITH DEFAULT	Type of database: <b>blank</b> Not a work file database or a TEMP database. <b>W</b> A work file database. The database is DSNDB07, or it was created with the WORKFILE clause and used as a work file database by a member of a DB2 data sharing group.	G
GROUP_MEMBER	VARCHAR(24) NOT NULL WITH DEFAULT	The DB2 data sharing member name of the DB2 subsystem that uses this work file database. This column is blank if the work file database was not created in a DB2 data sharing environment, or if the database is not a work file database as indicated by the TYPE column.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the database. For DSNDB04 and DSNDB06, the value is '1985-04-01.00.00.00.000000'.	G

Column name	Data type	Description	Use
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER DATABASE statement was applied. If no ALTER DATABASE statement has been applied, ALTEREDTS has the value of CREATEDTS.	G
ENCODING_SCHEME	CHAR(1) NOT NULL WITH DEFAULT 'E'	Default encoding scheme for the database: <b>E</b> EBCDIC <b>A</b> ASCII <b>U</b> UNICODE <b>blank</b> For DSNDB04, a work file database, and a TEMP database.	G
SBCS_CCSID	INTEGER NOT NULL WITH DEFAULT	Default SBCS CCSID for the database. For a TEMP database, a work file database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
DBCS_CCSID	INTEGER NOT NULL WITH DEFAULT	Default DBCS CCSID for the database. If mixed data is not used and the CCSID for the database is defined as EBCDIC or ASCII, the default value is 0.  For a TEMP database, a work file database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
MIXED_CCSID	INTEGER NOT NULL WITH DEFAULT	Default mixed CCSID for the database. If mixed data is not used and the CCSID for the database is defined as EBCDIC or ASCII, the default value is 0.  For a TEMP database, a work file database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
INDEXBP	CHAR(8) NOT NULL WITH DEFAULT 'BP0'	Name of the default buffer pool for indexes.	G
IMPLICIT	CHAR(1) NOT NULL WITH DEFAULT 'N'	Indicates whether the database was implicitly created: <b>Y</b> The database was implicitly created <b>N</b> The database was explicitly created	G
CREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>blank</b> Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSDATATYPES table

The SYSIBM.SYSDATATYPES table contains one row for each distinct type defined to the system.

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the distinct type.	G
OWNER	VARCHAR(128) NOT NULL	Owner of the distinct type.	G
NAME	VARCHAR(128) NOT NULL	Name of the distinct type.	G
CREATEDBY	VARCHAR(128) NOT NULL	Primary authorization ID of the user who created the distinct type.	G
SOURCESCHEMA	VARCHAR(128) NOT NULL	Schema of the source data type.	G
SOURCETYPE	VARCHAR(128) NOT NULL	Name of the source type.	G
METATYPE	CHAR(1) NOT NULL	The class of data type: T      Distinct type	G
DATATYPEID	INTEGER NOT NULL	Internal identifier of the distinct type.	S
SOURCETYPEID	INTEGER NOT NULL	Internal ID of the built-in data type on which the distinct type is based.	S
LENGTH	INTEGER NOT NULL	Maximum length or precision of a distinct type that is based on the IBM-defined DECIMAL data type.	G
SCALE	SMALLINT NOT NULL	Scale for a distinct type that is based on the IBM-defined DECIMAL type. For all other distinct types, the value is 0.	G
SUBTYPE	CHAR(1) NOT NULL	Subtype of the distinct type, which is based on the subtype of the source type: <b>B</b> The subtype is FOR BIT DATA. <b>S</b> The subtype is FOR SBCS DATA. <b>M</b> The subtype is FOR MIXED DATA. <b>blank</b> The source type is not a character type.	G
CREATEDTS	TIMESTAMP NOT NULL	Time when the distinct type was created.	G
ENCODING_SCHEME	CHAR(1) NOT NULL	Encoding scheme of the distinct type: <b>A</b> ASCII <b>E</b> EBCDIC <b>U</b> UNICODE	G

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
REMARKS	VARCHAR(762) NOT NULL	A character string provided by the user with the COMMENT statement.	G
OWNER TYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>b</b> lank Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSDBAUTH table

The SYSIBM.SYSDBAUTH table records the privileges that are held by users over databases.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID or role of the user who granted the privileges. Could also be PUBLIC or PUBLIC followed by an asterisk. (PUBLIC followed by an asterisk (PUBLIC*) denotes PUBLIC AT ALL LOCATIONS. For the conditions where GRANTOR can be PUBLIC or PUBLIC*, see <i>DB2 Administration Guide</i> .)	G
GRANTEE	VARCHAR(128) NOT NULL	Application ID of the user who holds the privilege. Could also be PUBLIC for a grant to PUBLIC.	G
NAME	VARCHAR(24) NOT NULL	Database name.	G
	CHAR(12) NOT NULL	Internal use only	I
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N
GRANTEETYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantee: <b>blank</b> Authorization ID <b>L</b> Role	G
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor. <b>blank</b> Not applicable <b>C</b> DBCTRL <b>D</b> DBADM <b>L</b> SYSCTRL <b>M</b> DBMAINT <b>S</b> SYSADM	G
CREATETABAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can create tables within the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
CREATETSAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can create table spaces within the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

Column name	Data type	Description	Use
DBADMAUTH	CHAR(1) NOT NULL	Whether the GRANTEE has DBADM authority over the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DBCTRLAUTH	CHAR(1) NOT NULL	Whether the GRANTEE has DBCTRL authority over the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DBMAINTAUTH	CHAR(1) NOT NULL	Whether the GRANTEE has DBMAINT authority over the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DISPLAYBAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can issue the DISPLAY command for the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DROPAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can issue the ALTER DATABASE and DROP DATABASE statement: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IMAGCOPYAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the COPY, MERGECOPY, MODIFY, and QUIESCE utilities on the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
LOADAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the LOAD utility to load tables in the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
REORGAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the REORG utility to reorganize table spaces and indexes in the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
RECOVERDBAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the RECOVER and REPORT utilities on table spaces in the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
REPAIRAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the DIAGNOSE and REPAIR utilities on table spaces and indexes in the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

Column name	Data type	Description	Use
STARTDBAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the START command against the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
STATSAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the CHECK and RUNSTATS utilities against the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
STOPAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can issue the STOP command against the database: <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed.	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSDBRM table

The SYSIBM.SYSDBRM table contains one row for each DBRM of each application plan.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Name of the DBRM.	G
TIMESTAMP	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	Consistency token.	S
PDSNAME	VARCHAR(132) NOT NULL	Name of the partitioned data set of which the DBRM is a member.	G
PLNAME	VARCHAR(24) NOT NULL	Name of the application plan of which this DBRM is a part.	G
PLCREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the application plan.	G
	CHAR(8) NOT NULL	Not used	N
	CHAR(6) NOT NULL	Not used	N
QUOTE	CHAR(1) NOT NULL	SQL string delimiter for the SQL statements in the DBRM:  N      Apostrophe Y      Quotation mark	G
COMMA	CHAR(1) NOT NULL	Decimal point representation for SQL statements in the DBRM:  N      Period Y      Comma	G
HOSTLANG	CHAR(1) NOT NULL	The host language used:  B      Assembler language C      OS/VS COBOL D      C F      Fortran P      PL/I 2      VS COBOL II or IBM COBOL Release 1 (formerly called COBOL/370) 3      IBM COBOL (Release 2 or subsequent releases) 4      C++	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CHARSET	CHAR(1) NOT NULL WITH DEFAULT	Indicates whether the system CCSID for SBCS data was 290 (Katakana) when the program was precompiled:  A      No K      Yes	G

Column name	Data type	Description	Use
MIXED	CHAR(1) NOT NULL WITH DEFAULT	Indicates if mixed data was in effect when the application program was precompiled (for more on when mixed data is in effect, see "Character strings" on page 73):  N No Y Yes	G
DEC31	CHAR(1) NOT NULL WITH DEFAULT	Indicates whether DEC31 was in effect when the program was precompiled (for more on when DEC31 is in effect, see "Arithmetic with two decimal operands" on page 183):  blank No Y Yes	G
VERSION	VARCHAR(122) NOT NULL WITH DEFAULT	Version identifier for the DBRM.	G
PRECOMPTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the DBRM was precompiled.	G
PLCREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator:  blank Authorization ID L Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSDEPENDENCIES table

The SYSIBM.SYSDEPENDENCIES table records the dependencies between objects.

Column name	Data type	Description	Use
BNAME	VARCHAR(128) NOT NULL	Name of the object on which another object is dependent.  If BTTYPE is F, the name is the specific name of the function.	G
BSHEMA	VARCHAR(128) NOT NULL	Schema or qualifier of the object on which another object is dependent.	G
BCOLNAME	VARCHAR(128) NOT NULL WITH DEFAULT	Column name of the object on which another object is dependent.	G
BCOLNO	SMALLINT NOT NULL WITH DEFAULT	Column number of the object on which another object is dependent.	G
BTYPE	CHAR(1) NOT NULL	The type of object that is identified by BNAME, BSHEMA, and BCOLNAME:  F Function	G
BOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the object on which another object is dependent.	G
BOWNERTYPE	CHAR(1) NOT NULL	Type of creator of the object on which another object is dependent:  L Role blank Authorization ID that is not a role	G
DNAME	VARCHAR(128) NOT NULL	Name of the object that has dependencies on another object.	G
DSHEMA	VARCHAR(128) NOT NULL	Schema or qualifier of the object that has dependencies on another object.	G
DCOLNAME	VARCHAR(128) NOT NULL	Column name of the object that has dependencies on another object.	G
DCOLNO	SMALLINT NOT NULL WITH DEFAULT	Column number of the object that has dependencies on another object.	G
DTYPE	CHAR(1) NOT NULL	The type of the object that is identified by DSHEMA, DNAME, and DCOLNAME:  I Index	G
DOWNER	VARCHAR(128) NOT NULL	Authorization ID of the owner of the object that has dependencies on another object.	G

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
DOWNERTYPE	CHAR(1) NOT NULL	Type of creator of the object that has dependencies on another object: <b>L</b> Role <b>blank</b> Authorization ID if not a role	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSDUMMY1 table

The SYSIBM.SYSDUMMY1 table contains one row. The table is used for SQL statements in which a table reference is required, but the contents of the table are not important.

Unlike the other catalog tables, which reside in Unicode table spaces, SYSIBM.SYSDUMMY1 resides in table space SYSEBCDC, which is an EBCDIC table space.

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSENVIRONMENT table

The SYSIBM.SYSENVIRONMENT table records the environment variables when an object is created.

Column name	Data type	Description	Use
ENVID	INTEGER NOT NULL	Internal identifier of the environment.	G
CURRENT_SCHEMA	VARCHAR(128) NOT NULL	The current schema.	G
RELCREATED	CHAR(1) NOT NULL	The release when the environment information is created. SeeRelease dependency indicators for values.	G
PATHSCHEMAS	VARCHAR(2048) NOT NULL	The schema path.	G
APPLICATION_ENCODING_CCSID	INTEGER NOT NULL	The CCSID of the application environment.	G
ORIGINAL_ENCODING_CCSID	INTEGER NOT NULL	The original CCSID of the statement text string.	G
DECIMAL_POINT	CHAR(1) NOT NULL	The decimal point indicator: <b>C</b> Comma <b>P</b> Period	G
MIN_DIVIDE_SCALE	CHAR(1) NOT NULL	The minimum divide scale: <b>N</b> The usual rules apply for decimal division in SQL <b>Y</b> Retain at least three digits to the right of the decimal point after any decimal division.	G
STRING_DELIMITER	CHAR(1) NOT NULL	The string delimiter that is used in COBOL string constants: <b>A</b> Apostrophe ('') <b>Q</b> Quote ("")	G
SQL_STRING_DELIMITER	CHAR(1) NOT NULL	The SQL string delimiter that is used in string constants: <b>A</b> Apostrophe ('') <b>Q</b> Quote ("")	G
MIXED_DATA	CHAR(1) NOT NULL	Uses mixed DBCS data: <b>N</b> No mixed data <b>Y</b> Mixed data	G
DECIMAL_ARITHMETIC	CHAR(1) NOT NULL	The rules that are to be used for CURRENT PRECISION and when both operands in a decimal operation have a precision of 15 or less: <b>1</b> DEC15 specifies that the rules do not allow a precision greater than 15 digits <b>2</b> DEC31 specifies that the rules allow a precision of up to 31 digits	G

Column name	Data type	Description	Use
DATE_FORMAT	CHAR(1) NOT NULL	The date format:  I ISO - yyyy-mm-dd J JIS - yyyy-mm-dd U USA - mm/dd/yyyy E EUR - dd.mm.yyyy L Locally defined by an installation exit routine	G
TIME_FORMAT	CHAR(1) NOT NULL	The time format:  I ISO - hh.mm.ss J JIS - hh.mm.ss U USA - hh:mm AM or hh:mm PM E EUR - hh.mm.ss L Locally defined by an installation exit routine	G
FLOAT_FORMAT	CHAR(1) NOT NULL	The floating point format:  I IEEE floating point format S System/390 floating point format	G
HOST_LANGUAGE	CHAR(8) NOT NULL	The host language:  • ASM • C • CPP • IBMCOB • PLI • FORTRAN	G
CHARSET	CHAR(1) NOT NULL	The character set:  A Alphanumeric	G
FOLD	CHAR(1) NOT NULL	FOLD is only applicable when HOST_LANGUAGE is C or CPP. Otherwise FOLD is blank.  N Lower case letters in SBCS ordinary identifiers are not folded to uppercase Y Lower case letters in SBCS ordinary identifiers are folded to uppercase blank Not applicable	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
ROUNDING	CHAR(1) NOT NULL WITH DEFAULT	The rounding mode that is used when arithmetic and casting operations are performed on DECFLOAT data:  C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP	G

## SYSIBM.SYSFIELDS table

The SYSIBM.SYSFIELDS table contains one row for every column that has a field procedure.

Column name	Data type	Description	Use
TBCREATOR	VARCHAR(128) NOT NULL	Schema or qualifier of the table that contains the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
COLNO	SMALLINT NOT NULL	Numeric place of this column in the table.	G
NAME	VARCHAR(128) NOT NULL	Name of the column.	G
FLDTYPE	VARCHAR(24) NOT NULL	Data type of the encoded values in the field (This columns might contain statistical values from a prior release.): <b>INTEGER</b> Large integer <b>SMALLINT</b> Small integer <b>FLOAT</b> Floating-point <b>CHAR</b> Fixed-length character string <b>VARCHAR</b> Varying-length character string <b>DECIMAL</b> Decimal <b>GRAPHIC</b> Fixed-length graphic string <b>VARG</b> Varying-length graphic string	G
LENGTH	SMALLINT NOT NULL	The length attribute of the field; or, for a decimal field, its precision.(This columns might contain statistical values from a prior release.) The number does not include the internal prefixes that can be used to record actual length and null state. <b>INTEGER</b> 4 <b>SMALLINT</b> 2 <b>FLOAT</b> 8 <b>CHAR</b> Length of string <b>VARCHAR</b> Maximum length of string <b>DECIMAL</b> Precision of number <b>GRAPHIC</b> Number of DBCS characters <b>VARG</b> Maximum number of DBCS characters	G
SCALE	SMALLINT NOT NULL	Scale if FLDTYPE is DECIMAL; otherwise, the value is 0.	G

Column name	Data type	Description	Use
FLDPROC	VARCHAR(24) NOT NULL	For a row describing a field procedure, the name of the procedure. (This column might contain statistical values from a prior release.)	G
WORKAREA	SMALLINT NOT NULL	For a row describing a field procedure, the size, in bytes, of the work area required for the encoding and decoding of the procedure. (This column might contain statistical values from a prior release.)	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
EXITPARML	SMALLINT NOT NULL	For a row describing a field procedure, the length of the field procedure parameter value block. (This column might contain statistical values from a prior release.)	G
PARMLIST	VARCHAR(735) NOT NULL	For a row describing a field procedure, the parameter list following FIELDPROC in the statement that created the column, with insignificant blanks removed. (This column might contain statistical values from a prior release.)	G
EXITPARM	VARCHAR(1530) NOT NULL WITH DEFAULT FOR BIT DATA	For a row describing a field procedure, the parameter value block of the field procedure (the control block passed to the field procedure when it is invoked). (This column might contain statistical values from a prior release.)	G

## SYSIBM.SYSFOREIGNKEYS table

The SYSIBM.SYSFOREIGNKEYS table contains one row for every column of every foreign key.

Column name	Data type	Description	Use
CREATOR	VARCHAR(128) NOT NULL	Schema or qualifier of the table that contains the column.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table that contains the column.	G
RELNAME	VARCHAR(128) NOT NULL	Constraint name for the constraint for which the column is part of the foreign key.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the column.	G
COLNO	SMALLINT NOT NULL	Numeric place of the column in its table.	G
COLSEQ	SMALLINT NOT NULL	Numeric place of the column in the foreign key.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSINDEXES table

The SYSIBM.SYSINDEXES table contains one row for every index.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the index.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the index.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the index is defined.	G
TBCREATOR	VARCHAR(128) NOT NULL	The schema of the table.	G
UNIQUERULE	CHAR(1) NOT NULL	Whether the index is unique:  D No (duplicates are allowed) U Yes P Yes, and it is a primary index (As in prior releases of DB2, a value of P is used for primary keys that are used to enforce a referential constraint.) C Yes, and it is an index used to enforce UNIQUE constraint N Yes, and it is defined with UNIQUE WHERE NOT NULL R Yes, and it is an index used to enforce the uniqueness of a non-primary parent key G Yes, and it is an index used to enforce the uniqueness of values in a column defined as ROWID GENERATED BY DEFAULT X Yes, and it is an index used to enforce the uniqueness of values in a column that is used to identify or find XML values associated with a specific row.	G
COLCOUNT	SMALLINT NOT NULL	The number of columns in the key.	G
CLUSTERING	CHAR(1) NOT NULL	Whether CLUSTER was specified for the index:  N No Y Yes	G
CLUSTERED	CHAR(1) NOT NULL	Whether the table is actually clustered by the index:  N A significant number of rows are not in clustering order, or statistics have not been gathered. Y Most of the rows are in clustering order. blank Not applicable. This is an updatable column that can also be changed by the RUNSTATS utility.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database.	S

Column name	Data type	Description	Use
OBID	SMALLINT NOT NULL	Internal identifier of the index fan set descriptor.	S
ISOBID	SMALLINT NOT NULL	Internal identifier of the index page set descriptor.	S
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the index.	G
INDEXSPACE	VARCHAR(24) NOT NULL	Name of the index space.	G
	INTEGER NOT NULL	Not used	N
	INTEGER NOT NULL	Not used	N
NLEAF	INTEGER NOT NULL	Number of active leaf pages in the index. The value is -1 if statistics have not been gathered. This is an updatable column.	S
NLEVELS	SMALLINT NOT NULL	Number of levels in the index tree. If the index is partitioned, it is the maximum of the number of levels in the index tree for all the partitions. The value is -1 if statistics have not been gathered. This is an updatable column.	S
BPOOL	CHAR(8) NOT NULL	Name of the buffer pool used for the index.	G
PGSIZE	SMALLINT NOT NULL	Contains the value 4, 8, 16, or 32 which indicates the size, in KB, of the leaf pages in the index.	G
		If the index was created prior to Version 9, the value will be 4096 for a 4 KB page size.	
ERASERULE	CHAR(1) NOT NULL	Whether the data sets are erased when dropped. The value is meaningless if the index is partitioned: N No Y Yes	G
	VARCHAR(24) NOT NULL	Not used	N
CLOSERULE	CHAR(1) NOT NULL	Whether the data sets are candidates for closure when the limit on the number of open data sets is reached: N No Y Yes	G
SPACE	INTEGER NOT NULL	Number of kilobytes of DASD storage allocated to the index, as determined by the last execution of the STOSPACE utility. The value is 0 if the index is not related to a storage group, or if STOSPACE has not been run. If the index space is partitioned, the value is the total kilobytes of DASD storage allocated to all partitions that are defined in a storage group.	G

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CLUSTERRATIO	SMALLINT NOT NULL WITH DEFAULT	Percentage of rows that are in clustering order. For a partitioning index, it is the weighted average of all index partitions in terms of the number of rows in the partition. The value is 0 if statistics have not been gathered. The value is -2 if the index is for an auxiliary table. This is an updatable column.	S
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the index.	G
	SMALLINT NOT NULL	Internal use only	I
	SMALLINT NOT NULL	Not used	N
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'. This is an updatable column.	G
INDEXTYPE	CHAR(1) NOT NULL WITH DEFAULT	The index type: <b>2</b> Type 2 index <b>blank</b> Type 1 index <b>D</b> Data-partitioned secondary index <b>P</b> An index that is both partitioned and is a partitioning index (index that is on a table that uses table-controlled partitioning).	G
FIRSTKEYCARDF	FLOAT NOT NULL WITH DEFAULT -1	Number of distinct values of the first key column. This number is an estimate if updated while collecting statistics on a single partition. The value is -1 if statistics have not been gathered. This is an updatable column.	S
FULLKEYCARDF	FLOAT NOT NULL WITH DEFAULT -1	Number of distinct values of the key. The value is -1 if statistics have not been gathered. This is an updatable column.	S
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the index. If the index was created in a DB2 release prior to Version 5, the value is '0001-01-01.00.00.00.000000'.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER INDEX statement was executed for the index. If no ALTER INDEX statement has been applied, ALTEREDTS has the value of CREATEDTS. If the index was created in a DB2 release prior to Version 5, the value is '0001-01-01.00.00.00.000000'.	G
PIECESIZE	INTEGER NOT NULL WITH DEFAULT	Maximum size of a data set in kilobytes for secondary indexes.  A value of zero (0) indicates that the index is a partitioning index or that the index was created in a DB2 release prior to Version 5.	G

Column name	Data type	Description	Use
COPY	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether COPY YES was specified for the index, which indicates if the index can be copied and if SYSIBM.SYSLGRNX recording is enabled for the index.  N No Y Yes	G
COPYLSRN	CHAR(6) NOT NULL WITH DEFAULT X'000000000000' FOR BIT DATA	The value can be either an RBA or LRSN. (LRSN is only for data sharing.) If the index is currently defined as COPY YES, the value is the RBA or LRSN when the index was created with COPY YES or altered to COPY YES, not the current RBA or LRSN. If the index is currently defined as COPY NO, the value is set to X'000000000000' if the index was created with COPY NO; otherwise, if the index was altered to COPY NO, the value in COPYLSRN is not changed when the index is altered to COPY NO.	G
CLUSTERRATIOF	FLOAT NOT NULL WITH DEFAULT	When multiplied by 100, the value of the column is the percentage of rows that are in clustering order. For example, a value of '.9125' indicates 91.25%. For a partitioning index, it is the weighted average of all index partitions in terms of the number of rows in the partition. The value is 0 if statistics have not been gathered. The value is -2 if the index is for an auxiliary table, a node ID index or an XML index. This is an updatable column.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Kilobytes of DASD storage. The value is -1 if statistics have not been gathered. This is an updatable column.	G
REMARKS	VARCHAR(762) NOT NULL WITH DEFAULT	A character field string provided by the user with the COMMENT statement.	G
PADDED	CHAR(1) NOT NULL WITH DEFAULT	Indicates whether keys within the index are padded for varying-length column data:  Y The index contains varying-length character or graphic data and is PADDED (the varying-length columns are padded to their maximum length). N The index contains varying-length character or graphic data and is NOT PADDED (the varying-length columns are not padded to their maximum length). Index-only access to all column data is possible. blank The index does not contain varying-length character or graphic data. The value is blank for indexes that have been created or altered prior to Version 8.	G
VERSION	SMALLINT NOT NULL WITH DEFAULT	The version of the data row format for this index. A value of zero indicates that a version-creating alter has never occurred against this index.	G
OLDEST_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number describing the oldest format of data in the index space and any image copies of the index.	G

Column name	Data type	Description	Use
CURRENT_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number describing the newest format of data in the index space. A zero indicates that the index space has never had been versioned. After the version number reaches the maximum value, the number will wrap back to one.	G
RELCREATED	CHAR(1) NOT NULL WITH DEFAULT	Release of DB2 that was used to create the object, blank for indexes created before Version 8. For all other values, see Release dependency indicators.	G
AVGKEYLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of keys within the index. The value is -1 if statistics have not been gathered.	G
	CHAR(1) NOT NULL	Not used	N
KEYTARGET_COUNT	SMALLINT NOT NULL WITH DEFAULT	The number of key-targets for an extended index. The value is 0 for a simple index.	G
UNIQUE_COUNT	SMALLINT NOT NULL WITH DEFAULT	The value is 0 for a simple index or if the index has no unique key. Otherwise, the value is the number of key-targets that are required for the unique key of the index.	G
IX_EXTENSION_TYPE	CHAR(1) NOT NULL WITH DEFAULT	Identifies the type of extended index:  N Node ID index S Index on a scalar expression T Spatial index V XML index blank Simple index	G
COMPRESS	CHAR(1) NOT NULL WITH DEFAULT ' N'	Indicates whether index compression is active:  N Index compression is not active Y Index compression is active	G
OWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the index, empty string for indexes created in a DB2 release prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner:  blank Authorization ID L Role	G
DATA_REPEAT_FACTOR_F	FLOAT NOT NULL WITH DEFAULT -1	The anticipated number of data pages that will be touched following an index key order. This statistic is only collected when the STATCLUS subsystem parameter is set to ENHANCED. This number is -1 if statistics have not been collected. The valid value is -1 or any value that is equal to or greater than 1. This is an updatable column.	G
ENVID	INTEGER NOT NULL WITH DEFAULT	Internal environment identifier.	G

## SYSIBM.SYSINDEXES\_HIST table

The SYSIBM.SYSINDEXES\_HIST table contains rows from SYSINDEXES.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the index.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the index.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the index is defined.	G
TBCREATOR	VARCHAR(128) NOT NULL	The schema of the table.	G
CLUSTERING	CHAR(1) NOT NULL	Whether CLUSTER was specified when the index was created: N No Y Yes	G
NLEAF	INTEGER NOT NULL WITH DEFAULT -1	Number of active leaf pages in the index. The value is -1 if statistics have not been gathered.	S
NLEVELS	SMALLINT NOT NULL WITH DEFAULT -1	Number of levels in the index tree. If the index is partitioned, it is the maximum of the number of levels in the index tree for all the partitions. The value is -1 if statistics have not been gathered.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
FIRSTKEYCARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of distinct values of the first key column. This number is an estimate if updated while collecting statistics on a single partition. The value is -1 if statistics have not been gathered.	S
FULLKEYCARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of distinct values of the key. The value is -1 if statistics have not been gathered.	S
CLUSTERRATIOF	FLOAT(8) NOT NULL	Percentage of rows that are in clustering order. For a partitioning index, it is the weighted average of all index partitions in terms of the number of rows in the partition. The value is 0 if statistics have not been gathered. The value is -2 if the index is for an auxiliary table.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of kilobytes of DASD storage allocated to the index space partition. The value is -1 if statistics have not been gathered.	G

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
AVGKEYLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of keys within the index. The value is -1 if G statistics have not been gathered.	G
DATAREPEAT- FACTORTF	FLOAT NOT NULL WITH DEFAULT -1	The anticipated number of data pages that will be touched following an index key order. This statistic is only collected when the STATCLUS subsystem parameter is set to ENHANCED. This number is -1 if statistics have not been collected. The valid value is -1 or any value that is equal to or greater than 1. This is an updatable column.	G

## SYSIBM.SYSINDEXPART table

The SYSIBM.SYSINDEXPART table contains one row for each nonpartitioned secondary index (NPSI) and one row for each partition of a partitioning index or a data-partitioned secondary index.

Column name	Data type	Description	Use
PARTITION	SMALLINT NOT NULL	Partition number; Zero if index is not partitioned.	G
IXNAME	VARCHAR(128) NOT NULL	Name of the index.	G
IXCREATOR	VARCHAR(128) NOT NULL	The schema of the index.	G
PQTY	INTEGER NOT NULL	<p>For user-managed data sets, the value is the primary space allocation in units of 4KB storage blocks or -1.</p> <p>PQTY is based on a value of PRIQTY in the appropriate CREATE or ALTER INDEX statement. Unlike PQTY, however, PRIQTY asks for space in 1KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>PRIQTY was not specified for a CREATE INDEX statement or for any subsequent ALTER INDEX statements.</li> <li>-1 was the most recently specified value for PRIQTY, either on the CREATE INDEX statement or a subsequent ALTER INDEX statement.</li> </ul>	G
SQTY	SMALLINT NOT NULL	<p>For user-managed data sets, the value is the secondary space allocation in units of 4KB storage blocks or -1.</p> <p>SQTY is based on a value of SECQTY in the appropriate CREATE or ALTER INDEX statement. Unlike SQTY, however, SECQTY asks for space in 1KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>SECQTY was not specified for a CREATE INDEX statement or for any subsequent ALTER INDEX statements.</li> <li>-1 was the most recently specified value for SECQTY, either on the CREATE INDEX statement or a subsequent ALTER INDEX statement.</li> </ul>	G
STORTYPE	CHAR(1) NOT NULL	Type of storage allocation:  <b>E</b> Explicit, and STORNAME names an integrated catalog facility catalog <b>I</b> Implicit, and STORNAME names a storage group	G
STORNAME	VARCHAR(128) NOT NULL	Name of storage group or integrated catalog facility catalog used for space allocation.	G

Column name	Data type	Description	Use
VCATNAME	VARCHAR(24) NOT NULL	Name of integrated catalog facility catalog used for space allocation.	G
	INTEGER NOT NULL	Not used	N
	INTEGER NOT NULL	Not used	N
LEAFDIST	INTEGER NOT NULL	100 times the average number of leaf pages between successive active leaf pages of the index. The value is -1 if statistics have not been gathered. The value is -2 if the index is an auxiliary index, a node ID index, or an XML index.	S
	INTEGER NOT NULL	Not used	S
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
LIMITKEY	VARCHAR(512) NOT NULL WITH DEFAULT FOR BIT DATA	The high value of the limit key of the partition in an internal format. An empty string if the index is not partitioned or for a data-partitioned secondary index (DPSI).  If any column of the key has a field procedure, the internal format is the encoded form of the value.	S
FREEPAGE	SMALLINT NOT NULL	Number of pages that are loaded before a page is left as free space.	G
PCTFREE	SMALLINT NOT NULL	Percentage of each leaf or nonleaf page that is left as free space.	G
SPACE	INTEGER NOT NULL WITH DEFAULT	Number of kilobytes of DASD storage allocated to the index space partition, as determined by the last execution of the STOSPACE utility.  0 The STOSPACE or RUNSTATS utility has not been run.  -1 The index was defined with the DEFINE NO clause, which defers the physical creation of the data sets until data is first inserted into the index, and data has yet to be inserted into the index.  The value is updated by STOSPACE if the index is related to a storage group. The value is updated by RUNSTATS if the utility is executed as RUNSTATS INDEX with UPDATE(ALL) or UPDATE(SPACE).	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G

Column name	Data type	Description	Use
	CHAR(1) NOT NULL	Not used	N
GBPCACHE	CHAR(1) NOT NULL WITH DEFAULT	Group buffer pool cache option specified for this index or index partition. <b>blank</b> Only changed pages are cached in the group buffer pool. <b>A</b> Changed and unchanged pages are cached in the group buffer pool. <b>N</b> No data is cached in the group buffer pool.	G
FAROFFPOSF	FLOAT NOT NULL WITH DEFAULT -1	Number of referred to rows far from optimal position because of an insert into a full page. The value is -1 if statistics have not been gathered. The value is -2 if the index is an auxiliary index, a node ID index, or an XML index. The column is not applicable for an index on an auxiliary table.	S
NEAROFFPOSF	FLOAT NOT NULL WITH DEFAULT -1	Number of referred to rows near, but not at optimal position, because of an insert into a full page. The value is -2 if the index is an auxiliary index, a node ID index, or an XML index. Not applicable for an index on an auxiliary table.	S
CARDF	FLOAT NOT NULL WITH DEFAULT -1	Number of RIDs in the index that refer to data rows or LOBs. The value is -1 if statistics have not been gathered.	S
SECQTYI	INTEGER NOT NULL WITH DEFAULT	Secondary space allocation in units of 4KB storage. For user-managed data sets, the value is the secondary space allocation in units of 4KB blocks.	G
IPREFIX	CHAR(1) NOT NULL WITH DEFAULT T	The first character of the instance qualifier for this index's data set name. 'T' or 'J' are the only valid characters for this field. The default is 'T'.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER INDEX statement was executed for the index. If no ALTER INDEX statement has been applied, the value is '0001-01-01.00.00.00.000000'.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Kilobytes of DASD storage. The value is -1 if statistics have not been gathered. This is an updatable column.	G
DSNUM	INTEGER NOT NULL WITH DEFAULT -1	Number of data sets. The value is -1 if statistics have not been gathered. This is an updatable column.	G
EXTENTS	INTEGER NOT NULL WITH DEFAULT -1	Number of data set extents. The value is -1 if statistics have not been gathered. This is an updatable column. This value is only for the last DSNUM for the object.	G

Column name	Data type	Description	Use
PSEUDO_DEL_ENTRIES	INTEGER NOT NULL WITH DEFAULT -1	Number of pseudo deleted entries (entries that are logically deleted but still physically present in the index). For a non-unique index, value is the number of RIDs that are pseudo deleted. For a unique index, the value is the number of keys and RIDs that are pseudo deleted. The value is -1 if statistics have not been gathered. This is an updatable column.	G
LEAFNEAR	INTEGER NOT NULL WITH DEFAULT -1	Number of leaf pages physically near previous leaf page for successive active leaf pages. The value is -1 if statistics have not been gathered. This is an updatable column.	S
LEAFFAR	INTEGER NOT NULL WITH DEFAULT -1	Number of leaf pages located physically far away from previous leaf pages for successive (active leaf) pages accessed in an index scan. The value is -1 if statistics have not been gathered. This is an updatable column.	S
OLDEST_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number describing the oldest format of data in the index part and any image copies of the index part.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT -1	Time when the partition was created.	G
AVGKEYLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of keys within the index. The value is -1 if statistics have not been gathered.	G

## SYSIBM.SYSINDEXPART\_HIST table

The SYSIBM.SYSINDEXPART\_HIST table contains rows from SYSINDEXPART.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
PARTITION	SMALLINT NOT NULL	Partition number. Zero if index is not partitioned.	G
IXNAME	VARCHAR(128) NOT NULL	Name of the index.	G
IXCREATOR	VARCHAR(128) NOT NULL	The schema of the index.	G
PQTY	INTEGER NOT NULL	<p>For user-managed data sets, the value is the primary space allocation in units of 4KB storage blocks or -1.</p> <p>For user-specified values of PRIQTY other than -1, the value is set to the primary space allocation only if RUNSTATS INDEX with UPDATE(ALL) or UPDATE(SPACE) is executed; otherwise, the value is zero. PQTY is based on a value of PRIQTY in the appropriate CREATE or ALTER INDEX statement. Unlike PQTY, however, PRIQTY asks for space in 1KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>• PRIQTY was not specified for a CREATE INDEX statement or for any subsequent ALTER INDEX statements.</li> <li>• -1 was the most recently specified value for PRIQTY, either on the CREATE INDEX statement or a subsequent ALTER INDEX statement.</li> </ul>	G
SECQTYI	INTEGER NOT NULL	<p>If a storage group is not used, the value is 0.</p> <p>For user-managed data sets, the value is the secondary space allocation in units of 4KB storage blocks or -1.</p> <p>For user-specified values of SECQTY other than -1, the value is set to the secondary space allocation only if RUNSTATS INDEX with UPDATE(ALL) or UPDATE(SPACE) is executed; otherwise, the value is zero. SQTY is based on a value of SECQTY in the appropriate CREATE or ALTER INDEX statement. Unlike SQTY, however, SECQTY asks for space in 1KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>• SECQTY was not specified for a CREATE INDEX statement or for any subsequent ALTER INDEX statements.</li> <li>• -1 was the most recently specified value for SECQTY, either on the CREATE INDEX statement or a subsequent ALTER INDEX statement.</li> </ul>	G

Column name	Data type	Description	Use
LEAFDIST	INTEGER NOT NULL WITH DEFAULT -1	100 times the average number of leaf pages between successive active leaf pages of the index. The value is -1 if statistics have not been gathered.	S
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of kilobytes of DASD storage allocated to the index space partition. The value is -1 if statistics have not been gathered.	G
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
FAROFFPOSF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of referred to rows far from optimal position because of an insert into a full page. The value is -1 if statistics have not been gathered. The column is not applicable for an index on an auxiliary table.	S
NEAROFFPOSF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of referred to rows near, but not at optimal position, because of an insert into a full page. Not applicable for an index on an auxiliary table. The value is -1 if statistics have not been gathered.	S
CARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of RIDs in the index that refer to data rows or LOBs. The value is -1 if statistics have not been gathered.	S
EXTENTS	INTEGER NOT NULL WITH DEFAULT -1	Number of data set extents. The value is -1 if statistics have not been gathered. This value is only for the last DSNUM for the object.	G
PSEUDO_DEL_ENTRIES	INTEGER NOT NULL WITH DEFAULT -1	Number of pseudo deleted entries. The value is -1 if statistics have not been gathered.	G
DSNUM	INTEGER NOT NULL WITH DEFAULT -1	Data set number within the table space. For partitioned index spaces, this value corresponds to the partition number for a single partition copy, or 0 for a copy of an entire partitioned index space. The value is -1 if statistics have not been gathered.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
LEAFNEAR	INTEGER NOT NULL WITH DEFAULT -1	Number of leaf pages physically near previous leaf page for successive active leaf pages. The value is -1 if statistics have not been gathered. This is an updatable column.	S
LEAFFAR	INTEGER NOT NULL WITH DEFAULT -1	Number of leaf pages located physically far away from previous leaf pages for successive (active leaf) pages accessed in an index scan. The value is -1 if statistics have not been gathered. This is an updatable column.	S
AVGKEYLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of keys within the index. The value is -1 if statistics have not been gathered.	G

## SYSIBM.SYSINDEXSPACESTATS table

The SYSIBM.SYSINDEXSPACESTATS table contains real time statistics for index spaces.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
UPDATESTATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	The timestamp that the row in the SYSINDEXSPACESTATS table is inserted or last updated.	G
NLEVELS	SMALLINT	The number of levels in the index tree.  A null value indicates that the number of levels is unknown.	G
NPAGES	INTEGER	The number of distinct pages with active rows in the associated table. This is an updatable column.	G
NLEAF	INTEGER	The number of leaf pages in the index. This is an updatable column.	G
NACTIVE	INTEGER	The number of active pages in the index space or partition. This value is equivalent to the number of pre-formatted pages.  A null value indicates that the number of active pages is unknown.	G
SPACE	INTEGER	The amount of space, in KB, that is allocated to the index space or partition. For multi-piece, linear page sets, this value is the amount of space in all data sets. A null value indicates the amount of space is unknown.	G
EXTENTS	SMALLINT	The number of extents in the index space or partition. For multi-piece index spaces, this value is the number of extents for the last data sets. For a data set that is striped across multiple volumes, the value is the number of logical extents. A null value indicates the number of extents is unknown.	G
LOADRLASTTIME	TIMESTAMP	The timestamp that the LOAD REPLACE utility was last run on the index space or partition.  A null value indicates that the LOAD REPLACE utility has never been run on the index space or partition or that the timestamp is unknown.	G
REBUILDLASTTIME	TIMESTAMP	The timestamp that the REBUILD INDEX utility was last run on the index space or partition.  A null value indicates that the timestamp that the REBUILD INDEX was last run is unknown.	G
REORGLASTTIME	TIMESTAMP	The timestamp when the REORG INDEX utility was last run on the index space or partition, or if the REORG INDEX utility has not been run, the time when the index space or partition was created. A null value indicates that the timestamp is unknown.	G

Column name	Data type	Description	Use
REORGINSERTS	INTEGER	The number of index entries that have been inserted into the index space or partition since the last time the REORG, REBUILD INDEX, or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of inserted index entries is unknown.	G
REORGDELETES	INTEGER	The number of index entries that have been deleted from the index space or partition since the last time the REORG, REBUILD INDEX, or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of deleted index entries is unknown.	G
REORGAPPEND- INSERT	INTEGER	The number of index entries that have a key value that is greater than the maximum key value in the index or partition that have been inserted into the index space or partition since the last time the REORG, REBUILD INDEX, or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of inserted index entries is unknown.	G
REORGPSEUDO- DELETES	INTEGER	The number of index entries that have been pseudo-deleted since the last REORG, REBUILD INDEX, or LOAD REPLACE on the index space or partition, or since the object was created. A pseudo-delete is a RID entry that has been marked as deleted.  A null value indicates that the number of pseudo-deleted index entries is unknown.	G
REORGMASSDELETE	INTEGER	The number of mass deletes from a segmented or LOB table space, or the number of dropped tables from a segmented table space since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of mass deletes is unknown.	G

Column name	Data type	Description	Use
REORGLEAFNEAR	INTEGER	<p>The net number of leaf pages located physically near previous pages for successive active leaf pages that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE, or since the object was created.</p> <p>The distance between leaf pages is optimal if the difference is 1 and considered near if the distance is 2-16.</p> <p>An index page is added during a page split and the distance between the predecessor and successor pages can lower this count if the distance between the two was near. The distance between the predecessor and new page increase the count if they are near. The distance between the new page and successor increment the count if they are near.</p> <p>If a leaf page is deleted the distance between the new predecessor and successor pages can increment this count if the distance between the two is near. The distance between the predecessor and the deleted page decrement the count if it was near. The distance between the successor and the deleted page decrement the count if it was near.</p> <p>A null value means that the value is unknown. A negative value is possible in some cases.</p>	G
REORGLEAFFAR	INTEGER	<p>The net number of leaf pages located physically far away from previous leaf pages for successive active leaf pages that occurred since the last REORG, REBUILD INDEX, or LOAD REPLACE, or since the object was created.</p> <p>The distance between leaf pages is optimal if the difference is 1 and considered far if the distance is greater than 16.</p> <p>An index page is added during a page split and the distance between the predecessor and successor pages can decrement this count if the distance between the two was far. The distance between the predecessor and new page increment the count if they are far. The distance between the new page and successor increment the count if they are far.</p> <p>If a leaf page is deleted the distance between the new predecessor and successor pages can increment this count if the distance between the two is far. The distance between the predecessor and the deleted page decrement the count if it was far. The distance between the successor and the deleted page decrement the count if it was far.</p> <p>A null value means that the value is unknown.</p>	G
REORGNUMLEVELS	INTEGER	<p>The number of levels in the index tree that were added or removed since the last REORG, REBUILD INDEX, or LOAD REPLACE, or the object was created.</p> <p>A null value means that the number of added or deleted levels is unknown.</p>	G

Column name	Data type	Description	Use
STATSLASTTIME	TIMESTAMP	The timestamp of the last time that the RUNSTATS utility is run on the table space or partition.  A null value means that RUNSTATS has never been run on the index space or partition, or that the timestamp of the last RUNSTATS is unknown.	G
STATSINSERTS	INTEGER	The number of records or LOBs that have been inserted into the table space or partition since the last time that the RUNSTATS utility was run, or since the object was created.  A null value indicates that the number of inserted records or LOBs is unknown.	G
STATSDELETES	INTEGER	The number of index entries that have been deleted since the last RUNSTATS on the index space or partition, or since the object was created.  A null value means that the number of deleted index entries is unknown.	G
STATSMASSDELETES	INTEGER	The number of times that the index or index space partition was mass deleted since the last RUNSTATS, or the object was created.  A null value indicates that the number of mass deletes is unknown.	G
COPYLASTTIME	TIMESTAMP	The timestamp of the last full image copy on the index space or partition.  A null value means that COPY has never been run on the index space or partition, or that the timestamp of the last full image copy is unknown.	G
COPYUPDATED-PAGES	INTEGER	The number of distinct types that have been updated since the last time that the COPY utility was run, or since the object was created.  A null value indicates that the number of updated pages is unknown.	G
COPYCHANGES	INTEGER	The number of insert, update, and delete operations since the last time that the COPY utility was run, or since the object was created.  A null value indicates that the number of insert, update, and delete operations is unknown.	G
COPYUPDATELRSN	CHAR(6) FOR BIT DATA	The LRSN or RBA of the first update that occurs after the last time the COPY utility was run.  A null value indicates that the LRSN or RBA is unknown.	G
COPYUPDATETIME	TIMESTAMP	The timestamp of the first update that occurs after the last time that the COPY utility was run.  A null value indicates that the timestamp is unknown.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
DBID	SMALLINT NOT NULL	The internal identifier of the database.	G
ISOBID	SMALLINT NOT NULL	The internal identifier of the index space page set descriptor.	I
PSID	SMALLINT NOT NULL	The internal identifier of the table space page set descriptor for the table space that is associated with the index.	G
PARTITION	SMALLINT NOT NULL	The data set number within the index space. For partitioned index spaces, this value corresponds to the partition number for a single partition. For non-partitioned table spaces, this value is 0.	G
INSTANCE	SMALLINT NOT NULL WITH DEFAULT 1	Indicates if the object is associated with data set 1 or 2. This is an updatable column.	G
TOTALENTRIES	BIGINT	The number of entries, including duplicate entries, in the index space or partition.  A null value indicates that the number of entries is unknown.	G
DBNAME	VARCHAR(24) NOT NULL	The name of the database.	G
NAME	VARCHAR(128) NOT NULL	The name of the index.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the index.	G
INDEXSPACE	VARCHAR(24) NOT NULL	The name of the index space.	G
LASTUSED	DATE	The date when the index is used for SELECT, FETCH, searched UPDATE, searched DELETE, or used to enforce referential integrity constraints. The default value is NULL.	G

## SYSIBM.SYSINDEXSTATS table

The SYSIBM.SYSINDEXSTATS table contains one row for each partition of a partitioning index or a data-partitioned secondary index.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
FIRSTKEYCARD	INTEGER NOT NULL	For the index partition, number of distinct values of the first key column.	S
FULLKEYCARD	INTEGER NOT NULL	For the index partition, number of distinct values of the key.	S
NLEAF	INTEGER NOT NULL	Number of active leaf pages in the index partition.	S
NLEVELS	SMALLINT NOT NULL	Number of levels in the index tree.	S
	SMALLINT NOT NULL	Not used	N
	SMALLINT NOT NULL	Not used	N
CLUSTERRATIO	SMALLINT NOT NULL	For the index partition, the percentage of rows that are in clustering order. The value is 0 if statistics have not been gathered.	N
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PARTITION	SMALLINT NOT NULL	Partition number of the index.	G
OWNER	VARCHAR(128) NOT NULL	The schema of the index.	G
NAME	VARCHAR(128) NOT NULL	Name of the index.	G
KEYCOUNT	INTEGER NOT NULL	Total number of rows in the partition.	S
FIRSTKEYCARDF	FLOAT NOT NULL WITH DEFAULT -1	For the index partition, number of distinct values of the first key column.	S

Column name	Data type	Description	Use
FULLKEYCARDF	FLOAT NOT NULL WITH DEFAULT -1	For the index partition, number of distinct values of the key.	S
KEYCOUNTF	FLOAT WITH DEFAULT -1	Total number of rows in the partition.	S
CLUSTERRATIOF	FLOAT NOT NULL WITH DEFAULT	For the index partition, the value, when multiplied by 100, is the percentage of rows that are in clustering order. For example, a value of '.9125' indicates 91.25%. The value is 0 if statistics have not been gathered.	G
	VARCHAR(1000) NOT NULL WITH DEFAULT FOR BIT DATA	Internal use only	I
DATAREPEAT- FACTORF	FLOAT NOT NULL WITH DEFAULT -1	The anticipated number of data pages that will be touched following an index key order. This statistic is only collected when the STATCLUS subsystem parameter is set to ENHANCED. This number is -1 if statistics have not been collected. The valid value is -1 or any value that is equal to or greater than 1. This is an updatable column.	G

## SYSIBM.SYSINDEXSTATS\_HIST table

The SYSIBM.SYSINDEXSTATS\_HIST table contains rows from SYSINDEXSTATS.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
NLEAF	INTEGER NOT NULL WITH DEFAULT -1	Number of active leaf pages in the index partition. The value is -1 if statistics have not been gathered.	S
NLEVELS	SMALLINT NOT NULL WITH DEFAULT -1	Number of levels in the index tree. The value is -1 if statistics have not been gathered.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
PARTITION	SMALLINT NOT NULL	Partition number of the index.	G
OWNER	VARCHAR(128) NOT NULL	The schema of the index.	G
NAME	VARCHAR(128) NOT NULL	Name of the index.	G
FIRSTKEYCARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	For the index partition, number of distinct values of the first key column. The value is -1 if statistics have not been gathered.	S
FULLKEYCARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	For the index partition, number of distinct values of the key. The value is -1 if statistics have not been gathered.	S
KEYCOUNTF	FLOAT(8) NOT NULL WITH DEFAULT -1	Total number of rows in the partition. The value is -1 if statistics have not been gathered.	S
CLUSTERRATIOF	FLOAT(8) NOT NULL	For the index partition, the value, when multiplied by 100, is the percentage of rows that are in clustering order. For example, a value of '0.9125' indicates 91.25%. The value is 0 if statistics have not been gathered.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DATAREPEAT- FACTORTF	FLOAT NOT NULL WITH DEFAULT -1	The anticipated number of data pages that will be touched following an index key order. This statistic is only collected when the STATCLUS subsystem parameter is set to ENHANCED. This number is -1 if statistics have not been collected. The valid value is -1 or any value that is equal to or greater than 1. This is an updatable column.	G

## **SYSIBM.SYSJARCLASS\_SOURCE table**

The SYSIBM.SYSJARCLASS\_SOURCE table is an auxiliary table for SYSIBM.SYSJARCONTENTS.

Column name	Data type	Description	Use
CLASS_SOURCE	CLOB(10M) NOT NULL	The contents of the class in the JAR file.	G

## SYSIBM.SYSJARCONTENTS table

The SYSIBM.SYSJARCONTENTS table contains Java class source for an installed JAR file.

Column name	Data type	Description	Use
JARSCHEMA	VARCHAR(128) NOT NULL	The schema of the JAR file.	G
JAR_ID	VARCHAR(128) NOT NULL	The name of the JAR file.	G
CLASS	VARCHAR(384) NOT NULL	The class name contained in the JAR file.	G
CLASS_SOURCE_ROWID	ROWID NOT NULL GENERATED ALWAYS	ID used to support CLOB data type.	G
CLASS_SOURCE	CLOB(10M) NOT NULL	The contents of the class in the JAR file.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSJARDATA table

The SYSIBM.SYSJARDATA table is an auxiliary table for SYSIBM.SYSJAROBJECTS.

Column name	Data type	Description	Use
JAR_DATA	BLOB(100M) NOT NULL	The contents of the JAR file.	G

## SYSIBM.SYSJAROBJECTS table

The SYSIBM.SYSJAROBJECTS table contains binary large object representing the installed JAR file.

Column name	Data type	Description	Use
JARSCHEMA	VARCHAR(128) NOT NULL	The schema of the JAR file.	G
JAR_ID	VARCHAR(128) NOT NULL	The name of the JAR file.	G
OWNER	VARCHAR(128) NOT NULL	Authorization ID of the owner of the JAR object.	G
JAR_DATA_ROWID	ROWID NOT NULL GENERATED ALWAYS	ID used to support BLOB data type.	G
JAR_DATA	BLOB(100M) NOT NULL	The contents of the JAR file. This is an updatable column.	G
PATH	VARCHAR(2048) NOT NULL	The class resolution path of the JAR file. This is an updatable column.	G
CREATEDTS	TIMESTAMP NOT NULL	Time when the JAR object was created.	G
ALTEREDTS	TIMESTAMP NOT NULL	Time when the JAR object was altered.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSJAVAOPTS table

The SYSIBM.SYSJAVAOPTS table contains build options used during INSTALL\_JAR.

Column name	Data type	Description	Use
JARSCHEMA	VARCHAR(128) NOT NULL	The schema of the JAR file.	G
JAR_ID	VARCHAR(128) NOT NULL	The name of the JAR file.	G
BUILDSchema	VARCHAR(128) NOT NULL	Schema name for BUILDNAME.	G
BUILDNAME	VARCHAR(128) NOT NULL	Procedure used to create the routine.	G
BUILDFOWNER	VARCHAR(128) NOT NULL	Authorization ID used to create the routine.	G
DBRMLIB	VARCHAR(256) NOT NULL	PDS name where DBRM is located.	G
HPJCOMPILE_OPTS	VARCHAR(512) NOT NULL	HPJ compile options used to install the routine.	G
BIND_OPTS	VARCHAR(2048) NOT NULL	Bind options used to install the routine.	G
POBJECT_LIB	VARCHAR(256) NOT NULL	PDSE name where program object is located.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSJAVAPaths table

The SYSIBM.SYSJAVAPaths table contains the complete class resolution path of a JAR file, and records the dependencies that one JAR file has on the JAR files in its Java path.

Column name	Data type	Description	Use
JARSCHEMA	VARCHAR(128) NOT NULL	The schema of the JAR file.	G
JAR_ID	VARCHAR(128) NOT NULL	The name of the JAR file.	G
OWNER	VARCHAR(128) NOT NULL	Authorization ID of the owner of the JAR object.	G
ORDINAL	SMALLINT NOT NULL	The ordinal number of the path element within the JAR file's Java path.	G
PE_CLASS_PATTERN	VARCHAR(2048) NOT NULL	The pattern for the names of the classes that are to be searched for in this path element's JAR file.	G
PE_JARSCHEMA	VARCHAR(128) NOT NULL	The schema of this path element's JAR file.	G
PE_JAR_ID	VARCHAR(128) NOT NULL	The name of this path element's JAR file.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSKEYCOLUSE table

The SYSIBM.SYSKEYCOLUSE table contains a row for every column in a unique constraint (primary key or unique key) from the SYSIBM.SYSTABCONST table.

Column name	Data type	Description	Use
CONSTNAME	VARCHAR(128) NOT NULL	Name of the constraint.	G
TBCREATOR	VARCHAR(128) NOT NULL	Schema or qualifier of the table on which the constraint is defined.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the constraint is defined.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the column	G
COLSEQ	SMALLINT NOT NULL	Numeric position of the column in the key (the first position in the key is 1).	G
COLNO	SMALLINT NOT NULL	Numeric position of the column in the table on which the constraint is defined.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSKEYS table

The SYSIBM.SYSKEYS table contains one row for each column of an index key.

Column name	Data type	Description	Use
IXNAME	VARCHAR(128) NOT NULL	Name of the index.	G
IXCREATOR	VARCHAR(128) NOT NULL	Schema or qualifier of the index.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the column of the key.	G
COLNO	SMALLINT NOT NULL	Numeric position of the column in the table. For example, 4 (out of 10).	G
COLSEQ	SMALLINT NOT NULL	Numeric position of the column in the key for an index on columns. For example, 4 (out of 4). The value is meaningless for an index that is based on expressions.	G
ORDERING	CHAR(1) NOT NULL	Order of the column in the key: <b>blank</b> Index is an index based on expressions <b>A</b> Ascending order <b>D</b> Descending order <b>R</b> Random order	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSKEYTARGETS table

The SYSIBM.SYSKEYTARGETS table contains one row for each key-target that is participating in an extended index definition.

Column name	Data type	Description	Use
IXNAME	VARCHAR(128) NOT NULL	Name of the index.	G
IXSCHEMA	VARCHAR(128) NOT NULL	Qualifier of the index.	G
KEYSEQ	SMALLINT NOT NULL	Numeric position of the key-target in the index.	G
COLNO	SMALLINT NOT NULL	Numeric position of the column in the table if the expression is a single column. Otherwise the value is 0. For XML indexes, this field is also 0.	G
ORDERING	CHAR(1) NOT NULL	Order of the key:  A      Ascending	G
TYPESCHEMA	VARCHAR(128) NOT NULL	Schema of the data type.	G
TYPENAME	VARCHAR(128) NOT NULL	Name of the data type.	G
DATATYPEID	INTEGER NOT NULL	The internal ID of the data type.	G
SOURCETYPEID	INTEGER NOT NULL	For a built-in data type, this column contains 0. For a distinct type, this column contains the internal ID of the built-in type on which the distinct type is based.	G

Column name	Data type	Description	Use
LENGTH	SMALLINT NOT NULL	The length attribute of the key-target or its precision for a decimal key-target. The number does not include the internal prefixes that are used to record the actual length and null states, when applicable.	G
		<b>data type</b> <b>value of the LENGTH column</b>	
	INTEGER	4	
	SMALLINT	2	
	FLOAT	4 or 8	
	CHAR	The length of the string	
	VARCHAR	The maximum length of the string	
	DECIMAL	The precision of the number	
	GRAPHIC	The number of DBCS characters	
	VARGRAPHIC	The maximum number of DBCS characters	
	DATE	4	
	TIME	3	
	TIMESTAMP	10	
	BIGINT	8	
	BINARY	The length of the string	
	VARBINARY	The maximum length of the string	
	DECFLOAT	8 or 16	
LENGTH2	INTEGER NOT NULL	The maximum length of the data that is retrieved from the column. Possible values include the following values: <b>0</b> Not a ROWID column <b>40</b> For a ROWID column, the length of the value that is returned	G
SCALE	SMALLINT NOT NULL	The scale of decimal data. SCALE contains 0 if the key is not a decimal key.	G
NULLS	CHAR(1) NOT NULL	Whether the key can contain null values: <b>N</b> No <b>Y</b> Yes. Y also indicates that the index is an XML index.	G
CCSID	INTEGER NOT NULL	The CCSID of the key. CCSID contains 0 if the key is a non-character type key.	G
SUBTYPE	CHAR(1) NOT NULL	SUBTYPE applies to character keys only and indicated the subtype of the data: <b>B</b> BIT data <b>M</b> MIXED data <b>S</b> SBCS data <b>blank</b> non-character data	G

Column name	Data type	Description	Use
	VARCHAR(512) NOT NULL FOR BIT DATA	Internal use.	I
CREATEDTS	TIMESTAMP NOT NULL	The timestamp for when the key-target is created.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 in which the key-target is created. See Release dependency indicators for values.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DERIVED_FROM	VARCHAR(4000) NOT NULL	For an index on a scalar expression, DERIVED_FROM contains the text of the scalar expression that is used to generate the key-target value. For an XML index, this is the XML pattern that is used to generate the key-target value. Otherwise DERIVED_FROM contains an empty string.	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	The timestamp of the most recent RUNSTATS. The default value is '0001-01-01.00.00.00.00000'. STATSTIME is an updatable column.	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	The number of distinct values for the key-target. The value is -2 if the index is a node ID index. For an XML value index, the statistic is collected for the second key target (the DOCID column). For all other key targets of the XML value index, a value of -2 is set.	G
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second highest key-value. HIGH2KEY is an updatable column.	G
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second lowest key-value. LOW2KEY is an updatable column.	G
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	The type of statistics that are gathered: <b>N</b> VARCHAR column statistical values are not padded <b>blank</b> Statistics have not been collects or VARCHAR column statistical values are padded STATS_FORMAT is an updatable column.	G

## SYSIBM.SYSKEYTARGETSTATS table

The SYSIBM.SYSKEYTARGETSTATS table contains partition statistics for selected key-targets. For each key-target, a row exists for each partition in the table.

Rows are inserted when RUNSTATS collects indexed key statistics or non-indexed key statistics for a partitioned table space. No row is inserted if the table space is nonpartitioned. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
IXSCHEMA	VARCHAR(128) NOT NULL	The qualifier of the index.	G
IXNAME	VARCHAR(128) NOT NULL	The name of the index.	G
KEYSEQ	SMALLINT NOT NULL	Numeric position of the key-target in the index.	G
HIGHKEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The highest key value.	S
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second highest key-value.	S
LOWKEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The lowest key value.	S
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second lowest key-value.	S
PARTITION	SMALLINT NOT NULL	The partition number of the table space.	G
	VARCHAR(1000) NOT NULL WITH DEFAULT FOR BIT DATA	Internal use only.	I
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	The timestamp of the most recent RUNSTATS. The default value is '0001-01-01.00.00.00.000000'.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	The type of statistics that are gathered:  N      VARCHAR column statistical values are not padded  <b>blank</b> Statistics have not been collects or VARCHAR column statistical values are padded	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	Number of distinct values for the key target.	G

## SYSIBM.SYSKEYTARGETS\_HIST table

The SYSIBM.SYSKEYTARGETS\_HIST table contains rows from the SYSKEYTARGETS table.

Whenever rows are added or changed in SYSKEYTARGETS, the rows are also written to this table. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
IXNAME	VARCHAR(128) NOT NULL	Name of the index.	G
IXSCHEMA	VARCHAR(128) NOT NULL	Qualifier of the index.	G
KEYSEQ	SMALLINT NOT NULL	Numeric position of the key-target in the index.	G
TYPESCHEMA	VARCHAR(128) NOT NULL	Schema of the data type.	G
TYPENAME	VARCHAR(128) NOT NULL	Name of the data type.	G
DATATYPEID	INTEGER NOT NULL	The internal ID of the data type.	G
SOURCETYPEID	INTEGER NOT NULL	For a built-in data type, this field contains 0. For a distinct type, this field contains the internal ID of the built-in type on which the distinct type is based.	G

Column name	Data type	Description	Use
LENGTH	SMALLINT NOT NULL	The length attribute of the key-target or its precision for a decimal key-target. The number does not include the internal prefixes that are used to record the actual length and null states, when applicable.	G
		<b>data type</b> <b>value of the LENGTH column</b>	
	INTEGER	4	
	SMALLINT	2	
	FLOAT	4 or 8	
	CHAR	The length of the string	
	VARCHAR	The maximum length of the string	
	DECIMAL	The precision of the number	
	GRAPHIC	The number of DBCS characters	
	VARGRAPHIC	The maximum number of DBCS characters	
	DATE	4	
	TIME	3	
	TIMESTAMP	10	
	BIGINT	8	
	BINARY	The length of the string	
	VARBINARY	The maximum length of the string	
	DECFLOAT	8 or 16	
LENGTH2	INTEGER NOT NULL	The maximum length of the data that is retrieved from the column. Possible values include the following values: <b>0</b> Not a ROWID column <b>40</b> For a ROWID column, the length of the value that is returned	G
SCALE	SMALLINT NOT NULL	The scale of decimal data. SCALE contains 0 if the key is not a decimal key.	G
NULLS	CHAR(1) NOT NULL	Whether the key can contain null values: <b>N</b> No <b>Y</b> Yes	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	The timestamp of the most recent RUNSTATS. The default value is '0001-01-01.00.00.00.000000'. STATSTIME is an updatable column.	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	The number of distinct values for the key-target. The value is -2 if the index is a node ID index. For an XML value index, the statistic is collected for the second key target (the DOCID column). For all other key targets of the XML value index, a value of -2 is set.	G

Column name	Data type	Description	Use
HIGH2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second highest key-value.	G
LOW2KEY	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	The second lowest key-value.	G
STATS_FORMAT	CHAR(1) NOT NULL WITH DEFAULT	<p>The type of statistics that are gathered:</p> <p><b>N</b>      VARCHAR column statistical values are not padded</p> <p><b>blank</b> Statistics have not been collects or VARCHAR column statistical values are padded</p>	G

## SYSIBM.SYSKEYTGTDIST table

The SYSIBM.SYSKEYTGTDIST table contains one or more rows for the first key-target of an extended index key.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If the RUNSTATS utility updated the statistics, this column contains the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.000000'.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
IXSCHEMA	VARCHAR(128) NOT NULL	The qualifier of the index.	G
IXNAME	VARCHAR(128) NOT NULL	The name of the index.	G
KEYSEQ	SMALLINT NOT NULL	The numeric position of the key-target in the index.	G
KEYVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	KEYVALUE contains the data of a frequently occurring value. If the value has a non-character data type, the data might not be printable.	G
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics that are gathered:  C Cardinality F Frequent value N Non-padded frequent value H Histogram statistics	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='C', CARDF contains the number of distinct values for the key group.  When TYPE='H', CARDF contains the number of distinct values for the key group in a quantile indicated by QUANTILENO.	G
KEYGROUPKEYNO	VARCHAR(254) NOT NULL WITH DEFAULT FOR BIT DATA	KEYGROUPKEYNO contains a value that identifies the set of keys that are associated with the statistics.  KEYGROUPKEYNO contains 0 if the statistics are only associated with a single key.  If the statistics are associated with more than a single key, KEYGROUPKEYNO contains an array of SMALLINT key numbers with a dimension that is equal to the value in NUMKEYS.	G
NUMKEYS	SMALLINT NOT NULL WITH DEFAULT -1	The number of keys that are associated with the statistics.	G

Column name	Data type	Description	Use
FREQUENCYF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='F' or 'N', FREQUENCYF contains a value that indicates the percentage of entries in the index that have the value that is contained in the KEYVALUE column.	G
		When TYPE='H', FREQUENCYF contains a value that indicates the percentage of entries in the index that have a value that is in the range of the quantile that is indicated in the QUANTILENO column.	
		To determine the percentage from the value of FREQUENCYF, multiply the value by 100. For example, a value of '1' indicates 100 percent. A value of '.153' indicates '15.3' percent.	
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	QUANTILENO contains an ordinary sequence number of a quantile in the whole consecutive value range, from low to high.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', LOWVALUE contains the lower bound for the quantile that is in QUANTILENO. LOWVALUE is not used if TYPE does not equal 'H'.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', HIGHVALUE contains the upper bound for the quantile that is in QUANTILENO. HIGHVALUE is not used if TYPE does not equal 'H'.	G

## SYSIBM.SYSKEYTGTDISTSTATS table

The SYSIBM.SYSKEYTGTDISTSTATS table contains zero or more rows per partition for the first key-target of a data-partitioned secondary index.

Rows are inserted when RUNSTATS scans a data-partitioned secondary index. No row is inserted if the index is a secondary index. Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, STATSTIME contains the timestamp of the most recent RUNSTATS. The default value is '0001-01-01.00.00.00.000000'.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PARTITION	SMALLINT NOT NULL	The partition number of the table space that contains the index in which the key is defined.	G
IXSCHEMA	VARCHAR(128) NOT NULL	The qualifier of the index.	G
IXNAME	VARCHAR(128) NOT NULL	The name of the index.	G
KEYSEQ	SMALLINT NOT NULL	Numeric position of the key-target in the index.	G
KEYVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	KEYVALUE contains the data of a frequently occurring value. If the value has a non-character data type, the data might not be printable.	G
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics that are gathered:  C Cardinality F Frequent value N Non-padded frequent value H Histogram statistics	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='C', CARDF contains the number of distinct values for the key group.  When TYPE='H', CARDF contains the number of distinct values for the key group in the quantile that is in QUANTILENO.	G
KEYGROUPKEYNO	VARCHAR(254) NOT NULL WITH DEFAULT	Identifies the set of keys that are associated with the statistics. If the statistics are only associated with a single key, KEYGROUPKEYNO contains a zero length value. Otherwise, KEYGROUPKEYNO contains an array of SMALLINT key numbers that have a dimension that is equal to the value in NUMKEYS.	G
NUMKEYS	SMALLINT NOT NULL WITH DEFAULT	Identifies the number of keys that are associated with the statistics.	G

Column name	Data type	Description	Use
FREQUENCYF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='F' or 'N', FREQUENCYF contains the percentage of entries in the index that have the value that is specified in KEYVALUE when the number of entries is multiplied by 100. For example, a value of '1' indicates 100 percent. A value of '.153' indicates 15.3 percent.	G
		When TYPE='H', FREQUENCYF contains the percentage of entries in the index that have a value that is in the range of the quantile that is indicated in QUANTILENO.	
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	QUANTILENO contains an ordinary sequence number of a quantile in the whole consecutive value range, from low to high.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', LOWVALUE is the lower bound for the quantile that is indicated in QUANTILENO. LOWVALUE is not used if TYPE does not equal 'H'.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', HIGHVALUE is the upper bound for the quantile that is indicated in QUANTILENO. HIGHVALUE is not used if TYPE does not equal 'H'.	G
	VARCHAR(1000)	Internal use only	I

## SYSIBM.SYSKEYTGTDIST\_HIST table

The SYSIBM.SYSKEYTGTDIST\_HIST table contains rows from the SYSKEYTGTDIST table. Whenever rows are added or changed in SYSKEYTGTDIST, the rows are also written to this table.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If the RUNSTATS utility updated the statistics, this column contains the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.00000'.	G
IBMRREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
IXSCHEMA	VARCHAR(128) NOT NULL	The qualifier of the index.	G
IXNAME	VARCHAR(128) NOT NULL	The name of the index.	G
KEYSEQ	SMALLINT NOT NULL	The numeric position of the key-target in the index.	G
KEYVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	KEYVALUE contains the data of a frequently occurring value. If the value has a non-character data type, the data might not be printable.	G
TYPE	CHAR(1) NOT NULL WITH DEFAULT 'F'	The type of statistics that are gathered:  C      Cardinality F      Frequent value N      Non-padded frequent value H      Histogram statistics	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='C', CARDF contains the number of distinct values for the key group.  When TYPE='H', CARDF contains the number of distinct values for the key group in a quantile indicated by QUANTILENO.	G
KEYGROUPKEYNO	VARCHAR(254) NOT NULL WITH DEFAULT FOR BIT DATA	KEYGROUPKEYNO contains a value that identifies the set of keys that are associated with the statistics.  KEYGROUPKEYNO contains 0 if the statistics are only associated with a single key.  If the statistics are associated with more than a single key, KEYGROUPKEYNO contains an array of SMALLINT key numbers with a dimension that is equal to the value in NUMKEYS.	G
NUMKEYS	SMALLINT NOT NULL WITH DEFAULT -1	The number of keys that are associated with the statistics.	G

Column name	Data type	Description	Use
FREQUENCYF	FLOAT NOT NULL WITH DEFAULT -1	When TYPE='F' or 'N', FREQUENCYF contains the percentage of entries in the index that have the value that is specified in KEYVALUE when the number of entries is multiplied by 100. For example, a value of '1' indicates 100 percent. A value of '.153' indicates 15.3 percent.	G
		When TYPE='H', FREQUENCYF contains the percentage of entries in the index that have a value that is in the range of the quantile that is indicated in QUANTILENO.	
QUANTILENO	SMALLINT NOT NULL WITH DEFAULT -1	QUANTILENO contains an ordinary sequence number of a quantile in the whole consecutive value range, from low to high.	G
LOWVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', LOWVALUE contains the lower bound for the quantile that is in QUANTILENO. LOWVALUE is not used if TYPE does not equal 'H'.	G
HIGHVALUE	VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA	When TYPE='H', HIGHVALUE contains the upper bound for the quantile that is in QUANTILENO. HIGHVALUE is not used if TYPE does not equal 'H'.	G

## SYSIBM.SYSLOBSTATS table

The SYSIBM.SYSLOBSTATS table contains one row for each LOB table space.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL	Timestamp of RUNSTATS statistics update.	G
AVGSIZE	INTEGER NOT NULL	Average size of a LOB, measured in bytes, in the LOB table space.	S
FREESPACE	INTEGER NOT NULL	Number of kilobytes of available space in the LOB table space.	S
ORGRATIO	DECIMAL(5,2) NOT NULL	The percentage of organization in the LOB table space. A value of '100' indicates perfect organization of the LOB table space. A value of '1' indicates that the LOB table space is disorganized.  A value of '0' indicates that the LOB table space is totally disorganized.	S
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the LOB table space named in NAME.	G
NAME	VARCHAR(24) NOT NULL	Name of the LOB table space.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSLOBSTATS\_HIST table

The SYSIBM.SYSLOBSTATS\_HIST table contains rows from SYSIBM.SYSLOBSTATS.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL	Timestamp of RUNSTATS statistics update.	G
FREESPACE	INTEGER NOT NULL	Number of pages of free space in the LOB table space.	S
ORGRATIO	DECIMAL(5,2) NOT NULL	The percentage of organization in the LOB table space. A value of '100' indicates perfect organization of the LOB table space. A value of '1' indicates that the LOB table space is disorganized.  A value of '0' indicates that the LOB table space is totally disorganized.	A S
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the LOB table space named in NAME.	G
NAME	VARCHAR(24) NOT NULL	Name of the LOB table space.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSOBJROLEDEP table

The SYSIBM.SYSOBJROLEDEP table lists the dependent objects for each role.

Column name	Data type	Description	Use
DEFINER	VARCHAR(128) NOT NULL	The authorization ID or role that created the object.	G
DEFINERTYPE	CHAR(1) NOT NULL	The type of definer:  L      Role  blank    Authorization ID	G
ROLENAME	VARCHAR(128) NOT NULL	Name of the role on which there is a dependency.	G
DSCHHEMA	VARCHAR(128) NOT NULL	Name of the schema of the dependent object.	G
DNAME	VARCHAR(762) NOT NULL	Name of the dependent object.	G
DTYPE	CHAR(1) NOT NULL	The type of the dependent object in DNAME:  A      Alias  B      Trigger  D      Database  E      Distinct type  F      User-defined function  I      Index  J      JAR file  K      Package  L      Role  M      Materialized query table  N      Trusted context  O      Stored procedure  P      Plan  Q      Sequence  R      Table space  S      Storage group  T      Table  V      View	G
IBMRREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSPACKAGE table

The SYSIBM.SYSPACKAGE table contains a row for every package.

Column name	Data type	Description	Use
LOCATION	VARCHAR(128) NOT NULL	Always contains blanks	S
COLLID	VARCHAR(128) NOT NULL	Name of the package collection. For a trigger package, it is the schema name of the trigger.	G
NAME	VARCHAR(128) NOT NULL	Name of the package.	G
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	Consistency token for the package. For a package derived from a DB2 DBRM, this is either: <ul style="list-style-type: none"><li>• The “level” as specified by the LEVEL option when the package’s program was precompiled</li><li>• The timestamp indicating when the package’s program was precompiled, in an internal format.</li></ul>	S
OWNER	VARCHAR(128) NOT NULL	Authorization ID of the package owner. For a trigger package, the value is the authorization ID of the owner of the trigger, which is set to the current authorization ID (the plan or package owner for static CREATE TRIGGER statement; the CURRENT SQLID for a dynamic CREATE TRIGGER statement).	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the creator of the package version. For a trigger package, the value is determined differently. For dynamic SQL, it is the primary authorization ID of the user who issued the CREATE TRIGGER statement. For static SQL, it is the authorization ID of the plan or package owner.	G
TIMESTAMP	TIMESTAMP NOT NULL	Timestamp indicating when the package was created.	G
BINDTIME	TIMESTAMP NOT NULL	Timestamp indicating when the package was last bound.	G
QUALIFIER	VARCHAR(128) NOT NULL	Implicit qualifier for the unqualified table, view, index, and alias names in the static SQL statements of the package.	G
PKSIZE	INTEGER NOT NULL	Size of the base section <sup>39</sup> of the package, in bytes.	G
AVGSIZE	INTEGER NOT NULL	Average size, in bytes, of those sections <sup>39</sup> of the plan that contain SQL statements processed at bind time.	G
SYSENTRIES	SMALLINT NOT NULL	Number of enabled or disabled entries for this package in SYSIBM.SYSPKSYSTEM. A value of 0 if all types of connections are enabled.	G

39. Packages are divided into *sections*. The base section of the package must be in the EDM pool during the entire time the package is executing. Other sections of the package, corresponding roughly to sets of related SQL statements, are brought into the pool as needed.

Column name	Data type	Description	Use
VALID	CHAR(1) NOT NULL	Whether the package is valid:  A An ALTER statement changed the description of the table or base table of a view referred to by the package. For a CREATE INDEX statement involving data sharing, VALID is also marked as "A". The changes do not invalidate the package.  H An ALTER TABLE statement changed the description of the table or base table of a view referred to by the package. For releases of DB2 prior to Version 5, the change invalidates the package.  N No Y Yes	G
OPERATIVE	CHAR(1) NOT NULL	Whether the package can be allocated:  N No; an explicit BIND or REBIND is required before the package can be allocated.  Y Yes	G
VALIDATE	CHAR(1) NOT NULL	Whether validity checking can be deferred until run time:  B All checking must be performed at bind time.  R Validation is done at run time for tables, views, and privileges that do not exist at bind time.	G
ISOLATION	CHAR(1) NOT NULL	Isolation level when the package was last bound or rebound  R RR (repeatable read) S CS (cursor stability) T RS (read stability) U UR (uncommitted read) blank Not specified, and therefore at the level specified for the plan executing the package	G
RELEASE	CHAR(1) NOT NULL	The value used for RELEASE when the package was last bound or rebound:  C Value used was COMMIT. D Value used was DEALLOCATE. I The local package is inheriting the value from the plan  blank Not specified, and therefore the value specified for the plan executing the package.	G
EXPLAIN	CHAR(1) NOT NULL	EXPLAIN option specified for the package; that is, whether information on the package's statements was added to the owner of the PLAN_TABLE table:  N No Y Yes	G
QUOTE	CHAR(1) NOT NULL	SQL string delimiter for SQL statements in the package:  N Apostrophe Y Quotation mark	G
COMMA	CHAR(1) NOT NULL	Decimal point representation for SQL statements in package:  N Period Y Comma	G

Column name	Data type	Description	Use
HOSTLANG	CHAR(1) NOT NULL	Host language for the package's DBRM:  <b>B</b> Assembler language <b>C</b> OS/VS COBOL <b>D</b> C <b>F</b> Fortran <b>P</b> PL/I <b>2</b> VS COBOL II or IBM COBOL Release 1 (formerly called COBOL/370) <b>3</b> IBM COBOL (Release 2 or subsequent releases) <b>4</b> C++ <b>blank</b> For remotely bound packages, or trigger packages (TYPE='T')	G
CHARSET	CHAR(1) NOT NULL	Indicates whether the system CCSID for SBCS data was 290 (Katakana) when the program was precompiled:  <b>K</b> Yes <b>A</b> No	G
MIXED	CHAR(1) NOT NULL	Indicates if mixed data was in effect when the package's program was precompiled (for more on when mixed data is in effect, see "Character strings" on page 73):  <b>N</b> No <b>Y</b> Yes	G
DEC31	CHAR(1) NOT NULL	Indicates whether DEC31 was in effect when the package's program was precompiled (for more on when DEC31 is in effect, see "Arithmetic with two decimal operands" on page 183):  <b>N</b> No <b>Y</b> Yes	G
DEFERPREP	CHAR(1) NOT NULL	Indicates the CURRENTDATA option when the package was bound or rebound:  <b>A</b> Data currency is required for all cursors. Inhibit blocking for all cursors. <b>B</b> Data currency is not required for ambiguous cursors. <b>C</b> Data currency is required for ambiguous cursors. <b>blank</b> The package was created before the CURRENTDATA option was available.	G
SQLERROR	CHAR(1) NOT NULL	Indicates the SQLERROR option on the most recent subcommand that bound or rebound the package:  <b>C</b> CONTINUE <b>N</b> NOPACKAGE	G
REMOTE	CHAR(1) NOT NULL	Source of the package:  <b>C</b> Package was created by BIND COPY. <b>D</b> Package was created by BIND COPY with the OPTIONS(COMMAND) option. <b>K</b> The package was copied from a package that was originally bound on behalf of a remote requester. <b>L</b> The package was copied with the OPTIONS(COMMAND) option from a package that was originally bound on behalf of a remote requester. <b>N</b> Package was locally bound from a DBRM. <b>Y</b> Package was bound on behalf of a remote requester.	G

Column name	Data type	Description	Use
PCTIMESTAMP	TIMESTAMP NOT NULL	Date and time the application program was precompiled, or '0001-01-01-00.00.00.000000' if the LEVEL precompiler option was used, or if the package came from a non-DB2 location.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
VERSION	VARCHAR(122) NOT NULL	Version identifier for the package. The value is blank for a trigger package (TYPE='T').	G
PDSNAME	VARCHAR(132) NOT NULL	For a locally bound package, the name of the PDS (library) in which the package's DBRM is a member. For a locally copied package, the value in SYSPACKAGE.PDSNAME for the source package. Otherwise, the product signature of the bind requester followed by one of the following: <ul style="list-style-type: none"><li>• The requester's location name if the product is DB2</li><li>• Otherwise, the requester's LU name enclosed in angle brackets; for example, "&lt;LUSQLDS&gt;".</li></ul>	G
DEGREE	CHAR(3) NOT NULL WITH DEFAULT	The DEGREE option used when the package was last bound: <b>ANY DEGREE(ANY)</b> <b>1 or blank</b> DEGREE(1). Blank if the package was migrated.	G
GROUP_MEMBER	VARCHAR(24) NOT NULL WITH DEFAULT	The DB2 data sharing member name of the DB2 subsystem that performed the most recent bind. This column is blank if the DB2 subsystem was not in a DB2 data sharing environment when the bind was performed.	G

Column name	Data type	Description	Use
DYNAMICRULES	CHAR(1) NOT NULL WITH DEFAULT	<p>The DYNAMICRULES option used when the package was last bound:</p> <p><b>B</b> BIND. Dynamic SQL statements are executed with DYNAMICRULES bind behavior.</p> <p><b>D</b> DEFINEBIND. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES define behavior.</p> <p><b>E</b> DEFINERUN. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES define behavior.</p> <p><b>F</b> When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES run behavior.</p> <p><b>H</b> INVOKEBIND. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES invoke behavior.</p> <p><b>I</b> When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES bind behavior.</p> <p><b>J</b> INVOKERUN. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES invoke behavior.</p> <p><b>R</b> RUN. Dynamic SQL statements are executed with DYNAMICRULES run behavior.</p> <p><b>blank</b> DYNAMICRULES is not specified for the package. The package uses the DYNAMICRULES value of the plan to which the package is appended at execution time.</p>	G

For a description of the DYNAMICRULES behaviors, see “Authorization IDs and dynamic SQL” on page 64.

Column name	Data type	Description	Use
REOPTVAR	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether the access path is determined again at execution time using input variable values:  A Bind option REOPT(AUTO) indicates that the access path is determined multiple times at execution time depending on the parameter value.  N Bind option REOPT(NONE) indicates that the access path is determined at bind time.  Y Bind option REOPT(ALWAYS) indicates that the access path is determined at execution time for SQL statements with variable values.  1 Bind option REOPT(ONCE) indicates that the access path is determined only once at execution time, using the first set of input variable values, regardless of how many times the same statement is executed.	G
DEFERPREPARE	CHAR(1) NOT NULL WITH DEFAULT	Whether PREPARE processing is deferred until OPEN is executed:  N Bind option NODEFER(PREPARE) indicates that PREPARE processing is not deferred until OPEN is executed.  Y Bind option DEFER(PREPARE) indicates that PREPARE processing is deferred until OPEN is executed.  blank Bind option not specified for the package. It is inherited from the plan.	G
KEEPDYNAMIC	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether prepared dynamic statements are to be purged at each commit point:  N The bind option is KEEPDYNAMIC(NO). Prepared dynamic SQL statements are destroyed at commit.  Y The bind option is KEEPDYNAMIC(YES). Prepared dynamic SQL statements are kept past commit.	G
PATHSCHEMAS	VARCHAR(2048) NOT NULL WITH DEFAULT	SQL path specified on the BIND or REBIND command that bound the package. The path is used to resolve unqualified data type, function, and stored procedure names used in certain contexts. If the PATH bind option was not specified, the value in the column is a zero length string; however, DB2 uses a default SQL path of: SYSIBM, SYSFUN, SYSPROC, <i>package qualifier</i> .	G
TYPE	CHAR(1) NOT NULL WITH DEFAULT	Type of package. Identifies how the package is created:  N CREATE PROCEDURE or ALTER PROCEDURE statement, or BIND PACKAGE DEPLOY command created the package, and this package is a native SQL routine package.  T CREATE TRIGGER statement created the package, and the package is a trigger package.  blank BIND PACKAGE command created the package.	G
DBPROTOCOL	CHAR(1) NOT NULL WITH DEFAULT 'P'	Whether remote access for SQL with three-part names is implemented with DRDA or DB2 private protocol access:  D DRDA  P DB2 private protocol	G

Column name	Data type	Description	Use
FUNCTIONTS	TIMESTAMP NOT NULL WITH DEFAULT	Timestamp when the function was resolved. Set by the BIND and REBIND commands, but not by AUTOBIND.	G
OPTHINT	VARCHAR(128) NOT NULL WITH DEFAULT	Value of the OPTHINT bind option. Identifies rows in the owner.PLAN_TABLE to be used as input to DB2. Contains blanks if no rows in the owner.PLAN_TABLE are to be used as input.	G
ENCODING_CCSID	INTEGER NOT NULL WITH DEFAULT	The CCSID corresponding to the encoding scheme or CCSID as specified for the bind option ENCODING. The Encoding Scheme specified on the bind command: <b>ccsid</b> The specified or derived CCSID. <b>0</b> The default CCSID as specified on panel DSNTIPF at installation time. Used when the package was bound prior to Version 7.	G
IMMEDWRITE	CHAR(1) NOT NULL WITH DEFAULT	Indicates when writes of updated group buffer pool dependent pages are to be done. This option is only applicable for data sharing environments. <b>N</b> Bind option IMMEDWRITE(NO) indicates normal write activity is done. <b>Y</b> Bind option IMMEDWRITE(YES) indicates that immediate writes are done for updated group buffer pool dependent pages. <b>1</b> Bind option IMMEDWRITE(PH1) indicates that updated group buffer pool dependent pages are written at or before phase 1 commit. <b>blank</b> A migrated package.	G
RELBOUND	CHAR(1) NOT NULL WITH DEFAULT	The release when the package was bound or rebound. <b>blank</b> Bound prior to Version 7 For all other values, see Release dependency indicators	G
	CHAR(1)	Not used.	N
REMARKS	VARCHAR(550) NOT NULL WITH DEFAULT	A character string provided by the user with the COMMENT statement.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner <b>blank</b> Authorization ID <b>L</b> Role	G
ROUNDING	CHAR(1) NOT NULL WITH DEFAULT	The ROUNDING option used when the package was last bound: <b>C</b> ROUND_CEILING <b>D</b> ROUND_DOWN <b>F</b> ROUND_FLOOR <b>G</b> ROUND_HALF_DOWN <b>E</b> ROUND_HALF_EVEN <b>H</b> ROUND_HALF_UP <b>U</b> ROUND_UP <b>blank</b> The package created in a DB2 release prior to Version 9.	G

Column name	Data type	Description	Use
DISTRIBUTE	CHAR(1) NOT NULL WITH DEFAULT 'N'	Determines if DB2 should gather location names from SQL statements, and create remote packages for the user (This only has effect during local bind):  A      DB2 will collect remote location names from SQL statements during local bind, and automatically create remote packages at those sites. The site names are gathered from object names in static SQL statements and literals on CONNECT statements. The sites at which the package is remotely bound can be determined by the location (BTYPE='X') records in SYSIBM.SYSPACKDEP for this package.  L      DB2 will automatically create remote packages at the sites specified in the list of location-names. The sites at which the package is remotely bound can be determined by the location (BTYPE='X') records in SYSIBM.SYSPACKDEP for this package.	G
	DATE NOT NULL WITH DEFAULT	Not used	N

## SYSIBM.SYSPACKAUTH table

The SYSIBM.SYSPACKAUTH table records the privileges that are held by users over packages.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privilege. Could also be PUBLIC or PUBLIC followed by an asterisk <sup>40</sup> .	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user who holds the privileges, the name of a plan that uses the privileges or PUBLIC for a grant to PUBLIC.	G
LOCATION	VARCHAR(128) NOT NULL	Always contains blanks	S
COLLID	VARCHAR(128) NOT NULL	Collection name for the package or packages on which the privilege was granted.	G
NAME	VARCHAR(128) NOT NULL	Name of the package on which the privileges are held. An asterisk (*) if the privileges are held on all packages in a collection.	G
	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	Not used	N
TIMESTAMP	TIMESTAMP NOT NULL	Timestamp indicating when the privilege was granted.	G
GRANTEETYPE	CHAR(1) NOT NULL	Type of grantee: <b>blank</b> An authorization ID <b>L</b> Role <b>P</b> An application plan	G
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor. <b>blank</b> Not applicable <b>A</b> PACKADM (on collection *) <b>C</b> DBCTRL <b>D</b> DBADM <b>L</b> SYSCTRL <b>M</b> DBMAINT <b>P</b> PACKADM (on a specific collection) <b>S</b> SYSADM	G
BINDAUTH	CHAR(1) NOT NULL	Whether GRANTEE can use the BIND and REBIND subcommands on the package: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

40. PUBLIC followed by an asterisk (PUBLIC\*) denotes PUBLIC AT ALL LOCATIONS. For the conditions where GRANTOR can be PUBLIC or PUBLIC\*, see *DB2 Administration Guide*.

Column name	Data type	Description	Use
COPYAUTH	CHAR(1) NOT NULL	Whether GRANTEE can COPY the package: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
EXECUTEAUTH	CHAR(1) NOT NULL	Whether GRANTEE can execute the package: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSPACKDEP table

The SYSIBM.SYSPACKDEP table records the dependencies of packages on local tables, views, synonyms, table spaces, indexes, aliases, functions, and stored procedures.

Column name	Data type	Description	Use																										
BNAME	VARCHAR(128) NOT NULL	The name of an object that a package depends on.	G																										
BQUALIFIER	VARCHAR(128) NOT NULL	<p>The value of the column depends on the type of object:</p> <ul style="list-style-type: none"> <li>• If BNAME identifies a table space (BTYPE is R), the value is the name of its database.</li> <li>• If BNAME identifies user-defined function, a cast function, a stored procedure, or a sequence (BTYPE is F, O, or Q), the value is the schema name.</li> <li>• If BNAME identifies a role, the value is blank.</li> <li>• Otherwise, the value is the schema of BNAME.</li> </ul>	G																										
BTYPE	CHAR(1) NOT NULL	<p>Type of object identified by BNAME and BQUALIFIER:</p> <table> <tr><td>A</td><td>Alias</td></tr> <tr><td>E</td><td>INSTEAD OF trigger</td></tr> <tr><td>F</td><td>User-defined function or cast function</td></tr> <tr><td>G</td><td>Global temporary table</td></tr> <tr><td>I</td><td>Index</td></tr> <tr><td>M</td><td>Materialized query table</td></tr> <tr><td>O</td><td>Stored procedure</td></tr> <tr><td>P</td><td>Partitioned table space if it is defined as LARGE or with the DSSIZE parm</td></tr> <tr><td>Q</td><td>Sequence object</td></tr> <tr><td>R</td><td>Table space</td></tr> <tr><td>S</td><td>Synonym</td></tr> <tr><td>T</td><td>Table</td></tr> <tr><td>V</td><td>View</td></tr> </table>	A	Alias	E	INSTEAD OF trigger	F	User-defined function or cast function	G	Global temporary table	I	Index	M	Materialized query table	O	Stored procedure	P	Partitioned table space if it is defined as LARGE or with the DSSIZE parm	Q	Sequence object	R	Table space	S	Synonym	T	Table	V	View	G
A	Alias																												
E	INSTEAD OF trigger																												
F	User-defined function or cast function																												
G	Global temporary table																												
I	Index																												
M	Materialized query table																												
O	Stored procedure																												
P	Partitioned table space if it is defined as LARGE or with the DSSIZE parm																												
Q	Sequence object																												
R	Table space																												
S	Synonym																												
T	Table																												
V	View																												
DLOCATION	VARCHAR(128) NOT NULL	Always contains blanks	S																										
DCOLLID	VARCHAR(128) NOT NULL	Name of the package collection.	G																										
DNAME	VARCHAR(128) NOT NULL	Name of the package.	G																										
DCONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	<p>Consistency token for the package. This is either:</p> <ul style="list-style-type: none"> <li>• The “level” as specified by the LEVEL option when the package’s program was precompiled</li> <li>• The timestamp indicating when the package’s program was precompiled, in an internal format.</li> </ul>	S																										
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G																										
DOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Owner of the package:	G																										

Column name	Data type	Description	Use
DTYPE		Type of package:	G
	CHAR(1)	N Native SQL routine package	
	NOT NULL WITH	O Original copy of a package	
	DEFAULT	P Previous copy of a package	
		T Trigger package	
		blank Not a trigger package or a native SQL routine package	
DOWNERTYPE		Indicates the type of owner of the package:	G
	CHAR(1)	blank Authorization ID	
	NOT NULL WITH	L Role	
	DEFAULT		

## SYSIBM.SYSPACKLIST table

The SYSIBM.SYSPACKLIST table contains one or more rows for every local application plan bound with a package list. Each row represents a unique entry in the plan's package list.

Column name	Data type	Description	Use
PLANNNAME	VARCHAR(24) NOT NULL	Name of the application plan.	G
SEQNO	SMALLINT NOT NULL	Sequence number of the entry in the package list.	G
LOCATION	VARCHAR(128) NOT NULL	Location of the package. Blank if this is local. An asterisk (*) indicates location to be determined at run time.	G
COLLID	VARCHAR(128) NOT NULL	Collection name for the package. An asterisk (*) indicates that the collection name is determined at run time.	G
NAME	VARCHAR(128) NOT NULL	Name of the package. An asterisk (*) indicates an entire collection.	G
TIMESTAMP	TIMESTAMP NOT NULL	Timestamp indicating when the row was created.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSPACKSTMT table

The SYSIBM.SYSPACKSTMT table contains one or more rows for each statement in a package.

Column name	Data type	Description	Use				
LOCATION	VARCHAR(128) NOT NULL	Always contains blanks	S				
COLLID	VARCHAR(128) NOT NULL	Name of the package collection.	G				
NAME	VARCHAR(128) NOT NULL	Name of the package.	G				
CONTOKEN	CHAR(8) NOT NULL FOR BIT DATA	Consistency token for the package. This is either: <ul style="list-style-type: none"> <li>The “level” as specified by the LEVEL option when the package’s program was precompiled</li> <li>The timestamp indicating when the package’s program was precompiled, in an internal format</li> </ul>	S				
SEQNO	INTEGER NOT NULL	Sequence number of the row with respect to a statement in the package <sup>41</sup> . The numbering starts with 0.	G				
STMTNO	SMALLINT NOT NULL	The statement number of the statement in the source program. A statement number greater than 32767 is stored as zero <sup>41</sup> or as a negative number <sup>42</sup> . If the value is zero, see STMTNOI for the statement number.	G				
SECTNO	SMALLINT NOT NULL	The section number of the statement. <sup>42</sup>	G				
BINDERROR	CHAR(1) NOT NULL	Whether an SQL error was detected at bind time: <table> <tr> <td>N</td> <td>No</td> </tr> <tr> <td>Y</td> <td>Yes</td> </tr> </table>	N	No	Y	Yes	G
N	No						
Y	Yes						
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G				
VERSION	VARCHAR(122) NOT NULL	Version identifier for the package.	G				
STMT	VARCHAR(3500) NOT NULL WITH DEFAULT FOR BIT DATA	All or a portion of the text for the SQL statement that the row represents.	S				

41. Rows in which the value of SEQNO, STMTNO, and SECTNO are zero are for internal use.

42. To convert a negative STMTNO to a meaningful statement number that corresponds to your precompile output, add 65536 to it. For example, -26472 is equivalent to +39064 (-26472 + 65536).

Column name	Data type	Description	Use
ISOLATION	CHAR(1) NOT NULL WITH DEFAULT	<p>Isolation level for the SQL statement:</p> <p><b>R</b> RR (repeatable read)  <b>T</b> RS (read stability)  <b>S</b> CS (cursor stability)  <b>U</b> UR (uncommitted read)  <b>L</b> RS isolation, with a <i>lock-clause</i>  <b>X</b> RR isolation, with a <i>lock-clause</i>  <b>blank</b> The WITH clause was not specified on this statement. The isolation level is recorded in SYSPACKAGE.ISOLATION and in SYSPLAN.ISOLATION.</p>	G
STATUS	CHAR(1) NOT NULL WITH DEFAULT	<p>Status of binding the statement:</p> <p><b>A</b> Distributed - statement uses DB2 private protocol access. The statement will be parsed and executed at the server using defaults for input variables during access path selection.</p> <p><b>B</b> Distributed - statement uses DB2 private protocol access. The statement will be parsed and executed at the server using values for input variables during access path selection.</p> <p><b>C</b> Compiled - statement was bound successfully using defaults for input variables during access path selection.</p> <p><b>D</b> Distributed - statement references a remote object using a three-part name. DB2 will implicitly use DRDA access either because the DBPROTOCOL bind option was not specified (defaults to DRDA), or the bind option DBPROTOCOL(DRDA) was explicitly specified. This option allows the use of three-part names with DRDA access but it requires that the package be bound at the target remote site.</p> <p><b>E</b> Explain - statement is an SQL EXPLAIN statement. The explain is done at bind time using defaults for input variables during access path selection.</p> <p><b>F</b> Parsed - statement did not bind successfully and VALIDATE(RUN) was used. The statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>G</b> Compiled - statement bound successfully, but REOPT is specified. The statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>H</b> Parsed - statement is either a data definition statement or a statement that did not bind successfully and VALIDATE(RUN) was used. The statement will be rebound at execution time using defaults for input variables during access path selection. Data manipulation statements use defaults for input variables during access path selection.</p> <p><b>I</b> Indefinite - statement is dynamic. The statement will be bound at execution time using defaults for input variables during access path selection.</p>	S

Column name	Data type	Description	Use
STATUS (cont.)		<p><b>J</b> Indefinite - statement is dynamic. The statement will be bound at execution time using values for input variables during access path selection.</p> <p><b>K</b> Control - CALL statement.</p> <p><b>L</b> Bad - the statement has some allowable error. The bind continues but the statement cannot be executed.</p> <p><b>M</b> Parsed - statement references a table that is qualified with SESSION and was not bound because the table reference could be for a declared temporary table that will not be defined until the package or plan is run. The SQL statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>blank</b> The statement is non-executable, or was bound in a DB2 release prior to Version 5.</p>	
ACCESSPATH	CHAR(1) NOT NULL WITH DEFAULT	For static statements, indicates if the access path for the statement is based on user-specified optimization hints. A value of 'H' indicates that optimization hints were used. A blank value indicates that the access path was determined without the use of optimization hints, or that there is no access path associated with the statement.	G
		For dynamic statements, the value is blank.	
STMTNOI	INTEGER NOT NULL WITH DEFAULT	If the value of STMTNO is zero, the column contains the statement number of the statement in the source program. If both STMTNO and STMTNOI are zero, the statement number is greater than 32767.	G
SECTNOI	INTEGER NOT NULL WITH DEFAULT	The section number of the statement.	G
EXPLAINABLE	CHAR(1) NOT NULL WITH DEFAULT	<p>Contains one of the following values:</p> <p><b>Y</b> Indicates that the SQL statement can be used with the EXPLAIN function and might have rows describing its access path in the owner.PLAN_TABLE.</p> <p><b>N</b> Indicates that the SQL statement does not have any rows describing its access path in the owner.PLAN_TABLE.</p> <p><b>blank</b> Indicates that the SQL statement was bound prior to Version 7.</p>	G
QUERYNO	INTEGER NOT NULL WITH DEFAULT -1	The query number of the SQL statement in the source program. SQL statements bound prior to Version 7 have a default value of -1. Statements bound in Version 7 or later use the value specified on the QUERYNO clause on SELECT, UPDATE, INSERT, DELETE, EXPLAIN, DECLARE CURSOR, or REFRESH TABLE statements. If the QUERYNO clause is not specified, the query number is set to the statement number.	G

## SYSIBM.SYSPARMS table

The SYSIBM.SYSPARMS table contains a row for each parameter of a routine or multiple rows for table parameters (one for each column of the table).

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the routine.	G
OWNER	VARCHAR(128) NOT NULL	Owner of the routine.	G
NAME	VARCHAR(128) NOT NULL	Name of the routine.	G
SPECIFICNAME	VARCHAR(128) NOT NULL	Specific name of the routine.	G
ROUTINETYPE	CHAR(1) NOT NULL	Type of routine:  F User-defined function or cast function P Stored procedure	G
CAST_FUNCTION	CHAR(1) NOT NULL	Whether the routine is a cast function:  N Not a cast function Y A cast function	G
		The only way to get a value of Y is if a user creates a distinct type when DB2 implicitly generates cast functions for the distinct type.	
PARMNAME	VARCHAR(128) NOT NULL	Name of the parameter. For a table parameter, the parameter name in the row corresponding to the first column of the table is the parameter name specified on CREATE; an empty string or blanks are stored for the parameter name for the rows corresponding to the remaining columns.	G
ROUTINEID	INTEGER NOT NULL	Internal identifier of the routine.	S

Column name	Data type	Description	Use
ROWTYPE	CHAR(1) NOT NULL	The following values indicate the type of parameter described by this row:  <b>P</b> Input parameter. <b>O</b> Output parameter; not applicable for functions <b>B</b> Both an input and an output parameter; not applicable for functions <b>R</b> Result before casting; not applicable for stored procedures <b>C</b> Result after casting; not applicable for stored procedures <b>S</b> Input parameter of the underlying built-in source function. For a sourced function and a given ORDINAL value: <ul style="list-style-type: none"> <li>• The row with ROWTYPE = P describes the input parameter of the user-defined function (identified by ROUTINEID).</li> <li>• The row with ROWTYPE = S describes the corresponding input parameter of the built-in function that is the underlying source function (identified by the SOURCESCHEMA and SOURCESPECIFIC values).</li> </ul>	G
		A value of 'X' indicates that the row is not used to describe a particular parameter of the routine. Instead, for a routine that was created prior to Version 9, the row is used to record a CCSID for the encoding scheme specified in a PARAMETER CCSID clause, or a DATATYPEID for the representation of the variable length character string parameters of a LANGUAGE C routine, as specified in a PARAMETER VARCHAR clause. For routines created with Version 8 (new function mode) or later releases, the CCSID is recorded in the PARAMETER_CCSID column of SYSROUTINES. For routines created with Version 9 or later releases, the DATATYPEID information to support PARAMETER VARCHAR is recorded in the PARAMETER_VARCHARFORM column of SYSIBM.SYSROUTINES.	
ORDINAL	SMALLINT NOT NULL	If ROWTYPE is B, O, P, or S, the value is the ordinal number of the parameter within the routine signature.  If ROWTYPE is C or R, the value depends on the type of function: <ul style="list-style-type: none"> <li>• For a scalar function, the value is 0.</li> <li>• For a table function, the value is the ordinal number of the column of the output table.</li> </ul> If ROWTYPE is X, the value is 0.	G
TYPESCHEMA	VARCHAR(128) NOT NULL	Schema of the data type of the parameter.	G
TYPENAME	VARCHAR(128) NOT NULL	Name of the data type of the parameter.	G

Column name	Data type	Description	Use
DATATYPEID	INTEGER NOT NULL	For a built-in data type, the internal ID of the built-in type. For a distinct type, the internal ID of the distinct type.	S
		When ROWTYPE is X and ORDINAL is 0, a non-zero DATATYPEID indicates that actual representation, for a LANGUAGE C routine, of any varying length string parameters that appear in the routine's parameter list or in the RETURNS clause.	
SOURCETYPEID	INTEGER NOT NULL	For a built-in data type, 0. For a distinct type, the internal ID of the built-in data type upon which the distinct type is based.	S
LOCATOR	CHAR(1) NOT NULL	Indicates whether a locator to a value, instead of the actual value, is to be passed or returned when the routine is called:  N      The actual value is to be passed. Y      A locator to a value is to be passed	G
TABLE	CHAR(1) NOT NULL	The data type of a column for a table parameter:  N      This is not a table parameter. Y      This is a table parameter.	G
TABLE_COLNO	SMALLINT NOT NULL	For table parameters, the column number of the table. Otherwise, the value is 0.	G
LENGTH	INTEGER NOT NULL	Length attribute of the parameter or result; If the parameter or result length is determined during function resolution, the length attribute can also be 0. In the case of a decimal parameter or result this is the precision.	G
SCALE	SMALLINT NOT NULL	Scale of the parameter or result. If the parameter or result scale is determined during function resolution, the scale can also be 0.	G
SUBTYPE	CHAR(1) NOT NULL	If the data type is a distinct type, the subtype of the distinct type, which is based on the subtype of its source type:  B      The subtype is FOR BIT DATA. S      The subtype is FOR SBCS DATA. M      The subtype is FOR MIXED DATA. blank   The source type is not a character type.	G
CCSID	INTEGER NOT NULL	CCSID of the data type for character, graphic, date, time, and timestamp data types. When ROWTYPE is X and ORDINAL is 0, the CCSID column is the CCSID for all character and graphic string parameters.	G
CAST_FUNCTION_ID	INTEGER NOT NULL	Internal function ID of the function used to cast the argument, if this function is sourced on another function, or result. Otherwise, the value is 0. Not applicable for stored procedures.	S
ENCODING_SCHEME	CHAR(1) NOT NULL	Encoding scheme of the parameter:  A      ASCII E      EBCDIC U      UNICODE blank   The source type is not a character, graphic, or datetime type.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
VERSION	VARCHAR(122) NOT NULL WITH DEFAULT	The version identifier for the routine. The column is a zero-length string if the value of ORIGIN is not 'T' or if the rows were created prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSPKSYSTEM table

The SYSIBM.SYSPKSYSTEM table contains zero or more rows for every package. Each row for a given package represents one or more connections to an environment in which the package could be executed.

Column name	Data type	Description	Use				
LOCATION	VARCHAR(128) NOT NULL	Always contains blanks	S				
COLLID	VARCHAR(128) NOT NULL	Name of the package collection.	G				
NAME	VARCHAR(128) NOT NULL	Name of the package.	G				
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	Consistency token for the package. This is either: <ul style="list-style-type: none"> <li>• The “level” as specified by the LEVEL option when the package’s program was precompiled</li> <li>• The timestamp indicating when the package’s program was precompiled, in an internal format.</li> </ul>	S				
SYSTEM	VARCHAR(24) NOT NULL	Environment. Values can be: <b>BATCH</b> TSO batch <b>CICS</b> Customer Information Control System <b>DB2CALL</b> DB2 call attachment facility <b>DLIBATCH</b> DLI batch support facility <b>IMSBMP</b> IMS BMP region <b>IMSMPP</b> IMS MPP and IFP region <b>REMOTE</b> remote server	G				
ENABLE	CHAR(1) NOT NULL	Indicates whether the connections represented by the row are enabled or disabled: <table> <tr> <td>N</td> <td>Disabled</td> </tr> <tr> <td>Y</td> <td>Enabled</td> </tr> </table>	N	Disabled	Y	Enabled	G
N	Disabled						
Y	Enabled						
CNAME	VARCHAR(60) NOT NULL	Identifies the connection or connections to which the row applies. Interpretation depends on the environment specified by SYSTEM. Values can be: <ul style="list-style-type: none"> <li>• Blank if SYSTEM=BATCH or SYSTEM=DB2CALL</li> <li>• The LU name for a database server if SYSTEM=REMOTE</li> <li>• Either the requester’s location (if the product is DB2) or the requester’s LU name enclosed in angle brackets if SYSTEM=REMOTE.</li> <li>• The name of a single connection if SYSTEM has any other value.</li> </ul>	G				
		CNAME can also be blank when SYSTEM is not equal to BATCH or DB2CALL. When this is so, the row applies to all servers or connections for the indicated environment.					

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSPLAN table

The SYSIBM.SYSPLAN table contains one row for each application plan.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Name of the application plan.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the application plan.	G
	CHAR(6) NOT NULL	Not used	N
VALIDATE	CHAR(1) NOT NULL	Whether validity checking can be deferred until run time:  <b>B</b> All checking must be performed during BIND. <b>R</b> Validation is done at run time for tables, views, and privileges that do not exist at bind time.	G
ISOLATION	CHAR(1) NOT NULL	Isolation level for the plan:  <b>R</b> RR (repeatable read) <b>T</b> RS (read stability) <b>S</b> CS (cursor stability) <b>U</b> UR (uncommitted read)	G
VALID	CHAR(1) NOT NULL	Whether the application plan is valid:  <b>A</b> An ALTER TABLE statement changed the description of the table or base table of a view that is referred to by the application plan. For a CREATE INDEX statement involving data sharing, VALID is also marked as "A". <b>H</b> An ALTER TABLE statement changed the description of the table or base table of a view that is referred to by the application plan. <b>N</b> No <b>Y</b> Yes	G
OPERATIVE	CHAR(1) NOT NULL	Whether the application plan can be allocated:  <b>N</b> No; an explicit BIND or REBIND is required before the plan can be allocated <b>Y</b> Yes	G
	CHAR(8) NOT NULL	Not used	N
PLSIZE	INTEGER NOT NULL	Size of the base section <sup>43</sup> of the plan, in bytes.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
AVGSIZE	INTEGER NOT NULL	Average size, in bytes, of those sections <sup>43</sup> of the plan that contain SQL statements processed at bind time.	G

43. Plans are divided into *sections*. The base section of the plan must be in the EDM pool during the entire time the application program is executing. Other sections of the plan, corresponding roughly to sets of related SQL statements, are brought into the pool as needed.

Column name	Data type	Description	Use
ACQUIRE	CHAR(1) NOT NULL	When resources are acquired:  A At allocation U At first use	G
RELEASE	CHAR(1) NOT NULL	When resources are released:  C At commit D At deallocation	G
	CHAR(1) NOT NULL	Not used	N
	CHAR(1) NOT NULL	Not used	N
	CHAR(1) NOT NULL	Not used	N
EXPLAIN	CHAR(1) NOT NULL	EXPLAIN option specified for the plan; that is, whether information on the plan's statements was added to the owner's PLAN_TABLE table:  N No Y Yes	G
EXPREDICATE	CHAR(1) NOT NULL	Indicates the CURRENTDATA option when the plan was bound or rebound:  B Data currency is not required for ambiguous cursors. Allow blocking for ambiguous cursors. C Data currency is required for ambiguous cursors. Inhibit blocking for ambiguous cursors. N Blocking is inhibited for ambiguous cursors, but the plan was created before the CURRENTDATA option was available.	G
BOUNDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the binder of the plan.	G
QUALIFIER	VARCHAR(128) NOT NULL WITH DEFAULT	Implicit qualifier for the unqualified table, view, index, and alias names in the static SQL statements of the plan.	G
CACHESIZE	SMALLINT NOT NULL WITH DEFAULT	Size, in bytes, of the cache to be acquired for the plan. A value of zero indicates that no cache is used.	G
PLENTRIES	SMALLINT NOT NULL WITH DEFAULT	Number of package list entries for the plan. The negative of that number if there are rows for the plan in SYSIBM.SYSPACKLIST but the plan was bound in a prior release after fall back.	G
DEFERPREP	CHAR(1) NOT NULL WITH DEFAULT	Whether the package was last bound with the DEFER(PREPARE) option:  N No Y Yes	G

Column name	Data type	Description	Use
CURRENTSERVER	VARCHAR(128) NOT NULL WITH DEFAULT	Location name specified with the CURRENTSERVER option when the plan was last bound. Blank if none was specified, implying that the first server is the local DB2 subsystem.	G
SYSENTRIES	SMALLINT NOT NULL WITH DEFAULT	Number of rows associated with the plan in SYSIBM.SYSPLSYSTEM. The negative of that number if such rows exist but the plan was bound in a prior release after fall back. A negative value or zero means that all connections are enabled.	G
DEGREE	CHAR(3) NOT NULL WITH DEFAULT	The DEGREE option used when the plan was last bound: <b>ANY</b> DEGREE(ANY) <b>1 or blank</b> DEGREE(1). Blank if the plan was migrated.	G
SQLRULES	CHAR(1) NOT NULL WITH DEFAULT	The SQLRULES option used when the plan was last bound: <b>D or blank</b> SQLRULES(DB2) <b>S</b> SQLRULES(STD) <b>blank</b> A migrated plan	G
DISCONNECT	CHAR(1) NOT NULL WITH DEFAULT	The DISCONNECT option used when the plan was last bound: <b>E or blank</b> DISCONNECT(EXPLICIT) <b>A</b> DISCONNECT(AUTOMATIC) <b>C</b> DISCONNECT(CONDITIONAL) <b>blank</b> A migrated plan	G
GROUP_MEMBER	VARCHAR(24) NOT NULL WITH DEFAULT	The DB2 data sharing member name of the DB2 subsystem that performed the most recent bind. This column is blank if the DB2 subsystem was not in a DB2 data sharing environment when the bind was performed.	G
DYNAMICRULES	CHAR(1) NOT NULL WITH DEFAULT	The DYNAMICRULES option used when the plan was last bound: <b>B</b> BIND. Dynamic SQL statements are executed with DYNAMICRULES bind behavior. <b>blank</b> RUN. Dynamic SQL statements in the plan are executed with DYNAMICRULES run behavior.	G
BOUNDTIME	TIMESTAMP NOT NULL WITH DEFAULT	Time when the plan was bound.	G

Column name	Data type	Description	Use
REOPTVAR	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether the access path is determined again at execution time using input variable values:  A Bind option REOPT(AUTO) indicates that the access path is determined multiple times at execution time depending on the parameter value.  N Bind option REOPT(NONE) indicates that the access path is determined at bind time.  Y Bind option REOPT(ALWAYS) indicates that the access path is determined at execution time for SQL statements with variable values.  1 Bind option REOPT(ONCE) indicates that the access path is determined only once at execution time, using the first set of input variable values, regardless of how many times the same statement is executed.	G
KEEPDYNAMIC	CHAR(1) NOT NULL WITH DEFAULT 'N'	Whether prepared dynamic statements are to be purged at each commit point:  N The bind option is KEEPDYNAMIC(NO). Prepared dynamic SQL statements are destroyed at commit or rollback.  Y The bind option is KEEPDYNAMIC(YES). Prepared dynamic SQL statements are kept past commit or rollback.	G
PATHSCHEMAS	VARCHAR(2048) NOT NULL WITH DEFAULT	SQL path specified on the BIND or REBIND command that bound the plan. The path is used to resolve unqualified data type, function, and stored procedure names used in certain contexts. If the PATH bind option was not specified, the value in the column is a zero length string; however, DB2 uses a default SQL path of: SYSIBM, SYSFUN, SYSPROC, <i>plan qualifier</i> .	G
DBPROTOCOL	CHAR(1) NOT NULL WITH DEFAULT 'P'	Whether remote access for SQL with three-part names is implemented with DRDA or DB2 private protocol access:  D DRDA P DB2 private protocol	G
FUNCTIONTS	TIMESTAMP NOT NULL WITH DEFAULT	Timestamp when the function was resolved. Set by the BIND and REBIND commands, but not by AUTOBIND.	G
OPTHINT	VARCHAR(128) NOT NULL WITH DEFAULT	Value of the OPTHINT bind option. Identifies rows in the owner.PLAN_TABLE to be used as input to DB2. Contains blanks if no rows in the owner.PLAN_TABLE are to be used as input.	G
ENCODING_CCSID	INTEGER NOT NULL WITH DEFAULT	The CCSID corresponding to the encoding scheme or CCSID as specified for the bind option ENCODING. The Encoding Scheme specified on the bind command:  ccsid The specified or derived CCSID. 0 The default CCSID as specified on panel DSNTIPF at installation time. Used when the plan was bound prior to Version 7	G

Column name	Data type	Description	Use
IMMEDWRITE	CHAR(1) NOT NULL WITH DEFAULT	Indicates when writes of updated group buffer pool dependent pages are to be done. This option is only applicable for data sharing environments.  N Bind option IMMEDWRITE(NO) indicates normal write activity is done. Y Bind option IMMEDWRITE(YES) indicates that immediate writes are done for updated group buffer pool dependent pages. 1 Bind option IMMEDWRITE(PH1) indicates that updated group buffer pool dependent pages are written at or before phase 1 commit.  blank A migrated package.	G
RELBOUND	CHAR(1) NOT NULL WITH DEFAULT	The release when the package was bound or rebound.  blank Bound prior to Version 7 K Bound on Version 7 L Bound on Version 8	G
	CHAR(1)	Not used.	N
REMARKS	VARCHAR(762) NOT NULL WITH DEFAULT	A character string provided by the user with the COMMENT statement.	G
CREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator:  blank Authorization ID L Role	G
ROUNDING	CHAR(1) NOT NULL WITH DEFAULT	The ROUNDING option used when the plan was last bound:  C ROUND_CEILING D ROUND_DOWN F ROUND_FLOOR G ROUND_HALF_DOWN E ROUND_HALF_EVEN H ROUND_HALF_UP U ROUND_UP  blank The plan was created in a DB2 release prior to Version 9.	G
	DATE NOT NULL WITH DEFAULT		N

## SYSIBM.SYSPLANAUTH table

The SYSIBM.SYSPLANAUTH table records the privileges that are held by users over application plans.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privileges.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user who holds the privileges. Could also be PUBLIC for a grant to PUBLIC.	G
NAME	VARCHAR(24) NOT NULL	Name of the application plan on which the privileges are held.	G
	CHAR(12) NOT NULL	Internal use only	I
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N
	CHAR(1) NOT NULL	Not used	N
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor. <b>blank</b> Not applicable <b>C</b> DBCTRL <b>D</b> DBADM <b>L</b> SYSCTRL <b>M</b> DBMAINT <b>S</b> SYSADM	G
BINDAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the BIND, REBIND, or FREE subcommands against the plan: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
EXECUTEAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can run application programs that use the application plan: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed.	G

Column name	Data type	Description	Use
GRANTEE TYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantee: <b>blank</b> Authorization ID <b>L</b> Role	G
GRANTOR TYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSPLANDEP table

The SYSIBM.SYSPLANDEP table records the dependencies of plans on tables, views, aliases, synonyms, table spaces, indexes, functions, and stored procedures.

Column name	Data type	Description	Use
BNAME	VARCHAR(128) NOT NULL	The name of an object the plan depends on.	G
BCREATOR	VARCHAR(128) NOT NULL	If BNAME is a table space, its database. Otherwise, the schema of BNAME. If BNAME is a role, the value is blank.	G
BTYPE	CHAR(1) NOT NULL	Type of object identified by BNAME:  A Alias E INSTEAD OF trigger F User-defined function or cast function G Global temporary table I Index M Materialized query table O Stored procedure P Partitioned table space if it is defined as LARGE or with the DSSIZE parm Q Sequence object R Table space S Synonym T Table V View	G
DNAME	VARCHAR(24) NOT NULL	Name of the plan.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSPLSYSTEM table

The SYSIBM.SYSPLSYSTEM table contains zero or more rows for every plan. Each row for a given plan represents one or more connections to an environment in which the plan could be used.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Name of the plan.	G
SYSTEM	VARCHAR(24) NOT NULL	Environment. Values can be: <b>BATCH</b> TSO batch <b>DB2CALL</b> DB2 call attachment facility <b>CICS</b> Customer Information Control System <b>DLIBATCH</b> DLI batch support facility <b>IMSBMP</b> IMS BMP region <b>IMSMPP</b> IMS MPP or IFP region	G
ENABLE	CHAR(1) NOT NULL	Indicates whether the connections represented by the row are enabled or disabled: <b>N</b> Disabled <b>Y</b> Enabled	G
CNAME	VARCHAR(60) NOT NULL	Identifies the connection or connections to which the row applies. Interpretation depends on the environment specified by SYSTEM. Values can be: <ul style="list-style-type: none"> <li>• Blank if SYSTEM=BATCH or SYSTEM=DB2CALL</li> <li>• The name of a single connection if SYSTEM has any other value</li> </ul> CNAME can also be blank when SYSTEM is not equal to BATCH or DB2CALL. When this is so, the row applies to all connections for the indicated environment.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSRELS table

The SYSIBM.SYSRELS table contains one row for every referential constraint.

Column name	Data type	Description	Use
CREATOR	VARCHAR(128) NOT NULL	The schema of the dependent table of the referential constraint.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the dependent table of the referential constraint.	G
RELNAME	VARCHAR(128) NOT NULL	Constraint name.	G
REFTBNAME	VARCHAR(128) NOT NULL	Name of the parent table of the referential constraint.	G
REFTBCREATOR	VARCHAR(128) NOT NULL	The schema of the parent table.	G
COLCOUNT	SMALLINT NOT NULL	Number of columns in the foreign key.	G
DELETERULE	CHAR(1) NOT NULL	Type of delete rule for the referential constraint:  A NO ACTION C CASCADE N SET NULL R RESTRICT	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
RELOBID1	SMALLINT NOT NULL WITH DEFAULT	Internal identifier of the constraint with respect to the database that contains the parent table.	S
RELOBID2	SMALLINT NOT NULL WITH DEFAULT	Internal identifier of the constraint with respect to the database that contains the dependent table.	S
TIMESTAMP	TIMESTAMP NOT NULL WITH DEFAULT	Date and time the constraint was defined. If the constraint is between catalog tables prior to DB2 Version 2 Release 3, the value is '1985-04-01-00.00.00.000000.'	G
IXOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	The schema of unique non-primary index used for the parent key. '99999999' if the enforcing index has been dropped. Blank if the enforcing index is a primary index.	G
IXNAME	VARCHAR(128) NOT NULL WITH DEFAULT	Name of unique non-primary index used for a parent key. '99999999' if the enforcing index has been dropped. Blank if the enforcing index is a primary index.	G

Column name	Data type	Description	Use
ENFORCED	CHAR(1) NOT NULL WITH DEFAULT 'Y'	Enforced by the system or not:  Y Enforced by the system N Not enforced by the system (trusted)	G
CHECKEXISTING- DATA	CHAR(1) NOT NULL WITH DEFAULT	Option for checking existing data:  I Immediately check existing data. If ENFORCED = 'Y', this column will have a value of 'I'. N Never check existing data. If ENFORECED = 'N', this column will have a value of 'N'.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSRESAUTH table

The SYSIBM.SYSRESAUTH table records CREATE IN and PACKADM ON privileges for collections; USAGE privileges for distinct types; and USE privileges for buffer pools, storage groups, and table spaces.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privilege.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user who holds the privilege. Could also be PUBLIC for a grant to PUBLIC.	G
QUALIFIER	VARCHAR(128) NOT NULL	Qualifier of the table space (the database name) if the privilege is for a table space (OBTYPE='R'). The schema name of the distinct type if the privilege is for a distinct type (OBTYPE='D'). The schema name of the JAR file if the privilege is for a JAR file (OBTYPE='J'). The value is PACKADM if the privilege is for a collection (OBTYPE='C') and the authority held is PACKADM. Otherwise, the value is blank.	G
NAME	VARCHAR(128) NOT NULL	Name of the buffer pool, collection, DB2 storage group, distinct type, or table space. Could also be ALL when USE OF ALL BUFFERPOOLS is granted.	G
	CHAR(1) NOT NULL	Internal use only	I
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor.  blank Not applicable A PACKADM (on collection *) C DBCTRL D DBADM L SYSCTRL M DBMAINT P PACKADM (on a specific collection) S SYSADM	G
OBTYPE	CHAR(1) NOT NULL	Type of object:  B Buffer pool C Collection D Distinct type R Table space S Storage group J JAR file (Java archive file)	G
	CHAR(12) NOT NULL	Internal use only	I
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N

Column name	Data type	Description	Use
USEAUTH	CHAR(1) NOT NULL	Whether the privilege is held with the GRANT option: <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
		The authority held is PACKADM when the OBTYPE is C (a collection) and QUALIFIER is PACKADM. The authority held is CREATE IN when the OBTYPE is C and QUALIFIER is blank.	
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed.	G
GRANTEETYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantee: <b>blank</b> Authorization ID <b>L</b> Role	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSROLES table

The SYSIBM.SYSROLES table contains one row for each role.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	The name of the role.	G
DEFINER	VARCHAR(128) NOT NULL	The authorization ID or role that defined this role listed in the NAME column.	G
DEFINERTYPE	CHAR(1) NOT NULL	The type of definer:  L      Role  blank    Authorization ID	G
CREATEDTS	TIMESTAMP NOT NULL	The time when the role is created.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the role. See Release dependency indicators for the values.	G
REMARKS	VARCHAR(762) NOT NULL	A character string that is provided using the COMMENT statement.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSROUTINEAUTH table

The SYSIBM.SYSROUTINEAUTH table records the privileges that are held by users on routines. (A routine can be a user-defined function, cast function, or stored procedure.)

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privilege.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user who holds the privilege or the name of a plan or package that uses the privilege. Can also be PUBLIC for a grant to PUBLIC.	G
SCHEMA	VARCHAR(128) NOT NULL	Schema of the routine	G
SPECIFICNAME	VARCHAR(128) NOT NULL	Specific name of the routine. An asterisk (*) if the privilege is held on all routines in the schema.	G
GRANTEDTS	TIMESTAMP NOT NULL	Time when the GRANT statement was executed.	G
ROUTINETYPE	CHAR(1) NOT NULL	Type of routine: <b>F</b> User-defined function or cast function <b>P</b> Stored procedure	G
GRANTEETYPE	CHAR(1) NOT NULL	Type of grantee: <b>blank</b> An authorization ID <b>L</b> Role <b>P</b> An application plan or package. The grantee is a package if COLLID is not blank. <b>R</b> Internal use only	G
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor.  This field is also used to indicate that the privilege was held on all schemas by the grantor. <b>blank</b> Not applicable <b>1</b> Grantor had privilege on schema.* at time of grant <b>L</b> SYSCTRL <b>S</b> SYSADM	G
EXECUTEAUTH	CHAR(1) NOT NULL	Whether GRANTEE can execute the routine: <b>Y</b> Privilege is held without GRANT option. <b>G</b> Privilege is held with GRANT option.	G
COLLID	VARCHAR(128) NOT NULL	If the GRANTEE is a package, its collection name. Otherwise, the value is blank.	G
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	If the GRANTEE is a package, the consistency token of the DBRM from which the package was derived. Otherwise, the value is blank.	G

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSROUTINES table

The SYSIBM.SYSROUTINES table contains a row for every routine. (A routine can be a user-defined function, cast function, or stored procedure.)

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the routine.	G
OWNER	VARCHAR(128) NOT NULL	Owner of the routine.	G
NAME	VARCHAR(128) NOT NULL	Name of the routine.	G
ROUTINETYPE	CHAR(1) NOT NULL	Type of routine:  F User-defined function or cast function P Stored procedure	G
CREATEDBY	VARCHAR(128) NOT NULL	Primary authorization ID of the user who created the routine.	G
SPECIFICNAME	VARCHAR(128) NOT NULL	Specific name of the routine.	G
ROUTINEID	INTEGER NOT NULL	Internal identifier of the routine.	S
RETURN_TYPE	INTEGER NOT NULL	Internal identifier of the result data type of the function. The column contains a -2 if the function is a table function.	S
ORIGIN	CHAR(1) NOT NULL	Origin of the routine:  E External routine or external SQL procedure N Native SQL procedure Q SQL function S System-generated function U Sourced on user-defined function or built-in function	G
FUNCTION_TYPE	CHAR(1) NOT NULL	Type of function:  C Aggregate function S Scalar function T Table function blank For a stored procedure (ROUTINETYPE = 'P')	G
PARM_COUNT	SMALLINT NOT NULL	Number of parameters for the routine.	G

Column name	Data type	Description	Use
LANGUAGE	VARCHAR(24) NOT NULL	<p>Implementation language of the routine:</p> <ul style="list-style-type: none"> <li>• ASSEMBLE</li> <li>• C</li> <li>• COBOL</li> <li>• COMPJAVA</li> <li>• JAVA</li> <li>• PLI</li> <li>• REXX</li> <li>• SQL</li> </ul> <p>The value is blank if ROUTINETYPE = 'F' and ORIGIN is not 'E' or not 'Q'.</p>	G
COLLID	VARCHAR(128) NOT NULL	Name of the package collection to be used when the routine is executed. A blank value indicates the package collection is the same as the package collection of the program that invoked the routine.	G
SOURCESCHEMA	VARCHAR(128) NOT NULL	If ORIGIN is 'U' and ROUTINETYPE is 'F', the schema of the source user-defined function ('SYSIBM' for a source built-in function). Otherwise, the value is blank.	G
SOURCESPECIFIC	VARCHAR(128) NOT NULL	If ORIGIN is 'U' and ROUTINETYPE is 'F', the specific name of the source user-defined function or source built-in function name. Otherwise, the value is blank.	G
DETERMINISTIC	CHAR(1) NOT NULL	<p>The deterministic option of an external function or a stored procedure:</p> <p><b>N</b> Indeterminate (results might differ with a given set of input values).</p> <p><b>Y</b> Deterministic (results are consistent).</p> <p><b>blank</b> ROUTINETYPE='F' and ORIGIN is not 'E' or not 'Q' (the routine is a function, but not an external function or an SQL function).</p>	G
EXTERNAL_ACTION	CHAR(1) NOT NULL	<p>The external action option of an external function or SQL function:</p> <p><b>N</b> Function has no side effects.</p> <p><b>E</b> Function has external side effects so that the number of invocations is important.</p> <p><b>blank</b> ORIGIN is not 'E' or 'Q' for the function (ROUTINETYPE='F'), or it is a stored procedure (ROUTINETYPE='P').</p>	G
NULL_CALL	CHAR(1) NOT NULL	<p>The CALLED ON NOT NULL INPUT option of an external function or stored procedure:</p> <p><b>N</b> The routine is not called if any parameter has a NULL value.</p> <p><b>Y</b> The routine is called if any parameter has a NULL value.</p> <p><b>blank</b> ROUTINETYPE='F' and ORIGIN is not 'E' (the routine is a function, but not an external function).</p>	G
CAST_FUNCTION	CHAR(1) NOT NULL	<p>Whether the routine is a cast function:</p> <p><b>N</b> The routine is not a cast function.</p> <p><b>Y</b> The routine is a cast function.</p> <p><b>blank</b> ORIGIN is not 'E' for the function (ROUTINETYPE='F'), or it is a stored procedure (ROUTINETYPE='P').</p> <p>A cast function is generated by DB2 for a CREATE TYPE statement.</p>	G

Column name	Data type	Description	Use
SCRATCHPAD	CHAR(1) NOT NULL	The SCRATCHPAD option of an external function:  N This function does not have a SCRATCHPAD. Y This function has a SCRATCHPAD. blank ORIGIN is not 'E' for the function (ROUTINETYPE='F'), or it is a stored procedure (ROUTINETYPE='P').	G
SCRATCHPAD_LENGTH	INTEGER NOT NULL	Length of the scratchpad if the ORIGIN is 'E' for the function (ROUTINETYPE='F') and NO SCRATCHPAD is not specified. Otherwise, the value is 0.	G
FINAL_CALL	CHAR(1) NOT NULL	The FINAL CALL option of an external function:  N A final call will not be made to the function. Y A final call will be made to the function. blank ORIGIN is not 'E' for the function (ROUTINETYPE='F'), or it is a stored procedure (ROUTINETYPE='P').	G
PARALLEL	CHAR(1) NOT NULL	The PARALLEL option of an external function:  A This function can be invoked by parallel tasks. D This function cannot be invoked by parallel tasks. blank ORIGIN is not 'E' for the function (ROUTINETYPE='F'), or it is a stored procedure (ROUTINETYPE='P').	G
PARAMETER_STYLE	CHAR(1) NOT NULL	The PARAMETER STYLE option of an external function or stored procedure:  D DB2SQL. All parameters are passed to the external function or stored procedure according to the DB2SQL standard convention. G GENERAL. All parameters are passed to the stored procedure according to the GENERAL standard convention. N GENERAL CALL WITH NULLS. All parameters are passed to the stored procedure according to the GENERAL WITH NULLS convention. J JAVA. All parameters are passed to the function or procedure according to the conventions for JAVA and SQLJ specifications. blank The column is blank if the ORIGIN is not 'E' or if LANGUAGE is SQL.	G
FENCED	CHAR(1) NOT NULL	Y Indicates that this routine runs separately from the DB2 address space in a WLM managed DB2 address space. All user-defined routines that are not marked with Y in this column run in the DB2 address space.  blank ORIGIN is 'Q' or ORIGIN is 'N'.	G
SQL_DATA_ACCESS	CHAR(1) NOT NULL	The SQL statements that are allowed in an external function, SQL function, or stored procedure:  C CONTAINS SQL - Only SQL that does not read or modify data is allowed. M MODIFIES SQL DATA - All SQL is allowed, including SQL that reads or modifies data. N NO SQL - SQL is not allowed. R READS SQL DATA - Only SQL that reads data is allowed. blank Not applicable.	G

Column name	Data type	Description	Use
DBINFO	CHAR(1) NOT NULL	The DBINFO option of an external function or stored procedure:  N No, the DBINFO parameter will not be passed to the external function or stored procedure. Y Yes, the DBINFO parameter will be passed to the external function or stored procedure. blank ORIGIN is not 'E'.	G
STAYRESIDENT	CHAR(1) NOT NULL	The STAYRESIDENT option of the routine, which determines whether the routine is to be deleted from memory when the routine ends.  N The load module is to be deleted from memory after the routine terminates. Y The load module is to remain resident in memory after the routine terminates. blank ORIGIN is not 'E'.	G
ASUTIME	INTEGER NOT NULL	Number of CPU service units permitted for any single invocation of this routine. If ASUTIME is zero, the number of CPU service units is unlimited. The value is 0 if ROUTINETYPE = 'F' and ORIGIN is not 'E'.  If a routine consumes more CPU service units than the ASUTIME value allows, DB2 cancels the routine.	G
WLM_ENVIRONMENT	VARCHAR(96) NOT NULL	Name of the WLM environment to be used to run this routine.  When ORIGIN = 'N', this is the name of the WLM ENVIRONMENT FOR DEBUG MODE that is to be used when debugging a native SQL procedure.  The column is blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'. If the ROUTINETYPE = 'P', the value might be blank. If this value is blank the stored procedure cannot be run.	G
WLM_ENV_FOR_NESTED	CHAR(1) NOT NULL	For nested routine calls, indicates whether the address space of the calling stored procedure or user-defined function is used to run the nested stored procedure or user-defined function:  N The nested stored procedure or user-defined function runs in an address space other than the specified WLM environment if the calling stored procedure or user-defined function is not running in the specified WLM environment. 'WLM ENVIRONMENT name,*' was specified. Y The nested stored procedure or user-defined function runs in the environment used by the calling stored procedure or user-defined function. 'WLM ENVIRONMENT(name,*)' was specified. blank WLM_ENVIRONMENT is blank. The column is blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
PROGRAM_TYPE	CHAR(1) NOT NULL	Indicates whether the routine runs as a Language Environment main routine or a subroutine:  M The routine runs as a main routine. S The routine runs as a subroutine. blank ORIGIN is not 'E'.	G

Column name	Data type	Description	Use
EXTERNAL_SECURITY	CHAR(1) NOT NULL	Specifies the authorization ID to be used if the routine accesses resources protected by an external security product:  D DB2 - The authorization ID associated with the WLM-established stored procedure address space. U SESSION_USER - The authorization ID of the SQL user that invoked the routine. C DEFINER - The authorization ID of the owner of the routine. blank ORIGIN is not 'E'.	G
COMMIT_ON_RETURN	CHAR(1) NOT NULL	If ROUTINETYPE = 'P', whether the transaction is always to be committed immediately on successful return (non-negative SQLCODE) from this stored procedure:  N The unit of work is to continue. Y The unit of work is to be committed immediately.  If ROUTINETYPE = 'F', the value is blank.	G
RESULT_SETS	SMALLINT NOT NULL	If ROUTINETYPE = 'P', the maximum number of ad hoc result sets that this stored procedure can return.  If no ad hoc result sets exist or ROUTINETYPE = 'F', the value is zero.	G
LOBCOLUMNS	SMALLINT NOT NULL	If ORIGIN = 'E' or 'Q', the number of LOB columns found in the parameter list for this user-defined function.  If no LOB columns are found in the parameter list or ORIGIN is not 'E' or not 'Q', the value is 0.	I
CREATEDTS	TIMESTAMP NOT NULL	Time when the CREATE statement was executed for this routine.	G
ALTEREDTS	TIMESTAMP NOT NULL	Time when the last ALTER statement was executed for this routine.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PARM1	SMALLINT NOT NULL	Internal use only	I
PARM2	SMALLINT NOT NULL	Internal use only	I
PARM3	SMALLINT NOT NULL	Internal use only	I
PARM4	SMALLINT NOT NULL	Internal use only	I

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
PARM5	SMALLINT NOT NULL	Internal use only	I
PARM6	SMALLINT NOT NULL	Internal use only	I
PARM7	SMALLINT NOT NULL	Internal use only	I
PARM8	SMALLINT NOT NULL	Internal use only	I
PARM9	SMALLINT NOT NULL	Internal use only	I
PARM10	SMALLINT NOT NULL	Internal use only	I
PARM11	SMALLINT NOT NULL	Internal use only	I
PARM12	SMALLINT NOT NULL	Internal use only	I
PARM13	SMALLINT NOT NULL	Internal use only	I
PARM14	SMALLINT NOT NULL	Internal use only	I
PARM15	SMALLINT NOT NULL	Internal use only	I
PARM16	SMALLINT NOT NULL	Internal use only	I
PARM17	SMALLINT NOT NULL	Internal use only	I
PARM18	SMALLINT NOT NULL	Internal use only	I
PARM19	SMALLINT NOT NULL	Internal use only	I
PARM20	SMALLINT NOT NULL	Internal use only	I

Column name	Data type	Description	Use
PARM21	SMALLINT NOT NULL	Internal use only	I
PARM22	SMALLINT NOT NULL	Internal use only	I
PARM23	SMALLINT NOT NULL	Internal use only	I
PARM24	SMALLINT NOT NULL	Internal use only	I
PARM25	SMALLINT NOT NULL	Internal use only	I
PARM26	SMALLINT NOT NULL	Internal use only	I
PARM27	SMALLINT NOT NULL	Internal use only	I
PARM28	SMALLINT NOT NULL	Internal use only	I
PARM29	SMALLINT NOT NULL	Internal use only	I
PARM30	SMALLINT NOT NULL	Internal use only	I
IOS_PER_INVOC	FLOAT NOT NULL WITH DEFAULT -1	Estimated number of I/Os that required to execute the routine. The value is -1 if the estimated number is not known.	S
INSTS_PER_INVOC	FLOAT NOT NULL WITH DEFAULT -1	Estimated number of machine instructions that required to execute the routine. The value is -1 if the estimated number is not known.	S
INITIAL_IOS	FLOAT NOT NULL WITH DEFAULT -1	Estimated number of I/O's that are performed the first time or the last time the routine is invoked. The value is -1 if the estimated number is not known.	S
INITIAL_INSTS	FLOAT NOT NULL WITH DEFAULT -1	Estimated number of machine instructions that are performed the first time or the last time the routine is invoked. The value is -1 if the estimated number is not known.	S
CARDINALITY	FLOAT NOT NULL WITH DEFAULT -1	The predicted cardinality of the routine, -1 to trigger the use of the default value (10,000).	S

Column name	Data type	Description	Use
RESULT_COLS	SMALLINT NOT NULL DEFAULT 1	For a table function, the number of columns in the result table. Otherwise, the value is 1.	S
EXTERNAL_NAME	VARCHAR(762) NOT NULL	The path/module/function that DB2 should load to execute the routine. The column is blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
PARM_SIGNATURE	VARCHAR(150) NOT NULL WITH DEFAULT FOR BIT DATA	Internal use only	I
RUNOPTS	VARCHAR(762) NOT NULL	The Language Environment run-time options to be used for this routine. An empty string indicates that the installation default Language Environment run-time options are to be used. The column is blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
REMARKS	VARCHAR(762) NOT NULL	A character string provided by the user with the COMMENT statement.	G
JAVA_SIGNATURE	VARCHAR(3072) NOT NULL WITH DEFAULT	The signature of the JAR file. <b>blank</b> When PARAMETER STYLE is not JAVA. The column is also blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
CLASS	VARCHAR(384) NOT NULL WITH DEFAULT	The class name contained in the JAR file. <b>blank</b> When PARAMETER STYLE is not JAVA. The column is also blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
JARSCHEMA	VARCHAR(128) NOT NULL WITH DEFAULT	The schema of the JAR file. <b>blank</b> When PARAMETER STYLE is not JAVA. The column is also blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
JAR_ID	VARCHAR(128) NOT NULL WITH DEFAULT	The name of the JAR file. <b>blank</b> When PARAMETER STYLE is not JAVA. The column is also blank if ROUTINETYPE = 'F' and ORIGIN is not 'E'.	G
SPECIAL_REGS	CHAR(1) NOT NULL WITH DEFAULT 'T'	The SPECIAL REGISTER option for a routine. <b>I</b> INHERIT SPECIAL REGISTERS <b>D</b> DEFAULT SPECIAL REGISTERS <b>blank</b> ROUTINETYPE = 'F' and ORIGIN is not 'E' or not 'Q'.	G
NUM_DEP_MQTS	SMALLINT NOT NULL WITH DEFAULT	Number of dependent materialized query tables. The value is 0 if the row does not describe a user-defined table function, or if no materialized query tables are defined on the table function.	G
MAX_FAILURE	SMALLINT NOT NULL WITH DEFAULT -1	Allowable failures for this routine (0-32767). If zero is specified, the routine will never be stopped. If no value is specified for this routine, the default will be -1 to indicate that the DB2 installation parameter (STORMXAB) will be used.	G

Column name	Data type	Description	Use
PARAMETER_CCSID	INTEGER NOT NULL WITH DEFAULT	A CCSID that specifies how character, graphic, date, time, and timestamp data types for system generated parameters to the routine such as message tokens and DBINFO should be passed. The value is dependent on the encoding scheme specified implicitly or explicitly for the PARAMETER CCSID clause defined at the system for that encoding scheme. The following list describes the CCSID for each encoding scheme:  <b>ASCII</b> If mixed data is allowed, this CCSID is for mixed ASCII data, SBCS data uses the corresponding SBCS CCSID, and graphic data uses the corresponding DBCS CCSID. Otherwise, this CCSID is for SBCS ASCII data.  <b>EBCDIC</b> If mixed data is allowed, this CCSID is for mixed EBCDIC data, SBCS data uses the corresponding SBCS CCSID, and graphic data uses the corresponding DBCS CCSID. Otherwise, this is the CCSID for SBCS EBCDIC data.  <b>UNICODE</b> This CCSID is for mixed data (1208).  A value of zero means that the CCSIDs used are those CCSIDs for the encoding scheme of other string or datetime parameters in the parameter list or RETURNS clause CCSID clauses, or the value in the DEF ENCODING SCHEME on installation panel DSNTIPF.	G
VERSION	VARCHAR(122) NOT NULL WITH DEFAULT	The version identifier for a native SQL procedure (indicated by the value 'N' in the column ORIGIN).	G
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	A zero length string for the rows that are created prior to Version 9 and for the rows in which the value of ORIGIN is not 'N'.	G
ACTIVE	CHAR(1) NOT NULL WITH DEFAULT	The consistency token for the routine. The column is set to X'20' if the value of ORIGIN is not 'N'  Identifies the active version of the routine: <b>Y</b> The routine is the active version. <b>N</b> The routine is not the active version. <b>blank</b> The value of ORIGIN is not 'N' or the row was created prior to Version 9.	G

Column name	Data type	Description	Use
DEBUG_MODE	CHAR(1) NOT NULL WITH DEFAULT	Identifies whether or not this routine is enabled for debugging:  1 This routine is enabled for debugging and can be debugged in a client debug session using the DB2 Unified Debugger. 0 This routine is not enabled for debugging. N This routine can never be enabled for debugging. blank The LANGUAGE is not specified as JAVA, the value of ORIGIN is not 'N', or the row was created prior to Version 9.	G
TEXT_ENVID	INTEGER NOT NULL WITH DEFAULT	Internal identifier of the environment. The column is 0 if the value of ORIGIN is not 'N' or if the row was created prior to Version 9.	G
TEXT_ROWID	ROWID NOT NULL GENERATED ALWAYS	ID to support LOB columns for source text.	G
TEXT	CLOB(2M) NOT NULL WITH DEFAULT	The source text of the CREATE statement or the ALTER statement with the body for the routine. The column is a zero-length string if the value of ORIGIN is not 'N' or if the row was created prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner:  blank Authorization ID L Role	G
PARAMETER_VARCHARFORM	INTEGER NOT NULL WITH DEFAULT	A non-zero value that indicates the actual representation, to a LANGUAGE C routine, of any varying length string parameter that appears in the parameter list or RETURNS clause for that routine.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G
PACKAGEPATH	VARCHAR(4096)	The value of the PACKAGE PATH option of the CREATE FUNCTION, CREATE PROCEDURE, ALTER FUNCTION, or ALTER PROCEDURE statement that created or last changed the routine. PACKAGE PATH identifies the package path to use when the routine is executed. A blank value indicates the package path is the same as the package path of the program that invoked the routine.	G

## SYSIBM.SYSROUTINESTEXT table

The SYSIBM.SYSROUTINESTEXT is an auxiliary table for the TEXT column of SYSIBM.SYSROUTINES and is required to hold the LOB data.

Column name	Data type	Description	Use
TEXT	CLOB(2M) NOT NULL WITH DEFAULT	The source text of the CREATE PROCEDURE statement for the routine. TEXT can also hold the source text of the ALTER PROCEDURE statement for the routine if the routine is a native SQL procedure and the SQL procedure body is included in the ALTER PROCEDURE statement.	G

## SYSIBM.SYSROUTINES\_OPTS table

The SYSIBM.SYSROUTINES\_OPTS table Contains a row for each generated routine, such as one created by DB2 for z/OS Procedure Processor DSNTPSMP, that records the build options for the routine.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the routine.	G
ROUTINENAME	VARCHAR(128) NOT NULL	Name of the routine.	G
BUILDDATE	DATE NOT NULL WITH DEFAULT	Date the routine was built.	G
BUILDTIME	TIME NOT NULL WITH DEFAULT	Time the routine was built.	G
BUILDSTATUS	CHAR(1) NOT NULL WITH DEFAULT 'C'	Whether this version of the routine's options is the current version.	G
BUILDSchema	VARCHAR(128) NOT NULL	Schema name for BUILDNAME.	G
BUILDNAME	VARCHAR(128) NOT NULL	Procedure used to create the routine.	G
BUILDFOWNER	VARCHAR(128) NOT NULL	Authorization ID used to create the routine.	G
IBMRREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
PRECOMPILE_OPTS	VARCHAR(765) NOT NULL WITH DEFAULT	Precompiler options used to build the routine.	G
COMPILE_OPTS	VARCHAR(765) NOT NULL WITH DEFAULT	Compiler options used to build the routine.	G
PRELINK_OPTS	VARCHAR(765) NOT NULL WITH DEFAULT	Prelink-edit options used to build the routine.	G

Column name	Data type	Description	Use
LINK_OPTS	VARCHAR(765) NOT NULL WITH DEFAULT	Link-edit options used to build the routine.	G
BIND_OPTS	VARCHAR(3072) NOT NULL WITH DEFAULT	Bind options used to build the routine.	G
SOURCEDSN	VARCHAR(765) NOT NULL WITH DEFAULT	Name of the source data set.	G
DEBUG_MODE	CHAR(1) NOT NULL	Debugging is on or off for this object.  0      Debugging is off. Default and value on migration are both 0.  1      Debugging is on.	G

## SYSIBM.SYSROUTINES\_SRC table

The SYSIBM.SYSROUTINES\_SRC table contains source for generated routines, such as those created by DB2 for z/OS Procedure Processor DSNTPSMP.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the routine.	G
ROUTINENAME	VARCHAR(128) NOT NULL	Name of the routine.	G
BUILDDATE	DATE NOT NULL WITH DEFAULT	Date the routine was built.	G
BUILDTIME	TIME NOT NULL WITH DEFAULT	Time the routine was built.	G
BUILDSTATUS	CHAR(1) NOT NULL WITH DEFAULT 'C'	Whether this version of the routine's source is the current version.	G
SEQNO	INTEGER NOT NULL	Number of the source statement piece in CREATESTMT.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CREATESTMT	VARCHAR(7500) NOT NULL	Routine source statement.	G

## SYSIBM.SYSSCHEMAAUTH table

The SYSIBM.SYSSCHEMAAUTH table contains one or more rows for each user that is granted a privilege on a particular schema in the database.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privileges or SYSADM.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user or group who holds the privileges. Can also be PUBLIC for a grant to PUBLIC.	G
SCHEMANAME	VARCHAR(128) NOT NULL	Name of the schema or '*' for all schemas.	G
AUTHHOWGOT	CHAR(1) NOT NULL	<p>Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor.</p> <p>This field is also used to indicate that the privilege was held on all schemas by the grantor.</p> <ul style="list-style-type: none"> <li>1      Grantor had privilege on all schemas at time of grant</li> <li>L      SYSCTRL</li> <li>S      SYSADM</li> </ul>	G
CREATEINAUTH	CHAR(1) NOT NULL	<p>Indicates whether grantee holds CREATEIN privilege on the schema:</p> <ul style="list-style-type: none"> <li>blank    Privilege is not held</li> <li>G        Privilege is held with the GRANT option</li> <li>Y        Privilege is held without the GRANT option</li> </ul>	G
ALTERINAUTH	CHAR(1) NOT NULL	<p>Indicates whether grantee holds ALTERIN privilege on the schema:</p> <ul style="list-style-type: none"> <li>blank    Privilege is not held</li> <li>G        Privilege is held with the GRANT option</li> <li>Y        Privilege is held without the GRANT option</li> </ul>	G
DROPINAUTH	CHAR(1) NOT NULL	<p>Indicates whether grantee holds DROPIN privilege on the schema:</p> <ul style="list-style-type: none"> <li>blank    Privilege is not held</li> <li>G        Privilege is held with the GRANT option</li> <li>Y        Privilege is held without the GRANT option</li> </ul>	G
GRANTEDTS	TIMESTAMP NOT NULL	Time when the GRANT statement was executed.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
GRANTEETYPE	CHAR(1) NOT NULL WITH DEFAULT	<p>Indicates the type of grantee:</p> <ul style="list-style-type: none"> <li>blank    Authorization ID</li> <li>L        Role</li> </ul>	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor:	G
		<ul style="list-style-type: none"> <li>blank    Authorization ID</li> <li>L        Role</li> </ul>	

## SYSIBM.SYSSEQUENCEAUTH table

The SYSIBM.SYSSEQUENCEAUTH table records the privileges that are held by users over sequences.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privileges.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user or group that holds the privileges or the name of an application plan or package that uses the privileges. PUBLIC for a grant to PUBLIC.	G
SCHEMA	VARCHAR(128) NOT NULL	Schema of the sequence.	G
NAME	VARCHAR(128) NOT NULL	Name of the sequence.	G
GRANTEETYPE	CHAR(1) NOT NULL	Type of grantee: <b>blank</b> An authorization ID. <b>L</b> Role <b>P</b> An application plan or package. The grantee is a package if COLLID is not blank. <b>R</b> Internal use only.	G
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor: <b>blank</b> Not applicable <b>L</b> SYSCTRL <b>S</b> SYSADM	G
ALTERAUTH	CHAR(1) NOT NULL	Indicates whether grantee holds ALTER privilege on the sequence: <b>blank</b> Privilege is not held. <b>G</b> Privilege is held with the GRANT option. <b>Y</b> Privilege is held without the GRANT option.	G
USEAUTH	CHAR(1) NOT NULL	Indicates whether grantee holds USAGE privilege on the sequence: <b>blank</b> Privilege is not held. <b>G</b> Privilege is held with the GRANT option. <b>Y</b> Privilege is held without the GRANT option.	G
COLLID	VARCHAR(128) NOT NULL	If the GRANTEE is a package, its collection name. Otherwise, a string of length zero.	G
CONTOKEN	CHAR(8) NOT NULL FOR BIT DATA	If the GRANTEE is a package, the consistency token of the DBRM from which the package was derived. Otherwise, blank.	G
GRANTEDTS	TIMESTAMP NOT NULL	Time when the GRANT statement was executed.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSSEQUENCES table

The SYSIBM.SYSSEQUENCES table contains one row for each identity column or user-defined sequence.

Column name	Data type	Description	Use
SCHEMA	VARCHAR(128) NOT NULL	Schema of the sequence. For an identity column, the value of TBCREATOR from the SYSCOLUMNS entry for the column.	G
OWNER	VARCHAR(128) NOT NULL	Owner of the sequence. For an identity column, the value of TBCREATOR from the SYSCOLUMNS entry for the column.	G
NAME	VARCHAR(128) NOT NULL	Name of the identity column or sequence. (The name for an identity is generated by DB2.)	G
SEQTYPE	CHAR(1) NOT NULL	Type of sequence object:  I An identity column S A user-defined sequence X An implicitly created DOCID column for a base table that contains XML data.	G
SEQUENCEID	INTEGER NOT NULL	Internal identifier of the identity column or sequence.	G
CREATEDBY	VARCHAR(128) NOT NULL	Primary authorization ID of the user who created the sequence or identity column.	G
INCREMENT	DECIMAL(31,0) NOT NULL	Increment value (positive or negative, within INTEGER scope).	G
START	DECIMAL(31,0) NOT NULL	Start value.	G
MAXVALUE	DECIMAL(31,0) NOT NULL	Maximum value allowed for the identity column or sequence.	G
MINVALUE	DECIMAL(31,0) NOT NULL	Minimum value allowed for the identity column or sequence.	G
CYCLE	CHAR(1) NOT NULL	Whether cycling will occur when a boundary is reached:  N No Y Yes, cycling will occur	G
CACHE	INTEGER NOT NULL	Number of sequence values to preallocate in memory for faster access. A value of 0 indicates that values are not to be preallocated.	G
ORDER	CHAR(1) NOT NULL	Whether the values must be generated in order:  Y Yes N No	G
DATATYPEID	INTEGER NOT NULL	For a built-in data type, the internal ID of the built-in type. For a distinct type, the internal ID of the distinct type.	S
SOURCETYPEID	INTEGER NOT NULL	For a built-in data type, 0. For a distinct type, the internal ID of the built-in data type upon which the distinct type is based.	S

Column name	Data type	Description	Use
CREATEDTS	TIMESTAMP NOT NULL	Timestamp when the identity column or sequence was created.	G
ALTEREDTS	TIMESTAMP NOT NULL	Timestamp when the last ALTER statement was executed for this identity column or sequence.	G
MAXASSIGNEDVAL	DECIMAL(31,0)	Last possible assigned value. Initialized to null when the object is created. Updated each time the next chunk of $n$ values is cached, where $n$ is the value for CACHE.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
REMARKS	VARCHAR(762) NOT NULL	Character string provided by user with the COMMENT statement. The value is blank for an identity column.	G
PRECISION	SMALLINT NOT NULL WITH DEFAULT	The precision defined for a sequence with a decimal or numeric type. The value is 5 for SMALLINT, 10 for INTEGER, or the actual precision specified by the user for the decimal data type. The value is 0 for rows created prior to Version 8.	G
RESTARTWITH	DECIMAL(31,0) NULLABLE WITH DEFAULT	The RESTART WITH value specified for a sequence during ALTER or NULL. The value is NULL if no ALTER with RESTART WITH has happened.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>blank</b> Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSSEQUENCESDEP table

The SYSIBM.SYSSEQUENCESDEP table records the dependencies of identity columns and sequences.

Column name	Data type	Description	Use
BSEQUENCEID	INTEGER NOT NULL	Internal identifier of the identity column or sequence.	G
DCREATOR	VARCHAR(128) NOT NULL	The owner of the object that is dependent on this identity column or sequence.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DNAME	VARCHAR(128) NOT NULL	Name of the object that is dependent on this identity column or sequence.	G
DCOLNAME	VARCHAR(128) NOT NULL	Name of the identity column. Blank for SQL function rows.	G
DTYPE	CHAR(1) NOT NULL WITH DEFAULT T	The type of object that is dependent on this sequence:  F SQL function I Identity column X Implicit DOCID column that is created on a base table with XML  blank Represents an identity column created prior to Version 8	G
BSHEMA	VARCHAR(128) NOT NULL WITH DEFAULT	The schema name of the sequence, will be a string of length zero for an object created prior to Version 8.	G
BNAME	VARCHAR(128) NOT NULL WITH DEFAULT	The sequence name (generated by DB2 for an identity column), will be a string of length zero for an object created prior to Version 8.	G
DSHEMA	VARCHAR(128) NOT NULL WITH DEFAULT	The qualifier of the object that is dependent on this sequence, will be a string of length zero for an object created prior to Version 8.	G
DOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	The owner of the object that is dependent on this sequence. This will be a string of length zero for an object that was created prior to Version 9.	G
DOWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	The type of owner:  Blank An authorization ID L A role	G

## SYSIBM.SYSSTMT table

The SYSIBM.SYSSTMT table contains one or more rows for each SQL statement of each DBRM.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Name of the DBRM.	G
PLNAME	VARCHAR(24) NOT NULL	Name of the application plan.	G
PLCREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the application plan.	G
SEQNO	SMALLINT NOT NULL	Sequence number of this row with respect to a statement of the DBRM. Rows in which the values of SEQNO, STMTNO, and SECTNO are zero are for internal use. The numbering starts with zero.	G
STMTNO	SMALLINT NOT NULL	The statement number of the statement in the source program. A statement number greater than 32767 is stored as zero. If the value is zero, see STMTNOI for the statement number. Rows in which the values of SEQNO, STMTNO, and SECTNO are zero are for internal use.	G
SECTNO	SMALLINT NOT NULL	The section number of the statement. Rows in which the values of SEQNO, STMTNO, and SECTNO are zero are for internal use.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
TEXT	VARCHAR(3800) NOT NULL WITH DEFAULT FOR BIT DATA	Text or portion of the text of the SQL statement.	S
ISOLATION	CHAR(1) NOT NULL WITH DEFAULT	Isolation level for the SQL statement: R      RR (repeatable read) T      RS (read stability) S      CS (cursor stability) U      UR (uncommitted read) L      RS isolation, with a <i>lock-clause</i> X      RR isolation, with a <i>lock-clause</i> <b>blank</b> The WITH clause was not specified on this statement. The isolation level is recorded in SYSPACKAGE.ISOLATION and in SYSPLAN.ISOLATION.	G

Column name	Data type	Description	Use
STATUS	CHAR(1) NOT NULL WITH DEFAULT	<p>Status of binding the statement:</p> <p><b>A</b> Distributed - statement uses DB2 private protocol access. The statement will be parsed and executed at the server using defaults for input variables during access path selection.</p> <p><b>B</b> Distributed - statement uses DB2 private protocol access. The statement will be parsed and executed at the server using values for input variables during access path selection.</p> <p><b>C</b> Compiled - statement was bound successfully using defaults for input variables during access path selection.</p> <p><b>D</b> Distributed - statement references a remote object using a three-part name. DB2 will implicitly use DRDA access either because the DBPROTOCOL bind option was not specified (defaults to DRDA), or the bind option DBPROTOCOL(DRDA) was explicitly specified. This option allows the use of three-part names with DRDA access but it requires that the package be bound at the target remote site.</p> <p><b>E</b> Explain - statement is an SQL EXPLAIN statement. The explain is done at bind time using defaults for input variables during access path selection.</p> <p><b>F</b> Parsed - statement did not bind successfully and VALIDATE(RUN) was used. The statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>G</b> Compiled - statement bound successfully, but REOPT is specified. The statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>H</b> Parsed - statement is either a data definition statement or a statement that did not bind successfully and VALIDATE(RUN) was used. The statement will be rebound at execution time using defaults for input variables during access path selection. Data manipulation statements use defaults for input variables during access path selection.</p> <p><b>I</b> Indefinite - statement is dynamic. The statement will be bound at execution time using defaults for input variables during access path selection.</p>	S

Column name	Data type	Description	Use
STATUS		<p><b>J</b> Indefinite - statement is dynamic. The statement will be bound at execution time using values for input variables during access path selection.</p> <p><b>K</b> Control - CALL statement.</p> <p><b>L</b> Bad - the statement has some allowable error. The bind continues but the statement cannot be executed.</p> <p><b>M</b> Parsed - statement references a table that is qualified with SESSION and was not bound because the table reference could be for a declared temporary table that will not be defined until the package or plan is run. The SQL statement will be rebound at execution time using values for input variables during access path selection.</p> <p><b>blank</b> The statement is non-executable, or was bound in a DB2 release prior to Version 5.</p>	
ACCESSPATH	CHAR(1) NOT NULL WITH DEFAULT	For static statements, indicates if the access path for the statement is based on user-specified optimization hints. A value of 'H' indicates that optimization hints were used. A blank value indicates that the access path was determined without the use of optimization hints, or that there is no access path associated with the statement.	G
		For dynamic statements, the value is blank.	
STMTNOI	INTEGER NOT NULL WITH DEFAULT	If the value of STMTNOI is not zero, the column contains the statement number of the statement in the source program.	G
SECTNOI	INTEGER NOT NULL WITH DEFAULT	The section number of the statement.	G
EXPLAINABLE	CHAR(1) NOT NULL WITH DEFAULT	<p>Contains one of the following values:</p> <p><b>Y</b> Indicates that the SQL statement can be used with the EXPLAIN function and might have rows describing its access path in the owner.PLAN_TABLE.</p> <p><b>N</b> Indicates that the SQL statement does not have any rows describing its access path in the owner.PLAN_TABLE.</p> <p><b>blank</b> Indicates that the SQL statement was bound prior to Version 7.</p>	G
QUERYNO	INTEGER NOT NULL WITH DEFAULT -1	The query number of the SQL statement in the source program. SQL statements bound prior to Version 7 have a default value of -1. Statements bound in Version 7 or later use the value specified on the QUERYNO clause on SELECT, UPDATE, INSERT, DELETE, EXPLAIN, and DECLARE CURSOR statements. If the QUERYNO clause is not specified, the query number is set to the statement number.	G

Column name	Data type	Description	Use
PLCREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSSTOGROUP table

The SYSIBM.SYSSTOGROUP table contains one row for each storage group.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the storage group.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the storage group.	G
VCATNAME	VARCHAR(24) NOT NULL	Name of the integrated catalog facility catalog.	G
	VARCHAR(24) NOT NULL	Not used	N
SPACE	INTEGER NOT NULL	Number of kilobytes of DASD storage allocated to the storage group as determined by the last execution of the STOSPACE utility.	G
	CHAR(5) NOT NULL	Not used	N
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the storage group.	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If the STOSPACE utility was executed for the storage group, date and time when STOSPACE was last executed.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the storage group.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER STOGROUP statement was executed for the storage group. If no ALTER STOGROUP statement has been applied, ALTEREDTS has the value of CREATEDTS.	G
SPACEF	FLOAT NOT NULL WITH DEFAULT	Kilobytes of DASD storage for the storage group. The value is -1 if statistics have not been gathered. This is an updatable column.	G
DATACLAS	VARCHAR(24) NOT NULL	Name of the SMS data class. Blank if data class is not used.	G
MGMTCLAS	VARCHAR(24) NOT NULL	Name of the SMS management class. Blank if management class is not used.	G

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
STORCLAS	VARCHAR(24) NOT NULL	Name of the SMS storage class. Blank if storage class is not used.	G
CREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>blank</b> Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSSTRINGS table

The SYSIBM.SYSSTRINGS table contains information about character conversion. Each row describes a conversion from one coded character set to another.

Also refer to z/OS C/C++ Programming Guide for information on the additional conversions that are supported.

Each row in the table must have a unique combination of values for its INCCSID, OUTCCSID, and IBMREQD columns. Rows for which the value of IBMREQD is N can be deleted, inserted, and updated subject to this uniqueness constraint and to the constraints imposed by a VALIDPROC defined on the table. An inserted row could have values for the INCCSID and OUTCCSID columns that match those of a row for which the value of IBMREQD is Y. DB2 then uses the information in the inserted row instead of the information in the IBM-supplied row. Rows for which the value of IBMREQD is Y cannot be deleted, inserted, or updated. For information about the use of inserted rows for character conversion, see *DB2 Installation Guide*.

DB2 has two methods for character conversions and applies them in the following order:

1. Conversions specified by the various combinations of the INCCSID and OUTCCSID columns in the SYSIBM.SYSSTRINGS catalog table.
2. Conversions provided by z/OS support for Unicode. For more information, see z/OS Support for Unicode: Using Conversion Services.

If neither of these methods can be used for a particular character conversion, DB2 returns an error.

Conversions with the following combinations of source CCSID and target CCSID will always use the conversion services that are provided by z/OS support for Unicode. Any rows in the SYSIBM.SYSSTRINGS table with the following CCSID combinations will be ignored:

- Either the source CCSID (INCCSID column) or the target CCSID (OUTCCSID column) is 1200 or 1208.
- The source CCSID (INCCSID column) is 17584 and the target CCSID (OUTCCSID column) is 16684.

Column name	Data type	Description	Use
INCCSID	INTEGER NOT NULL	The source CCSID for the character conversion represented by this row. The value of the source CCSID must be in the range of 1 to 65533 and must not be the same as the value for the OUTCCSID column.	G
OUTCCSID	INTEGER NOT NULL	The target CCSID for the character conversion represented by this row. The value of the target CCSID must be in the range of 1 to 65533 and must not be the same as the value for the INCCSID column.	G

Column name	Data type	Description	Use
TRANSTYPE	CHAR(2) NOT NULL	Indicates the nature of the conversion. Values can be:  GG GRAPHIC to GRAPHIC MM EBCDIC MIXED to EBCDIC MIXED MS EBCDIC MIXED to SBCS PM ASCII MIXED to EBCDIC MIXED PS ASCII MIXED to SBCS SM SBCS to EBCDIC MIXED SS SBCS to SBCS MP EBCDIC MIXED to ASCII MIXED PP ASCII MIXED to ASCII MIXED SP SBCS to ASCII MIXED	G
ERRORBYTE	CHAR(1) FOR BIT DATA (Nulls are allowed)	The byte used in the conversion table as an error byte. Any non-null value that is specified for the ERRORBYTE column must not be the same as the value that is specified for the SUBBYTE column.	S
		Null indicates the absence of an error byte.	
SUBBYTE	CHAR(1) FOR BIT DATA (Nulls are allowed)	The byte used in the conversion table as a substitution character. Any non-null value that is specified for the SUBBYTE column must not be the same as the value that is specified for the ERRORBYTE column.	S
		Null indicates the absence of a substitution character.	
TRANSPROC	VARCHAR(24) NOT NULL WITH DEFAULT	The name of a module or blanks. A nonblank value must conform to the rules for z/OS program names.  If IBMREQD is 'N', a nonblank value is the name of a conversion procedure provided by the user. The first five characters of the name of a user-provided conversion procedure must not be 'DSNXV'; these characters are used to distinguish user-provided conversion procedures from DB2 modules that contain DBCS conversion tables.  If IBMREQD is 'Y', a nonblank value is the name of a DB2 module that contains DBCS conversion tables.	G

Column name	Data type	Description	Use
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape.	G
		<b>Value    Meaning</b>	
	<b>B</b>	Version 1R3 dependency indicator, not from the machine-readable material (MRM) tape	
	<b>C</b>	Version 2R1 dependency indicator, not from MRM tape	
	<b>D</b>	Version 2R2 dependency indicator, not from MRM tape	
	<b>E</b>	Version 2R3 dependency indicator, not from MRM tape	
	<b>F</b>	Version 3R1 dependency indicator, not from MRM tape	
	<b>G</b>	Version 4 dependency indicator, not from MRM tape	
	<b>H</b>	Version 5 dependency indicator, not from MRM tape	
	<b>I</b>	Version 6 dependency indicator, not from MRM tape	
	<b>J</b>	Version 6 dependency indicator, not from MRM tape	
	<b>K</b>	Version 7 dependency indicator, not from MRM tape	
	<b>L</b>	Version 8 dependency indicator, not from MRM tape	
	<b>M</b>	Version 9 dependency indicator, not from MRM tape	
	<b>N</b>	Not from MRM tape, no dependency	
TRANSTAB	VARCHAR(256) FOR BIT DATA NOT NULL WITH DEFAULT	Either a 256-byte conversion table or an empty (0 length) string.	S

## SYSIBM.SYSSYNONYMS table

The SYSIBM.SYSSYNONYMS table contains one row for each synonym of a table or view.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Synonym for the table or view.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the synonym.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table or view.	G
TBCREATOR	VARCHAR(128) NOT NULL	The schema of the table or view.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the synonym.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the synonym. The value is '0001-01.01.00.00.00.00000' for synonyms created in a DB2 release prior to Version 5.	G
CREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>b</b> lank Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSTABAUTH table

The SYSIBM.SYSTABAUTH table records the privileges that users hold on tables and views.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID or role of the user who granted the privileges. Could also be PUBLIC, or PUBLIC followed by an asterisk. <sup>44</sup> .	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID or role of the user who holds the privileges or the name of an application plan or package that uses the privileges. PUBLIC for a grant to PUBLIC. PUBLIC followed by an asterisk for a grant to PUBLIC AT ALL LOCATIONS.	G
GRANTEETYPE	CHAR(1) NOT NULL	Type of grantee: <b>blank</b> An authorization ID <b>L</b> Role <b>P</b> An application plan or a package. The grantee is a package if COLLID is not blank.	G
DBNAME	VARCHAR(24) NOT NULL	If the privileges were received from a user with DBADM, DBCTRL, or DBMAINT authority, DBNAME is the name of the database on which the GRANTOR has that authority. Otherwise, DBNAME is blank.	G
SCREATOR	VARCHAR(128) NOT NULL	If the row of SYSIBM.SYSTABAUTH was created as a result of a CREATE VIEW statement, SCREATOR is the schema of a table or view referred to in the CREATE VIEW statement. Otherwise, SCREATOR is the same as TCREATOR.	G
STNAME	VARCHAR(128) NOT NULL	If the row of SYSIBM.SYSTABAUTH was created as a result of a CREATE TABLE statement or a materialized query table, STNAME is the name of a table or view referred to in the fullselect of the CREATE TABLE statement.	G
TCREATOR	VARCHAR(128) NOT NULL	The schema of the table or view.	G
TTNAME	VARCHAR(128) NOT NULL	Name of the table or view.	G
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor. <b>blank</b> Not applicable <b>C</b> DBCTRL <b>D</b> DBADM <b>L</b> SYSCTRL <b>M</b> DBMAINT <b>S</b> SYSADM	G
	CHAR(12) NOT NULL	Internal use only	I

44. PUBLIC followed by an asterisk (PUBLIC\*) denotes PUBLIC AT ALL LOCATIONS.

Column name	Data type	Description	Use
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N
UPDATECOLS	CHAR(1) NOT NULL	The value of this column is blank if the value of UPDATEAUTH applies uniformly to all columns of the table or view. The value is an asterisk (*) if the value of UPDATEAUTH applies to some columns but not to others. In this case, rows will exist in SYSIBM.SYSCOLAUTH with matching timestamps and PRIVILEGE = blank. These rows list the columns on which update privileges have been granted.	G
ALTERAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can alter the table: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DELETEAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can delete rows from the table or view: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
INDEXAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can create indexes on the table: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
INSERTAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can insert rows into the table or view: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
SELECTAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can select rows from the table or view: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
UPDATEAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can update rows of the table or view: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
	VARCHAR(128) NOT NULL WITH DEFAULT	Not used	N
	VARCHAR(128) NOT NULL WITH DEFAULT	Not used	N

Column name	Data type	Description	Use
COLLID	VARCHAR(128) NOT NULL WITH DEFAULT	If the GRANTEE is a package, its collection name. Otherwise, the value is blank.	G
CONTOKEN	CHAR(8) NOT NULL WITH DEFAULT FOR BIT DATA	If the GRANTEE is a package, the consistency token of the DBRM from which the package was derived. Otherwise, the value is blank.	S
	CHAR(1) NOT NULL WITH DEFAULT	Not used	N
REFERENCESAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE can create or drop referential constraints in which the table is a parent. <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege held without the GRANT option	G
REFCOLS	CHAR(1) NOT NULL WITH DEFAULT	The value of this column is blank if the value of REFERENCESAUTH applies uniformly to all columns of the table. The value is an asterisk(*) if the value of REFERENCESAUTH applies to some columns but not to others. In this case, rows will exist in SYSIBM.SYSCOLAUTH with PRIVILEGE = R and matching timestamps that list the columns on which reference privileges have been granted.	G
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed.	G
TRIGGERAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE can create triggers in which the table is named as the subject table: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSTABCONST table

The SYSIBM.SYSTABCONST table contains one row for each unique constraint (primary key or unique key) created in DB2 Version 7 or later.

Column name	Data type	Description	Use
CONSTNAME	VARCHAR(128) NOT NULL	Name of the constraint.	G
TBCREATOR	VARCHAR(128) NOT NULL	The schema of the table on which the constraint is defined.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table on which the constraint is defined.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID under which the constraint was created.	G
TYPE	CHAR(1) NOT NULL	Type of constraint:  P Primary key U Unique key	G
IXOWNER	VARCHAR(128) NOT NULL	The schema of the index enforcing the constraint or blank if index has not been created yet.	G
IXNAME	VARCHAR(128) NOT NULL	Name of the index enforcing the constraint or blank if index has not been created yet.	G
CREATEDTS	TIMESTAMP NOT NULL	Time when the statement to create the constraint was executed.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
COLCOUNT	SMALLINT NOT NULL	Number of columns in the constraint.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSTABLEPART table

The SYSIBM.SYSTABLEPART table contains one row for each nonpartitioned table space and one row for each partition of a partitioned table space.

Column name	Data type	Description	Use
PARTITION	SMALLINT NOT NULL	Partition number; 0 if table space is not partitioned.	G
TSNAME	VARCHAR(24) NOT NULL	Name of the table space.	G
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the table space.	G
IXNAME	VARCHAR(128) NOT NULL	Name of the partitioning index. This column is blank unless this is a table that uses index-controlled partitioning.	G
IXCREATOR	VARCHAR(128) NOT NULL	The schema of the partitioning index. This column is blank unless this is a table that uses index-controlled partitioning.	G
PQTY	INTEGER NOT NULL	<p>For user-managed data sets, the value is the primary space allocation in units of 4 KB storage blocks or -1.</p> <p>PQTY is based on a value of PRIQTY in the appropriate CREATE or ALTER TABLESPACE statement. Unlike PQTY, however, PRIQTY asks for space in 1 KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>PRIQTY was not specified for a CREATE TABLESPACE statement or for any subsequent ALTER TABLESPACE statements.</li> <li>-1 was the most recently specified value for PRIQTY, either on the CREATE TABLESPACE statement or a subsequent ALTER TABLESPACE statement.</li> </ul>	G
SQTY	SMALLINT NOT NULL	<p>For user-managed data sets, the value is the secondary space allocation in units of 4 KB storage blocks or -1.</p> <p>SQTY is based on a value of SECQTY in the appropriate CREATE or ALTER TABLESPACE statement. Unlike SQTY, however, SECQTY asks for space in 1 KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>SECQTY was not specified for a CREATE TABLESPACE statement or for any subsequent ALTER TABLESPACE statements.</li> <li>-1 was the most recently specified value for SECQTY, either on the CREATE TABLESPACE statement or a subsequent ALTER TABLESPACE statement.</li> </ul>	G
STORTYPE	CHAR(1) NOT NULL	If the value does not fit into the column, the value of the column is 32767. See the description of column SECQTYI.	G
		Type of storage allocation: E      Explicit (storage group not used) I      Implicit (storage group used)	

Column name	Data type	Description	Use
STORNAME	VARCHAR(128) NOT NULL	Name of storage group used for space allocation. Blank if storage group not used.	G
VCATNAME	VARCHAR(24) NOT NULL	Name of integrated catalog facility catalog used for space allocation.	G
CARD	INTEGER NOT NULL	Number of rows in the table space or partition or, if the table space is a LOB table space, the number of LOBs in the table space. The value is '2 147 483 647' if the number of rows is greater than or equal to '2 147 483 647'. The value is -1 if statistics have not been gathered.	G
FARINDREF	INTEGER NOT NULL	Number of rows that have been relocated far from their original page. The value is -1 if statistics have not been gathered. Not applicable if the table space is a LOB table space.	S
NEARINDREF	INTEGER NOT NULL	Number of rows that have been relocated near their original page. The value is -1 if statistics have not been gathered. Not applicable if the table space is a LOB table space.	S
PERCACTIVE	SMALLINT NOT NULL	Percentage of space occupied by rows of data from active tables. The value is -1 if statistics have not been gathered. The value is -2 if the table space is a LOB table space.	S
PERCDROP	SMALLINT NOT NULL	Percentage of space occupied by rows of dropped tables. The value is -1 if statistics have not been gathered. The value is 0 for segmented table spaces. Not applicable if the table is an auxiliary table.	S
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
LIMITKEY	VARCHAR(765) NOT NULL	The high value of the partition in external format. If the table space was converted from index-controlled partitioning to table-controlled partitioning, the value is the highest possible value for an ascending key, or the lowest possible value for a descending key. If the table space is not partitioned, the value is an empty string.	G
FREEPAGE	SMALLINT NOT NULL	Number of pages loaded before a page is left as free space.	G
PCTFREE	SMALLINT NOT NULL	Percentage of each page left as free space.	G
CHECKFLAG	CHAR(1) NOT NULL WITH DEFAULT	<p><b>b</b>lank    The table space is not a partition, or does not contain rows that might violate referential constraints, check constraints, or both.</p> <p><b>C</b>    The table space partition is in a check pending status and there are rows in the table that can violate referential constraints, check constraints, or both.</p>	G
	CHAR(4) NOT NULL WITH DEFAULT FOR BIT DATA	Not used	N

Column name	Data type	Description	Use
SPACE	INTEGER NOT NULL WITH DEFAULT	<p>Number of kilobytes of DASD storage allocated to the table space partition, as determined by the last execution of the STOSPACE utility or RUNSTATS utility.</p> <p><b>0</b> The STOSPACE or RUNSTATS utility has not been run.</p> <p><b>-1</b> The table space was defined with the DEFINE NO clause, which defers the physical creation of the data sets until data is first inserted into one of the partitions, and data has yet to be inserted.</p> <p><b>non-zero or non-negative value</b> An auxiliary table in the LOB table space. The value is if The value is updated by STOSPACE if the table space is related to a storage group. The value is updated by RUNSTATS if the utility is executed as RUNSTATS TABLESPACE with UPDATE(ALL) or UPDATE(SPACE).</p>	G
COMPRESS	CHAR(1) NOT NULL WITH DEFAULT	<p>Indicates the following:</p> <ul style="list-style-type: none"> <li>For a table space partition, whether the COMPRESS attribute for the partition is YES.</li> <li>For a nonpartitioned table space, whether the COMPRESS attribute is YES for the table space.</li> </ul> <p>Values for the column can be:  <b>Y</b> Compression is defined for the table space  <b>blank</b> No compression</p>	G
PAGESAVE	SMALLINT NOT NULL WITH DEFAULT	Percentage of pages saved in the table space or partition as a result of defining the table space with COMPRESS YES or other compression routines. For example, a value of 25 indicates a savings of 25 percent, so that the pages required are only 75 percent of what would be required without data compression. The calculation includes overhead bytes for each row, the bytes required for dictionary, and the bytes required for the current FREEPAGE and PCTFREE specification for the table space or partition. This calculation is based on an average row length, and the result varies depending on the actual lengths of the rows. The value is 0 if there are no savings from using data compression, or if statistics have not been gathered. The value can be negative, if for example, data compression causes an increase in the number of pages in the data set.	S
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
GBPCACHE	CHAR(1) NOT NULL WITH DEFAULT	<p>Group buffer pool cache option specified for this table space or table space partition.</p> <p><b>A</b> Changed and unchanged pages are cached in the group buffer pool.</p> <p><b>N</b> No data is cached in the group buffer pool.</p> <p><b>S</b> Only changed system pages, such as space map pages that do not contain actual data values, are cached in the group buffer pool.</p> <p><b>blank</b> Only changed pages are cached in the group buffer pool.</p>	G

Column name	Data type	Description	Use
CHECKRID5B	CHAR(5) NOT NULL WITH DEFAULT FOR BIT DATA	Blank if the table or partition is not in a check pending status (CHECKFLAG is blank), or if the table space is not partitioned. Otherwise, the RID of the first row of the table space partition that can violate referential constraints, check constraints, or both; or the value is X'0000000000', indicating that any row can violate referential constraints.	S
TRACKMOD	CHAR(1) NOT NULL WITH DEFAULT	Whether to track the page modifications in the space map pages: N No blank Yes	G
EPOCH	INTEGER NOT NULL WITH DEFAULT	A number that increments whenever a utility operation that changes the location of rows in a table occurs.	G
SECQTYI	INTEGER NOT NULL WITH DEFAULT	Secondary space allocation in units of 4KB storage. For user-managed data sets, the value is the secondary space allocation in units of 4KB blocks.	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	Number of rows in the table space or partition, or if the table space is a LOB table space, the number of LOBs in the table space. The value is -1 if statistics have not been gathered.	G
IPREFIX	CHAR(1) NOT NULL WITH DEFAULT 'T'	The first character of the instance qualifier for the data set name for the table space or partition. 'T' or 'J' are the only valid characters for this field. The default is 'T'.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER TABLESPACE statement was executed for the table space or partition. If no ALTER TABLESPACE statement has been applied, the value is '0001-01-01.00.00.00.000000'.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Kilobytes of DASD storage. The value is -1 if statistics have not been gathered. The value might be non-zero for an auxiliary table in the LOB table space. This is an updatable column.	G
DSNUM	INTEGER NOT NULL WITH DEFAULT -1	Number of data sets. The value is -1 if statistics have not been gathered. This is an updatable column.	G
EXTENTS	INTEGER NOT NULL WITH DEFAULT -1	Number of data set extents. The value is -1 if statistics have not been gathered. This is an updatable column. This value is only for the last DSNUM for the object.	G
LOGICAL_PART	SMALLINT NOT NULL WITH DEFAULT	The logical partition (logical ascending or descending order) for table spaces created with either table-controlled partitioning or index-controlled partitioning. The physical partition number is kept in column PART and is zero for partitioned table spaces created prior to Version 8 and for nonpartitioned table spaces.	G

Column name	Data type	Description	Use
LIMITKEY_INTERNAL	VARCHAR(512) NOT NULL WITH DEFAULT FOR BIT DATA	The highest value of the limit key of the partition in an internal format. If the uses index-controlled partitioning instead of table-controlled partitioning or the table is not partitioned, the value is an empty string. If the table space was converted from index-controlled partitioning to table-controlled partitioning, the value is the highest possible value for an ascending key, or the lowest possible value for a descending key. If any column of the key has a field procedure, the internal format is the encoded form of the value.	G
OLDEST_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number of the oldest format of data in the table part and any image copies at the part level.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the partition was created.	G
AVGROWLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of rows for the tables in the table space or part. If the table space or part is compressed, the value is the compressed row length. If the table space or part is not compressed, the value is the uncompressed row length. The value is -1 if statistics have not been gathered.	G
FORMAT	CHAR(1) NOT NULL WITH DEFAULT	Indicates the format of the rows in the table space or partition:  R      Indicates reordered row format blank    Indicates basic row format or a LOB tablespace	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G
REORG_LR_TS	TIMESTAMP NOT NULL WITH DEFAULT	The time when the REORG or LOAD REPLACE utility last occurred. The default value is '0001-01-01.00.00.00.000000'.	G

## SYSIBM.SYSTABLEPART\_HIST table

The SYSIBM.SYSTABLEPART\_HIST table contains rows from SYSTABLEPART.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
PARTITION	SMALLINT NOT NULL	Partition number. 0 if table space is not partitioned.	G
TSNAME	VARCHAR(24) NOT NULL	Name of the table space.	G
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the table space.	G
PQTY	INTEGER NOT NULL	<p>For user-managed data sets, the value is the primary space allocation in units of 4 KB storage blocks or -1.</p> <p>For user-specified values of PRIQTY other than -1, the value is set to the primary space allocation only if RUNSTATS TABLESPACE with UPDATE(ALL) or UPDATE(SPACE) is executed; otherwise, the value is zero. PQTY is based on a value of PRIQTY in the appropriate CREATE or ALTER TABLESPACE statement. Unlike PQTY, however, PRIQTY asks for space in 1 KB units.</p> <p>A value of -1 indicates that either of the following cases is true:</p> <ul style="list-style-type: none"> <li>• PRIQTY was not specified for a CREATE TABLESPACE statement or for any subsequent ALTER TABLESPACE statements.</li> <li>• -1 was the most recently specified value for PRIQTY, either on the CREATE TABLESPACE statement or a subsequent ALTER TABLESPACE statement.</li> </ul> <p>If a storage group is not used, the value is 0.</p>	G

Column name	Data type	Description	Use
SECQTYI	INTEGER NOT NULL	For user-managed data sets, the value is the secondary space allocation in units of 4 KB storage blocks or -1.  For user-specified values of SECQTY other than -1, the value is set to the secondary space allocation only if RUNSTATS TABLESPACE with UPDATE(ALL) or UPDATE(SPACE) is executed; otherwise, the value is zero. SQTY is based on a value of SECQTY in the appropriate CREATE or ALTER TABLESPACE statement. Unlike SQTY, however, SECQTY asks for space in 1 KB units.	G
		A value of -1 indicates that either of the following cases is true: <ul style="list-style-type: none"><li>• SECQTY was not specified for a CREATE TABLESPACE statement or for any subsequent ALTER TABLESPACE statements.</li><li>• -1 was the most recently specified value for SECQTY, either on the CREATE TABLESPACE statement or a subsequent ALTER TABLESPACE statement.</li></ul>	
		If a storage group is not used, the value is 0.	
FARINDREF	INTEGER NOT NULL WITH DEFAULT -1	Number of rows that have been relocated far from their original page. The value is -1 if statistics have not been gathered. Not applicable if the table space is a LOB table space.	S
NEARINDREF	INTEGER NOT NULL WITH DEFAULT -1	Number of rows that have been relocated near their original page. The value is -1 if statistics have not been gathered. Not applicable if the table space is a LOB table space.	S
PERCACTIVE	SMALLINT NOT NULL WITH DEFAULT -1	Percentage of space occupied by rows of data from active tables. The value is -1 if statistics have not been gathered. The value is -2 if the table space is a LOB table space.	S
PERCDROP	SMALLINT NOT NULL WITH DEFAULT -1	Percentage of space occupied by rows of dropped tables. The value is -1 if statistics have not been gathered. The value is 0 for segmented table spaces. Not applicable if the table is an auxiliary table.	S
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of kilobytes of DASD storage allocated to the table space partition. The value is -1 if statistics have not been gathered.	G

Column name	Data type	Description	Use
PAGESAVE	SMALLINT NOT NULL	Percentage of pages saved in the table space or partition as a result of defining the table space with COMPRESS YES or other compression routines. For example, a value of 25 indicates a savings of 25 percent, so that the pages required are only 75 percent of what would be required without data compression.	S
		The calculation includes overhead bytes for each row, the bytes required for dictionary, and the bytes required for the current FREEPAGE and PCTFREE specification for the table space or partition. This calculation is based on an average row length, and the result varies depending on the actual lengths of the rows.	
		The value is 0 if there are no savings from using data compression, or if statistics have not been gathered. The value can be negative, if for example, data compression causes an increase in the number of pages in the data set.	
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'.	G
CARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of rows in the table space or partition, or if the table space is a LOB table space, the number of LOBS in the table space. The value is '-1' if statistics have not been gathered.	S
EXTENTS	INTEGER NOT NULL WITH DEFAULT -1	Number of data set extents. The value is '-1' if statistics have not been gathered. This value is only for the last DSNUM for the object.	G
DSNUM	INTEGER NOT NULL WITH DEFAULT -1	Data set number within the table space. For partitioned table spaces, this value corresponds to the partition number for a single partition copy, or 0 for a copy of an entire partitioned table space or index space. The value is '-1' if statistics have not been gathered.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
AVGROWLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of rows for the tables in the table space or part. If the table space or part is compressed, the value is the compressed row length. If the table space or part is not compressed, the value is the uncompressed row length. The value is '-1' if statistics have not been gathered.	G

## SYSIBM.SYSTABLES table

The SYSIBM.SYSTABLES table contains one row for each table, view, or alias.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the table, view, or alias.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the table, view, or alias.	G
TYPE	CHAR(1) NOT NULL	Type of object:  A Alias C Clone table G Created global temporary table M Materialized query table P Implicit table created for XML columns T Table V View X Auxiliary table	G
DBNAME	VARCHAR(24) NOT NULL	For a table, or a view of tables, the name of the database that contains the table space named in TSNAME. For a created temporary table, an alias, or a view of a view, the value is DSNDB06.	G
TSNAME	VARCHAR(24) NOT NULL	For a table, or a view of one table, the name of the table space that contains the table. For a view of more than one table, the name of a table space that contains one of the tables. For a created temporary table, the value is SYSPKAGE. Although SYSPKAGE is used as the value, created temporary tables are not stored in the SYSPKAGE table space. For a view of a view, the value is SYSVIEWS. For an alias, it is SYSDBAUT.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database; 0 if the row describes a view, alias, or created temporary table. Non-zero if the view has an INSTEAD OF trigger defined.	S
OBID	SMALLINT NOT NULL	Internal identifier of the table; 0 if the row describes a view, an alias, or a created temporary table. Non-zero if the view has an INSTEAD OF trigger defined.	S
COLCOUNT	SMALLINT NOT NULL	Number of columns in the table or view. The value is 0 if the row describes an alias.	G
EDPROC	VARCHAR(24) NOT NULL	Name of the edit procedure; blank if the row describes a view or alias or a table without an edit procedure.	G
VALPROC	VARCHAR(24) NOT NULL	Name of the validation procedure; blank if the row describes a view or alias or a table without a validation procedure.	G
CLUSTERTYPE	CHAR(1) NOT NULL	Whether RESTRICT ON DROP applies:  blank No Y Yes. Neither the table nor any table space or database that contains the table can be dropped.	G
	INTEGER NOT NULL	Not used	N

Column name	Data type	Description	Use
	INTEGER NOT NULL	Not used	N
NPAGES	INTEGER NOT NULL	Total number of pages on which rows of the table appear. The value is -1 if statistics have not been gathered, or the row describes a view, an alias, a created temporary table, or an auxiliary table. This is an updatable column.	S
PCTPAGES	SMALLINT NOT NULL	Percentage of active table space pages that contain rows of the table. A page is termed active if it is formatted for rows, regardless of whether it contains any. If the table space is segmented, the percentage is based on the number of active pages in the set of segments assigned to the table. The value is -1 if statistics have not been gathered, or the row describes a view, alias, created temporary table, or auxiliary table. This is an updatable column.	S
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
REMARKS	VARCHAR(762) NOT NULL	A character string provided by the user with the COMMENT statement.	G
PARENTS	SMALLINT NOT NULL	Number of relationships in which the table is a dependent. The value is 0 if the row describes a view, an alias, a created temporary table, or a materialized query table.	G
CHILDREN	SMALLINT NOT NULL	Number of relationships in which the table is a parent. The value is 0 if the row describes a view, an alias, a created temporary table, or a materialized query table.	G
KEYCOLUMNS	SMALLINT NOT NULL	Number of columns in the primary key of the table. The value is 0 if the row describes a view, an alias, or a created temporary table.	G
RECLENGTH	SMALLINT NOT NULL	<p>For user tables, the maximum length of any record in the table. Length is <math>8+N+L</math>, where:</p> <ul style="list-style-type: none"> <li>• The number 8 accounts for the header (6 bytes) and the ID map entry (2 bytes).</li> <li>• <math>N</math> is 10 if the table has an edit procedure, or 0 otherwise.</li> <li>• <math>L</math> is the sum of the maximum column lengths. In determining the maximum length of a column, take into account whether the column allows nulls and the data type of the column. If the column can contain nulls and is not a LOB or ROWID column, add 1 byte for a null indicator. Use 4 bytes for the length of a LOB column and 19 bytes for the length of a ROWID column. If the column has a varying-length data type (for example, VARCHAR, CLOB, or BLOB), add 2 bytes for a length indicator. For more information on column lengths, see "Data types" on page 69.</li> </ul> <p>The value is 0 if the row describes a view, alias, or auxiliary table. For maximum row and record sizes, see Maximum record size.</p>	G

Column name	Data type	Description	Use
STATUS	CHAR(1) NOT NULL	Indicates the status of the table definition:  <b>I</b> The definition of the table is incomplete. The TABLESTATUS column indicates the reason for the table definition being incomplete. <b>R</b> An error occurred when an attempt was made to regenerate the internal representation of the view. <b>X</b> The table has a unique constraint (primary key or unique key) and the table definition is complete. <b>blank</b> The table has no unique constraint (primary key or unique key), the table is a catalog table, or the row describes a view or alias. The definition of the table, view, or alias is complete.	G
KEYOBID	SMALLINT NOT NULL	Internal DB2 identifier of the index that enforces uniqueness of the primary key of the table; 0 if not applicable.	S
LABEL	VARCHAR(90) NOT NULL	The label as given by a LABEL statement; otherwise, the value is an empty string.	G
CHECKFLAG	CHAR(1) NOT NULL WITH DEFAULT	  <b>C</b> The table space that contains the table is in a check pending status. One of the following conditions is true: <ul style="list-style-type: none"> <li>• There are rows in the table that violate referential constraints, check constraints, or both</li> <li>• The table is a materialized query table that might contain inconsistent data</li> </ul> <b>blank</b> Indicates the following: <ul style="list-style-type: none"> <li>• The table contains no rows that violate referential constraints, check constraints, or both</li> <li>• The table is a materialized query table that contains consistent data</li> <li>• The row describes a view, an alias, or a temporary table</li> </ul>	G
I CHECKRID	CHAR(4) NOT NULL WITH DEFAULT FOR BIT DATA	A value of 'FFFFFF00' in this column indicates that the edit procedure on this table is defined without row attribute sensitivity. Any other value indicates that the edit procedure is defined with row attribute sensitivity.	G
AUDITING	CHAR(1) NOT NULL WITH DEFAULT	Value of the audit option:  <b>A</b> AUDIT ALL <b>C</b> AUDIT CHANGE <b>blank</b> AUDIT NONE, or the row describes a view, an alias, or a created temporary table.	G
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the table, view, or alias.	G

Column name	Data type	Description	Use				
LOCATION	VARCHAR(128) NOT NULL WITH DEFAULT	Location name of the object of an alias, or the name of the accelerator server that is used for a materialized query table.	G				
		Blank for a table, a view, for an alias that was not defined with a three-part object name, or a materialized query table that is not accelerated.					
TBCREATOR	VARCHAR(128) NOT NULL WITH DEFAULT	<ul style="list-style-type: none"> <li>For an alias, the schema of the referred to table or view</li> <li>For a base table that is involved in a clone relationship, the name of the creator of the clone table</li> <li>For a clone table that is involved in a clone relationship, the name of the creator of the base table</li> <li>For a view, the name of the underlying table.</li> <li>Otherwise, TBCREATOR is blank</li> </ul>	G				
TBNAME	VARCHAR(128) NOT NULL WITH DEFAULT	<ul style="list-style-type: none"> <li>For an alias, the name for the referred to table or view</li> <li>For a base table that is involved in a clone relationship, the name of the clone table</li> <li>For a clone table that is involved in a clone relationship, the name of the base table</li> <li>For a view, the name of the underlying table.</li> <li>Otherwise, TBNAME is blank</li> </ul>	G				
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the table, view, or alias	G				
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	For a table, the time when the latest ALTER TABLE statement was applied. If no ALTER TABLE statement has been applied, or if the row is for an alias, ALTEREDTS has the value of CREATEDTS. For a view, the time when the last ALTER VIEW REGENERATE statement was applied.	G				
DATA_CAPTURE	CHAR(1) NOT NULL WITH DEFAULT	<p>Records the value of the DATA_CAPTURE option for a table:</p> <table> <tr> <td><b>blank</b></td> <td>No</td> </tr> <tr> <td><b>Y</b></td> <td>Yes</td> </tr> </table> <p>For a created temporary table, DATA_CAPTURE is always blank.</p>	<b>blank</b>	No	<b>Y</b>	Yes	G
<b>blank</b>	No						
<b>Y</b>	Yes						
RBA1	CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA	The log RBA when the table was created. Otherwise, RBA1 is X'000000000000', indicating that the log RBA is not known, or that the object is a view, an alias, or a created temporary table. In a data sharing environment, RBA1 is the LRSN (Log Record Sequence Number) value.	S				
RBA2	CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA	The log RBA when the table was last altered. Otherwise, RBA2 is X'000000000000' indicating that the log RBA is not known, or that the object is a view, an alias, or a created temporary table. RBA1 will equal RBA2 if the table has not been altered. In a data sharing environment, RBA2 is the LRSN (Log Record Sequence Number) value.	S				
PCTROWCOMP	SMALLINT NOT NULL WITH DEFAULT	Percentage of rows compressed within the total number of active rows in the table. This includes any row in a table space that is defined with COMPRESS YES. The value is -1 if statistics have not been gathered, or the row describes a view, alias, created temporary table, or auxiliary table. This is an updatable column.	S				

Column name	Data type	Description	Use
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'. For a created temporary table, the value of STATSTIME is always the default value. This is an updatable column.	G
CHECKS	SMALLINT NOT NULL WITH DEFAULT	Number of check constraints defined on the table. The value is 0 if the row describes a view, an alias, a created temporary table, a materialized query table, or if no constraints are defined on the table.	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	Total number of rows in the table or total number of LOBs in an auxiliary table. The value is -1 if statistics have not been gathered or the row describes a view, alias, or created temporary table. This is an updatable column.	S
CHECKRID5B	CHAR(5) NOT NULL WITH DEFAULT FOR BIT DATA	Blank if the table or partition is not in a check pending status (CHECKFLAG is blank), if the table space is not partitioned, or if the table is a created temporary table. Otherwise, the RID of the first row of the table space partition that can violate referential constraints, check constraints, or both; or the value is X'0000000000', indicating that any row can violate referential constraints.	S
ENCODING_SCHEME	CHAR(1) NOT NULL WITH DEFAULT 'E'	<p>Encoding scheme for tables, views, and local aliases:</p> <ul style="list-style-type: none"> <li><b>E</b> EBCDIC</li> <li><b>A</b> ASCII</li> <li><b>M</b> Multiple CCSID set or multiple encoding schemes</li> <li><b>U</b> UNICODE</li> <li><b>blank</b> For remote aliases</li> </ul> <p>The value is 'E' for tables in non work file databases and blank for tables in work file databases created prior to Version 5 or the default database, DSNDB04.</p>	G
TABLESTATUS	VARCHAR(30) NOT NULL WITH DEFAULT	<p>Not applicable for tables that were created prior to DB2 for z/OS Version 5. Indicates the reason for an incomplete table definition:</p> <ul style="list-style-type: none"> <li><b>L</b> Definition is incomplete because an auxiliary table or auxiliary index has not been defined for a LOB column.</li> <li><b>P</b> Definition is incomplete because the table lacks a primary index.</li> <li><b>R</b> Definition is incomplete because the table lacks a required index on a row ID.</li> <li><b>U</b> Definition is incomplete because the table lacks a required index on a unique key.</li> <li><b>V</b> An error occurred when an attempt was made to regenerate the internal representation of the view.</li> <li><b>blank</b> Definition is complete.</li> </ul>	G
NPAGESF	FLOAT(8) NOT NULL WITH DEFAULT -1	Number of pages used by the table. The value is -1 if statistics have not been gathered or this is an auxiliary table. This is an updatable column.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Kilobytes of DASD storage. The value is -1 if statistics have not been gathered. The value might be non-zero for an auxiliary table in the LOB table space. This is an updatable column.	G

Column name	Data type	Description	Use
AVGROWLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of rows for the tables in the table space. If the table space is compressed, the value is the compressed row length. If the table space is not compressed, the value is the uncompressed row length. The value is -1 if statistics have not been gathered.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G
NUM_DEP_MQTS	SMALLINT NOT NULL WITH DEFAULT	Number of dependent materialized query tables. The value is zero if the row describes an alias or a created temporary table, or if no materialized query tables are defined on the table.	G
VERSION	SMALLINT NOT NULL WITH DEFAULT	<p>The version of the data row format for this table.</p> <ul style="list-style-type: none"> <li>A value of zero indicates that a version-creating alter operation has never occurred against this table.</li> <li>A value of -1 indicates that the view has been regenerated because a column of the base table has been altered.</li> <li>A value of 800 indicates that a successful CREATE VIEW or ALTER VIEW statement has occurred against this table in Version 8 or later.</li> </ul>	G
PARTKEYCOLNUM	SMALLINT NOT NULL WITH DEFAULT	The number of columns in the partitioning key. This value is zero for tables that do not have partitioning or use index-controlled partitioning. The value is non-zero for tables that use table-controlled partitioning.	G
SPLIT_ROWS	CHAR(1) NOT NULL WITH DEFAULT	Value is blank, except for VOLATILE tables, which will have 'Y' in the field to indicate to DB2 to use index access on this table whenever possible.	G
SECURITY_LABEL	CHAR(1) NOT NULL	<p>This column is only meaningful if the TYPE column is a T (for table) or M (for materialized query table). The value indicates whether the table has multilevel security:</p> <p><b>Blank</b> The table does not have multilevel security.</p> <p><b>R</b> The table has multilevel security with row granularity.</p>	G
OWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the table, view, or alias, blank for tables, views or aliases that were created in a DB2 release prior to Version 9.	G
APPEND	CHAR(1) NOT NULL WITH DEFAULT	<p>Indicates whether the APPEND option is specified for the table.</p> <p><b>Y</b> The APPEND option is specified.</p> <p><b>N</b> The APPEND option is not specified.</p>	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>blank</b> Authorization ID <b>L</b> Role	G

## SYSIBM.SYSTABLESPACE table

The SYSIBM.SYSTABLESPACE table contains one row for each table space.

Column name	Data type	Description	Use
NAME	VARCHAR(24) NOT NULL	Name of the table space.	G
CREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the table space.	G
DBNAME	VARCHAR(24) NOT NULL	Name of the database that contains the table space.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database which contains the table space.	S
OBID	SMALLINT NOT NULL	Internal identifier of the table space file descriptor.	S
PSID	SMALLINT NOT NULL	Internal identifier of the table space page set descriptor.	S
BPOOL	CHAR(8) NOT NULL	Name of the buffer pool used for the table space.	G
PARTITIONS	SMALLINT NOT NULL	Number of partitions of the table space; 0 if the table space is not partitioned.	G
LOCKRULE	CHAR(1) NOT NULL	Lock size of the table space:  A Any L Large object (LOB) P Page R Row S Table space T Table X implicitly created XML table space	G
PGSIZE	SMALLINT NOT NULL	Size of pages in the table space in kilobytes.	G
ERASERULE	CHAR(1) NOT NULL	Whether the data sets are to be erased when dropped. The value is meaningless if the table space is partitioned.  N No erase Y Erase	G
STATUS	CHAR(1) NOT NULL	Availability status of the table space:  A Available C Definition is incomplete because the table space does not use table-controlled partitioning and a partitioning index has not been created. P Table space is in a check pending status. S Table space is in a check pending status with the scope less than the entire table space. T Definition is incomplete because no table has been created.	G

Column name	Data type	Description	Use
IMPLICIT	CHAR(1) NOT NULL	Whether the table space was created implicitly:  N No Y Yes	G
NTABLES	SMALLINT NOT NULL	Number of tables defined in the table space.	G
NACTIVE	INTEGER NOT NULL	Number of active pages in the table space. A page is termed active if it is formatted for rows, even if it currently contains none. The value is 0 if statistics have not been gathered. This is an updatable column.	S
	VARCHAR(24) NOT NULL	Not used	N
CLOSERULE	CHAR(1) NOT NULL	Whether the data sets are candidates for closure when the limit on the number of open data sets is reached.  N No Y Yes	G
SPACE	INTEGER NOT NULL	Number of kilobytes of DASD storage allocated to the table space, as determined by the last execution of the STOSPACE utility. The value is 0 if the table space is not related to a storage group, or if STOSPACE has not been run. If the table space is partitioned, the value is the total kilobytes of DASD storage allocated to all partitions that are storage group defined.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
	VARCHAR(54) NOT NULL	Internal use only	I
	VARCHAR(24) NOT NULL	Internal use only	I
SEGSIZE	SMALLINT NOT NULL WITH DEFAULT	Number of pages in each segment of a segmented table space. The value is 0 if the table space is not segmented.	G
CREATEDBY	VARCHAR(128) NOT NULL WITH DEFAULT	Primary authorization ID of the user who created the table space.	G
STATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.00.000000'. This is an updatable column.	G

Column name	Data type	Description	Use
LOCKMAX	INTEGER	The maximum number of locks per user to acquire for the table or table space before escalating to the next locking level.  0 Lock escalation does not occur.  <i>n</i> , where <i>n</i> > 0, is the maximum number of locks (row, page, or LOB locks for the table or table space) an application process can acquire before lock escalation occurs.  -1 Represents LOCKMAX SYSTEM. The value of field LOCKS PER TABLE(SPACE) on installation panel DSNTIPJ determines lock escalation. If the value of the field is 0, lock escalation does not occur. If the value is <i>n</i> , where <i>n</i> > 0, lock escalation occurs as it does for LOCKMAX <i>n</i> .	G
TYPE	CHAR(1) NOT NULL WITH DEFAULT	The type of table space:  <b>blank</b> The table space was created without the LOB or MEMBER CLUSTER options. If the DSSIZE column is zero, the table space is not greater than 64 gigabytes.  <b>I</b> The table space was defined with the MEMBER CLUSTER option and is not greater than 64 gigabytes.  <b>G</b> The table space was defined with the MAXPARTITIONS option (a partitioned-by-growth table space) with the underlying structure of a universal table space.  <b>K</b> The table space was defined with the MEMBER CLUSTER option and can be greater than 64 gigabytes.  <b>L</b> The table space can be greater than 64 gigabytes.  <b>O</b> The table space was defined with the LOB option (the table space is a LOB table space).  <b>P</b> Implicit table space created for XML columns.  <b>R</b> Range-partitioned universal table space.	G
CREATEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the CREATE statement was executed for the table space. If the table space was created in a DB2 release prior to Version 5, the value is '0001-01-01.00.00.00.000000'.	G
ALTEREDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the most recent ALTER TABLESPACE statement was executed for the table space. If no ALTER TABLESPACE statement has been applied, ALTEREDTS has the value of CREATEDTS. If the index was created in a DB2 release prior to Version 5, the value is '0001-01-01.00.00.00.000000'.	G
ENCODING_SCHEME	CHAR(1) NOT NULL WITH DEFAULT 'E'	Default encoding scheme for the table space:  <b>E</b> EBCDIC <b>A</b> ASCII <b>U</b> UNICODE  <b>blank</b> For table spaces in a work file database or a TEMP database (a database that was created AS TEMP, which is for declared temporary tables.)  The value is 'E' for tables in non work file databases and blank for tables in work file databases created prior to Version 5 or the default database, DSNDB04.	G

Column name	Data type	Description	Use
SBCS_CCSID	INTEGER NOT NULL WITH DEFAULT	Default SBCS CCSID for the table space. For a table space in a work file database, a TEMP database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
DBCS_CCSID	INTEGER NOT NULL WITH DEFAULT	Default DBCS CCSID for the table space. For a table space in a work file database, a TEMP database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
MIXED_CCSID	INTEGER NOT NULL WITH DEFAULT	Default mixed CCSID for the table space. For a table space in a work file database, a TEMP database, or a database created in a DB2 release prior to Version 5, the value is 0.	G
MAXROWS	SMALLINT NOT NULL DEFAULT 255	The maximum number of rows that DB2 will place on a data page. The default value is 255. For a LOB table space, the value is 0 to indicate that the column is not applicable.	G
	CHAR(1) NOT NULL WITH DEFAULT	Not used	N
LOG	CHAR(1) NOT NULL WITH DEFAULT 'Y'	Whether the changes to a table space are to be logged.  N     This table space has the NOT LOGGED attribute. Undo and redo logging for the table space and all indexes for tables in the table space is suppressed. Logging is also suppressed for the auxiliary indexes for all auxiliary tables associated with tables in the table space.  Y     This table space has the LOGGED attribute. Normal logging is associated with modifications to this table space, all indexes for tables in this table space, and all auxiliary indexes for all auxiliary tables associated with tables in the table space.  X     This LOB or XML table space has the NOT LOGGED attribute. Undo and redo logging for the table space is suppressed. Also, the logging attribute for this LOB or XML table space is linked to the logging attribute of the associated base table space and might not be able to be altered independently. If the logging attribute of the base table space is altered to LOGGED, the logging attribute of the LOB or XML table space will also be altered to LOGGED.	G
NACTIVEF	FLOAT NOT NULL WITH DEFAULT -1	Number of active pages in the table space. A page is termed active if it is formatted for rows, even if it currently contains none. The value is -1 if statistics have not been gathered. This is an updatable column.	S
DSSIZE	INTEGER NOT NULL WITH DEFAULT	Maximum size of a data set in kilobytes.	G

Column name	Data type	Description	Use
OLDEST_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number of the oldest format of data in the table space and any image copies.	G
CURRENT_VERSION	SMALLINT NOT NULL WITH DEFAULT	The version number describing the newest format of data in the table space. A zero indicates that the table space has never had versioning. After the version number reaches the maximum value, the number wraps back to one.	G
AVGROWLEN	INTEGER NOT NULL WITH DEFAULT -1	Average length of rows for the tables in the table space or part. If the table space or part is compressed, the value is the compressed row length. If the table space or part is not compressed, the value is the uncompressed row length. The value is -1 if statistics have not been gathered.	G
SPACEF	FLOAT NOT NULL WITH DEFAULT	Kilobytes of DASD storage for the storage group. The value is -1 if statistics have not been gathered. This is an updatable column.	G
CREATORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>blank</b> Authorization ID <b>L</b> Role	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G
INSTANCE	SMALLINT NOT NULL WITH DEFAULT	INSTANCE indicates the data set instance number of the current base object (table and index).	G
CLONE	CHAR(1) NOT NULL WITH DEFAULT	Indicates whether the table space contains any objects that are involved in a clone relationship: <b>Y</b> Table space contains objects that are involved in a clone relationship <b>N</b> Table space does not contain any objects that are involved in a clone relationship	G
MAXPARTITIONS	SMALLINT NOT NULL WITH DEFAULT	Identifies the maximum number of partitions to which the table space can grow. 0 if the table space is not a partition-by-growth table space.	G

## SYSIBM.SYSTABLESPACESTATS table

The SYSIBM.SYSTABLESPACESTATS table contains real time statistics for table spaces.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
UPDATESTATSTIME	TIMESTAMP NOT NULL WITH DEFAULT	The timestamp that the row in the TABLESPACESTATS table is inserted or updated.	G
NACTIVE	INTEGER	The number of active pages in the table space or partition.	G
NPAGES	INTEGER	The number of distinct pages with active rows in the partition or table space. This is an updatable column.	G
EXTENTS	SMALLINT	The number of extents in the table space. For multi-piece table spaces, this value is the number of extents for the last data set. For a data set that is striped across multiple volumes, the value is the number of logical extents. A null value indicates the number of extents is unknown.	G
LOADLASTTIME	TIMESTAMP	The timestamp that the LOAD REPLACE utility was last run on the table space or partition.  A null value indicates that the LOAD REPLACE utility has never been run on the table space or partition or that the timestamp is unknown.	G
REORGLASTTIME	TIMESTAMP	The timestamp the REORG utility was last run on the table space or partition, or when the REORG utility has not been run, the time when the table space or partition was created. A null value indicates that the timestamp is unknown.	G
REORGINSERTS	INTEGER	The number of records or LOBs that have been inserted into the table space or partition or loaded into the table space or partition using the LOAD utility specified without the REPLACE option since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of inserted records or LOBs is unknown.	G
REORGDELETES	INTEGER	The number of records or LOBs that have been deleted from the table space or partition since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of deleted records or LOBs is unknown.	G
REORGUPDATES	INTEGER	The number of rows that have been updated in the table space or partition since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created.  A null value indicates that the number of updated rows is unknown.	G

Column name	Data type	Description	Use
REORGUNCLUSTINS	INTEGER	The number of records that were inserted that are not well-clustered with respect to the clustering index since the last REORG or LOAD REPLACE , or since the object was created. A record is well-clustered if the record is inserted into a page that is within 16 pages of the ideal candidate page. The clustering index determines the ideal candidate page.	G
		A null value indicates that the number of not well clustered pages is unknown.	
REORGDISORGLOB	INTEGER	The number of LOBs that were inserted that are not perfectly chunked since the last REORG or LOAD REPLACE, or since the object was created. A LOB is perfectly chunked if the allocated pages are in the minimum number of chunks.	G
		A null value indicates that the number of not perfectly chunked LOBs is unknown.	
REORGMASSDELETE	INTEGER	The number of mass deletes from a segmented or LOB table space, or the number of dropped tables from a segmented table space since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created.	G
		A null value indicates that the number of mass deletes is unknown.	
REORGNEARINDREF	INTEGER	The number of overflow records that are created and relocated near the pointer record since the last time the REORG and LOAD REPLACE utilities were run, or since the object was created. For non-segmented table spaces, a page is near the present page if the two page numbers differ by 16 or less. For segmented table spaces, a page is near the present page if the two page numbers differ by SEGSIZE*2 or less.	G
		A null value indicates that the number of overflow records that are near the pointer record is unknown.	
REORGFARINDREF	INTEGER	The number of overflow records that are created and relocated far from the pointer record since the last time the REORG and LOAD REPLACE utilities were run, or since the object was created. For non-segmented table spaces, a page is far from the present page if the two page numbers differ by more than 16. For segmented table spaces, a page is far from the present page if the two page numbers differ by at least (SEGSIZE*2)+1.	G
		A null value indicates that the number of overflow records that are near the pointer record is unknown.	
STATSLASTTIME	TIMESTAMP	The timestamp of the last time that the RUNSTATS utility is run on the table space or partition.	G

Column name	Data type	Description	Use
STATSINSERTS	INTEGER	The number of records or LOBs that have been inserted into the table space or partition or loaded into the table space or partition using the LOAD utility specified without the REPLACE option since the last time that the RUNSTATS utility was run, or since the object was created.  A null value indicates that the number of inserted records or LOBs is unknown.	G
STATSDELETES	INTEGER	The number of records or LOBs that have been deleted from the table space or partition since the last time that the RUNSTATS utility was run, or since the object was created.  A null value indicates that the number of deleted records or LOBs is unknown.	G
STATSUPDATES	INTEGER	The number of rows that have been updated in the table space or partition since the last time that the RUNSTATS utility was run, or since the object was created.  A null value indicates that the number of updated rows is unknown.	G
STATSMASSDELETE	INTEGER	The number of mass deletes from a segmented or LOB table space, or the number of tables that are dropped from a segmented table space, since the last time the RUNSTATS utility was run, or since the object was created.  A null value indicates that the number of mass deletes is unknown.	G
COPYLASTTIME	TIMESTAMP	The timestamp of the last full or incremental image copy of the table space or partition, or since the object was created.  A null value indicates that the COPY utility has never been run on the table space or partition. A null value can also indicate that the timestamp of the last image copy is unknown.	G
COPYUPDATED-PAGES	INTEGER	The number of distinct types that have been updated since the last time that the COPY utility was run, or since the object was created.  A null value indicates that the number of updated pages is unknown.	G
COPYCHANGES	INTEGER	The number of insert, update, and delete operations, or the number of records loaded, since the last time that the COPY utility was run, or since the object was created.  A null value indicates that the number of insert, update, and delete operations or the number of records loaded is unknown.	G
COPYUPDATELSN	CHAR(6) FOR BIT DATA	The LRSN or RBA of the first update that occurs after the last time the COPY utility was run, or since the object was created.  A null value indicates that the LRSN or RBA is unknown.	G

Column name	Data type	Description	Use
COPYUPDATETIME	TIMESTAMP	The timestamp of the first update that occurs after the last time that the COPY utility was run, or since the object was created.  A null value indicates that the timestamp is unknown.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DBID	SMALLINT NOT NULL	The internal identifier of the database. This column is used to map a DBID to its statistics.	G
PSID	SMALLINT NOT NULL	The internal identifier of the table space page set descriptor. This column is used to map a PSID to its statistics.	G
PARTITION	SMALLINT NOT NULL	The data set number within the table space. This column is used to map a data set number in a table space to its statistics. For partitioned table spaces, this value corresponds to the partition number for a single partition. For non-partitioned table spaces, this value is 0.	G
INSTANCE	SMALLINT NOT NULL WITH DEFAULT 1	Indicates if the object is associated with data set instance 1 or 2. This is an updatable column.	G
SPACE	BIGINT	The amount of space, in KB, that is allocated to the table space or partition. For multi-piece, linear page sets, this value is the amount of space in all data sets. A null value indicates the amount of space is unknown.	G
TOTALROWS	BIGINT	The number of rows or LOBs that are in the table space or partition.	G
DATASIZE	BIGINT	The total number of bytes that row data occupy in the data rows or LOB rows. This is an updatable column.	G
UNCOMPRESSED-DATASIZE	BIGINT	This column is not used. The value is always set to 0.	G
DBNAME	VARCHAR(24) NOT NULL	The name of the database. This column is used to map a database to its statistics.	G
NAME	VARCHAR(24) NOT NULL	The name of the table space. This column is used to map a table space to its statistics.	G

## SYSIBM.SYSTABLES\_HIST table

The SYSIBM.SYSTABLES\_HIST table contains rows from SYSTABLES.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the table, view, or alias.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the table, view, or alias.	G
DBNAME	VARCHAR(24) NOT NULL	For a table, or a view of tables, the name of the database that contains the table space named in TSNAME. For a temporary table, an alias, or a view of a view, the value is DSNDB06.	G
TSNAME	VARCHAR(24) NOT NULL	For a table, or a view of one table, the name of the table space that contains the table. For a view of more than one table, the name of a table space that contains one of the tables. For a temporary table, the value is SYSPKAGE. For a view of a view, the value is SYSVIEWS. For an alias, it is SYSDBAUT.	G
COLCOUNT	SMALLINT NOT NULL	Number of columns in the table or view. The value is 0 if the row describes an alias.	G
PCTPAGES	SMALLINT NOT NULL WITH DEFAULT -1	Percentage of active table space pages that contain rows of the table. A page is termed active if it is formatted for rows, regardless of whether it contains any. If the table space is segmented, the percentage is based on the number of active pages in the set of segments assigned to the table. The value is -1 if statistics have not been gathered, or the row describes a view, alias, temporary table, or auxiliary table.	S
PCTROWCOMP	SMALLINT NOT NULL WITH DEFAULT -1	Percentage of rows compressed within the total number of active rows in the table. This includes any row in a table space that is defined with COMPRESS YES. The value is -1 if statistics have not been gathered, or the row describes a view, alias, temporary table, or auxiliary table.	G
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01.00.00.000000'. For a temporary table, the value of STATSTIME is always the default value.	G
CARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Total number of rows in the table or total number of LOBs in an auxiliary table. The value is -1 if statistics have not been gathered or the row describes a view, alias, or temporary table.	S
NPAGESF	FLOAT(8) NOT NULL WITH DEFAULT -1	Total number of pages on which rows of the partition appear. The value is -1 if statistics have not been gathered.	S

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
AVGROWLEN	INTEGER NOT NULL WITH DEFAULT -1	Average row length of the table specified in the table space. The value is -1 if statistics have not been gathered.	G
SPACEF	FLOAT(8) NOT NULL WITH DEFAULT -1	Kilobytes of DASD storage. The value is -1 if statistics have not been gathered. This is an updatable column.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSTABSTATS table

The SYSIBM.SYSTABSTATS table contains one row for each partition of a partitioned table space.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
CARD	INTEGER NOT NULL	Total number of rows in the partition.	S
NPAGES	INTEGER NOT NULL	Total number of pages on which rows of the partition appear.	S
PCTPAGES	SMALLINT NOT NULL	Percentage of total active pages in the partition that contain rows of the table.	S
NACTIVE	INTEGER NOT NULL	Number of active pages in the partition.	S
PCTROWCOMP	SMALLINT NOT NULL	Percentage of rows compressed within the total number of active rows in the partition. This includes any row in a table space that is defined with COMPRESS YES.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
DBNAME	VARCHAR(24) NOT NULL	Database that contains the table space named in TSNAME.	G
TSNAME	VARCHAR(24) NOT NULL	Table space that contains the table.	G
PARTITION	SMALLINT NOT NULL	Partition number of the table space that contains the table.	G
OWNER	VARCHAR(128) NOT NULL	The schema of the table.	G
NAME	VARCHAR(128) NOT NULL	Name of the table.	G
CARDF	FLOAT NOT NULL WITH DEFAULT -1	Total number of rows in the partition.	S

## SYSIBM.SYSTABSTATS\_HIST table

The SYSIBM.SYSTABSTATS\_HIST table contains rows from SYSTABSTATS.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

Column name	Data type	Description	Use
NPAGES	INTEGER NOT NULL	Total number of pages on which rows of the partition appear.	S
STATSTIME	TIMESTAMP NOT NULL	If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics.	G
DBNAME	VARCHAR(24) NOT NULL	Database that contains the table space named in TSNAME.	G
TSNAME	VARCHAR(24) NOT NULL	Table space that contains the table.	G
PARTITION	SMALLINT NOT NULL	Partition number of the table space that contains the table.	G
OWNER	VARCHAR(128) NOT NULL	The schema of the table.	G
NAME	VARCHAR(128) NOT NULL	Name of the table.	G
CARDF	FLOAT(8) NOT NULL WITH DEFAULT -1	Total number of rows in the partition. The value is -1 if statistics have not been gathered.	S
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.SYSTRIGGERS table

The SYSIBM.SYSTRIGGERS table contains one row for each trigger.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the trigger and trigger package.	G
SCHEMA	VARCHAR(128) NOT NULL	Schema of the trigger. This implicit or explicit qualifier for the trigger name is also used for the collection ID of the trigger package.	G
SEQNO	SMALLINT NOT NULL	Sequence number of this row; the first portion of the trigger definition is in row 1, and successive rows have increasing SEQNO values.	G
DBID	SMALLINT NOT NULL	Internal identifier of the database for the trigger.	G
OBID	SMALLINT NOT NULL	Internal identifier of the trigger.	G
OWNER	VARCHAR(128) NOT NULL	Owner of the trigger.	G
CREATEDBY	VARCHAR(128) NOT NULL	Primary authorization ID of the user who created the trigger.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the table or view.	G
TBOWNER	VARCHAR(128) NOT NULL	Qualifier of the name of the table or view to which this trigger applies.	G
TRIGTIME	CHAR(1) NOT NULL	Time when triggered actions are applied to the base table, relative to the event that activated the trigger:  A Trigger is applied after the event. B Trigger is applied before the event. I Trigger is applied instead of the event	G
TRIGEVENT	CHAR(1) NOT NULL	Operation that activates the trigger:  I Insert D Delete U Update	G
GRANULARITY	CHAR(1) NOT NULL	Trigger is executed once per:  S Statement R Row	G
CREATEDTS	TIMESTAMP NOT NULL	Time when the CREATE statement was executed for this trigger. The time value is used in resolving functions, distinct types, and stored procedures. It is also used to order the execution of multiple triggers.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

Column name	Data type	Description	Use
TEXT	VARCHAR(6000) NOT NULL	Full text of the CREATE TRIGGER statement.	G
REMARKS	VARCHAR(762) NOT NULL	A character string provided by the user with the COMMENT statement.	G
TRIGNAME	VARCHAR(128) NOT NULL	Unused	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of creator: <b>blank</b> Authorization ID <b>L</b> Role	G
ENVID	INTEGER NOT NULL WITH DEFAULT	Internal environment identifier.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSUSERAUTH table

The SYSIBM.SYSUSERAUTH table records the system privileges that are held by users.

Column name	Data type	Description	Use
GRANTOR	VARCHAR(128) NOT NULL	Authorization ID of the user who granted the privileges.	G
GRANTEE	VARCHAR(128) NOT NULL	Authorization ID of the user that holds the privilege. Could also be PUBLIC for a grant to PUBLIC.	G
	CHAR(12) NOT NULL	Internal use only	I
	CHAR(6) NOT NULL	Not used	N
	CHAR(8) NOT NULL	Not used	N
	CHAR(1) NOT NULL	Not used	N
AUTHHOWGOT	CHAR(1) NOT NULL	Authorization level of the user from whom the privileges were received. This authorization level is not necessarily the highest authorization level of the grantor.  <b>blank</b> Not applicable <b>C</b> DBCTRL <b>D</b> DBADM <b>L</b> SYSCTRL <b>M</b> DBMAINT <b>O</b> SYSOPR <b>S</b> SYSADM	G
	CHAR(1) NOT NULL	Not used	N
BINDADDAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the BIND subcommand with the ADD option:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
BSDSAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can issue the RECOVER BSDS command:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
CREATEDBAAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can create databases and automatically receive DBADM authority over the new databases:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

Column name	Data type	Description	Use
CREATEDBCAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can execute the CREATE DATABASE statement to create new databases and automatically receive DBCTRL authority over the new databases: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
CREATESGAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can execute the CREATE STOGROUP statement to create new storage groups: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
DISPLAYAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the DISPLAY commands: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
RECOVERAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the RECOVER INDOUBT command: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
STOPALLAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the STOP command: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
STOSPACEAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can use the STOSPACE utility: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
SYSADMAUTH	CHAR(1) NOT NULL	Whether the GRANTEE has system administration authority: <b>blank</b> Privilege is not held <b>G</b> Privilege was granted with the GRANT option <b>Y</b> Privilege was granted without the GRANT option  GRANTEE has the privilege with the GRANT option for a value of either Y or G.	G
SYSOPRAUTH	CHAR(1) NOT NULL	Whether the GRANTEE has system operator authority: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
TRACEAUTH	CHAR(1) NOT NULL	Whether the GRANTEE can issue the START TRACE and STOP TRACE commands: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
MON1AUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE can obtain IFC serviceability data: <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

Column name	Data type	Description	Use
MON2AUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE can obtain IFC data:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
CREATEALIASAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE can execute the CREATE ALIAS statement:  <b>blank</b> Privilege is not held <b>G</b> Privilege held with the GRANT option <b>Y</b> Privilege held without the GRANT option	G
SYSCTRLAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE has SYSCTRL authority:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option  GRANTEE has the privilege with the GRANT option for a value of either Y or G.	G
BINDAGENTAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE has BINDAGENT privilege:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
ARCHIVEAUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE is privileged to use the ARCHIVE LOG command:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
	CHAR(1) NOT NULL WITH DEFAULT	Not used	N
	CHAR(1) NOT NULL WITH DEFAULT	Not used	N
GRANTEDTS	TIMESTAMP NOT NULL WITH DEFAULT	Time when the GRANT statement was executed. The value is '1985-04-01.00.00.00.00000' for the one installation row.	G
CREATETMTAB-AUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE has CREATETMTABAUTH privilege:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G
GRANTEETYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantee:  <b>blank</b> Authorization ID <b>L</b> Role	G
GRANTORTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of grantor:  <b>blank</b> Authorization ID <b>L</b> Role	G
DEBUGSESSION-AUTH	CHAR(1) NOT NULL WITH DEFAULT	Whether the GRANTEE has DEBUGSESSION privilege:  <b>blank</b> Privilege is not held <b>G</b> Privilege is held with the GRANT option <b>Y</b> Privilege is held without the GRANT option	G

## SYSIBM.SYSVIEWDEP table

The SYSIBM.SYSVIEWDEP table records the dependencies of views on tables, functions, and other views.

Column name	Data type	Description	Use
BNAME	VARCHAR(128) NOT NULL	Name of the object on which the view is dependent. If the object type is a function (BTYPE='F'), the name is the specific name of the function.	G
BCREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of BNAME. For functions, it is the schema name of the BNAME.	G
BTYPE	CHAR(1) NOT NULL	Type of object:  F Function M Materialized query table T Table V View	G
DNAME	VARCHAR(128) NOT NULL	Name of the view.	G
DCREATOR	VARCHAR(128) NOT NULL	The schema of the view.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
BSHEMA	VARCHAR(128) NOT NULL WITH DEFAULT	Schema of BNAME.	G
DTYPE	CHAR(1) NOT NULL	Type of table:  F SQL function M Materialized query table V View	G
DOWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the view, blank for views that were created in a DB2 release prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner:  blank Authorization ID L Role	G

## SYSIBM.SYSVIEWS table

The SYSIBM.SYSVIEWS table contains one or more rows for each view, materialized query table, or user-defined SQL function.

Column name	Data type	Description	Use
NAME	VARCHAR(128) NOT NULL	Name of the object.	G
CREATOR	VARCHAR(128) NOT NULL	The schema of the object.	G
SEQNO	SMALLINT NOT NULL	Sequence number of this row; the first portion of the view is on row one and successive rows have increasing values of SEQNO.	G
CHECK	CHAR(1) NOT NULL	Whether the WITH CHECK OPTION clause was specified in the CREATE VIEW statement:  N No C Yes with the <i>cascaded</i> semantic Y Yes with the <i>local</i> semantic  The value is N if the view has no WHERE clause, or the object is not a view.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
TEXT	VARCHAR(1500) NOT NULL	Text or portion of the text of the statement that was used to create the object.	G
PATHSCHEMAS	VARCHAR(2048) NOT NULL WITH DEFAULT	SQL path at the time the object was defined. The path is used to resolve unqualified data type and function names used in the object definition.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G
TYPE	CHAR(1) NOT NULL	Type of table:  F SQL function M Materialized query table V View	G
REFRESH	CHAR(1) NOT NULL WITH DEFAULT	Refresh mode:  D A materialized query table with a deferred refresh mode blank Not a materialized query table	G
ENABLE	CHAR(1) NOT NULL WITH DEFAULT	Indicates whether query optimization is enabled:  Y Enabled N Disabled blank Not a materialized query table	G
MAINTENANCE	CHAR(1) NOT NULL WITH DEFAULT	Maintenance mode:  S For a REFRESH = 'D', a materialized query table that is maintained by the system. U For a REFRESH = 'D', a materialized query table that is maintained by the user. blank Not a materialized query table.	G

Column name	Data type	Description	Use
REFRESH_TIME	TIMESTAMP NOT NULL WITH DEFAULT	For REFRESH = 'D' and MAINTENANCE = 'S', the timestamp of the REFRESH TABLE statement that last refreshed the data. Otherwise, this is the default timestamp ('0001-01-01.00.00.00.000000').	G
ISOLATION	CHAR(1) NOT NULL WITH DEFAULT	Isolation level when the materialized query table is created or altered from a base table: <b>R</b> RR (repeatable read) <b>S</b> CS (cursor stability) <b>T</b> RS (read stability) <b>U</b> UR (uncommitted read) <b>blank</b> Not a materialized query table	G
SIGNATURE	VARCHAR(1024) NOT NULL WITH DEFAULT FOR BIT DATA	Contains an internal description. Used for materialized query tables.	G
APP_ENCODING_CCSID	INTEGER NOT NULL WITH DEFAULT	CCSID of the current application encoding scheme at the time the object was created. For objects created prior to Version 8 of DB2, the value is 0.	G
OWNER	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID of the owner of the view, blank for views that were created in a DB2 release prior to Version 9.	G
OWNERTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates the type of owner: <b>blank</b> Authorization ID <b>L</b> Role	G
ENVID	INTEGER NOT NULL WITH DEFAULT	Internal environment identifier.	G

## SYSIBM.SYSVOLUMES table

The SYSIBM.SYSVOLUMES table contains one row for each volume of each storage group.

Column name	Data type	Description	Use
SGNAME	VARCHAR(128) NOT NULL	Name of the storage group.	G
SGCREATOR	VARCHAR(128) NOT NULL	Authorization ID of the owner of the storage group.	G
VOLID	VARCHAR(18) NOT NULL	Serial number of the volume or * if SMS-managed.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. Blank if created prior to Version 9. See Release dependency indicators for all other values.	G

## SYSIBM.SYSXMLRELS table

The SYSIBM.SYSXMLRELS table contains one row for each XML table that is created for an XML column.

Column name	Data type	Description	Use
TBOWNER	VARCHAR(128) NOT NULL	Schema or qualifier of the base table.	G
TBNAME	VARCHAR(128) NOT NULL	Name of the base table.	G
COLNAME	VARCHAR(128) NOT NULL	Name of the XML column in the base table.	G
XMLTBOWNER	VARCHAR(128) NOT NULL	Schema or qualifier of the XML table.	G
XMLTBNAME	VARCHAR(128) NOT NULL	Name of the XML table.	G
XMLRELOBID	INTEGER NOT NULL	Internal identifier of the relationship between the base table and the XML table.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G
CREATEDTS	TIMESTAMP NOT NULL	Time when the XML table was created.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.SYSXMLSTRINGS table

Each row of the SYSIBM.SYSXMLSTRINGS table contains a single string and its unique ID that are used to condense XML data. The string can be an element name, attribute name, name space prefix, or a namespace URI.

Column name	Data type	Description	Use
STRINGID	INTEGER NOT NULL GENERATED ALWAYS AS IDENTITY	Unique ID for the string.	G
STRING	VARCHAR(1000) NOT NULL	The string data.	G
IBMREQD	CHAR(1) NOT NULL	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.USERNAMES table

Each row in the SYSIBM.USERNAMES table is used to carry out one outbound ID translation or inbound ID translation and “come from” checking.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
TYPE	CHAR(1) NOT NULL	How the row is to be used:  I     For inbound translation and “come from” checking. O     For outbound translation. S     For outbound system AUTHID to establish a trusted connection.	G
AUTHID	VARCHAR(128) NOT NULL WITH DEFAULT	Authorization ID to be translated. Applies to any authorization ID if blank.	G
LINKNAME	VARCHAR(24) NOT NULL	Identifies the VTAM or TCP/IP network locations associated with this row. A blank value in this column indicates this name translation rule applies to any TCP/IP or SNA partner.  If a non-blank LINKNAME is specified, one or both of the following statements must be true: <ul style="list-style-type: none"><li>• A row exists in SYSIBM.LUNAMES whose LUNAME matches the value specified in the SYSIBM.USERNAMES LINKNAME column. This row specifies the VTAM site associated with this name translation rule.</li><li>• A row exists in SYSIBM.IPNAMES whose LINKNAME matches the value specified in the SYSIBM.USERNAMES LINKNAME column. This row specifies the TCP/IP host associated with this name translation rule.</li></ul> Inbound name translation and “come from” checking are not performed for TCP/IP clients.	G
NEWAUTHID	VARCHAR(128) NOT NULL WITH DEFAULT	Translated value of AUTHID. Blank specifies no translation. NEWAUTHID can be stored as encrypted data by calling the DSNLEUSR stored procedure. To send the encrypted value of AUTHID across a network, one of the encryption security options in the SYSIBM.IPNAMES table should be specified.	G
PASSWORD	VARCHAR(24) NOT NULL WITH DEFAULT	Password to accompany an outbound request, if passwords are not encrypted by RACF. If passwords are encrypted, or the row is for inbound requests, the column is not used. PASSWORD can be stored as encrypted data by calling the DSNLEUSR stored procedure. To send the encrypted value of PASSWORD across a network, one of the encryption security options in the SYSIBM.IPNAMES table should be specified.	G
IBMREQD	CHAR(1) NOT NULL WITH DEFAULT 'N'	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	G

## SYSIBM.XSRCOMPONENT table

The SYSIBM.XSRCOMPONENT table is an auxiliary table for the BLOB column COMPONENT in SYSIBM.SYSXSROBJECTCOMPONENTS. It is in LOB table space SYSXSRA3.

Column name	Data type	Description	Use
COMPONENT	BLOB(30M)	Contents of the XML schema document	G

## SYSIBM.XSROBJECTS table

The SYSIBM.XSROBJECTS table contains one row for each registered XML schema.

Rows in this table can only be changed using static SQL statements issued by the DB2-supplied XSR stored procedures.

Column name	Data type	Description	Use
XSROBJECTID	INTEGER NOT NULL	Internal identifier of the XML schema. XSROBJECTID is generated as an identity column.	G
XSROBJECTSCHEMA	VARCHAR(128) NOT NULL	Qualifier of the XML schema name. This is always set to 'SYSXSR'.	G
XSROBJECTNAME	VARCHAR(128) NOT NULL	Name of the XML schema.	G
TARGETNAMESPACE	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the target namespace URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS	G
SCHEMALOCATION	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the schema location URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS	G
ROWID	ROWID NOT NULL GENERATED ALWAYS	The ID that is used to support BLOB data type values.	G
GRAMMAR	BLOB(250M)	The internal binary representation of the XML schema.	G
PROPERTIES	BLOB(5M)	Additional property information of the entire XML schema.	G
CREATEDBY	VARCHAR(128) NOT NULL	Authorization ID under which the XML schema was created.	G
CREATEDTS	TIMESTAMP NOT NULL	The time that the DB2-supplied stored procedure XSR_REGISTER was executed for the XML schema.	G
STATUS	CHAR(1) NOT NULL WITH DEFAULT	Registration status of the XML schema:  C Complete I Incomplete T Temporary	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G
DECOMPOSITION	CHAR(1)	Indicates the decomposition status of the XSR object:  Y Enabled N Not enabled X Inoperative	G

<b>Column name</b>	<b>Data type</b>	<b>Description</b>	<b>Use</b>
DECOMPOSITION_ VERSION	VARCHAR(128)	Indicates the version of the XDB map that is used for decomposition.	G
REMARKS	VARCHAR(762)	Character string that contains comments about this XML schema.	G

## SYSIBM.XSROBJECTCOMPONENTS table

The SYSIBM.XSROBJECTCOMPONENTS table contains one row for each component (document) in an XML schema.

Rows in this table can only be changed using static SQL statements issued by the DB2-supplied XSR stored procedures.

Column name	Data type	Description	Use
XSRCOMPONENTID	INTEGER NOT NULL	Internal identifier of the XML schema document. XSRCOMPONENTID is generated as an identity column.	G
TARGETNAMESPACE	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the target namespace URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS.	G
SCHEMALOCATION	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the schema location URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS.	G
ROWID	ROWID NOT NULL GENERATED ALWAYS	The ID that is used to support BLOB data type values.	G
COMPONENT	BLOB(30M) NOT NULL	Contents of the XML schema document.	G
PROPERTIES	BLOB(5M)	If available, additional property information of the XML schema document	G
CREATEDTS	TIMESTAMP NOT NULL	The time that the XML schema document was registered.	G
STATUS	CHAR(1) NOT NULL WITH DEFAULT	Registration status of the XML schema:  C      Complete I      Incomplete	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.XSROBJECTGRAMMAR table

SYSIBM.XSROBJECTGRAMMAR is an auxiliary table for the BLOB column GRAMMAR in SYSIBM.SYSXSROBJECTS. It is in LOB table space SYSXSRA1.

Column name	Data type	Description	Use
GRAMMAR	BLOB(250M)	Internal binary representation of the XML schema	G

## SYSIBM.XSROBJECTHIERARCHIES table

The SYSIBM.XSROBJECTHIERARCHIES table contains one row for each component (document) in an XML schema to record the XML schema document hierarchy relationship.

Rows in this table can only be changed using static SQL statements issued by the DB2-supplied XSR stored procedures.

Column name	Data type	Description	Use
XSROBJECTID	INTEGER	Internal identifier of the XML schema.	G
XSRCOMPONENTID	INTEGER	Internal identifier of the XML schema document.	G
HTYPE	CHAR(1)	Hierarchy type:  D Document  P Primary document	G
TARGETNAMESPACE	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the target namespace URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS.	G
SCHEMALOCATION	INTEGER	The value of the STRINGID column in SYSIBM.SYSXMLSTRINGS when the schema location URI of the primary XML schema document is stored in SYSIBM.SYSXMLSTRINGS.	G
RELCREATED	CHAR(1) NOT NULL	The release of DB2 that is used to create the object. See Release dependency indicators for the values.	G

## SYSIBM.XSROBJECTPROPERTY table

SYSIBM.XSROBJECTPROPERTY is an auxiliary table for the BLOB column PROPERTIES in SYSIBM.SYSXSROBJECTS. It is in LOB table space SYSXSRA2.

Column name	Data type	Description	Use
PROPERTIES	BLOB(5M)	Contents of the additional property information of the entire XML schema.	G

## SYSIBM.XSRPROPERTY table

The SYSIBM.XSRPROPERTY table is an auxiliary table for the BLOB column COMPONENT in SYSIBM.SYSXSROBJECTCOMPONENTS. It is in LOB table space SYSXSRA3.

Column name	Data type	Description	Use
COMPONENT	BLOB(5M)	Contents of the additional property information of the XML schema document.	G

---

## EXPLAIN tables

EXPLAIN tables contain information about SQL statements and functions that run on DB2 for z/OS.

You can create and maintain a set of EXPLAIN tables to capture and analyze information about the performance of SQL statements and functions that run on DB2 for z/OS. Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods. DB2 creates EXPLAIN output and populates EXPLAIN tables in the following situations:

- When an EXPLAIN statement is executed.
- At BIND or REBIND with the EXPLAIN(YES) option. Rows are added for every explainable statement in the plan or package being bound. For a plan, these do not include statements in the packages that can be used with the plan. For either a package or plan, they do not include explainable statements within EXPLAIN statements nor do they include explainable statements that refer to declared temporary tables, which are incrementally bound at run time.
- When the DSNAEXP stored procedure executes successfully.

| **Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that  
| are encoded in EBCDIC are deprecated.

## PLAN\_TABLE

The plan table, PLAN\_TABLE, contains information about access paths that is collected from the results of EXPLAIN statements.

### PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Optional PLAN\_TABLE formats

A PLAN\_TABLE instance can have a format with fewer columns than those shown in the sample CREATE TABLE statement. However instances of PLAN\_TABLE must have one of the following formats:

- All the columns up to and including REMARKS (COLCOUNT = 25)
- All the columns up to and including MIXOPSEQ (COLCOUNT = 28)

- All the columns up to and including COLID (COLCOUNT = 30)
- All the columns up to and including JOIN\_PGROUP\_ID (COLCOUNT = 34)
- All the columns up to and including IBM\_SERVICE\_DATA (COLCOUNT = 43)
- All the columns up to and including BIND\_TIME (COLCOUNT = 46)
- All the columns up to and including PRIMARY\_ACCESTYPE (COLCOUNT = 49)
- All the columns up to and including TABLE\_TYPE (COLCOUNT = 51)
- All the columns up to and including STMTTOKEN (COLCOUNT = 58)
- All the columns shown in the CREATE statement (COLCOUNT=59)

Whichever set of columns you choose, the columns must appear in the order in which the CREATE statement indicates. You can add columns to an existing plan table with the ALTER TABLE statement only if the modified table satisfies one of the allowed sets of columns. For example, you cannot add column PREFETCH by itself, but must add columns PREFETCH, COLUMN\_FN\_EVAL, and MIXOPSEQ. If you add any NOT NULL columns, give them the NOT NULL WITH DEFAULT attribute.

When using the 58-column format for the plan table, remember that many columns (PROGNAME, COLLID, CREATOR, TNAME, ACCESSCREATOR, ACCESSNAME, CORRELATION\_NAME) must be defined as VARCHAR(128). In previous releases of DB2, these columns were smaller.

Missing columns are ignored when rows are added to a plan table.

## Column descriptions

**PSPI** Your subsystem or data sharing group can contain more than one of these tables, including a table with the qualifier SYSIBM, a table with the qualifier DB2OSCA, and additional tables that are qualified by user IDs.

The following table shows the descriptions of the columns in PLAN\_TABLE.

Table 153. Descriptions of columns in PLAN\_TABLE

Column name	Data Type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>            The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>            DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
QBLOCKNO	SMALLINT NOT NULL	A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
PLANNO	SMALLINT NOT NULL	The number of the step in which the query that is indicated in QBLOCKNO was processed. This column indicates the order in which the steps were executed.
METHOD	SMALLINT NOT NULL	<p>A number that indicates the join method that is used for the step:</p> <ul style="list-style-type: none"> <li><b>0</b> The table in this step is the first table that is accessed, a continuation of a previous table that was accessed, or a table that is not used.</li> <li><b>1</b> A nested loop join is used. For each row of the current composite table, matching rows of a new table are found and joined.</li> <li><b>2</b> A merge scan join is used. The current composite table and the new table are scanned in the order of the join columns, and matching rows are joined.</li> <li><b>3</b> Sorts are needed by ORDER BY, GROUP BY, SELECT DISTINCT, UNION, INTERSECT, EXCEPT, a quantified predicate, or an IN predicate. This step does not access a new table.</li> <li><b>4</b> A hybrid join was used. The current composite table is scanned in the order of the join-column rows of the new table. The new table is accessed using list prefetch.</li> </ul>
CREATOR	VARCHAR(128) NOT NULL	The creator of the new table that is accessed in this step, blank if METHOD is 3.

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
TNAME	VARCHAR(128) NOT NULL	The name of one of the following objects: <ul style="list-style-type: none"><li>• Materialized query table</li><li>• Created or declared temporary table</li><li>• Accelerated query table</li><li>• Materialized view</li><li>• materialized table expression</li></ul>
TABNO	SMALLINT NOT NULL	The value is blank if METHOD is 3. The column can also contain the name of a table in the form DSNWFQB( <i>qblockno</i> ). DSNWFQB( <i>qblockno</i> ) is used to represent the intermediate result of a UNION ALL, INTERSECT ALL, EXCEPT ALL, or an outer join that is materialized. If a view is merged, the name of the view does not appear. DSN_DIM_TBLX( <i>qblockno</i> ) is used to represent the work file of a star join dimension table.
ACCESSTYPE	CHAR(2) NOT NULL	Values are for IBM use only.
		The method of accessing the new table: <b>A</b> Accelerated query table access. <b>DI</b> By an intersection of multiple DOCID lists to return the final DOCID list <b>DU</b> By a union of multiple DOCID lists to return the final DOCID list <b>DX</b> By an XML index scan on the index that is named in ACCESSNAME to return a DOCID list <b>E</b> By direct row access using a row change timestamp column. <b>I</b> By an index (identified in ACCESSCREATOR and ACCESSNAME) <b>I1</b> By a one-fetch index scan <b>M</b> By a multiple index scan (followed by MX, MI, or MU) <b>MI</b> By an intersection of multiple indexes <b>MU</b> By a union of multiple indexes <b>MX</b> By an index scan on the index named in ACCESSNAME. When the access method MX follows the access method DX, DI, or DU, the table is accessed by the DOCID index by using the DOCID list that is returned by DX, DI, or DU. <b>N</b> • By an index scan when the matching predicate contains the IN keyword <b>O</b> By a work file scan, as a result of a subquery. <b>P</b> By a dynamic pair-wise index scan <b>R</b> By a table space scan <b>RW</b> By a work file scan of the result of a materialized user-defined table function <b>V</b> By buffers for an INSERT statement within a SELECT <b>blank</b> Not applicable to the current row
MATCHCOLS	SMALLINT NOT NULL	For ACESSTYPE I, I1, N, MX, or DX, the number of index keys that are used in an index scan; otherwise, 0.

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
ACCESSCREATOR	VARCHAR(128) NOT NULL	For ACESSTYPE I, I1, N, MX, or DX, the creator of the index; otherwise, blank.
ACCESSNAME	VARCHAR(128) NOT NULL	For ACESSTYPE I, I1, N, MX, or DX, the name of the index; for ACESSTYPE P, DSNPJW( <i>mixopseqno</i> ) is the starting pair-wise join leg in MIXOPSEQ; otherwise, blank.
INDEXONLY	CHAR(1) NOT NULL	Indication of whether access to an index alone is enough to perform the step, or Indication of whether data too must be accessed.  Y Yes N No
SORTN_UNIQ	CHAR(1) NOT NULL	Indication of whether the new table is sorted to remove duplicate rows.  Y Yes N No
SORTN_JOIN	CHAR(1) NOT NULL	Indication of whether the new table is sorted for join method 2 or 4.  Y Yes N No
SORTN_ORDERBY	CHAR(1) NOT NULL	Indication of whether the new table is sorted for ORDER BY.  Y Yes N No
SORTN_GROUPBY	CHAR(1) NOT NULL	Indication of whether the new table is sorted for GROUP BY.  Y Yes N No
SORTC_UNIQ	CHAR(1) NOT NULL	Indication of whether the composite table is sorted to remove duplicate rows.  Y Yes N No
SORTC_JOIN	CHAR(1) NOT NULL	Indication of whether the composite table is sorted for join method 1, 2 or 4.  Y Yes N No
SORTC_ORDERBY	CHAR(1) NOT NULL	Indication of whether the composite table is sorted for an ORDER BY clause or a quantified predicate.  Y Yes N No

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
SORTC_GROUPBY	CHAR(1) NOT NULL	Indication of whether the composite table is sorted for a GROUP BY clause.  Y Yes N No
TSLOCKMOD	CHAR(3) NOT NULL	An indication of the mode of lock that is acquired on either the new table, or its table space or table space partitions. If the isolation can be determined at bind time, the values are:  IS Intent share lock IX Intent exclusive lock S Share lock U Update lock X Exclusive lock SIX Share with intent exclusive lock N UR isolation; no lock  If the isolation level cannot be determined at bind time, the lock mode is determined by the isolation level at run time is shown by the following values.  NS For UR isolation, no lock; for CS, RS, or RR, an S lock. NIS For UR isolation, no lock; for CS, RS, or RR, an IS lock. NSS For UR isolation, no lock; for CS or RS, an IS lock; for RR, an S lock. SS For UR, CS, or RS isolation, an IS lock; for RR, an S lock.
		The data in this column is right justified. For example, IX appears as a blank, followed by I, followed by X. If the column contains a blank, then no lock is acquired.
TIMESTAMP	CHAR(16) NOT NULL	If the access method in the ACESSTYPE column is DX, DI, or DU, no latches are acquired on the XML index page and no lock is acquired on the new base table data page or row, nor on the XML table and the corresponding table spaces. The value of TSLOCKMODE is a blank in this case.
REMARKS	VARCHAR(762) NOT NULL	Usually, the time at which the row is processed, to the last .01 second. If necessary, DB2 adds .01 second to the value to ensure that rows for two successive queries have different values.
PREFETCH	CHAR(1) NOT NULL	A field into which you can insert any character string of 762 or fewer characters.
		Indication of whether data pages are to be read in advance by prefetch:  D Optimizer expects dynamic prefetch S Pure sequential prefetch L Prefetch through a page list blank Unknown or no prefetch

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
COLUMN_FN_EVAL	CHAR(1) NOT NULL	When an SQL aggregate function is evaluated:  <b>R</b> While the data is being read from the table or index <b>S</b> While performing a sort to satisfy a GROUP BY clause <b>blank</b> After data retrieval and after any sorts
MIXOPSEQ	SMALLINT NOT NULL	The sequence number of a step in a multiple index operation.  <b>1, 2, ... n</b> For the steps of the multiple index procedure (ACCESSTYPE is MX, MI, MU, DX, DI, or DU).  <b>0</b> For any other rows.
VERSION	VARCHAR(122) NOT NULL	The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
ACCESS_DEGREE	SMALLINT	The number of parallel tasks or operations that are activated by a query. This value is determined at bind time; the actual number of parallel operations that are used at execution time could be different. This column contains 0 if a host variable is used. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
ACCESS_PGROUP_ID	SMALLINT	The identifier of the parallel group for accessing the new table. A parallel group is a set of consecutive operations, executed in parallel, that have the same number of parallel tasks. This value is determined at bind time; it could change at execution time. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
JOIN_DEGREE	SMALLINT	The number of parallel operations or tasks that are used in joining the composite table with the new table. This value is determined at bind time and can be 0 if a host variable is used. The actual number of parallel operations or tasks used at execution time could be different. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
JOIN_PGROUP_ID	SMALLINT	The identifier of the parallel group for joining the composite table with the new table. This value is determined at bind time; it could change at execution time. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
SORTC_PGROUP_ID	SMALLINT	The parallel group identifier for the parallel sort of the composite table. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
SORTN_PGROUP_ID	SMALLINT	The parallel group identifier for the parallel sort of the new table. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
PARALLELISM_MODE	CHAR(1)	<p>The kind of parallelism, if any, that is used at bind time:</p> <ul style="list-style-type: none"> <li>C      Query CP parallelism</li> <li>I      Query I/O parallelism</li> <li>X      Sysplex query parallelism</li> </ul> <p>This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</p>
MERGE_JOIN_COLS	SMALLINT	The number of columns that are joined during a merge scan join (Method=2). This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.
CORRELATION_NAME	VARCHAR(128)	The correlation name of a table or view that is specified in the statement. If no correlation name exists, then the column is null. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
PAGE_RANGE	CHAR(1)	<p>Indication of whether the table qualifies for page range screening, so that plans scan only the partitions that are needed.</p> <p><b>Y</b> Yes  <b>blank</b> No</p>
JOIN_TYPE	CHAR(1)	<p>The type of join:</p> <p><b>F</b> FULL OUTER JOIN  <b>L</b> LEFT OUTER JOIN  <b>P</b> Pair-wise join  <b>S</b> Star join  <b>blank</b> INNER JOIN or no join</p> <p>RIGHT OUTER JOIN converts to a LEFT OUTER JOIN when you use it, so that JOIN_TYPE contains L.</p>
GROUP_MEMBER	VARCHAR(128)	<p>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</p>
IBM_SERVICE_DATA	VARCHAR(254) FOR BIT DATA	<p>This column contains values that are for IBM use only.</p>
WHEN_OPTIMIZE	CHAR(1) NOT NULL WITH DEFAULT	<p>When the access path was determined:</p> <p><b>blank</b> At bind time, using a default filter factor for any host variables, parameter markers, or special registers.</p> <p><b>B</b> At bind time, using a default filter factor for any host variables, parameter markers, or special registers; however, the statement is re-optimized at run time using input variable values for input host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS), REOPT(AUTO), or REOPT(ONCE) must be specified for reoptimization to occur.</p> <p><b>R</b> At run time, using input variables for any host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS), REOPT(AUTO), or REOPT(ONCE) must be specified for this to occur.</p>

*Table 153. Descriptions of columns in PLAN\_TABLE (continued)*

Column name	Data Type	Description
QBLOCK_TYPE	CHAR(6) NOT NULL WITH DEFAULT	For each query block, an indication of the type of SQL operation that is performed. For the outermost query, this column identifies the statement type. Possible values include:  <b>SELECT</b> SELECT  <b>INSERT</b> INSERT  <b>UPDATE</b> UPDATE  <b>MERGE</b> MERGE  <b>DELETE</b> DELETE  <b>SELUPD</b> SELECT with FOR UPDATE OF  <b>DELCUR</b> DELETE WHERE CURRENT OF CURSOR  <b>UPDCUR</b> UPDATE WHERE CURRENT OF CURSOR  <b>CORSUB</b> Correlated subselect or fullselect  <b>TRUNCA</b> TRUNCATE  <b>NCOSUB</b> Noncorrelated subselect or fullselect  <b>TABLEX</b> Table expression  <b>TRIGGR</b> WHEN clause on CREATE TRIGGER  <b>UNION</b> UNION  <b>UNIONA</b> UNION ALL  <b>INTERS</b> INTERSECT  <b>INTERA</b> INTERSECT ALL  <b>EXCEPT</b> EXCEPT  <b>EXCEPTA</b> EXCEPT ALL

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
BIND_TIME	TIMESTAMP NOT NULL WITH DEFAULT	The time when the EXPLAIN information was captured:  <b>All cached statements</b> When the statement entered the cache, in the form of a full-precision timestamp value.  <b>Non-cached static statements</b> When the statement was bound, in the form of a full precision timestamp value.  <b>Non-cached dynamic statements</b> When EXPLAIN was executed, in the form of a value equivalent to the value of the TIMESTAMP column appended by 4 zeros.
OPTHINT	VARCHAR(128) NOT NULL WITH DEFAULT	A string that you use to identify this row as an optimization hint for DB2. DB2 uses this row as input when choosing an access path.
HINT_USED	VARCHAR(128) NOT NULL WITH DEFAULT	If DB2 used one of your optimization hints, it puts the identifier for that hint (the value in OPTHINT) in this column.
PRIMARY_ACESSTYPE	CHAR(1) NOT NULL WITH DEFAULT	Indicates Indication of whether direct row access is attempted first:  <b>D</b> DB2 tries to use direct row access with a rowid column. If DB2 cannot use direct row access with a rowid column at run time, it uses the access path that is described in the ACESSTYPE column of PLAN_TABLE.  <b>T</b> The base table or result file is materialized into a work file, and the work file is accessed via sparse index access. If a base table is involved, then ACESSTYPE indicates how the base table is accessed.  <b>blank</b> DB2 does not try to use direct row access by using a rowid column or sparse index access for a work file. The value of the ACESSTYPE column of PLAN_TABLE provides information on the method of accessing the table.
PARENT_QBLOCKNO	SMALLINT NOT NULL	A number that indicates the QBLOCKNO of the parent query block.

Table 153. Descriptions of columns in PLAN\_TABLE (continued)

Column name	Data Type	Description
TABLE_TYPE	CHAR(1)	<p>The type of new table:</p> <ul style="list-style-type: none"> <li>       <b>B</b>      Buffers for SELECT from INSERT, SELECT from UPDATE, SELECT from MERGE, or SELECT from DELETE statement.</li> <li>       <b>C</b>      Common table expression</li> <li>       <b>F</b>      Table function</li> <li>       <b>M</b>      Materialized query table</li> <li>       <b>Q</b>      Temporary intermediate result table (not materialized). For the name of a view or nested table expression, a value of Q indicates that the materialization was virtual and not actual. Materialization can be virtual when the view or nested table expression definition contains a UNION ALL that is not distributed.</li> <li>       <b>R</b>      Recursive common table expression</li> <li>       <b>S</b>      Subquery (correlated or non-correlated)</li> <li>       <b>T</b>      Table</li> <li>       <b>W</b>      Work file</li> </ul> <p>The value of the column is null if the query uses GROUP BY, ORDER BY, or DISTINCT, which requires an implicit sort.</p>
TABLE_ENCODE	CHAR(1) NOT NULL WITH DEFAULT	<p>The encoding scheme of the table. The possible values are:</p> <ul style="list-style-type: none"> <li>       <b>A</b>      ASCII</li> <li>       <b>E</b>      EBCDIC</li> <li>       <b>U</b>      Unicode</li> <li>       <b>M</b>      The table contains multiple CCSID sets</li> </ul>
TABLE_SCCSID	SMALLINT NOT NULL WITH DEFAULT	The SBCS CCSID value of the table. If column TABLE_ENCODE is M, the value is 0.
TABLE_MCCSID	SMALLINT NOT NULL WITH DEFAULT	The mixed CCSID value of the table. If the value of the TABLE_ENCODE column is M, the value is 0. If MIXED=NO in the DSNHDECP module, the value is -2.
TABLE_DCCSID	SMALLINT NOT NULL WITH DEFAULT	The DBCS CCSID value of the table. If the value of the TABLE_ENCODE column is M, the value is 0. If MIXED=NO in the DSNHDECP module, the value is -2.
ROUTINE_ID	INTEGER NOT NULL WITH DEFAULT	The values in this column are for IBM use only.
CTEREF	SMALLINT NOT NULL WITH DEFAULT	If the referenced table is a common table expression, the value is the top-level query block number.
STMTTOKEN	VARCHAR(240)	User-specified statement token.

*Table 153. Descriptions of columns in PLAN\_TABLE (continued)*

Column name	Data Type	Description
PARENT_PLANNO	SMALLINT NOT NULL	Corresponds to the plan number in the parent query block where a correlated subquery is invoked. Or, for non-correlated subqueries, corresponds to the plan number in the parent query block that represents the work file for the subquery.

## DSN\_DETcost\_TABLE

The detailed cost table, DSN\_DETcost\_TABLE, contains information about detailed cost estimation of the mini-plans in a query.

### PSPI

When a query block is accelerated, a single row is added to DSN\_DETcost\_TABLE. In rows for acceleration query blocks only the COMPCARD and COMPCOST columns contain meaningful information.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_DETCOST\_TABLE.

*Table 154. DSN\_DETCOST\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b></p> <p>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b></p> <p>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
PLANNO	SMALLINT NOT NULL	The plan number, a number used to identify each mini-plan with a query block.
OPENIO	FLOAT(4) NOT NULL	The Do-at-open IO cost for non-correlated subquery.

Table 154. DSN\_DETcost\_TABLE description (continued)

Column name	Data type	Description
OPENCPU	FLOAT(4) NOT NULL	The Do-at-open CPU cost for non-correlated subquery.
OPENCOST	FLOAT(4) NOT NULL	The Do-at-open total cost for non-correlated subquery.
DMIO	FLOAT(4) NOT NULL	IBM internal use only.
DMCPU	FLOAT(4) NOT NULL	IBM internal use only.
DMTOT	FLOAT(4) NOT NULL	IBM internal use only.
SUBQIO	FLOAT(4) NOT NULL	IBM internal use only.
SUBQCOST	FLOAT(4) NOT NULL	IBM internal use only.
BASEIO	FLOAT(4) NOT NULL	IBM internal use only.
BASECPU	FLOAT(4) NOT NULL	IBM internal use only.
BASETOT	FLOAT(4) NOT NULL	IBM internal use only.
ONECOMPROWS	FLOAT(4) NOT NULL	The number of rows qualified after applying local predicates.
IMLEAF	FLOAT(4) NOT NULL	The number of index leaf pages scanned by Data Manager.
IMIO	FLOAT(4) NOT NULL	IBM internal use only.
IMPREFH	CHAR(2) NOT NULL	IBM internal use only.
IMMPRED	INTEGER NOT NULL	IBM internal use only.
IMFF	FLOAT(4) NOT NULL	The filter factor of matching predicates only.
IMSRPRED	INTEGER NOT NULL	IBM internal use only.
IMFFADJ	FLOAT(4) NOT NULL	The filter factor of matching and screening predicates.
IMSCANCST	FLOAT(4) NOT NULL	IBM internal use only.
IMROWCST	FLOAT(4) NOT NULL	IBM internal use only.
IMPAGECST	FLOAT(4) NOT NULL	IBM internal use only.
IMRIDSORT	FLOAT(4) NOT NULL	IBM internal use only.
IMMERGCST	FLOAT(4) NOT NULL	IBM internal use only.
IMCPU	FLOAT(4) NOT NULL	IBM internal use only.
IMTOT	FLOAT(4) NOT NULL	IBM internal use only.
IMSEQNO	SMALLINT NOT NULL	IBM internal use only.
DMPEREFH	FLOAT(4) NOT NULL	IBM internal use only.
DMCLUDIO	FLOAT(4) NOT NULL	IBM internal use only.
DMPREDS	INTEGER NOT NULL	IBM internal use only.
DMSROWS	FLOAT(4) NOT NULL	IBM internal use only.
DMSCANCST	FLOAT(4) NOT NULL	IBM internal use only.
DMCOLS	FLOAT(4) NOT NULL	The number of data manager columns.
DMROWS	FLOAT(4) NOT NULL	The number of data manager rows returned (after all stage 1 predicates are applied).
RDSROWCST	FLOAT(4) NOT NULL	IBM internal use only.

Table 154. DSN\_DET COST\_TABLE description (continued)

Column name	Data type	Description
DMPAGECST	FLOAT(4) NOT NULL	IBM internal use only.
DMDATAIO	FLOAT(4) NOT NULL	IBM internal use only.
DMDATAIO	FLOAT(4) NOT NULL	IBM internal use only.
DMDATACPU	FLOAT(4) NOT NULL	IBM internal use only.
DMDATACPU	FLOAT(4) NOT NULL	IBM internal use only.
RDSROW	FLOAT(4) NOT NULL	The number of RDS rows returned (after all stage 1 and stage 2 predicates are applied).
SNCOLS	SMALLINT NOT NULL	The number of columns as sort input for new table.
SNROWS	FLOAT(4) NOT NULL	The number of rows as sort input for new table.
SNRECSZ	INTEGER NOT NULL	The record size for new table.
SNPAGES	FLOAT(4) NOT NULL	The page size for new table.
SNRUNS	FLOAT(4) NOT NULL	The number of runs generated for sort of new table.
SNMERGES	FLOAT(4) NOT NULL	The number of merges needed during sort.
SNIOCOST	FLOAT(4) NOT NULL	IBM internal use only.
SNCPUCOST	FLOAT(4) NOT NULL	IBM internal use only.
SNCOST	FLOAT(4) NOT NULL	IBM internal use only.
SNCSCANIO	FLOAT(4) NOT NULL	IBM internal use only.
SNSCANCPU	FLOAT(4) NOT NULL	IBM internal use only.
SNCCOLS	FLOAT(4) NOT NULL	The number of columns as sort input for Composite table.
SCROWS	FLOAT(4) NOT NULL	The number of rows as sort input for Composite Table.
SCRECSZ	FLOAT(4) NOT NULL	The record size for Composite table.
SCPAGES	FLOAT(4) NOT NULL	The page size for Composite table.
SCRUNS	FLOAT(4) NOT NULL	The number of runs generated during sort of composite.
SCMERGES	FLOAT(4) NOT NULL	The number of merges needed during sort of composite.
SCIOCOST	FLOAT(4) NOT NULL	IBM internal use only.
SCCPUCOST	FLOAT(4) NOT NULL	IBM internal use only.
SCCOST	FLOAT(4) NOT NULL	IBM internal use only.
SCSCANIO	FLOAT(4) NOT NULL	IBM internal use only.
SCSCANCPU	FLOAT(4) NOT NULL	IBM internal use only.
SCSCANCOST	FLOAT(4) NOT NULL	IBM internal use only.
COMPCARD	FLOAT(4) NOT NULL	The total composite cardinality.
COMPIOCOST	FLOAT(4) NOT NULL	IBM internal use only.
COMP CPU COST	FLOAT(4) NOT NULL	IBM internal use only.
COMP COST	FLOAT(4) NOT NULL	The total cost.

Table 154. DSN\_DETCOST\_TABLE description (continued)

Column name	Data type	Description
JOINCOLS	SMALLINT NOT NULL	IBM internal use only.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The EXPLAIN timestamp.
COSTBLK	INTEGER NOT NULL	IBM internal use only.
COSTSTOR	INTEGER NOT NULL	IBM internal use only.
MPBLK	INTEGER NOT NULL	IBM internal use only.
MPSTOR	INTEGER NOT NULL	IBM internal use only.
COMPOSITES	INTEGER NOT NULL	IBM internal use only.
CLIPPED	INTEGER NOT NULL	IBM internal use only.
TABREF	VARCHAR(64) NOT NULL	IBM internal use only.
MAX_COMPOSITES	INTEGER NOT NULL	IBM internal use only.
MAX_STOR	INTEGER NOT NULL	IBM internal use only.
MAX_CPU	INTEGER NOT NULL	IBM internal use only.
MAX_ELAP	INTEGER NOT NULL	IBM internal use only.
TBL_JOINED_THRESH	INTEGER NOT NULL	IBM internal use only.
STOR_USED	INTEGER NOT NULL	IBM internal use only.
CPU_USED	INTEGER NOT NULL	IBM internal use only.
ELAPSED	INTEGER NOT NULL	IBM internal use only.
MIN_CARD_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_CARD_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_COST_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_COST_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_CARD_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_COST_KEEP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_CARD_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_CARD_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_COST_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_COST_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_CARD_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MIN_VALUE_COST_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_VALUE_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_VALUE_CARD_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
MAX_VALUE_COST_CLIP	FLOAT(4) NOT NULL	IBM internal use only.
GROUP_MEMBER	VARCHAR(240)	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.
PSEQIOCOST	FLOAT(4) NOT NULL	IBM internal use only.

*Table 154. DSN\_DET COST\_TABLE description (continued)*

Column name	Data type	Description
PSEQIOCOST	FLOAT(4) NOT NULL	IBM internal use only.
PSEQCPUCOST	FLOAT(4) NOT NULL	IBM internal use only.
PSEQCOST	FLOAT(4) NOT NULL	IBM internal use only.
PADJIOCOST	FLOAT(4) NOT NULL	IBM internal use only.
PADJCPUCOST	FLOAT(4) NOT NULL	IBM internal use only.
PADJCOST	FLOAT(4) NOT NULL	IBM internal use only.

 PSPI

## DSN\_FILTER\_TABLE

The filter table, DSN\_FILTER\_TABLE, contains information about how predicates are used during query processing.

**PSPI**

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_FILTER\_TABLE.

*Table 155. DSN\_FILTER\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>            The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>            DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
PLANNO	SMALLINT	The plan number, a number used to identify each miniplan with a query block.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL WITH DEFAULT	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
COLLID	INTEGER NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
ORDERNO	INTEGER NOT NULL	The sequence number of evaluation. Indicates the order in which the predicate is applied within each stage
PREDNO	INTEGER NOT NULL	The predicate number, a number used to identify a predicate within a query.
STAGE	CHAR(9) NOT NULL	Indicates at which stage the Predicate is evaluated. The possible values are: <ul style="list-style-type: none"> <li>• 'Matching',</li> <li>• 'Screening',</li> <li>• 'Stage 1'</li> <li>• 'Stage 2'</li> </ul>
ORDERCLASS	INTEGER NOT NULL	IBM internal use only.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The explain timestamp.

*Table 155. DSN\_FILTER\_TABLE description (continued)*

Column name	Data type	Description
MIXOPSEQNO	SMALLINT NOT NULL	IBM internal use only.
REEVAL	CHAR(1) NOT NULL	IBM internal use only.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

◀ **PSPI**

## DSN\_FUNCTION\_TABLE

The function table, DSN\_FUNCTION\_TABLE, contains descriptions of functions that are used in specified SQL statements.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

### Column descriptions

The following table describes the columns of DSN\_FUNCTION\_TABLE.

Table 156. Descriptions of columns in DSN\_FUNCTION\_TABLE

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	INTEGER NOT NULL	A number that identifies each query block within a query.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row, or blank.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 that executed EXPLAIN, or blank. For more information about the GROUP_MEMBER column, see
EXPLAIN_TIME	TIMESTAMP NOT NULL	The time at which the statement is processed. This time is the same as the BIND_TIME column in PLAN_TABLE.
SCHEMA_NAME	VARCHAR(128) NOT NULL	The schema name of the function invoked in the explained statement.
FUNCTION_NAME	VARCHAR(128) NOT NULL	The name of the function invoked in the explained statement.
SPEC_FUNC_NAME	VARCHAR(128) NOT NULL	The specific name of the function invoked in the explained statement.
FUNCTION_TYPE	CHAR(2) NOT NULL	<p>The type of function invoked in the explained statement. Possible values are:</p> <ul style="list-style-type: none"> <li>  CU Column function</li> <li>  SU Scalar function</li> <li>  TU Table function</li> </ul>
VIEW_CREATOR	VARCHAR(128) NOT NULL	If the function specified in the FUNCTION_NAME column is referenced in a view definition, the creator of the view. Otherwise, blank.
VIEW_NAME	VARCHAR(128) NOT NULL	If the function specified in the FUNCTION_NAME column is referenced in a view definition, the name of the view. Otherwise, blank.
PATH	VARCHAR(2048) NOT NULL	The value of the SQL path that was used to resolve the schema name of the function.

*Table 156. Descriptions of columns in DSN\_FUNCTION\_TABLE (continued)*

Column name	Data type	Description
FUNCTION_TEXT	VARCHAR(1500) NOT NULL	The text of the function reference (the function name and parameters). If the function reference is over 100 bytes, this column contains the first 100 bytes. For functions specified in infix notation, FUNCTION_TEXT contains only the function name. For example, for a function named /, which overloads the SQL divide operator, if the function reference is A/B, FUNCTION_TEXT contains only /.

## DSN\_PGRANGE\_TABLE

The page range table, DSN\_PGRANGE\_TABLE, contains information about qualified partitions for all page range scans in a query.

**PSPI**

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_PGRANGE\_TABLE.

Table 157. DSN\_PGRANGE\_TABLE description

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:  <b>For rows produced by EXPLAIN statements</b> The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.  <b>For rows not produced by EXPLAIN statements</b> DB2 assigns a number that is based on the line number of the SQL statement in the source program.  When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
TABNO	SMALLINT NOT NULL	The table number, a number which uniquely identifies the corresponding table reference within a query.
RANGE	SMALLINT NOT NULL	The sequence number of the current page range.
FIRSTPART	SMALLINT NOT NULL	The starting partition in the current page range.
LASTPART	SMALLINT NOT NULL	The ending partition in the current page range.
NUMPARTS	SMALLINT NOT NULL	The number of partitions in the current page range.
EXPLAIN_TIME	SMALLINT NOT NULL	The EXPLAIN timestamp.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

## DSN\_PGROUP\_TABLE

The parallel group table, DSN\_PGROUP\_TABLE, contains information about the parallel groups in a query.

**PSPI**

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_PGROUP\_TABLE

*Table 158. DSN\_PGROUP\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>            The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>            DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
PLANNAM	VARCHAR(24) NOT NULL	The application plan name.
COLLID	VARCHAR(128) NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The explain timestamp.
VERSION	VARCHAR(122) NOT NULL	The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.
GROUPID	SMALLINT NOT NULL	The parallel group identifier within the current query block.
FIRSTPLAN	SMALLINT NOT NULL	The plan number of the first contributing mini-plan associated within this parallel group.
LASTPLAN	SMALLINT NOT NULL	The plan number of the last mini-plan associated within this parallel group.
CPUCOST	REAL NOT NULL	The estimated total CPU cost of this parallel group in milliseconds.
IOCOST	REAL NOT NULL	The estimated total I/O cost of this parallel group in milliseconds.
BESTTIME	REAL NOT NULL	The estimated elapsed time for each parallel task for this parallel group.

Table 158. DSN\_PGROUP\_TABLE description (continued)

Column name	Data type	Description
DEGREE	SMALLINT NOT NULL	The degree of parallelism for this parallel group determined at bind time. Max parallelism degree if the Table space is large is 255, otherwise 64.
MODE	CHAR(1) NOT NULL	The parallel mode: 'I' IO parallelism 'C' CPU parallelism 'X' multiple CPU Sysplex parallelism (highest level) 'N' No parallelism
REASON	SMALLINT NOT NULL	The reason code for downgrading parallelism mode.
LOCALCPU	SMALLINT NOT NULL	The number of CPUs currently online when preparing the query.
TOTALCPU	SMALLINT NOT NULL	The total number of CPUs in Sysplex. LOCALCPU and TOTALCPU are different only for the DB2 coordinator in a Sysplex.
FIRSTBASE	SMALLINT	The table number of the table that partitioning is performed on.
LARGETS	CHAR(1)	'Y' if the TableSpace is large in this group.
PARTKIND	CHAR(1)	The partitioning type: 'L' Logical partitioning 'P' Physical partitioning
GROUPTYPE	CHAR(3)	Determines what operations this parallel group contains: table Access, Join, or Sort 'A' 'AJ' 'AJS'
ORDER	CHAR(1)	The ordering requirement of this parallel group : 'N' No order. Results need no ordering. 'T' Natural Order. Ordering is required but results already ordered if accessed via index. 'K' Key Order. Ordering achieved by sort. Results ordered by sort key. This value applies only to parallel sort.
STYLE	CHAR(4)	The Input/Output format style of this parallel group. Blank for IO Parallelism. For other modes: 'RIRO' Records IN, Records OUT 'WIRO' Work file IN, Records OUT 'WIWO' Work file IN, Work file OUT

Table 158. DSN\_PGROUP\_TABLE description (continued)

Column name	Data type	Description
RANGEKIND	CHAR(1)	The range type:  'K' Key range  'P' Page range
NKEYCOLS	SMALLINT	The number of interesting key columns, that is, the number of columns that will participate in the key operation for this parallel group.
LOWBOUND	VARCHAR(40)	The low bound of parallel group.
HIGHBOUND	VARCHAR(40)	The high bound of parallel group.
LOWKEY	VARCHAR(40)	The low key of range if partitioned by key range.
HIGHKEY	VARCHAR(40)	The high key of range if partitioned by key range.
FIRSTPAGE	CHAR(4)	The first page in range if partitioned by page range.
LASTPAGE	CHAR(4)	The last page in range if partitioned by page range.
GROUP_MEMBER	CHAR(8) NOT NULL	IBM internal use only.
HOST_REASON	SMALLINT	IBM internal use only.
PARA_TYPE	CHAR(4)	IBM internal use only.
PART_INNER	CHAR(1)	IBM internal use only.
GRNU_KEYRNG	CHAR(1)	IBM internal use only.
OPEN_KEYRNG	CHAR(1)	IBM internal use only.

## DSN\_PREDICAT\_TABLE

The predicate table, DSN\_PREDICAT\_TABLE, contains information about all of the predicates in a query.

### PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of the DSN\_PREDICAT\_TABLE

*Table 159. DSN\_PREDICAT\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
PREDNO	INTEGER NOT NULL	The predicate number, a number used to identify a predicate within a query.
TYPE	CHAR(8) NOT NULL	<p>A string used to indicate the type or the operation of the predicate. The possible values are:</p> <ul style="list-style-type: none"> <li>• 'AND'</li> <li>• 'OR'</li> <li>• 'EQUAL'</li> <li>• 'RANGE'</li> <li>• 'BETWEEN'</li> <li>• 'IN'</li> <li>• 'LIKE'</li> <li>• 'NOT LIKE'</li> <li>• 'EXISTS'</li> <li>• 'NOTEXIST'</li> <li>• 'SUBQUERY'</li> <li>• 'HAVING'</li> <li>• 'OTHERS'</li> </ul>

Table 159. DSN\_PREDICAT\_TABLE description (continued)

Column name	Data type	Description
LEFT_HAND_SIDE	VARCHAR(128) NOT NULL	If the LHS of the predicate is a table column (LHS_TABNO > 0), then this column indicates the column name. Other possible values are: <ul style="list-style-type: none"><li>• 'VALUE'</li><li>• 'COLEXP'</li><li>• 'NONCOLEXP'</li><li>• 'CORSUB'</li><li>• 'NONCORSUB'</li><li>• 'SUBQUERY'</li><li>• 'EXPRESSION'</li><li>• Blanks</li></ul>
LEFT_HAND_PNO	INTEGER NOT NULL	If the LHS of the predicate is a table column (LHS_TABNO > 0), then this column indicates the column name. Other possible values are: <ul style="list-style-type: none"><li>• 'VALUE'</li><li>• 'COLEXP'</li><li>• 'NONCOLEXP'</li><li>• 'CORSUB'</li><li>• 'NONCORSUB'</li><li>• 'SUBQUERY'</li><li>• 'EXPRESSION'</li><li>• Blanks</li></ul>
LHS_TABNO	SMALLINT NOT NULL	If the LHS of the predicate is a table column, then this column indicates a number which uniquely identifies the corresponding table reference within a query.
LHS_QBNO	SMALLINT NOT NULL	If the LHS of the predicate is a table column, then this column indicates a number which uniquely identifies the corresponding table reference within a query.
RIGHT_HAND_SIDE	VARCHAR(128) NOT NULL	If the RHS of the predicate is a table column (RHS_TABNO > 0), then this column indicates the column name. Other possible values are: <ul style="list-style-type: none"><li>• 'VALUE'</li><li>• 'COLEXP'</li><li>• 'NONCOLEXP'</li><li>• 'CORSUB'</li><li>• 'NONCORSUB'</li><li>• 'SUBQUERY'</li><li>• 'EXPRESSION'</li><li>• Blanks</li></ul>
RIGHT_HAND_PNO	INTEGER NOT NULL	If the predicate is a compound predicate (AND/OR), then this column indicates the second child predicate. However, this column is not reliable when the predicate tree consolidation happens. Use PARENT_PNO instead to reconstruct the predicate tree.
RHS_TABNO	CHAR(1) NOT NULL	If the RHS of the predicate is a table column, then this column indicates a number which uniquely identifies the corresponding table reference within a query.

Table 159. DSN\_PREDICAT\_TABLE description (continued)

Column name	Data type	Description
RHS_QBNO	CHAR(1) NOT NULL	If the RHS of the predicate is a subquery, then this column indicates a number which uniquely identifies the corresponding query block within a query.
FILTER_FACTOR	FLOAT NOT NULL	The estimated filter factor.
BOOLEAN_TERM	CHAR(1) NOT NULL	Whether this predicate can be used to determine the truth value of the whole WHERE clause.
SEARCHARG	CHAR(1) NOT NULL	Whether this predicate can be processed by data manager (DM). If it is not, then the relational data service (RDS) needs to be used to take care of it, which is more costly.
AFTER_JOIN	CHAR(1) NOT NULL	Indicates the predicate evaluation phase:  'A' After join  'D' During join  blank Not applicable
ADDED_PRED	CHAR(1) NOT NULL	Whether it is generated by transitive closure, which means DB2 can generate additional predicates to provide more information for access path selection, when the set of predicates that belong to a query logically imply other predicates.
REDUNDANT_PRED	CHAR(1) NOT NULL	Whether it is a redundant predicate, which means evaluation of other predicates in the query already determines the result that the predicate provides.
DIRECT_ACCESS	CHAR(1) NOT NULL	Whether the predicate is direct access, which means one can navigate directly to the row through ROWID.
KEYFIELD	CHAR(1) NOT NULL	Whether the predicate includes the index key column of the involved table for all applicable indexes considered by DB2.
EXPLAIN_TIME	TIMESTAMP	The EXPLAIN timestamp.
CATEGORY	SMALLINT	IBM internal use only.
CATEGORY_B	SMALLINT	IBM internal use only.
TEXT	VARCHAR(2000)	The transformed predicate text; truncated if exceeds 2000 characters.
PRED_ENCODE	CHAR(1)	IBM internal use only.
PRED_CCSID	SMALLINT	IBM internal use only.
PRED_MCCSID	SMALLINT	IBM internal use only.
MARKER	CHAR(1)	Whether this predicate includes host variables, parameter markers, or special registers.
PARENT_PNO	INTEGER	The parent predicate number. If this predicate is a root predicate within a query block, then this column is 0.
NEGATION	CHAR(1)	Whether this predicate is negated via NOT.
LITERALS	VARCHAR(128)	This column indicates the literal value or literal values separated by colon symbols.
CLAUSE	CHAR(8)	The clause where the predicate exists:  'HAVING' The HAVING clause  'ON' The ON clause  'WHERE' The WHERE clause

*Table 159. DSN\_PREDICAT\_TABLE description (continued)*

Column name	Data type	Description
GROUP_MEMBER	CHAR(8)	The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

PSPI

## DSN\_PTASK\_TABLE

The parallel tasks table, DSN\_PTASK\_TABLE, contains information about all of the parallel tasks in a query.

### PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_PTASK\_TABLE.

*Table 160. DSN\_PTASK\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
LPTNO	SMALLINT NOT NULL	The parallel task number.
KEYCOLID	SMALLINT	The key column ID (KEY range only).
DPSI	CHAR(1) NOT NULL	Indicates if a data partition secondary index (DPSI) is used.
LPTLOKEY	VARCHAR(40)	The low key value for this key column for this parallel task (KEY range only).
LPTHIKEY	VARCHAR(40)	The high key value for this key column for this parallel task (KEY range only).
LPTLOPAG	CHAR(4)	The low page information if partitioned by page range.
LPTLHIPAG	CHAR(4)	The high page information if partitioned by page range.
LPTLOPG <sup>1</sup>	CHAR(4)	The lower bound page number for this parallel task (Page range or DPSI enabled only).
LPTHIPG <sup>1</sup>	CHAR(4)	The upper bound page number for this parallel task (Page range or DPSI enabled only).
LPTLOPT <sup>1</sup>	SMALLINT	The lower bound partition number for this parallel task (Page range or DPSI enabled only).
LPTHIPT <sup>1</sup>	SMALLINT	The upper bound partition number for this parallel task (Page range or DPSI enabled only).
KEYCOLDT	SMALLINT	The data type for this key column (KEY range only).
KEYCOLPREC	SMALLINT	The precision/length for this key column (KEY range only).

*Table 160. DSN\_PTASK\_TABLE description (continued)*

Column name	Data type	Description
KEYCOLSCAL	SMALLINT	The scale for this key column (KEY range with Decimal datatype only).
EXPLAIN_TIME	TIMESTAMP NOT NULL	The EXPLAIN timestamp.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

**Notes:**

1. The name of these columns originally contained the # symbol as the last character in the names. However, the names that contain these characters are obsolete and are no longer supported.

 PSPI

## DSN\_QUERYINFO\_TABLE

The query information table, DSN\_QUERYINFO\_TABLE, contains information about the eligibility of query blocks for automatic query rewrite, information about the materialized query tables that are considered for eligible query blocks, and reasons why ineligible query blocks are not eligible.

PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

*Table 161. Descriptions of columns in DSN\_QUERYINFO\_TABLE*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:  <b>For rows produced by EXPLAIN statements</b> The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.  <b>For rows not produced by EXPLAIN statements</b> DB2 assigns a number that is based on the line number of the SQL statement in the source program.  When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.
QBLOCKNO	INTEGER NOT NULL	A number that identifies each query block within a query.
QINAME1	VARCHAR(128) NOT NULL WITH DEFAULT	When TYPE='A' this is the creator of the accelerated query table.
QINAME2	VARCHAR(128) NOT NULL WITH DEFAULT	When TYPE='A' this is the name of the accelerated query table.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row, or blank.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
VERSION	VARCHAR(122) NOT NULL WITH DEFAULT	The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 that executed EXPLAIN, or blank. For more information about the GROUP_MEMBER column, see
SECTNOI	INTEGER NOT NULL WITH DEFAULT	The section number of the statement.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The time at which the statement is processed. This time is the same as the BIND_TIME column in PLAN_TABLE.
TYPE	CHAR(8) NOT NULL WITH DEFAULT	The type of the output for this row:  <b>A</b> This row is for an accelerated query table.
QI_DATA	CLOB(2M) NOT NULL WITH DEFAULT	When TYPE='A': This column contains the description of the value in REASON_CODE.

| *Table 161. Descriptions of columns in DSN\_QUERYINFO\_TABLE (continued)*

Column name	Data type	Description
SERVICE_INFO	BLOB(2M) NOT NULL WITH DEFAULT	IBM internal use only.

| **Notes:**

- | 1. The REASON\_CODE column has the following values:

- | 0      The query block qualifies for routing to an accelerator with the DB2 internal object specified in QINAME1 and QINAME2. For example, the IBM Smart Analytics Optimizer, the associated data-mart name is recorded in the QINAME2 column and the following naming convention is used: DATAMARTNAME@ACCELERATORNAME@DIGITS
- | 1      No accelerator was found when EXPLAIN was executed. If an accelerator is available, make sure it is started.
- | 2      Rewrite not done because CURRENT REFRESH AGE <> ANY
- | 3      The query was not routed to an accelerator because the estimated cost of the query is too low.
- | 4      The query could not be routed to an accelerator because the query is not read-only. You can explicitly mark a query as read-only by using the FOR FETCH ONLY, FOR READ ONLY or WITH UR clause.
- | 5      The query could not be routed to an accelerator because the query isolation level is not supported. Use isolation level cursor stability (CS) or uncommitted read (UR) to enable query acceleration.
- | 201     There is at least one table referenced in the query block that does not appear in any of the defined data marts.
- | 204     The query block could not be routed to an accelerator because the query block contains a table expression with correlated references.
- | 205     The query block could not be routed to an accelerator because the query block contains an unsupported expression. The QI\_DATA column contains the unsupported expression.
- | 206     The query block could not be routed to an accelerator because the query block is a correlated subquery. Consider using a join instead of a correlated subquery.
- | 207     The query block could not be routed to an accelerator because the query block is a type of work file that cannot be routed to an accelerator. A work file is the intermediate result of a UNION ALL, INTERSECT ALL, EXCEPT ALL, or an outer join that is materialized.
- | 208     The query block could not be routed to an accelerator because an accelerator could not be found. For example, the IBM Smart Analytics Optimizer, the accelerator name shown in the QI\_DATA column (naming convention: DATAMARTNAME@ACCELERATORNAME@DIGITS) was not found. If the accelerator is available, make sure that it is started.
- | 501     The query block could not be routed to an accelerator because one or more tables in the FROM clause are not referenced by the DB2 internal object.

- | 502 The query block could not be routed to an accelerator because one or more columns in the GROUP BY clause are not referenced by the DB2 internal object.
- | 503 The query block could not be routed to an accelerator because one or more columns in the SELECT clause are not referenced by the DB2 internal object. The QI\_DATA column contains the non-matching SELECT clause.
- | 504 The query block could not be routed to an accelerator because one or more columns in the HAVING clause are not referenced by the DB2 internal object. When available, the QI\_DATA column contains the non-matching HAVING clause.
- | 505 The query block could not be routed to an accelerator because one or more columns in the WHERE clause are not referenced by the DB2 internal object.. When available, the QI\_DATA column contains the non-matching WHERE clause.
- | 506 The query block could not be routed to an accelerator because the ON clause does not match with the defined references in the DB2 internal object. When available the QI\_DATA column contains the non-matching ON clause.
- | 508 Lossless checking failed for left outer join AQT. When available, the QI\_DATA column contains the table name.

## DSN\_QUERY\_TABLE

The query table, DSN\_QUERY\_TABLE, contains information about a SQL statement, and displays the statement before and after query transformation.

PSPI

Unlike other EXPLAIN tables, rows in DSN\_QUERY\_TABLE are not populated for static SQL statements at BIND or REBIND with the EXPLAIN(YES) option.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_QUERY\_TABLE.

*Table 162. DSN\_QUERY\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
TYPE	CHAR(8) NOT NULL	The type of the data in the NODE_DATA column.
QUERY STAGE	CHAR(8) NOT NULL WITH DEFAULT	The stage during query transformation when this row is populated.
SEQNO	NOT NULL	The sequence number for this row if NODE_DATA exceeds the size of its column.
NODE_DATA	CLOB(2M)	The XML data containing the SQL statement and its query block, table, and column information.
EXPLAIN_TIME	TIMESTAMP	The EXPLAIN timestamp.
QUERY_ROWID	ROWID NOT NULL GENERATED ALWAYS	The ROWID of the statement.
GROUP MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.
HASHKEY	INTEGER NOT NULL	The hash value of the contents in NODE_DATA
HAS_PRED	CHAR(1) NOT NULL	When NODE_DATA contains an SQL statement, this column indicates if the statement contains a parameter marker literal, non-parameter marker literal, or no predicates.

## DSN\_SORTKEY\_TABLE

The sort key table, DSN\_SORTKEY\_TABLE, contains information about sort keys for all of the sorts required by a query.

PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_SORTKEY\_TABLE.

*Table 163. DSN\_SORTKEY\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>            The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>            DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
PLANNO	SMALLINT NOT NULL	The plan number, a number used to identify each miniplan with a query block.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL WITH DEFAULT	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
SORTNO	SMALLINT NOT NULL	The sequence number of the sort
ORDERNO	SMALLINT NOT NULL	The sequence number of the sort key
EXPTYPE	CHAR(3) NOT NULL	The type of the sort key. The possible values are: <ul style="list-style-type: none"> <li>• 'COL'</li> <li>• 'EXP'</li> <li>• 'QRY'</li> </ul>
TEXT	VARCHAR(128) NOT NULL	The sort key text, can be a column name, an expression, or a scalar subquery, or 'Record ID'.
TABNO	SMALLINT NOT NULL	The table number, a number which uniquely identifies the corresponding table reference within a query.

*Table 163. DSN\_SORTKEY\_TABLE description (continued)*

Column name	Data type	Description
COLNO	SMALLINT NOT NULL	The column number, a number which uniquely identifies the corresponding column within a query. Only applicable when the sort key is a column.
DATATYPE	CHAR(18)	<p>The data type of sort key. The possible values are</p> <ul style="list-style-type: none"> <li>• 'HEXADECIMAL'</li> <li>• 'CHARACTER'</li> <li>• 'PACKED FIELD '</li> <li>• 'FIXED(31)'</li> <li>• 'FIXED(15)'</li> <li>• 'DATE'</li> <li>• 'TIME'</li> <li>• 'VARCHAR'</li> <li>• 'PACKED FLD'</li> <li>• 'FLOAT'</li> <li>• 'TIMESTAMP'</li> <li>• 'UNKNOWN DATA TYPE'</li> </ul>
LENGTH	INTEGER NOT NULL	The length of sort key.
CCSID	INTEGER NOT NULL	IBM internal use only.
ORDERCLASS	INTEGER NOT NULL	IBM internal use only.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The EXPLAIN timestamp.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

PSPI

## DSN\_SORT\_TABLE

The sort table, DSN\_SORT\_TABLE, contains information about the sort operations required by a query.

### PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_SORT\_TABLE.

*Table 164. DSN\_SORT\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
PLANNO	SMALLINT NOT NULL	The plan number, a number used to identify each miniplan with a query block.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL WITH DEFAULT	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
SORTC	CHAR(5) NOT NULL WITH DEFAULT	<p>Indicates the reasons for sort of the composite table. The reasons are shown as a series of bytes:</p> <ul style="list-style-type: none"> <li>• Byte 1 is 'G' if the reason is GROUP BY, or otherwise blank.</li> <li>• The second byte is 'J' if the reason is JOIN, or otherwise blank.</li> <li>• Byte is 'O' if the reason is ORDER BY, or otherwise blank.</li> <li>• The fourth byte is 'U' if the reason is uniqueness, or otherwise blank.</li> </ul>

Table 164. DSN\_SORT\_TABLE description (continued)

Column name	Data type	Description
SORTN	CHAR(5) NOT NULL WITH DEFAULT	Indicates the reasons for sort of the new table. The reasons are shown as a series of bytes: <ul style="list-style-type: none"><li>• The first byte is 'G' if the reason is GROUP BY, or otherwise blank.</li><li>• The second byte is 'J' if the reason is JOIN, or otherwise blank.</li><li>• The third byte is 'O' if the reason is ORDER BY, or otherwise blank.</li><li>• The fourth by is 'U' if the reason is uniqueness, or otherwise blank.</li></ul>
SORTNO	SMALLINT NOT NULL	The sequence number of the sort.
KEYSIZE	SMALLINT NOT NULL	The sum of the lengths of the sort keys.
ORDERCLASS	INTEGER NOT NULL	IBM internal use only.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The EXPLAIN timestamp.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

## **DSN\_STATEMENT\_CACHE\_TABLE**

The statement cache table, DSN\_STATEMENT\_CACHE\_TABLE, contains information about the SQL statements in the statement cache, information captured as the results of an EXPLAIN STATEMENT CACHE ALL statement.

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### **Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

#### **SYSIBM**

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### **DB2OSCA**

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### **Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

### **Column descriptions**

The following table shows the descriptions of the columns in DSN\_STATEMENT\_CACHE\_TABLE.

Table 165. Descriptions of columns in DSN\_STATEMENT\_CACHE\_TABLE

Column name	Data Type	Description
STMT_ID	INTEGER NOT NULL	The statement ID; this value is the EDM unique token for the statement.
STMT_TOKEN	VARCHAR(240) NOT NULL	The statement token; you provide this value as an identification string.
COLLID	VARCHAR(128) NOT NULL	The collection ID; because DSN_STATEMENT_CACHE_TABLE is used to explain cached statements, the value of this column is DSNDYNAMICSQLCACHE.
PROGRAM_NAME	VARCHAR(128) NOT NULL	The name of the package or DBRM that performed the initial PREPARE for the statement.
INV_DROPALT	CHAR(1) NOT NULL	This column indicates if the statement has been invalidated by a DROP or ALTER statement.
INV_REVOKE	CHAR(1) NOT NULL	This column indicates if the statement has been invalidated by a REVOKE statement.
INV_LRU	CHAR(1) NOT NULL	This column indicates if the statement has been removed from the cache by LRU.
INV_RUNSTATS	CHAR(1) NOT NULL	This column indicates if the statement has been invalidated by RUNSTATS.
CACHED_TS	TIMESTAMP NOT NULL	The timestamp when the statement was stored in the dynamic statement cache.
USERS	INTEGER NOT NULL	The number of current users of the statement. This number indicates the users that have prepared or run the statement during their current unit of work. 1 on page 1984,
COPIES	INTEGER NOT NULL	The number of copies of the statement that are owned by all threads in the system. 1 on page 1984,
LINES	INTEGER NOT NULL	The precompiler line number from the initial PREPARE of the statement. 1 on page 1984
PRIMAUTH	VARCHAR(128) NOT NULL	The primary authorization ID that did the initial PREPARE of the statement.
CURSQLID	VARCHAR(128) NOT NULL	The CURRENT SQLID that did the initial PREPARE of the statement.
BIND_QUALIFIER	VARCHAR(128) NOT NULL	The BIND qualifier. For unqualified table names, this is the object qualifier.
BIND_ISO	CHAR(2) NOT NULL	The value of the ISOLATION BIND option that is in effect for this statement. The value will be one of the following values: 'UR' Uncommitted read 'CS' Cursor stability 'RS' Read stability 'RR' Repeatable read
BIND_CDATA	CHAR(1) NOT NULL	The value of the CURRENTDATA BIND option that is in effect for this statement. The value will be one of the following values: 'Y' CURRENTDATA(YES) 'N' CURRENTDATA(NO)
BIND_DYNRL	CHAR(1) NOT NULL	The value of the DYNAMICRULES BIND option that is in effect for this statement. The value will be one of the following values: 'B' DYNAMICRULE(BIND) 'R' DYNAMICRULES(RUN)

Table 165. Descriptions of columns in DSN\_STATEMENT\_CACHE\_TABLE (continued)

Column name	Data Type	Description
BIND_DEGRE	CHAR(1) NOT NULL	The value of the CURRENT DEGREE special register that is in effect for this statement. The value will be one of the following values: 'A' CURRENT DEGREE = ANY 'T' CURRENT DEGREE = 1
BIND_SQLRL	CHAR(1) NOT NULL	The value of the CURRENT RULES special register that is in effect for this statement. The value will be one of the following values: 'D' CURRENT RULES = DB2 'S' CURRENT RULES = SQL
BIND_CHOLD	CHAR(1) NOT NULL	The value of the WITH HOLD attribute of the PREPARE for this statement. The value will be one of the following values: 'Y' Initial PREPARE specified WITH HOLD 'N' Initial PREPARE specified WITHOUT HOLD
STAT_TS	TIMESTAMP NOT NULL	Timestamp of the statistics. This is the timestamp when IFCID 318 is started.
STAT_EXEC	INTEGER NOT NULL	The number of times this statement has been run. For a statement with a cursor, this is the number of OPENS. 1 on page 1984,
STAT_GPAG	INTEGER NOT NULL	The number of getpage operations that are performed for the statement. 1 on page 1984
STAT_SYNCR	INTEGER NOT NULL	The number of synchronous buffer reads that are performed for the statement. 1 on page 1984
STAT_WRIT	INTEGER NOT NULL	The number of buffer write operations that are performed for the statement. 1 on page 1984
STAT_EROW	INTEGER NOT NULL	The number of rows that are examined for the statement. 1 on page 1984
STAT_PROW	INTEGER NOT NULL	The number of rows that are processed for the statement. 1 on page 1984
STAT_SORT	INTEGER NOT NULL	The number of sorts that are performed for the statement. 1 on page 1984
STAT_INDX	INTEGER NOT NULL	The number of index scans that are performed for the statement. 1 on page 1984,
STAT_RSCN	INTEGER NOT NULL	The number of table space scans that are performed for the statement. 1 on page 1984,
STAT_PGRP	INTEGER NOT NULL	The number of parallel groups that are created for the statement. 1 on page 1984,
STAT_ELAP	FLOAT NOT NULL	The accumulated elapsed time that is used for the statement.
STAT_CPU	FLOAT NOT NULL	The accumulated CPU time that is used for the statement.
STAT_SUS_SYNIO	FLOAT NOT NULL	The accumulated wait time for synchronous I/O operations for the statement.
STAT_SUS_LOCK	FLOAT NOT NULL	The accumulated wait time for lock and latch requests for the statement.
STAT_SUS_SWIT	FLOAT NOT NULL	The accumulated wait time for synchronous execution unit switch for the statement.
STAT_SUS_GLCK	FLOAT NOT NULL	The accumulated wait time for global locks for this statement.
STAT_SUS_OTHR	FLOAT NOT NULL	The accumulated wait time for read activity that is done by another thread.

Table 165. Descriptions of columns in DSN\_STATEMENT\_CACHE\_TABLE (continued)

Column name	Data Type	Description
STAT_SUS_OTHW	FLOAT NOT NULL	The accumulated wait time for write activity done by another thread.
STAT RIDLIMT	INTEGER NOT NULL	The number of times a RID list was not used because the number of RIDs would have exceeded DB2 limits. 1,
STAT RIDSTOR	INTEGER NOT NULL	The number of times a RID list was not used because there is not enough storage available to hold the list of RIDs. 1,
EXPLAIN_TS	TIMESTAMP NOT NULL	The timestamp for when the statement cache table is populated.
SCHEMA	VARCHAR(128) NOT NULL	The value of the CURRENT SCHEMA special register.
STMT_TEXT	CLOB(2M) NOT NULL	The statement that is being explained.
STMT_ROWID	ROWID NOT NULL	The ROWID of the statement.
BIND_RO_TYPE	CHAR(1) NOT NULL	The current specification of the REOPT option for the statement: 'N' REOPT(NONE) or its equivalent 'T' REOPT(ONCE) or its equivalent 'A' REOPT(AUTO) or its equivalent 'O' The current plan is deemed optimal and there is no need for REOPT(AUTO)
BIND_RA_TOT	INTEGER NOT NULL	The total number of REBIND commands that have been issued for the dynamic statement because of the REOPT(AUTO) option.1,

**Notes:**

1. If the specified value exceeds 2147483647, the column contains the value 2147483647.

## DSN\_STATEMNT\_TABLE

The statement table, DSN\_STATEMNT\_TABLE, contains information about the estimated cost of specified SQL statements.

PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

#### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the content of each column in STATEMNT\_TABLE.

*Table 166. Descriptions of columns in DSN\_STATEMNT\_TABLE*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128) NOT NULL	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 that executed EXPLAIN, or blank. See the description of the GROUP_MEMBER column in PLAN_TABLE for more information.
EXPLAIN_TIME	TIMESTAMP NOT NULL	The time at which the statement is processed. This time is the same as the BIND_TIME column in PLAN_TABLE.

Table 166. Descriptions of columns in DSN\_STATEMNT\_TABLE (continued)

Column name	Data type	Description
STMT_TYPE	CHAR(6) NOT NULL	The type of statement being explained. Possible values are:  <b>SELECT</b> SELECT <b>INSERT</b> INSERT <b>UPDATE</b> UPDATE <b>MERGE</b> MERGE <b>DELETE</b> DELETE <b>TRUNCA</b> TRUNCATE <b>SELUPD</b> SELECT with FOR UPDATE OF <b>DELCUR</b> DELETE WHERE CURRENT OF CURSOR <b>UPDCUR</b> UPDATE WHERE CURRENT OF CURSOR
COST_CATEGORY	CHAR(1) NOT NULL	Indicates if DB2 was forced to use default values when making its estimates. Possible values:  <b>A</b> Indicates that DB2 had enough information to make a cost estimate without using default values. <b>B</b> Indicates that some condition exists for which DB2 was forced to use default values. See the values in REASON to determine why DB2 was unable to put this estimate in cost category A.
PROCMS	INTEGER NOT NULL	The estimated processor cost, in milliseconds, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 milliseconds, which is equivalent to approximately 24.8 days. If the estimated value exceeds this maximum, the maximum value is reported. If an accelerator product is used the difference is reflected in this value.
PROCSU	INTEGER NOT NULL	The estimated processor cost, in service units, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 service units. If the estimated value exceeds this maximum, the maximum value is reported. If an accelerator product is used, this value represents the estimated cost including any impact of acceleration.

Table 166. Descriptions of columns in DSN\_STATEMNT\_TABLE (continued)

Column name	Data type	Description						
REASON	VARCHAR(254)	<p>A string that indicates the reasons for putting an estimate into cost category B.</p> <p><b>HAVING CLAUSE</b> A subselect in the SQL statement contains a HAVING clause.</p> <p><b>HOST VARIABLES</b> The statement uses host variables, parameter markers, or special registers.</p> <p><b>MATERIALIZATION</b> Statistics are missing because the statement uses materialized views or nested table expresses.</p> <p><b>PROFILEID value</b> When profile monitoring is used for the statement, the value of the PROFILEID column in SYSIBM.DSN_PROFILE_TABLE.</p> <p><b>REFERENTIAL CONSTRAINTS</b> Referential constraints of the type CASCADE or SET NULL exist on the target table of a DELETE statement.</p> <p><b>TABLE CARDINALITY</b> The cardinality statistics are missing for one or more of the tables that are used in the statement.</p> <p><b>TRIGGERS</b> Triggers are defined on the target table of an insert, update, or delete operation.</p> <p><b>UDF</b> The statement uses user-defined functions.</p>						
STMT_ENCODE	CHAR(1)	<p>Encoding scheme of the statement. If the statement represents a single CCSID set, the possible values are:</p> <table> <tr> <td>A</td> <td>ASCII</td> </tr> <tr> <td>E</td> <td>EBCDIC</td> </tr> <tr> <td>U</td> <td>Unicode</td> </tr> </table> <p>If the statement has multiple CCSID sets, the value is M.</p>	A	ASCII	E	EBCDIC	U	Unicode
A	ASCII							
E	EBCDIC							
U	Unicode							
TOTAL_COST	FLOAT NOT NULL	The overall estimated cost of the statement. If an accelerator product is used the benefit is reflected in this value. This cost should be used only for reference purposes.						

◀ PSPI

## **DSN\_STRUCT\_TABLE**

The structure table, DSN\_STRUCT\_TABLE, contains information about all of the query blocks in a query.

**PSPI**

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

### **Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

#### **SYSIBM**

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

#### **DB2OSCA**

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

### **Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_STRUCT\_TABLE

Table 167. DSN\_STRUCT\_TABLE description

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b> The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b> DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
QBLOCKNO	SMALLINT NOT NULL	The query block number, a number used to identify each query block within a query.
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
PARENT	SMALLINT NOT NULL	The parent query block number of the current query block in the structure of SQL text; this is the same as the PARENT_QBLOCKNO in PLAN_TABLE.
TIMES	FLOAT NOT NULL	The estimated number of rows returned by Data Manager; also the estimated number of times this query block is executed.
ROWCOUNT	INTEGER NOT NULL	The estimated number of rows returned by RDS (Query Cardinality).
ATOPEN	CHAR(1) NOT NULL	Whether the query block is moved up for do-at-open processing; 'Y' if done-at-open; 'N': otherwise.
CONTEXT	CHAR(10) NOT NULL	<p>This column indicates what the context of the current query block is. The possible values are:</p> <ul style="list-style-type: none"> <li>• 'TOP LEVEL'</li> <li>• 'UNION'</li> <li>• 'UNION ALL'</li> <li>• 'PREDICATE'</li> <li>• 'TABLE EXP'</li> <li>• 'UNKNOWN'</li> </ul>
ORDERNO	SMALLINT NOT NULL	Not currently used.
DOATOPEN_PARENT	SMALLINT NOT NULL	The parent query block number of the current query block; Do-at-open parent if the query block is done-at-open, this may be different from the PARENT_QBLOCKNO in PLAN_TABLE.

Table 167. DSN\_STRUCT\_TABLE description (continued)

Column name	Data type	Description
QBLOCK_TYPE	CHAR(6) NOT NULL WITH DEFAULT	<p>This column indicates the type of the current query block. The possible values are</p> <ul style="list-style-type: none"> <li>• 'SELECT'</li> <li>• 'INSERT'</li> <li>• 'UPDATE'</li> <li>• 'DELETE'</li> <li>• 'SELUPD'</li> <li>• 'DELCUR'</li> <li>• "UPDCUR"</li> <li>• 'CORSUB'</li> <li>• 'NCOSUB'</li> <li>• 'TABLEX'</li> <li>• 'TRIGGR'</li> <li>• 'UNION'</li> <li>• 'UNIONA'</li> <li>• 'CTE'</li> </ul> <p>It is equivalent to QBLOCK_TYPE column in PLAN_TABLE, except for CTE.</p>
EXPLAIN_TIME	TIMESTAMP NOT NULL	The EXPLAIN timestamp.
QUERY_STAGE	CHAR(8) NOT NULL	IBM internal use only.
GROUP_MEMBER	CHAR(8) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

## DSN\_VIEWREF\_TABLE

The view reference table, DSN\_VIEWREF\_TABLE, contains information about all of the views and materialized query tables that are used to process a query.

### PSPI

**Recommendation:** Do not manually insert data into or delete data from EXPLAIN tables. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools.

**Important:** If mixed data strings are allowed on a DB2 subsystem, EXPLAIN tables must be created with CCSID UNICODE. This includes, but is not limited to, mixed data strings that are used for tokens, SQL statements, application names, program names, correlation names, and collection IDs.

**Important:** EXPLAIN tables in any pre-Version 8 format or EXPLAIN tables that are encoded in EBCDIC are deprecated.

## Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

### SYSIBM

One instance of each EXPLAIN table can be created with the SYSIBM qualifier. SQL optimization tools use these tables. You can find the SQL statement for creating these tables in member DSNTESC of the SDSNSAMP library.

*userID* You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

### DB2OSCA

SQL optimization tools, such as Optimization Service Center for DB2 for z/OS, create EXPLAIN tables to collect information about SQL statements and workloads to enable analysis and tuning processes. You can find the SQL statements for creating EXPLAIN tables in member DSNTIJOS of the SDSNSAMP library. You can also create this table from the Optimization Service Center interface on your workstation.

## Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the SDSNSAMP library.

## Column descriptions

The following table describes the columns of DSN\_VIEWREF\_TABLE.

*Table 168. DSN\_VIEWREF\_TABLE description*

Column name	Data type	Description
QUERYNO	INTEGER NOT NULL	<p>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</p> <p><b>For rows produced by EXPLAIN statements</b>  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</p> <p><b>For rows not produced by EXPLAIN statements</b>  DB2 assigns a number that is based on the line number of the SQL statement in the source program.</p> <p>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in a very long program, the value is not guaranteed to be unique. If QUERYNO is not unique, the value of EXPLAIN_TIME is unique.</p>
APPLNAME	VARCHAR(24) NOT NULL	The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.
PROGNAME	VARCHAR(128) NOT NULL	The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.
VERSION	VARCHAR(128)	The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.
COLLID	VARCHAR(128)	The collection ID for the package. Applies only to an embedded EXPLAIN statement that is executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. The value DSNDYNAMICSQLCACHE indicates that the row is for a cached statement.
CREATOR	VARCHAR(128)	Authorization ID of the owner of the object.
NAME	VARCHAR(128)	Name of the object.
TYPE	CHAR(1) NOT NULL WITH DEFAULT	<p>The type of the object:</p> <p>'V' View</p> <p>'R' MQT that has been used to replace the base table for rewrite</p> <p>'M' MQT</p>
MQTUSE	SMALLINT	IBM internal use only.
EXPLAIN TIME	TIMESTAMP	The EXPLAIN timestamp.
GROUP_MEMBER	VARCHAR(24) NOT NULL	The member name of the DB2 subsystem that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.

 PSPI

---

## | **Tables that are used by accelerators**

|

## Table spaces and indexes for accelerators

Tables that are used for accelerators are contained in certain table spaces and have indexes.

The following table lists the table space and indexes for each table that is used for accelerators and lists the index fields for each index. The indexes are in ascending order, except where noted.

*Table 169. Table spaces and indexes for the tables that are used for accelerators*

TABLE SPACE	TABLE	INDEX	INDEX FIELDS
DSNDB06. ...	SYSACCEL. ...	SYSACCEL. ...	
	SYSACCELERATORS	DSNACC01	ACCELERATORNAME
	SYSACCELIPLIST	DSNACI01	ACCELIPNAME.ACCELIPADDR

## SYSACCEL.SYSACCELERATORS table

The SYSACCEL.SYSACCELERATORS table contains one row that describes the characteristics of each accelerator server.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
ACCELERATORNAME	VARCHAR(128) NOT NULL	A unique name for the accelerator server. This is the name by which the accelerator server is known to the local DB2 accelerated query tables.	
ACCELERATOR-IPNAME	VARCHAR(24) NOT NULL	Identifies the TCP/IP attributes that are associated with this accelerator server. The value of this column corresponds to a row in the SYSACCEL.SYSACCELIPLIST table (identified by the value of the ACCELIPNAME column). The corresponding row in the SYSACCEL.SYSACCELIPLIST specifies the TCP/IP communication attributes for this accelerator server. <b>Note:</b> While this column is defined as VARCHAR(24) it must not contain more than 8 EBCDIC characters.	
ACCELERATORPORT	VARCHAR(96) NOT NULL	Identifies the TCP/IP port number or service name of the remote database server:  <b>Format Meaning</b> <b>Left justified with 1-5 numeric characters</b> Assumed to be the TCP/IP port number of the remote database server <b>Any other value</b> Assumed to be a TCP/IP service name If the value is a TCP/IP service name, the value can be converted to a TCP/IP port number by using the TCP/IP getservbyname socket call. TCP/IP service names are not case sensitive. <b>Note:</b> While this column is defined as VARCHAR(96) it must not contain more than 32 EBCDIC characters.	
ACCELERATOR-AUTHTOKEN	VARCHAR(256) NOT NULL	The authentication token for the accelerator server.	
ACCELERATOR-SECURE	CHAR(1) NOT NULL	Indicates if the use of the Secure Socket Layer (SSL) protocol is required:  Y      Indicates a secure connection using SSL is required. N      Indicates a secure connection is not required.	
IBMREQD	CHAR(1)	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators	

## SYSACCEL.SYSACCELIPLIST table

The SYSACCEL.SYSACCELIPLIST table contains one row for each IP addresse that is associated with each accelerator server.

Rows in this table can be inserted, updated, and deleted.

Column name	Data type	Description	Use
ACCELIPNAME	VARCHAR(24)	This value corresponds to the value of the ACCELERATORIPNAME column of the SYSACCEL.SYSACCELERATORS table. The values of the other columns in the row of the SYSACCELIPLIST table apply to the server that is identified by the ACCELERATORIPNAME column of the SYSACCEL.SYSACCELERATORS table. <b>Note:</b> While this column is defined as VARCHAR(24) it must not contain more than 8 EBCDIC characters.	
ACCELIPADDR	VARCHAR(254)	Contains the IP address or domain name of a remote TCP/IP host of the server.	
IBMREQD	CHAR(1)	A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators.	

## Using the catalog in database design

Retrieving information from the catalog by using SQL statements, can be helpful in designing your relational database.

*DB2 SQL Reference* lists all the DB2 catalog tables and the information stored in them.

The information in the catalog is vital to normal DB2 operation. You can *retrieve* catalog information, but *changing* it can have serious consequences. Therefore you cannot execute insert or delete operations that affect the catalog, and only a limited number of columns exist that you can update. Exceptions to these restrictions are the SYSIBM.SYSSTRINGS, SYSIBM.SYSCOLDIST, and SYSIBM.SYSCOLDISTSTATS catalog tables, into which you can insert rows and proceed to update and delete rows.

To retrieve information from the catalog, you need at least the SELECT privilege on the appropriate catalog tables.

**Note:** Some catalog queries can result in long table space scans.

## Retrieving catalog information about DB2 storage groups

Query SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES to obtain information DB2 storage groups and the volumes in those storage groups.

SYSIBM.SYSSTOGROUP and SYSIBM.SYSVOLUMES contain information about DB2 storage groups and the volumes in those storage groups. The following query shows what volumes are in a DB2 storage group, how much space is used, and when that space was last calculated.

```
SELECT SGNAME, VOLID, SPACE, SPCDATE  
  FROM SYSIBM.SYSVOLUMES, SYSIBM.SYSSTOGROUP  
 WHERE SGNAME=NAME  
 ORDER BY SGNAME;
```

GUPI

## Retrieving catalog information about a table

Query SYSIBM.SYSTABLES to obtain information about every table, view, and alias in your DB2 system.

**GUPI** SYSIBM.SYSTABLES contains a row for every table, view, and alias in your DB2 system. Each row tells you whether the object is a table, a view, or an alias, its name, who created it, what database it belongs to, what table space it belongs to, and other information. SYSTABLES also has a REMARKS column in which you can store your own information about the table in question.

See “Adding and retrieving comments” on page 2006 for more information about how to do this.

The following statement displays all the information for the project activity sample table:

```
SELECT *  
  FROM SYSIBM.SYSTABLES  
 WHERE NAME = 'PROJACT'  
   AND CREATOR = 'DSN8910';
```

GUPI

## Retrieving catalog information about partition order

Query SYSIBM.SYSTABLEPART to obtain information about the key order or logical partition order of a table.

GUPI

The LOGICAL\_PART column in SYSIBM.SYSTABLEPART contains information for key order or logical partition order.

The following statement displays information on partition order in ascending limit value order:

```
SELECT LIMITKEY, PARTITION  
  FROM SYSIBM.SYSTABLEPART  
 ORDER BY LOGICAL_PART;
```

GUPI

## Retrieving catalog information about aliases

Query SYSIBM.SYSTABLES to obtain information about aliases.

GUPI

Three columns in SYSIBM.SYSTABLES are used only for aliases:

- LOCATION contains your subsystem's location name for the remote system, if the object on which the alias is defined resides at a remote subsystem.
- TBCREATOR contains the schema table or view.
- TBNAME contains the name of the table or the view.

These sample user-defined functions make it easy to find information about aliases.

See *DB2 SQL Reference* for more information.

- TABLE\_NAME returns the name of a table, view, or undefined object found after resolving aliases for a user-specified object.
- TABLE\_SCHEMA returns the schema name of a table, view, or undefined object found after resolving aliases for a user-specified object.
- TABLE\_LOCATION returns the location name of a table, view, or undefined object found after resolving aliases for a user-specified object.

The NAME and CREATOR columns of SYSTABLES contain the name and schema of the alias, and three other columns contain the following information for aliases:

- TYPE is A.
- DBNAME is DSNDB06.
- TSNAME is SYSDBAUT.

If similar tables at different locations have names with the same second and third parts, you can retrieve the aliases for them with a query like this one:

```
SELECT LOCATION, CREATOR, NAME  
      FROM SYSIBM.SYSTABLES  
     WHERE TBCREATOR='DSN8910' AND TBNAME='EMP'  
          AND TYPE='A';
```

GUPI

## Retrieving catalog information about columns

Query SYSIBM.SYSCOLUMNS to obtain information about the columns of a table or view.

GUPI

SYSIBM.SYSCOLUMNS has one row for each column of every table and view. Query it, for example, if you cannot remember the column names of a table or view.

The following statement retrieves information about columns in the sample department table:

```
SELECT NAME, TBNAME, COLTYPE, LENGTH, NULLS, DEFAULT  
      FROM SYSIBM.SYSCOLUMNS  
     WHERE TBNAME='DEPT'  
          AND TBCREATOR = 'DSN8910';
```

The result is shown below; for each column, the following information about each column is given:

- The column name
- The name of the table that contains it
- Its data type
- Its length attribute
- Whether it allows nulls
- Whether it allows default values

NAME	TBNAME	COLTYPE	LENGTH	NULLS	DEFAULT
DEPTNO	DEPT	CHAR	3	N	N
DEPTNAME	DEPT	VARCHAR	36	N	N
MGRNO	DEPT	CHAR	6	Y	N
ADMRDEPT	DEPT	CHAR	3	N	N

For LOB columns, the LENGTH column shows the length of the pointer to the LOB. For an example of a query showing the actual LOB length, see “Retrieving catalog information about LOBs” on page 2004.

## Retrieving catalog information about indexes

Query SYSIBM.SYSINDEXES to obtain information about indexes.

SYSIBM.SYSINDEXES contains a row for every index, including indexes on catalog tables. The following example retrieves a row about an index named XEMPL2.

```
SELECT *
  FROM SYSIBM.SYSINDEXES
 WHERE NAME = 'XEMPL2'
   AND CREATOR = 'DSN8910';
```

A table can have more than one index. To display information about all the indexes of a table, enter a statement like this one:

```
SELECT *
  FROM SYSIBM.SYSINDEXES
 WHERE TBNAME = 'EMP'
   AND TBCREATOR = 'DSN8910';
```

## Retrieving catalog information about views

For every view you create, DB2 stores descriptive information in several catalog tables. Query these catalog tables to obtain information about views in your database.

The following actions occur in the catalog after the execution of CREATE VIEW:

- A row is inserted into SYSIBM.SYSTABLES.
- A row is inserted into SYSIBM.SYSTABAUTH to record the owner's privileges on the view.
- For each column of the view, a row is inserted into SYSIBM.SYSCOLUMNS.

- One or more rows are inserted into the SYSIBM.SYSVIEWS table to record the text of the CREATE VIEW statement.
- For each table or view on which the view is dependent, a row is inserted into SYSIBM.SYSVIEWDEP to record the dependency.
- A row is inserted into SYSIBM.SYSPRTREE, and possibly into SYSIBM.SYSPRLTREE, to record the parse tree of the view (an internal representation of its logic).

Users might want a view of one or more of those tables, containing information about their own tables and views.

## Retrieving catalog information about authorizations

Query SYSIBM.SYSTABAUTH to obtain information about who can access your data.

SYSIBM.SYSTABAUTH contains information about the privileges held by authorization IDs over tables and views

The following query retrieves the names of all users who have been granted access to the DSN8910.DEPT table.

```
SELECT GRANTEE
  FROM SYSIBM.SYSTABAUTH
 WHERE TTNAME = 'DEPT'
   AND GRANTEETYPE <> 'P'
   AND TCREATOR = 'DSN8910';
```

GRANTEE is the name of the column that contains authorization IDs for users of tables. TTNAME and TCREATOR specify the DSN8910.DEPT table. The clause GRANTEETYPE <> 'P' ensures that you retrieve the names only of users (not application plans or packages) that have authority to access the table.

## Retrieving catalog information about primary keys

Query SYSIBM.SYSCOLUMNS for information about primary keys.

SYSIBM.SYSCOLUMNS identifies columns of a primary key in column KEYSEQ; a nonzero value indicates the place of a column in the primary key. To retrieve the creator, database, and names of the columns in the primary key of the sample project activity table using SQL statements, execute:

```
SELECT TBCREATOR, TBNAME, NAME, KEYSEQ
  FROM SYSIBM.SYSCOLUMNS
 WHERE TBCREATOR = 'DSN8910'
   AND TBNAME = 'PROJACT'
   AND KEYSEQ > 0
 ORDER BY KEYSEQ;
```

SYSIBM.SYSINDEXES identifies the primary index of a table by the value P in column UNIQUERULE. To find the name, creator, database, and index space of the primary index on the project activity table, execute:

```
SELECT TBCREATOR, TBNAME, NAME, CREATOR, DBNAME, INDEXSPACE  
  FROM SYSIBM.SYSINDEXES  
 WHERE TBCREATOR = 'DSN8910'  
   AND TBNAME = 'PROJACT'  
   AND UNIQUERULE = 'P';
```

GUPI

## Retrieving catalog information about foreign keys

Query SYSIBM.SYSRELS and SYSIBM.SYSFOREIGNKEYS to obtain information about referential constraints and the columns of the foreign key that defines the constraint.

GUPI

SYSIBM.SYSRELS contains information about referential constraints, and each constraint is uniquely identified by the schema and name of the dependent table and the constraint name (RELNAME). SYSIBM.SYSFOREIGNKEYS contains information about the columns of the foreign key that defines the constraint. To retrieve the constraint name, column names, and parent table names for every relationship in which the project table is a dependent, execute:

```
SELECT A.CREATOR, A.TBNAME, A.RELNAME, B.COLNAME, B.COLSEQ,  
      A.REFTBCREATOR, A.REFTBNAME  
  FROM SYSIBM.SYSRELS A, SYSIBM.SYSFOREIGNKEYS B  
 WHERE A.CREATOR = 'DSN8910'  
   AND B.CREATOR = 'DSN8910'  
   AND A.TBNAME = 'PROJ'  
   AND B.TBNAME = 'PROJ'  
   AND A.RELNAME = B.RELNAME  
 ORDER BY A.RELNAME, B.COLSEQ;
```

You can use the same tables to find information about the foreign keys of tables to which the project table is a parent, as follows:

```
SELECT A.RELNAME, A.CREATOR, A.TBNAME, B.COLNAME, B.COLNO  
  FROM SYSIBM.SYSRELS A, SYSIBM.SYSFOREIGNKEYS B  
 WHERE A.REFTBCREATOR = 'DSN8910'  
   AND A.REFTBNAME = 'PROJ'  
   AND A.RELNAME = B.RELNAME  
 ORDER BY A.RELNAME, B.COLNO;
```

GUPI

## Retrieving catalog information about check pending

Query SYSIBM.SYSTABLESPACE to obtain information about table spaces that are in check-pending status.

GUPI

SYSIBM.SYSTABLESPACE indicates that a table space is in check-pending status by a value in column STATUS: P if the entire table space has that status, S if the status has a scope of less than the entire space. To list all table spaces whose use is restricted for *any* reason, issue this command:

```
-DISPLAY DATABASE (*) SPACENAM(*) RESTRICT
```

To retrieve the names of table spaces in check-pending status only, with the names of the tables they contain, execute:

```
SELECT A.DBNAME, A.NAME, B.CREATOR, B.NAME
  FROM SYSIBM.SYSTABLESPACE A, SYSIBM.SYSTABLES B
 WHERE A.DBNAME = B.DBNAME
   AND A.NAME = B.TSNAME
   AND (A.STATUS = 'P' OR A.STATUS = 'S')
 ORDER BY 1, 2, 3, 4;
```

 GUPI

## Retrieving catalog information about check constraints

Query SYSIBM.SYSCHECKS and SYSIBM.SYSCHECKDEP to obtain information about check constraints.

 GUPI

Information about check constraints is stored in the DB2 catalog in:

- SYSIBM.SYSCHECKS, which contains one row for each check constraint defined on a table
- SYSIBM.SYSCHECKDEP, which contains one row for each reference to a column in a check constraint

The following query shows all check constraints on all tables named SIMPDEPT and SIMPEMPL in order by column name within table schema. It shows the name, authorization ID of the creator, and text for each constraint. A constraint that uses more than one column name appears more than once in the result.

```
CREATE TABLE SIMPDEPT
  (DEPTNO  CHAR(3) NOT NULL,
   DEPTNAME VARCHAR(12) CONSTRAINT CC1 CHECK (DEPTNAME IS NOT NULL),
   MGRNO   CHAR(6),
   MGRNAME CHAR(6));

SELECT A.TBOWNER, A.TBNAME, B.COLNAME,
       A.CHECKNAME, A.CREATOR, A.CHECKCONDITION
  FROM SYSIBM.SYSCHECKS A, SYSIBM.SYSCHECKDEP B
 WHERE A.TBOWNER = B.TBOWNER
   AND A.TBNAME = B.TBNAME
   AND B.TBNAME = 'SIMPDEPT'
   AND A.CHECKNAME = B.CHECKNAME
 ORDER BY TBOWNER, TBNAME, COLNAME;
```

 GUPI

## Retrieving catalog information about LOBs

Query SYSIBM.SYSAUXRELS to obtain information about the relationship between a base table and an auxiliary table.

 GUPI

SYSIBM.SYSAUXRELS contains information about the relationship between a base table and an auxiliary table. For example, this query returns information about the name of the LOB columns for the employee table and its associated auxiliary table schema and name:

```
SELECT COLNAME, PARTITION, AUXTBOWNER, AUXTBNAME  
      FROM SYSIBM.SYSAUXRELS  
     WHERE TBNAME = 'EMP' AND TBOWNER = 'DSN8910';
```

Information about the length of a LOB is in the LENGTH2 column of SYSCOLUMNS. You can query information about the length of the column as it is returned to an application with the following query:

```
SELECT NAME, TBNAME, COLTYPE, LENGTH2, NULLS, DEFAULT  
      FROM SYSIBM.SYSCOLUMNS  
     WHERE TBNAME='DEPT'  
       AND TBCREATOR = 'DSN8910';
```

GUPI

## Retrieving catalog information about user-defined functions and stored procedures

Query SYSIBM.SYSROUTINES to obtain information about user-defined functions and stored procedures.

GUPI

You can use this example to find packages with stored procedure that were created prior to Version 6 and then migrated to SYSIBM.SYSROUTINES:

```
SELECT SCHEMA, NAME FROM SYSIBM.SYSROUTINES  
   WHERE ROUTINETYPE = 'P';
```

You can use this query to retrieve information about user-defined functions:

```
SELECT SCHEME, NAME, FUNCTION_TYPE, PARM_COUNT FROM SYSIBM.SYSROUTINES  
   WHERE ROUTINETYPE='F';
```

Stored procedures created before Version 6 have different authorization requirements than those created in Version 6. See *DB2 Application Programming and SQL Guide* for more information.

GUPI

## Retrieving catalog information about triggers

Query SYSIBM.SYSTRIGGERS to obtain information about the triggers defined in your databases.

GUPI

To find all the triggers defined on a particular table, their characteristics, and to determine the order they are activated in, issue this query:

```
SELECT DISTINCT SCHEMA, NAME, TRIGTIME, TRIGEVENT, GRANULARITY, CREADEDTS  
      FROM SYSIBM.SYSTRIGGERS  
     WHERE TBNAME = 'EMP' AND TBOWNER = 'DSN8910';
```

Issue this query to retrieve the text of a particular trigger:

```
SELECT TEXT, SEQNO  
      FROM SYSIBM.SYSTRIGGERS  
     WHERE SCHEMA = schema_name  
       AND NAME = trigger_name  
      ORDER BY SEQNO;
```

Or to determine triggers that must be rebound because they are invalidated after objects are dropped or altered, issue this query:

```
SELECT COLLID, NAME  
      FROM SYSIBM.SYSPACKAGE  
     WHERE TYPE = 'T'  
       AND (VALID = 'N' OR OPERATIVE = 'N');
```

 GUPI

## Retrieving catalog information about sequences

Query SYSIBM.SYSSEQUENCES and SYSIBM.SYSSEQUENCEAUTH to obtain information about sequences.

 GUPI

SYSIBM.SYSSEQUENCES and SYSIBM.SYSSEQUENCEAUTH contains information about sequences. To retrieve the attributes of a sequence, issue this query:

```
SELECT *  
      FROM SYSIBM.SYSSEQUENCES  
     WHERE NAME = 'MYSEQ' AND SCHEMA = 'USER1B';
```

Issue this query to determine the privileges that user USER1B has on sequences:

```
SELECT GRANTOR, NAME, DATEGRANTED, ALTERAUTH, USEAUTH  
      FROM SYSIBM.SEQUENCEAUTH  
     WHERE GRANTEE = 'USER1B';
```

 GUPI

## Adding and retrieving comments

After you create an object, you can provide explanatory information about it for future reference. For example, you can provide information about the purpose of the object, who uses it, and anything unusual about it.

 GUPI

You can create comments about tables, views, indexes, aliases, packages, plans, distinct types, triggers, stored procedures, and user-defined functions. You can store a comment about the table or the view as a whole, and you can also include a comment for *each column*. A comment must not exceed 762 bytes.

A comment is especially useful if your names do not clearly indicate the contents of columns or tables. In that case, use a comment to describe the specific contents of the column or table.

Below are two examples of COMMENT:

```
COMMENT ON TABLE DSN8910.EMP IS  
  'Employee table. Each row in this table represents one  
   employee of the company.';  
COMMENT ON COLUMN DSN8910.PROJ.PRSTDATE IS  
  'Estimated project start date. The format is DATE.';
```

After you execute a COMMENT statement, your comments are stored in the REMARKS column of SYSIBM.SYSTABLES or SYSIBM.SYSCOLUMNS. (Any

comment that is already present in the row is replaced by the new one.) The next two examples retrieve the comments that are added by the previous COMMENT statements.

```
SELECT REMARKS  
  FROM SYSIBM.SYSTABLES  
 WHERE NAME = 'EMP'  
   AND CREATOR = 'DSN8910';  
  
SELECT REMARKS  
  FROM SYSIBM.SYSCOLUMNS  
 WHERE NAME = 'PRSTDATE' AND TBNAME = 'PROJ'  
   AND TBCREATOR = 'DSN8910';
```

GUPI

## Verifying the accuracy of the database definition

You can use the catalog to verify the accuracy of your database definition.

GUPI

After you have created the objects in your database, display selected information from the catalog to check that no errors are in your CREATE statements. By examining the catalog tables, you can verify that your tables are in the correct table space, your table spaces are in the correct storage group, and so on.

GUPI

## Sample user-defined functions

Some sample user-defined functions are provided with DB2. You can use the functions in your applications just as you would use other user-defined functions, or as examples to help you define your own user-defined functions..

- To use these functions in your applications: Use the functions only if installation job DSNTEJ2U, which prepares the functions for use, has been run. Because the external programs that implement the logic of the sample functions are written in C and C++, the installation job requires that your site has IBM C/C++ for OS/390. For information on installation job DSNTEJ2U, see *DB2 Installation Guide*.
- If you want to use these functions as examples to help you define and implement your own user-defined functions: Data set *prefix.SDSNSAMP* contains the code for the sample functions.

The following table lists the sample user-defined functions. The detailed descriptions of the functions include their external program names and specific names. The functions are in schema DSN8. The functions are defined to treat character or graphic string parameters, both input and output, as EBCDIC-encoded data.

Table 170. DB2 sample user-defined functions

Function Name	Description
ALTDAT	Returns the current date or a user-specified date in a user-specified format
ALTTIME	Returns the current time or a user-specified time in a user-specified format
CURRENCY	Returns a floating-point number as a currency value

*Table 170. DB2 sample user-defined functions (continued)*

Function Name	Description
DAYNAME	Returns the name of the day of the week on which a date in ISO format falls
MONTHNAME	Returns the name of the month in which a date in ISO format falls
TABLE_LOCATION	Returns the location name of a table or view after resolving any aliases
TABLE_NAME	Returns the unqualified name of a table or view after resolving any aliases
TABLE_SCHEMA	Returns the schema name of a table or view after resolving any aliases
WEATHER	Shows how to use a user-defined table function to make non-relational data available for SQL manipulation

## ALTDATe

The ALTDATe function returns the current date in the specified format or converts a user-specified date from one format to another.

```
►►—ALTDATe(—input-date, input-format,—output-format)—►►
```

The schema is DSN8.

The ALTDATe function returns the current date in one of the following formats or converts a user-specified date from one format to another:

D MONTH YY	D MONTH YYYY	DD MONTH YY	DD MONTH YYYY
D.M.YY	D.M.YYYY	DD.MM.YY	DD.MM.YYYY
D-M-YY	D-M-YYYY	DD-MM-YY	DD-MM-YYYY
D/M/YY	D/M/YYYY	DD/MM/YY	DD/MM/YYYY
M/D/YY	M/D/YYYY	MM/DD/YY	MM/DD/YYYY
YY/M/D	YYYY/M/D	YY/MM/DD	YYYY/MM/DD
YY.M.D	YYYY.M.D	YY.MM.DD	YYYY.MM.DD
	YYYY-M-D		YYYY-MM-DD
	YYYY-D-XX		YYYY-DD-XX
	YYYY-XX-D		YYYY-XX-DD

where:

D: Suppress leading zero if the day is less than 10  
DD: Retain leading zero if the day is less than 10  
M: Suppress leading zero if the month is less than 10  
MM: Retain leading zero if the month is less than 10  
MONTH: Use English-language name of month  
XX: Use a capital Roman numeral for month  
YY: Use a year format without century  
YYYY: Use a year format with century

The ALTDATe function demonstrates how you can create an overloaded function—a function name for which there are multiple function instances. Each instance supports a different parameter list enabling you to group related but distinct functions in a single user-defined function. The ALTDATe function has two forms.

### Form 1: ALTDATe(*output-format*)

This form of the function converts the current date into the specified format.

#### *output-format*

A character string that matches one of the 34 date formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 13 bytes.

The result of the function is VARCHAR(17).

### Form 2: ALTDATe(*input-date, input-format, output-format*)

This form of the function converts a date (*input-date*) in one user-specified format (*input-format*) into another format (*output-format*).

#### *input-date*

The argument must be a date or a character string representation of a date

in the format specified by *input-format*. The character string must have a data type of VARCHAR and an actual length that is not greater than 17 bytes.

*input-format*

A character string that matches one of the 34 date formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 13 bytes.

*output-format*

A character string that matches one of the 34 date formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 13 bytes.

The result of the function is VARCHAR(17).

The following table shows the external and specific names for the two forms of the function, which are based on the input to the function.

*Table 171. External program and specific names for ALTDATE*

Conversion type	Input arguments	External name	Specific name
Current date	<i>output-format</i> (VARCHAR)	DSN8DUAD	DSN8.DSN8DUADV
User-specified date	<i>input-date</i> (VARCHAR) <i>input-format</i> (VARCHAR) <i>output-format</i> (VARCHAR)	DSN8DUCD	DSN8.DSN8DUCDVVV
		DSN8DUCD	DSN8.DSN8DUCDDVV
	<i>input-date</i> (DATE) <i>input-format</i> (VARCHAR) <i>output-format</i> (VARCHAR)		

*Example 1:* Convert the current date into format 'DD MONTH YY', a format that will include any leading zero for the month, the name of the month in English, and the year without the two digits for the century.

```
VALUES DSN8.ALTDAT( 'DD MONTH YY' );
```

*Example 2:* Convert the current date into format 'D.M.YYYY', a format that will suppress any leading zero for the day or month and include the year with the century.

```
VALUES DSN8.ALTDAT( 'D.M.YYYY' );
```

*Example 3:* Convert the current date into format 'YYYY-XX-DD', a format that will include the century, the month of the year as a roman numeral, and the day of the month with any leading zero.

```
VALUES DSN8.ALTDAT( 'YYYY-XX-DD' );
```

*Example 4:* Convert a date in the format of 'DD MONTH YYYY' to a date in the format of 'YYYY/MM/DD'.

```
VALUES DSN8.ALTDAT( '11 November 1918',
'DD MONTH YYYY',
'YYYY/MM/DD' );
```

The result of the above example is '1918/11/18'.

*Example 5:* Convert the date that employee 000130 was hired, a date in ISO format, into the format of 'D.M.YY'.

```
SELECT FIRSTNME || ' '
  || LASTNAME || ' was hired on '
  || DSN8.ALTDAT( HIREDATE,
                  'YYYY-MM-DD',
                  'D.M.YY' )
   FROM EMP
 WHERE EMPNO = '000130';
```

Assuming that the HIREDATE is '1971-07-28', the above example returns: 'DELORES QUINTANA was hired on 28.7.71'.

## ALTTIME

The ALTTIME function returns the current time in the specified format or converts a user-specified time from one format to another.

```
►►—ALTTIME(—input-time, input-format, —output-format—)—►►
```

The schema is DSN8.

The ALTTIME function returns the current time in one of the following formats or converts a user-specified time from one of the formats to another:

H:MM AM/PM	HH:MM AM/PM
HH:MM:SS AM/PM	HH:MM:SS
H.MM	HH.MM
H.MM.SS	HH.MM.SS

where:

H:	Suppress leading zero if the hour is less than 10
HH:	Retain leading zero if the hour is less than 10
M:	Suppress leading zero if the minute is less than 10
MM:	Retain leading zero if the minute is less than 10
AM/PM:	Return time in 12-hour clock format, else 24-hour

The ALTTIME function demonstrates how you can create an overloaded function—a function name for which there are multiple function instances. Each instance supports a different parameter list enabling you to group related but distinct functions in a single user-defined function. The ALTTIME function has two forms.

### Form 1: ALTTIME(*output-format*)

This form of the function converts the current time into the specified format.

#### *output-format*

A character string that matches one of the 8 time formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

The result of the function is VARCHAR(11).

### Form 2: ALTTIME(*input-time, input-format, output-format*)

This form of the function converts a time (*input-date*) in one user-specified format (*input-format*) into another format (*output-format*).

#### *input-time*

The argument must be a time or a character string representation of a time in the format specified by *input-format*. A character string argument must have a data type of VARCHAR and an actual length that is not greater than 11 bytes.

#### *input-format*

A character string that matches one of the 8 time formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

#### *output-format*

A character string that matches one of the 8 time formats that are shown

above. The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

The result of the function is VARCHAR(11).

The following table shows the external program and specific names for the two forms of the function, which are based on the input to the function.

*Table 172. External and specific names for ALTTIME*

Conversion type	Input arguments	External name	Specific name
Current time	<i>output-format</i> (VARCHAR)	DSN8DUAT	DSN8.DSN8DUATV
User-specified time	<i>input-time</i> (VARCHAR) <i>input-format</i> (VARCHAR) <i>output-format</i> (VARCHAR)	DSN8DUCT	DSN8.DSN8DUCTVVV
		DSN8DUCT	DSN8.DSN8DUCTTVV
	<i>input-time</i> (TIME) <i>input-format</i> (VARCHAR) <i>output-format</i> (VARCHAR)		

*Example 1:* Convert the current time into a 12-hour clock format without seconds, 'H.MM AM/PM'.

```
VALUES DSN8.ALTTIME( 'H:MM AM/PM' );
```

*Example 2:* Convert the current time into a 24-hour clock format without seconds, 'HH.MM'.

```
VALUES DSN8.ALTTIME( 'HH.MM' );
```

*Example 3:* Convert the current time into a 24-hour clock format with seconds, 'HH.MM.SS'.

```
VALUES DSN8.ALTTIME( 'HH.MM.SS' );
```

*Example 4:* Convert '00:00:00', a time in 24-hour clock format with seconds, to a time in 12-hour clock format without seconds.

```
VALUES DSN8.ALTTIME( '00:00:00','HH:MM:SS','HH:MM AM/PM' );
```

The function returns '12:00 AM'.

*Example 5:* Convert '00:00:00', a time in 24-hour clock format with seconds, to a time in 12-hour clock format without seconds and without any leading zero on the hour.

```
VALUES DSN8.ALTTIME( '06.42.37','HH.MM.SS','H:MM AM/PM' );
```

The function returns '6:42 AM'.

## CURRENCY

The CURRENCY function returns a value that is formatted as an amount with a user-specified currency symbol and, if specified, one of three symbols that indicate debit or credit.

```
►—CURRENCY (—input-amount, currency-symbol—  
                  [ , credit/debit-indicator] )—►
```

The schema is DSN8.

### *input-amount*

An expression that specifies the value to be formatted. The expression must be a floating-point value.

### *currency-symbol*

A character string that specifies the currency symbol. The string must have a data type of VARCHAR and an actual length that is not greater than 2 bytes.

### *credit/debit-indicator*

A character string that specifies the symbol that is included with the result to indicate whether the value is negative or positive. The string must have a data type of VARCHAR and an actual length that is not greater than 5 bytes. If *credit/debit-indicator* is not specified or is the value null, the result is formatted without an indicator symbol. You can specify the following symbols:

#### CR/DB

*Bank style*. Negative input values are appended with 'DB'; positive input values are appended with 'CR'.

+/- *Arithmetic style*. Negative input values are prefixed with a minus sign '-'; positive values are formatted without symbols.

(/) *Accounting style*. Negative input values are enclosed in parentheses '()' ; positive values are formatted without symbols.

The result of the function is VARCHAR(19).

The CURRENCY function uses the C language functions strfmon to facilitate formatting of money amounts and setlocale to initialize strfmon for local conventions. If setlocale fails, the CURRENCY function returns an error.

The following table shows the external program and specific names for CURRENCY. The specific names differ depending on the input to the function.

*Table 173. External program and specific names for CURRENCY*

Input arguments	External name	Specific name
<i>input-amount</i> <i>currency-symbol</i>	DSN8DUCY	DSN8.DSN8DUCYFV
	DSN8DUCY	DSN8.DSN8DUCYFVV
<i>input-amount</i> <i>currency-symbol</i> <i>credit/debit-indicator</i>		

*Example 1:* Express® '-1234.56' as an amount in US dollars, using the bank style debit/credit indicator to indicate whether the value is negative or positive.

```
VALUES DSN8.CURRENCY( -1234.56,'$', 'CR/DB' );
```

The result of the function is '\$1,234.56 DB'.

*Example 2:* Express '-1234.56' as an amount in Deutsche marks, using the accounting style debit/credit indicator to indicate whether the value is negative or positive.

```
VALUES DSN8.CURRENCY( -1234.56,'DM','(/)' );
```

The result of the function is '(DM 1,234.56)'.

*Example 3:* Express '-1234.56' as an amount in Canadian dollars, using the accounting style debit/credit indicator to indicate whether the value is negative or positive.

```
VALUES DSN8.CURRENCY( -1234.56,'CD','+/-' );
```

The result of the function is '-CD 1,234.56'.

## DAYNAME

The DAYNAME function returns the name of the weekday on which a given date falls. The name is returned in English.

```
►►DAYNAME(input-date)—————►►
```

The schema is DSN8.

*input-date*

A valid date or valid character string representation of a date. A character string representation. The string must have a data type of VARCHAR and an actual length that is not greater than 10 bytes. The date must be in ISO format.

The result of the function is VARCHAR(9).

The DAYNAME function uses the IBM C++ classIDate.

The following table shows the external and specific names for DAYNAME. The specific names differ depending on the data type of the input argument.

*Table 174. External and specific names for DAYNAME*

Input arguments	External name	Specific name
<i>input-date</i> (VARCHAR)	DSN8EUDN	DSN8.DSN8EUDNV
<i>input-date</i> (DATE)	DSN8EUDN	DSN8.DSN8EUDND

*Example 1:* For the current date, find the day of the week.

```
VALUES DSN8.DAYNAME( CURRENT DATE );
```

*Example 2:* Find the day of the week on which leap year falls in the year 2008.

```
VALUES DSN8.DAYNAME( '2008-02-29' );
```

The result of the function is 'Friday'.

*Example 3:* Find the day of the week on which Delores Quintana, employee number 000130, was hired.

```
SELECT FIRSTNME || ' '
  || LASTNAME || ' was hired on '
  || DSN8.DAYNAME( HIREDATE ) || ', '
  || CHAR( HIREDATE )
FROM   EMP
WHERE  EMPNO = '000130';
```

The result of the function is 'DELORES QUINTANA was hired on Wednesday, 1971-07-28'.

## MONTHNAME

The MONTHNAME function returns the calendar name of the month in which a given date falls. The name is returned in English.

►►—MONTHNAME(*input-date*)—►►

The schema is DSN8.

*input-date*

A valid date or valid character string representation of a date. A character string representation must have a data type of VARCHAR and an actual length that is no greater than 10 bytes. The date must be in ISO format.

The result of the function is VARCHAR(9).

The MONTHNAME function uses the IBM C++ class IDate.

The following table shows the external and specific names for MONTHNAME. The specific names differ depending on the data type of the input argument.

*Table 175. External and specific names for MONTHNAME*

Input arguments	External name	Specific name
<i>input-date</i> (VARCHAR)	DSN8EUMN	DSN8.DSN8EUMNV
<i>input-date</i> (DATE)	DSN8EUMN	DSN8.DSN8EUMND

*Example 1:* For the current date, find the name of the month.

```
VALUES DSN8.MONTHNAME( CURRENT DATE );
```

*Example 2:* Find the month of the year in which Delores Quintana, employee number 000130, was hired.

```
SELECT FIRSTNAME || ' '
  || LASTNAME || ' was hired in the month of '
  || DSN8.MONTHNAME( HIREDATE )
  || CHAR( HIREDATE )
  FROM EMP
 WHERE EMPNO = '000130';
```

The result of the function is 'DELORES QUINTANA was hired in the month of July'.

## TABLE\_LOCATION

The TABLE\_LOCATION function searches for an object and returns the location name of the object after any alias chains have been resolved.

```
►►—TABLE_LOCATION(—object-name—  
      , object-schema—  
      , location-name—)  
      )—►►
```

The schema is DSN8.

The starting point of the resolution is the object that is specified by *object-name* and, if specified, *object-schema* and *location-name*. If the starting point does not refer to an alias, the location name of the starting point is returned. The resulting name can be of a table, view, or undefined object. The function returns a blank if there is no location name.

### *object-name*

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. *object-name* must have a data type of VARCHAR and an actual length that is no greater than 18 bytes.

### *object-schema*

A character expression that represents the schema that is used to qualify the value specified in *object-name* before resolution. *object-schema* must have a data type of VARCHAR and an actual length that is no greater than 8 bytes.

If *object-schema* is not specified or is null, the default schema is used for the qualifier.

### *location-name*

A character expression that represents the location that is used to qualify the value specified in *object-name* before resolution. *location-name* must have a data type of VARCHAR and an actual length that is no greater than 16 bytes.

If *location-name* is not specified or is null, the location name is equivalent to “any”.

The result of the function is VARCHAR(16). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value.

The following table shows the external and specific names for TABLE\_LOCATION. The specific names differ depending on the number of input arguments to the function.

Table 176. External and specific names for TABLE\_LOCATION

Input arguments	External name	Specific name
<i>object-name</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTILV
<i>object-name</i> (VARCHAR) <i>object-schema</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTILVV

*Table 176. External and specific names for TABLE\_LOCATION (continued)*

Input arguments	External name	Specific name
	DSN8DUTI	DSN8.DSN8DUTILVVV
<i>object-name</i> (VARCHAR)		
<i>object-schema</i> (VARCHAR)		
<i>location-name</i> (VARCHAR)		

*Example:* Assume that:

- DSN8.ALIAS\_RS\_SYSTABLES is an alias of SYSIBM.SYSTABLES at location name 'REMOTE\_SITE'.
- The CURRENT SQLID is DSN8.

Use TABLE\_LOCATION to find the location name where the base object for ALIAS\_RS\_SYSTABLES resides.

```
VALUES DSN8.TABLE_LOCATION( 'ALIAS_RS_SYSTABLES' );
```

The result of the function is 'REMOTE\_SITE'.

## TABLE\_NAME

The TABLE\_NAME function searches for an object and returns the unqualified name of the object after any alias chains have been resolved.

```
►►—TABLE_NAME(—object-name—  
    └, object-schema └, location-name—)  
    └—————►►
```

The schema is DSN8.

The starting point of the resolution is the object that is specified by *object-name* and, if specified, *object-schema* and *location name*. If the starting point does not refer to an alias, the unqualified name of the starting point is returned. The resulting name can be of a table, view, or undefined object.

### *object-name*

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. *object-name* must have a data type of VARCHAR and an actual length that is no greater than 18 bytes.

### *object-schema*

A character expression that represents the schema that is used to qualify the value specified in *object-name* before resolution. *object-schema* must have a data type of VARCHAR and an actual length that is no greater than 8 bytes.

If *object-schema* is not specified or is null, the default schema is used for the qualifier.

### *location-name*

A character expression that represents the location that is used to qualify the value specified in *object-name* before resolution. *location-name* must have a data type of VARCHAR and an actual length that is no greater than 16 bytes.

If *location-name* is not specified or is null, the location name is equivalent to "any".

The result of the function is VARCHAR(128). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value.

The following table shows the external and specific names for TABLE\_NAME. The specific names differ depending on the number of input arguments to the function.

Table 177. External and specific names for TABLE\_NAME

Input arguments	External name	Specific name
<i>object-name</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTINV
<i>object-name</i> (VARCHAR) <i>object-schema</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTINVV

*Table 177. External and specific names for TABLE\_NAME (continued)*

Input arguments	External name	Specific name
	DSN8DUTI	DSN8.DSN8DUTINVVV
<i>object-name</i> (VARCHAR)		
<i>object-schema</i> (VARCHAR)		
<i>location-name</i> (VARCHAR)		

*Example:* Assume that:

- DSN8.VIEW\_OF\_SYSTABLES is a view of SYSIBM.SYSTABLES.
- DSN8.ALIAS\_OF\_VIEW is an alias of DSN8.VIEW\_OF\_SYSTABLES.
- The CURRENT SQLID is DSN8.

Use TABLE\_NAME to find the name of the base object for ALIAS\_OF\_VIEW.

```
VALUES DSN8.TABLE_NAME( 'ALIAS_OF_VIEW' );
```

The result of the function is 'VIEW\_OF\_SYSTABLES'.

## TABLE\_SCHEMA

The TABLE\_SCHEMA function searches for an object and returns the schema name of the object after any synonyms or alias chains have been resolved.

```
►►—TABLE_SCHEMA(—object-name—  
    , object-schema  
    , location-name—)  
—————►
```

The schema is DSN8.

The starting point of the resolution is the object that is specified by *objectname* and *objectschema*. If the starting point does not refer to an alias or synonym, the schema name of the starting point is returned. The resulting schema name can be of a table, view, or undefined object.

### *object-name*

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. *object-name* must have a data type of VARCHAR and an actual length that is no greater than 18 bytes.

### *object-schema*

A character expression that represents the schema that is used to qualify the value specified in *object-name* before resolution. *object-schema* must have a data type of VARCHAR and an actual length that is no greater than 8 bytes.

If *object-schema* is not specified or is null, the default schema is used for the qualifier.

### *location-name*

A character expression that represents the location that is used to qualify the value specified in *object-name* before resolution. *location-name* must have a data type of VARCHAR (and an actual length that is no greater than 16 bytes).

If *location-name* is not specified or is null, the location name is equivalent to "any".

The result of the function is VARCHAR(128). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value.

The following table shows the external and specific names for TABLE\_SCHEMA. The specific names differ depending on the number of input arguments.

Table 178. External and specific names for function TABLE\_SCHEMA

Input arguments	External name	Specific name
<i>object-name</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTISV
<i>object-name</i> (VARCHAR) <i>object-schema</i> (VARCHAR)	DSN8DUTI	DSN8.DSN8DUTISVV

*Table 178. External and specific names for function TABLE\_SCHEMA (continued)*

Input arguments	External name	Specific name
	DSN8DUTI	DSN8.DSN8DUTISVVV
<i>object-name</i> (VARCHAR)		
<i>object-schema</i> (VARCHAR)		
<i>location-name</i> (VARCHAR)		

*Example:* Assume that:

- DSN8.ALIAS\_OF\_SYSTABLES is an alias of SYSIBM.SYSTABLES.
- The CURRENT SQLID is DSN8.

Find the name of the schema of the base table for ALIAS\_OF\_SYSTABLES.

```
VALUES DSN8.TABLE_SCHEMA( 'ALIAS_OF_SYSTABLES' );
```

The result of the function is 'SYSIBM'.

## WEATHER

The WEATHER function returns information from a TSO data set as a DB2 table. The TSO data set contains sample weather statistics for various cities in the United States. The statistics are returned to the client with a row for each city and a column for each statistic. The WEATHER function is provided primarily to help you design and implement table functions.

►►WEATHER( <i>input-data-set-name</i> )—RETURNS TABLE(	<i>name-of-city</i>	)	►►
	<i>temperature-in-fahrenheit</i>		
	<i>percent-humidity</i>		
	<i>wind-direction</i>		
	<i>wind-velocity</i>		
	<i>barometer</i>		
	<i>forecast</i>		

The schema is DSN8.

Unlike the other sample user-defined functions, which are scalar functions, WEATHER is a table function. WEATHER shows how to use a table function to make non-relational data available to a client for manipulation by SQL.

*input-data-set-name*

The name of the TSO data set that contains sample weather statistics. The name is a character string with a data type of VARCHAR and an actual length that is not greater than 44 bytes.

The result of the function is a DB2 table with the following columns. Each column can be null.

<i>name-of-city</i>	VARCHAR(30)
<i>temperature-in-fahrenheit</i>	INTEGER
<i>percent-humidity</i>	INTEGER
<i>wind-direction</i>	VARCHAR(5)
<i>wind-velocity</i>	INTEGER
<i>barometer</i>	FLOAT
<i>forecast</i>	VARCHAR(25)

The external program name for the function is DSN8DUWF, and the specific name is DSN8.DSN8DUWF.

*Example:* Find the name of and the forecast for the cities that have a temperature less than 25 degrees.

```
SELECT CITY, FORECAST
  FROM TABLE(DSN8.WEATHER('prefix.SDSNIVPD(DSN8LWC)')) AS W
 WHERE TEMP_IN_F < 25
 ORDER BY CITY;
```

This example returns:

Bessemer, MI	Slight chance of snow
Cheyenne, WY	Continued cooling
Helena, MT	Heavy snow
Pierre, SD	Continued cold

---

# Information resources for DB2 for z/OS and related products

Many information resources are available to help you use DB2 for z/OS and many related products. A large amount of technical information about IBM products is now available online in information centers or on library websites.

**Disclaimer:** Any web addresses that are included here are accurate at the time this information is being published. However, web addresses sometimes change. If you visit a web address that is listed here but that is no longer valid, you can try to find the current web address for the product information that you are looking for at either of the following sites:

- <http://www.ibm.com/support/publications/us/library/index.shtml>, which lists the IBM information centers that are available for various IBM products
- <http://www.ibm.com/shop/publications/order>, which is the IBM Publications Center, where you can download online PDF books or order printed books for various IBM products

## DB2 for z/OS product information

The primary place to find and use information about DB2 for z/OS is the Information Management Software for z/OS Solutions Information Center (<http://publib.boulder.ibm.com/infocenter/imzic>), which also contains information about IMS, QMF, and many DB2 and IMS Tools products. This information center is also available as an installable information center that can run on a local system or on an intranet server. You can order the Information Management for z/OS Solutions Information Center DVD (SK5T-7377) for a low cost from the IBM Publications Center (<http://www.ibm.com/shop/publications/order>).

The majority of the DB2 for z/OS information in this information center is also available in the books that are identified in the following table. You can access these books at the DB2 for z/OS library website (<http://www.ibm.com/software/data/db2/zos/library.html>) or at the IBM Publications Center (<http://www.ibm.com/shop/publications/order>).

Table 179. DB2 Version 9.1 for z/OS book titles

Title	Publication number	Available in information center	Available in PDF	Available in BookManager® format	Available in printed book
<i>DB2 Version 9.1 for z/OS Administration Guide</i>	SC18-9840	X	X	X	X
<i>DB2 Version 9.1 for z/OS Application Programming &amp; SQL Guide</i>	SC18-9841	X	X	X	X
<i>DB2 Version 9.1 for z/OS Application Programming Guide and Reference for Java</i>	SC18-9842	X	X	X	X
<i>DB2 Version 9.1 for z/OS Codes</i>	GC18-9843	X	X	X	X
<i>DB2 Version 9.1 for z/OS Command Reference</i>	SC18-9844	X	X	X	X
<i>DB2 Version 9.1 for z/OS Data Sharing: Planning and Administration</i>	SC18-9845	X	X	X	X

Table 179. DB2 Version 9.1 for z/OS book titles (continued)

Title	Publication number	Available in information center	Available in PDF	Available in BookManager® format	Available in printed book
DB2 Version 9.1 for z/OS Diagnosis Guide and Reference <sup>1</sup>	LY37-3218		X	X	X
DB2 Version 9.1 for z/OS Diagnostic Quick Reference	LY37-3219				X
DB2 Version 9.1 for z/OS Installation Guide	GC18-9846	X	X	X	X
DB2 Version 9.1 for z/OS Introduction to DB2	SC18-9847	X	X	X	X
DB2 Version 9.1 for z/OS Licensed Program Specifications	GC18-9848		X		X
DB2 Version 9.1 for z/OS Messages	GC18-9849	X	X	X	X
DB2 Version 9.1 for z/OS ODBC Guide and Reference	SC18-9850	X	X	X	X
DB2 Version 9.1 for z/OS Performance Monitoring and Tuning Guide	SC18-9851	X	X	X	X
DB2 Version 9.1 for z/OS Optimization Service Center			X		
DB2 Version 9.1 for z/OS Program Directory	GI10-8737		X		X
DB2 Version 9.1 for z/OS RACF Access Control Module Guide	SC18-9852	X	X	X	
DB2 Version 9.1 for z/OS Reference for Remote DRDA Requesters and Servers	SC18-9853	X	X	X	
DB2 Version 9.1 for z/OS Reference Summary	SX26-3854		X		
DB2 Version 9.1 for z/OS SQL Reference	SC18-9854	X	X	X	X
DB2 Version 9.1 for z/OS Utility Guide and Reference	SC18-9855	X	X	X	X
DB2 Version 9.1 for z/OS What's New?	GC18-9856	X	X		X
DB2 Version 9.1 for z/OS XML Extender Administration and Programming	SC18-9857	X	X	X	X
DB2 Version 9.1 for z/OS XML Guide	SC18-9858	X	X	X	X
IRLM Messages and Codes for IMS and DB2 for z/OS	GC19-2666	X	X	X	

**Note:**

1. DB2 Version 9.1 for z/OS Diagnosis Guide and Reference is available in PDF and BookManager formats on the DB2 Version 9.1 for z/OS Licensed Collection kit, LK3T-7195. You can order this License Collection kit on the IBM Publications Center site (<http://www.ibm.com/e-business/linkweb/publications/servlet/pbi.wss>). This book is also available in online format in DB2 data set DSN910.SDSNIVPD(DSNDR).

## Information resources for related products

In the following table, related product names are listed in alphabetic order, and the associated web addresses of product information centers or library web pages are indicated.

*Table 180. Related product information resource locations*

Related product	Information resources
C/C++ for z/OS	Library website: <a href="http://www.ibm.com/software/awdtools/czos/library/">http://www.ibm.com/software/awdtools/czos/library/</a>  This product is now called z/OS XL C/C++.
CICS Transaction Server for z/OS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/cicsts/v3r1/index.jsp">http://publib.boulder.ibm.com/infocenter/cicsts/v3r1/index.jsp</a>
COBOL	Information center: <a href="http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp">http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp</a>  This product is now called Enterprise COBOL for z/OS.
DB2 Connect	Information center: <a href="http://publib.boulder.ibm.com/infocenter/db2luw/v9/index.jsp">http://publib.boulder.ibm.com/infocenter/db2luw/v9/index.jsp</a>  This resource is for DB2 Connect 9.
DB2 Database for Linux, UNIX, and Windows	Information center: <a href="http://publib.boulder.ibm.com/infocenter/db2luw/v9/index.jsp">http://publib.boulder.ibm.com/infocenter/db2luw/v9/index.jsp</a>  This resource is for DB2 9 for Linux, UNIX, and Windows.
DB2 Query Management Facility™	Information center: <a href="http://publib.boulder.ibm.com/infocenter/imzic">http://publib.boulder.ibm.com/infocenter/imzic</a>
DB2 Server for VSE & VM	Product website: <a href="http://www.ibm.com/software/data/db2/vse-vm/">http://www.ibm.com/software/data/db2/vse-vm/</a>
DB2 Tools	<p>One of the following locations:</p> <ul style="list-style-type: none"> <li>• Information center: <a href="http://publib.boulder.ibm.com/infocenter/imzic">http://publib.boulder.ibm.com/infocenter/imzic</a></li> <li>• Library website: <a href="http://www.ibm.com/software/data/db2imstools/library.html">http://www.ibm.com/software/data/db2imstools/library.html</a></li> </ul> <p>These resources include information about the following products and others:</p> <ul style="list-style-type: none"> <li>• DB2 Administration Tool</li> <li>• DB2 Automation Tool</li> <li>• DB2 Log Analysis Tool</li> <li>• DB2 Object Restore Tool</li> <li>• DB2 Query Management Facility</li> <li>• DB2 SQL Performance Analyzer</li> </ul>
DB2 Universal Database for iSeries®	Information center: <a href="http://www.ibm.com/systems/i/infocenter/">http://www.ibm.com/systems/i/infocenter/</a>
Debug Tool for z/OS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp">http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp</a>
Enterprise COBOL for z/OS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp">http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp</a>
Enterprise PL/I for z/OS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp">http://publib.boulder.ibm.com/infocenter/pdthelp/v1r1/index.jsp</a>
InfoSphere™ Replication Server for z/OS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/dzichelp/v2r2/topic/com.ibm.swg.im.iis.db.prod.repl.nav.doc/dochome/iiyrcnav_dochome.html">http://publib.boulder.ibm.com/infocenter/dzichelp/v2r2/topic/com.ibm.swg.im.iis.db.prod.repl.nav.doc/dochome/iiyrcnav_dochome.html</a>  This product was also known as DB2 DataPropagator, DB2 Information Integrator Replication Edition for z/OS, and WebSphere Replication Server for z/OS.
IMS	Information center: <a href="http://publib.boulder.ibm.com/infocenter/imzic">http://publib.boulder.ibm.com/infocenter/imzic</a>

*Table 180. Related product information resource locations (continued)*

Related product	Information resources
IMS Tools	<p>One of the following locations:</p> <ul style="list-style-type: none"> <li>• Information center: <a href="http://publib.boulder.ibm.com/infocenter/imzic">http://publib.boulder.ibm.com/infocenter/imzic</a></li> <li>• Library website: <a href="http://www.ibm.com/software/data/db2imstools/library.html">http://www.ibm.com/software/data/db2imstools/library.html</a></li> </ul>

	<p>The product is also known as WebSphere MQ Integrator Broker.</p>
WebSphere MQ	<p>Information center: <a href="http://publib.boulder.ibm.com/infocenter/wmqv6/v6r0/index.jsp">http://publib.boulder.ibm.com/infocenter/wmqv6/v6r0/index.jsp</a></p>
	<p>The resource includes information about MQSeries.</p>
z/Architecture®	<p>Library Center site: <a href="http://www.ibm.com/servers/eserver/zseries/zos/bkserv/">http://www.ibm.com/servers/eserver/zseries/zos/bkserv/</a></p>

*Table 180. Related product information resource locations (continued)*

Related product	Information resources
z/OS	<p>Library Center site: <a href="http://www.ibm.com/servers/eserver/zseries/zos/bkserv/">http://www.ibm.com/servers/eserver/zseries/zos/bkserv/</a></p> <p>This resource includes information about the following z/OS elements and components:</p> <ul style="list-style-type: none"> <li>• Character Data Representation Architecture</li> <li>• Device Support Facilities</li> <li>• DFSORT</li> <li>• Fortran</li> <li>• High Level Assembler</li> <li>• NetView®</li> <li>• SMP/E for z/OS</li> <li>• SNA</li> <li>• TCP/IP</li> <li>• TotalStorage Enterprise Storage Server®</li> <li>• VTAM</li> <li>• z/OS C/C++</li> <li>• z/OS Communications Server</li> <li>• z/OS DCE</li> <li>• z/OS DFSMS</li> <li>• z/OS DFSMS Access Method Services</li> <li>• z/OS DFSMSdss</li> <li>• z/OS DFSShsm</li> <li>• z/OS DFSMSdfp</li> <li>• z/OS ICSF</li> <li>• z/OS ISPF</li> <li>• z/OS JES3</li> <li>• z/OS Language Environment</li> <li>• z/OS Managed System Infrastructure</li> <li>• z/OS MVS</li> <li>• z/OS MVS JCL</li> <li>• z/OS Parallel Sysplex</li> <li>• z/OS RMF™</li> <li>• z/OS Security Server</li> <li>• z/OS UNIX System Services</li> </ul>
z/OS XL C/C++	<a href="http://www.ibm.com/software/awdtools/czos/library/">http://www.ibm.com/software/awdtools/czos/library/</a>

The following information resources from IBM are not necessarily specific to a single product:

- The DB2 for z/OS Information Roadmap; available at: <http://www.ibm.com/software/data/db2/zos/roadmap.html>
- DB2 Redbooks® and Redbooks about related products; available at: <http://www.ibm.com/redbooks>
- IBM Educational resources:
  - Information about IBM educational offerings is available on the web at: <http://www.ibm.com/software/sw-training/>

- A collection of glossaries of IBM terms in multiple languages is available on the IBM Terminology website at: <http://www.ibm.com/software/globalization/terminology/index.jsp>
- National Language Support information; available at the IBM Publications Center at: <http://www.elink.ibmlink.ibm.com/public/applications/publications/cgibin/pbi.cgi>
- *SQL Reference for Cross-Platform Development*; available at the following developerWorks® site: <http://www.ibm.com/developerworks/db2/library/techarticle/0206sqlref/0206sqlref.html>

The following information resources are not published by IBM but can be useful to users of DB2 for z/OS and related products:

- Database design topics:
  - *DB2 for z/OS and OS/390 Development for Performance Volume I*, by Gabrielle Wiorkowski, Gabrielle & Associates, ISBN 0-96684-605-2
  - *DB2 for z/OS and OS/390 Development for Performance Volume II*, by Gabrielle Wiorkowski, Gabrielle & Associates, ISBN 0-96684-606-0
  - *Handbook of Relational Database Design*, by C. Fleming and B. Von Halle, Addison Wesley, ISBN 0-20111-434-8
- Distributed Relational Database Architecture (DRDA) specifications; <http://www.opengroup.org>
- Domain Name System: *DNS and BIND*, Third Edition, Paul Albitz and Cricket Liu, O'Reilly, ISBN 0-59600-158-4
- Microsoft Open Database Connectivity (ODBC) information; <http://msdn.microsoft.com/library/>
- Unicode information; <http://www.unicode.org>

---

## How to obtain DB2 information

You can access the official information about the DB2 product in a number of ways.

- “DB2 on the web”
- “DB2 product information”
- “DB2 education” on page 2034
- “How to order the DB2 library” on page 2034

### DB2 on the web

Stay current with the latest information about DB2 by visiting the DB2 home page on the web:

<http://www.ibm.com/software/db2zos>

On the DB2 home page, you can find links to a wide variety of information resources about DB2. You can read news items that keep you informed about the latest enhancements to the product. Product announcements, press releases, fact sheets, and technical articles help you plan and implement your database management strategy.

### DB2 product information

The official DB2 for z/OS information is available in various formats and delivery methods. IBM provides mid-version updates to the information in the information center and in softcopy updates that are available on the web and on CD-ROM.

#### Information Management Software for z/OS Solutions Information Center

DB2 product information is viewable in the information center, which is the primary delivery vehicle for information about DB2 for z/OS, IMS, QMF, and related tools. This information center enables you to search across related product information in multiple languages for data management solutions for the z/OS environment and print individual topics or sets of related topics. You can also access, download, and print PDFs of the publications that are associated with the information center topics. Product technical information is provided in a format that offers more options and tools for accessing, integrating, and customizing information resources. The information center is based on Eclipse open source technology.

The Information Management Software for z/OS Solutions Information Center is viewable at the following website:

<http://publib.boulder.ibm.com/infocenter/imzic>

#### CD-ROMs and DVD

Books for DB2 are available on a CD-ROM that is included with your product shipment:

- DB2 V9.1 for z/OS Licensed Library Collection, LK3T-7195, in English

The CD-ROM contains the collection of books for DB2 V9.1 for z/OS in PDF and BookManager formats. Periodically, IBM refreshes the books on subsequent editions of this CD-ROM.

The books for DB2 for z/OS are also available on the following DVD collection kit, which contains online books for many IBM products:

- IBM z/OS Software Products DVD Collection, SK3T-4271, in English

#### **PDF format**

Many of the DB2 books are available in PDF (Portable Document Format) for viewing or printing from CD-ROM or the DB2 home page on the web or from the information center. Download the PDF books to your intranet for distribution throughout your enterprise.

#### **BookManager format**

You can use online books on CD-ROM to read, search across books, print portions of the text, and make notes in these BookManager books. Using the IBM Softcopy Reader, appropriate IBM Library Readers, or the BookManager Read product, you can view these books in the z/OS, Windows, and VM environments. You can also view and search many of the DB2 BookManager books on the web.

### **DB2 education**

IBM Education and Training offers a wide variety of classroom courses to help you quickly and efficiently gain DB2 expertise. IBM schedules classes are in cities all over the world. You can find class information, by country, at the IBM Learning Services website:

<http://www.ibm.com/services/learning>

IBM also offers classes at your location, at a time that suits your needs. IBM can customize courses to meet your exact requirements. For more information, including the current local schedule, contact your IBM representative.

### **How to order the DB2 library**

To order books, visit the IBM Publication Center on the web:

<http://www.ibm.com/shop/publications/order>

From the IBM Publication Center, you can go to the Publication Notification System (PNS). PNS users receive electronic notifications of updated publications in their profiles. You have the option of ordering the updates by using the publications direct ordering application or any other IBM publication ordering channel. The PNS application does not send automatic shipments of publications. You will receive updated publications and a bill for them if you respond to the electronic notification.

You can also order DB2 publications and CD-ROMs from your IBM representative or the IBM branch office that serves your locality. If your location is within the United States or Canada, you can place your order by calling one of the toll-free numbers:

- In the U.S., call 1-800-879-2755.
- In Canada, call 1-800-426-4968.

To order additional copies of licensed publications, specify the SOFTWARE option. To order additional publications or CD-ROMs, specify the PUBLICATIONS option. Be prepared to give your customer number, the product number, and either the feature codes or order numbers that you want.

---

## How to use the DB2 library

Titles of books in the library begin with DB2 Version 9.1 for z/OS. However, references from one book in the library to another are shortened and do not include the product name, version, and release. Instead, they point directly to the section that holds the information. The primary place to find and use information about DB2 for z/OS is the Information Management Software for z/OS Solutions Information Center (<http://publib.boulder.ibm.com/infocenter/imzic>).

If you are new to DB2 for z/OS, *Introduction to DB2 for z/OS* provides a comprehensive introduction to DB2 Version 9.1 for z/OS. Topics included in this book explain the basic concepts that are associated with relational database management systems in general, and with DB2 for z/OS in particular.

The most rewarding task associated with a database management system is asking questions of it and getting answers, the task called *end use*. Other tasks are also necessary—defining the parameters of the system, putting the data in place, and so on. The tasks that are associated with DB2 are grouped into the following major categories.

### Installation

If you are involved with installing DB2, you will need to use a variety of resources, such as:

- *DB2 Program Directory*
- *DB2 Installation Guide*
- *DB2 Administration Guide*
- *DB2 Application Programming Guide and Reference for Java*
- *DB2 Codes*
- *DB2 Internationalization Guide*
- *DB2 Messages*
- *DB2 Performance Monitoring and Tuning Guide*
- *DB2 RACF Access Control Module Guide*
- *DB2 Utility Guide and Reference*

If you will be using data sharing capabilities you also need *DB2 Data Sharing: Planning and Administration*, which describes installation considerations for data sharing.

If you will be installing and configuring DB2 ODBC, you will need *DB2 ODBC Guide and Reference*.

If you are installing IBM Spatial Support for DB2 for z/OS, you will need *IBM Spatial Support for DB2 for z/OS User's Guide and Reference*.

If you are installing IBM OmniFind® Text Search Server for DB2 for z/OS, you will need *IBM OmniFind Text Search Server for DB2 for z/OS Installation, Administration, and Reference*.

## **End use**

End users issue SQL statements to retrieve data. They can also insert, update, or delete data, with SQL statements. They might need an introduction to SQL, detailed instructions for using SPUFI, and an alphabetized reference to the types of SQL statements. This information is found in *DB2 Application Programming and SQL Guide*, and *DB2 SQL Reference*.

End users can also issue SQL statements through the DB2 Query Management Facility (QMF) or some other program, and the library for that licensed program might provide all the instruction or reference material they need.

## **Application programming**

Some users access DB2 without knowing it, using programs that contain SQL statements. DB2 application programmers write those programs. Because they write SQL statements, they need the same resources that end users do.

Application programmers also need instructions for many other topics:

- How to transfer data between DB2 and a host program—written in Java, C, or COBOL, for example
- How to prepare to compile a program that embeds SQL statements
- How to process data from two systems simultaneously, for example, DB2 and IMS or DB2 and CICS
- How to write distributed applications across operating systems
- How to write applications that use Open Database Connectivity (ODBC) to access DB2 servers
- How to write applications that use JDBC and SQLJ with the Java programming language to access DB2 servers
- How to write applications to store XML data on DB2 servers and retrieve XML data from DB2 servers.

The material needed for writing a host program containing SQL is in *DB2 Application Programming and SQL Guide*.

The material needed for writing applications that use JDBC and SQLJ to access DB2 servers is in *DB2 Application Programming Guide and Reference for Java*. The material needed for writing applications that use DB2 CLI or ODBC to access DB2 servers is in *DB2 ODBC Guide and Reference*. The material needed for working with XML data in DB2 is in *DB2 XML Guide*. For handling errors, see *DB2 Messages and DB2 Codes*.

If you are a software vendor implementing DRDA clients and servers, you will need *DB2 Reference for Remote DRDA Requesters and Servers*.

Information about writing applications across operating systems can be found in *IBM DB2 SQL Reference for Cross-Platform Development*.

## **System and database administration**

*Administration* covers almost everything else. *DB2 Administration Guide* divides some of those tasks among the following sections:

- Designing a database: Discusses the decisions that must be made when designing a database and tells how to implement the design by creating and altering DB2 objects, loading data, and adjusting to changes.
- Security and auditing: Describes ways of controlling access to the DB2 system and to data within DB2, to audit aspects of DB2 usage, and to answer other security and auditing concerns.
- Operation and recovery: Describes the steps in normal day-to-day operation and discusses the steps one should take to prepare for recovery in the event of some failure.

*DB2 Performance Monitoring and Tuning Guide* explains how to monitor the performance of the DB2 system and its parts. It also lists things that can be done to make some parts run faster.

If you will be using the RACF access control module for DB2 authorization checking, you will need *DB2 RACF Access Control Module Guide*.

If you are involved with DB2 only to design the database, or plan operational procedures, you need *DB2 Administration Guide*. If you also want to carry out your own plans by creating DB2 objects, granting privileges, running utility jobs, and so on, you also need:

- *DB2 SQL Reference*, which describes the SQL statements you use to create, alter, and drop objects and grant and revoke privileges
- *DB2 Utility Guide and Reference*, which explains how to run utilities
- *DB2 Command Reference*, which explains how to run commands

If you will be using data sharing, you need *DB2 Data Sharing: Planning and Administration*, which describes how to plan for and implement data sharing.

Additional information about system and database administration can be found in *DB2 Messages* and *DB2 Codes*, which list messages and codes issued by DB2, with explanations and suggested responses.

## Diagnosis

Diagnosticians detect and describe errors in the DB2 program. They might also recommend or apply a remedy. The documentation for this task is in *DB2 Diagnosis Guide and Reference*, *DB2 Messages*, and *DB2 Codes*.

---

## Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing  
IBM Corporation  
North Castle Drive  
Armonk, NY 10504-1785  
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

## **Programming Interface Information**

This information is intended to help you to code SQL statements. This information primarily documents General-use Programming Interface and Associated Guidance Information provided by DB2 Version 9.1 for z/OS. This information also documents Product-sensitive Programming Interface and Associated Guidance Information provided by DB2 Version 9.1 for z/OS.

## **General-use Programming Interface and Associated Guidance Information**

General-use Programming Interfaces allow the customer to write programs that obtain the services of DB2 Version 9.1 for z/OS.

General-use Programming Interface and Associated Guidance Information is identified where it occurs by the following markings:

General-use Programming Interface and Associated Guidance Information...

## **Product-sensitive Programming Interface and Associated Guidance Information**

Product-sensitive Programming Interfaces allow the customer installation to perform tasks such as diagnosing, modifying, monitoring, repairing, tailoring, or tuning of this IBM software product. Use of such interfaces creates dependencies on the detailed design or implementation of the IBM software product.

Product-sensitive Programming Interfaces should be used only for these specialized purposes. Because of their dependencies on detailed design and implementation, it is to be expected that programs written to such interfaces may need to be changed in order to run with new product releases or versions, or as a result of service.

Product-sensitive Programming Interface and Associated Guidance Information is identified where it occurs by the following markings:

 Product-sensitive Programming Interface and Associated Guidance  
Information... 

---

## **Trademarks**

IBM, the IBM logo, and ibm.com® are trademarks or registered marks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at <http://www.ibm.com/legal/copytrade.shtml>.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

---

## Glossary

<b>abend</b>	See abnormal end of task.	
<b>abend reason code</b>	A 4-byte hexadecimal code that uniquely identifies a problem with DB2.	
<b>abnormal end of task (abend)</b>	Termination of a task, job, or subsystem because of an error condition that recovery facilities cannot resolve during execution.	
<b>access method services</b>	The facility that is used to define, alter, delete, print, and reproduce VSAM key-sequenced data sets.	
<b>access path</b>	The path that is used to locate data that is specified in SQL statements. An access path can be indexed or sequential.	
<b>access path stability</b>	A characteristic of an access path that defines reliability for dynamic or static queries. Access paths are not regenerated unless there is a schema change or manual intervention.	
<b>active log</b>	The portion of the DB2 log to which log records are written as they are generated. The active log always contains the most recent log records. See also archive log.	
<b>address space</b>	A range of virtual storage pages that is identified by a number (ASID) and a collection of segment and page tables that map the virtual pages to real pages of the computer's memory.	
<b>address space connection</b>	The result of connecting an allied address space to DB2. See also allied address space and task control block.	
<b>address space identifier (ASID)</b>	A unique system-assigned identifier for an address space.	
<b>AFTER trigger</b>	A trigger that is specified to be activated after a defined trigger event (an insert, update, or delete operation on the table that is specified in a trigger definition).	
		Contrast with BEFORE trigger and INSTEAD OF trigger.
<b>agent</b>	In DB2, the structure that associates all processes that are involved in a DB2 unit of work. See also allied agent and system agent.	
<b>aggregate function</b>	An operation that derives its result by using values from one or more rows. Contrast with scalar function.	
<b>alias</b>	An alternative name that can be used in SQL statements to refer to a table or view in the same or a remote DB2 subsystem. An alias can be qualified with a schema qualifier and can thereby be referenced by other users. Contrast with synonym.	
<b>allied address space</b>	An area of storage that is external to DB2 and that is connected to DB2. An allied address space can request DB2 services. See also address space.	
<b>allied agent</b>	An agent that represents work requests that originate in allied address spaces. See also system agent.	
<b>allied thread</b>	A thread that originates at the local DB2 subsystem and that can access data at a remote DB2 subsystem.	
<b>allocated cursor</b>	A cursor that is defined for a stored procedure result set by using the SQL ALLOCATE CURSOR statement.	
<b>ambiguous cursor</b>	A database cursor for which DB2 cannot determine whether it is used for update or read-only purposes.	
<b>APAR</b>	See authorized program analysis report.	
<b>APPF</b>	See authorized program facility.	
<b>API</b>	See application programming interface.	
<b>APPL</b>	A VTAM network definition statement that is used to define DB2 to VTAM as an application program that uses SNA LU 6.2 protocols.	

<b>application</b>	A program or set of programs that performs a task; for example, a payroll application.	<b>attachment facility</b>	An interface between DB2 and TSO, IMS, CICS, or batch address spaces. An attachment facility allows application programs to access DB2.
<b>application period</b>	A pair of columns with application-maintained values that indicate the period of time when a row is valid.	<b>attribute</b>	A characteristic of an entity. For example, in database design, the phone number of an employee is an attribute of that employee.
<b>application-period temporal table</b>	A table that includes an application period.	<b>authorization ID</b>	A string that can be verified for connection to DB2 and to which a set of privileges is allowed. An authorization ID can represent an individual or an organizational group.
<b>application plan</b>	The control structure that is produced during the bind process. DB2 uses the application plan to process SQL statements that it encounters during statement execution.	<b>authorized program analysis report (APAR)</b>	A report of a problem that is caused by a suspected defect in a current release of an IBM supplied program.
<b>application process</b>	The unit to which resources and locks are allocated. An application process involves the execution of one or more programs.	<b>authorized program facility (APF)</b>	A facility that allows an installation to identify system or user programs that can use sensitive system functions.
<b>application programming interface (API)</b>	A functional interface that is supplied by the operating system or by a separately ordered licensed program that allows an application program that is written in a high-level language to use specific data or functions of the operating system or licensed program.	<b>automatic bind</b>	(More correctly <i>automatic rebind</i> .) A process by which SQL statements are bound automatically (without a user issuing a BIND command) when an application process begins execution and the bound application plan or package it requires is not valid.
<b>application requester</b>	The component on a remote system that generates DRDA requests for data on behalf of an application.	<b>automatic query rewrite</b>	A process that examines an SQL statement that refers to one or more base tables or materialized query tables, and, if appropriate, rewrites the query so that it performs better.
<b>application server</b>	The target of a request from a remote application. In the DB2 environment, the application server function is provided by the distributed data facility and is used to access DB2 data from remote applications.	<b>auxiliary index</b>	An index on an auxiliary table in which each index entry refers to a LOB or XML document.
<b>archive log</b>	The portion of the DB2 log that contains log records that have been copied from the active log. See also active log.	<b>auxiliary table</b>	A table that contains columns outside the actual table in which they are defined. Auxiliary tables can contain either LOB or XML data.
<b>ASCII</b>	An encoding scheme that is used to represent strings in many environments, typically on personal computers and workstations. Contrast with EBCDIC and Unicode.	<b>backout</b>	The process of undoing uncommitted changes that an application process made. A backout is often performed in the event
<b>ASID</b>	See address space identifier.		

of a failure on the part of an application process, or as a result of a deadlock situation.	with a CCSID. Binary string data type can be further classified as BINARY, VARBINARY, or BLOB.
<b>backward log recovery</b> The final phase of restart processing during which DB2 scans the log in a backward direction to apply UNDO log records for all aborted changes.	
<b>base table</b> A table that is created by the SQL CREATE TABLE statement and that holds persistent data. Contrast with clone table, materialized query table, result table, temporary table, and transition table.	
<b>base table space</b> A table space that contains base tables.	
<b>basic row format</b> A row format in which values for columns are stored in the row in the order in which the columns are defined by the CREATE TABLE statement. Contrast with reordered row format.	<b>bind</b> A process by which a usable control structure with SQL statements is generated; the structure is often called an access plan, an application plan, or a package. During this bind process, access paths to the data are selected, and some authorization checking is performed. See also automatic bind.
<b>basic sequential access method (BSAM)</b> An access method for storing or retrieving data blocks in a continuous sequence, using either a sequential-access or a direct-access device.	<b>bit data</b> <ul style="list-style-type: none"> <li>• Data with character type CHAR or VARCHAR that is defined with the FOR BIT DATA clause. Note that using BINARY or VARBINARY rather than FOR BIT DATA is highly recommended.</li> <li>• Data with character type CHAR or VARCHAR that is defined with the FOR BIT DATA clause.</li> <li>• A form of character data. Binary data is generally more highly recommended than character-for-bit data.</li> </ul>
<b>BEFORE trigger</b> A trigger that is specified to be activated before a defined trigger event (an insert, an update, or a delete operation on the table that is specified in a trigger definition). Contrast with AFTER trigger and INSTEAD OF trigger.	<b>bitemporal table</b> A table that is both a system-period temporal table and an application-period temporal table.
<b>begin column</b> In a system period or an application period, the column that indicates the beginning of the period.	<b>BLOB</b> See binary large object.
<b>binary large object (BLOB)</b> A binary string data type that contains a sequence of bytes that can range in size from 0 bytes to 2 GB, less 1 byte. This string does not have an associated code page and character set. BLOBs can contain, for example, image, audio, or video data. In general, BLOB values are used whenever a binary string might exceed the limits of the VARBINARY type.	<b>block fetch</b> A capability in which DB2 can retrieve, or fetch, a large set of rows together. Using block fetch can significantly reduce the number of messages that are being sent across the network. Block fetch applies only to non-rowset cursors that do not update data.
<b>binary string</b> A sequence of bytes that is not associated	<b>bootstrap data set (BSDS)</b> A VSAM data set that contains name and status information for DB2 and RBA range specifications for all active and archive log data sets. The BSDS also contains passwords for the DB2 directory and catalog, and lists of conditional restart and checkpoint records.
	<b>BSAM</b> See basic sequential access method.

<b>BSDS</b>	See bootstrap data set.
<b>buffer pool</b>	An area of memory into which data pages are read, modified, and held during processing.
<b>built-in data type</b>	A data type that IBM supplies. Among the built-in data types for DB2 for z/OS are string, numeric, XML, ROWID, and datetime. Contrast with distinct type.
<b>built-in function</b>	A function that is generated by DB2 and that is in the SYSIBM schema. Contrast with user-defined function. See also function, cast function, external function, sourced function, and SQL function.
<b>business dimension</b>	A category of data, such as products or time periods, that an organization might want to analyze.
<b>cache structure</b>	A coupling facility structure that stores data that can be available to all members of a Sysplex. A DB2 data sharing group uses cache structures as group buffer pools.
<b>CAF</b>	See call attachment facility.
<b>call attachment facility (CAF)</b>	A DB2 attachment facility for application programs that run in TSO or z/OS batch. The CAF is an alternative to the DSN command processor and provides greater control over the execution environment. Contrast with Recoverable Resource Manager Services attachment facility.
<b>call-level interface (CLI)</b>	A callable application programming interface (API) for database access, which is an alternative to using embedded SQL.
<b>cascade delete</b>	A process by which DB2 enforces referential constraints by deleting all descendent rows of a deleted parent row.
<b>CASE expression</b>	An expression that is selected based on the evaluation of one or more conditions.
<b>cast function</b>	A function that is used to convert instances of a (source) data type into instances of a different (target) data type.
<b>castout</b>	The DB2 process of writing changed pages from a group buffer pool to disk.
<b>castout owner</b>	The DB2 member that is responsible for casting out a particular page set or partition.
<b>catalog</b>	In DB2, a collection of tables that contains descriptions of objects such as tables, views, and indexes.
<b>catalog table</b>	Any table in the DB2 catalog.
<b>CCSID</b>	See coded character set identifier.
<b>CDB</b>	See communications database.
<b>CDRA</b>	See Character Data Representation Architecture.
<b>CEC</b>	See central processor complex.
<b>central electronic complex (CEC)</b>	See central processor complex.
<b>central processor complex (CPC)</b>	A physical collection of hardware that consists of main storage, one or more central processors, timers, and channels.
<b>central processor (CP)</b>	The part of the computer that contains the sequencing and processing facilities for instruction execution, initial program load, and other machine operations.
<b>CFRM</b>	See coupling facility resource management.
<b>CFRM policy</b>	The allocation rules for a coupling facility structure that are declared by a z/OS administrator.
<b>character conversion</b>	The process of changing characters from one encoding scheme to another.
<b>Character Data Representation Architecture (CDRA)</b>	An architecture that is used to achieve consistent representation, processing, and interchange of string data.
<b>character large object (CLOB)</b>	A character string data type that contains a sequence of bytes that represent

characters (single-byte, multibyte, or both) that can range in size from 0 bytes to 2 GB, less 1 byte. In general, CLOB values are used whenever a character string might exceed the limits of the VARCHAR type.

#### **character set**

A defined set of characters.

#### **character string**

A sequence of bytes that represent bit data, single-byte characters, or a mixture of single-byte and multibyte characters. Character data can be further classified as CHARACTER, VARCHAR, or CLOB.

#### **check constraint**

A user-defined constraint that specifies the values that specific columns of a base table can contain.

#### **check integrity**

The condition that exists when each row in a table conforms to the check constraints that are defined on that table.

#### **check pending**

A state of a table space or partition that prevents its use by some utilities and by some SQL statements because of rows that violate referential constraints, check constraints, or both.

#### **checkpoint**

A point at which DB2 records status information on the DB2 log; the recovery process uses this information if DB2 abnormally terminates.

#### **child lock**

For explicit hierarchical locking, a lock that is held on either a table, page, row, or a large object (LOB). Each child lock has a parent lock. See also parent lock.

#### **CI**

See control interval.

#### **CICS**

Represents (in this information): CICS Transaction Server for z/OS: Customer Information Control System Transaction Server for z/OS.

#### **CICS attachment facility**

A facility that provides a multithread connection to DB2 to allow applications that run in the CICS environment to execute DB2 statements.

#### **claim**

A notification to DB2 that an object is being accessed. Claims prevent drains

from occurring until the claim is released, which usually occurs at a commit point. Contrast with drain.

#### **claim class**

A specific type of object access that can be one of the following isolation levels:

- Cursor stability (CS)
- Repeatable read (RR)
- Write

#### **class of service**

A VTAM term for a list of routes through a network, arranged in an order of preference for their use.

#### **clause**

In SQL, a distinct part of a statement, such as a SELECT clause or a WHERE clause.

#### **CLI**

See call-level interface.

#### **client**

See requester.

#### **CLOB**

See character large object.

#### **clone object**

An object that is associated with a clone table, including the clone table itself and check constraints, indexes, and BEFORE triggers on the clone table.

#### **clone table**

A table that is structurally identical to a base table. The base and clone table each have separate underlying VSAM data sets, which are identified by their data set instance numbers. Contrast with base table.

#### **closed application**

An application that requires exclusive use of certain statements on certain DB2 objects, so that the objects are managed solely through the external interface of that application.

#### **clustering index**

An index that determines how rows are physically ordered (*clustered*) in a table space. If a clustering index on a partitioned table is not a partitioning index, the rows are ordered in cluster sequence within each data partition instead of spanning partitions.

#### **CM**

See conversion mode.

#### **CM\***

See conversion mode\*.

**C++ member**

A data object or function in a structure, union, or class.

**C++ member function**

An operator or function that is declared as a member of a class. A member function has access to the private and protected data members and to the member functions of objects in its class. Member functions are also called methods.

**C++ object**

A region of storage. An object is created when a variable is defined or a new function is invoked.

An instance of a class.

**coded character set**

A set of unambiguous rules that establish a character set and the one-to-one relationships between the characters of the set and their coded representations.

**coded character set identifier (CCSID)**

A 16-bit number that uniquely identifies a coded representation of graphic characters. It designates an encoding scheme identifier and one or more pairs that consist of a character set identifier and an associated code page identifier.

**code page**

A set of assignments of characters to code points. Within a code page, each code point has only one specific meaning. In EBCDIC, for example, the character *A* is assigned code point X'C1', and character *B* is assigned code point X'C2'.

**code point**

In CDRA, a unique bit pattern that represents a character in a code page.

**code unit**

The fundamental binary width in a computer architecture that is used for representing character data, such as 7 bits, 8 bits, 16 bits, or 32 bits. Depending on the character encoding form that is used, each code point in a coded character set can be represented by one or more code units.

**coexistence**

During migration, the period of time in which two releases exist in the same data sharing group.

**cold start**

A process by which DB2 restarts without processing any log records. Contrast with warm start.

**collection**

A group of packages that have the same qualifier.

**column**

The vertical component of a table. A column has a name and a particular data type (for example, character, decimal, or integer).

**column function**

See aggregate function.

**"come from" checking**

An LU 6.2 security option that defines a list of authorization IDs that are allowed to connect to DB2 from a partner LU.

**command**

A DB2 operator command or a DSN subcommand. A command is distinct from an SQL statement.

**command prefix**

A 1- to 8-character command identifier. The command prefix distinguishes the command as belonging to an application or subsystem rather than to z/OS.

**command recognition character (CRC)**

A character that permits a z/OS console operator or an IMS subsystem user to route DB2 commands to specific DB2 subsystems.

**command scope**

The scope of command operation in a data sharing group.

**commit**

The operation that ends a unit of work by releasing locks so that the database changes that are made by that unit of work can be perceived by other processes. Contrast with rollback.

**commit point**

A point in time when data is considered consistent.

**common service area (CSA)**

In z/OS, a part of the common area that contains data areas that are addressable by all address spaces. Most DB2 use is in the extended CSA, which is above the 16-MB line.

<b>communications database (CDB)</b>	A set of tables in the DB2 catalog that are used to establish conversations with remote database management systems.
<b>comparison operator</b>	A token (such as =, >, or <) that is used to specify a relationship between two values.
<b>compatibility mode</b>	See conversion mode.
<b>compatibility mode* (CM*)</b>	See conversion mode*.
<b>composite key</b>	An ordered set of key columns or expressions of the same table.
<b>compression dictionary</b>	The dictionary that controls the process of compression and decompression. This dictionary is created from the data in the table space or table space partition.
<b>concurrency</b>	The shared use of resources by more than one application process at the same time.
<b>conditional restart</b>	A DB2 restart that is directed by a user-defined conditional restart control record (CRCR).
<b>connection</b>	In SNA, the existence of a communication path between two partner LUs that allows information to be exchanged (for example, two DB2 subsystems that are connected and communicating by way of a conversation).
<b>connection context</b>	In SQLJ, a Java object that represents a connection to a data source.
<b>connection declaration clause</b>	In SQLJ, a statement that declares a connection to a data source.
<b>connection handle</b>	The data object containing information that is associated with a connection that DB2 ODBC manages. This includes general status information, transaction status, and diagnostic information.
<b>connection ID</b>	An identifier that is supplied by the attachment facility and that is associated with a specific address space connection.
<b>consistency token</b>	A timestamp that is used to generate the version identifier for an application. See also version.
<b>constant</b>	A language element that specifies an unchanging value. Constants are classified as string constants or numeric constants. Contrast with variable.
<b>constraint</b>	A rule that limits the values that can be inserted, deleted, or updated in a table. See referential constraint, check constraint, and unique constraint.
<b>context</b>	An application's logical connection to the data source and associated DB2 ODBC connection information that allows the application to direct its operations to a data source. A DB2 ODBC context represents a DB2 thread.
<b>contracting conversion</b>	A process that occurs when the length of a converted string is smaller than that of the source string. For example, this process occurs when an EBCDIC mixed-data string that contains DBCS characters is converted to ASCII mixed data; the converted string is shorter because the shift codes are removed.
<b>control interval (CI)</b>	<ul style="list-style-type: none"> <li>• A unit of information that VSAM transfers between virtual and auxiliary storage.</li> <li>• In a key-sequenced data set or file, the set of records that an entry in the sequence-set index record points to.</li> </ul>
<b>conversation</b>	Communication, which is based on LU 6.2 or Advanced Program-to-Program Communication (APPC), between an application and a remote transaction program over an SNA logical unit-to-logical unit (LU-LU) session that allows communication while processing a transaction.
<b>conversion mode* (CM*)</b>	A stage of the version-to-version migration process that applies to a DB2 subsystem or data sharing group that was in enabling-new-function mode (ENFM), enabling-new-function mode* (ENFM*), or

new-function mode (NFM) at one time. Fallback to a prior version is not supported. When in conversion mode\*, a DB2 data sharing group cannot coexist with members that are still at the prior version level. Contrast with conversion mode, enabling-new-function mode, enabling-new-function mode\*, and new-function mode.

Previously known as compatibility mode\* (CM\*).

#### **conversion mode (CM)**

The first stage of the version-to-version migration process. In a DB2 data sharing group, members in conversion mode can coexist with members that are still at the prior version level. Fallback to the prior version is also supported. When in conversion mode, the DB2 subsystem cannot use most new functions of the new version. Contrast with conversion mode\*, enabling-new-function mode, enabling-new-function mode\*, and new-function mode.

Previously known as compatibility mode (CM).

#### **coordinator**

The system component that coordinates the commit or rollback of a unit of work that includes work that is done on one or more other systems.

#### **coprocessor**

See SQL statement coprocessor.

#### **copy pool**

A collection of names of storage groups that are processed collectively for fast replication operations.

#### **copy target**

A named set of SMS storage groups that are to be used as containers for copy pool volume copies. A copy target is an SMS construct that lets you define which storage groups are to be used as containers for volumes that are copied by using FlashCopy functions.

#### **copy version**

A point-in-time FlashCopy copy that is managed by HSM. Each copy pool has a version parameter that specifies the number of copy versions to be maintained on disk.

#### **correlated columns**

A relationship between the value of one column and the value of another column.

#### **correlated subquery**

A subquery (part of a WHERE or HAVING clause) that is applied to a row or group of rows of a table or view that is named in an outer subselect statement.

#### **correlation ID**

An identifier that is associated with a specific thread. In TSO, it is either an authorization ID or the job name.

#### **correlation name**

An identifier that is specified and used within a single SQL statement as the exposed name for objects such as a table, view, table function reference, nested table expression, or result of a data change statement. Correlation names are useful in an SQL statement to allow two distinct references to the same base table and to allow an alternative name to be used to represent an object.

#### **cost category**

A category into which DB2 places cost estimates for SQL statements at the time the statement is bound. The cost category is externalized in the COST\_CATEGORY column of the DSN\_STATEMENT\_TABLE when a statement is explained.

#### **coupling facility**

A special PR/SM logical partition (LPAR) that runs the coupling facility control program and provides high-speed caching, list processing, and locking functions in a Parallel Sysplex.

#### **coupling facility resource management (CFRM)**

A component of z/OS that provides the services to manage coupling facility resources in a Parallel Sysplex. This management includes the enforcement of CFRM policies to ensure that the coupling facility and structure requirements are satisfied.

**CP** See central processor.

**CPC** See central processor complex.

**CRC** See command recognition character.

#### **created temporary table**

A persistent table that holds temporary data and is defined with the SQL statement CREATE GLOBAL

**TEMPORARY TABLE.** Information about created temporary tables is stored in the DB2 catalog and can be shared across application processes. Contrast with declared temporary table. See also temporary table.

**cross-system coupling facility (XCF)**

A component of z/OS that provides functions to support cooperation between authorized programs that run within a Sysplex.

**cross-system extended services (XES)**

A set of z/OS services that allow multiple instances of an application or subsystem, running on different systems in a Sysplex environment, to implement high-performance, high-availability data sharing by using a coupling facility.

**CS** See cursor stability.

**CSA** See common service area.

**CT** See cursor table.

**current data**

Data within a host structure that is current with (identical to) the data within the base table.

**current status rebuild**

The second phase of restart processing during which the status of the subsystem is reconstructed from information on the log.

**cursor** A control structure that an application program uses to point to a single row or multiple rows within some ordered set of rows of a result table. A cursor can be used to retrieve, update, or delete rows from a result table.

**cursor sensitivity**

The degree to which database updates are visible to the subsequent FETCH statements in a cursor.

**cursor stability (CS)**

The isolation level that provides maximum concurrency without the ability to read uncommitted data. With cursor stability, a unit of work holds locks only on its uncommitted changes and on the current row of each of its cursors. See also read stability, repeatable read, and uncommitted read.

**cursor table (CT)**

The internal representation of a cursor.

**cycle** A set of tables that can be ordered so that each table is a descendent of the one before it, and the first table is a descendent of the last table. A self-referencing table is a cycle with a single member. See also referential cycle.

**database**

A collection of tables, or a collection of table spaces and index spaces.

**database access thread (DBAT)**

A thread that accesses data at the local subsystem on behalf of a remote subsystem.

**database administrator (DBA)**

An individual who is responsible for designing, developing, operating, safeguarding, maintaining, and using a database.

**database alias**

The name of the target server if it is different from the location name. The database alias is used to provide the name of the database server as it is known to the network.

**database descriptor (DBD)**

An internal representation of a DB2 database definition, which reflects the data definition that is in the DB2 catalog. The objects that are defined in a database descriptor are table spaces, tables, indexes, index spaces, relationships, check constraints, and triggers. A DBD also contains information about accessing tables in the database.

**database exception status**

In a data sharing environment, an indication that something is wrong with a database.

**database identifier (DBID)**

An internal identifier of the database.

**database management system (DBMS)**

A software system that controls the creation, organization, and modification of a database and the access to the data that is stored within it.

**database request module (DBRM)**

A data set member that is created by the DB2 precompiler and that contains

information about SQL statements.  
DBRMs are used in the bind process.

#### **database server**

The target of a request from a local application or a remote intermediate database server.

#### **data currency**

The state in which the data that is retrieved into a host variable in a program is a copy of the data in the base table.

#### **data-dependent pagination**

The process used when applications need to access part of a DB2 result set that is based on a logical key value.

#### **data dictionary**

A repository of information about an organization's application programs, databases, logical data models, users, and authorizations.

#### **data partition**

A VSAM data set that is contained within a partitioned table space.

#### **data-partitioned secondary index (DPSI)**

A secondary index that is partitioned according to the underlying data.  
Contrast with nonpartitioned secondary index.

#### **| data set instance number**

A number that indicates the data set that contains the data for an object.

#### **data sharing**

A function of DB2 for z/OS that enables applications on different DB2 subsystems to read from and write to the same data concurrently.

#### **data sharing group**

A collection of one or more DB2 subsystems that directly access and change the same data while maintaining data integrity.

#### **data sharing member**

A DB2 subsystem that is assigned by XCF services to a data sharing group.

#### **data source**

A local or remote relational or non-relational data manager that is capable of supporting data access via an ODBC driver that supports the ODBC

APIs. In the case of DB2 for z/OS, the data sources are always relational database managers.

#### **data type**

An attribute of columns, constants, variables, parameters, special registers, and the results of functions and expressions.

#### **data warehouse**

A system that provides critical business information to an organization. The data warehouse system cleanses the data for accuracy and currency, and then presents the data to decision makers so that they can interpret and use it effectively and efficiently.

**DBA** See database administrator.

**DBAT** See database access thread.

#### **DB2 catalog**

A collection of tables that are maintained by DB2 and contain descriptions of DB2 objects, such as tables, views, and indexes.

#### **DBCLOB**

See double-byte character large object.

#### **DB2 command**

An instruction to the DB2 subsystem that a user enters to start or stop DB2, to display information on current users, to start or stop databases, to display information on the status of databases, and so on.

**DBCS** See double-byte character set.

**DBD** See database descriptor.

**DB2I** See DB2 Interactive.

**DBID** See database identifier.

#### **DB2 Interactive (DB2I)**

An interactive service within DB2 that facilitates the execution of SQL statements, DB2 (operator) commands, and programmer commands, and the invocation of utilities.

#### **DBMS**

See database management system.

#### **DBRM**

See database request module.

#### **DB2 thread**

The database manager structure that

describes an application's connection, traces its progress, processes resource functions, and delimits its accessibility to the database manager resources and services. Most DB2 for z/OS functions execute under a thread structure.

#### DCLGEN

See declarations generator.

#### DDF

See distributed data facility.

#### deadlock

Unresolved contention for the use of a resource, such as a table or an index.

#### declarations generator (DCLGEN)

A subcomponent of DB2 that generates SQL table declarations and COBOL, C, or PL/I data structure declarations that conform to the table. The declarations are generated from DB2 system catalog information.

#### declared temporary table

A non-persistent table that holds temporary data and is defined with the SQL statement DECLARE GLOBAL TEMPORARY TABLE. Information about declared temporary tables is not stored in the DB2 catalog and can be used only by the application process that issued the DECLARE statement. Contrast with created temporary table. See also temporary table.

#### default value

A predetermined value, attribute, or option that is assumed when no other value is specified. A default value can be defined for column data in DB2 tables by specifying the DEFAULT keyword in an SQL statement that changes data (such as INSERT, UPDATE, and MERGE).

#### deferred embedded SQL

SQL statements that are neither fully static nor fully dynamic. These statements are embedded within an application and are prepared during the execution of the application.

#### deferred write

The process of asynchronously writing changed data pages to disk.

#### degree of parallelism

The number of concurrently executed operations that are initiated to process a query.

#### delete hole

The location on which a cursor is positioned when a row in a result table is refetched and the row no longer exists on the base table. See also update hole.

#### delete rule

The rule that tells DB2 what to do to a dependent row when a parent row is deleted. Delete rules include CASCADE, RESTRICT, SET NULL, or NO ACTION.

#### delete trigger

A trigger that is defined with the triggering delete SQL operation.

#### delimited identifier

A sequence of one or more characters enclosed by escape characters, such as quotation marks ("").

#### delimiter token

A string constant, a delimited identifier, an operator symbol, or any of the special characters that are shown in DB2 syntax diagrams.

#### denormalization

The intentional duplication of columns in multiple tables to increase data redundancy. Denormalization is sometimes necessary to minimize performance problems. Contrast with normalization.

#### dependent

An object (row, table, or table space) that has at least one parent. The object is also said to be a dependent (row, table, or table space) of its parent. See also parent row, parent table, and parent table space.

#### dependent row

A row that contains a foreign key that matches the value of a primary key in the parent row.

#### dependent table

A table that is a dependent in at least one referential constraint.

#### descendent

An object that is a dependent of an object or is the dependent of a descendent of an object.

#### descendent row

A row that is dependent on another row, or a row that is a descendent of a dependent row.

**descendent table**

A table that is a dependent of another table, or a table that is a descendent of a dependent table.

**deterministic function**

A user-defined function whose result is dependent on the values of the input arguments. That is, successive invocations with the same input values produce the same answer. Sometimes referred to as a *not-variant* function. Contrast with nondeterministic function (sometimes called a *variant function*).

**dimension**

A data category such as time, products, or markets. The elements of a dimension are referred to as members. See also dimension table.

**dimension table**

The representation of a dimension in a star schema. Each row in a dimension table represents all of the attributes for a particular member of the dimension. See also dimension, star schema, and star join.

**directory**

The DB2 system database that contains internal objects such as database descriptors and skeleton cursor tables.

**disk** A direct-access storage device that records data magnetically.

**distinct type**

A user-defined data type that is represented as an existing type (its source type), but is considered to be a separate and incompatible type for semantic purposes.

**distributed data**

Data that resides on a DBMS other than the local system.

**distributed data facility (DDF)**

A set of DB2 components through which DB2 communicates with another relational database management system.

**Distributed Relational Database Architecture (DRDA)**

A connection protocol for distributed relational database processing that is used by IBM relational database products. DRDA includes protocols for communication between an application and a remote relational database

management system, and for communication between relational database management systems. See also DRDA access.

**DNS** See domain name server.

**DOCID**

See document ID.

**document ID**

A value that uniquely identifies a row that contains an XML column. This value is stored with the row and never changes.

**domain**

The set of valid values for an attribute.

**domain name**

The name by which TCP/IP applications refer to a TCP/IP host within a TCP/IP network.

**domain name server (DNS)**

A special TCP/IP network server that manages a distributed directory that is used to map TCP/IP host names to IP addresses.

**double-byte character large object (DBCLOB)**

A graphic string data type in which a sequence of bytes represent double-byte characters that range in size from 0 bytes to 2 GB, less 1 byte. In general, DBCLOB values are used whenever a double-byte character string might exceed the limits of the VARGRAPHIC type.

**double-byte character set (DBCS)**

A set of characters, which are used by national languages such as Japanese and Chinese, that have more symbols than can be represented by a single byte. Each character is 2 bytes in length. Contrast with single-byte character set and multibyte character set.

**double-precision floating point number**

A 64-bit approximate representation of a real number.

**DPSI** See data-partitioned secondary index.

**drain** The act of acquiring a locked resource by quiescing access to that object. Contrast with claim.

**drain lock**

A lock on a claim class that prevents a claim from occurring.

<b>DRDA</b>	See Distributed Relational Database Architecture.	version-to-version migration process that applies to a DB2 subsystem or data sharing group that was in new-function mode (NFM) at one time. When in enabling-new-function mode*, a DB2 subsystem or data sharing group is preparing to use the new functions of the new version but cannot yet use them. A data sharing group that is in enabling-new-function mode* cannot coexist with members that are still at the prior version level. Fallback to a prior version is not supported. Contrast with conversion mode, conversion mode*, enabling-new-function mode, and new-function mode.
<b>DRDA access</b>	An open method of accessing distributed data that you can use to connect to another database server to execute packages that were previously bound at the server location.	
<b>DSN</b>	<ul style="list-style-type: none"> <li>The default DB2 subsystem name.</li> <li>The name of the TSO command processor of DB2.</li> <li>The first three characters of DB2 module and macro names.</li> </ul>	
<b>dynamic cursor</b>	A named control structure that an application program uses to change the size of the result table and the order of its rows after the cursor is opened. Contrast with static cursor.	
<b>dynamic dump</b>	A dump that is issued during the execution of a program, usually under the control of that program.	
<b>dynamic SQL</b>	SQL statements that are prepared and executed at run time. In dynamic SQL, the SQL statement is contained as a character string in a host variable or as a constant, and it is not precompiled.	
<b>EA-enabled table space</b>	A table space or index space that is enabled for extended addressability and that contains individual partitions (or pieces, for LOB table spaces) that are greater than 4 GB.	
<b>EB</b>	See exabyte.	
<b>EBCDIC</b>	Extended binary coded decimal interchange code. An encoding scheme that is used to represent character data in the z/OS, VM, VSE, and iSeries environments. Contrast with ASCII and Unicode.	
<b>embedded SQL</b>	SQL statements that are coded within an application program. See static SQL.	
<b>enabling-new-function mode* (ENFM*)</b>	A transitional stage of the	
		enabling-new-function mode (ENFM)
		A transitional stage of the version-to-version migration process during which the DB2 subsystem or data sharing group is preparing to use the new functions of the new version. When in enabling-new-function mode, a DB2 data sharing group cannot coexist with members that are still at the prior version level. Fallback to a prior version is not supported, and most new functions of the new version are not available for use in enabling-new-function mode. Contrast with conversion mode, conversion mode*, enabling-new-function mode*, and new-function mode.
		<b>enclave</b>
		In Language Environment , an independent collection of routines, one of which is designated as the main routine. An enclave is similar to a program or run unit. See also WLM enclave.
		<b>encoding scheme</b>
		A set of rules to represent character data (ASCII, EBCDIC, or Unicode).
		<b>end column</b>
		In a system period or an application period, the column that indicates the end of the period.
	<b>ENFM</b>	See enabling-new-function mode.
	<b>ENFM*</b>	See enabling-new-function mode*.
	<b>entity</b>	A person, object, or concept about which information is stored. In a relational database, entities are represented as tables. A database includes information

about the entities in an organization or business, and their relationships to each other.

#### enumerated list

A set of DB2 objects that are defined with a LISTDEF utility control statement in which pattern-matching characters (\*, %;, \_ or ?) are not used.

#### environment

A collection of names of logical and physical resources that are used to support the performance of a function.

#### environment handle

A handle that identifies the global context for database access. All data that is pertinent to all objects in the environment is associated with this handle.

#### equijoin

A join operation in which the join-condition has the form *expression = expression*. See also join, full outer join, inner join, left outer join, outer join, and right outer join.

#### error page range

A range of pages that are considered to be physically damaged. DB2 does not allow users to access any pages that fall within this range.

#### escape character

The symbol, a double quotation ("") for example, that is used to enclose an SQL delimited identifier.

#### exabyte

A unit of measure for processor, real and virtual storage capacities, and channel volume that has a value of 1 152 921 504 606 846 976 bytes or  $2^{60}$ .

#### exception

An SQL operation that involves the EXCEPT set operator, which combines two result tables. The result of an exception operation consists of all of the rows that are in only one of the result tables.

#### exception table

A table that holds rows that violate referential constraints or check constraints that the CHECK DATA utility finds.

#### exclusive lock

A lock that prevents concurrently

executing application processes from reading or changing data. Contrast with share lock.

#### executable statement

An SQL statement that can be embedded in an application program, dynamically prepared and executed, or issued interactively.

#### execution context

In SQLJ, a Java object that can be used to control the execution of SQL statements.

#### exit routine

A user-written (or IBM-provided default) program that receives control from DB2 to perform specific functions. Exit routines run as extensions of DB2.

#### expanding conversion

A process that occurs when the length of a converted string is greater than that of the source string. For example, this process occurs when an ASCII mixed-data string that contains DBCS characters is converted to an EBCDIC mixed-data string; the converted string is longer because shift codes are added.

#### explicit hierarchical locking

Locking that is used to make the parent-child relationship between resources known to IRLM. This kind of locking avoids global locking overhead when no inter-DB2 interest exists on a resource.

#### explicit privilege

A privilege that has a name and is held as the result of an SQL GRANT statement and revoked as the result of an SQL REVOKE statement. For example, the SELECT privilege.

#### exposed name

A correlation name or a table or view name for which a correlation name is not specified.

#### expression

An operand or a collection of operators and operands that yields a single value.

#### Extended Recovery Facility (XRF)

A facility that minimizes the effect of failures in z/OS, VTAM, the host processor, or high-availability applications during sessions between high-availability applications and designated terminals.

This facility provides an alternative subsystem to take over sessions from the failing subsystem.

#### **Extensible Markup Language (XML)**

A standard metalanguage for defining markup languages that is a subset of Standardized General Markup Language (SGML).

#### **external function**

A function that has its functional logic implemented in a programming language application that resides outside the database, in the file system of the database server. The association of the function with the external code application is specified by the EXTERNAL clause in the CREATE FUNCTION statement. External functions can be classified as external scalar functions and external table functions. Contrast with sourced function, built-in function, and SQL function.

#### **external procedure**

A procedure that has its procedural logic implemented in an external programming language application. The association of the procedure with the external application is specified by a CREATE PROCEDURE statement with a LANGUAGE clause that has a value other than SQL and an EXTERNAL clause that implicitly or explicitly specifies the name of the external application. Contrast with external SQL procedure and native SQL procedure.

#### **external routine**

A user-defined function or stored procedure that is based on code that is written in an external programming language.

#### **external SQL procedure**

An SQL procedure that is processed using a generated C program that is a representation of the procedure. When an external SQL procedure is called, the C program representation of the procedure is executed in a stored procedures address space. Contrast with external procedure and native SQL procedure.

#### **failed member state**

A state of a member of a data sharing group in which the member's task,

address space, or z/OS system terminates before the state changes from active to quiesced.

#### **fallback**

The process of returning to a previous release of DB2 after attempting or completing migration to a current release. Fallback is supported only from a subsystem that is in conversion mode.

#### **false global lock contention**

A contention indication from the coupling facility that occurs when multiple lock names are hashed to the same indicator and when no real contention exists.

#### **fan set**

A direct physical access path to data, which is provided by an index, hash, or link; a fan set is the means by which DB2 supports the ordering of data.

#### **federated database**

The combination of a DB2 server (in Linux, UNIX, and Windows environments) and multiple data sources to which the server sends queries. In a federated database system, a client application can use a single SQL statement to join data that is distributed across multiple database management systems and can view the data as if it were local.

#### **fetch orientation**

The specification of the desired placement of the cursor as part of a FETCH statement. The specification can be before or after the rows of the result table (with BEFORE or AFTER). The specification can also have either a single-row fetch orientation (for example, NEXT, LAST, or ABSOLUTE *n*) or a rowset fetch orientation (for example, NEXT ROWSET, LAST ROWSET, or ROWSET STARTING AT ABSOLUTE *n*).

#### **field procedure**

A user-written exit routine that is designed to receive a single value and transform (encode or decode) it in any way the user can specify.

#### **file reference variable**

A host variable that is declared with one of the derived data types (BLOB\_FILE, CLOB\_FILE, DBCLOB\_FILE); file

	reference variables direct the reading of a LOB from a file or the writing of a LOB into a file.		result of the fullselect is the result of the specified subselect or fullselect.
	<b>filter factor</b>		<b>fully escaped mapping</b>
	A number between zero and one that estimates the proportion of rows in a table for which a predicate is true.		A mapping from an SQL identifier to an XML name when the SQL identifier is a column name.
	<b>fixed-length string</b>		<b>function</b>
	A character, graphic, or binary string whose length is specified and cannot be changed. Contrast with varying-length string.		A mapping, which is embodied as a program (the function body) that can be invoked by means of zero or more input values (arguments) to a single value (the result). See also aggregate function and scalar function.
	<b>FlashCopy</b>		Functions can be user-defined, built-in, or generated by DB2. (See also built-in function, cast function, external function, sourced function, SQL function, and user-defined function.)
	A function on the IBM Enterprise Storage Server that can, in conjunction with the BACKUP SYSTEM utility, create a point-in-time copy of data while an application is running.		<b>function definer</b>
	<b>foreign key</b>		The authorization ID of the owner of the schema of the function that is specified in the CREATE FUNCTION statement.
	A column or set of columns in a dependent table of a constraint relationship. The key must have the same number of columns, with the same descriptions, as the primary key of the parent table. Each foreign key value must either match a parent key value in the related parent table or be null.		<b>function package</b>
	<b>forest</b>	An ordered set of subtrees of XML nodes.	A package that results from binding the DBRM for a function program.
	<b>forward log recovery</b>		<b>function package owner</b>
	The third phase of restart processing during which DB2 processes the log in a forward direction to apply all REDO log records.		The authorization ID of the user who binds the function program's DBRM into a function package.
	<b>free space</b>		<b>function signature</b>
	The total amount of unused space in a page; that is, the space that is not used to store records or control information is free space.		The logical concatenation of a fully qualified function name with the data types of all of its parameters.
	<b>full outer join</b>		<b>GB</b>
	The result of a join operation that includes the matched rows of both tables that are being joined and preserves the unmatched rows of both tables. See also join, equijoin, inner join, left outer join, outer join, and right outer join.		Gigabyte. A value of (1 073 741 824 bytes).
	<b>fullselect</b>		<b>GBP</b>
	A subselect, a fullselect in parentheses, or a number of both that are combined by set operators. Fullselect specifies a result table. If a set operator is not used, the		See group buffer pool.
			<b>GBP-dependent</b>
			The status of a page set or page set partition that is dependent on the group buffer pool. Either read/write interest is active among DB2 subsystems for this page set, or the page set has changed pages in the group buffer pool that have not yet been cast out to disk.
			<b>generalized trace facility (GTF)</b>
			A z/OS service program that records significant system events such as I/O interrupts, SVC interrupts, program interrupts, or external interrupts.
			<b>generic resource name</b>
			A name that VTAM uses to represent

	<p>several application programs that provide the same function in order to handle session distribution and balancing in a Sysplex environment.</p>		<p>which is established when the first member migrates to a new release.</p>
<b>getpage</b>	An operation in which DB2 accesses a data page.	<b>group name</b>	The z/OS XCF identifier for a data sharing group.
<b>global lock</b>	A lock that provides concurrency control within and among DB2 subsystems. The scope of the lock is across all DB2 subsystems of a data sharing group.	<b>group restart</b>	A restart of at least one member of a data sharing group after the loss of either locks or the shared communications area.
<b>global lock contention</b>	Conflicts on locking requests between different DB2 members of a data sharing group when those members are trying to serialize shared resources.	<b>GTF</b>	See generalized trace facility.
<b>governor</b>	See resource limit facility.	<b>handle</b>	In DB2 ODBC, a variable that refers to a data structure and associated resources. See also statement handle, connection handle, and environment handle.
<b>graphic string</b>	A sequence of DBCS characters. Graphic data can be further classified as GRAPHIC, VARGRAPHIC, or DBCLOB.	<b>hash access</b>	Access to a table using the hash value of a key that is defined by the <i>organization-clause</i> of a CREATE TABLE statement or ALTER TABLE statement.
<b>GRECP</b>	See group buffer pool recovery pending.	<b>hash overflow index</b>	A DB2 index used to track data rows that do not fit into the fixed hash space, and therefore, reside in the hash overflow space. DB2 accesses the hash overflow index to fetch rows from the hash overflow area.
<b>gross lock</b>	The <i>shared</i> , <i>update</i> , or <i>exclusive</i> mode locks on a table, partition, or table space.	<b>help panel</b>	A screen of information that presents tutorial text to assist a user at the workstation or terminal.
<b>group buffer pool duplexing</b>	The ability to write data to two instances of a group buffer pool structure: a primary group buffer pool and a secondary group buffer pool. z/OS publications refer to these instances as the "old" (for primary) and "new" (for secondary) structures.	<b>heuristic damage</b>	The inconsistency in data between one or more participants that results when a heuristic decision to resolve an indoubt LUW at one or more participants differs from the decision that is recorded at the coordinator.
<b>group buffer pool (GBP)</b>	A coupling facility cache structure that is used by a data sharing group to cache data and to ensure that the data is consistent for all members.	<b>heuristic decision</b>	A decision that forces indoubt resolution at a participant by means other than automatic resynchronization between coordinator and participant.
<b>group buffer pool recovery pending (GRECP)</b>	The state that exists after the buffer pool for a data sharing group is lost. When a page set is in this state, changes that are recorded in the log must be applied to the affected page set before the page set can be used.	<b>histogram statistics</b>	A way of summarizing data distribution. This technique divides up the range of possible values in a data set into intervals, such that each interval contains approximately the same percentage of the values. A set of statistics are collected for each interval.
<b>group level</b>	The release level of a data sharing group,		

**history table**

A base table that is associated with a system-period temporal table. A history table is used by DB2 to store the historical versions of the rows from the associated system-period temporal table.

**hole** A row of the result table that cannot be accessed because of a delete or an update that has been performed on the row. See also delete hole and update hole.

**home address space**

The area of storage that z/OS currently recognizes as *dispatched*.

**host** The set of programs and resources that are available on a given TCP/IP instance.

**host expression**

A Java variable or expression that is referenced by SQL clauses in an SQLJ application program.

**host identifier**

A name that is declared in the host program.

**host language**

A programming language in which you can embed SQL statements.

**host program**

An application program that is written in a host language and that contains embedded SQL statements.

**host structure**

In an application program, a structure that is referenced by embedded SQL statements.

**host variable**

In an application program written in a host language, an application variable that is referenced by embedded SQL statements.

**host variable array**

An array of elements, each of which corresponds to a value for a column. The dimension of the array determines the maximum number of rows for which the array can be used.

**IBM System z9 Integrated Processor (zIIP)**

A specialized processor that can be used for some DB2 functions.

**IDCAMS**

An IBM program that is used to process access method services commands. It can

be invoked as a job or jobstep, from a TSO terminal, or from within a user's application program.

**IDCAMS LISTCAT**

A facility for obtaining information that is contained in the access method services catalog.

**identity column**

A column that provides a way for DB2 to automatically generate a numeric value for each row. Identity columns are defined with the AS IDENTITY clause. Uniqueness of values can be ensured by defining a unique index that contains only the identity column. A table can have no more than one identity column.

**IFCID** See instrumentation facility component identifier.

**IFI** See instrumentation facility interface.

**IFI call**

An invocation of the instrumentation facility interface (IFI) by means of one of its defined functions.

**image copy**

An exact reproduction of all or part of a table space. DB2 provides utility programs to make full image copies (to copy the entire table space) or incremental image copies (to copy only those pages that have been modified since the last image copy).

**IMS attachment facility**

A DB2 subcomponent that uses z/OS subsystem interface (SSI) protocols and cross-memory linkage to process requests from IMS to DB2 and to coordinate resource commitment.

**in-abort**

A status of a unit of recovery. If DB2 fails after a unit of recovery begins to be rolled back, but before the process is completed, DB2 continues to back out the changes during restart.

**in-commit**

A status of a unit of recovery. If DB2 fails after beginning its phase 2 commit processing, it "knows," when restarted, that changes made to data are consistent. Such units of recovery are termed *in-commit*.

**independent**

An object (row, table, or table space) that is neither a parent nor a dependent of another object.

**index**

A set of pointers that are logically ordered by the values of a key. Indexes can provide faster access to data and can enforce uniqueness on the rows in a table.

**index-controlled partitioning**

A type of partitioning in which partition boundaries for a partitioned table are controlled by values that are specified on the CREATE INDEX statement. Partition limits are saved in the LIMITKEY column of the SYSIBM.SYSINDEXPART catalog table.

**index key**

The set of columns in a table that is used to determine the order of index entries.

**index partition**

A VSAM data set that is contained within a partitioning index space.

**index space**

A page set that is used to store the entries of one index.

**indicator column**

A 4-byte value that is stored in a base table in place of a LOB column.

**indicator variable**

A variable that is used to represent the null value in an application program. If the value for the selected column is null, a negative value is placed in the indicator variable.

**indoubt**

A status of a unit of recovery. If DB2 fails after it has finished its phase 1 commit processing and before it has started phase 2, only the commit coordinator knows if an individual unit of recovery is to be committed or rolled back. At restart, if DB2 lacks the information it needs to make this decision, the status of the unit of recovery is *indoubt* until DB2 obtains this information from the coordinator. More than one unit of recovery can be indoubt at restart.

**indoubt resolution**

The process of resolving the status of an indoubt logical unit of work to either the committed or the rollback state.

**inflight**

A status of a unit of recovery. If DB2 fails before its unit of recovery completes phase 1 of the commit process, it merely backs out the updates of its unit of recovery at restart. These units of recovery are termed *inflight*.

**inheritance**

The passing downstream of class resources or attributes from a parent class in the class hierarchy to a child class.

**initialization file**

For DB2 ODBC applications, a file containing values that can be set to adjust the performance of the database manager.

**inline copy**

A copy that is produced by the LOAD or REORG utility. The data set that the inline copy produces is logically equivalent to a full image copy that is produced by running the COPY utility with read-only access (SHRLEVEL REFERENCE).

**inline SQL PL**

A subset of SQL procedural language that can be used in SQL functions, triggers, and dynamic compound statements. See also SQL procedural language.

**inner join**

The result of a join operation that includes only the matched rows of both tables that are being joined. See also join, equijoin, full outer join, left outer join, outer join, and right outer join.

**inoperative package**

In DB2 Version 9.1 for z/OS and earlier, a package that cannot be used because one or more user-defined functions or procedures that the package depends on were dropped. Such a package must be explicitly rebound. Contrast with invalid package.

**insensitive cursor**

A cursor that is not sensitive to inserts, updates, or deletes that are made to the underlying rows of a result table after the result table has been materialized.

**insert trigger**

A trigger that is defined with the triggering SQL operation, an insert.

<b>install</b>	The process of preparing a DB2 subsystem to operate as a z/OS subsystem.
<b>INSTEAD OF trigger</b>	A trigger that is associated with a single view and is activated by an insert, update, or delete operation on the view and that can define how to propagate the insert, update, or delete operation on the view to the underlying tables of the view. Contrast with BEFORE trigger and AFTER trigger.
<b>instrumentation facility component identifier (IFCID)</b>	A value that names and identifies a trace record of an event that can be traced. As a parameter on the START TRACE and MODIFY TRACE commands, it specifies that the corresponding event is to be traced.
<b>instrumentation facility interface (IFI)</b>	A programming interface that enables programs to obtain online trace data about DB2, to submit DB2 commands, and to pass data to DB2.
<b>Interactive System Productivity Facility (ISPF)</b>	An IBM licensed program that provides interactive dialog services in a z/OS environment.
<b>inter-DB2 R/W interest</b>	A property of data in a table space, index, or partition that has been opened by more than one member of a data sharing group and that has been opened for writing by at least one of those members.
<b>intermediate database server</b>	The target of a request from a local application or a remote application requester that is forwarded to another database server.
<b>internal resource lock manager (IRLM)</b>	A z/OS subsystem that DB2 uses to control communication and database locking.
<b>internationalization</b>	The support for an encoding scheme that is able to represent the code points of characters from many different geographies and languages. To support all geographies, the Unicode standard requires more than 1 byte to represent a single character. See also Unicode.
<b>intersection</b>	An SQL operation that involves the INTERSECT set operator, which combines two result tables. The result of an intersection operation consists of all of the rows that are in both result tables.
<b>invalid package</b>	In DB2 Version 9.1 for z/OS and earlier, a package that depends on an object (other than a user-defined function) that is dropped. Such a package is implicitly rebound on invocation. Contrast with inoperative package.
<b>IP address</b>	A value that uniquely identifies a TCP/IP host.
<b>IRLM</b>	See internal resource lock manager.
<b>isolation level</b>	The degree to which a unit of work is isolated from the updating operations of other units of work. See also cursor stability, read stability, repeatable read, and uncommitted read.
<b>ISPF</b>	See Interactive System Productivity Facility.
<b>iterator</b>	In SQLJ, an object that contains the result set of a query. An iterator is equivalent to a cursor in other host languages.
<b>iterator declaration clause</b>	In SQLJ, a statement that generates an iterator declaration class. An iterator is an object of an iterator declaration class.
<b>JAR</b>	See Java Archive.
<b>Java Archive (JAR)</b>	A file format that is used for aggregating many files into a single file.
<b>JDBC</b>	A Sun Microsystems database application programming interface (API) for Java that allows programs to access database management systems by using callable SQL.
<b>join</b>	A relational operation that allows retrieval of data from two or more tables based on matching column values. See also equijoin, full outer join, inner join, left outer join, outer join, and right outer join.
<b>KB</b>	Kilobyte. A value of 1024 bytes.

## Kerberos

A network authentication protocol that is designed to provide strong authentication for client/server applications by using secret-key cryptography.

## Kerberos ticket

A transparent application mechanism that transmits the identity of an initiating principal to its target. A simple ticket contains the principal's identity, a session key, a timestamp, and other information, which is sealed using the target's secret key.

**key** A column, an ordered collection of columns, or an expression that is identified in the description of a table, index, or referential constraint. The same column or expression can be part of more than one key.

## key-sequenced data set (KSDS)

A VSAM file or data set whose records are loaded in key sequence and controlled by an index.

**KSDS** See key-sequenced data set.

## large object (LOB)

A sequence of bytes representing bit data, single-byte characters, double-byte characters, or a mixture of single- and double-byte characters. A LOB can be up to 2 GB minus 1 byte in length. See also binary large object, character large object, and double-byte character large object.

## last agent optimization

An optimized commit flow for either presumed-nothing or presumed-abort protocols in which the last agent, or final participant, becomes the commit coordinator. This flow saves at least one message.

**latch** A DB2 mechanism for controlling concurrent events or the use of system resources.

**LCID** See log control interval definition.

**LDS** See linear data set.

## leaf page

An index page that contains pairs of keys and RIDs and that points to actual data. Contrast with nonleaf page.

## left outer join

The result of a join operation that

includes the matched rows of both tables that are being joined, and that preserves the unmatched rows of the first table. See also join, equijoin, full outer join, inner join, outer join, and right outer join.

## limit key

The highest value of the index key for a partition.

## linear data set (LDS)

A VSAM data set that contains data but no control information. A linear data set can be accessed as a byte-addressable string in virtual storage.

## linkage editor

A computer program for creating load modules from one or more object modules or load modules by resolving cross references among the modules and, if necessary, adjusting addresses.

## link-edit

The action of creating a loadable computer program using a linkage editor.

**list** A type of object, which DB2 utilities can process, that identifies multiple table spaces, multiple index spaces, or both. A list is defined with the LISTDEF utility control statement.

## list structure

A coupling facility structure that lets data be shared and manipulated as elements of a queue.

**L-lock** See logical lock.

## load module

A program unit that is suitable for loading into main storage for execution. The output of a linkage editor.

**LOB** See large object.

## LOB locator

A mechanism that allows an application program to manipulate a large object value in the database system. A LOB locator is a fullword integer value that represents a single LOB value. An application program retrieves a LOB locator into a host variable and can then apply SQL operations to the associated LOB value using the locator.

## LOB lock

A lock on a LOB value.

**LOB table space**

A table space that contains all the data for a particular LOB column in the related base table.

**local** A way of referring to any object that the local DB2 subsystem maintains. A *local table*, for example, is a table that is maintained by the local DB2 subsystem. Contrast with remote.

**locale** The definition of a subset of a user's environment that combines a CCSID and characters that are defined for a specific language and country.

**local lock**

A lock that provides intra-DB2 concurrency control, but not inter-DB2 concurrency control; that is, its scope is a single DB2.

**local subsystem**

The unique relational DBMS to which the user or application program is directly connected (in the case of DB2, by one of the DB2 attachment facilities).

**location**

The unique name of a database server. An application uses the location name to access a DB2 database server. A database alias can be used to override the location name when accessing a remote server.

**location alias**

Another name by which a database server identifies itself in the network.

Applications can use this name to access a DB2 database server.

**lock** A means of controlling concurrent events or access to data. DB2 locking is performed by the IRLM.

**lock duration**

The interval over which a DB2 lock is held.

**lock escalation**

The promotion of a lock from a row, page, or LOB lock to a table space lock because the number of page locks that are concurrently held on a given resource exceeds a preset limit.

**locking**

The process by which the integrity of data is ensured. Locking prevents concurrent users from accessing inconsistent data. See also claim, drain, and latch.

**lock mode**

A representation for the type of access that concurrently running programs can have to a resource that a DB2 lock is holding.

**lock object**

The resource that is controlled by a DB2 lock.

**lock promotion**

The process of changing the size or mode of a DB2 lock to a higher, more restrictive level.

**lock size**

The amount of data that is controlled by a DB2 lock on table data; the value can be a row, a page, a LOB, a partition, a table, or a table space.

**lock structure**

A coupling facility data structure that is composed of a series of lock entries to support shared and exclusive locking for logical resources.

**log** A collection of records that describe the events that occur during DB2 execution and that indicate their sequence. The information thus recorded is used for recovery in the event of a failure during DB2 execution.

**log control interval definition**

A suffix of the physical log record that tells how record segments are placed in the physical control interval.

**logical claim**

A claim on a logical partition of a nonpartitioning index.

**logical index partition**

The set of all keys that reference the same data partition.

**logical lock (L-lock)**

The lock type that transactions use to control intra- and inter-DB2 data concurrency between transactions. Contrast with physical lock (P-lock).

**logically complete**

A state in which the concurrent copy process is finished with the initialization of the target objects that are being copied. The target objects are available for update.

**logical page list (LPL)**

A list of pages that are in error and that cannot be referenced by applications until the pages are recovered. The page is in *logical error* because the actual media (coupling facility or disk) might not contain any errors. Usually a connection to the media has been lost.

**logical partition**

A set of key or RID pairs in a nonpartitioning index that are associated with a particular partition.

**logical recovery pending (LRECP)**

The state in which the data and the index keys that reference the data are inconsistent.

**logical unit (LU)**

An access point through which an application program accesses the SNA network in order to communicate with another application program. See also LU name.

**logical unit of work**

The processing that a program performs between synchronization points.

**logical unit of work identifier (LUWID)**

A name that uniquely identifies a thread within a network. This name consists of a fully-qualified LU network name, an LUW instance number, and an LUW sequence number.

**log initialization**

The first phase of restart processing during which DB2 attempts to locate the current end of the log.

**log record header (LRH)**

A prefix, in every log record, that contains control information.

**log record sequence number (LRSN)**

An identifier for a log record that is associated with a data sharing member. DB2 uses the LRSN for recovery in the data sharing environment.

**log truncation**

A process by which an explicit starting RBA is established. This RBA is the point at which the next byte of log data is to be written.

**LPL** See logical page list.

**LRECP**

See logical recovery pending.

**LRH** See log record header.

**LRSN** See log record sequence number.

**LU** See logical unit.

**LU name**

Logical unit name, which is the name by which VTAM refers to a node in a network.

**LUW** See logical unit of work.

**LUWID**

See logical unit of work identifier.

**mapping table**

A table that the REORG utility uses to map the associations of the RIDs of data records in the original copy and in the shadow copy. This table is created by the user.

**mass delete**

The deletion of all rows of a table.

**materialize**

- The process of putting rows from a view or nested table expression into a work file for additional processing by a query.
- The placement of a LOB value into contiguous storage. Because LOB values can be very large, DB2 avoids materializing LOB data until doing so becomes absolutely necessary.

**materialized query table**

A table that is used to contain information that is derived and can be summarized from one or more source tables. Contrast with base table.

**MB** Megabyte (1 048 576 bytes).

**MBCS** See multibyte character set.

**member name**

The z/OS XCF identifier for a particular DB2 subsystem in a data sharing group.

**menu** A displayed list of available functions for selection by the operator. A menu is sometimes called a *menu panel*.

**metalanguage**

A language that is used to create other specialized languages.

**migration**

The process of converting a subsystem with a previous release of DB2 to an updated or current release. In this process, you can acquire the functions of the updated or current release without losing the data that you created on the previous release.

**mixed data string**

A character string that can contain both single-byte and double-byte characters.

**mode name**

A VTAM name for the collection of physical and logical characteristics and attributes of a session.

**modify locks**

An L-lock or P-lock with a MODIFY attribute. A list of these active locks is kept at all times in the coupling facility lock structure. If the requesting DB2 subsystem fails, that DB2 subsystem's modify locks are converted to retained locks.

**multibyte character set (MBCS)**

A character set that represents single characters with more than a single byte. UTF-8 is an example of an MBCS. Characters in UTF-8 can range from 1 to 4 bytes in DB2. Contrast with single-byte character set and double-byte character set. See also Unicode.

**multidimensional analysis**

The process of assessing and evaluating an enterprise on more than one level.

**Multiple Virtual Storage (MVS)**

An element of the z/OS operating system. This element is also called the Base Control Program (BCP).

**multisite update**

Distributed relational database processing in which data is updated in more than one location within a single unit of work.

**multithreading**

Multiple TCBs that are executing one copy of DB2 ODBC code concurrently (sharing a processor) or in parallel (on separate central processors).

**MVS** See Multiple Virtual Storage.

**native SQL procedure**

An SQL procedure that is processed by converting the procedural statements to a

native representation that is stored in the database directory, as is done with other SQL statements. When a native SQL procedure is called, the native representation is loaded from the directory, and DB2 executes the procedure. Contrast with external procedure and external SQL procedure.

**nested table expression**

A fullselect in a FROM clause (surrounded by parentheses).

**network identifier (NID)**

The network ID that is assigned by IMS or CICS, or if the connection type is RRSAF, the RRS unit of recovery ID (URID).

**new-function mode (NFM)**

The normal mode of operation that exists after successful completion of a version-to-version migration. At this stage, all new functions of the new version are available for use. A DB2 data sharing group cannot coexist with members that are still at the prior version level, and fallback to a prior version is not supported. Contrast with conversion mode, conversion mode\*, enabling-new-function mode, and enabling-new-function mode\*.

**NFM** See new-function mode.

**NID** See network identifier.

**node ID index**

See XML node ID index.

**nondeterministic function**

A user-defined function whose result is not solely dependent on the values of the input arguments. That is, successive invocations with the same argument values can produce a different answer. This type of function is sometimes called a *variant* function. Contrast with deterministic function (sometimes called a *not-variant* function).

**nonleaf page**

A page that contains keys and page numbers of other pages in the index (either leaf or nonleaf pages). Nonleaf pages never point to actual data. Contrast with leaf page.

**nonpartitioned index**

An index that is not physically

	<p>partitioned. Both partitioning indexes and secondary indexes can be nonpartitioned.</p>		<p>many sources; transforming and analyzing the consolidated data quickly and interactively; and examining the results across different dimensions of the data by looking for patterns, trends, and exceptions within complex relationships of that data.</p>
<b>nonpartitioned secondary index (NPSI)</b>	An index on a partitioned table space that is not the partitioning index and is not partitioned. Contrast with data-partitioned secondary index.		
<b>nonpartitioning index</b>	See secondary index.		
<b>nonscrollable cursor</b>	A cursor that can be moved only in a forward direction. Nonscrollable cursors are sometimes called forward-only cursors or serial cursors.		
<b>normalization</b>	A key step in the task of building a logical relational database design. Normalization helps you avoid redundancies and inconsistencies in your data. An entity is normalized if it meets a set of constraints for a particular normal form (first normal form, second normal form, and so on). Contrast with denormalization.		
<b>not-variant function</b>	See deterministic function.		
<b>NPSI</b>	See nonpartitioned secondary index.		
<b>NUL</b>	The null character ('\0'), which is represented by the value X'00'. In C, this character denotes the end of a string.		
<b>null</b>	A special value that indicates the absence of information.		
<b>null terminator</b>	In C, the value that indicates the end of a string. For EBCDIC, ASCII, and Unicode UTF-8 strings, the null terminator is a single-byte value (X'00'). For Unicode UTF-16 or UCS-2 (wide) strings, the null terminator is a double-byte value (X'0000').		
<b>ODBC</b>	See Open Database Connectivity.		
<b>ODBC driver</b>	A dynamically-linked library (DLL) that implements ODBC function calls and interacts with a data source.		
<b>OLAP</b>	See online analytical processing.		
<b>online analytical processing (OLAP)</b>	The process of collecting data from one or		
			<p><b>Open Database Connectivity (ODBC)</b></p> <p>A Microsoft database application programming interface (API) for C that allows access to database management systems by using callable SQL. ODBC does not require the use of an SQL preprocessor. In addition, ODBC provides an architecture that lets users add modules called <i>database drivers</i>, which link the application to their choice of database management systems at run time. This means that applications no longer need to be directly linked to the modules of all the database management systems that are supported.</p>
			<p><b>ordinary identifier</b></p> <p>An uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character. An ordinary identifier must not be a reserved word.</p>
			<p><b>ordinary token</b></p> <p>A numeric constant, an ordinary identifier, a host identifier, or a keyword.</p>
			<p><b>originating task</b></p> <p>In a parallel group, the primary agent that receives data from other execution units (referred to as <i>parallel tasks</i>) that are executing portions of the query in parallel.</p>
			<p><b>outer join</b></p> <p>The result of a join operation that includes the matched rows of both tables that are being joined and preserves some or all of the unmatched rows of the tables that are being joined. See also join, equijoin, full outer join, inner join, left outer join, and right outer join.</p>
			<p><b>overloaded function</b></p> <p>A function name for which multiple function instances exist.</p>
			<p><b>package</b></p> <p>An object containing a set of SQL statements that have been statically bound and that is available for</p>

processing. A package is sometimes also called an *application package*.

#### package list

An ordered list of package names that may be used to extend an application plan.

#### package name

The name of an object that is used for an application package or an SQL procedure package. An application package is a bound version of a database request module (DBRM) that is created by a BIND PACKAGE or REBIND PACKAGE command. An SQL procedural language package is created by a CREATE or ALTER PROCEDURE statement for a native SQL procedure. The name of a package consists of a location name, a collection ID, a package ID, and a version ID.

**page** A unit of storage within a table space (4 KB, 8 KB, 16 KB, or 32 KB) or index space (4 KB, 8 KB, 16 KB, or 32 KB). In a table space, a page contains one or more rows of a table. In a LOB or XML table space, a LOB or XML value can span more than one page, but no more than one LOB or XML value is stored on a page.

#### page set

Another way to refer to a table space or index space. Each page set consists of a collection of VSAM data sets.

#### page set recovery pending (PSRCP)

A restrictive state of an index space. In this case, the entire page set must be recovered. Recovery of a logical part is prohibited.

**panel** A predefined display image that defines the locations and characteristics of display fields on a display surface (for example, a *menu panel*).

#### parallel complex

A cluster of machines that work together to handle multiple transactions and applications.

#### parallel group

A set of consecutive operations that execute in parallel and that have the same number of parallel tasks.

#### parallel I/O processing

A form of I/O processing in which DB2

initiates multiple concurrent requests for a single user query and performs I/O processing concurrently (*in parallel*) on multiple data partitions.

#### parallelism assistant

In Sysplex query parallelism, a DB2 subsystem that helps to process parts of a parallel query that originates on another DB2 subsystem in the data sharing group.

#### parallelism coordinator

In Sysplex query parallelism, the DB2 subsystem from which the parallel query originates.

#### Parallel Sysplex

A set of z/OS systems that communicate and cooperate with each other through certain multisystem hardware components and software services to process customer workloads.

#### parallel task

The execution unit that is dynamically created to process a query in parallel. A parallel task is implemented by a z/OS service request block.

#### parameter marker

A question mark (?) that appears in a statement string of a dynamic SQL statement. The question mark can appear where a variable could appear if the statement string were a static SQL statement.

#### parameter-name

An SQL identifier that designates a parameter in a routine that is written by a user. Parameter names are required for SQL procedures and SQL functions, and they are used in the body of the routine to refer to the values of the parameters. Parameter names are optional for external routines.

#### parent key

A primary key or unique key in the parent table of a referential constraint. The values of a parent key determine the valid values of the foreign key in the referential constraint.

#### parent lock

For explicit hierarchical locking, a lock that is held on a resource that might have child locks that are lower in the hierarchy.

A parent lock is usually the table space lock or the partition intent lock. See also child lock.

#### **parent row**

A row whose primary key value is the foreign key value of a dependent row.

#### **parent table**

A table whose primary key is referenced by the foreign key of a dependent table.

#### **parent table space**

A table space that contains a parent table. A table space containing a dependent of that table is a dependent table space.

#### **participant**

An entity other than the commit coordinator that takes part in the commit process. The term participant is synonymous with agent in SNA.

#### **partition**

A portion of a page set. Each partition corresponds to a single, independently extendable data set. The maximum size of a partition depends on the number of partitions in the partitioned page set. All partitions of a given page set have the same maximum size.

#### **partition-by-growth table space**

A table space whose size can grow to accommodate data growth. DB2 for z/OS manages partition-by-growth table spaces by automatically adding new data sets when the database needs more space to satisfy an insert operation. Contrast with range-partitioned table space. See also universal table space.

#### **partitioned data set (PDS)**

A data set in disk storage that is divided into partitions, which are called members. Each partition can contain a program, part of a program, or data. A program library is an example of a partitioned data set.

#### **partitioned index**

An index that is physically partitioned. Both partitioning indexes and secondary indexes can be partitioned.

#### **partitioned page set**

A partitioned table space or an index space. Header pages, space map pages,

data pages, and index pages reference data only within the scope of the partition.

#### **partitioned table space**

A table space that is based on a single table and that is subdivided into partitions, each of which can be processed independently by utilities. Contrast with segmented table space and universal table space.

#### **partitioning index**

An index in which the leftmost columns are the partitioning columns of the table. The index can be partitioned or nonpartitioned.

#### **partner logical unit**

An access point in the SNA network that is connected to the local DB2 subsystem by way of a VTAM conversation.

#### **path**

See SQL path.

#### **PDS**

See partitioned data set.

#### **period**

An interval of time that is defined by two

datetime columns in a temporal table. A

period contains a begin column and an

end column. See also begin column and

end column.

#### **physical consistency**

The state of a page that is not in a partially changed state.

#### **physical lock (P-lock)**

A type of lock that DB2 acquires to provide consistency of data that is cached in different DB2 subsystems. Physical locks are used only in data sharing environments. Contrast with logical lock (L-lock).

#### **physically complete**

The state in which the concurrent copy process is completed and the output data set has been created.

#### **piece**

A data set of a nonpartitioned page set.

#### **plan**

See application plan.

#### **plan allocation**

The process of allocating DB2 resources to a plan in preparation for execution.

#### **plan member**

The bound copy of a DBRM that is identified in the member clause.

**plan name**

The name of an application plan.

**P-lock** See physical lock.

**point of consistency**

A time when all recoverable data that an application accesses is consistent with other data. The term point of consistency is synonymous with sync point or commit point.

**policy** See CFRM policy.

**postponed abort UR**

A unit of recovery that was inflight or in-abort, was interrupted by system failure or cancellation, and did not complete backout during restart.

**precision**

In SQL, the total number of digits in a decimal number (called the *size* in the C language). In the C language, the number of digits to the right of the decimal point (called the scale in SQL). The DB2 information uses the SQL terms.

**precompilation**

A processing of application programs containing SQL statements that takes place before compilation. SQL statements are replaced with statements that are recognized by the host language compiler. Output from this precompilation includes source code that can be submitted to the compiler and the database request module (DBRM) that is input to the bind process.

**predicate**

An element of a search condition that expresses or implies a comparison operation.

**prefix** A code at the beginning of a message or record.

**preformat**

The process of preparing a VSAM linear data set for DB2 use, by writing specific data patterns.

**prepare**

The first phase of a two-phase commit process in which all participants are requested to prepare for commit.

**prepared SQL statement**

A named object that is the executable

form of an SQL statement that has been processed by the PREPARE statement.

**primary authorization ID**

The authorization ID that is used to identify the application process to DB2.

**primary group buffer pool**

For a duplexed group buffer pool, the structure that is used to maintain the coherency of cached data. This structure is used for page registration and cross-validation. The z/OS equivalent is *old* structure. Compare with secondary group buffer pool.

**primary index**

An index that enforces the uniqueness of a primary key.

**primary key**

In a relational database, a unique, nonnull key that is part of the definition of a table. A table cannot be defined as a parent unless it has a unique key or primary key.

**principal**

An entity that can communicate securely with another entity. In Kerberos, principals are represented as entries in the Kerberos registry database and include users, servers, computers, and others.

**principal name**

The name by which a principal is known to the DCE security services.

**privilege**

The capability of performing a specific function, sometimes on a specific object. See also explicit privilege.

**privilege set**

- For the installation SYSADM ID, the set of all possible privileges.
- For any other authorization ID, including the PUBLIC authorization ID, the set of all privileges that are recorded for that ID in the DB2 catalog.

**process**

In DB2, the unit to which DB2 allocates resources and locks. Sometimes called an application process, a process involves the execution of one or more programs. The execution of an SQL statement is always associated with some process. The means of initiating and terminating a process are dependent on the environment.

**program**

A single, compilable collection of executable statements in a programming language.

**program temporary fix (PTF)**

A solution or bypass of a problem that is diagnosed as a result of a defect in a current unaltered release of a licensed program. An authorized program analysis report (APAR) fix is corrective service for an existing problem. A PTF is preventive service for problems that might be encountered by other users of the product. A PTF is *temporary*, because a permanent fix is usually not incorporated into the product until its next release.

**protected conversation**

A VTAM conversation that supports two-phase commit flows.

**PSRCP**

See page set recovery pending.

**PTF**

See program temporary fix.

**QSAM**

See queued sequential access method.

**query**

A component of certain SQL statements that specifies a result table.

**query block**

The part of a query that is represented by one of the FROM clauses. Each FROM clause can have multiple query blocks, depending on DB2 processing of the query.

**query CP parallelism**

Parallel execution of a single query, which is accomplished by using multiple tasks. See also Sysplex query parallelism.

**query I/O parallelism**

Parallel access of data, which is accomplished by triggering multiple I/O requests within a single query.

**queued sequential access method (QSAM)**

An extended version of the basic sequential access method (BSAM). When this method is used, a queue of data blocks is formed. Input data blocks await processing, and output data blocks await transfer to auxiliary storage or to an output device.

**quiesce point**

A point at which data is consistent as a result of running the DB2 QUIESCE utility.

**RACF**

Resource Access Control Facility. A component of the z/OS Security Server.

**range-partitioned table space**

A type of universal table space that is based on partitioning ranges and that contains a single table. Contrast with partition-by-growth table space. See also universal table space.

**RBA**

See relative byte address.

**RCT**

See resource control table.

**RDO**

See resource definition online.

**read stability (RS)**

An isolation level that is similar to repeatable read but does not completely isolate an application process from all other concurrently executing application processes. See also cursor stabilityrepeatable read, and uncommitted read.

**rebind**

The creation of a new application plan for an application program that has been bound previously. If, for example, you have added an index for a table that your application accesses, you must rebinding the application in order to take advantage of that index.

**rebuild**

The process of reallocating a coupling facility structure. For the shared communications area (SCA) and lock structure, the structure is repopulated; for the group buffer pool, changed pages are usually cast out to disk, and the new structure is populated only with changed pages that were not successfully cast out.

**record**

The storage representation of a row or other data.

**record identifier (RID)**

A unique identifier that DB2 uses to identify a row of data in a table. Compare with row identifier.

**record identifier (RID) pool**

An area of main storage that is used for sorting record identifiers during list-prefetch processing.

**record length**

The sum of the length of all the columns in a table, which is the length of the data as it is physically stored in the database. Records can be fixed length or varying length, depending on how the columns are defined. If all columns are fixed-length columns, the record is a fixed-length record. If one or more columns are varying-length columns, the record is a varying-length record.

**Recoverable Resource Manager Services attachment facility (RRSAF)**

A DB2 subcomponent that uses Resource Recovery Services to coordinate resource commitment between DB2 and all other resource managers that also use RRS in a z/OS system.

**recovery**

The process of rebuilding databases after a system failure.

**recovery log**

A collection of records that describes the events that occur during DB2 execution and indicates their sequence. The recorded information is used for recovery in the event of a failure during DB2 execution.

**recovery manager**

A subcomponent that supplies coordination services that control the interaction of DB2 resource managers during commit, abort, checkpoint, and restart processes. The recovery manager also supports the recovery mechanisms of other subsystems (for example, IMS) by acting as a participant in the other subsystem's process for protecting data that has reached a point of consistency.

A coordinator or a participant (or both), in the execution of a two-phase commit, that can access a recovery log that maintains the state of the logical unit of work and names the immediate upstream coordinator and downstream participants.

**recovery pending (RECP)**

A condition that prevents SQL access to a table space that needs to be recovered.

**recovery token**

An identifier for an element that is used in recovery (for example, NID or URID).

**RECP** See recovery pending.

**redo** A state of a unit of recovery that indicates that changes are to be reapplied to the disk media to ensure data integrity.

**reentrant code**

Executable code that can reside in storage as one shared copy for all threads. Reentrant code is not self-modifying and provides separate storage areas for each thread. See also threadsafe.

**referential constraint**

The requirement that nonnull values of a designated foreign key are valid only if they equal values of the primary key of a designated table.

**referential cycle**

A set of referential constraints such that each base table in the set is a descendent of itself. The tables that are involved in a referential cycle are ordered so that each table is a descendent of the one before it, and the first table is a descendent of the last table.

**referential integrity**

The state of a database in which all values of all foreign keys are valid. Maintaining referential integrity requires the enforcement of referential constraints on all operations that change the data in a table on which the referential constraints are defined.

**referential structure**

A set of tables and relationships that includes at least one table and, for every table in the set, all the relationships in which that table participates and all the tables to which it is related.

**refresh age**

The time duration between the current time and the time during which a materialized query table was last refreshed.

**registry**

See registry database.

**registry database**

A database of security information about principals, groups, organizations, accounts, and security policies.

**relational database**

A database that can be perceived as a set of tables and manipulated in accordance with the relational model of data.

<b>relational database management system (RDBMS)</b>	A collection of hardware and software that organizes and provides access to a relational database.	varying-length columns are stored at the end of the row. Contrast with basic row format.
<b>relational schema</b>	See SQL schema.	
<b>relationship</b>	A defined connection between the rows of a table or the rows of two tables. A relationship is the internal representation of a referential constraint.	
<b>relative byte address (RBA)</b>	The offset of a data record or control interval from the beginning of the storage space that is allocated to the data set or file to which it belongs.	
<b>remigration</b>	The process of returning to a current release of DB2 following a fallback to a previous release. This procedure constitutes another migration process.	
<b>remote</b>	Any object that is maintained by a remote DB2 subsystem (that is, by a DB2 subsystem other than the local one). A <i>remote view</i> , for example, is a view that is maintained by a remote DB2 subsystem. Contrast with local.	
<b>remote subsystem</b>	Any relational DBMS, except the local subsystem, with which the user or application can communicate. The subsystem need not be remote in any physical sense, and might even operate on the same processor under the same z/OS system.	
<b>reoptimization</b>	The DB2 process of reconsidering the access path of an SQL statement at run time; during reoptimization, DB2 uses the values of host variables, parameter markers, or special registers.	
<b>reordered row format</b>	A row format that facilitates improved performance in retrieval of rows that have varying-length columns. DB2 rearranges the column order, as defined in the CREATE TABLE statement, so that the fixed-length columns are stored at the beginning of the row and the	
		<b>REORG pending (REORP)</b>
		A condition that restricts SQL access and most utility access to an object that must be reorganized.
		<b>REORP</b>
		See REORG pending.
		<b>repeatable read (RR)</b>
		The isolation level that provides maximum protection from other executing application programs. When an application program executes with repeatable read protection, rows that the program references cannot be changed by other programs until the program reaches a commit point. See also cursor stability, read stability, and uncommitted read.
		<b>repeating group</b>
		A situation in which an entity includes multiple attributes that are inherently the same. The presence of a repeating group violates the requirement of first normal form. In an entity that satisfies the requirement of first normal form, each attribute is independent and unique in its meaning and its name. See also normalization.
		<b>replay detection mechanism</b>
		A method that allows a principal to detect whether a request is a valid request from a source that can be trusted or whether an untrustworthy entity has captured information from a previous exchange and is replaying the information exchange to gain access to the principal.
		<b>request commit</b>
		The vote that is submitted to the prepare phase if the participant has modified data and is prepared to commit or roll back.
		<b>requester</b>
		The source of a request to access data at a remote server. In the DB2 environment, the requester function is provided by the distributed data facility.
		<b>resource</b>
		The object of a lock or claim, which could be a table space, an index space, a data partition, an index partition, or a logical partition.

**resource allocation**

The part of plan allocation that deals specifically with the database resources.

**resource control table**

A construct of previous versions of the CICS attachment facility that defines authorization and access attributes for transactions or transaction groups. Beginning in CICS Transaction Server Version 1.3, resources are defined by using resource definition online instead of the resource control table. See also [resource definition online](#).

**resource definition online (RDO)**

The recommended method of defining resources to CICS by creating resource definitions interactively, or by using a utility, and then storing them in the CICS definition data set. In earlier releases of CICS, resources were defined by using the resource control table (RCT), which is no longer supported.

**resource limit facility (RLF)**

A portion of DB2 code that prevents dynamic manipulative SQL statements from exceeding specified time limits. The resource limit facility is sometimes called the governor.

**resource limit specification table (RLST)**

A site-defined table that specifies the limits to be enforced by the resource limit facility.

**resource manager**

- A function that is responsible for managing a particular resource and that guarantees the consistency of all updates made to recoverable resources within a logical unit of work. The resource that is being managed can be physical (for example, disk or main storage) or logical (for example, a particular type of system service).
- A participant, in the execution of a two-phase commit, that has recoverable resources that could have been modified. The resource manager has access to a recovery log so that it can commit or roll back the effects of the logical unit of work to the recoverable resources.

**restart pending (RESTRP)**

A restrictive state of a page set or

partition that indicates that restart (backout) work needs to be performed on the object.

**RESTRP**

See [restart pending](#).

**result set**

The set of rows that a stored procedure returns to a client application.

**result set locator**

A 4-byte value that DB2 uses to uniquely identify a query result set that a stored procedure returns.

**result table**

The set of rows that are specified by a [SELECT statement](#).

**retained lock**

A MODIFY lock that a DB2 subsystem was holding at the time of a subsystem failure. The lock is retained in the coupling facility lock structure across a DB2 for z/OS failure.

**RID**

See [record identifier](#).

**RID pool**

See [record identifier pool](#).

**right outer join**

The result of a join operation that includes the matched rows of both tables that are being joined and preserves the unmatched rows of the second join operand. See also [join](#), [equijoin](#), [full outer join](#), [inner join](#), [left outer join](#), and [outer join](#).

**RLF**

See [resource limit facility](#).

**RLST**

See [resource limit specification table](#).

**role**

A database entity that groups together one or more privileges and that can be assigned to a primary authorization ID or to PUBLIC. The role is available only in a trusted context.

**rollback**

The process of restoring data that was changed by SQL statements to the state at its last commit point. All locks are freed. Contrast with [commit](#).

**root page**

The index page that is at the highest level (or the beginning point) in an index.

**routine**

A database object that encapsulates

	procedural logic and SQL statements, is stored on the database server, and can be invoked from an SQL statement or by using the CALL statement. The main classes of routines are procedures and functions.	<b>SBCS</b> See single-byte character set.
<b>row</b>	The horizontal component of a table. A row consists of a sequence of values, one for each column of the table.	<b>SCA</b> See shared communications area.
<b>row identifier (ROWID)</b>	A value that uniquely identifies a row. This value is stored with the row and never changes.	<b>scalar function</b> An SQL operation that produces a single value from another value and is expressed as a function name, followed by a list of arguments that are enclosed in parentheses.
<b>row lock</b>	A lock on a single row of data.	<b>scale</b> In SQL, the number of digits to the right of the decimal point (called the precision in the C language). The DB2 information uses the SQL definition.
<b>row-positioned fetch orientation</b>	The specification of the desired placement of the cursor as part of a FETCH statement, with respect to a single row (for example, NEXT, LAST, or ABSOLUTE <i>n</i> ). Contrast with rowset-positioned fetch orientation.	<b>schema</b> The organization or structure of a database.  A collection of, and a way of qualifying, database objects such as tables, views, routines, indexes or triggers that define a database. A database schema provides a logical classification of database objects.
<b>rowset</b>	A set of rows for which a cursor position is established.	<b>scrollability</b> The ability to use a cursor to fetch in either a forward or backward direction. The FETCH statement supports multiple fetch orientations to indicate the new position of the cursor. See also fetch orientation.
<b>rowset cursor</b>	A cursor that is defined so that one or more rows can be returned as a rowset for a single FETCH statement, and the cursor is positioned on the set of rows that is fetched.	<b>scrollable cursor</b> A cursor that can be moved in both a forward and a backward direction.
<b>rowset-positioned fetch orientation</b>	The specification of the desired placement of the cursor as part of a FETCH statement, with respect to a rowset (for example, NEXT ROWSET, LAST ROWSET, or ROWSET STARTING AT ABSOLUTE <i>n</i> ). Contrast with row-positioned fetch orientation.	<b>search condition</b> A criterion for selecting rows from a table. A search condition consists of one or more predicates.
<b>row trigger</b>	A trigger that is defined with the trigger granularity FOR EACH ROW.	<b>secondary authorization ID</b> An authorization ID that has been associated with a primary authorization ID by an authorization exit routine.
<b>RRSAF</b>	See Recoverable Resource Manager Services attachment facility.	<b>secondary group buffer pool</b> For a duplexed group buffer pool, the structure that is used to back up changed pages that are written to the primary group buffer pool. No page registration or cross-validation occurs using the secondary group buffer pool. The z/OS equivalent is <i>new</i> structure.
<b>RS</b>	See read stability.	<b>secondary index</b> A nonpartitioning index that is useful for enforcing a uniqueness constraint, for clustering data, or for providing access
<b>savepoint</b>	A named entity that represents the state of data and schemas at a particular point in time within a unit of work.	

paths to data for queries. A secondary index can be partitioned or nonpartitioned. See also data-partitioned secondary index (DPSI) and nonpartitioned secondary index (NPSI).

#### section

The segment of a plan or package that contains the executable structures for a single SQL statement. For most SQL statements, one section in the plan exists for each SQL statement in the source program. However, for cursor-related statements, the DECLARE, OPEN, FETCH, and CLOSE statements reference the same section because they each refer to the SELECT statement that is named in the DECLARE CURSOR statement. SQL statements such as COMMIT, ROLLBACK, and some SET statements do not use a section.

#### security label

A classification of users' access to objects or data rows in a multilevel security environment."

#### segment

A group of pages that holds rows of a single table. See also segmented table space.

#### segmented table space

A table space that is divided into equal-sized groups of pages called segments. Segments are assigned to tables so that rows of different tables are never stored in the same segment. Contrast with partitioned table space and universal table space.

#### self-referencing constraint

A referential constraint that defines a relationship in which a table is a dependent of itself.

#### self-referencing table

A table with a self-referencing constraint.

#### sensitive cursor

A cursor that is sensitive to changes that are made to the database after the result table has been materialized.

#### sequence

A user-defined object that generates a sequence of numeric values according to user specifications.

#### sequential data set

A non-DB2 data set whose records are organized on the basis of their successive physical positions, such as on magnetic tape. Several of the DB2 database utilities require sequential data sets.

#### sequential prefetch

A mechanism that triggers consecutive asynchronous I/O operations. Pages are fetched before they are required, and several pages are read with a single I/O operation.

#### serialized profile

A Java object that contains SQL statements and descriptions of host variables. The SQLJ translator produces a serialized profile for each connection context.

**server** The target of a request from a remote requester. In the DB2 environment, the server function is provided by the distributed data facility, which is used to access DB2 data from remote applications.

#### service class

An eight-character identifier that is used by the z/OS Workload Manager to associate user performance goals with a particular DDF thread or stored procedure. A service class is also used to classify work on parallelism assistants.

#### service request block

A unit of work that is scheduled to execute.

#### session

A link between two nodes in a VTAM network.

#### session protocols

The available set of SNA communication requests and responses.

#### set operator

The SQL operators UNION, EXCEPT, and INTERSECT corresponding to the relational operators union, difference, and intersection. A set operator derives a result table by combining two other result tables.

#### shared communications area (SCA)

A coupling facility list structure that a DB2 data sharing group uses for inter-DB2 communication.

<b>share lock</b>	A lock that prevents concurrently executing application processes from changing data, but not from reading data. Contrast with exclusive lock.	<b>SNA</b> See Systems Network Architecture.
<b>shift-in character</b>	A special control character (X'0F') that is used in EBCDIC systems to denote that the subsequent bytes represent SBCS characters. See also shift-out character.	<b>SNA network</b> The part of a network that conforms to the formats and protocols of Systems Network Architecture (SNA).
<b>shift-out character</b>	A special control character (X'0E') that is used in EBCDIC systems to denote that the subsequent bytes, up to the next shift-in control character, represent DBCS characters. See also shift-in character.	<b>socket</b> A callable TCP/IP programming interface that TCP/IP network applications use to communicate with remote TCP/IP partners.
<b>sign-on</b>	A request that is made on behalf of an individual CICS or IMS application process by an attachment facility to enable DB2 to verify that it is authorized to use DB2 resources.	<b>sourced function</b> A function that is implemented by another built-in or user-defined function that is already known to the database manager. This function can be a scalar function or an aggregate function; it returns a single value from a set of values (for example, MAX or AVG). Contrast with built-in function, external function, and SQL function.
<b>simple page set</b>	A nonpartitioned page set. A simple page set initially consists of a single data set (page set piece). If and when that data set is extended to 2 GB, another data set is created, and so on, up to a total of 32 data sets. DB2 considers the data sets to be a single contiguous linear address space containing a maximum of 64 GB. Data is stored in the next available location within this address space without regard to any partitioning scheme.	<b>source program</b> A set of host language statements and SQL statements that is processed by an SQL precompiler.
<b>simple table space</b>	A table space that is neither partitioned nor segmented. Creation of simple table spaces is not supported in DB2 Version 9.1 for z/OS. Contrast with partitioned table space, segmented table space, and universal table space.	<b>source table</b> A table that can be a base table, a view, a table expression, or a user-defined table function.
<b>single-byte character set (SBCS)</b>	A set of characters in which each character is represented by a single byte. Contrast with double-byte character set or multibyte character set.	<b>source type</b> An existing type that DB2 uses to represent a distinct type.
<b>single-precision floating point number</b>	A 32-bit approximate representation of a real number.	<b>space</b> A sequence of one or more blank characters.
<b>SMP/E</b>	See System Modification Program/Extended.	<b>special register</b> A storage area that DB2 defines for an application process to use for storing information that can be referenced in SQL statements. Examples of special registers are SESSION_USER and CURRENT DATE.
		<b>specific function name</b> A particular user-defined function that is known to the database manager by its specific name. Many specific user-defined functions can have the same function name. When a user-defined function is defined to the database, every function is assigned a specific name that is unique within its schema. Either the user can provide this name, or a default name is used.
		<b>SPUFI</b> See SQL Processor Using File Input.

**SQL** See Structured Query Language.

**SQL authorization ID (SQL ID)**

The authorization ID that is used for checking dynamic SQL statements in some situations.

**SQLCA**

See SQL communication area.

**SQL communication area (SQLCA)**

A structure that is used to provide an application program with information about the execution of its SQL statements.

**SQL connection**

An association between an application process and a local or remote application server or database server.

**SQLDA**

See SQL descriptor area.

**SQL descriptor area (SQLDA)**

A structure that describes input variables, output variables, or the columns of a result table.

**SQL escape character**

The symbol that is used to enclose an SQL delimited identifier. This symbol is the double quotation mark ("). See also escape character.

**SQL function**

A user-defined function in which the CREATE FUNCTION statement contains the source code. The source code is a single SQL expression that evaluates to a single value. The SQL user-defined function can return the result of an expression. See also built-in function, external function, and sourced function.

**SQL ID**

See SQL authorization ID.

**SQLJ** Structured Query Language (SQL) that is embedded in the Java programming language.

**SQL path**

An ordered list of schema names that are used in the resolution of unqualified references to user-defined functions, distinct types, and stored procedures. In dynamic SQL, the SQL path is found in the CURRENT PATH special register. In static SQL, it is defined in the PATH bind option.

**SQL PL**

See SQL procedural language.

**SQL procedural language (SQL PL)**

A language extension of SQL that consists of statements and language elements that can be used to implement procedural logic in SQL statements. SQL PL provides statements for declaring variables and condition handlers, assigning values to variables, and for implementing procedural logic. See also inline SQL PL.

**SQL procedure**

A user-written program that can be invoked with the SQL CALL statement. An SQL procedure is written in the SQL procedural language. Two types of SQL procedures are supported: external SQL procedures and native SQL procedures. See also external procedure and native SQL procedure.

**SQL processing conversation**

Any conversation that requires access of DB2 data, either through an application or by dynamic query requests.

**SQL Processor Using File Input (SPUFI)**

A facility of the TSO attachment subcomponent that enables the DB2I user to execute SQL statements without embedding them in an application program.

**SQL return code**

Either SQLCODE or SQLSTATE.

**SQL routine**

A user-defined function or stored procedure that is based on code that is written in SQL.

**SQL schema**

A collection of database objects such as tables, views, indexes, functions, distinct types, schemas, or triggers that defines a database. An SQL schema provides a logical classification of database objects.

**SQL statement coprocessor**

An alternative to the DB2 precompiler that lets the user process SQL statements at compile time. The user invokes an SQL statement coprocessor by specifying a compiler option.

**SQL string delimiter**

A symbol that is used to enclose an SQL string constant. The SQL string delimiter

	<p>is the apostrophe ('), except in COBOL applications, where the user assigns the symbol, which is either an apostrophe or a double quotation mark (").</p>
<b>SRB</b>	See service request block.
<b>stand-alone</b>	An attribute of a program that means that it is capable of executing separately from DB2, without using DB2 services.
<b>star join</b>	A method of joining a dimension column of a fact table to the key column of the corresponding dimension table. See also join, dimension, and star schema.
<b>star schema</b>	The combination of a fact table (which contains most of the data) and a number of dimension tables. See also star join, dimension, and dimension table.
<b>statement handle</b>	In DB2 ODBC, the data object that contains information about an SQL statement that is managed by DB2 ODBC. This includes information such as dynamic arguments, bindings for dynamic arguments and columns, cursor information, result values, and status information. Each statement handle is associated with the connection handle.
<b>statement string</b>	For a dynamic SQL statement, the character string form of the statement.
<b>statement trigger</b>	A trigger that is defined with the trigger granularity FOR EACH STATEMENT.
<b>static cursor</b>	A named control structure that does not change the size of the result table or the order of its rows after an application opens the cursor. Contrast with dynamic cursor.
<b>static SQL</b>	SQL statements, embedded within a program, that are prepared during the program preparation process (before the program is executed). After being prepared, the SQL statement does not change (although values of variables that are specified by the statement might change).

	<p><b>storage group</b> A set of storage objects on which DB2 for z/OS data can be stored. A storage object can have an SMS data class, a management class, a storage class, and a list of volume serial numbers.</p>
	<p><b>stored procedure</b> A user-written application program that can be invoked through the use of the SQL CALL statement. Stored procedures are sometimes called procedures.</p>
<b>string</b>	See binary string, character string, or graphic string.
<b>strong typing</b>	A process that guarantees that only user-defined functions and operations that are defined on a distinct type can be applied to that type. For example, you cannot directly compare two currency types, such as Canadian dollars and U.S. dollars. But you can provide a user-defined function to convert one currency to the other and then do the comparison.
<b>structure</b>	<ul style="list-style-type: none"> <li>• A name that refers collectively to different types of DB2 objects, such as tables, databases, views, indexes, and table spaces.</li> <li>• A construct that uses z/OS to map and manage storage on a coupling facility. See also cache structure, list structure, or lock structure.</li> </ul>
	<p><b>Structured Query Language (SQL)</b> A standardized language for defining and manipulating data in a relational database.</p>
<b>structure owner</b>	In relation to group buffer pools, the DB2 member that is responsible for the following activities: <ul style="list-style-type: none"> <li>• Coordinating rebuild, checkpoint, and damage assessment processing</li> <li>• Monitoring the group buffer pool threshold and notifying castout owners when the threshold has been reached</li> </ul>
<b>subcomponent</b>	A group of closely related DB2 modules that work together to provide a general function.

**subject table**

The table for which a trigger is created. When the defined triggering event occurs on this table, the trigger is activated.

**subquery**

A SELECT statement within the WHERE or HAVING clause of another SQL statement; a nested SQL statement.

**subselect**

That form of a query that includes only a SELECT clause, FROM clause, and optionally a WHERE clause, GROUP BY clause, HAVING clause, ORDER BY clause, or FETCH FIRST clause.

**substitution character**

A unique character that is substituted during character conversion for any characters in the source program that do not have a match in the target coding representation.

**subsystem**

In z/OS, a service provider that performs one or many functions, but does nothing until a request is made. For example, each WebSphere MQ for z/OS queue manager or instance of a DB2 for z/OS database management system is a z/OS subsystem.

**surrogate pair**

A coded representation for a single character that consists of a sequence of two 16-bit code units, in which the first value of the pair is a high-surrogate code unit in the range U+D800 through U+DBFF, and the second value is a low-surrogate code unit in the range U+DC00 through U+DFFF. Surrogate pairs provide an extension mechanism for encoding 917 476 characters without requiring the use of 32-bit characters.

**SVC dump**

A dump that is issued when a z/OS or a DB2 functional recovery routine detects an error.

**sync point**

See commit point.

**syncpoint tree**

The tree of recovery managers and resource managers that are involved in a logical unit of work, starting with the recovery manager, that make the final commit decision.

**synonym**

In SQL, an alternative name for a table or view. Synonyms can be used to refer only to objects at the subsystem in which the synonym is defined. A synonym cannot be qualified and can therefore not be used by other users. Contrast with alias.

**Sysplex**

See Parallel Sysplex.

**Sysplex query parallelism**

Parallel execution of a single query that is accomplished by using multiple tasks on more than one DB2 subsystem. See also query CP parallelism.

**system administrator**

The person at a computer installation who designs, controls, and manages the use of the computer system.

**system agent**

A work request that DB2 creates such as prefetch processing, deferred writes, and service tasks. See also allied agent.

**system authorization ID**

The primary DB2 authorization ID that is used to establish a trusted connection. A system authorization ID is derived from the system user ID that is provided by an external entity, such as a middleware server.

**system conversation**

The conversation that two DB2 subsystems must establish to process system messages before any distributed processing can begin.

**system-defined routine**

In DB2 10 for z/OS and later, an object (function or procedure) for which system DBADM and SQLADM authorities have implicit execute privilege on the routine and any packages executed within the routine.

**System Modification Program/Extended (SMP/E)**

A z/OS tool for making software changes in programming systems (such as DB2) and for controlling those changes.

**system period**

A pair of columns with system-maintained values that indicate the period of time when a row is valid.

<b>system-period data versioning</b>	A table space set can contain both types of relationships.
<b>Automatic maintenance of historical data by DB2 using a system period.</b>	
<b>system-period temporal table</b>	
A table that is defined with system-period data versioning.	
<b>Systems Network Architecture (SNA)</b>	
The description of the logical structure, formats, protocols, and operational sequences for transmitting information through and controlling the configuration and operation of networks.	
<b>table</b>	A named data object consisting of a specific number of columns and some number of unordered rows. See also base table or temporary table. Contrast with auxiliary table, clone table, materialized query table, result table, and transition table.
<b>table-controlled partitioning</b>	A type of partitioning in which partition boundaries for a partitioned table are controlled by values that are defined in the CREATE TABLE statement.
<b>table function</b>	A function that receives a set of arguments and returns a table to the SQL statement that references the function. A table function can be referenced only in the FROM clause of a subselect.
<b>table locator</b>	A mechanism that allows access to trigger tables in SQL or from within user-defined functions. A table locator is a fullword integer value that represents a transition table.
<b>table space</b>	A page set that is used to store the records in one or more tables. See also partitioned table space, segmented table space, and universal table space.
<b>table space set</b>	A set of table spaces and partitions that should be recovered together for one of the following reasons: <ul style="list-style-type: none"> <li>• Each of them contains a table that is a parent or descendent of a table in one of the others.</li> <li>• The set contains a base table and associated auxiliary tables.</li> </ul>
<b>task control block (TCB)</b>	A z/OS control block that is used to communicate information about tasks within an address space that is connected to a subsystem. See also address space connection.
<b>TB</b>	Terabyte. A value of 1 099 511 627 776 bytes.
<b>TCB</b>	See task control block.
<b>TCP/IP</b>	A network communication protocol that computer systems use to exchange information across telecommunication links.
<b>TCP/IP port</b>	A 2-byte value that identifies an end user or a TCP/IP network application within a TCP/IP host.
<b>template</b>	A DB2 utilities output data set descriptor that is used for dynamic allocation. A template is defined by the TEMPLATE utility control statement.
<b>temporal table</b>	A table which records the period of time when a row is valid. See also system-period temporal table, application-period temporal table, and bitemporal table.
<b>temporary table</b>	A table that holds temporary data. Temporary tables are useful for holding or sorting intermediate results from queries that contain a large number of rows. The two types of temporary table, which are created by different SQL statements, are the created temporary table and the declared temporary table. Contrast with result table. See also created temporary table and declared temporary table.
<b>textual XML format</b>	A system of storing XML data in text, as opposed to binary, that allows for direct human reading.
<b>thread</b>	See DB2 thread.
<b>threadsafe</b>	A characteristic of code that allows

multithreading both by providing private storage areas for each thread, and by properly serializing shared (global) storage areas.

#### **three-part name**

The full name of a table, view, or alias. It consists of a location name, a schema name, and an object name, separated by a period.

**time** A three-part value that designates a time of day in hours, minutes, and seconds.

#### **timeout**

Abnormal termination of either the DB2 subsystem or of an application because of the unavailability of resources. Installation specifications are set to determine both the amount of time DB2 is to wait for IRLM services after starting, and the amount of time IRLM is to wait if a resource that an application requests is unavailable. If either of these time specifications is exceeded, a timeout is declared.

#### **Time-Sharing Option (TSO)**

An option in z/OS that provides interactive time sharing from remote terminals.

#### **timestamp**

A seven-part value that consists of a date and time. The timestamp is expressed in years, months, days, hours, minutes, seconds, and microseconds.

#### **timestamp with time zone**

A two-part value that consists of a timestamp and time zone. The timestamp with time zone is expressed in years, months, days, hours, minutes, seconds, microseconds, time zone hours, and time zone minutes.

**trace** A DB2 facility that provides the ability to monitor and collect DB2 monitoring, auditing, performance, accounting, statistics, and serviceability (global) data.

#### **transaction**

An atomic series of SQL statements that make up a logical unit of work. All of the data modifications made during a transaction are either committed together as a unit or rolled back as a unit.

#### **transaction lock**

A lock that is used to control concurrent execution of SQL statements.

#### **transaction program name**

In SNA LU 6.2 conversations, the name of the program at the remote logical unit that is to be the other half of the conversation.

#### **transition table**

A temporary table that contains all the affected rows of the subject table in their state before or after the triggering event occurs. Triggered SQL statements in the trigger definition can reference the table of changed rows in the old state or the new state. Contrast with auxiliary table, base table, clone table, and materialized query table.

#### **transition variable**

A variable that contains a column value of the affected row of the subject table in its state before or after the triggering event occurs. Triggered SQL statements in the trigger definition can reference the set of old values or the set of new values.

#### **tree structure**

A data structure that represents entities in nodes, with a most one parent node for each node, and with only one root node.

#### **trigger**

A database object that is associated with a single base table or view and that defines a rule. The rule consists of a set of SQL statements that run when an insert, update, or delete database operation occurs on the associated base table or view.

#### **trigger activation**

The process that occurs when the trigger event that is defined in a trigger definition is executed. Trigger activation consists of the evaluation of the triggered action condition and conditional execution of the triggered SQL statements.

#### **trigger activation time**

An indication in the trigger definition of whether the trigger should be activated before or after the triggered event.

#### **trigger body**

The set of SQL statements that is executed when a trigger is activated and its triggered action condition evaluates to

true. A trigger body is also called triggered SQL statements.

### trigger cascading

The process that occurs when the triggered action of a trigger causes the activation of another trigger.

### triggered action

The SQL logic that is performed when a trigger is activated. The triggered action consists of an optional triggered action condition and a set of triggered SQL statements that are executed only if the condition evaluates to true.

### triggered action condition

An optional part of the triggered action. This Boolean condition appears as a WHEN clause and specifies a condition that DB2 evaluates to determine if the triggered SQL statements should be executed.

### triggered SQL statements

The set of SQL statements that is executed when a trigger is activated and its triggered action condition evaluates to true. Triggered SQL statements are also called the trigger body.

### trigger granularity

In SQL, a characteristic of a trigger, which determines whether the trigger is activated:

- Only once for the triggering SQL statement
- Once for each row that the SQL statement modifies

### triggering event

The specified operation in a trigger definition that causes the activation of that trigger. The triggering event is comprised of a triggering operation (insert, update, or delete) and a subject table or view on which the operation is performed.

### triggering SQL operation

The SQL operation that causes a trigger to be activated when performed on the subject table or view.

### trigger package

A package that is created when a CREATE TRIGGER statement is executed. The package is executed when the trigger is activated.

### trust attribute

An attribute on which to establish trust. A trusted relationship is established based on one or more trust attributes.

### trusted connection

A database connection whose attributes match the attributes of a unique trusted context defined at the DB2 database server.

### trusted connection reuse

The ability to switch the current user ID on a trusted connection to a different user ID.

### trusted context

A database security object that enables the establishment of a trusted relationship between a DB2 database management system and an external entity.

### trusted context default role

A role associated with a trusted context. The privileges granted to the trusted context default role can be acquired only when a trusted connection based on the trusted context is established or reused.

### trusted context user

A user ID to which switching the current user ID on a trusted connection is permitted.

### trusted context user-specific role

A role that is associated with a specific trusted context user. It overrides the trusted context default role if the current user ID on the trusted connection matches the ID of the specific trusted context user.

### trusted relationship

A privileged relationship between two entities such as a middleware server and a database server. This relationship allows for a unique set of interactions between the two entities that would be impossible otherwise.

### TSO

See Time-Sharing Option.

### TSO attachment facility

A DB2 facility consisting of the DSN command processor and DB2I.

Applications that are not written for the CICS or IMS environments can run under the TSO attachment facility.

**typed parameter marker**

A parameter marker that is specified along with its target data type. It has the general form:  
CAST(?) AS data-type)

**type 2 indexes**

Indexes that are created on a release of DB2 after Version 7 or that are specified as type 2 indexes in Version 4 or later.

**UCS-2** Universal Character Set, coded in 2 octets, which means that characters are represented in 16-bits per character.

**UDF** See user-defined function.

**UDT** User-defined data type. In DB2 for z/OS, the term distinct type is used instead of user-defined data type. See distinct type.

**uncommitted read (UR)**

The isolation level that allows an application to read uncommitted data. See also cursor stability, read stability, and repeatable read.

**underlying view**

The view on which another view is directly or indirectly defined.

**undo** A state of a unit of recovery that indicates that the changes that the unit of recovery made to recoverable DB2 resources must be backed out.

**Unicode**

A standard that parallels the ISO-10646 standard. Several implementations of the Unicode standard exist, all of which have the ability to represent a large percentage of the characters that are contained in the many scripts that are used throughout the world.

**union** An SQL operation that involves the UNION set operator, which combines the results of two SELECT statements. Unions are often used to merge lists of values that are obtained from two tables.

**unique constraint**

An SQL rule that no two values in a primary key, or in the key of a unique index, can be the same.

**unique index**

An index that ensures that no identical key values are stored in a column or a set of columns in a table.

**unit of recovery (UOR)**

A recoverable sequence of operations within a single resource manager, such as an instance of DB2. Contrast with unit of work.

**unit of work (UOW)**

A recoverable sequence of operations within an application process. At any time, an application process is a single unit of work, but the life of an application process can involve many units of work as a result of commit or rollback operations. In a multisite update operation, a single unit of work can include several *units of recovery*. Contrast with unit of recovery.

**universal table space**

A table space that is both segmented and partitioned. Contrast with partitioned table space, segmented table space, partition-by-growth table space, and range-partitioned table space.

**unlock**

The act of releasing an object or system resource that was previously locked and returning it to general availability within DB2.

**untyped parameter marker**

A parameter marker that is specified without its target data type. It has the form of a single question mark (?).

**updatability**

The ability of a cursor to perform positioned updates and deletes. The updatability of a cursor can be influenced by the SELECT statement and the cursor sensitivity option that is specified on the DECLARE CURSOR statement.

**update hole**

The location on which a cursor is positioned when a row in a result table is fetched again and the new values no longer satisfy the search condition. See also delete hole.

**update trigger**

A trigger that is defined with the triggering SQL operation update.

**UR** See uncommitted read.

**user-defined data type (UDT)**

See distinct type.

<b>user-defined function (UDF)</b>	A function that is defined to DB2 by using the CREATE FUNCTION statement and that can be referenced thereafter in SQL statements. A user-defined function can be an external function, a sourced function, or an SQL function. Contrast with built-in function.	issuing the CREATE or ALTER PROCEDURE statement for a native SQL procedure.
<b>user view</b>	In logical data modeling, a model or representation of critical information that the business requires.	
<b>UTF-16</b>	Unicode Transformation Format, 16-bit encoding form, which is designed to provide code values for over a million characters and a superset of UCS-2. The CCSID value for data in UTF-16 format is 1200. DB2 for z/OS supports UTF-16 in graphic data fields.	
<b>UTF-8</b>	Unicode Transformation Format, 8-bit encoding form, which is designed for ease of use with existing ASCII-based systems. The CCSID value for data in UTF-8 format is 1208. DB2 for z/OS supports UTF-8 in mixed data fields.	
<b>value</b>	The smallest unit of data that is manipulated in SQL.	
<b>variable</b>	A data element that specifies a value that can be changed. A COBOL elementary data item is an example of a host variable. Contrast with constant.	
<b>variant function</b>	See nondeterministic function.	
<b>varying-length string</b>	A character, graphic, or binary string whose length varies within set limits. Contrast with fixed-length string.	
<b>version</b>	A member of a set of similar programs, DBRMs, packages, or LOBs. <ul style="list-style-type: none"> <li>• <b>A version of a program</b> is the source code that is produced by precompiling the program. The program version is identified by the program name and a timestamp (consistency token).</li> <li>• <b>A version of an SQL procedural language routine</b> is produced by</li> </ul>	<ul style="list-style-type: none"> <li>• <b>A version of a DBRM</b> is the DBRM that is produced by precompiling a program. The DBRM version is identified by the same program name and timestamp as a corresponding program version.</li> <li>• <b>A version of an application package</b> is the result of binding a DBRM within a particular database system. The application package version is identified by the same program name and consistency token as the DBRM.</li> <li>• <b>A version of a LOB</b> is a copy of a LOB value at a point in time. The version number for a LOB is stored in the auxiliary index entry for the LOB.</li> <li>• <b>A version of a record</b> is a copy of the record at a point in time.</li> </ul>
<b>view</b>	A logical table that consists of data that is generated by a query. A view can be based on one or more underlying base tables or views, and the data in a view is determined by a SELECT statement that is run on the underlying base tables or views.	
<b>Virtual Storage Access Method (VSAM)</b>	An access method for direct or sequential processing of fixed- and varying-length records on disk devices.	
<b>Virtual Telecommunications Access Method (VTAM)</b>	An IBM licensed program that controls communication and the flow of data in an SNA network (in z/OS).	
<b>volatile table</b>	A table for which SQL operations choose index access whenever possible.	
<b>VSAM</b>	See Virtual Storage Access Method.	
<b>VTAM</b>	See Virtual Telecommunications Access Method.	
<b>warm start</b>	The normal DB2 restart process, which involves reading and processing log records so that data that is under the control of DB2 is consistent. Contrast with cold start.	

<b>WLM application environment</b>	A z/OS Workload Manager attribute that is associated with one or more stored procedures. The WLM application environment determines the address space in which a given DB2 stored procedure runs.
<b>WLM enclave</b>	A construct that can span multiple dispatchable units (service request blocks and tasks) in multiple address spaces, allowing them to be reported on and managed by WLM as part of a single work request.
<b>write to operator (WTO)</b>	An optional user-coded service that allows a message to be written to the system console operator informing the operator of errors and unusual system conditions that might need to be corrected (in z/OS).
<b>WTO</b>	See write to operator.
<b>WTOR</b>	Write to operator (WTO) with reply.
<b>XCF</b>	See cross-system coupling facility.
<b>XES</b>	See cross-system extended services.
<b>XML</b>	See Extensible Markup Language.
<b>XML attribute</b>	A name-value pair within a tagged XML element that modifies certain features of the element.
<b>XML column</b>	A column of a table that stores XML values and is defined using the data type XML. The XML values that are stored in XML columns are internal representations of well-formed XML documents.
<b>XML data type</b>	A data type for XML values.
<b>XML element</b>	A logical structure in an XML document that is delimited by a start and an end tag. Anything between the start tag and the end tag is the content of the element.
<b>XML index</b>	An index on an XML column that provides efficient access to nodes within an XML document by providing index keys that are based on XML patterns.
<b>XML lock</b>	A column-level lock for XML data. The operation of XML locks is similar to the operation of LOB locks.
<b>XML node</b>	The smallest unit of valid, complete structure in a document. For example, a node can represent an element, an attribute, or a text string.
<b>XML node ID index</b>	An implicitly created index, on an XML table that provides efficient access to XML documents and navigation among multiple XML data rows in the same document.
<b>XML pattern</b>	A slash-separated list of element names, an optional attribute name (at the end), or kind tests, that describe a path within an XML document in an XML column. The pattern is a restrictive form of path expressions, and it selects nodes that match the specifications. XML patterns are specified to create indexes on XML columns in a database.
<b>XML publishing function</b>	A function that returns an XML value from SQL values. An XML publishing function is also known as an XML constructor.
<b>XML schema</b>	In XML, a mechanism for describing and constraining the content of XML files by indicating which elements are allowed and in which combinations. XML schemas are an alternative to document type definitions (DTDs) and can be used to extend functionality in the areas of data typing, inheritance, and presentation.
<b>XML schema repository (XSR)</b>	A repository that allows the DB2 database system to store XML schemas. When registered with the XSR, these objects have a unique identifier and can be used to validate XML instance documents.
<b>XML serialization function</b>	A function that returns a serialized XML string from an XML value.
<b>XML table</b>	An auxiliary table that is implicitly created when an XML column is added to

| a base table. This table stores the XML  
| data, and the column in the base table  
| points to it.

| **XML table space**

A table space that is implicitly created when an XML column is added to a base table. The table space stores the XML table. If the base table is partitioned, one partitioned table space exists for each XML column of data.

**X/Open**

An independent, worldwide open systems organization that is supported by most of the world's largest information systems suppliers, user organizations, and software companies. X/Open's goal is to increase the portability of applications by combining existing and emerging standards.

**XRF** See Extended Recovery Facility.

| **XSR** See XML schema repository.

| **zIIP** See IBM System z9 Integrated Processor.

**z/OS** An operating system for the System z product line that supports 64-bit real and virtual storage.

**z/OS Distributed Computing Environment (z/OS**

**DCE**) A set of technologies that are provided by the Open Software Foundation to implement distributed computing.
